Person records hold demographic information about the individuals and businesses with whom your organization communicates. Demographic information includes phone number(s), names and aliases, identification numbers, life support equipment needs, employment information, etc.

In the above example, 2 person records would be needed; one for Pam Jones and another for Joe Smith.

A new person is added when you first have contact with a person; the person does not have to be a customer before it is added. So, for example, if your company is starting a new marketing campaign, you can add information about potential customers the moment they are identified.

NOTE:

Businesses are persons too. In addition to humans, you use person records to maintain basic information about the businesses with which your organization has contact.

FASTPATH:

For a description of the control tables that must be set up before you can define a person, refer to [Setting Up Person Options](#).

Accounts

An account is analogous to an account at a bank:

- A person or business with no financial dealings with a bank will have no account (but the bank may choose to keep demographic information about the person as part of their marketing efforts). The exact analogy exists in this system.
- Individuals with financial dealings with a bank will have one or more accounts. The number of accounts is up to the customer. The exact analogy exists in this system.

A simple way to determine the number of accounts a customer will have is to ask "how many bills do they want each period?" because a customer receives one bill for each account. For example:

- A residential customer who also owns a small business may choose to receive two bills each month; one for the residence, the other for the business. This way, the charges for their business would be segregated from their personal charges. This customer would have two accounts.
- A conglomerate that owns several factories may want their transportation gas charges to appear on a single bill rather than have a separate bill for each factory. This customer would have a single account.

Account ID Is Non-Intelligent

The unique number of an account is referred to as the "account ID". You are probably very comfortable with this concept. You may, however, have difficulty dealing with the fact that the account id in this system has no intelligence built into it (e.g., many systems include the bill cycle and geographic location in the account id). In this system, the account ID is a random, system-assigned value.

Because the account ID contains no meaning, it can remain with a customer for life, regardless of where they live, when they are billed, the type of service they receive, etc. This is important because it means that all of the financial history linked to the account remains with the customer for life.

NOTE:

The non-intelligence of the account ID is also important from the perspective of the parallel processing that takes place when the system creates bills. Because the collection of accounts to be billed in any given bill cycle will be randomly

distributed through the number spectrum, the system can distribute account number ranges to parallel threads and each thread will process roughly the same number of accounts.

Account / Person Cross-Reference

A person may be linked to zero or more accounts. A person won't be linked to an account when they have no financial relationship with your organization. A person will be linked to multiple accounts when they have financial relationships with more than one account.

An account must reference at least one person (i.e., the main customer), but may reference an unlimited number of individuals. Multiple persons are linked to an account when several parties have some type of financial relationship with the account (e.g., third party guarantors, account contact, bill copy recipients, etc.).

When Is An Account Created?

A person can exist without an account until such time as the person formally requests the commencement of service. The moment the customer requests service, an account must be created (and the person must be linked to the account).

When Is An Account Expired?

Accounts never expire. Once a customer has an account, the account remains in the system forever. Linked to the account are service agreements that define the price and conditions of a service supplied to the customer. When an account has active service agreements, the system produces bills for it. If the account doesn't have active service agreements, the system will not produce a bill for it. You can think of an account without active service agreements as being "dormant", waiting for the day when the customer again starts service. If the customer never restarts, the account (along with its financial history) remains dormant forever.

Service Agreements

A service agreement is a contract (either formal or implied) between your organization and a customer. Every service agreement contains the price and conditions of a service supplied to a customer.

A service agreement is linked to an account. There is no limit to the number of service agreements that may be linked to an account.

When Is A Service Agreement Created?

A service agreement is created when the customer requests service (not when service commences). Typically, service agreements are created in the pending state and field activities are generated to connect service. When the field activities are complete, the service agreement becomes active and the billing process starts generating bill segments for the service agreement.

FASTPATH:

For more information about starting service, refer to [The Big Picture Of Starting Service](#). For more information about bill segments, refer to [Bill Details](#).

Financial Transactions Are Linked To Service Agreements

FASTPATH:

For more information about how financial transactions are linked to service agreements, refer to [The Financial Big Picture](#).

When Is A Service Agreement Expired?

A service agreement is expired when the customer requests service be stopped. At that time, the service agreement is transitioned to the pending stop state and field activities are generated to stop service (these activities might involve simply reading the meter or they could involve disconnecting or removing the meter). When the field activities are complete, the system transitions the service agreement to the stopped state and the billing process generates a final bill for the service agreement. When the customer pays the final bill, the system transitions the service agreement to the closed state

FASTPATH:

For more information about stopping service, refer to [The Big Picture Of Stopping Service](#).

Setting Up Person Options

This section describes tables that must be set up before you can define persons.

Setting Up Identifier Types

When you set up a person, you may define the various types of identification associated with the person, e.g., their driver's license number, their tax identity, etc. Every piece of identification associated with a person has an identification type. These identifier type codes are defined using **Admin > Customer > Identifier Type**.

NOTE:

How are person identifiers used? The reason why identifiers are defined on a person is so that users can look for a customer using one of their person identifiers (see [Control Central - Search Facilities](#) for more information). In addition, person identifiers help prevent duplicate persons from being added to the database. The base product provides an algorithm type **C1-PERSONVAL** that can issue a warning or error to a user before they add a new person or update an existing person when another person exists with the same identifier. This is a BO validation algorithm on the person MO's identifying BO.

Person identifier types are optional. An [installation option](#) controls whether at least one identifier type is required on every person.

Description of Page

Enter an easily recognizable **ID Type** and **Description** for the Identifier Type.

If the identifier type has a format against which validation can be performed, use **Identifier Format** to define the algorithm. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).

- On this algorithm, reference an Algorithm Type that validates identifier types. Click [here](#) to see the algorithm types available for this plug-in spot.

Person identifiers are validated for duplicates to help prevent duplicate persons from being added to the system. Some identifier types represent a unique Id such as a government-issued Id. Other identifier types may be used for other purposes and the values may not be unique. Set the **Validate for Duplicates** accordingly to indicate if the system should validate the value against other person records when the person identifier is added or updated.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_ID_TYPE](#).

Setting Up Person Relationship Types

It is possible to associate persons to other person. For example,

- You might want to define the subsidiaries of a parent corporation
- You might want to define spouses as separate persons and then link each person to another person

When you link a person to another person, you must define in what way the person is related to the other person by using a person relationship type code. These codes are defined using **Admin > Person Relationship Type**.

Description of Page

Enter the following for each relationship type:

- Enter an easily recognizable **Relationship Type** code.
- Use **Description (Person1=>Person2)** to describe how the first person is related to the second person.
- Use **Description (Person2=>Person1)** to describe how the second person is related to the first person.

NOTE:

Person1 versus Person 2. When you link persons together, you do it in respect of one of the persons (which we call Person 1). For example, if you want to link the subsidiaries to a parent company, you do this in respect of the parent company (i.e., you define the parent company's subsidiaries using the [Person - Persons](#) transaction).

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_PER_REL_TYPE](#).

Setting Up Contact Routings

Base values for Contact Routing are supplied. You can add your specific contact routings using the **Contact Routing** extendable lookup. You can add more contact routings, but the ones supplied with the system cannot be edited or deleted.

NOTE: Person contacts that reference the CSS routing type cannot be added by a user, and are not permitted to be edited or deleted. As well, records with this contact routing are only visible in the Person - Main page and are not displayed in the Account Portal or other places in the system.

Refer to [Defining Extendable Lookups](#) and for more information on lookups.

If your implementation is using notification preferences, you may need to set up delivery types before setting up contact routings. Refer to [Setting Up Delivery Types](#) for more information.

Setting Up Person Contact Status

Person contacts can have a status; for example, the status of an email contact could be pending, verified, or bounced. The product is delivered with statuses that are used in conjunction with opt-in functionality. When new person contacts are added, the initial status can be defaulted from the person contact type. See [The Person Contact Status Can Be Controlled By A Process](#), *System Person Contact Statuses* and *Opt-in Process* sections for more information.

Your implementation may choose to introduce other logic to update the status. See [The Person Contact Status Can Be Controlled By A Process](#) for more information. You can add your specific person contact statuses by updating the value for the CND_VERIF_STATUS_FLG lookup field.

When new person contacts are added, the initial status can be defaulted from the person contact type. Refer to the Person Contact zone's help text for more information.

Setting Up Person Contact Type Algorithms

Format Validation

Person contact information can be subject to format validation such as ensuring a phone number is entered in a particular format.

Click [here](#) to see the algorithm types available for this system event.

The base product provides the algorithms [C1-VALEMFMT](#) (Validate Email Format), [C1-VALPHFMT](#) (Validate Phone Format), and [C1-VALANYFMT](#)(Any Format Valid), which your implementation may use (and if so, no further configuration is needed). If your implementation's business rules require additional format validation algorithms, you may introduce your own.

NOTE: These algorithms confirm that a specific format exists and do not reformat or apply formatting to the corresponding field; for example, the *C1-VALEMFMT* (Validate Email Format) algorithm confirms that the email address contains required features (such as an @ symbol and domain). It will not, however, insert these features.

If your implementation's business rules require additional format validation algorithms, you may introduce your own.

Setting Up Person Contact Types

Person contact types define the format for entering person contacts and information about the person contact.

To set up contact types, select **Admin > Customer > Person Contact Type > Add**.

The [Person Contact Type portal](#) contains the following zones:

- [Person Contact Type List](#)
- [Person Contact Type Zone](#)

Person Contact Type Portal

This section describes the zones associated to the Person Contact Type Portal:

- [Person Contact Type List](#)
- [Person Contact Type Zone](#)

Person Contact Type List

The Person Contact List zone lists all person contact types. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent person contact type.
- The standard actions of Edit, Delete and Duplicate are available for each person contact type.
- Click the Add link in the zone's title bar to add a new person contact type.

Person Contact Type Zone

The Person Contact Type zone contains display-only information about the Person Contact Type. This zone appears when a Person Contact Type has been broadcast from the Person Contact Type List zone or if this portal is opened via drill down from another page.

Please see the zone's help text for information about this zone's fields.

Where Used

Follow this link to open the data dictionary where you can view tables that reference [CI_PER_CONTDDET](#).

Choosing to Use Person Contact or Person Phone

Person contact is an updated and more configurable alternative to person phone and email. In this release, a feature is introduced that some system processes use to determine if person contact or person phone and email is being used. Person phone and email are referred to as legacy behavior. Legacy behavior is enabled when the Legacy Person Phone and Email **Option Type** on the Customer Information Options is set to Y. When set to N or not set legacy behavior is not enabled.

If your implementation uses functionality that has not been updated to use the feature, such as campaigns and order, you may wish to enable legacy behavior and continue to use person phone and email. It is important to note that Person Contacts are required for notifications.

The following system processes have been updated to alter functionality based on whether legacy behavior is enabled or not.

System Process	Behavior When Feature is Not Set	Behavior When Feature is Set
Person	The Person Phone Grid and the Person Email field are not shown	The Person Phone Grid and the Person Email field are shown. Person Contact is always shown.
Person	The functionality to maintain person contacts from person phone is not triggered even when a person contact type is associated with a phone type.	The functionality to maintain person contacts from person phone is enabled.
Account/ Person	When an email or fax bill or quote route type is chosen, then information displayed is related to person contacts.	When an email or fax bill or quote route type is chosen, then information displayed is related to person phone or email.
Start/Stop	The Person Contact collection is shown and can be edited.	The Person Phone collection and Person Email are shown and can be edited.
Case	The Preferred Contact Methods associated with legacy person phone and email are not shown.	The Preferred Contact Methods associated with legacy person phone and email are available. Person Contact is always available.
Customer Contact	The Preferred Contact Methods associated with legacy person phone and email are not shown.	The Preferred Contact Methods associated with legacy person phone and email are available. Person Contact is always available.

Person Contact Status Can Be Controlled By A Process

Overview

Person contact types can be configured to allow a status. For some person contact types, your implementation may want to control the status through a process instead of allowing the status to be set manually. An example of this is using person contact status to capture opting in for receiving text messages, which is required in some jurisdictions. Opt-in is seeking permission from a customer to use a person contact for a purpose such as sending a customer text messages.

Opt-in works in conjunction with the functionality to enable opt-in for a delivery type. Each can function independently, but together they offer a complete solution. Since they can function apart from each other, each is described independently. See [Enabling Opt-in for a Delivery Type](#) for more detail on this logic.

To control a person contact status with a process, the person contact type must first be configured to allow status. The person contact type must then be set up in the opt-in section of the **Notification Preferences** [master configuration](#). By defining a Status Script, the person contact status can only be changed by the logic contained in or initiated from the script. The product is delivered with a script that creates an opt-in service task. This is designed specifically to support opting in to receiving notifications via text messages (SMS).

Opt-In Process

To use the delivered functionality, configure a new service task type for opt-in. This task type should reference the Notification Preference Opt-In Task Type Business Object (C1-NotifPrefOptInTaskType). The product is delivered with a service task business object. The service task is responsible for initiating an opt-in request, updating the person contact status, and logging the user response. An inbound web service receives responses and transitions the service task. These components are designed to integrate with Notification Center. When a customer is sent an opt-in request, they are asked to confirm. The content of the message explains the commands to the user. Examples are CONFIRM or STOP. Notification Center is configured to interpret the specific commands and map them to those expected by the inbound service, which transitions the service task appropriately.

Aside from the initial opt-in request, users can stop or unsubscribe from notifications at any time. The delivered solution supports two modes for this functionality: unsubscribing from all notifications for a particular person contact or unsubscribing from a specific notification type for a particular person contact. This is controlled through configuration, and relies on the external system such as Notification Center to determine the notification type.

The **Notification Preferences** [master configuration](#) help text contains detailed information about the configuration required to control person contact status and setting up opt-in processes.

It is important to note that while the delivered process to control person contact status was designed to work in conjunction with the opt-in process, your implementation can design a custom process that can create a service task or do something completely different. Also, it can be independent of opt-in and notifications. For example, the process can be used to verify that an email address is valid by sending the customer a verification request.

There is another concept, which is enabling opt-in for a delivery type. This is closely related to the functionality described here, but has different implications in the system. See [Enabling Opt-in for a Delivery Type](#) for more information.

There is a limitation worth noting. A person contact type may be set up to allow multiple delivery types, however the delivered solution only allows a single delivery type to be associated with the process used to automate person contact status. Without this limitation, different processes would be responsible for updating a single person contact status and those updates could be conflicting.

The System Person Contact Statuses

The opt-in solution delivered with the product utilizes the three delivered status values. They are: **Pending**, **Approved**, and **Rejected**. Your implementation can add your own person contact statuses, but they will not work with the solution delivered with the product. See [Setting Up Person Contact Status](#).

How the System Automates Person Contact Status

There are many ways that the process that controls person contact status can be invoked. For all of these, the person contact type must be set up in the [Notification Preferences master configuration](#) to have its status controlled by a process and, unless noted otherwise, the person contact is not already *Approved*.

- The primary way to initiate the process to control person contact status is when a person contact is used to add a contact preference and the contact preference's delivery type matches the delivery type associated with the person contact type as defined in the Notification Preferences master configuration. This method relies on enabling opt-in for a delivery type. This is how the two processes work with each other. See [Enabling Opt-in for a Delivery Type](#) for more information. An example of this scenario is that a person contact exists and is of a type that can receive text messages, such as "Mobile Phone". Until the person contact is used on a contact preference to receive a notification, there is no reason to initiate an opt-in process.
- This process can be automatically initiated by configuring a person contact to default to an initial status of *Pending*. When a person contact is added, the process is initiated. An example of this scenario is an email person contact initiating a process to verify the email address as soon as it is added to the system.
- When the value of an approved person contact is changed, the process is reinitiated. For example, even though the approval is attached to a specific person contact in the system, which has a unique ID, externally the approval was for a particular phone number or email address. When the person contact value (i.e. the phone number or email address) is changed, the prior approval is no longer valid. The person contact status is changed to *Pending*.

A user can manually initiate the process. A button is provided on the Person Contact row on Person - Main. The button can be used to reinitiate the process when the customer does not have the request and needs it resent. It can also be used to manually initiate the process upfront - before the person contact is used on a contact preference.

Maintaining Person Contact via Person Phone

Person phone is referenced extensively throughout the system. All system processes have been updated to determine if phone data and email data is being maintained on person contacts or being maintained on person phone and email. See [Choosing to Use Person Contact or Person Phone](#) for more information.

To keep person contacts records in sync with a person phone, you should consider which phone types should be stored as contacts, configure the person contact type corresponding to each phone type, and update the person contact type to reference the corresponding phone type. Many phone types may be associated with a single person contact type, but a single phone type may only be associated with one person contact type.

The base product provides a batch process [C1-INPUS](#) (Create Person Contact from Person Phone/Email) that creates a person contact for all person phone records whose phone type is associated with a person contact type. The batch process can also create person contact records for the email address on the person. You would run this process to create person contact records if you already have phone or email data for persons, and you wanted to start leveraging person contact as the repository for phone and email information. See the batch process description for more information.

NOTE:

There is a primary switch on person contact records; one person contact for each unique contact routing must be set as the primary contact. When the batch process creates person contacts from person phone data, the first person contact added for each unique contact routing is set as primary. This can be controlled to some extent by your implementation by associating phone types with person contact types sequentially and running the batch process multiple times. For example, you may prefer that a home phone be the primary over a cell phone if both exist. To ensure this happens, associate the home phone with a person contact type and run the batch process. Then associate the cell phone with a person contact type and run the batch process again. This will force all home phone records to be processed first. It is recommended that regardless of how many times the batch processes run, they are run back to back. This should be thought of as a conversion of data and should be treated as such.

When a phone type is associated with a person contact type the following occurs:

- When a phone record is added, a corresponding person contact is added if one does not already exist.
- When a phone record is updated, corresponding updates are made to the person contact.
- When a phone record is deleted, the system tries to delete the corresponding person contact. All business rules for person contacts are enforced. If the person contact is associated with a contact preference, the person contact cannot be deleted, and in turn the phone record cannot be deleted.
- Person contacts associated with phone types cannot be deleted directly. The delete function is disabled.
- Contact information on person contacts associated with phone types cannot be updated directly. The contact information and extension are disabled.
- Person contacts whose person contact type is associated with a phone type cannot be added from the account contact information zone in the account portal. These need to be added through person phone.

There is no direct association between a person phone record and person contact (i.e. there are no foreign keys on either record pointing to the other). The system uses the association between phone type and person contact type and the specific phone number in order to find the associated person contact.

Your implementation may decide to use person contacts to store phone data and not associate them with phone types. Functionality related to the system use of person phone will not be available such as updating a phone number through an order.

If your implementation associates phone types with person contact types and wishes to remove this association, it is best to remove all phone types from all person contact types.

WARNING: Making changes to the association of phone type to person contact type can have serious implications for your data. Changing the person contact type associated to a phone type will likely result in difficulty maintaining both person phone and person contact data.

Setting Up Statement Construct Options

This section describes tables that must be set up before a statement construct can be set up for a person to begin receiving financial statements.

FASTPATH:

For more information, refer to [The Big Picture of Complex Statements](#).

Setting Up Statement Route Types

Statement route types define the method used to route statements to persons. To define a statement route type, open **Admin** > **Billing** > **Statement Route Type**.

Description of Page

Enter a unique **Statement Route Type**, **Description** and **Statement Routing Method** for every statement route type.

NOTE:

The values for Statement Routing Method are customizable using the Lookup table. This field name is STM_RTG_METH_FLG.

The next two fields control how statements that are routed using this route type are printed (both in batch and online). Refer to [Technical Implementation Of Batch Statement Production](#) for more information about producing statements in

batch. Refer to [Technical Implementation Of Online Statement Production](#) for more information about online statement production.

- Use **Batch Control** to define the process that creates the flat file that is passed to your statement printing software. If you use an **Extract Algorithm** to construct the downloaded information, you can use the STMDWLD process.
- Use **Extract Algorithm** to define the plug-in component that constructs the "flat file records" that contain the information to be merged onto statements routed using this route type. This algorithm is called when a user requests an online image of a statement on [Statement - Main](#) and it may also be called by the batch statement extraction process defined above. Click [here](#) to see the algorithm types available for this plug-in spot.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_STM_RTE_TY](#).

Setting Up Account Options

This section describes tables that must be set up before an account can receive a bill.

Setting Up Account Management Groups

Users are informed that something requires their attention by entries that appear in To Do lists. For example, consider what happens when billing can't find a reading (and it's not allowed to estimate):

- The billing process creates a bill segment that is in error - meter read cannot be found.
- This error bill segment, in turn, triggers the creation of a To Do entry.
- The To Do entry is addressed to a role. A role is one or more users who can "action" the To Do entry.
- When a user views their To Do entries, they see all entries addressed to all roles of which they are part.

You can optionally use account management groups (AMG) to define the respective role to be assigned to To Do entries that are associated with an account and a given To Do type. For example, you can create an AMG called Credit Risks and assign this to accounts with suspect credit. Then, whenever an account-oriented To Do entry is created for such an account, it will be assigned a role based on the Credit Risks AMG. Refer to [Assigning A To Do Role](#) for more information..

NOTE:

Account management groups are optional. You need only set up account management groups (and link them to accounts) if you wish to address specific To Do entries associated with specific accounts to specific roles.

Account management groups are defined using **Admin > Customer > Account Management Group > Add.**

Description of Page

Enter an easily recognizable **Account Management Group** code and **Description** for each account management group. Use the grid to define the **To Do Role** to be assigned to entries of a given **To Do Type** that are associated with accounts that reference the **Account Management Group**.

NOTE:

Only To Do entries that are account-oriented take advantage of the roles defined for an account management group (because only accounts reference an account management group).

Where Used

Follow this link to view the tables that reference [CI_ACCT_MGMT_GR](#) in the data dictionary schema viewer.

Setting Up Account Relationship Codes

When you link a person to an account, you must define in what way the person is related to the account by using an account relationship code. These codes are defined using **Admin > General > Account Relationship Type**.

Description of Page

Enter an easily recognizable **Relationship Type** and **Description** for each relationship type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_ACCT_REL_TYP](#).

Setting Up Alert Types

Account based alerts that appear in control central have an **AlertType**. To define valid alert types, navigate to **Admin > Customer > Alert Type**.

Description of Page

Enter an easily recognizable **Alert Type Code** and **Description** for each alert type. Specify the **Alert Days** to indicate the amount of time that alerts of this type will be effective by default. Specify a value of zero to indicate that alerts of this type will be effective indefinitely by default.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_ALERT_TYPE](#).

Setting Up Bill Messages

There are various informational and warning messages that may appear on an account's bills. Each message is identified with a bill message code. To define a bill message code, open **Admin > Billing > Bill Message > Add**.

Description of Page

Enter a unique **Message Code** and **Description** for every bill message.

The following attributes control how and where the bill message appears on the customer's bill:

Priority controls the order in which the message appears when multiple messages appear on a bill.

NOTE:

The values for this field are customizable using the Lookup table. This field name is MSG_PRIORITY_FLG.

Insert Code controls whether a document should be inserted into the bill envelope when the bill message appears on a bill.

Message on Bill is the actual verbiage that appears on the customer's bill. If the message text is not static (e.g., field values need to be substituted into the body of the message), you can use the % *n* notation within the **Message on Bill** to cause field values to be substituted into a message. Refer to [Substituting Field Values Into A Bill Message](#) for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_BILL_MSG](#).

Setting Up Bill Route Types

Bill route types define the method used to route bills to accounts. To define a bill route type, open **Admin > Billing > Bill Route Type**.

Description of Page

Enter a unique **Bill Route Type** and **Description** for every bill route type.

Bill Routing Method controls the type of information that may be defined when the respective **Bill Route Type** is selected on [Account - Person Information](#). The following options are available:

- **Postal**: Use this method if the routing is via the postal service.
- **Fax**: Use this method if the routing is via fax.
- **Email**: Use this method if the routing is via email.

NOTE:

The values for **Bill Routing Method** are customizable using the [Lookup](#) table. This field name is BILL_RTG_METH_FLG.

The next two fields control how bills that are routed using this method are [printed](#) (both in batch and online).

- Use **Batch Control** to define the background process that performs the actual download of the billing information. Refer to [Technical Implementation of Printing Bills In Batch](#) for more information about these processes.
- Use **Extract Algorithm** to define the algorithm that constructs the records that contain the information that appears on a printed bill. Refer to [Printing Bills](#) for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_BILL_RT_TYPE](#).

Setting Up Bill Cycles

FASTPATH:

Refer to [Defining Bill and](#) for a description of how to set up bill cycles.

Setting Up Customer Classes

When you set up an account, you must assign it a customer class. The topics in this section describe the customer class control table.

Customer Class - Main

To set up customer classes, navigate to **Admin > Customer > Customer Class > Add** and use the **Main** page to define your Customer Class.

Description of Page

Enter a unique **Customer Class** code and **Description** for every customer class.

Use **Collection Class** to define the collection class that defaults onto new accounts that belong to this customer class. An account's collection class may be subsequently modified if the account has special collection problems or needs.

FASTPATH:

For more information about the significance of collection class, refer to [Designing Your Collection Classes](#).

Turn on **Business Activity Required** if service agreements linked to accounts with this customer class require a Business Activity description to be entered.

Turn on **Open Item Accounting** if accounts belonging to this customer class are subject to open-item account. Refer to [Open Item Accounting](#) for a complete explanation of the significance of this switch.

Turn on **Non CIS Payment** if accounts belonging to this customer class are used for payments made to reduce non-CIS debt. For example, assume your company accepts payments for a county assessor and you don't want to set up a separate account for each person who pays their assessment bill. You should set up the following information to accept such payments:

- Create a new customer class called "Non CIS Customer".
 - Create a SA type for each type of non-CIS payment that customers can make. Make sure to enter a distribution code on each SA type that references the appropriate revenue (or payable) account. Don't forget to indicate that each SA type is not billed.
-

NOTE:

Payment Templates can be used for common types of non-CIS payment allocations. These templates are used to default the payment distribution and allow non-CIS payments to be directly allocated to specific distribution codes.

FASTPATH:

For more information about using Payment Templates to process non-CIS payments, refer to [Non-CIS Payments](#).

- Create an account to which you'll book such payments. Have this account reference the new customer class. We recommend creating a separate account for each SA type that you created in the previous step.
- Create and activate a service agreement for the new account(s).

When someone pays for non-CIS debt, the operator will add a payment for the above account. On the payment, the operator should record reference information in order to know exactly why the payment was made. Refer to [Payment Event - Main](#) for more information.

You must define a variety of business rules for every division in which a customer class has customers. For example, if you operate in both California and Nevada AND you have CIS divisions for each state AND you have residential customers in each state, you must define **Customer Class Controls** for each CIS division. You do this on the [Customer Class - Controls](#) page. The grid that follows simply shows the CIS divisions for which business rules have been set up.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CUST_CL](#).

Customer Class - Bill Messages

When a customer class has bill messages, the system will sweep these messages onto bills created for accounts belonging to the customer class. Use this page to define a customer class's bill messages. Navigate to **Admin > Customer > Customer Class > Search** and then navigate to the **Bill Messages** page to maintain this information.

Description of Page

Use the bill messages collection to define **Bill Message** codes that should appear on bills that created for accounts that belong to a given customer class. For each message, also specify the **Start Date** and **End Date** when such a message should appear on the bill (leave **End Date** blank if the message should appear indefinitely).

Where Used

The system snaps customer class bill messages on a bill during bill completion. For more information about bill messages, refer to [The Source Of Bill Messages](#).

Customer Class - Controls

You must define a variety of business rules for every division in which a customer class has customers. For example, if you operate in both California and Nevada AND you have CIS divisions for each state AND you have residential customers in each state, you must define **Customer Class Controls** for each CIS division in respect of the residential customer class. Open **Admin > Customer > Customer Class > Search** and then navigate to the **Controls** page to maintain this information.

Description of Page

The **Customer Class Controls** scroll contains business rules governing accounts that belong to a **CIS Division** and **Customer Class**. The following fields should be defined for each **CIS Division**:

- Use **Days Till Bill Due** to define the number of days after the bill date that the customer's bill is due. If the due date is a weekend or company holiday, the system will move the due date forward to the next workday (using the workday calendar defined on the account's CIS division).
- Specify the **Budget Plan** that defaults onto new accounts belonging to this customer class. Please note that an account's budget plan may be subsequently modified if the account has special budget processing needs. Refer to [Setting Up Budget Plans](#) for more information.
- Use **Min Credit Review Freq (Days)** to define the maximum number of days that can elapse between the reviews of an account's debt by the [account debt monitor](#). Note, a value of zero (0) means that accounts in this customer class will be reviewed every day.
- Use **Credit Review Grace Days** to define the number of days after the bill due date that an account should be reviewed by the [account debt monitor](#).
- Turn on the **Late Payment Charge** if customers in the class / division combination are eligible for late payment charges.
- Use **LPC Grace Days** to define the number of days after a bill's due date that a late payment charge will be generated (if the various LPC algorithms allow such - refer to [How Late Payment Charges Get Calculated](#) for the details). If the grace date falls on a weekend or holiday, the system moves the grace date to the next available workday (using the workday calendar defined on the account's CIS division).
- Specify an **Access Group** to default an access group onto an account based on the account's CIS Division and customer class. This will override the access group defaulted from the user's default access group. Note: the access group defined here will not apply if a Customer Class Control - Determine Access Group algorithm is defined and successfully returns an access group.

The grid that follows contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

WARNING:

These algorithms are typically significant system processes. The absence of an algorithm may prevent the system from operating correctly.

You can define algorithms for the following **System Events**:

System Event	Optional / Required	Description
Auto Pay Amount Over Limit	Optional	<p>This algorithm is called to handle the situation when a system-initiated automatic payment is created that exceeds the customer's maximum withdrawal limit. Specifically, this algorithm is called when:</p> <ul style="list-style-type: none"> - The account has a maximum withdrawal limit on their automatic payment options - The system attempts to create an automatic payment that exceeds this amount - The automatic payment algorithm that's plugged into the installation record has logic that invokes this algorithm when the above conditions are true <p>If you do not plug-in this type of algorithm and the above situation is detected, the automatic payment will be created and no error will be issued.</p> <p>Refer to How To Implement Maximum Withdrawal Limits for more information.</p> <p>Click here to see the algorithm types available for this system event.</p>
Bill Completion	Optional	<p>When a bill for an account is completed, bill completion algorithms are called to do additional work.</p> <p>Refer to the description of the Complete button under Bill Lifecycle for a description of when this algorithm is called during the completion process.</p> <p>Click here to see the algorithm types available for this system event.</p>
Bill Eligibility	Optional	<p>Algorithms for this plug-in spot are called when generating a bill in batch billing. It provides the ability to determine if an account is ineligible for billing and should therefore be skipped from further processing.</p> <p>If an eligibility algorithm is not used, a bill is created for any account in the open bill cycle and is later deleted by the billing process if it detects that there is no information linked to the bill.</p> <p>Click here to see the algorithm types available for this system event.</p>

Bill Segment Freeze/Cancel	Optional	<p>When a bill segment for an account in this customer class / division is frozen or canceled, an algorithm of this type may be called to do additional work.</p> <p>Refer to Bill Segment Lifecycle for more information about freezing and canceling bill segments.</p> <p>Click here to see the algorithm types available for this system event.</p>
Cancel Bill	Optional	<p>This algorithm provides the ability to include additional cancel logic when canceling online.</p> <p>Algorithms of this type can be called in two modes: D (Determine Bill Page Buttons) and X (Cancel Bill). Mode 'D' governs whether an action button to cancel the bill will appear on the Bill page and mode 'X' performs the actual cancellation logic.</p> <p>Click here to see the algorithm types available for this system event.</p>
Determine Access Group	Optional	<p>When an account is added or an account's CIS Division or customer class is changed, this plug-in spot can be used to determine the appropriate access group. This plug-in spot allows more complex logic to be defined, such as checking the access group on the main person's others account's.</p> <p>If a determine access group is not used, the access group can be defaulted from the customer class control or the user.</p> <p>Click here to see the algorithm types available for this system event.</p>
FT Freeze	Optional	<p>When an FT is frozen, this algorithm is called to do additional work.</p> <p>For example, if you practice Open Item Accounting, you will need such an algorithm to handle the cancellation of match events when a financial transaction is canceled that appears on a match event. Refer to How Are Match Events Cancelled? for more information about cancellation.</p> <p>Click here to see the algorithm types available for this system event.</p>
LPC Eligibility	Required if the customer class / division is eligible for late payment charges	<p>This algorithm is called by the late payment process to determine eligibility for late payments.</p> <p>Just because an account's customer class allows late payment charges to be calculated doesn't mean the account's delinquent service agreements will be levied late payment</p>

charges. In addition, a delinquent service agreement's SA type must reference a late payment charge algorithm. Refer to [SA Type - Main](#) for more information about SA type late payment charge issues. Refer to [How Late Payment Charges Get Calculated](#) for more information about late payment charges in general.

NOTE:

Only One Algorithm. Only one late payment charge eligibility algorithm may be defined for a customer class / CIS division combination.

Click [here](#) to see the algorithm types available for this system event.

Levy NSF Charge

Optional

This algorithm is called when a payment is canceled with a cancellation reason that indicates an NSF.

Refer to [NSF Cancellations](#) for more information about what happens when a payment is canceled due to non-sufficient funds.

NOTE:

Only One Algorithm. Only one algorithm to levy an NSF charge may be defined for a customer class / CIS division combination.

Click [here](#) to see the algorithm types available for this system event.

Order Completion

Optional

When an [order](#) is completed for a customer linked to this customer class, this algorithm is called to do additional work (e.g., create a customer contact). You need only specify this type of algorithm if you require additional work to be performed when an order is completed for customers who belong to this customer class.

Click [here](#) to see the algorithm types available for this system event.

Overpayment Distribution

Required

When a customer pays more than they owe, this algorithm is called to determine what to do with the excess funds. Refer to [Overpayment Segmentation](#) for a description on how to configure the system to handle your overpayment requirements.

NOTE:

Only One Algorithm. Only one overpayment distribution algorithm may be

defined for a customer class / CIS division combination.

Click [here](#) to see the algorithm types available for this system event.

Override Due Date	Optional	An account's bill due date will be equal to the bill date plus its customer class' Days Till Due. If you need to override this method for accounts in a specific customer class, specify the appropriate algorithm here.
-------------------	----------	--

NOTE:

Only One Algorithm. Only one due date override algorithm may be defined for a customer class / CIS division combination.

Click [here](#) to see the algorithm types available for this system event.

Payment Cancellation	Optional	Algorithms of this type are called when a payment is canceled.
----------------------	----------	--

Click [here](#) to see the algorithm types available for this system event.

Payment Distribution	Required	This algorithm is called to distribute a payment amongst an account's service agreements. Refer to Payment Distribution for more information about how payment distribution works.
----------------------	----------	--

NOTE:

Only One Algorithm. Only one payment distribution algorithm may be defined for a customer class / CIS division combination.

Click [here](#) to see the algorithm types available for this system event.

Payment Freeze	Optional	When a payment is frozen, this algorithm is called to do additional work. If you practice Open Item Accounting , you will need such an algorithm to link the payment's financial transactions to the match event that was originally created when the payment was distributed. Refer to Payments and Match Events for more information.
----------------	----------	---

Click [here](#) to see the algorithm types available for this system event.

Post Bill Completion	Optional	When a customer class has algorithms of this type, they are called after the completion of a bill for an account linked to this customer class.
----------------------	----------	---

Refer to the description of the Complete button under [Bill Lifecycle](#) for a description

of when this algorithm is called during the completion process.

Click [here](#) to see the algorithm types available for this system event.

Pre Bill Completion

Optional

When a customer class has algorithms of this type, they are called immediately before completion starts for an account linked to this customer class. These algorithms have the potential of:

- Deleting a bill. You might want a pre completion algorithm to delete a bill if a condition is detected that should inhibit the sending of a bill to a customer (e.g., the bill just contains information about recent payments).
- Aborting the completion process and creating a bill exception. If the algorithm indicates this should be done, the bill is left in the pending state and a bill exception is created describing why completion was aborted. You might want a pre completion algorithm to do this if, for example, integrity checks detect there is something wrong with the account or its service agreements. If the integrity check fails, the bill can be left in the pending state and a bill exception created describing why.

Refer to the description of the Complete button under [Bill Lifecycle](#) for a description of when this algorithm is called during the completion process.

Click [here](#) to see the algorithm types available for this system event.

Quote Completion

Optional

When [aquote](#) is completed for a customer linked to this customer class, this algorithm is called to do additional work (e.g., create a customer contact). You need only specify this type of algorithm if you require additional work to be performed when a quote is completed for customers who belong to this customer class.

Click [here](#) to see the algorithm types available for this system event.

Write Off Method

Required if you allow users to write-off debt real time using the [write off transaction](#)

When a user presses the create button on the [write off transaction](#), this algorithm is executed to write-off the selected debt. Refer to [The Ramifications of Write Offs in the General Ledger](#) for more information.

Setting Up Collection Classes

FASTPATH:

Refer to [Setting Up Collection Classes](#) for a description of how to set up collection classes.

Setting Up Customer Information Options

When you add a new person, the system is set up by default to add an account for the person and go to the Start Service page when you save the new person information. You can change this functionality by configuring the following option types on the Customer Information Options feature configuration:

- **Add Account and Start Service Default:** Indicates whether the Add Account and Start Service option is selected on the person page, by default. If this option is not configured, the Add Account and Start Service option is selected by default.
- **Post Add Person BPA Script:** Indicates a BPA script to invoke when a user successfully adds or changes a person on the person page.

When you use control central to search for accounts, the system limits your search results based on your access rights. You can change this functionality by configuring the following option type.

- **Search All Accounts:** Indicates whether a Control Central search should allow a user to search all accounts without validating the user's access rights. If the user tries to select an account without having the required access, they will not be able to navigate to the Account Information tab on Control Central for the selected account.

For more information about Feature Configurations, see [Defining Feature Configurations](#).

Setting Up Customer Contact Options

This section describes tables that must be set up before you can define customer contacts.

FASTPATH:

Refer to [The Big Picture Of Customer Contacts](#) for more information about customer contacts.

Setting Up Customer Contact Classes

Every customer contact record has a contact type that classifies the record for reporting purposes. And every contact type, in turn, references a customer contact "class". The class categorizes customer contacts into larger groupings for reporting purposes.

Open **Admin > Customer > Customer Contact Class** to define your customer contact classes.

Description of Page

Enter a unique **Contact Class** and **Description** for each customer contact class.

After you have created your customer contact classes, you'll be ready to setup your [customer contact types](#).

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CC_CL](#).

Setting Up Customer Contact Types

Every customer contact record has a contact type that controls the behavior of the customer contact.

FASTPATH:

Refer to [The Big Picture Of Customer Contacts](#) for more information about customer contacts.

Open **Admin > Customer > Customer Contact Type > Add** to define your customer contact types.

Description of Page

Every customer contact type is identified by a unique combination of **Contact Class** and **Contact Type**.

Enter a brief **Description** of the customer contact type.

Only specify a **Contact Shorthand** if customer contacts of this type can be added in the [Customer Contact Zone](#). The value you specify in this field is what the user selects to add a customer contact in this zone.

If your implementation requires restricting customer contact types by CIS Division, specify a **CIS Division** on the customer contact type.

Person Usage controls the applicability of a person on customer contacts of this type. Select **Required** if a person must be defined on this type of customer contact. Select **Optional** if a person can optionally be defined on this type of customer contact. Select **Not Allowed** if a person is not allowed on this type of customer contact.

Account Usage controls the applicability of an account on customer contacts of this type. Select **Required** if an account must be defined on this type of customer contact. Select **Optional** if an account can optionally be defined on this type of customer contact. Select **Not Allowed** if an account is not allowed on this type of customer contact.

Premise Usage controls the applicability of a premise on customer contacts of this type. Select **Required** if a premise must be defined on this type of customer contact. Select **Optional** if a premise can optionally be defined on this type of customer contact. Select **Not Allowed** if a premise is not allowed on this type of customer contact.

NOTE:

Person usage and premise usage cannot both be set to not allowed, as the customer contact must at least one of them.

Account usage is dependent on person usage.

Entity Relationship controls the validation of relationships on customer contacts of this type. **All** ensures that the account belongs to the person and that the account and premise are related. **Person and Account Only** disables the account and premise validation. **Premise and Account Only** disables the person and account validation. **None** disables all validation and allows any values. This setting only impacts the validation of values entered and works in conjunction with the three usage fields described above.

Use **Contact Action** if something should be triggered when customer contacts of this type are added. The only valid value in this release is Send Letter. If you select this option, you must also specify a **Letter Template**. Refer to [Printing Letters](#) for more information about how letters are produced.

Set the **Custom Archive Eligibility Criteria** flag to Applicable if customer contacts of this type require additional custom eligibility criteria checks when being evaluated for archiving.

NOTE: The base product provides an ILM Eligibility algorithm for Customer Contact ([C1-CCILMELIG](#)) that marks a customer contact as eligible for archiving based on the customer contact's age and the state of the related person's information. This algorithm will not mark the customer contact as eligible for archive if the customer contact type's Custom Archive Eligibility Criteria flag is Applicable. Your implementation is responsible for providing the additional criteria checks for customer contact types that require custom eligibility criteria.

Use the **Customer Contact Type Characteristics** collection to define characteristics that can be defined for contacts of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on customer contacts of a given type. Turn on the **Default** switch to default the **Characteristic Type** when customer contacts of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CC_TYPE](#).

Setting Up Notification Preference Options

The topics in this section provide background information about notification preferences.

Notification Preferences Overview

The Notification Preferences functionality is comprised of two main components: sending messages out of the system and maintaining customers' communication preferences for receiving these messages.

Notifications are created by an algorithm plugged into the Create Notification plug-in spot on the Notification Type (BO). Click [here](#) to see the algorithm types available for this system event. The base product provides the [C1-CRE-NTF](#) algorithm, which creates the notification via an outbound message.

The following sections describe specific notification preference concepts and how to configure the system to use notification preferences.

Push vs. Subscription Notification Types

Notification types are defined as either push – which means that a customer need not sign up to receive notifications of this type, or subscription – which means that a customer must sign up to receive this type of notification. As you can tell, they have different uses and different behaviors.

Push notification types allow users to specify communication preferences for a general type of notification. These preferences include contact preferences and opt-out preferences, which are applied to individual notifications belonging to the general type. For example, “marketing” may be the general type, and the individual notification types may include several different types of marketing notifications that contain different messages and are targeted at different channels. Refer to [Parent vs. Individual Push Notification Types](#) for more information.

In the absence of any contact preference or opt-out preference, push-based notifications can determine a default contact and send the notification using it. The logic to determine a default contact is defined via an algorithm plugged into the Determine Default Contact plug-in spot on the Notification Type (BO). Click [here](#) to see the algorithm types available for this system event. The base product provides the [C1-NTF-DFPRF](#) (Determine Default Contact for Notification Type) algorithm, which looks to retrieve a default contact from the account's main person.

Subscription notification types define a particular notification and its message. Customers must have an active contact preference to receive these notifications. Subscription-based notification types can use an underlying service task. Refer to [Some Notification Types Use Service Task](#) for more information. A subscription-based notification type can also be set up to allow routing of bills or quotes to multiple destinations.

Parent vs. Individual Push Notification Types

Push notification types are configured as either a parent or individual notification type. An individual notification type references a parent notification type; a parent cannot reference another parent. Customers define communication preferences for parent push notification types. Notifications are sent out for individual push notification types. The preferences defined for parent push notification types are applied to the associated individual push notification types.

This means that customers do not have to supply their preferences for every individual notification that your implementation may send. Storing customer preferences for a parent notification type permits those preferences to be inherited for individual notification types added later in time under the same parent. The parent push notification types can be thought of as categories of notifications for which your customers define contact preferences and opt-out preferences.

When system processes or your custom processes attempt to send out a push notification, it should be for an individual notification type. The system will retrieve the parent notification type from the individual notification type when checking for communication preferences.

One function available to push-based notifications as described in [Push vs. Subscription Notification Types](#) is the ability to determine a default contact in the absence of a contact preference or opt-out preference. If your implementation wants to take advantage of this function, but would like the customer to supply preferences for receiving an individual notification, a parent push notification type can be set up with only one individual push notification type.

Delivery Type

Delivery Type is the channel used to send a notification. Examples are email, text message (SMS), fax, and outbound IVR. Delivery type is used throughout notification preferences. If your implementation is not using notification preferences, you would not utilize delivery type.

- Notification types list the supported delivery types. For example, a bill ready notification type may support email and SMS while a notification type to encourage customers to enroll in a budget plan may only support email. The message subject and body are configured for each notification type's supported delivery type.
- Person contact types list the allowable delivery types. For example, a cell phone person contact type may allow SMS while a home phone person contact type may not allow any delivery types. An email person contact type would allow an email delivery type unless the person contact type exists to capture a customer's email address and not to be used in conjunction with notification preferences. Note: the delivery types that can be specified on a person contact type are restricted to those defined on the person contact types contact routing. Refer to [Setting Up Contact Routings](#) for more information.
- A contact preference for a customer consists of the combination of notification type, delivery type, and person contact.

Enabling Opt-In for a Delivery Type

Overview

Opt-in can be enabled for a delivery type and is configured using the [Notification Preferences master configuration](#); for example, opt-in can be enabled for SMS, but not email.

To help clarify some terminology, as explained in [Person Contact Status Can Be Controlled by a Process](#), the product is delivered with a process that initiates a service task to request opt-in or permission to use a person contact. This solution requires that opt-in is enabled for the delivery type associated with the person contact type. In this regard, the two concepts are intertwined, but enabling opt-in for a delivery type can function independently.

Enabling opt-in is centered on the person contact status, while the process that controls the status can vary; therefore, it is possible to use enable opt-in for a delivery type while manually controlling the person contact status. Enabling opt-in for a delivery type has two key impacts system behavior.

- When a contact preference is added and the delivery type is enabled for opt-in, there is logic that checks if the person contact associated with the contact preference is in the **Approved** status. If it is not, and the person contact type is associated with a process to control the status, that process is initiated. If the person contact type is not associated with a process to control its status, a To Do Entry is created. The To Do Type is configured on the [Notification Preferences](#) master configuration. The system is delivered with To Do Type Opt-In Errors (C1-OPTIN) for this purpose.
- Notifications will not be delivered to person contacts that are not **Approved**. When a system process initiates an outbound notification based on an active preference, if the person contact associated with the contact preference is not **Approved**, a flag is set in the notification indicating that it should not be delivered. It is up to the receiving system, such as

Notification Center, not to deliver the notification based on this flag. This is designed so that a record of the notification being generated is still captured. Also the [C1-NTF-DFPRF](#) (Determine Default Contact for Notification Type) will not choose a person contact that is not approved.

The **Notification Preferences** [master configuration](#) help text contains detailed information about the configuration required to enable opt-in for a delivery type.

Some Notification Types Use Service Task

Prior to the introduction of notification preferences functionality, the system supported notifications set up through self-service. These notifications used service tasks to store customer preferences and in some cases trigger notifications. The destination information for the notification existed outside of the system. Notification preferences, and more particularly communication preferences, define the user’s preferences on how to be notified for each notification type and where the notification is to be sent. This reduces, but does not eliminate, the need to use a service task to store a customer’s preference. These service tasks will not contain the self-service information when created internally by the system

There are four existing notification types that rely on service tasks to trigger a notification. Additionally, one of the prepaid notifications uses a service task type business object with specific fields for that notification type. Refer to [Designing Notification Types](#) for information regarding the configuration requirements for certain notification types.

Notification Preferences supports configuring notification types with or without a service task and only subscription-based notification types can be configured with an underlying service task.

Designing Notification Types

Some notification types require a specific configuration in order for the system to create notifications for that type.

Service Task Based Notification Types

There are system processes that rely on a hard-coded notification type lookup, referred to as notification type (legacy) on the notification type configuration. The system identifies the user-defined notification type from the lookup value.

The following identifies the configuration requirements for the notification types that are supported by existing processes in the system that rely on service tasks.

Notification Type (User Defined)	Push/Subscription	Controlled By	Notification Type (Legacy)	Service Task Type
Prepaid billing new charge	Subscription	Service Task	C1PC	Self-Service Task with BO C1-NotifyTaskType
Prepaid billing payment request	Subscription	Service Task	C1PP	Self-Service Task with BO C1-PPBPaymentNotifyTaskType
Payment Received	Subscription	Service Task	WSPR	Self-Service Task with BO C1-NotifyTaskType
Bill Ready	Subscription	Service Task	WXBR	Self-Service Task with BO C1-NotifyTaskType
Bill Due	Subscription	Service Task	WXBD	Self-Service Task with BO C1-NotifyTaskType
Late Payment	Subscription	Service Task	WSLP	Self-Service Task with BO C1-NotifyTaskType

Non-Service Task Based Notification Types

The following identifies the configuration requirements for the notification types that are supported by existing processes in the system that rely on the user-defined notification type to be configured.

NOTE:

Marketing and forms notification types can be set up one of two ways: as subscription-based or as push-based. For it to be push-based, it would be an individual push, meaning that it references a parent push notification type specified by the implementer.

Notification Type (User Defined)	Push/Subscription	Controlled By	Notes
Marketing Preference (Lead Event)	Subscription or Individual Push	N/A	Notification type configured on lead event type of BO C1-LeadEvtTypeNotificationPref
Forms Update	Subscription or Individual Push	N/A	Notification type configured on form task type of C1-FormTaskTypeForNotification
Forms Closed	Subscription or Individual Push	N/A	Notification type configured on form task type of C1-FormTaskTypeForNotification

Bill and Quote Routing

Notification types can also be used to define contact preferences for bill and quote routing for email and fax. This can enable a bill or quote to create a routing for each active contact preference. For example for a single person on an account that receives a copy of the bill, the bill can be sent to more than one email address.

Some specific configuration is needed to support this.

The notification types are to be set up as follows:

Notification Type (User Defined)	Push/Subscription	Controlled By	Bill/Quote Route Type
Bill Route	Subscription	Bill Route	Specify the Bill Route Type
Quote Route	Subscription	Quote Route	Specify the Quote Route Type

Configure only the delivery type that corresponds with the bill or quote route’s routing method. For example, if the bill route type’s routing method is email, configure the email delivery type on the notification type.

Configure only person contact types whose contact routing corresponds with the bill or quote route’s routing method. For example, if the bill route type’s routing method is email, configure only person contact types with a contact routing of email. Ensure that the person contact type allows only the delivery type specified on the notification type.

This very specific configuration is needed because the system will override the existing logic that creates bill and quote routings when a notification type exists as described above and there are active contact preferences for that notification type with the specified delivery type and the person contact’s person contact type.

Setting Up Notification Type Algorithms

Suppression Criteria

Notification types can be suppressed from appearing in a list for a particular customer. This is done by plugging in a suppression criteria algorithm on the notification type.

Click [here](#) to see the algorithm types available for this system event.

The base product provides the **CI-ALWY-SUP** (Always Suppressed) algorithm, which suppresses the notification type for all customers. This does not impact active contact preferences for the notification type, nor does it prevent processes from

creating notifications of this type. This should be used with business process changes to stop sending notifications of this type. This can also be used temporarily after a notification type has been configured, but before it should be used.

The base product provides the [C1-CKSP-PPB](#) (Check Prepaid Biller Suppression) algorithm, which suppresses the notification type if the customer does not have an active prepaid biller task. This should be used on prepaid related notification types so that only customers on prepaid billing receive these notifications.

If your implementation's business rules require additional notification type suppression rules, you may introduce your own algorithm.

Override Do Not Disturb

Do not disturb information can be captured on person contacts. Person contacts are associated with a notification type to define a contact preference. When notifications are sent out, do not disturb information is included in the message to the receiving system. Some notification types might be important enough to not honor the customer's do not disturb information. For example, a notification might be sent to a subset of customers to warn of a gas leak and evacuation and needs to be sent regardless of the customers do not disturb wishes. This is done by plugging in an override do not disturb algorithm on the notification type. Note: this does not actually override the customer's information, but sends an indicator in the message to the receiving system that the do not disturb information should be overridden or ignored.

Click [here](#) to see the algorithm types available for this system event.

The base product provides the [C1-OVR-DND](#) (Override Do Not Disturb) algorithm, which returns a value of true that is passed to the receiving system in the notification.

If your implementation has more specific business rules related to overriding a customer's do not disturb preference, you may introduce your own algorithm.

Setting Up Delivery Types

Base values for Delivery Type are supplied. You can add your specific delivery types by updating the value for the C1_SS_DELIVERY_TYPE lookup field.

Setting Up Notification Types

Each notification type defines the controls and behavior for defining communication preferences and sending out notifications of that type.

There are two main categories of notification types: subscription and push. These behave differently. Refer to [Push vs. Subscription Notification Types](#) for more information.

Push notification types are configured as either parent or individual push notification types. A parent push notification type is used to define communication preferences and an individual push notification type is used to send notifications. Refer to [Parent vs. Individual Push Notification Types](#) for more information.

The base product supplies one Notification Type business objects. For more details, refer to the specifications for this business object.

Some notification types require specific configuration. Refer to [Designing Notification Types](#) for more information.

To set up notification types, select **Admin > Customer > Notification Type +**.

The [Notification Type Portal](#) contains the following zones:

- [Notification Type List](#)
- [Notification Type Zone](#)

Notification Type Portal

This section describes the zones associated to the Notification Type Portal:

- [Notification Type List](#)
- [Notification Type Zone](#)

Notification Type List

The Notification Type List zone lists all notification types. The following functions are available:

Click a [broadcast](#) button to open other zones that contain more information about the adjacent notification type.

The standard actions of Edit, Delete, and Duplicate are available for each notification type.

Click the Add link in the zone's title bar to add a new notification type.

Notification Type Zone

The Notification Type zone contains display-only information about the Notification Type. This zone appears when a Notification Type has been broadcast from the Notification Type List zone or if this portal is opened via drill down from another page.

Please see the zone's help text for information about this zone's fields.

Where Used

Follow this link to open the data dictionary where you can view tables that reference [CI_NTF_TYPE](#).

Setting Up the Outbound Message Type

An outbound message type is required for the notification outbound message. This outbound message type must reference the base [C1-NotifPrefOutboundMessage](#) (Notification Preference Outbound Message) business object.

Setting Up the Message Sender

A Message Sender is required to define how to send notifications. Use the context of the Message Sender to define the web service interface.

Setting Up the External System and Configure the Messages

Define an external system and configure the valid outbound message types and the method of communication for each (XAI, Batch, or Real Time); Real Time is generally the appropriate choice notifications).

Setting Up Notification Preferences Master Configuration

General configuration details for the notification preferences functionality is captured in the **Notification Preferences**[master configuration](#).

For more information about specific fields in the master configuration, refer to the embedded help.

Other Edge Application Notification

Other applications such as *Oracle Utilities Network Management System* or *Oracle Utilities Meter Data Management* may initiate notifications; for example, the network management product can create notifications for outages or restoration information. The customer's preferences to receive these notifications will reside in Oracle Utilities Customer Care and Billing, since this is where their contact information exists. The other applications need to be notified when an active

contact preference is created for one of their notifications. The **Notification Preferences** [master configuration](#) provides the section to indicate if a Notification Type is owned by another edge application. When a contact preference is created or inactivated for one of these notification types, an outbound message is sent to notify the other edge product. When the system event in another edge application occurs that initiates a notification, that application calls and inbound web service that creates the notification.

The **Notification Preferences** [master configuration](#) help text contains detailed information about other edge applications.

Setting Up Service Agreement Options

This section describes tables that must be set up before you can define service agreements.

Setting Up Standard Industry Codes (SIC)

A service agreement for non-residential service should reference a standard industry code (SIC). This code is used to categorize service agreements for reporting purposes. To define a SIC, open **Admin > Customer > SIC Code**.

Description of Page

Enter a unique **SIC Code** and **Description** for the SIC.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_SIC](#).

Setting Up Tax Exempt Types

Your rates will probably have provisions for the calculation of taxes of one type or another. Frequently you will have customers who are completely or partially exempt from these taxes. The service agreements for these customers will need to have tax exemption information in order for them to be billed properly. Tax Exempt Type is used to define the precise nature of the applicable exemption. To define the Tax Exempt Types you will use, open **Admin > Customer > Tax Exempt Type**.

Description of Page

Enter a unique **Tax Exempt Type** and **Description** for each type of tax exemption.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_TAX_EX_TYPE](#).

Setting Up Contract Quantity Types

You may have customers whose contracts (service agreements) have contractual consumption limits. The service agreements for these customers must have information regarding this quantity in order to be billed properly. Contract Quantity Type is used to precisely define the nature of the quantity. To define the Contract Quantity Types, open **Admin > Rates > Contract Quantity Type**.

Description of Page

Enter a unique **Contract Quantity Type** and **Description** for each type of contract quantity.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CONT_QTY_TYP](#).

SA Type Controls Everything

Every service agreement references a SA type. The SA type controls all aspects of a service agreement's behavior including how service is started, how bills are created, how its financial transactions are booked in the general ledger, and much more. We don't explain how to set up SA types in this section because it's only after you have set up all of the control tables in this manual that you'll be able to finally define your SA types.

FASTPATH:

For more information about SA types, refer to [Defining Service Agreement Types](#).

Financial Controls

FASTPATH:

There are also a number of control tables that must be set up to control the bills, payments, and adjustments that are linked to a service agreement. For more information about these tables, please refer to [Defining Financial Transaction Options](#).

Setting Up Order Options

This section describes tables that must be set up before orders can be used to start service.

FASTPATH:

For more information, refer to [The Big Picture of Campaigns, Packages and Orders](#).

Setting Up Column References

A column reference must be created for each miscellaneous field that's captured on an order that doesn't reside in a characteristic. Refer to [Determine The Properties Of Every Miscellaneous Field](#) for more information.

Open **Admin > Sales & Marketing > Column Reference > Add** to define your column references.

Description of Page

Enter an easily recognizable **Column Reference** code and **Description** for each column reference.

Specify the **FK Reference** to use if this column reference uses field values from another table. Use **Long Description** to describe the data that fields using this column reference capture.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated. You can define algorithms for the following system events: Post when order completed, Retrieve current value, Validate field value, Service task order processing, and Pre-process field value. Refer to [Extract Column References](#) for a description of these events.
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

WARNING:

These algorithms are typically significant processes. The absence of an algorithm may prevent the system from operating correctly.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_COL_REF](#).

Setting Up Order Cancellation Reasons

An order cancellation reason must be supplied when an order is cancelled. Open **Admin > Sales & Marketing > Order Cancel Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Order Cancel Reason** and **Description** for each order cancellation reason.

Where Used

Cancellation reasons are used when an [order is canceled](#).

Setting Up Order Hold Reasons

An order hold reason must be supplied when an order is held. Open **Admin > Sales & Marketing > Order Hold Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Order Hold Reason** and **Description** for each order hold reason.

Where Used

Hold reasons are used when an [order is held](#).

Setting Up Order Feature Configurations

Defining a [feature configuration](#) with a feature type of Order Configuration can increase performance of the Order page when campaigns have a large number of packages or criteria. Open **Admin > Feature Configuration > Add** to define a configuration for the feature type Order Configuration.

NOTE:

Only one. The system expects only one order configuration feature configuration to be defined.

Description of Page

The following points describe the various **Option Types** that may be defined:

- Eligibility Tree - Suppress Error Packages node. Select this option type and define a value if you would like the [Order Eligibility Tree](#) to suppress the node that contains packages with errors in their eligibility criteria. This is an optional setting. If the option type is not defined, the error packages node is displayed, if applicable.
- Eligibility Tree - Suppress Ineligible Packages node. Select this option type and define a value if you would like the [Order Eligibility Tree](#) to suppress the node that contains packages that are not applicable to the customer based on the

eligibility criteria. This is an optional setting. If the option type is not defined, the ineligible packages node is displayed, if applicable.

- Eligibility Tree - Suppress Other Campaigns node. Select this option type and define a value if you would like the [Order Eligibility Tree](#) to suppress the node that contains other eligible campaigns. This is an optional setting. If the option type is not defined, the other campaigns node is displayed, if applicable.

Setting Up Program Management Options

This section describes how to set up the system for program management.

For more information about program management, see [The Big Picture of Program Management](#)

Designing Initiative Eligibility Criteria

The following describes guidelines for designing initiative eligibility criteria. These guidelines apply when using the base-supplied business objects and any additional business objects that the implementation defines.

There are two general types of initiative eligibility criteria business objects provided in base: specific and freeform. Your implementation decides whether to use only one of these types or a mixture of both.

NOTE: Initiative criteria has three categories: eligibility criteria, related object criteria, and participation criteria. (The participation criteria type is currently not used.) During criteria maintenance and lead generation, the system identifies the category to use through a business object option called Initiative Criteria Type. Eligibility criteria business objects are defined with an Initiative Criteria Type of either CIEC (Eligibility Criteria) or CIBT (Both Eligibility Criteria and Participation Criteria).

Specific Criteria Business Objects

Most of the base-supplied business objects are designed to perform comparisons to a specific field. The algorithm type for retrieving/determining the value to compare with is already preset in the business object, such that the Algorithm values that the user sees on the user interface are restricted to the instances of that algorithm type.

Refer to the following base business objects for more details:

- Communication Channel Criteria
- Conservation Program Criteria
- Contract Option Criteria
- Rate Schedule Criteria
- SP Type Criteria
- Service Type Criteria
- Is Account Current Criteria
- Account is on Autopay Criteria
- Account is on Budget Criteria
- Number of Days Since Last Lead Criteria
- Account Customer Class Criteria
- Average Service Quantity Criteria
- Premise Cities Criteria

To add similar business objects:

- Identify the specific value for comparison. This could be a reference to an object or entity in the system, or a character string; such as, true/false.
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Configure your business object schema so that the Algorithm field retrieves all algorithm instances of the algorithm type you created.
- Define algorithm instances of your algorithm type.

Freeform Criteria Business Object

The Freeform Criteria business object, on the other hand, is designed to perform comparisons for different types of values. The comparison value is determined by a Derive Value Algorithm Type that is defined as an option on this business object. A number of these Derive Value Algorithm Types are supplied with this business object and your implementation can add to these, as necessary.

NOTE: The supplied Derive Value Algorithm Types perform similar comparisons as those in the base-supplied specific criteria business objects (listed above). The Freeform Criteria business object should only be used if the available specific criteria business objects are not sufficient to perform the needed field value comparisons.

To add Derive Value Algorithm Types:

- Identify the specific value for comparison. It could be a reference to an object or entity in the system, a character string (such as, true/false), or a scalar value (such as, number of days or number of kwh).
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Define an algorithm instance for your algorithm type.
- Update the Freeform Criteria business object to add a Derive Value Algorithm Type business object option referencing your algorithm.

Repeat the above steps for each specific field to compare.

Designing Related Object Criteria

The following describes guidelines for designing related object criteria. These guidelines apply when using the base-supplied business objects and additional business objects that the implementation defines.

An initiative defines the related object(s) to associate with leads via the Object Nomination algorithm on the initiative business object. The lead generation process executes this object nomination algorithm after executing initiative eligibility criteria. The base supplied parent Initiative business object (C1–Initiative) is configured with an object nomination algorithm that retrieves the premises that are associated with the account’s active and pending start service agreement’s service points. This algorithm applies the related object criteria, which is configured on the initiative, to each premise. If the premise is determined to be eligible, it is returned as a related object for the lead. To override the base object nomination algorithm, add another instance of the Object Nomination System Event and specify your own algorithm.

The base product supplies related object criteria business objects that look for one or more premise to associate with a lead.

There are two general types of related object criteria business objects provided in base - specific and freeform. Your implementation decides whether to use only one of these types or a mixture of both.

NOTE: Initiative criteria has three categories: eligibility criteria, related object criteria, and participation criteria. (The participation criteria type is currently not used.) During criteria maintenance and lead generation, the system identifies

the category to use through a business object option called Initiative Criteria Type. Related object criteria business objects are defined with an Initiative Criteria Type of C1EO (Related Object Criteria).

Specific Criteria Business Objects

The base product supplies two business objects that perform comparisons to a specific premise-related field. The algorithm type for retrieving or determining the comparison value is preset in the business object, such that the Algorithm values that the user sees on the user interface are restricted to the instances of that algorithm type.

Refer to the following base business objects for more details:

- Premise SP Type Criteria
- Geographic Value Criteria

To add similar business objects:

- Identify the specific comparison value. It could be a reference to an object or entity in the system (such as, SP Type), or any other attribute that can be used to find the related object.
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Configure your business object schema so that the Algorithm field retrieves all algorithm instances of the algorithm type you created.
- Define algorithm instances of your algorithm type.

Freeform Premise Criteria Business Object

The Freeform Premise Criteria business object, on the other hand, is designed to perform comparisons to different types of values. The comparison value is determined by a Derive Value Algorithm Type that is defined as an option on this business object. Derive Value Algorithm Types are supplied with this business object and your implementation can add to these, as necessary.

NOTE: The supplied Derive Value Algorithm Types perform similar comparisons as those in the base-supplied specific criteria business objects (listed above). The Freeform Premise Criteria business object should only be used if the available specific criteria business objects are not sufficient to perform the needed field value comparisons.

To add Derive Value Algorithm Types:

- Identify the specific comparison value.
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Define an algorithm instance for your algorithm type.
- Update the Freeform Premise Criteria business object to add a Derive Value Algorithm Type business object option referencing your algorithm.

Repeat the above steps for each specific field to compare.

Setting Up Lead Event Types

Each initiative can define a structured marketing effort for the events that take place during the life of a lead. For example, one event could be that a letter or an email is sent to the customer.

Each event references a lead event type. An initiative defines a lead event type profile that specifies one or more lead event types and the sequence in which those event types should occur. Refer to [The Big Picture of Initiatives](#) for more information.

Some types of lead events may also involve sending outbound messages to an external system (*e.g.*, to notify a third party representative about a customer who has signed up). The lead event type business object can specify the outbound message type(s) to use.

Event types that involve additional workflow activities can define one or more steps; for instance, when work is outsourced to a third party representative (after customer sign-up), the third party lead event includes a list of steps to complete. Each event step has information (such as, completion date) that can be used to track progress.

The base product supplies a number of Lead Event Type business objects. For more details, refer to the specifications for these business objects.

To set up lead event types, select **Admin > Sales & Marketing > Lead Event Type**.

The Lead Event Type portal contains the following zones:

Lead Event Type List

The Lead Event Type List zone lists all lead event types. The following functions are available:

- Click a **broadcast** button to open other zones that contain more information about the adjacent lead event type.
- The standard actions of **Edit**, **Delete** and **Duplicate** are available for each lead event type.

Click the **Add** link in the zone's title bar to add a new lead event type.

Lead Event Type

The Lead Event Type zone contains display-only information about the Lead Event Type. This zone appears when a Lead Event Type has been broadcast from the Lead Event Type List zone or if this portal is opened via drill down from another page.

Please see the zone's help text for information about this zone's fields.

Where Used

Follow this link to open the data dictionary where you can view tables that reference [C1_LEAD_EVT_TYPE](#).

Overriding Initiative Sign Up Options

The behavior of the Sign Up action on Lead maintenance is controlled by two business object options on the initiative:

- Sign Up UI Map
- Sign Up Service Script

When invoking a lead's Sign Up action, the system retrieves these options and displays or executes them accordingly.

The base-owned parent initiative business object, C1-Initiative, is supplied with the Sign Up Service Script option referencing the C1-IntvSignU script. To override this, add another *Sign Up Service Script* option with a higher sequence number.

The Sign Up UI map, on the other hand, is not plugged in on the base BO, because this could vary across implementations. The Sign Up UI map C1-SignUpResponseCh provided in base simply prompts for a Response Channel. Implementations can use this map or their own specific map.

NOTE: The system does not issue an error if the Sign Up UI map is not specified. It proceeds with executing the Sign Up Service Script and, if there are no problems, displays a sign up confirmation. The base-supplied C1-IntvSignU script includes logic to recheck the account's eligibility for the initiative and update the *Has Signed Up* indicator on the lead.

Program Management Master Configuration

The master configuration business object for Program Management defines general configuration details for the program management functionality.

Navigate using **Admin > General > Master Configuration**. In the Master Configuration list, scroll to Program Management Configuration and click the add icon if there is no record yet or the edit icon to modify an existing record.

For more information about specific fields in the master configuration, refer to the embedded help.

Setting Up Letter Templates

You can set up a customer contact type to generate a form letter whenever a customer contact of this type is added. In fact, this is the only way to generate a letter in the system.

FASTPATH:

Refer to [Printing Letters](#) for more information about how letters are produced.

Every customer contact that causes a letter to be sent must reference a unique letter template. To define a letter template, open **Admin > Customer > Letter Template**.

NOTE:

Document composition application users. If you use the document composition software to produce letters, there will be a template in the software associated with each letter. The name of the template must be the same as the code associated with the letter template set up in the system.

Refer to the embedded help for details on the letter template fields.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_LETTER_TMPL](#).

Setting Up Customer Service Request Types

This portal is used to display and maintain a Customer Service Request Type.

A Customer Service Request Type ????

Refer to ??? for more information.

To maintain customer service request types, open **Admin > Customer > Customer Service Request Type**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CS_REQ_TYPE](#)

Defining Service Order Options

Service orders manage the activities that are required to enable service, disable service, and perform other operations. These activities can range from simple events (such as, a meter read) to complex events (such as, installing a power line and a new meter). They can also include both fieldwork and smart commands.

Service Orders

This section provides an overview of service order activities.

Service Order Overview

Service Order Management provides functionality that orchestrates the field activities and smart meter commands that are necessary to change the state of service at a service point. This can involve complicated business logic due to numerous, often continually-changing variables, such as:

- The type of service order request; such as, enable service, disable service, cut, reconnect, and back-to back.
- Whether the service point is connected to the source of power, or not.
- If there is a device installed. If a device is installed, is it a smart meter, non-smart meter, or an item?
- The device's state at the service point; for example, pre-commissioned, connected, or disconnected.
- If it's a smart meters, what is the head-end system that manages the device at the service point/ If it's a non-smart meter (scalar), how close is the scheduled read date to the start date?

Additionally:

- Every implementation performs field work requests differently; for example, a cut service for non-payment is performed differently in every locale.
- Every head-end vendor requires different messages, in terms of the number and type of messages, and they change over releases of *their* software
- Field workers may perform different work than was requested by the system; for example, the system might request a simple reading, and the worker might decide to exchange the meter because the meter is old and broken..
- A service order request may be cancelled after it is scheduled or has been dispatched

Service orders are designed to resolve all of the above concerns, and provide a flexible and configurable solution to meet the challenge of managing customer service requests.

Understanding Service Order Management

At a high level, service order handles requests for service as follows:

Receive / Create Service Order Request

A service order request can be as a result of a customer requesting a change to their service such as enabling or disabling service when moving into or out of a residence, but can also be the result of other business processes, such as a request to cut service due to non-payment. Within Oracle Utilities Customer To Meter actions such as start service, stop service, and cut for non-payment result in the creation of a field activity request for each effected service point. These requests are sent

to Service Order Management to be performed. In addition to requests that are created with Oracle Utilities Customer To Meter, service order requests can be received from other applications

Create Service Order Activity

When Service Order Management receives the service order request, it creates a service order activity. This activity will manage and orchestrate the other activities needed to fulfill the original service request.

Evaluate Service Point and/or Meter

The service order activity evaluates the current state of the service point, meter, or item, and determines the appropriate action(s) to take to fulfill the service request.

Create Activities as Needed

Based on the evaluation of the service point, meter, or item, the service order activity creates one or more activities perform the required actions.

- Service order field activities involve sending workers into the field to perform service. This can include meter installation, meter replacement, and other activities.
- Command activities are smart meter commands used to remotely change the state of the meter. This can include connect, disconnect, checking the device status (ping), or requesting an on-demand reading.

Following each of activities, the orchestration activity re-evaluates the state of the service point, meter, or item to determine the next appropriate action(s) required to fulfill the original service request.

For example, when enabling service at a service point with a smart scalar meter, a typical scenario might involve the following:

1. Service Order Field Activity - Install Meter
2. Command Activity: Commission Device
3. Command Activity: Remote Connect
4. Command Activity: On Demand Read - Scalar

Update Field Activity Request or Requesting System

Send Notification to Subscribing Systems

The service order activity can also be configured to send notifications to other subscribing systems regarding the status of the service point, meter, or item.

Supported Service Order Processes

Service Order Field Activity supports the following service order processes as part of the base package.

- [Enable Service](#)
- [Disable Service](#)
- [Cut for Non-Payment](#)
- [Reconnect for Payment](#)
- [Meter Exchange](#)
- [Back-to-Back](#)
- [Cancellation Service Order Requests](#)

- [Update Service Order Requests](#)

Enable Service

Enable Service is a request to start service for a particular service point. It is typically initiated by a *Start Service* field activity request, but can also be initiated by another CIS application.

A Start Service field activity request results in the creation of an Enable Service orchestration activity. The Enable Service orchestration activity then initiates the necessary field activities and smart meter commands to change the state of service at a service point to Enabled and confirm that an initial measurement exists; for example, an enable service orchestrating activity could involve the following service order field activities and smart meter commands based on the state of the service point:

- If there is no meter at the service point and the service point is not connected at the source, a service order field activity will be created to connect the service point to its source and install a meter.
- If a smart meter exists at the service point and it is in a disconnected state, a smart meter command will be sent to the appropriate head-end system to connect the meter.
- If there is a non-smart (manual) meter at the service point and it's On, a service order field activity will be created to request a read on or near the start date (depending when the next read is scheduled).

Disable Service

Disable Service is a request to stop service for a particular service point. It is typically initiated by a *Stop Service* field activity request, but can also be initiated by another CIS application.

A Stop Service field activity request will result in the creation of a Disable Service orchestration activity in Service Orders. The Disable Service orchestration activity will initiate the necessary field activities and smart meter commands to change the state of service at a service point to Disabled and confirm that a final measurement exists; for example, a disable service orchestration activity could invoke the following service order field activities and smart meter commands based on the state of the service point:

- If there is a non-smart (manual) meter at the service point and it's on, a service order field activity will be created to turn off the meter.
- If a smart meter exists at the service point and its state is connected or commissioned, a smart meter command will be sent to the appropriate head-end system to perform a remote disconnect of the meter.

Cut for Non-Payment

Disconnect for non-payment is a type of field work that is most often initiated from a collections process that has been created from within the Credit & Collection module. A collections process is created when the customer's current balance has been determined to be past due. One of the methods for eliciting payment is to issue a disconnect. A *Disconnect for Non-Payment* field activity request will result in the creation of a Cut Service for Non-Payment orchestration activity in Service Orders. The Cut Service for Non-Payment orchestration activity will initiate the field activities and/or smart meter commands necessary to change the state of service at a service point to the disabled state.

For a Cut for Non-Payment service order, the orchestrations steps will include determining if a smart meter command can be executed, or if a request to a mobile field work application (such as Oracle Utilities Mobile Workforce Management) to dispatch a truck needs to be executed. Another example might be to determine if a disconnect can be executed for a service point. These rules might include determining if there is life support equipment at the premise, or if the service point can be disconnected at the current time of year or business hours based on utility defined rules taking into account predominant weather conditions (for instance, the utility cannot disconnect someone in the dead of winter or the service point resides at a postal code that is affected by extreme cold weather).

Reconnect for Payment

Reconnect Service for Payment is a request to restart service for a particular service point after customer has paid off their past due balance. It is typically initiated from the Credit & Collection's Severance Process.

A Reconnect for Payment field activity request will result in the creation of a Reconnect Service for Payment orchestrator activity in Service Orders. The Reconnect for Payment orchestration activity will initiate the field activities and/or smart meter commands necessary to change the state of service at a service point to the enabled state; for example, a service order request to reconnect service could involve the following service order field activities and smart meter commands based on the status of the service point:

- If there is a non-smart (manual) meter at the service point and it's turned off, a service order field activity will be created to turn on the meter.
- If a smart meter exists at the service point and it is in a disconnected state, a smart meter command will be sent to the appropriate head-end system to connect the meter.

Meter Exchange

Meter Exchange service is basically an exchange of an old meter with a new meter. A meter exchange request may be initiated as the result of:

- A smart meter rollout.
- A customer opting-out of having a smart meter.
- A meter no longer working correctly.
- A meter reaching the end of its life expectancy.
- A customer with a manual meter enrolling in a program that requires a smart meter.
- A need to upgrade measurement capabilities.

Meter exchanges can be initiated in a variety of ways, including:

- Within service order field activities (internally)
- By an external CIS or asset management system such as Oracle Utilities Operational Device Management
- A pick-up order from a field work application such as Oracle Utilities Mobile Workforce Management
-
-
-

Meter Exchanges involving smart meters will include smart meter commands in addition to field activities. A request can optionally include information on the type of meter needed, depending on the requesting system; this information could be specific (the type of configuration) or general (smart or manual).

Back-to-Back

Back to Back service is service disablement and enablement in single step; for example, one customer moving out while another moves in. The main purpose of this service is to minimize dispatching field work to obtain readings for both a start and stop event.

Another example of a back-to-back scenario would involve an tenant moving out and another moving into the same premise. As long as the gap between tenants (vacancy) is within the utility company's threshold, the change would be considered as a back-to-back event. In this situation, a single field task is used for this event to take the meter reading.

A Back-to-Back Service field activity request will result in the creation of a Back-to-Back Service orchestration activity in Service Orders. The Back-to-Back Service orchestration activity will initiate the field activities and smart meter commands necessary to change the state of the service of both customers at a service point to the desired state and confirm that measurements exists for that period.

Canceling Service Order Requests

A cancellation request basically cancels any orchestration and/or specific activities that are in progress. If the cancellation request is for an orchestration activity then that orchestration activity along with corresponding activities will be discarded. If the cancellation request is for a specific activity then only that specific activity will be discarded.

Depending on the status of a specific activity, a Cancel orchestration activity will either discard the activity or an outbound communication will be sent to the field work system to request a cancel the specific activity. Once the cancellation sent to the field work system is confirmed as successful, the Cancel orchestration activity will also cancel the parent orchestration activity and/or specific activities. If the cancellation sent to the field work system is not successful then the Cancel orchestration activity will be discarded. When it is discarded, it will send a response message to the requester indicating the cancellation was unsuccessful. A cancellation request can be initiated in a variety of ways, including by cancelling a field activity request , within Service Orders itself (internally), and by an asset management system such as Oracle Utilities Operational Device Management. Cancellation requests can also be created as pick-up orders from a field work application such as Oracle Utilities Mobile Workforce Management.

Update Service Order Requests

An update request handles requests for updates to an existing enablement, disablement, cut for nonpayment, and reconnect for payment orchestration activity and their related specific field activities.

The types of data available for update include the following:

- Instructions
- Comments
- Start Date/Time
- Contact Name
- Main Phone

Additionally, an update request can check to see if appointment information is different between the specific activity and the update orchestration activity. Depending on the status of the specific activity, direct updates will be made to the activities and communications within Service Orders or an outbound communication will be sent to the field work system to request an update of the specific activity fields that have been changed. Once that update to the field work system is confirmed as successful the Update orchestration activity will update the effected orchestration activity. If the updates are not successful the Update orchestration activity will be discarded. When it is discarded, it will send a response message to the requester indicating the update was unsuccessful.

Update service requests can be initiated by a field activity request or within Service Orders itself (internally).

Defining Disconnect Locations

When a service point is disconnected from the supply source, a disconnect location must be specified. This location defines where service was severed.

To define disconnect location codes, open **Disconnect Location** page.

Description of Page

Enter a **Disconnect Location** and **Description** for every disconnect location.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_DISCON_LOC](#).

Defining Field Activity Profiles and Types

A field activity request initiates a service order to perform a task at a service point. Every field activity request references a field activity type.

Most field activity requests are created:

- When a customer service representative starts or stops service at a premise. When this happens, the system automatically creates field activity requests for each service point.
- When service is cut due to lack of payment.

If you set the system up correctly, your CSRs won't have to create these field activity requests. Rather, the system creates field activity requests based on the information you set up in your field activity type profiles.

- Refer to [Starting Service & Field Activities](#) for a description of how field activity requests are created to start service.
- Refer to [Stopping Service & Field Activities](#) for a description of how field activity requests are created to stop service.
- Field activities used to cut service due to non-payment are created by two modules:
 - If you use severance process to stop a service agreement due to nonpayment, refer to [Field Events And Their Activities](#) for a description of how these field activity requests are created.
 - If you use cut processes to stop a service agreement due to nonpayment, refer to [Field Activities To Cut and Reconnect Service](#) for a description of how these field activity requests are created.

The topics in this section describe how to design your field activity profiles and field activity types.

How Does A Field Activity Type Profile Get Used?

A field activity type profile contains:

- A list of the types of field activity requests that can be made for service points.
- A matrix defining the specific activity type(s) to generate in order to start service, stop service, or disconnect due to nonpayment.

You may wonder how field activity type profiles get related to your service points. It's a little indirect, but the indirection provides a great deal of flexibility:

- Every service point references an SP type.
- Every SP type references the specific field activity type profile used by the start/stop and credit and collections process to generate field activity requests.

An example will help illustrate how this works:

- When you start service at a specific service point, the system extracts the service point's SP type.
- Then, the system determines the field activity type profile that is to be used on this SP type.
- And finally, it generates the appropriate field activity request.

Designing Field Activity Type Profiles

With Service Order Management typically only a single field activity type profile will be needed for the meter and item related service points. This profile should have a template for each of the following with a service point condition of *External Fieldwork Orchestration* to indicate that Service Order Management is orchestrating the field work:

- Start Service
- Stop Service
- Start/Stop
- Cut for Non-Payment
- Reconnect for Payment

Designing Field Activity Types

A field activity type is required for the following events:

- Start service
- Stop service
- Cut for non-payment
- Reconnect for payment
- Back-to-back

Setting Up Field Activity Types

The topics in this section describe how to set up field activity types.

FASTPATH:

For more information about field activity types, refer to [Defining Field Activity Profiles and Types](#).

Field Activity Type - Main

You begin to define a field activity type by opening **Admin > Field Work > Field Activity Type > Add**.

Description of Page

Enter an easily recognizable **Activity Type** and **Description** for each field activity type.

Use **Field Activity Priority** to define the priority associated with field activity requests of a given type.

NOTE:

The values for this field are customizable using the Lookup table. This field name is FA_PRIORITY_FLG.

Field Service Class is not applicable when Service Order Management is used.

Set **Fieldwork Orchestration** to Service Order Management

Eligible for Dispatch is not applicable when Service Order Management is used.

Appointment Booking is not applicable when Service Order Management is used.

Turn on **Display as Alert** if Control Central should display an alert if its premise has a completed field activity request of this type. If this switch is on,

- Use **Nbr Days Alert Active** to define the number of days the alert should appear on Control Central. The field activity request's scheduled date is used as the start date for the alert period.
- Enter the **Alert Information** to appear on Control Central.

NOTE:

Recommendation. We recommend only using this feature on unusual field activity types (e.g., cut for non-payment) so that a CSR is not presented with an alert for every field activity request.

Enter the **Business Object** for this FA Type if the FA type will need access to the BO plug-in spots. If the FA type has a business object specified, the system applies the business object's rules when the FA is added, changed, or deleted. This includes the business object's validation algorithms (only executed after the "core validation" specified on the maintenance object is done), post-processing algorithms, and audit algorithms. The maintenance object for the FA should specify an algorithm that finds its business object using its FA Type. Refer to the base package Determine Standard Business Object algorithm for an example of this type of algorithm.

Field Activity Step is not applicable when Service Order Management is used.

Use the **Characteristic** collection to define **Characteristic Types** and their respective **Characteristic Values** to describe characteristics that are common to all field activity requests of this type.

NOTE:

You can only choose characteristic types defined as permissible on the field activity type record.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_FA_TYPE](#).

Field Activity Type - FA Characteristics

Description of Page

Use the **Characteristics** collection to define characteristics that can be defined for field activity requests of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on field activity requests of a given type. Turn on the **Default** switch to default the **Characteristic Type** when field activity requests of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

NOTE:

Field activity requests created by the system. When setting the Required switch, remember that most field activities are created by the system. Only turn on the required switch for these types of activities if a default characteristic value can also be indicated

Field Activity Type - FA Completion Control

Description of Page

NOTE:

These algorithms are optional. The use of completion algorithms on a field activity type is optional. You would only use them if you have special functions that should be executed when a given field activity type is completed.

The **Field Activity Completion Controls** tab is used when an algorithm should be executed when a field activity request is completed. The type of algorithm may differ based on the CIS division in which the service point's premise is located. The following fields must be defined:

CIS Division Defines the division associated for which the algorithm will be executed. The system will only execute the algorithm when a field activity request is performed at a service point whose premise is governed by the division.

FA Completion Algorithm Defines the algorithm that will be executed when a field activity request is performed at a service point whose premise is governed by the associated division. Click [here](#) to see the algorithm types available for this plug-in spot.

Field Activity Type - SP Type Review

Not applicable when Service Order Management is being used.

Setting Up Field Activity Type Profiles

The topics in this section describe the pages used to define a field activity type profile.

NOTE:

FASTPATH:

For more information about field activity type profiles, refer to [Designing Your Field Activity Profiles & Types](#).

Field Activity Type Profile - Main

Description of Page

Enter a unique **Field Activity Type Profile** and **Description** for the activity type profile.

The **FA Type Profile Templates** indicate the templates that exist for this field activity type profile. Use the drill down button to go directly to the desired template. Alternatively, you can go to the **Template** tab and scroll until you find the correct template.

Field Activity Type Profile - Template

Description of Page

The information in the **Field Activity Profile Template** collection defines the field activity request(s) created for each situation identified by the **Customer Event**. The possible customer events are Cut for Non-payment, Disconnect Warning, Reconnect for Payment, Reread, Stop Service, Start Service, and Start/Stop.

NOTE: Field activity requests do not need to be defined for Reread when Service Order Management is being used.

Other customer events can be defined on the [Look Up](#) page (search for the CUST_EVT_FLG field name). Refer to the following sections for more detail about customer events included with the base product.

The fields defined for each event are common. You define the field activity request(s) to be generated given the condition of the service point. The following fields display:

SP Field Condition Define the condition of the service point associated with the field activity. Define *External Fieldwork Orchestration* when Service Order Management is being used.

Sequence You will typically have a single field activity request for any specific combination of SP Field Condition and Disconnect Location. Therefore you'll just have a single sequence (say 10) for each combination. If you need to generate multiple field activities based on a given combination, use a unique sequence number for each activity.

No Activity Turn on this switch if no field activity should be generated for the condition.

Disconnect Location this is not applicable when Service Order Management is being used.

Activity Type Define the type of field activity request to be generated. You should take care to ensure that the activity type is defined as valid for the SP type (on the last page).

Where Used

Refer to the following sections for information about where each template is used.

Field Activity Requests Initiated To Start Service

Use the customer event Start to define the field activity request(s) used to start service at a service point whose SP type references this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The start service process uses this information to determine the type of field activity requests to create to start service at a service point.

WARNING:

Warning. Field activity requests will only be created for starts if you have defined the appropriate field work creation algorithm on the service agreement's SA type. Refer to [SA Type - Algorithms](#) for more information.

Field Activity Requests Initiated To Stop Service

Use the customer event Stop to define the field activity request(s) used to stop service at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The stop service process uses this information to determine the type of field activity requests to create to stop service at a service point.

WARNING:

Warning. Field activity requests will only be created for stops if you have defined the appropriate field work creation algorithm on the service agreement's SA type. Refer to [SA Type - Algorithms](#) for more information.

Field Activity Requests Initiated For Back-to-Back Service

Use the customer event Start/Stop to define the field activity request(s) used to stop service for one customer and start service for another at a service point whose SP type uses this profile.

NOTE:

Terminology. We use the term **back-to-back** to describe the situation when a single field activity request supports both the stop and start service requests. The system sets up a back-to-back situation by default when it is aware of both the start and stop customers at a premise.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The start/stop service process uses this information to determine the type of field activity requests to create to start service at a service point.

Field Activity Requests Initiated To Cut Service Due To Non-Payment

Use the customer event Cut for Non-Payment to define the field activity request(s) used to cut service at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

Severance and cut events use this information to determine the type of field activity requests to create to cut service at a service point.

Field Activity Requests Initiated To Place A Disconnect Warning At A Service Point

Use the customer event Disconnect Warning to define the field activity request(s) used to place a disconnect warning at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

Severance and cut events use this information to determine the type of field activity requests to create to leave a disconnect warning at a service point.

Field Activity Requests Initiated To Reconnect Service At A Service Point

Use the customer event Reconnect for Payment to define the field activity request(s) used to reconnect service (after being cut) at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

Severance and cut events use this information to determine the type of field activity requests to create to reconnect service at a service point.

Field Activity Requests Initiated To Reread A Meter At A Service Point

This template is not applicable when Service Order Management is being used.

Defining A Profile's Valid Field Activity Types

Description of Page

The **Field Activity Type** collection shows the field activity requests that may be created for at service points whose SP type references the field activity type profile.

Where Used

This information is used to control the types of field activity requests that may be created for at a service point.

Setting Up Fieldwork Cancellation Reasons

Description of Page

Enter a **Cancel Reason** and **Description** for every field activity request cancellation reason.

Only use **System Default** on those reason codes that are placed on field activity requests that are automatically canceled by the system. The following table lists the valid values and the condition where this cancel reason is used.

System Default	System Condition
Cut Process canceled	Placed on field activity requests that are canceled when a Cut Process is canceled.
SA Start/Stop canceled	Placed on field activity requests that are canceled when a pending start/stop is canceled.
Severance Process canceled	Placed on field activity requests that are canceled when a severance process is canceled .

NOTE:

Required values. You must have one reason code defined for each of the System Default values that corresponds to an event that may occur in your implementation.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_FA_CAN_RSN](#).

Setting Up Field Activity Remarks

NOTE: Field work remarks are typically processed by Service Order Management; therefore, field activity request remarks are not required.

Description of Page

Enter a unique **Field Activity Remark** and a **Description** for every field activity request remark.

Turn on **Eligible for Processing** if field activity requests marked with a given remark code should cause one or more algorithm to execute.

The grid contains **Algorithms** associated with the field activity request remark. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Field Activity Remark Activation	Optional	<p>These algorithms are executed when there are pending FA remarks linked to a field activity request and the FACT (Field activity remark activation) background process runs.</p> <p>Refer to Field Activity - Characteristics/Remarks for more information.</p> <p>Click here to see the algorithm types available for this system event.</p>

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_FA_REM_CD](#).

Defining Outage Call Options

When you create an outage call, you must supply an outage call type. Outage call types contain a great deal of information that is defaulted onto the outage call, including the outage category group codes or trouble codes. To set up outage call types, select **Admin > Field Work > Outage Call Type > Add**.

NOTE:

Refer to [The Big Picture of Outage Care Integration](#) for more information about how trouble calls are created and sent to NMS.

The topics in this section describe the base-package zones that appear on the Outage Call Type portal.

Outage Call Type List

The Outage Call Type [List zone](#) lists every outage call type, i.e. every service task type that has a service task type class of Outage Call. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent outage call type.
- Click the Add link in the zone's title bar to add a new outage call type.

Outage Call Type

The Outage Call Type zone contains display-only information about an outage call type. This zone appears when an outage call type has been broadcast from the Outage Call Type [List zone](#) or if this portal is opened via a drill down from another page. The following functions are available:

- **Edit:** to start a business process that updates the outage call type.
- **Delete:** start a business process that deletes the outage call type.
- **Duplicate:** to start a business process that duplicates the outage call type.

Please see the zone's help text for information about this zone's fields.

Service Order Management External Applications

The external systems used with Service Order Management must be defined as External Applications using the "External Application" (D1-ExternalApplication) business object. Examples of external systems can include:

- A customer information system (such as a separate installation of Oracle Utilities Customer Care and Billing)
- A field work system (such as Oracle Utilities Mobile Workforce Management)
- An asset management system (such as Oracle Utilities Operational Device Management or Oracle Utilities Work and Asset Management)

Information defined for external system service providers used by Service Order Management include:

- **Our Name/ID in Their System:** This is the value that the field work system uses to identify our system.
- **Utility Device ID Type:** This is the Device ID Type that will be used when communicating with the external application and it will be the assumed Device ID Type for any device identifiers sent from the external application.
- **Utility Service Point ID Type:** This is the Service Point ID Type that will be used when communicating with the external application and it will be the assumed Service Point ID Type for any service point identifiers sent from the external application.

Refer to [Understanding External Applications](#) and [Configuring External Applications](#) for more information about external applications.

Processing Roles

The external application's processing roles define how data relevant to the field work system is sent and/or created.

Field work service providers can use the following processing roles:

- **Activity Notification:** Used to send notifications to subscribing and/or requesting systems about the status of orchestration and/or service order field activities.
- **Appointment Request:** Used to send a request for an appointment to the field work system.
- **Cancelation Activity:** Used to send notifications to requesting systems when canceling orchestration and/or service order field activities.
- **Collection Details:** Used to retrieve details about collections processing (used with "Cut Service for Non-Payment" and "Restore Service for Payment" orchestration activities).
- **Customer Contact:** Used to send a contact to a customer regarding a service request

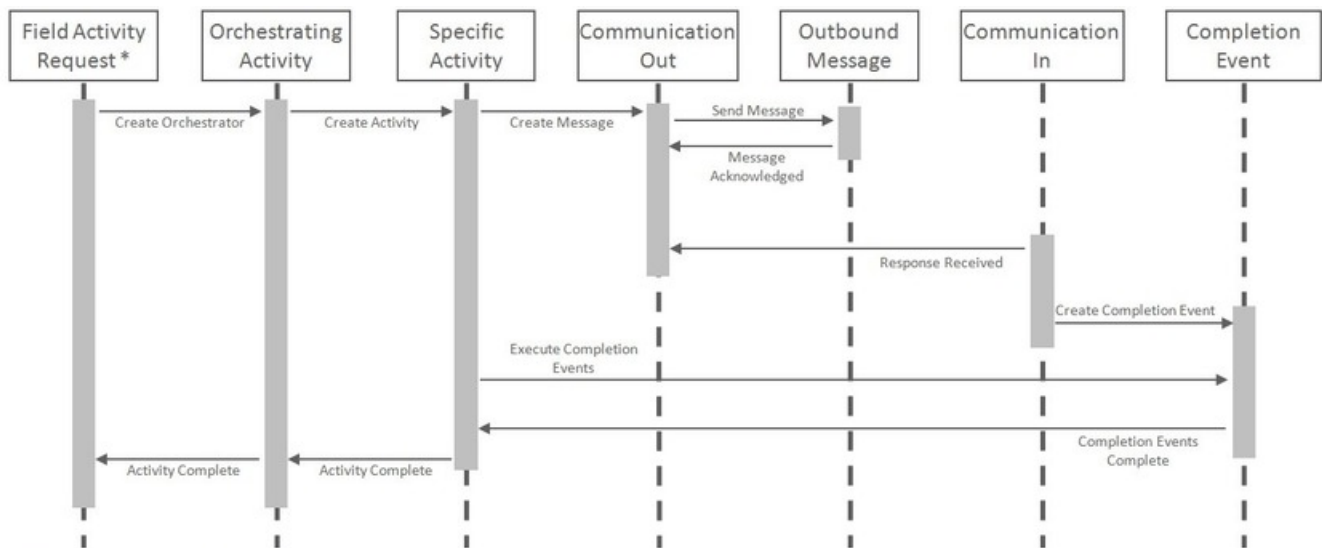

- **Field Activity:** Used to send a service order field activity to the field work system.
- **Field Activity Completion:** Used to send a notification regarding completion of a service order field activity.
- **Interim Status Update:** Used to send updates regarding the status of orchestration and service order field activities to requesting systems.
- **Meter Exchange Mapping:** Used to define how to define different types of meter exchanges based specific roles and device configurations. This can provide context to field crews to help ensure they install the correct type of device and device configuration when exchanging a meter.
- **Response - Appointment:** Used to send a request for an appointment to the field work system.
- **Response - Fail:** Used to send a response to an external system when Service Order Management fails to respond.
- **Response - Missed Appointment:** Used to send a response to the field work system when notification of a missed appointment is received.
- **Response - Negative Acknowledgement:** Used to send a negative acknowledgement response to an external system in the event that a request is rejected.
- **Response - Received:** Used to send a response to an external system to acknowledge receipt of a request.
- **Response - Success:** Used to send a response to an external system when Service Order Management successfully processes a request.
- **Send Field Activity Remark:** Used to send a service order field activity remark to a subscribing system
- **Update Activity:** Used to send notifications to requesting systems when updating orchestration and/or service order field activities.

Setting Up Service Order Activities

Understanding Service Order Activities

This section describes service order activities and how they manage the service order process.

Service order activities coordinate a large number of child transactions that represent the communication to and from an external application. The below diagram depicts a service order activity:

* Field Activity Request: Created by business processes; such as, start service, stop service, and credit & collection. A field activity request initiates an orchestrating activity to fulfill the request. Note: orchestrating activities can also be created manually and through external application requests.

Each object in the sequence diagram has a distinct set of duties within the context of the communication:

- **Orchestrating Activity:** controls the overall intent of the communication. For example an "Enable Service" could include initiating one-to-many specific activities to install the meter and begin the flow of the metered commodity to the service point.
- **Specific Activity:** can be initiated from an orchestrating activity or directly. These activities represent a single task to be carried out such as installing a meter or a remote disconnect smart meter command.
- **Communication Out:** orchestrates the communication to the external application and provides robust handling for any errors that might occur during that communication.
- **Outbound Message:** represents the message payload sent to the external system and the synchronous response.
- **Communication In:** orchestrates the handling of an asynchronous or unsolicited response from an external system.
- **Completion Event:** carries out the results of the communication. For example, in the case of a remote connect it would create the appropriate on off history entry for the device's installation event.

The base package provides the following types of service order activities:

- **Enable Service:** Used to enable service at a service point.
- **Disable Service:** Used to disable service at a service point.
- **Cut for Non-Payment:** Used to cut off service at a service point due to non-payment of past due amounts.
- **Reconnect Service for Payment:** Used to restore service at a service point after receipt of past due payment.
- **Exchange Meter:** Used to orchestrate the exchange of meters at service point, such as in the event that a customer upgrades their meter.
- **Back to Back Service:** Used to orchestrate a change of service when the customer at a service point changes (such as when owners/tenants change).

Service Order Activity Processing

To understand how service order activities manage the service order process, it's important understand the lifecycle of orchestration activity business objects.

Service Order Orchestration Activity Lifecycle

All service order orchestration activity business objects share a common parent business object that defines their lifecycles. This is the Service Point Activity Orchestration business object (DI-SPActivityOrchestration). The table below outlines the lifecycle for this business object.

State	Description
Pending	<p>The initial state for orchestration activities.</p> <p>An Enter algorithm sends an acknowledgement to the requesting system.</p> <p>The activity is transitioned to the next state via a monitor process.</p>
Validate	<p>Enter algorithms perform the following:</p> <p>Validate Activity Type</p> <p>Validate Service Point</p> <p>Check for a non-final duplicate service order request activity for the same service point.</p>
Validation Error	<p>If the business object fails any of the validations in the Pending state, it enters this state.</p> <p>Activities in this state can be corrected and retried.</p>
Discarded	<p>Activities discarded in other states enter this state.</p> <p>Enter algorithms perform the following:</p> <p>Validate that non-final child activities can be discarded without the need for a cancel activity</p> <p>Cancel non-final child activities</p> <p>Send a failure notification to the requesting system</p>
Waiting for Effective Date	<p>If an orchestration activity has a future effective date, it remains in this state until the effective date is reached.</p> <p>A Monitor algorithm transitions the activity to the next state when the activity's effective date time is reached (process date time >= effective date time).</p>
Are SP and Device Ready?	<p>Each type of orchestration activity business object has a unique set of Enter algorithms that perform operations as appropriate for the type of service order request.</p> <p>See Service Order Activity Algorithm Types for more information about these algorithms.</p>
Activity in Progress	<p>Orchestration activities remain in this state while their child activities are processed.</p> <p>A Monitor algorithm transitions the activity to the "Are the SP and Device Ready?" state if there are no non-final child activities related to the current activity.</p> <p>A Monitor algorithm validates that the orchestration activity has not been in its current state for too long, based on the Expiration Days parameter on the orchestration activity's type and the Expiration Date/Time on the orchestration activity</p> <p>An Exit algorithm resets the Expiration Date/Time on the orchestration activity such that each time the activity exits this state its Expiration Date/Time is updated.</p>
Activity Error	<p>If one or more child activities enters an Error state, the orchestration activity enters this state.</p> <p>Activities in this state can be corrected and retried.</p>
Retry	<p>When an orchestration activity is retried after correction of an error condition, it enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Check to determine if there are child service order field activities in progress that have outbound communications awaiting a response.</p> <p>Transition any non-final child activity to the "Reject" state (the state defined as "Reject" on the child activity business object lifecycle. This is most often the "Discarded" state).</p>

State	Description
Completed	Orchestration activities enter this state when all child activities have successfully completed. An Enter algorithm send a success notification to the requesting system.

Use the Business Object and Algorithm portals to view additional details about this business object and its lifecycle algorithms.

Cancel / Update Orchestration Lifecycle

The Cancel Orchestration (D1-CancelOrchestration) and Update Orchestration (D1-UpdateOrchestration) business objects have a similar lifecycle, with the following exceptions:

- There is no "Waiting for Effective Date" state.
- In place of the "Are SP and Device Ready?" state, they have "Cancel Specific Activity" / "Update Specific Activity" states. Enter algorithms on these states attempt to cancel or update a specific child activity.
- In the place of "Activity In Progress" and "Activity Error" states, they have "Communication in Progress" and "Communication in Error" states.

Use the Business Object and Algorithm portals to view additional details about this business object and its lifecycle algorithms.

Service Order Activity Algorithm Types

When an orchestration activity enters the "Are SP and Device Ready?" state, a set of Enter algorithms are used to evaluate the state of the service point / meter / item to determine which actions are required to complete the service request. These algorithms are based on the following algorithm types.

Customer-Device Compatibility Check (D1-DVCOMCHK)

Algorithms of this type execute the "Customer-Device Compatibility Algorithm" defined on the orchestration activity's activity type. Algorithms of this type uses the following parameters:

- **Activity BO To Create If Compatibility Detected:** Specifies the activity business object to instantiate if the algorithm detects an in compatibility between the customer/service point and device.

Note: The base package does not include algorithm types for the "Activity Type - Customer Device Compatibility" algorithm entity.

Connect Only If Previously Connected (D1-CONPRECON)

Algorithms of this type check if the "Connect New Device" flag has a value. If the flag is not populated, the algorithm sets the value of the flag based on the connection status of the device prior to the meter exchange (used only with Meter Exchange requests).

For additional information, refer to the [D1-CONPRECON](#) Algorithm Type.

Create Meter Exchange Field Activity (D1-CREMTREXC)

Algorithms of this type create a service order field activity based on details provided in the algorithm's parameters. Algorithms of this type uses the following parameters:

- **Activity and Specific Field Task to Create:** Specifies the type of activity business object and field task type to create for meter exchange service order field activities, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create.

Mnemonic	Description
specificFieldTask	Specifies the Field Task Type when creating a service order field activity. This value comes from the Field Task Type extendable lookup.

For example, to create a service order field activity based on the D1-FieldActivity business object and the Exchange Meter field task type, these mnemonics would be configured as follows:

```
activityBOTOCreate=D1-FieldActivity specificFieldTask=D1-ExchangeMeter
```

For additional information, refer to the [D1-CREMTREXC](#) Algorithm Type.

Decommission Removed Meter (D1-DCRMMTR)

Algorithms of this type create a decommissioning command for a removed meter (used only with Meter Exchange requests). Algorithms of this type uses the following parameters:

- **Decommission Activity BO to be created:** Specifies the type of activity business object to create when decommissioning a meter. The specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOTOCreate	Specifies the activity business object to create.

For example, to create a smart meter command activity based on the D1-DeviceDecommission business object, this parameter would be configured as follows:

```
activityBOTOCreate=D1-DeviceDecommission
```

For additional information, refer to the [D1-DCRMMTR](#) Algorithm Type.

Create Specific Activity (D1-CRSPACT)

Algorithms of this type determine if a specific activity needs to be created based on the state of the service point. Algorithms of this type use the following parameters to specify the conditions and activity to be created:

- **Field Activity BO:** Specifies the activity business object to instantiate if the algorithm creates a field task type (see next parameter).
- **SP State and Activity BO to Create:** Specifies the type of activity business object to create based on the state of the service point. This parameter can be repeated up to 20 times. Instances of the parameter are evaluated one at a time and the first condition matching the state of the service point is used. Parameters should be ordered from the most restrictive condition to the least restrictive. This parameters uses the following mnemonics to indicate the state (any combination of the following) of the service point:

Mnemonic	Description
servicePointConnected	Specifies if the service point is currently connected Valid values are "true" and "false".
disconnectLocation	Specifies the "Disconnect Location" for the service point. Valid values are "D1SR" (source) and "D1DV" (device).
deviceInstalledAtSP	Specifies if there is a device currently installed at the service point. Valid values are "true" and "false".
installationEventStatusOverride	Specifies the value of the "Installation Status" option type of the Install Event's Status ("Pending", "Conn-PreComm", "ManualOff", etc.)

Based on the unique combination of these mnemonics, a specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create (used most often to specify a command business object)
specificFieldTask	Specifies the field task type when creating a service order field activity. This value comes from the Field Task Type extendable lookup. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the activity business object to create.
spTypeCategory	Specifies a service point type category. Valid values include "D1MT" (meter), "D1IT" (item), "D1MI" (multi-item), from the SP_CATEGORY_FLG lookup. Specifying this mnemonic indicates that a service order field activity should be created only if the service point's category match the one specified by this mnemonic.
executeOverrideAlgorithm	Specifies whether or not to execute the algorithm specified for the Override Device/Task Algorithm on the service order orchestration activity type. This allows the activity business object to be dynamically determined based on an algorithm instead of the "activityBOToCreate" or "specificFieldTask" mnemonics. Valid values are "true" and "false".

For example, the following parameter configuration would create a "Connect Service Point and Install Meter" service order field activity given the following conditions:

- Service Point Connected: False
- Disconnect Location: Source
- Device Installed at Service Point: False
- Service Point Category: Meter

```
servicePointConnected=false disconnectLocation=D1SR deviceInstalledAtSP=false specificFieldTask=D1-ConnSPAtSrceAndInstMtr spTypeCategory=D1MT
```

For additional information, refer to the [D1-CRSPACT](#) Algorithm Type.

Update Device (D1-UPDDVC)

Algorithms of this type determine if an activity needs to be created to update the device based on the state of the service point and device installed at the service point. Algorithms of this type use the following parameters to specify the conditions and activity to be created.

- **Error if SP Not Connected or no Device Installed (Default is Yes):** Indicates if the algorithm should return an error if the service point is not connected or if a device is not currently installed. Valid values are "Yes" and "Con" (continue)
- **SP State and Activity BO to Create:** Specifies the type of activity business object to create based on the state of the service point. This parameter can be repeated up to 20 times. Instances of the parameter are evaluated one at a time and the first condition matching the state of the service point is used. Parameters should be ordered from the most restrictive condition to the least restrictive. These parameters use the following mnemonic to indicate the state (any combination of the following) of the service point:

Mnemonic	Description
installationEventStatusOverride	Specifies the value of the "Installation Status" option type of the Install Event's Status ("Pending", "Conn-PreComm", "ManualOff", etc.)

Based on the value of this mnemonic, a specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create (used most often to specify a command business object)
specificFieldTask	Specifies the Field Task Type when creating a service order field activity. This value comes from the Field Task Type extendable lookup. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the activity business object to create.
spTypeCategory	Specifies a service point type category. Valid values include "D1MT" (meter), "D1IT" (item), "D1MI" (multi-item), from the SP_CATEGORY_FLG lookup. Specifying this mnemonic indicates that a service order field activity should be created only if the service point's category match the one specified by this mnemonic.
alternativeFieldTask	Specifies an alternative Field Task Type to use when creating a service order field activity in the event that the device does not support the command indicated by the "activityBOToCreate" mnemonic. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the activity business object to create. A value of 'skip' will continue the evaluation of the algorithm's next parameter

For example, the following parameter configuration would create a "Turn On Meter" service order field activity given the following conditions:

- Installation Status: Manual Off
- Service Point Category: Meter

```
installEventStatusOverride=ManualOff specificFieldTask=D1-TurnOnMeter spTypeCategory=D1MT
```

Other parameters used by algorithms of this type include:

- **Field Activity BO:** Specifies the activity business object to instantiate if the algorithm creates a field task type (see above parameter).
- **XPath of Activity Element controlling Activity creation:** Defines an element within the activity business object schema that can be used to control whether or not this algorithm should create an activity. For example, to specify that the value of the "Connect New Device" flag be used to determine whether or not the algorithm should create an activity, this parameter could be set to "connectNewDevice".
- **Element value indication that Activity creation should not proceed:** Specifies a value for the element defined in the "XPath of Activity Element controlling Activity creation" parameter that would indicate that the algorithm should not create an activity. Valid values are based on the element defined for the "XPath of Activity Element controlling Activity creation" parameter. For example, to specify that an activity should not be created if the "Connect New Device" flag is

set to "Do Not Connect / Turn On", this parameter should be set to "D1NC" (from the D1_CONNECT_NEW_DEVICE_FLG lookup).

For additional information, refer to the [D1-UPDDVC](#) Algorithm Type.

Remote Turn Off Turn On (D1-REMONOFF)

Algorithms of this type remotely turn a device off and on for a Back to Back service request. Algorithms of this type use the following parameters:

- **Device Incompatibility Detected Activity BO:** Specifies the activity business object the algorithm will look for. If the algorithm finds an activity of this business object, the algorithm terminates.
- **Remote Connect BO:** Specifies the activity business object to instantiate when creating a remote connect command.
- **Remote Disconnect BO:** Specifies the activity business object to instantiate when creating a remote disconnect command.
- **Installation Event Status Override for Connect:** The override status to which the Installation Event Status is set after performing a remote connect command.
- **Installation Event Status Override for Disconnect:** The override status to which the Installation Event Status is set after performing a remote disconnect command.

For additional information, refer to the [D1-REMONOFF](#) Algorithm Type.

Check for Measurement (D1-CHKMSMT)

Algorithms of this type determine if measurements exist on activity's service point as of the service date/time. If no measurement is found, algorithms of this type create an activity to either obtain or wait for a measurement. The specific type of activity is based on the type and configuration of the device and service point. Algorithms of this type use the following parameters:

- **Activity BO To Wait For Measurement:** Specifies the activity business object to instantiate when the algorithm logic indicates it should wait for a measurement for the service point.
- **Activity BO For Field Read:** Specifies the field activity business object to instantiate when the algorithm logic indicates it should request a meter reading from the field.
- **Specific Field Task:** Specifies the field task type when creating a service order field activity for a meter reading from the field.
- **Activity BO To Wait For Scheduled Read:** Specifies the activity business object to instantiate when the algorithm logic indicates it should wait for a scheduled read for the service point.
- **Activity BO For On Demand Read - Scalar:** Specifies the activity business object to instantiate when the algorithm logic indicates it should issue an on-demand read (scalar) smart meter command.
- **Start Range for Normal Measurement Condition:** The start of the range of conditions that indicate "normal" measurements when the algorithm is searching for measurements for the service point.
- **End Range for Normal Measurement Condition:** The end of the range of conditions that indicate "normal" measurements when the algorithm is searching for measurements for the service point.
- **Minimum Range for bottom Measurement condition:** The minimum measurement condition used when searching for measurements for the service point. Used only when no measurements are found in the "normal" range defined by the "Start/End Range Normal Measurement Condition" parameters.

The following parameters on the orchestration activity type are also used by algorithms of this type when searching for measurements for the service point:

- **Look for Measurement within the Day:** Limits the search to the reference date (the service date).
- **Minimum and Maximum Offset Number of Days:** Numbers of days added to /subtracted from the reference date to expand the search period.

For additional information, refer to the [D1-CHKMSMT](#) Algorithm Type.

Algorithm Types and Orchestration Activity Business Objects

Each of the orchestration activity business objects uses a different set of these algorithm types. The table below lists which of these algorithm types are defined for each of the service order orchestration activity business objects.

	Enable Service	Disable Service	Cut for Non-Payment	Reconnect for Payment	Meter Exchange	Back-to-Back
Customer-Device Compatibility Check	X					X
Connect Only If Previously Connected					X	
Create Specific Activity	X					
Create Meter Exchange Field Activity					X	
Update Device	X	X	X	X	X	X
Remote Turn Off Turn On						X
Decommission Removed Meter					X	
Check For Measurement:	X	X	X			X

Cancel / Update Orchestration - Algorithm Types

Enter algorithms on the "Cancel Specific Activity" and "Update Specific Activity" states attempt to cancel or update a specific child activity. These algorithms are based on the following algorithm types.

- Cancel Specific Activity:** Algorithms of this type cancel the specific activity (either a service order field activity or a smart meter command) that is associated to the Cancel or Update orchestration activity, based on the current status of the specific activity.
- Update Specific Activity:** Algorithms of this type update the specific activity (either a service order field activity or a smart meter command) that is associated to the Cancel or Update orchestration activity, based on the current status of the specific activity.

Algorithm Type	Algorithm(s)
Cancel Specific Activity (D1-CANSPACT)	Cancel Specific Activity (D1-CANSPACT)
Update Specific Activity (D1-UPDSPAC)	Update Specific Activity (D1-UPDSPAC)

Use the Algorithm Type and Algorithm portals to view additional details about these algorithms.

Understanding Service Order Field Activity Types

Service order activity types must be configured for each type of service order activity.

Service order activity types are assigned to the following Activity Type Categories:

Service Order Activity	Activity Type Category
Back-to-Back	Service Request Orchestration

Cancel Orchestration	Orchestration Maintenance
Cut Service for Non-Payment	Request Orchestration
Disable Service	Request Orchestration
Enable Service	Request Orchestration
Exchange Meter	Request Orchestration
Reconnect Service for Payment	Request Orchestration
Update Orchestration	Orchestration Maintenance

Refer to [Understanding Activity Types](#) for more information about activity types.

Configuring Service Order Activity Types

The Activity Type portal is used to display and maintain service order activity types.

Refer to [Understanding Activity Types](#) for more information.

You can access the portal from the **Admin > Communication > Activity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type

Service Order Management Configuration

The following table outlines the activity types that must be configured for the service order activity types supported by Service Order Management:

Service Order Activity	Activity Type (Business Object)
Enable Service	Enable Service (D1-EnableServiceType)
Disable Service	Disable Service (D1-DisableServiceType)
Cut Service for Non-Payment	Cut Service for Non-Payment (D1-CutServiceForNonPaymentType)
Reconnect Service for Payment	Reconnect for Payment (D1-ReconnectForPaymentType)
Meter Exchange	Exchange Meter (D1-ExchangeMeterType)
Back-to-Back Service	Back-to-Back Service (D1-BackToBackServiceType)
Cancel Orchestration	Cancel Orchestration (D1-CancelOrchestrationType)
Update Orchestration	Update Orchestration (D1-UpdateOrchestrationType)

The demonstration database contains examples of each of these service order activity types.

Setting Up Service Order Field Activities

Understanding Service Order Field Activities

This section describes service order field activities and how they communicate with field work management systems such as Oracle Utilities Mobile Workforce Management.

Service order field activities are activities that involve sending workers into the field to perform service. This can include meter installation, meter replacement, and other activities.

Service order field activities send messages to a field work system, which in turn assigns them to crews to be completed in the field. Service Order Management supports integration with Oracle Utilities Mobile Workforce Management to support field activities, but can also integrate with other field work systems if needed.

Service Order Field Activity Information

All service order field activities are based on the Field Activity (D1-FieldActivity) business object, and include the following user-accessible information:

- **Status:** The current status of the service order field activity.
- **Service Date/Time:** The date and time the service order field activity was created.
- **Service Point:** The service point associated with the service order field activity.
- **Field Task Type:** The field task type for the service order field activity. This defines the type of task and other processing details regarding how Service Order Management processes the service order field activity. See [Field Task Types](#) for more details about field task types.
- **Recipient:** The field work system service provider to which the service order field activity is sent for scheduling and assignment.
- **Device ID:** The device related to the service order field activity (if applicable).
- **Request Information:** Details of the service order request, including requester and external system information.
- **Contact Details (or Customer Information):** Contact details for the customer associated with the service order request.
- **Address Information:** The address of the service point associated with the service order field activity.

The field activity business object also contains other information that is populated by algorithms and scripts as the service order field activity is processed by the system.

How Do Service Order Field Activities Work?

At a high level, service order field activities work as follows:

Create a Service Order Field Activity Request

A service order field activity request can be as a result of a customer requesting a change to their service; such as, enabling or disabling service when moving into or out of a residence. They can also be the result of other business processes; such as, a request to cut service due to non-payment. Within Oracle Utilities Customer To Meter actions (such as start service, stop service, and cut for non-payment) result in a field activity request being created for each affected service point. These requests are sent to Service Order Management to be performed. In addition to requests that are created with Oracle Utilities Customer To Meter, service order requests can be received from other applications.

Retrieve Required Data

The service order field activity uses a set of pre-processing algorithms to derive and populate data needed by the activity, such as the device, service point, address, effective date, and others.

Request Appointment (Optional)

If the service order field activity task type specifies that field tasks of this type require an appointment, the service order field activity checks for available appointment slots in the field work system and sends a notification to the appointment handling system.

Create Outbound Communication

The service order field activity creates an outbound communication to send the service order field activity to the field work system. The outbound communication gathers the information required by the field work system before being sent. This information is retrieved by a set of processing scripts defined on the field task type.

Receive Inbound Communication

When the service order field activity has been completed, the field work system sends an inbound communication back to Service Order Management.

Inbound communications can contain Field Activity Remarks (entered by field resources when they perform and complete their field work. If the Field Activity Remarks reference completion events, they are executed.

The inbound communications create completion events as defined on the field task type. If the service order field activity was successfully completed, it creates the "Completion Events When Successful" completion events. If the service order field activity was canceled, it creates the "Completion Events When Canceled" completion events.

Execute Completion Events

After receiving the inbound communication, a service order field activity algorithm transitions any active completion events into their executed state.

Complete Processing

The service order field activity completes its processing by doing the following:

- Updating the parent orchestration activity
- Sending a success response to the requester
- Transitioning the parent orchestration activity to the next state in its lifecycle
- Sending a service order field activity completion outbound communication to subscribing systems.

Service Order Field Activity Processing

This section outlines how service order field activities are processed.

Pre-Processing, Validation, and Post-Processing Algorithms

When service order field activities are first instantiated, a set of pre-processing algorithms populate and derive information needed for the activity, such as the activity type, service point, device, address, effective date, and other information.

Validation algorithms validate this information when first retrieved and when updated.

When service order field activities are completed, a post-processing algorithm populates the activity end date/time:

Service Order Field Activity Lifecycle

As a service order field activity moves through its lifecycle, it triggers various business processes based on the type of service order field activity. The table below outlines the lifecycle for the Field Activity (D1-FieldActivity) business object.

State	Description
Pending	The initial state for service order field activities. An Enter algorithm sends an acknowledgement to the requesting system. The activity is transitioned to the next state via a monitor process.

State	Description
Validate	<p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Validate Activity Type (and transition to error if invalid) Derive and validate service order recipient Validate duplicate and conflict service order activities Derive and validate service order service point Derive and validate service order device Validate address constituents Check for any existing cut service restrictions <p>The activity is transitioned to the next state via a monitor process.</p>
Validation Error	<p>If the business object fails any of the validations in the Pending state, it enters this state.</p> <p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Create a To Do based on specified To Do Type and To Do Role Set the "Allow Child to Transition Parent Activity" flag to yes. This allows the service order field activity to transition the parent orchestration activity if needed. <p>Activities in this state can be corrected and retried.</p>
Waiting to Request	<p>If a service order field activity has a future effective date, it remains in this state until the effective date is reached.</p> <p>A Monitor algorithm transitions the activity to the next state when the activity's effective date time is reached (process date time >= effective date time).</p> <p>An Enter algorithm sets the "Allow Child to Transition Parent Activity Based On Effective Date" flag to yes. This allows the service order field activity to transition the parent orchestration activity if needed.</p>
Waiting for Appointment	<p>If the service order field activity passes its validations and the effective date has been reached, the activity enters this state.</p> <p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Evaluate if an appointment is required for field tasks of this type. If not, the activity transitions to the "Communication in Progress" state. Create a To Do if an appointment is necessary but the system is not able to send an appointment request Set the "Allow Child to Transition Parent Activity" flag to yes. This allows the service order field activity to transition the parent orchestration activity if needed. Send a notification to the appointment handling system <p>Monitor algorithms perform the following:</p> <ul style="list-style-type: none"> Verify if an appointment has been supplied Send a notification to the appointment handling system <p>The activity is transitioned to the next state via a monitor process.</p> <p>See Waiting for Appointment for more information about this state.</p>
Communication in Progress	<p>Service order field activities enter this state following the "Waiting for Appointment" or "Retry" states.</p>

State	Description
	<p>Enter algorithms perform the following:</p> <p>Create an outbound communication for the service order field activity (see Communication in Progress for more information)</p> <p>Set the "Allow Child to Transition Parent Activity" flag to yes. This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Monitor algorithms perform the following:</p> <p>Check for existing child communications</p> <p>Check that the activity hasn't timed out</p>
Discarded	<p>Activities discarded in other states enter this state.</p> <p>Enter algorithms perform the following:</p> <p>Cancel outstanding outbound communications</p> <p>Cancel outstanding completion events</p> <p>Populate the cancel reason</p> <p>Send a failure notification to the requesting system</p> <p>Transition the parent activity to the " Activity Error" state (see Service Order Orchestration Activity Lifecycle for more information)</p> <p>Check if a Cancel Orchestration activity is required</p>
Communication Error	<p>If an outbound or inbound communication an Error state, the service order field activity enters this state.</p> <p>Monitor algorithms perform the following:</p> <p>Check that the activity hasn't timed out</p> <p>Enter algorithms perform the following:</p> <p>Create a To Do based on specified To Do Type and To Do Role</p> <p>Set the "Allow Child to Transition Parent Activity" flag to yes. This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Activities in this state can be corrected and retried.</p>
Retry	<p>When a service order field activity is retried after correction of an error condition, it enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Check to determine if there are associated outbound communications in progress.</p> <p>Cancel any outstanding outbound communications</p>
Execute Completion Events	<p>After an inbound communication is received, it enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Executes completion events defined on the field task type (these completion events were initially created by the inbound communication).</p> <p>Evaluates the "Field Activity Completed" flag on the service order field activity. If this is set to "No", the service order field activity is transitioned to the "Canceled In Field" state.</p> <p>The activity is transitioned to the next state via a monitor process.</p> <p>See Execute Completion Events for more information about this state.</p>

State	Description
Completion Event Error	<p>If an error occurs during completion event processing, the service order field activity enters this state.</p> <p>Monitor algorithms perform the following:</p> <p>Check that the activity hasn't timed out</p> <p>Enter algorithms perform the following:</p> <p>Create a To Do based on specified To Do Type and To Do Role</p> <p>Set the "Allow Child to Transition Parent Activity" flag to yes. This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Activities in this state can be corrected and retried.</p>
Completed	<p>Service order field activities enter this state when all completion events have successfully completed.</p> <p>Enter algorithms perform the following:</p> <p>Update the parent orchestration activity</p> <p>Send a success response to the requester</p> <p>Transition the parent orchestration activity to the next state in its lifecycle</p> <p>Send a service order field activity completion outbound communication to subscribing systems.</p>
Canceled in Field	<p>If the "Field Activity Completed" flag on the field activity is set to "No", the service order field activity enter this state.</p> <p>Enter algorithms perform the following:</p> <p>Send a failed response to the requester</p> <p>Transition the parent orchestration activity to the "Activity Error" state.</p> <p>Create a To Do to notify users that the service order field activity has been canceled.</p>

Waiting for Appointment

When a service order field activity enters the "Wait for Appointment" state, it first determines if an appointment is necessary for the service order field activity. If not, the activity moves on to the "Communication in Progress" state (see below).

If an appointment request cannot be sent for some reason, the service order field activity creates a To Do item to alert a user to attempt to manually request an appointment. Otherwise, the service order field activity sends an outbound message to the field work system requesting an appointment. The outbound message type is derived using the processing role defined on the "Send Notification to Appointment Handling System - Enter" algorithm.

Processing Role	Outbound Communication Business Object
Appointment Response (default)	Send Appointment Response Outbound Message (D1-SendApptRespOutboundMsg)
Used if: An appointment is required and needs to be scheduled	Note: An outbound message must be created based on this business object.

Processing Role**Outbound Communication Business Object**

Appointment has been set

The response from the field work system can be received by creating an Inbound Web Service that references the "Book selected appointment to Field Activity" (D1-BookAppt) service script.

While in this state, monitor algorithms verify if an appointment has been supplied and send notifications to the field work system.

Communication in Progress

Service order field activity communications are records of messages sent between Service Order Management and an external field work system, such as Oracle Utilities Mobile Workforce Management. Communications can flow both outbound and inbound.

See [Service Order Field Activity Communication](#) for more information about service order field activity communication.

Execute Completion Events

After receiving the inbound communication, the service order field activity enters the "Execute Completion Events" state.

The inbound communication will have previously created completion events for the service order field activity, based on those defined on the field task type or those referenced by field activity remarks. These creation events begin in the "Pending" state.

An Enter algorithm transitions completion events associated with the service order field activity into their "Executed" state.

Service Order Field Activity Communication

This section outlines how service order field activities communicate with field work systems.

When a service order field activity enters the "Communication in Progress" state, it sends an outbound communication to the field work system, and waits for an inbound communication response.

See **Understanding the Service Order Field Activity Communication Process** below for more information about the role of communications in the service order field activity communication process.

Outbound Communications

Outbound Communications represent messages sent from Service Order Management to an external field work system. Outbound communications use the following types of objects:

Outbound Communication Business Objects

An outbound communication business object exists for each type of message to be sent to an external system. For service order field activities, the following base package outbound communication objects can be used.

Type of Outbound Communication	Outbound Communication Business Object
Initial service order field activity outbound communication	Field Activity Outbound Communication (D1-FieldActivityOBComm)
Modify outbound communication Used to send an update to a service order field activity previously sent to the field work system.	Field Activity Outbound Communication (D1-ActivityModifyOBComm)

Outbound Message Types

A outbound message type must also be created for each type of message to be sent to an external system. Again, this is based on the types of messages the system is designed to accept. For service order field activities, the following outbound message types are needed:

Type of Outbound Communication	Outbound Message Type
Initial Service Order Field Activity Message	Field Activity Outbound Message
Modify Existing Service Order Field Activity	Modify Field Activity Outbound Message

Refer to the Oracle Utilities Application Framework documentation for more information about outbound message types.

External Systems

You must also create an External System for each external system to which Service Order Management will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch, XAI, or Real-time)
- Message Sender (if Processing Method is set to Real-time or XAI)
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

To continue the example above, you might create the following external system:

Outbound Message Type	Processing Method	Batch Control
Field Activity Outbound Message	Batch	Sync Request Monitor (F1-SYNRQ)
Modify Field Activity Outbound Message	Batch	Sync Request Monitor (F1-SYNRQ)

Refer to the Oracle Utilities Application Framework documentation for more information about external systems.

Inbound Communications

Inbound Communications represent messages sent from an external field work system such as Oracle Utilities Mobile Workforce to Service Order Management. Inbound communications are typically sent in response to a service order field activity. Inbound communications use the following types of objects:

Inbound Communication Business Objects

An inbound communication business object must be created for each type of message to be received from an external system. For service order field activities, the following base package inbound communication object can be used.

Inbound Communication Business Object
Field Activity Inbound Communication (D1-FieldActivityIBComm)

Inbound Web Service

You must also create an Inbound Web Service for each type of message to be received from an external system. Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send. To continue the example above, you might create the following inbound web services:

Inbound Web Service	Schema (Inbound Communication Business Object)
Field Activity Inbound Communication	Field Activity Inbound Communication D1-FieldActivityIBComm

Refer to the Oracle Utilities Application Framework documentation for more information about Inbound Web Services.

Field Activity Remarks

Inbound communications can contain activity remarks, which represent notes entered by the field worker as they perform and complete their field work. These can be solely informational, or can reference completion events via the "Remark Processing" section of the Field Activity Remark Type extendable lookup. This allows information sent with the inbound communication to initiate business processing if necessary.

Completion events specified on this extendable lookup are created by the inbound communication, and then executed when the service order field activity enters the "Execute Completion Events" state.

Understanding the Service Order Field Activity Communication Process

This section provides an overview of the communication process that takes place when a service order field activity is initiated. For each step in the process, the table below provides a brief description of the processing that takes place, and lists the specific base package objects used by Service Order Management

Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

Step	Process	Base Package Objects
1.	An orchestration activity creates a service order field activity as part of its processing. A service order field activity business object is instantiated for the command.	Field Activity Business Object: Field Activity (D1-FieldActivity)
2.	When the service order field activity enters the Communication in Progress state, it creates an outbound communication.	Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)
3.	A Enter algorithm on the "Awaiting Response" state of the outbound communication retrieves information needed by the outbound message to be sent to the field work system based on processing scripts specified on the field task type.	Enter Algorithm: Populate Send Detail for Field Activity (D1-POPSNDDTL)
4.	A Enter algorithm on the "Awaiting Response" state of the outbound communication creates an outbound message.	Enter Algorithm: Create Outbound Message (D1-COUTMSG) Note: An outbound message type for this message is not included in the base package.

Step	Process	Base Package Objects
5.	<p>The outbound message is sent to middleware components via an External System and Batch Control.</p> <p>Middleware components utilize Business Process Execution Language (BPEL).</p>	<p>External System: MWM</p> <p>Batch Control: Sync Request Monitor (F1-SYNRQ)</p>
6.	<p>The middleware converts the outbound message from SOM format into the format used by the field work system, and sends the message to the field work system.</p>	
7.	<p>When the field work system sends a response, the middleware receives the response message from the field work system, and converts it from the format used by the field work system to SOM format and invokes an Inbound Web Service.</p>	<p>Inbound Web Service: D1-FieldActivityIBComm</p>
8.	<p>The Inbound Web Service picks up the message, and creates a corresponding inbound communication.</p> <p>The specific type of inbound communication business object created is determined by the Inbound Web Service.</p>	<p>Inbound Web Service: D1-FieldActivityIBComm</p> <p>Inbound Communication Business Object: Field Activity Inbound Communication (D1-FieldActivityIBComm)</p>
9.	<p>The inbound communication identifies the parent outbound communication.</p>	<p>Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)</p>
10.	<p>The inbound communication creates the completion events defined on the field activity field task type (Successful or Canceled, as appropriate) in the "Pending" state.</p> <p>If the inbound communication contains field activity remarks, it also executes any field activity remark completion events.</p>	<p>Inbound Communication Business Object: Field Activity Inbound Communication</p> <p>D1-FieldActivityIBComm</p>
11.	<p>The inbound communication updates the outbound communication.</p> <p>This update is performed by an Enter algorithm on the "Completed" Status of the inbound communication business object's lifecycle.</p>	<p>Inbound Communication Business Object: Field Activity Inbound Communication</p> <p>D1-FieldActivityIBComm</p> <p>Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)</p>
12.	<p>The outbound communication updates the "Completion Flag" and the original service order field activity business object.</p> <p>This update is performed by an Enter algorithm on the "Completed" Status of the outbound communication business object's lifecycle.</p>	<p>Outbound Communication BO: Initiate Connect Disconnect (D3-InitiateConnectDisconnect)</p> <p>Field Activity Business Object: Field Activity (D1-FieldActivity)</p>

Unrelated Pickup Orders

When field work crews are out performing field work, it's possible that they will encounter other work unrelated to their current task that needs to be done. This type of work can be as simple as trimming a tree whose branches are too close to power lines, or the replacement of a meter for a different customer or service point. These types of task are referred to as "unrelated pickup activities." Crews can either work the field activity or leave it to be assigned to another crew at a later date.

When the crew creates an unrelated pickup activity in the field work system, it is sent to Service Order Management, and a corresponding service order field activity is created in the system.

Unrelated pickup activities can be created via one of the following Inbound Web Services:

- Field Activity Asynchronous Req Inbound (D1-FARequestAsynchronous)
- Field Activity Synchronous Req Inbound (D1-FARequestSynchronous)

Once created, they are processed like any other service order field activity. If the pickup activity was completed in the field before being sent to Service Order Management, it will quickly move through its lifecycle (as now further action is needed) until it reaches the "Completed" state.

Retrieving Service Point Information

If the unrelated pickup activity is customer-related it will require service point information to be created. This information can be queried by the field work crew via the "Field Work Service Point Query" (D1-FieldWorkSPQuery) Inbound web service.

This service uses a set of criteria to allow the field crew to search for a service point based upon either service point or device information. The service returns a list of service points that is configurable in length. If the number of results is larger than the configured maximum length the service indicates that additional records exist and the crew can request another set of results allowing them to identify the proper service point to associate to the activity.

There are times when an unrelated pick-up activity is identified but the field crew is out-of-coverage (i.e. no network connection) and they will not be able to immediately verify service point information. In this type of situation, the crew can input the service point criteria fields and create the activity, which, when imported into Service Order Management, will attempt to identify the service point based upon the information provided. If the service point can be uniquely identified everything should operate as normal. If the service point cannot be uniquely identified then the service order field activity is set to the error state.

Setting Up Service Order Field Activity Types

Understanding Service Order Field Activity Types

A single service order field activity type must be configured to support communication with external field work systems such as Oracle Utilities Module Workforce Management. Service order activity types are assigned to the "Field Activity" Activity Type Category.

Refer to [Understanding Activity Types](#) for more information about activity types.

Configuring Service Order Field Activity Types

The Activity Type portal is used to display and maintain service order field activity types.

Refer to [Understanding Activity Types](#) for more information.

You can access the portal from the **Admin > Communication > Activity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type

Service Order Management Configuration

The following table outlines the activity types that must be configured for the service order field activity type supported by Service Order Management:

Field Activity	Activity Type (Business Object)
Field Activity	Field Activity (D1-FieldActivityType)

The demonstration database contains examples of each of these service order activity types.

Setting Up Field Task Types

Understanding Field Task Types

A service order field activity's field task type defines details about the type of task to be performed and how the system will process the activity.

Field Task Type Information

Field task types are values for the Field Task Type (D1-FieldTaskTypeLookup) extendable lookup. Each field task type value includes the following information:

- **Routing:** Indicates if field tasks of this type can only be performed at a service point. Valid values are "SP Required" and "Pass-Through".
- **Appointment Option:** Indicates if an appointment (via a mobile workforce application) is required or applicable to field tasks of this type. Valid values are "Not Applicable", "Optional", and "Required".
- **Completion Events When Successful:** One or more completion events that are executed upon successful completion of field tasks of this type.
- **Completion Events When Canceled:** One or more completion events that are executed upon cancellation of field tasks of this type.
- **Duplicate Task Type Information:** Defines processing rules for handling potential duplicate field tasks, including:
 - **Allow Duplicates:** Specifies whether or not duplicate field tasks are allowed
 - **Duplicate Threshold:** A number of hours used to determine if a newly instantiated field task type should be considered a duplicate.
 - **Field Task Types:** A list of one or more field task types that are considered to be duplicates of the field task type
- **Conflict Task Type Information:** Defines processing rules for handling potentially conflicting field tasks, including:
 - **Allow Conflicts:** Specifies whether or not conflicting field tasks are allowed
 - **Conflict Threshold:** A number of hours used to determine if a newly instantiated field task type should be considered a conflict.

- **Field Task Types:** A list of one or more field task types that are considered to conflict with the field task type
- **Processing Scripts:** Defines one or more processing scripts to extract supplemental information needed by the mobile workforce application to schedule field tasks of this

Configuring Field Task Types

Field task types are configured using the extendable lookup portal.

You can access the extendable lookup portal from the **Admin > General > Extendable Lookup**.

Use the **Extendable Lookup Search** zone to search for and select the Field Task Type (D1-FieldTaskTypeLookup) extendable lookup.

The following zones may appear as part of the portal's **Main** tab page:

- **Extendable Lookup List:** This zone displays a list of values for the Field Task Type extendable lookup.
- **Extendable Lookup List:** This zone provides information about the selected value.

Service Order Management Configuration

The following table outlines the field task types that must be configured to support each of the service order activity types supported by Service Order Management:

Service Order Activity	Field Task Types
Enable Service — Meters	Connect SP at Source: D1-ConnectSPAtSource Connect SP at Meter: D1-ConnectSPAtMeter Connect SP at Source and Turn On: D1-ConnectSPAtSourceAndTurnOn Connect SP at Meter and Turn On: D1-ConnectSPAtMeterAndTurnOn Connect SP at Source and Install Meter: D1-ConnSPAtSrceAndInstMtr Connect SP at Meter and Install Meter: D1-ConnSPAtMtrAndInstMtr Install Meter: D1-InstallMeter Turn On Meter: D1-TurnOnMeter
Enable Service — Items	Connect SP at Source: D1-ConnectSPAtSource Item - Connect SP at Device: D1-ConnectSPAtDevice Item - Connect SP at Source and Turn On: D1-ConnSPAtSrceAndTurnOnDvc Item - Connect SP at Device and Turn On: D1-ConnectSPAtDvcAndTurnOn Connect SP at Source and Install Device: D1-ConnSPAtSrceAndInstDvc Connect SP at Device and Install Device: D1-ConnSPAtDvcAndInstDvc Item - Install Device: D1-InstallDevice Turn On Item: D1-TurnOnItem
Disable Service — Meters	Turn Off Meter: D1-TurnOffMeter
Disable Service — Items	Turn Off Item: D1-TurnOffItem
Cut Service for Non-Payment — Meters	Cut for Non-Payment: D1-CutForNonPayment
Cut Service for Non-Payment — Items	Item - Cut for Non-Payment: D1-CutItemForNonPayment

Service Order Activity	Field Task Types
Reconnect Service for Payment — Meters	Reconnect for Payment: D1-ReconnectForPayment
Reconnect Service for Payment — Items	Item - Reconnect for Payment: D1-ReconnectItemForPayment
Meter Exchange	Exchange Meter: D1-ExchangeMeter
Item Exchange	Exchange Device: D1-ExchangeDevice
Back-to-Back — Meters	Read Meter: D1-ReadMeter

Defining Credit & Collections Options

NOTE:

The functionality described in this section is meant to handle the collection of unpaid balances. If your organization practices [open-item accounting](#) and collects on unpaid bills, you will not use this functionality. Rather, you will use the functionality described under [Defining Overdue Processing Options](#).

The system periodically monitors how much your customers owe to ensure they haven't violated your collection criteria. When a violation is detected, the system generates the appropriate responses (e.g., letters, disconnect notices, collection agency referrals, and eventually write off). This section describes how to set up the tables that control your credit & collections processing.

WARNING:

Setting up the credit & collections control tables is as challenging as your organization's collection rules. If you have simple rules then your setup process will be straightforward. If your collection rules are complicated (e.g., they differ based on the type of customer, the type of debt, the age of debt, the type of service, etc.), then your setup process will be more challenging.

The Big Picture Of Credit & Collections

This section provides an overview of important C&C concepts with which you should be familiar before you set up your C&C control tables.

Collection Criteria vs. Severance Criteria vs. Write Off Criteria

The following diagram introduces important concepts related to the C&C processes:

There are many important concepts illustrated above:

An account's debt comes from its service agreements

An account's debt is managed at the service agreement level, i.e., the system keeps track of how much a customer owes in respect of each service agreement. In order to determine an account's balance, the system must add up the debt on each of the account's service agreements.

Collection criteria define intolerable debt

Collection criteria are control data that define intolerable debt. Most criteria are defined using a combination of number of days in arrears and a dollar amount.

Collection criteria may be compared to an account's total debt or to subsets of debt

If your organization has simple collection procedures, you will probably target collection criteria at an account's total debt. However, you have the option of segregating an account's debt into debt classes and targeting the collection criteria at each class. For more information about debt classes, see [Different Collection Criteria For Different Customers And Different Debt](#).

Collection criteria also define what to do when the level of intolerable debt is exceeded

When you define collection criteria, you also define how the system should respond if an account violates your criteria. These collection events are defined in respect of a "collection process template".

There are usually several collection events that take place when criteria are violated

A collection process template usually has several collection events. Each event is meant to prod the customer to pay. The initial collection events are typically letters. If payment is not received after several such attempts, the last collection event typically starts a severance process for each service agreement in arrears.

A severance process template defines how to sever a service agreement

A "severance process template" defines how to sever a given type of service agreement. A severance process template usually contains several severance events. These events are a series of letters and / or disconnection field activities that eventually result in the expiration of a service agreement if payment is not received.

Severance criteria define how to sever service agreements

Severance criteria define the severance process to be executed for service agreements of a given SA type. The severance process may differ depending on some attribute of the customer (or premise). For example, you may have a different severance process if the customer has life support equipment.

After a service agreement is severed, it will be final billed

When the last active service agreement linked to an account is stopped, the system changes the account's bill cycle to bill that evening. If only one of many SAs is stopped, the SA will only be final billed as per the account's original bill cycle schedule.

If a customer doesn't pay their final bill, the account's debt will be analyzed to determine if the system can reduce the debt to zero using a variety of mechanisms

The system will look at an account's finalized debt on its next scheduled credit review date (typically a few days after the bill's due date). The system will attempt to reduce the service agreement's debt to zero using all of the following methods:

- If the account has active service agreements, it will transfer the finalized debt to an active service agreement.
- If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit).
- If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).

If a customer's finalized debt cannot be reduced via any of the previous methods, the system creates a write-off process

A write-off process contains one or more write-off events. These events can generate a letter, send a To Do entry to a CSR, send a referral to a collection agency, etc.

When you set up the system, you define the type of write-off process to use for every collection class / write-off debt class combination. In addition, you can also indicate when the type of write-off process should differ depending on some attribute of the customer (or premise). For example, you may have a different write-off process if the customer has a non-cash deposit.

The last write-off event typically causes the debt to be written off

Ultimately, if the write-off events fail, the debt will have to be written off. When debt is written-off, the system creates a write-off service agreement and transfers the outstanding debt to it. This means the debt stays with the account for life and will have to be paid off if the customer ever returns.

NOTE:

Checkpoint. At this point, you should be familiar with the concept that an account's debt is compared to user-defined collection criteria. If the account violates the criteria, a series of events will ensue that prod the customer to pay. If the customer doesn't respond, every service agreement in arrears will be severed (i.e., disconnected). If lack of service doesn't inspire payment, the service agreement will be expired and a write-off process will be created to manage the write-off activities.

The C&C Monitors

Your collection, severance and write-off criteria described in the previous section exist to support the processes that manage the collection of overdue debt: The following diagram illustrates, at a high level, the major processes that manage the collection of overdue debt:

There are many important concepts illustrated above:

Bills, payments and adjustments affect an account's debt	An account's debt is the accumulation of all bills, payments and adjustments.
The Account Debt Monitor creates a collection process when an account violates collection criteria	Periodically, a background process referred to as the Account Debt Monitor determines if an account's debt violates your collection criteria. If so, a collection process is created using the violated criteria's collection process template. Refer to When Is An Account's Debt Monitored? for a description of when an account's debt is compared against collection criteria.
A collection process contains one or more collection events	The collection process contains a series of collection events. These events correspond with the collection event types associated with the collection process template. The initial collection events are typically letters. If payment is not received after several such communications, the last collection event typically starts a severance process for each service agreement in arrears.
The Collection Process Monitor cancels a collection process when warranted	The Collection Process Monitor cancels a collection process when its service agreements satisfy your cancellation criteria (e.g., when the service agreements have less than \$10 of debt older than 20 days). Refer to How Are Collection Processes Cancelled for more information about the cancellation process.
The last collection event starts one or more severance processes	The last collection event typically starts one or more severance processes. A severance process contains the activities necessary to sever a service agreement. The service agreement(s) that are severed may be all SAs that are associated with the collection process. Alternatively, you can nominate a service agreement to act as the primary service to cut (you'd do this if you cut electricity when the customer doesn't pay for their gas). The algorithm on the collection event that starts severance will control which service agreement(s) are severed. Refer to How To Nominate A Single Service Agreement To Sever for more information.
Each service agreement has its own severance process	Every service agreement that is severed has a severance process. The type of process is dependent on the severance criteria linked to the service agreement's SA type.
A severance process contains one or more severance events	The severance process contains a series of severance events. The events correspond with the severance process template's severance events.
The system cancels a severance process when warranted	The system cancels a severance process when its service agreement satisfies your cancellation criteria (note, it is possible to set up the system so that all service agreements in the debt class must satisfy your cancellation criteria before a severance process is cancelled). It's important to note that the cancellation is real time (as opposed to the cancellation of collection processes, which happens in a background process). Refer to How Are Severance Events Canceled? for more information.
The last severance event should expire the service agreement	The last severance event typically expires its service agreement. When the last service agreement linked to an account is expired, the system will schedule the account for billing (outside of its normal bill cycle schedule).
If you nominate a single SA to sever when multiple SAs are in arrears...	Earlier we indicated that you can nominate a service agreement to act as the primary service to cut (you'd do this if you cut electricity when the customer doesn't pay for their gas). If you do this, you also need

a severance event that will sever all other service agreements in the debt class if the severance of the nominated service agreement doesn't inspire payment. A severance event algorithm to do such is supplied with the base package. Refer to [How To Nominate A Single Service Agreement To Sever](#) for more information.

The Write-Off Monitor creates a write off process to collect stopped, unpaid debt

The Write-Off Monitor reviews stopped and reactivated service agreements after their closing bill's due date (plus grace period). The Write-Off Monitor attempts to reduce the service agreement's debt to zero using all of the following methods:

- If the account has active service agreements, it will transfer the finalized debt to an active service agreement.
- If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit).
- If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).
If the system is unsuccessful in reducing the account's debt to zero, a write-off process will be created using the appropriate write-off process template. Refer to [The Big Picture Of Write Off Processing](#) for more information about the write-off process.

A write-off process contains one or more write-off events

The write-off process contains a series of write-off events. These events correspond with the write-off event types associated with the write-off process template. The initial write-off events are typically collection agency referrals and/or letters. If payment is not received as a result of such efforts, the last write-off event typically writes off the customer's debt.

The system cancels a write-off process when warranted

The system cancels a write-off process when its service agreements no longer have debt (i.e., they become closed).

Another write-off process will be created if a closed service agreement ever reactivates

If a service agreement becomes reactivated (e.g., because the final payment bounces), the service agreement will be processed by the Write-Off Monitor and the whole write-off process starts again.

NOTE:

Checkpoint. At this point, you should be familiar with the concept that a collection process will be created for an account that violates collection criteria. The collection process consists of a series of events that typically generate letters and / or To Do entries. If the customer doesn't respond, a severance process will be started for one or more service agreements. A severance process consists of a series of events that typically generate letters and/or disconnection field activities. If lack of service doesn't inspire payment, the last severance event expires the service agreement (and a final bill will be scheduled when the last service agreement is expired). If the customer doesn't pay the final bill, a write-off process will be created for each type of unpaid debt. The write-off process consists of a series of events that ultimately result in the write-off of the customer's debt. When debt is written-off, the system creates a write-off service agreement and transfers the outstanding debt to it. This means the debt stays with the account for life (because the write-off service agreement is linked to the account) and will have to be paid off if the customer ever returns.

The Big Picture Of Collection Processes

The topics in this section describe how collection processes are created and cancelled.

FASTPATH:

For more information refer to [The Lifecycle Of A Collection Process And Its Events](#).

How Does The Account Debt Monitor Work?

This section describes how the Account Debt Monitor uses your collection criteria and collection process templates to collect overdue debt.

Different Collection Criteria For Different Customers And Different Debt

Consider the following:

- You probably have different collection criteria for different jurisdictions (i.e., CIS Divisions). For example, if you have customers in different states / provinces, you may have different regulator-imposed criteria applied to each state's debt. You differentiate your debt in respect of the collection process via the **CIS division code on each customer's account**.
- You probably have different collection criteria for different customer segments. For example, customers with large bills probably have strict criteria, whereas you're probably more lenient with small customers (or vice versa). You differentiate your customers in respect of the collection process via a **collection class code on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You probably have different collection criteria for different classes of debt. For example, if a single customer has both regulated and unregulated debt, you probably have commission-imposed criteria to be applied to the regulated debt, but you have the freedom to apply stricter criteria to the unregulated debt. You differentiate your debt in respect of the collection process via a **debt class code on the customers' service agreements** (note: the debt class is actually defined on the service agreement's SA type).
- You will have different criteria for every currency in which you work because the monitoring process always compares a customer's debt against some value and this value must be denominated in the customer's currency. A customer's currency is defined using a **currency code on the account**.

Given the above, you should understand that different collection criteria will exist for every combination of CIS division, collection class, debt class, and currency code. If you're confused, consider the following matrix (where we assume you have a single currency and division and therefore avoid the third and fourth dimensions):

SA's Debt Class	Account's Collection Class:	
	Commercial Customer	Residential Customer
Regulated	N/A - there is no regulated, commercial customer debt.	Highest Priority: If > \$5 in arrears by more than 50 days, create the accelerated collection process for residential customers. Lower Priority: If > \$25 in arrears by more than 25 days, create the courtesy reminder collection process for residential customers.
Unregulated	Highest Priority: If > \$10 in arrears by more than 50 days, create the accelerated collection process for commercial customers. Lower Priority: If > \$1000 in arrears by more than 25 days, create the normal collection process for commercial customers.	Highest Priority: If > \$10 in arrears by more than 25 days, create the normal collection process for residential customers.

Charitable Contribution

Highest Priority: If > \$10 in arrears by more than 50 days, create the charitable collection process.

Highest Priority: If > \$10 in arrears by more than 50 days, create the charitable collection process.

Also, notice that there can be multiple criteria for each cell in the matrix. What differentiates one collection criteria from another is its priority. The higher priority criteria will be compared first. If the debt meets the criteria, the collection process is initiated and no further comparisons are performed.

FASTPATH:

For more information about maintaining this matrix, refer to [Setting Up Collection Class Controls](#). For more information about how the system handles an element in this matrix that has multiple criteria, see [How Is An Account's Debt Monitored?](#).

Override Conditions

WARNING:

Your credit & collection requirements may not require any overrides and therefore this section may not be relevant for your organization.

The matrix presented in the previous section showed:

- You can have different collection criteria for different categories of debt and customers.
- When a collection criteria is violated, the system generates a specific collection process.

This works great for many organizations, but if your organization has other factors that affect either the collection criteria OR the collection process that is initiated when the criteria is violated, you may need to use override collection criteria. For example,

- If you have a different collection process for regulated, residential debt during the winter months, you'll need to use override collection criteria (where the override criteria is "if it's winter").
 - If you have different collection criteria for customers with a poor credit score, you'll need to use override collection criteria (where the override criteria is "if the customer's credit rating is poor").
-

FASTPATH:

Refer to [Designing Your Collection Class Control Overrides](#) for more information.

This section describes how and when the Account Debt Monitor analyzes an account's debt.

When Is An Account's Debt Monitored?

The account debt monitor (ADM) analyzes an account's debt at least every X days, where X is defined on the [customer class control](#) associated with the account's customer class and division (in the field Min Credit Review Freq (Days)).

In addition, an account's debt will also be monitored as follows:

- The ADM looks at an account's debt X days after an account's bill due date (X is defined on the account's customer class in the field Collection Grace Days).
- The ADM looks at an account's debt after a payment is canceled when the cancellation reason indicates NSF (non-sufficient funds).

- The ADM looks at an account's debt after a payment arrangement is broken (assuming you use the base package's break payment arrangement plug-in). Refer to [Monitoring Payment Arrangements](#) for more information.
- The ADM looks at an account's debt after a pay plan is broken. Refer to [The Pay Plan Monitor](#) for more information.

How Is An Account's Debt Monitored?

Assume the following collection control matrix exists for your organization:

SA's Debt Class	Account's Collection Class:	
	Commercial Customer	Residential Customer
Regulated	N/A - there is no regulated, large customer debt	Highest Priority: If > \$5 in arrears by more than 50 days, create the accelerated collection process for residential customers. Lower Priority: If > \$25 in arrears by more than 25 days, create the courtesy reminder collection process for residential customers.
Unregulated	Highest Priority: If > \$10 in arrears by more than 50 days, create the accelerated collection process for commercial customers. Lower Priority: If > \$1000 in arrears by more than 25 days, create the normal collection process for commercial customers.	Highest Priority: If > \$10 in arrears by more than 25 days, create the normal collection process for residential customers.

This matrix contains the information used by the Account Debt Monitor.

FASTPATH:

For more information about the information in this matrix, refer to [Different Collection Criteria For Different Customers And Different Debt](#).

This matrix can be overwhelming when viewed as a whole. So let's consider how to use it for a specific account's debt and things will become clearer.

First, because an account belongs to a unique collection class, we only have to worry about a single column in the matrix when monitoring an account's debt.

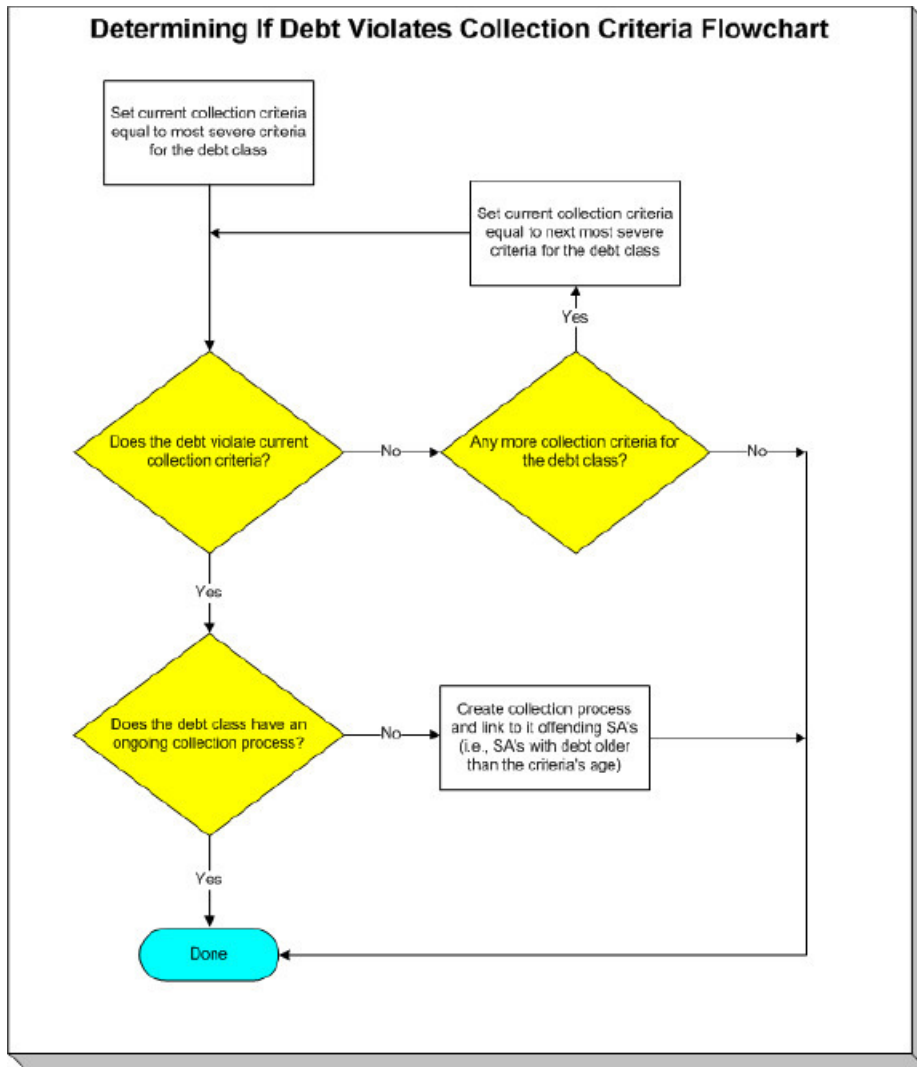

Next, we accumulate the total amount of aged debt for each unique debt class associated with the account's service agreements.

Next, we subject the accumulated aged debt to the override aged debt algorithm (plugged in on the debt class). This algorithm can cause aged debt to be reduced. This is an optional algorithm and is only used if you set up pay plans for customers. Refer to [How Pay Plans Affect The Account Debt Monitor](#) for more information.

Next, we determine if the debt for the debt class violates the collection criteria in the respective matrix element. If so, we kick off a collection process and link the offending service agreements to it. The logic associated with the determination of whether to kick off a collection process is rather sophisticated. The following flowchart explains the exact details.

NOTE:

Important. If a service agreement is part of an ongoing severance process, it will NOT be considered by the Account Debt Monitor (it's already being severed). If a service agreement is stopped, closed, or reactivated, it also will NOT be considered by the Account Debt Monitor (it's already severed).

NOTE:

Multiple collection processes may be kicked off. It's important to be aware that if an account's service agreements reference multiple debt classes, a collection process will be started for each offending debt class.

One collection process per debt class. A given debt class for an account may only have one ongoing collection process at any point in time.

What Happens When A Collection Process Is Started?

When you define collection criteria, you must define the collection process template to use if the criteria are violated. The system uses this template to create the account-specific collection process.

Every service agreement that is part of the offending debt class that has debt older than X days will be linked to the collection process (where X is the debt age on the collection criteria).

Also linked to the collection process will be one or more collection events. These events are typically a series of letters meant to prod the customer (you can also create an event that sends a To Do entry to a user to highlight the offensive debt). You define exactly which letters are generated and when they are generated when you set up the events on your collection process templates.

It's important to note that all of the collection events will be created when the collection process is created. Each of these collection events contains a trigger date. The trigger date of the first event(s) will typically be the current date. The trigger date of the other events will be in the future. Refer to [Calendar vs Work Days](#) for information that describes how the trigger date is set.

A separate process, Activate Collection Events, is responsible for activating collection events whose date is on or before the current date. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, start a severance processes, etc.)

If adequate payments / credits are recorded in the system, the collection process will be cancelled.

FASTPATH:

For more information about collection process templates, see [Setting Up Collection Process Templates](#). For more information about collection events, see [The Big Picture Of Collection Events](#). For more information about how a collection process is cancelled, see [How Are Collection Processes Cancelled](#).

Experimenting With Alternative Collection Process Templates

The system allows you to determine the efficacy of proposed collection process templates using a small subset of customers before implementing the templates on the entire customer base. We use the term "champion / challenger" to reference this functionality.

We'll use an example to explain. Let's assume your prevailing collection process template for residential customers starts with a "gentle reminder" letter followed 10 days later by a letter threatening collection agency referral if payment is not received. You may want to experiment with the impact of a change to this template. For example, you may want to change the "gentle reminder" to something more assertive and follow this up 5 days later with an even sterner warning. You can use the "champion / challenger" functionality to perform this experiment.

The following points describe how to implement "champion / challenger" functionality:

- Set up a "challenger" collection process template for each template that you want to experiment with.
- Insert a new **Champion/Challenger** option on the Collection Processing [Feature Configuration](#) for every champion template. Each option's value defines:
 - the "champion" collection process template code
 - the "challenger" collection process template code
 - the percentage of the time the system should use the "challenger" template
- Keep in mind that you can only experiment with one challenger template per champion template. For example, let's assume you have two prevailing collection process templates - one for residential customers and another for commercial customers. You can experiment with different challenger templates for the residential and commercial templates. However, you cannot experiment with two different challenger templates for the residential champion template (i.e., a champion template can have 0 or 1 challenger template).

After setting up the above, the [Account Debt Monitor](#) will use the challenger template X% of the time rather than the champion template.

If you are using the Oracle Utilities Analytics product, you can configure analytic zones in innumerable ways to compare the efficacy of the champion versus the challenger. For example,

- You can set up a graph to show the average duration of each type of process.
- You can set up a graph to show the average dollars that were successfully collected.
- You can set up a dimensional scorecard to show how each template performed in different regions (or customer classes or ...).
- Etc (the list is limited by your imagination).

How Are Collection Processes Cancelled?

A collection process may be cancelled via the mechanisms described in this section.

The Collection Process Monitor Can Cancel A Collection Process

The Collection Process Monitor (CPM or C1-CPM) is a background process that reviews a collection process when the debt associated with one of its service agreements is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment.
- The creation of a payment segment.
- The creation of an adjustment that credits a service agreement.

The review performed by the CPM occurs as follows:

- **Debt class cancel criteria.** In general, the sum of all debt associated with the collection process's debt class must be less than a given threshold amount for a collection process to be cancelled. If so, the collection process is cancelled.
- Please be aware that, if a [Pay Plan](#) exists for the account and debt class, the customer's debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount. Please be aware that this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

NOTE:

The above logic is not "hard coded". The CPM calls the [Collection Process Cancel Criteria Algorithm](#) defined on the debt class that is associated with the collection process. This algorithm will cancel a collection process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. However, because it's an algorithm, you can introduce whatever cancellation criteria you please.

-
- **Service agreement cancel criteria.** You can optionally introduce a special quirk to the cancellation logic. This quirk is a bit difficult to understand. To understand it, you should recall:
 - All service agreements that are in arrears in a given debt class are linked to the collection process.
 - The collection event called Start Severance creates a severance process for every service agreement that is in arrears on the collection process (the alternative is to [Nominate A Single Service Agreement To Sever](#)).
 - If you use the Start Severance collection event, you would want to remove a service agreement from a collection process when it no longer has intolerable debt (regardless of the state of the debt class's entire debt). You'd want to do this because, if you don't, the system would start a severance process for the paid up service agreement and if it's paid up, you wouldn't want a severance process created for it.
 - To "remove" service agreements from a collection process when they no longer have intolerable debt, you should plug-in a [Service Agreement-Oriented Cancel Criteria Algorithm](#) on your collection process templates. The CPM will call this algorithm if you've plugged it in.

NOTE:

When all service agreements are "removed" from a collection process, the CPM cancels all pending collection events and cancels the collection process.

WARNING:

Checking if individual service agreements should be removed from a collection process is optional (meaning that you don't have to plug one in on the collection process template).

A New Payment Plan Can Cancel A Collection Process

Refer to [Collection Process / Severance Process Cancellation When A Pay Plan Is Created](#) for the details.

NOTE:

Real time cancellation. Please be aware that the system will cancel a collection process real time when a pay plan is created (if the pay plan's scheduled payments are enough to pay-off the customer's outstanding debt).

A User May Cancel A Collection Process At Their Discretion

A user may cancel a collection process at their discretion.

Stopping A Service Agreement May Cancel A Collection Process

The system will "remove" a service agreement from a collection process when it is stopped (i.e., when the service agreement's status becomes Stopped). When the last service agreement is "removed" from the collection process, the collection process will be cancelled.

The Big Picture Of Collection Events

This section describes the various types of collection events and their lifecycle.

How Are Collection Events Created?

Collection events may be created as follows:

- The Account Debt Monitor creates a collection process when an account violates collection criteria. The collection process has one or more collection event(s). The number and type of events is controlled by the collection process template associated with the collection process.
 - Collection events are created when a user creates an ad hoc collection process. The number and type of events is controlled by the collection process template defined when the collection process is created.
 - An ad hoc collection event may be created and linked to an existing collection process by a user at their discretion.
-

NOTE:

Bottom line. Most collection events are created by the system when it creates a collection process for delinquent accounts. If you need to create an ad hoc collection event, you can either create a collection process whose template contains the desired event OR link the desired event to an existing collection process.

FASTPATH:

For more information about the creation of events by the Account Debt Monitor refer to [What Happens When A Collection Process Is Started?](#). For more information about creating ad hoc collection processes, refer to [Collection Process Maintenance](#). For more information about creating ad hoc events, refer to [Collection Process - Events](#).

Types Of Collection Events

The following table describes the various types of collection events and what happens when they are completed:

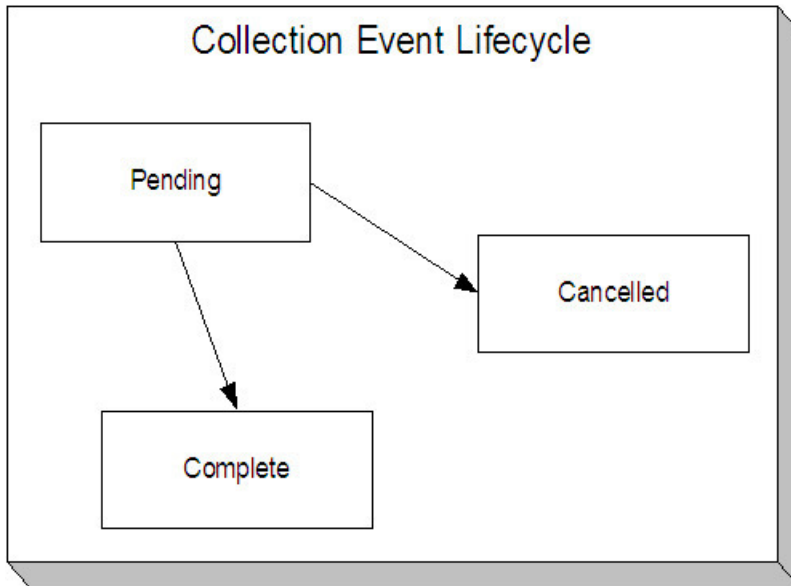

Type Of Collection Event	What Happens In The System
Send Letter	<p>A customer contact is created for every financially responsible person linked to the account. The customer contact causes a letter to be produced.</p> <p>The type of letter is defined on the customer contact's contact type.</p> <p>The recipient of each letter is defined on Account / Person (those persons marked as Receiving Notifications).</p>
Create To Do Entry	A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.
Affect Credit Rating/Cash-Only	An account credit rating demerit record is created. The number of demerits is defined on the collection event type.
Cancel Budget	Every service agreement linked to the account that is on a budget is "removed" from the budget (i.e., the recurring charge amount for the service agreement is set to zero). In addition, a syncing adjustment is issued to cause each SA's current balance to be set equal to their payoff balance (the adjustment type is defined on the SA's SA type). Also, the Budget Plan field on the Account - Budget page is cleared.
Generic Algorithm	The algorithm defined on the event's event type is executed.
Start Severance Process	A severance process is created for every service agreement linked to the collection process. The type of severance process is defined on the SA type table (every service agreement references an SA type).

FASTPATH:

Refer to [Setting Up Collection Event Types](#) for more information.

Collection Event Lifecycle

The following diagram shows the possible lifecycle of a collection event:

Collection events are initially created in the pending state.

When the system sees a pending event with a trigger date on or before the current date, the system executes the event's activity and completes the event.

FASTPATH:

For more information about a collection event's trigger date, see [Collection Event Trigger Date](#).

A pending event will be cancelled automatically by the system when the account's debt no longer violates the collection criteria that sparked the event's collection process. A pending event may also be cancelled by a user at their discretion. Refer to [How Are Collection Processes Cancelled](#) for more information about how the system will cancel a collection process (and its events).

Collection Event Trigger Date

When a collection event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to [Calendar vs. Work Days](#) for more information.

How Are Collection Events Completed

A background process runs periodically (at least daily) that looks for collection events with a trigger date on or before the current date. For each triggered event, the system executes its activity and then completes it. Refer to [Collection Event Activator](#) for more information.

The Last Collection Event Should Kick Off Severance Process(es)

The last collection event will typically kick off the severance process for every service agreement linked to the collection process. This will only happen if you set up the collection process template accordingly (i.e., the last event type in the process template is the kind that starts a severance process for every service agreement linked to the collection process).

NOTE:

Nominating a service agreement to sever. Many organizations that have multiple services in arrears will NOT sever every service agreement that's in arrears. Rather, they will nominate one service agreement and use it to encourage the customer to pay for the other services. If your organization works this way, then your last collection event should call the [Nominate A Service Agreement To Sever Algorithm](#).

How Are Collection Events Canceled?

Users can cancel a collection event at their discretion. In addition, the system can cancel a collection event when it automatically cancels a collection process. Refer to [How Are Collection Processes Cancelled](#) for the details.

The Big Picture Of Severance Process Cancellation

The topics in this section provide high level information about the cancellation of severance processes.

FASTPATH:

For more information refer to [The Lifecycle Of A Severance Process And Its Events](#).

How Are Severance Processes Cancelled?

A severance process may be cancelled via the mechanisms described in this section.

FASTPATH:

Refer to [What Happens When A Severance Process Is Cancelled?](#) for what happens when a severance process is cancelled.

The Freezing Of Certain Financial Transactions Can Cancel A Severance Process

NOTE:

The system will only cancel a severance process if its severance process template indicates that **Auto Cancel** is allowed. Typically, this switch is set on all severance process templates except for the odd ones that are used to [reconnect service](#).

The system reviews a severance process real-time whenever its service agreement's debt is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment.
 - The creation of a payment segment.
 - The creation of an adjustment that credits a service agreement.
-

NOTE:

Real time cancellation. Unlike collection processes, the system cancels severance processes real time (i.e., there is no background process that monitors severance processes). Why are severance processes canceled real time? Because a severance process may have events that create field activities to sever service. These events need to be canceled the moment the FT is frozen, we can't wait until a background process runs. This means that if a customer pays in person

for a service agreement that is pending severance, the system will cancel the process and its field activities (if any) the moment the payment is entered.

The review takes place as follows:

- **Debt class cancel criteria.** In general, the sum of all debt associated with the severance process's debt class must be less than or equal to a given threshold amount for a severance process to be cancelled. If so, the severance process is cancelled.
- Please be aware that, if a [Pay Plan](#) exists for the account and debt class, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount. Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

NOTE:

The above logic is not "hard coded". The system calls the Severance Process Cancel Criteria Algorithm defined on the [debt class](#) that is associated with the severance process. This algorithm cancels a severance process if the sum of ALL service agreements in the debt class have debt less than or equal to a given threshold amount. However, because it's an algorithm, you can introduce whatever cancellation criteria you please.

- **Service agreement cancel criteria.** You can optionally introduce a special quirk to the cancellation logic. This quirk is a bit difficult to understand. To understand it, you should recall:
 - The collection event called Start Severance creates a severance process for every service agreement that is in arrears. Note: you would only use this type of collection event if you do not [Nominate A Single Service Agreement To Sever](#).
 - If you use the Start Severance collection event, then you would want to cancel a severance process when its service agreement no longer has intolerable debt (regardless of the state of the debt class's entire debt).
- To cancel a severance process when its related service agreement no longer has intolerable debt, you should plug-in a Cancel Criteria Algorithm on your [severance process templates](#). The system will call this algorithm if you've plugged it in.

NOTE:

Manual Creation. A user can create a severance process for an account that does not qualify to be on severance according to the cancel criteria algorithm. For example, perhaps your cancel criteria algorithm cancels a severance process when the account's debt falls below a threshold amount. A user can create a severance process for an account whose debt is already below this threshold. Because cancellation is real time, there is no action that will cause this severance process to be canceled. When a manual severance process is created, the system executes the appropriate cancellation criteria algorithm. If the algorithm indicates that the system would have canceled this severance process, a warning is issued.

A New Payment Plan Can Cancel A Severance Process

Refer to [Collection Process / Severance Process Cancellation When A Pay Plan Is Created](#) for the details.

NOTE:

Real time cancellation. Please be aware that the system will cancel a severance process real time when a pay plan is created that pays off enough debt.

A User May Cancel A Severance Process At Their Discretion

A user may cancel a severance process at their discretion.

Stopping A Service Agreement Will Cancel A Severance Process

The system will cancel a severance process if its service agreement is stopped (i.e., when the service agreement's status becomes Stopped).

What Happens When A Severance Process Is Cancelled?

The following takes place when a severance process is canceled by the system:

- The system cancels all pending severance events and deactivates the severance process.
- If there are any field activities linked to the severance process, an optional plug-in spot defined on the installation record allows you to plug in an algorithm to cancel these field activities.
 - The base package [Severance Process Cancellation Algorithm](#) will cancel all pending field activities that were created as a result of the severance process that are not linked to a dispatched field order.
- If there are any pending field activities left associated with the severance process, it is marked to trigger the creation of a To Do entry to highlight that field activities exist for a canceled severance process. (This happens if you have not plugged in an algorithm to perform the cancellation or if the algorithm detected a condition that prevented cancellation.) To create the To Do entry, you must run the background process [TD-SPRO](#).
- There is an optional plug-in spot defined on the severance process' template. If an algorithm is plugged-in, it is called. The base package algorithm will create a reconnect process if there are completed field activities for a cut for nonpayment severance event associated with the severance process. Refer to [Severance Post Cancellation Algorithm](#) for more information about this algorithm.

The Big Picture Of Severance Events

This section describes the various types of severance events and their lifecycle:

How Are Severance Events Created?

Severance events may be created as follows:

- The process that completes (i.e., executes) collection events creates a severance process when it completes a "start severance process" collection event. The severance process has one or more severance event(s). The number and type of events is controlled by the severance process template associated with the severance process. Refer to [The Collection Event Activator](#) for more information about this process.
- Severance events will be created when a user creates an ad hoc severance process. The number and type of severance events is controlled by the severance process template associated with the severance process.
- An ad hoc severance event may be created and linked to an existing severance process by a user at their discretion.

NOTE:

Bottom line. Most severance events are created by the system when it creates a severance process for delinquent service agreements. If you need to create an ad hoc severance event, you can either create a severance process whose template contains the desired event OR link the desired event to an existing severance process.

FASTPATH:

For more information about creating ad hoc severance processes and events, refer to [How To Perform Common Severance Process Functions](#).

Types Of Severance Events

The following table describes the various types of severance events and what happens when they are completed:

Type Of Severance Event	What Happens In The System
Send Letter	<p>A customer contact is created for every financially responsible person linked to the service agreement's account. It is the customer contact that causes a letter to be produced.</p> <p>The type of letter is defined on the customer contact's contact type.</p> <p>The recipient of each letter is defined on Account / Person (those persons marked as Receiving Notifications).</p>
Create To Do Entry	<p>A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.</p>
Create Field Activities	<p>A field activity is created for each service point associated with the service agreement being severed. The type of activity is defined on the service point's SP type's field activity type profile.</p>
Generic Algorithm	<p>The algorithm defined on the event's event type is executed.</p>
Expire Service Agreement	<p>The service agreement is expired and, if earlier severance events created "cut for non-payment" field activities, these field activities will be used as the basis for stopping service. Refer to Finalizing Pending Stops for how the system use the meter reads on these field activities as the "stop reads" on the service agreement. Note, you can see the field activities that are used to "cut" and "stop" service by viewing the Field Activities grid on Service Agreement - Service Point.</p>
Affect Credit Rating/Cash-Only	<p>An account credit rating demerit record is created. The number of demerits is defined on the collection event type.</p>

FASTPATH:

Refer to [Setting Up Severance Event Types](#) for more information.

Field Events Versus Office Events

Severance events are considered either field or office events. Office events are just like collection events in that they don't involve any type of field activity in their completion. Field events, however, are not like collection events because they create one or more field activities. These activities cause these events to have a different lifecycle. Refer to [Severance Event Lifecycle](#) for more information.

Severance Event Lifecycle

The following diagram shows the possible lifecycle of a severance event:

The following points explain the lifecycle of severance events of the office variety:

- Office events are initially created in the pending state.
- A pending office event becomes complete when the system sees that its trigger date is on or before the current date. At this time, the system executes the event's activity (e.g., create a letter, create To Do entry).

FASTPATH:

For more information about a severance event's trigger date, see [Severance Event Dependencies & Trigger Date](#).

- A pending office event will be cancelled automatically by the system when the debt associated with the severance process's service agreement is sufficiently reduced. A pending office event may also be cancelled by a user at their discretion. Refer to [How Are Severance Processes Cancelled](#) for more information about how the system will cancel a severance process (and its events).

The following points explain the lifecycle of severance events of the field variety:

- Field events are initially created in the pending state.
- A pending field event becomes awaiting field activity completion when the system sees that its trigger date is on or before the current date. At this time, the system creates the field activities associated with the given event (e.g., disconnection warning, disconnect for nonpayment, etc.).

FASTPATH:

For more information about a severance event's trigger date, refer to [Severance Event Dependencies & Trigger Date](#). For more information about the field activities that are created for a field severance event, refer to [Field Events And Their Activities](#).

- An awaiting field activity completion field event becomes complete when the system sees that its field activities are all complete or cancelled.
- A pending field event will be cancelled automatically by the system when the service agreement associated with the severance event's severance process has sufficient credits. A pending field event may also be cancelled by a user at their discretion.
- An awaiting field activity completion field event will be cancelled automatically by the system when the service agreement associated with the severance event's severance process has sufficient credits if the field activity has not been dispatched (refer to [Designing Your Reconnection Procedures](#) for information on how the system handles the situation if the field activity is completed or dispatched). An awaiting field activity completion event may also be cancelled by a user at their discretion.

Severance Event Dependencies and Trigger Date

When a severance event is created by the system, its trigger date cannot be set. This is because, unlike collection events, the trigger date on severance events can only be set when ALL of the preceding severance events on which it depends are complete. An example will help explain why this design is necessary. Consider the following example that shows a standard severance process and its events:

Event Number	Severance Event	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Preceding Events
10	Field activity - Disconnect for non-payment warning	N/A - first event	0
20	Field activity - Disconnect for non-payment	10	2
30	Create To Do entry	20	0
40	Send letter to customer	20	0
50	Expire service agreement	20	10

This severance process is meant to execute as follows:

- On the first day, generate a 48-hour warning of impending disconnection. This is a field event as most organizations deliver this warning in person.
- After 2 days (i.e., 48 hours) have passed, create a field activity to disconnect for non-payment.
- When this is completed, generate a To Do entry to let a CSR know about the cutoff. Also, send a letter to the customer.
- If after 10 days from the cutoff, we still don't have payment, expire the service agreement.

As can be seen from the above example, the later events are dependent on the completion of the field activities in the earlier events. This means that when you set up a severance event, you must indicate the events on which it depends (and the number of days after their completion that the event should be triggered).

NOTE:

Bottom line. The system sets the trigger date on severance events when it detects that all of its dependent events are complete (this is the responsibility of the SED background process). Refer to [Calendar vs Work Days](#) for a description of your choices in respect of how the trigger date is calculated.

Field Events And Their Activities

When the system is told to start a severance event that creates field activities (e.g., disconnect for non-payment), it will generate a field activity for every service point linked to the service agreement.

The question is, where does it get the field activity type associated with the field activities? The answer is explained below:

- Every service point has an SP type.
- Every SP type references a field activity type profile.
- A field activity type profile contains a matrix defining activity types to generate under various situations. Some of these situations are those associated with severance.

FASTPATH:

For more information, refer to [Setting Up Field Activity Type Profiles](#).

Severance Event Activation & Completion

A background process runs periodically (at least daily) that looks for severance events with a trigger date on or before the current date. This process executes the activity associated with each event. If the event is an office event, the event then becomes complete. If the event is a field event, the event becomes "awaiting field activity completion" until the field activities are complete. At this time, the severance event is completed. Refer to [Severance Event Activator](#) for more information.

How Are Severance Events Canceled?

Users can cancel a severance event at their discretion. In addition, the system can cancel a severance event when it automatically cancels a severance process. Refer to [How Are Severance Processes Cancelled](#) for the details.

The Big Picture Of Write Off Processing

Before you financially write-off debt, most companies go to some effort to collect the past due funds. You control exactly what happens by setting up the various write-off control tables. The topics in this section provide background information that will help you understand how the information in these control tables is used.

How Is Debt Financially Written-Off?

Before debt can be written-off, a write-off service agreement must exist for the account. Why? Because when you write-off a normal service agreement's debt, you are actually transferring its debt to a write-off service agreement.

A write-off service agreement is just like other service agreements in that:

- It holds debt.
- When a payment is received, the service agreement's debt is reduced.

Debt is transferred to a write-off service agreement (WO SA) from the customer's uncollectable service agreements (SAs). The following points highlight important characteristics about the uncollectable SAs and the WO SA:

- The WO SA and the uncollectable SAs should be linked to the same account (note: this isn't a strict rule, it just makes sense because an account's written off funds should be linked to the account).
- Debt may be transferred to a WO SA from any type of service agreement regardless of debt class, i.e., a WO SA can contain debt that originated in any debt class.
- When you transfer debt from the uncollectable SAs to the WO SA, the debt is removed from the uncollectable SAs (and their status becomes closed - assuming their balance becomes zero).
- If you use the system's automated write-off processing, the system will create WO SAs for you. The system's automated write-off processing can write-off revenue in a different manner than is used to write-off liabilities. Refer to [The Ramifications of Write Offs in the General Ledger](#) for more information.
- WO SAs are immune from the account debt monitor (assuming their debt class is marked as not being subject to collection activities).
- WO SAs are not billed (assuming their SA type is marked as being not billable).

- WO SAs start their life with a non-zero payoff and current balances (i.e., they have debt when first started). This debt is transferred from the normal service agreement(s) whose uncollectable debt necessitated the creation of the WO SA.
- If the customer pays off the write-off debt, the WO SA remains active in case you ever need to write-off debt in the future. If you don't like the WO SA remaining active after it's paid off, you can indicate on the WO SA's SA Type that it is a "one time charge", this will cause the WO SA to be automatically closed when it's paid off.
- You can transfer additional uncollectable debt to the WO SA.

NOTE:

Bankruptcy write-offs. If you have to write-off debt because a customer declares bankruptcy, everything stated above is true. The only thing you have to do is use a different SA type for bankruptcy write-offs as compared to "normal" write-offs. On the bankruptcy write-off SA type, simply leave the payment segment type blank - this way the system will never distribute a payment to the bankrupt debt (because bankrupt debt is legally uncollectable).

The Ramifications of Write Offs in the General Ledger

WARNING:

If you practice cash accounting, refer to [Cash Accounting and Write-Offs](#).

When you write-off unpaid debt, you shouldn't book it all to a write-off expense account. Why? Because the debt that you're writing off typically contains both revenue and liabilities. At write-off time, you typically want to:

- Book the written off revenue to a write-off expense account, and
- Reduce the liabilities (you don't owe the liability if you don't get paid).

Consider the following example of a simple electric service agreement with two financial transactions:

Event	GL Accounting
Customer is billed	A/R 1000
	Revenue <900>
	State Tax Payable - Taxing State - California <80>
	City Tax Payable - Taxing City - San Francisco <20>
Customer is levied a late payment charge	A/R 50
	Late Payment Revenue <50>

After these two financial transactions are booked, the customer has debt of \$1050. Of this \$1,050; \$950 is revenue and \$100 is liability (money you owe the taxing authorities).

If the customer doesn't pay, you will eventually have to write-off this debt. Most organizations would issue the following types of financial transactions to do this:

Event	GL Accounting
Write-off the bill	Write-off Expense 900
	State Tax Payable - Taxing State - California 80
	City Tax Payable - Taxing City - San Francisco 20
	A/R <1000>
Write-off the late payment charge	Write-off Expense 50

Notice in the above transactions, the two separate revenue accounts are written off by booking to an expense account. However, the liability accounts are reversed. Why is revenue treated differently from liabilities at write-off time? There's a good reason for it (if you're an accountant), for the time being, just accept that this is how it works.

And finally, we need to worry about what happens if the customer eventually pays off his written off debt. If this happens, most organizations would pay off the write-off first, and, if there was still money left, they'd reimburse the taxing authorities. If we assume the customer pays off the entire written off debt, the following financial transactions would be issued:

Event	GL Accounting
Pay off the written off debt	Cash 900
	Write-off Expense <900>
Reinstate the liabilities	Cash 100
	State Tax Payable - Taxing State - California <80>
	City Tax Payable - Taxing City - San Francisco <20>

While the reinstatement of liabilities at payment time is possible in the system, the ramifications of doing such make this approach impracticable (the ramifications are a) if the check bounces, we would not be able to reduce the liabilities, and b) if there was a partial payment of the liabilities, the remaining unpaid amount could get written down). Therefore, when a write-off is paid the following financial transactions should be issued:

Event	GL Accounting
Pay off the written off debt	Cash 900
	Write-off Expense <900>
Reinstate the liabilities	Cash 100
	Reinstated liabilities <100>

Notice that rather than reinstating the individual liabilities, we simply reinstate all liabilities into a single account. This means your accountants will have to distribute this money to the appropriate liabilities manually.

So, how do we achieve the above in the system? This explanation is a little complicated, but it'll make sense if you keep the above financial transactions in mind:

- First of all, you'll need two different SA types - one to hold the written off revenue and another to hold the reduced liabilities.
 - On the SA type that holds written off revenue, indicate that it is not billable, indicate that it cannot have excess credits, and give it a high payment distribution priority. The distribution code on this SA type should reference your Write-off Expense account.
 - On the SA type that holds the reduced liabilities, indicate that it is not billable, indicate that it cannot have excess credits, and give it a high payment distribution priority. The distribution code on this SA type should reference a the "reinstated liabilities" GL account.

Next, you need to understand how the system's standard write-off logic works:

- The system accumulates the distribution codes from GL details associated with recent financial transactions linked to the service agreement being written-off.
- When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreement(s). The number and type of service agreements to which the bad debt is transferred is defined on the distribution codes. Refer to [Setting Up Distribution Codes](#) for how to define the type of write-off service agreement

associated with a distribution code. In our example, we'd need the two SA types described above - one for the revenue accounts, the other for the liability accounts.

- At write-off time, for those distribution codes associated with revenue, the system will create a transfer adjustment from the normal service agreement to the write-off revenue service agreement. This will reduce (credit) the receivable on the normal service agreement and increase (debit) the expense account defined on the write-off revenue service agreement.
- However, if we do the above for the distribution codes associated with liabilities, we have a problem. The problem is a bit hard to explain unless you understand tax accounting, but it basically comes down to this - if we simply transfer the portion of the receivable balance associated with the liabilities to the write-off liability SA, we will always be debiting the distribution code defined on the SA type. This isn't correct because we really want to debit the liability account (and reference the characteristic type and value from the original credit) when we reduce the liability. So how do we do this? For those distribution codes associated with liabilities, you need to indicate that you want to override the distribution code on the "transfer to" side of the transfer adjustment with the distribution code / characteristic type / characteristic value that was originally booked. Refer to [Setting Up Distribution Codes](#) for how to indicate you want to override the distribution code at write-off time. If you do the above, then at write-off time the transfer adjustment will reduce (credit) the receivable on the normal service agreement and increase (debit) the original liability accounts from the original financial transactions.

If you followed the above, you'll see that we now have everything debited and credited appropriately. And, if a payment materializes for the written off debt, we will simply debit cash and credit the distribution code on the respective SA (either Write Off Expense or Reinstated Liabilities).

NOTE:

Batch and real-time write-offs may use the above processing. The above logic is executed real time when a user writes off debt using the [write-off transaction](#) (assuming the base package [write off algorithm](#) is plugged into the account's [customer class](#)). The above logic is executed in batch when a write-off event that references a Write Off Using Distribution Codes [event type](#) is executed. Write-off events are described in detail below.

Automated versus Manual Write Offs

The system will automatically create write-off SAs and transfer uncollectable debt to them during the automated write-off processing described below.

If necessary, you can write-off debt outside of the automated write-off process using either of the following methods:

- You can transfer bad debt from any service agreement to a write-off service agreement using a transfer adjustment.
- You can use the [write-off transaction](#) to write-off debt real-time. When this transaction is used, the system executes the logic embedded in the Write Off Method algorithm that's plugged in on the account's [customer class](#).

How Does The Write-Off Monitor Work?

This section describes how the [Write Off Monitor](#) uses your write-off criteria and write-off process templates to collect overdue debt.

Different Write-Off Criteria For Different Customers And Different Debt

Consider the following:

- You probably have different write-off criteria for different customer segments. For example, customers with large bills probably have strict criteria, whereas you're probably more lenient with small customers (or vice versa). You differentiate your customers in respect of the collection process via a **collection class code on the customers' accounts**.

An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.

- You probably have different write-off criteria for different classes of debt. For example, if a customer has both regulated and unregulated debt, you probably have commission-imposed criteria to be applied to the regulated debt, but you have control over how to write-off unregulated debt. You differentiate your debt in respect of the collection process via a write-off **debt class on the customers' service agreements** (note the write-off debt class is actually defined on the SA type and every service agreement has a SA type).

NOTE:

Write Off Debt Class vs. Regular Debt Class. It's important to be aware that a SA type references both a regular debt class and a write-off debt class. The regular debt class controls the collection criteria applied against an account's service agreements. The regular debt class is also used to segregate an account's outstanding balance on several queries in the system. The write-off debt class controls the write-off criteria applied against an account's stopped service agreements. The reason the system supports two different debt classes is because you may categorize your service agreements differently when you try to collect overdue debt versus when you write-off debt.

Given the above, you should understand that different write-off criteria will exist for every combination of collection class and write-off debt class. If you're confused, then consider the following matrix:

SA's Write-Off Debt Class	Account's Collection Class:	
	Commercial Customer	Residential Customer
Regulated	N/A - there is no regulated, commercial customer debt.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. Attempt to transfer debt to another active service agreement linked to the account. If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment. If the debt is <= \$-1, create an A/P adjustment to refund the credit to the customer. If debt remains, create the default write-off process for regulated debt.
Unregulated	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. Attempt to transfer debt to another active service agreement linked to the account. If the debt / credit is < \$10 and > \$-10, write down the debt using a write-down adjustment. If the debt / credit is <= \$-10, create an A/P adjustment to refund the credit to the customer. If debt still remains: Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process.	Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. Attempt to transfer debt to another active service agreement linked to the account. If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment. If the debt is <= \$-1, create an A/P adjustment to refund the credit to the customer. If debt remains, create the default write-off process for unregulated residential debt.

Otherwise, create the default write-off process
for unregulated commercial debt.

Notice that each cell in the matrix has the same pattern:

- The system first attempts to reduce the SA's current and payoff balances to zero using the following methods (assuming you have set up the write-off control appropriately):
 - Sync the current balance with the payoff balance. If the SA's payoff balance is zero, this will cause the current balance to become zero and therefore close the SA.
 - If there's a debit balance, transfer the debt to any pending start or active SA in the same write-off debt class.
 - If there's a credit balance, transfer the debt to any non-closed / non-cancelled SA in the same write-off debt class
 - If the remaining debit / credit balance is within a user-defined tolerance (this is defined on the respective algorithm on the write-off control), create an adjustment to write-down the small balance.
 - If a credit balance remains, create an A/P adjustment to refund the balance with a check (the adjustment type is defined on the respective algorithm on the write-off control).
- All of the above points will cause the SA to close. If debt remains, the system starts some type of write-off process. The type of process is dependent on the respective criteria. What differentiates one write-off criteria from another is its priority. The higher priority criteria will be compared first. If the customer / debt meets the criteria, the write-off process is initiated; no further comparisons are performed.

FASTPATH:

For more information about maintaining this matrix, refer to [Setting Up Write-off Control](#).

When Is Debt Monitored For Write Off Purposes?

The write-off monitor only reviews a service agreement when the following conditions are true:

- The service agreement is stopped and reactivated.
- If the service agreement is a "billable charge" SA (as identified on its SA type), all of its billable charges must appear on a bill segment AND the bill segment's bill's due date plus grace period must be on or before the business date.
- If the service agreement is not a "billable charge" SA AND it is billable (as identified on its SA type), the SA must have a closing bill segment (i.e., it must be final billed) and the bill segment's bill's due date plus grace period must be on or before the business date.
- If the service agreement is a sub SA, its master SA must abide by the above conditions.
- If the service agreement is not billable, it is possible that adjustments, which affect the SA's debt, exist. The write-off monitor will only review a non-billable SA if all FTs for this SA that have been marked to include on a bill have been swept onto a bill and the bill for any of these FTs has a bill due date plus grace period on or before the business date.

NOTE:

Postponing write-off processing. You can prevent the write-off process from processing an eligible service agreement by populating the account's C&C Postpone Date with a future date.

Attempt To Close The SA Before Creating A Write Off Process

Before the write-off monitor creates a write-off process for a stopped and reactivated service agreement, it attempts to reduce the service agreement's debt to zero using all of the following methods:

- If the account has active service agreements, it will transfer the finalized debt to a pending start or active service agreement.
- If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit).
- If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).

NOTE:

Plug-in algorithms do the work. Algorithms that are plugged-in on the [write-off control](#) responsible for managing the service agreement's debt actually perform the above effort. You can customize these algorithms to behave exactly how your collections staff desires.

If the algorithms responsible for the above effort are successful in reducing the service agreement's debt to zero, then the service agreement closes and will not be subject to write-off processing. If the above algorithms don't result in the service agreement's debt being reduced to zero, a write-off process will be started (as describe below).

What Happens When A Write-Off Process Is Started?

When you define write-off criteria, you must define the write-off process template to use if the criteria are violated. The system uses this template to create the account-specific write-off process.

Every stopped or reactivated service agreement that is part of the offending write-off debt class will be linked to the write-off process.

Also linked to the write-off process will be one or more write-off events. These events are meant to prod the customer. You define the types of events and when they are generated when you set up your write-off process templates.

It's important to note that all of the write-off events will be created when the write-off process is created. Each of these write-off events contains a trigger date. The trigger date of the first event(s) will typically be the current date. The trigger date of the other events will be in the future. Refer to [Calendar vs Work Days](#) for a description of how the trigger date is calculated.

A separate process, Activate Write-off events, is responsible for activating write-off events whose date is on or before the current date. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do to an operator, refer debt to a collection agency, etc.)

NOTE:

Multiple write-off processes may be kicked off. It's important to be aware that if an account's service agreements reference multiple write off debt classes, a write-off process will be started for each offending write off debt class that has stopped or reactivated service agreements.

FASTPATH:

For more information about write-off process templates, see [Setting Up Write Off Process Templates](#). For more information about write-off events, see [The Big Picture Of Write-off Events](#). For more information about how a write-off process is cancelled, see [How Does A Write-Off Process Get Cancelled?](#).

How Does A Write-Off Process Get Cancelled?

The system "removes" a service agreement from a write-off process when its status becomes closed (i.e., when its balance is zero). When all service agreements are removed, the system cancels all pending write-off events and deactivates the write-

off process. When the write-off process is deactivated, all collection agency referrals associated with the write-off process are cancelled.

NOTE:

Removing closed service agreements from a write-off process. Service agreements aren't actually removed from the process. Rather, they are inactivated so a proper audit exists.

How Do Collection Agency Referrals Work?

The following points describe how collection agency referrals work.

- A write-off process has one or more events. One type of event causes overdue debt to be referred to a collection agency.
- When a referral write-off event is activated, the system marks the event for processing by the event's Collection Agency Referral Algorithm (refer to [Setting Up Write Off Event Types](#) for more information).
- The next time the Collection Agency Referral process executes (the frequency is dependent on your background process schedule), it will refer the process' debt to a collection agency. The specific agency to which the debt is referred is controlled by the event type's Collection Agency Referral Algorithm. The sample algorithm supplied with the system simply refers debt to the collection agency with the least amount of referred debt. If you prefer different logic, you must write your own algorithm.
- Regardless of the manner in which a collection agency is selected for an account's debt, the referral involves the creation of a collection agency referral history record. Refer to [Collection Referral](#) for more information.
- A collection agency referral history record is linked to an account. It contains the amount of debt referred to the collection agency. It is the creation of this record that, in turn, triggers the interface of information to the collection agency. The method used to interface the information to the agency is defined on the collection agency's record. Refer to [Setting Up Collection Agencies](#) for more information.
- If the collection agency is successful in obtaining the funds, simply add a payment. If the payment causes the SA's balance to become zero, the system will automatically close the service agreement. When the system closes a service agreement, it is "removed" from the write-off process. When a write-off process no longer contains active service agreements, the system cancels the write-off process. When a write off process is cancelled, all collection agency referrals are automatically cancelled.
- Collection agency referrals get cancelled by the creation of a new collection agency referral history record (with a type of cancel). This record will be interfaced to the agency in the same manner used to interface a new referral (see above).
- If the collection agency is not successful in obtaining your funds after a given amount of time, you probably want to cancel the referral and write-off the debt. The cancellation of the referral will happen automatically if you design your write-off process to generate a collection agency cancellation X days after the referral. Refer to [Setting Up Write Off Process Templates](#) for how to do this. You can cancel a referral manually by simply creating a new collection agency referral history record (with a type of cancel).

FASTPATH:

When you enable the Control Central alert algorithm, [C1-COLL-REF](#), an alert displays when an account has an active collection agency referral. This algorithm is plugged-in on the [installation record](#).

The Big Picture Of Write-off Events

This section describes the various types of write-off events and their lifecycle.

How Are Write-off Events Created?

Write-off events may be created as follows:

- The Write-Off Monitor creates a write-off process when an account has unpaid, final billed service agreements. The write-off process has one or more write-off event(s). Refer to [How Does The Write-Off Monitor Work?](#) for more information about how the system creates write-off processes and their events.
- Write-off events are created when an operator creates an ad hoc write-off process. The number and type of events is controlled by the write-off process template defined when the write-off process is created.
- An ad hoc write-off event may be created and linked to an existing write-off process by an operator at their discretion.

NOTE:

Bottom line. Most write-off events are created by the system when it creates a write-off process for unpaid, finalized service agreements. If you need to create an ad hoc write-off event, you can either create a write-off process using a template that contains the desired event OR link the desired event to an existing write-off process.

FASTPATH:

For more information about creating ad hoc write-off processes and events, refer to [How To Perform Common Write-off Maintenance Functions](#).

Types Of Write-off Events

The following table describes the various types of write-off events and what happens when they are completed:

Type Of Write-off Event	What Happens In The System
Affect Credit Rating/Cash-Only	An account credit rating demerit record is created. The number of demerits is defined on the write-off event type.
Cancel Agency Referral	All collection agency referrals associated with the write-off process will be cancelled.
Refer to Agency	The debt associated with the SAs linked to the write-off process will be referred to a collection agency.
Send Letter	A customer contact is created for every financially responsible person linked to the account. The customer contact causes a letter to be produced. The type of letter is defined on the customer contact type control table. The recipient of each letter is defined on Account / Person (those persons marked as Receiving Notifications).
Send To Do	A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.
Write Off using Distrib Code	This type of event is used to write-off bad debt in accordance with the distribution codes associated with the financial transactions that caused the debt in the first place. You'd use this method for example if you want to write-off revenue differently than you write-off liabilities. The system accumulates the distribution codes from GL details associated with recent financial transactions linked to each write-

off service agreement. When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreement. The type of service agreements to which the debt is transferred is defined on the distribution codes.

Write Off using SA Type

The service agreements linked to the process will be written-off by transferring their debt to a new or existing write-off service agreement. Note: the SA type of the write-off service agreement is defined on the algorithm defined on events of this type.

Generic Algorithm

The system calls the algorithm defined on the write-off event type. This type of event is used when what you need to do isn't handled by one of the above event types.

FASTPATH:

Refer to [Setting Up Write Off Event Types](#) for more information.

Write-off Event Lifecycle

The following diagram shows the possible lifecycle of a write-off event:

Write-off events are initially created in the pending state.

When the system sees a pending event with a trigger date on or before the current date, the system executes the event's activity and completes the event.

FASTPATH:

For more information about a write-off event's trigger date, see [Write-off Event Trigger Date](#).

A pending event will be cancelled automatically by the system when the service agreements linked to the process are all closed (i.e., they no longer have debt - either because it was paid or transferred to a write-off service agreement). A pending event may be cancelled by an operator at their discretion.

Write-off Event Trigger Date

When a write-off event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to [Calendar vs. Work Days](#) for more information.

How Are Write-off Events Completed

A background process runs periodically (at least daily) that looks for write-off events with a trigger date on or before the current date. For each triggered event, the system executes its activity and then completes it. Refer to [Write Off Event Activator](#) for more information.

The Last Write-off Event Should Write Off All Debt Associated With All SAs

The last write-off event will typically transfer all debt from the service agreement's linked to the process to a write off service agreement (linked to the account). This will only happen if you set up the write-off process template accordingly (i.e., the last event in the write-off process template is the kind that writes off debt for every service agreement linked to the write-off process).

How Are Write-off Events Canceled?

The system removes a service agreement from a write-off process when its status becomes closed (i.e., when its balance is zero). Be aware that any type of financial event could cause an SA's balance to fall to zero (e.g., the creation of an adjustment, the application or cancellation of a payment, the cancellation of a bill, ...). When all service agreements are removed, the system cancels all pending write-off events and deactivates the write-off process.

NOTE:

Real time cancellation. Unlike collection processes, the system cancels write-off processes real time when the service agreement becomes closed (i.e., there is no background process that monitors write-off processes).

Besides the automated cancellation process, an operator may cancel a write-off event at will.

NOTE:

Removing closed service agreements from a write-off process. Service agreements aren't actually removed from the process. Rather, they are inactivated so a proper audit exists.

Calendar vs. Work Days

When you set up your collection, severance and write-off process templates, you supply information that controls how the system determines the trigger date of each event in the related process. There are two different mechanisms for doing this:

- When you set up your severance process templates, you must define the number of days between each event. For example, the second event (send cutoff warning) may need to be triggered 7 days after the first event (send reminder letter).
- When you set up your collection and write-off process templates, you must define the number of days after the start of the process when each event should be triggered. For example, the second event (send cutoff warning) may need to be triggered 7 days after the start of the collection process.

The system uses this information in conjunction with the account's division's work calendar when it allocates a trigger date to the various collection, severance, and write-off events in your processes. The system offers you the following choices in respect of how it calculates an event's trigger date:

- You can indicate that the trigger date should be set to the next possible workday. For example, if you indicate that the second event is triggered 7 days after the first event, the system will add 7 days to the first event's completion date. It then checks if this is a workday (and not a holiday), if so, this is the trigger date of the event; if not, it assigns the trigger date to the next workday.
- You can indicate that the trigger date should be calculated by counting workdays. For example, if you indicate that the second event is triggered 7 days after the first event, the system will count 7 workdays (using the account's division's work calendar), and set the trigger date accordingly.

You must define which of the above methods is used in the following processes:

- Account Debt Monitor (**ADM**). Refer to [The Account Debt Monitor](#) for more information.
- Collection Event Trigger (**CET**). Refer to [The Collection Event Activator](#) for more information.
- Severance Event Set Trigger Date (**SED**). Refer to [Set Trigger Date](#) for more information.
- Write-off Monitor (**WPM**). Refer to [The Write Off Monitor](#) for more information.

The Big Picture Of Payment Arrangements and Pay Plans

The topics in this section describe two different mechanisms that allow a customer to payoff overdue debt in installments.

The Big Picture Of Payment Arrangement Requests

A Payment Arrangement Request is used to manage the process of starting a payment arrangement. It is a step-by-step process that can include:

- Checking the account's eligibility for payment arrangement
- Capturing the terms of the payment arrangement such as the included service agreements, down payment amount, number of installments and installment amount
- Evaluating whether or not the payment arrangement request requires approval
- User approval / rejection of the payment arrangement request
- Monitoring for the down payment, if applicable
- Creating the payment arrangement service agreement

The topics in this section describe how payment arrangement requests work.

Lifecycle Of A Payment Arrangement Request

The base product provides a Payment Arrangement Request (**C1-PARrequest**) business object that supports the functions needed to create a payment arrangement. Its lifecycle allows for managing and monitoring of the prerequisites of a payment arrangement:

- The first step in the payment arrangement request process is typically to check that the account is eligible for a payment arrangement. One or more eligibility criteria are executed and an overall assessment is made on the results, to determine the account's eligibility/ineligibility. The request goes into the **Eligibility Checked** state. The results are shown on the user interface, for the user to determine the next step.
- If the account is ineligible for a payment arrangement, the request process ends. The payment arrangement request goes into the **Denied** state.

- If the account is eligible, the process can proceed with setting up the terms of the payment arrangement. The agreed upon terms are submitted and the request proceeds to the next step. If there are no prerequisites (approvals, down payment etc.), the request can automatically go to the **Granted** state, where the payment arrangement service agreement is created
- A payment arrangement request may be subject to prior approval if it meets certain criteria — e.g. the payment arrangement amount exceeds a threshold amount. The payment arrangement request goes into the **Approval In Progress** state, where an authorized user will need to review the request and **Approve** or **Reject** it accordingly.
 - If the user approves the request, the request will proceed to the next step — i.e. either another prerequisite (such as a down payment) or granting the request.
 - If the user rejects the request, the request will automatically go to the **Denied** state.
- If a down payment must be paid prior to starting the payment arrangement, the request will stay in the **Waiting for Down Payment** state until the payment is received or until the down payment due date.
 - If the down payment is paid (i.e. according to implementation-specific criteria for considering it paid), the payment arrangement request goes into the **Granted** state, where the payment arrangement service agreement is created. The account's SA balances to include in the payment arrangement are recalculated, based on the actual down payment that was received.
 - On the other hand, if the down payment is not received or is received but insufficient, the payment arrangement request goes into the **Unpaid Down Payment** state.
- A payment arrangement in a **Waiting for Down Payment** or **Approval In Progress** state can be **Withdrawn**. This is for cases where a customer decides to not proceed with the payment arrangement.
- Any issues encountered during the recalculation of the SA balances or during the creation of the payment arrangement service agreement can put the request into the **Error** state.

Refer to the Payment Arrangement Request business object, for more details on these lifecycle rules.

Payment Arrangement Eligibility

An account's eligibility for payment arrangement is typically checked at the start of the request process. Based on the results of these eligibility checks, a user can determine whether or not the payment arrangement request can proceed.

Since the eligibility rules can vary across implementations, the base product provides plug-in spots on the Payment Arrangement Request Type (**C1-PARequestType**) business object for eligibility checking:

- The **PA Request Type – Eligibility Criteria** algorithm spot is responsible for checking specific conditions or activity on the account, to determine payment arrangement eligibility. Algorithms of this type commonly return a simple Pass/Fail result. The base product supplies a sample algorithm that checks the account's past broken payment arrangements.
- The **PA Request Type — Criteria Assessment** algorithm spot is responsible for taking the results of the execution of **PA Request Type – Eligibility Criteria** algorithms and determining the overall result, which is whether or not the account is eligible for payment arrangement. The base product supplies two sample algorithms for this spot:
 - One algorithm type checks for at least one Fail result from the **PA Request Type – Eligibility Criteria** algorithms and if it finds one, returns an *Ineligible* result
 - Another algorithm type simply returns an *Eligible* result. This is for implementations that do not need **PA Request Type – Eligibility Criteria** algorithms. This default algorithm would be the only algorithm to plug in.

You can view the available **PA Request Type – Eligibility Criteria** and **PA Request Type – Criteria Assessment** algorithms using the application viewer's algorithm viewer.

Payment Arrangement Request Approval

A payment arrangement request may require prior approval, based on the terms specified on the request. For instance, if the total payment arrangement amount exceeds a set threshold amount, the request may have to be routed to another user for approval. That user will need to review the request and Approve or Reject accordingly.

Since the approval requirements are implementation-specific, the base product provides a **PA Request Type — Determine Approval Requirement** plug-in spot on the Payment Arrangement Request Type (**C1-PARequestType**) business object. Algorithms of this type return an indicator of whether or not approval is needed. If the algorithm indicates that approval is needed, the payment arrangement request will go into the **Approval In Progress** state until a user reviews and approves/rejects the request.

Your implementation must configure an algorithm with your specific approval criteria. The base product does not currently supply an algorithm type for this spot.

You can view your **PA Request Type – Determine Approval Requirement** algorithms using the application viewer's algorithm viewer.

Payment Arrangement Down Payments

A down payment may be required/applicable as a prerequisite for starting the payment arrangement.

A setting on the Payment Arrangement Request Type controls whether down payments are required/optional/not applicable. If down payments are required or optional, the payment arrangement request type defines the down payment options, which are percentages of the total payment arrangement amount or a flat amount.

The down payment due date is calculated based on settings in the Payment Arrangement Request Type – e.g. number of days till due.

The down payment is monitored for the actual payment:

- If the down payment is paid, the request is granted. The SA balances are recalculated based on the down payment amount that was paid and the payment arrangement service agreement is created.
- If the down payment is unpaid or is insufficient (based on the implementation's rules), the request is denied and the payment arrangement service agreement will not be created.

Refer to the Payment Arrangement Request Type (**C1-PARequestType**) business object for more details on down payment option configuration and to the Payment Arrangement Request (**C1-PARequest**) business object, to see the monitor algorithm that checks if the down payment was made.

Setting Up Payment Arrangement Request Control Tables

This section describes the control tables needed to set up payment arrangement requests.

Setting Up Payment Arrangement Request Types

A payment arrangement request type defines properties that control how a request for payment arrangement is processed.

Refer to [The Big Picture Of Payment Arrangement Requests](#) for an overview of payment arrangement request functionality.

To maintain payment arrangement request types, open **Admin > Credit & Collection > Payment Arrangement Request Type > Search**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information on the fields.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [C1_PA_RQST_TYPE](#).

Setting Up Payment Arrangement Request Reasons

A payment arrangement request can capture the specific reason why a customer is asking to go on a payment arrangement. This reason is optional if using the base-owned Payment Arrangement Request (**C1-PARequest**) business object and the Payment Arrangement Request Process Flow Type (**C1-PAREQUEST**) on your Payment Arrangement Request Types.

To use Payment Arrangement Request Reasons, configure your specific values on the **C1-PARequestReasonLookup** extendable lookup. No base values are supplied for this lookup.

Setting Up Payment Arrangement Request Status Reasons

The Payment Arrangement Request (**C1-PARequest**) base business object provides the option to specify the reason for the request going into the **Denied** or **Canceled** state.

A few base-owned status reasons are supplied. To add other reasons for payment arrangement request cancellation/denial, go to the Status Reason portal and update the **C1-PARequest** business object's status reasons for the Denied and Canceled states.

Automatically Cancelling Inactive Payment Arrangement Requests

The system is delivered with a batch process, Cancel Inactive PA Requests (**C1-ACPAR**), that can be used to cancel payment arrangement requests that have been open for more than a specified number of days. Refer to the batch control description for more detail.

The delivered process is built using the [Plug-in Driven Background Processes](#) framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. For example, you can introduce a process record algorithm to create a To Do Entry instead of cancelling the payment arrangement request. Adjust the batch parameters according to your custom logic, if needed.

The Big Picture Of Pay Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in **billed** installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

NOTE:

Nomenclature. Some people refer to payment arrangements as "current bill plus" agreements because the customer's bills contain charges for both their current debt plus their installment amount. After the customer has paid off their overdue debt, the customer's bill only contains charges for their current debt.

The topics in this section describe how to set up a payment arrangement and how the system monitors the ongoing arrangements.

Creating Payment Arrangements

When you create a payment arrangement, you are actually creating a service agreement. This service agreement is just like other service agreements in that:

- It holds debt.

- It is periodically billed.
- When a payment is received, the service agreement's debt is reduced.
- If the service agreement becomes delinquent, a collection process is initiated to collect the overdue debt.

Debt is transferred to a payment arrangement service agreement (PA SA) from the customer's delinquent service agreements (SAs) at the inception of the payment arrangement.

When you transfer delinquent debt from the delinquent SAs to the PA SA, the debt is removed from the delinquent SAs. If you transfer all debt from the delinquent SAs, the customer will no longer be in arrears in a given debt class (and if the customer is no longer in arrears, active collection and severance processes will be cancelled).

NOTE:

Use the Payment Arrangement Request Transaction. You could do the above functions by adding a new service agreement and creating transfer adjustments. However, this is tedious. Rather, use the [Payment Arrangement Request process](#). This process is recommend when requests for payment arrangements require eligibility checking and other prerequisites such as down payments and approvals. When a payment arrangement request is granted, it creates the PA SA, transfers debt to it, and sets up the installment amount.

You can also create the payment arrangement service agreement directly using the [Payment Arrangement](#) transaction if you don't require any prior eligibility checks, down payments or approvals. This transaction is also used if you need to break or cancel the payment arrangement.

Installment, Payoff and Current Amounts

WARNING:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

When you set up a payment arrangement service agreement (PA SA), you transfer delinquent debt to the PA SA using transfer adjustments. After moneys are transferred, the system sets the PA SA's current balance to zero. At this point, neither the original service agreements nor the PA SA have delinquent debt. If the customer neglects to pay their payment arrangement, the PA SA will fall into arrears and a collection process will ensue. If the customer neglects to pay their previously delinquent SAs, they will again fall into arrears and a collection process will ensue.

PA SAs start their life with a non-zero payoff balance (i.e., they have debt when first started). This debt is transferred from the normal service agreement(s) whose outstanding debt necessitated the creation of the PA SA.

The installment amount that the customer is billed is determined by the number of installments used to payoff the debt. For example, if the customer owes \$500 on their electric and water service agreements and they want to pay this off in 10 installments, you'd set up the installment amount to be \$50. The installment amount is saved on the PA SA's recurring charge amount. If the customer again falls into arrears on their normal service agreements, you can transfer additional delinquent debt to the PA SA. You can also change the installment amount as needed.

A PA SA's payoff balance typically differs from its current balance. The payoff balance is the amount of debt remaining to be paid off under the terms of the payment arrangement. The current balance is the installment amount that has been billed but not paid. For example, a customer who is paying off \$500 with 10 installments of \$50 would have an initial payoff balance of \$500 and a current balance of \$0. After the first bill, the PA SA would still have a payoff balance of \$500, but its current balance would be \$50. When the customer pays, the PA SA's payoff balance would fall to \$450 and its current balance would return to \$0.

The following table contains a financial example of a customer who sets up a payment arrangement to payoff \$1,000 of debt in \$10 installments.

Event	Normal SA's GL Accounting	PA SA's GL Accounting	Normal SA's Current Balance	Normal SA's Payoff Balance	PA SA's Current Balance	PA SA's Payoff Balance
Prior to creation of payment arrangement	N/A	N/A	1000	1000	N/A	N/A
Transfer debt from normal SA(s) to PA SA	Xfer 1000 A/R <1000>	PA A/R 1000 Xfer <1000>	0	0	1000	1000
Set current balance to zero on PA SA	N/A	N/A	0	0	0	1000
Customer is billed (\$50 for new debt and \$10 of payment arrangement debt)	A/R 50 Revenue <50>	N/A	50	50	10	1000
Customer pays \$60	Cash 50 A/R <50>	Cash 10 PA A/R <10>	0	0	0	990

When the customer pays off the payment arrangement debt, the system automatically closes the PA SA after it final bills (assuming the PA SA's SA type references a bill segment type that has a bill segment creation algorithm of Recurring Charge With Auto Stop).

Monitoring Payment Arrangements

The PA SA should belong to its own debt class (let's call it Payment Arrangement Debt) so that you can have stricter collection criteria for payment arrangement debt (as compared to normal SAs). Because there will be a new debt class, there will be a unique collection class control (CCC) for payment arrangements. This CCC will have debt criteria associated with payment arrangement debt. If these criteria are violated, we will kick off a collection process that should have 1 collection event - Start Severance.

The severance process template for PA SAs will have 1 severance event that calls the Break Payment Arrangement Event algorithm. This algorithm does the following:

- Cancels ALL adjustments that were used to transfer the debt to the payment arrangement (identified by the XFER adjustment type on the PA SA's SA type). When these are cancelled, the original arrearage will be reinstated under the original SAs - this debt should be rather old by this point.
- Syncs up current balance with payoff balance on the PA SA.
- Makes the PA SA pending stop (SA activation will stop the SA when it next runs).
- If there is a credit left on the PA SA (because payments were made against the arrangement), the credit will be distributed amongst the account's debt using the standard distribution algorithm. Because the payment arrangement debt that was reinstated should be rather old, it should get relieved first. This relief will occur via transfer adjustments from the PA SA to the original SAs.
- If there is a debit left (e.g., because LPC were issued or some other type of adjustment was created by an operator), the debt will be transferred back to one of the SAs from which the arrangement was originally created.
- Inserts a characteristic under the PA SA to indicate that it has been broken (we need this for the account debt monitor (ADM) a few steps down).

- Inserts a row on the account debt monitor trigger. This trigger will cause the account to be reviewed by the ADM the next time it runs.

NOTE:

The PA SA must final bill before it closes. The PA SA will only close after the PA SA is final billed. This is OK as it won't have any money left on it.

When the ADM next runs, it will analyze the account's reinstated debt. We recommend creating a new override collection criteria for the normal debt class that will return a value of true if the account has a closed payment arrangement that has been broken in the last X days (where X is a parameter of the override collection criteria's algorithm). If this algorithm returns a true, kick off a unique collection process template (that has nasty events). A sample algorithm of this type is supplied in the base package - COLL COND PA.

To complete this discussion, we have to worry about the situation when the final bill of a payment arrangement goes unpaid. In this situation, the payment arrangement is stopped and will therefore not be processed by the ADM. In this case, the write off monitor will process the PA SA after its final bill's due date and a write-off process will start. This write off process will have a single event that calls the Break Payment Arrangement algorithm (described above). After the FT's are issued in this event, the SA will close (because it's been final billed and its balance will go to zero).

The Big Picture Of Pay Plans

A pay plan (PP) is an agreement with a customer to make payments on specific dates. Pay plans differ from payment arrangements in that pay plans have user-defined scheduled payment dates, which are independent from the customer's billing dates. In other words, payment arrangements appear on the customer's bills, pay plan scheduled payments do not.

If a customer is in arrears and you want to receive payments on specific dates (as opposed to with the customer's regular bills), you would set up a pay plan and define the dates on which you expect the payments.

The topics in this section describe how pay plans work.

A Pay Plan Has One Or More Scheduled Payments

When you create a pay plan for an account, you must define the number of scheduled payments and their respective amounts. There is no limit to the number of scheduled payments that may be set up under a pay plan.

Automatic Payments Can Be Created On The Scheduled Payment Dates

The system will create automatic payments on a pay plan's scheduled payment dates if:

- The account is set up for automatic payment (as described under [How To Set Up A Customer To Pay Automatically](#)), and
- The payment method defined on the pay plan indicates automatic payment is being used

The background process called PPAPAY is responsible for creating these automatic payments. It does this by calling the automatic payment creation algorithm plugged in on the installation record.

NOTE:

If the **Autopay Creation Option** on the [installation record](#) is set to Create On Extract Date, the automatic payment is NOT distributed and frozen when the automatic payment is initially created. Rather, a separate background process ([APAYDSFR](#)) distributes and freezes the automatic payment on the automatic payment GL distribution date (refer to

[Automatic Payment Dates](#) for more information on how this date is calculated). Refer to [Automatic Payments](#) for more information.

A Pay Plan Insulates Overdue Debt From The Account Debt Monitor

A pay plan's scheduled payments are used by the account debt monitor as "pseudo payments" that relieve the account's debt before it is subjected to the collection criteria (refer to [How Does The Account Debt Monitor Work](#) for more information about collection criteria).

It's important to understand that a pay plan only insulates the account's debt that belongs to the pay plan's debt class. Therefore, if a customer has debt that belongs to two debt classes (e.g., normal debt and 3rd party pass through debt), you would need to set up a separate pay plan for each debt class (assuming both types of debt are covered by a pay plan). Refer to [Different Collection Criteria For Different Customers and Different Debt](#) for more information about debt classes.

A Pay Plan Must Reference A Pay Plan Type

When you create a pay plan, you must define its pay plan type. The pay plan type controls the following functions:

- The debt class whose debt is insulated by the pay plan.
- The type of algorithm (if any) that is executed when the pay plan is broken. You might use such an algorithm to affect the customer's credit rating when the pay plan is broken.

A Pay Plan May Reference A Third-Party Payor

In addition to referencing the account whose debt is insulated by the pay plan, the pay plan must also reference the account that is responsible for making the payments. We refer to this second account as the pay plan's "payor".

While the payor's account is typically the same as the account whose debt is insulated by the pay plan, you can indicate a third-party payor (e.g., a social service agency) is responsible for making the pay plan's scheduled payments.

If your organization allows third-party payors, you can define each on the third-party payor control table. This control table exists to simplify the data-entry effort when you create a pay plan (as it defines the account associated with the third-party payor).

NOTE:

If a pay plan does not reference a third-party payor, any non-third-party payor (i.e., any account that is not defined in the third-party payor control table) can make payments on behalf of the customer. If a pay plan references a third-party payor, only payments made by the third party on behalf of the customer are counted towards the fulfillment of the pay plan.

The Lifecycle Of A Pay Plan

The following diagram shows the possible lifecycle of a pay plan:

The following points explain this lifecycle:

- Pay plans are initially created in the active state. Active pay plans are monitored for compliance by [The Pay Plan Monitor](#).
- A pay plan may be cancelled as follows:
 - A user can cancel a pay plan at will.
 - When a SA is stopped AND there are no other active SAs in the same debt class, all **Active** pay plans associated with the account and debt class will be will be **Canceled** .
 - The activation of a collection event that calls the "cancel pay plan" algorithm will cancel all active pay plans associated with the collection process's debt class. You may want to use such a collection event if your organization cancels active pay plans when new debt causes a collection process to kick-off. Note, the base package algorithm that performs this function will not cancel the pay plan if it's associated with a 3rd party payor.
- [The Pay Plan Monitor](#) causes active pay plans to become broken if sufficient payments have not been made to satisfy the pay plan's scheduled payments.
- [The Pay Plan Monitor](#) causes active pay plans to become kept when it detects that sufficient payments have been made to satisfy the pay plan's scheduled payments.

Highlighting The Existence Of Broken / Kept / Active and Denied Pay Plans

You can define on the installation record plug-in algorithms that format alert messages. (Refer to [Installation Options - Algorithms](#) for additional information.) We recommend that you take advantage of the following algorithms to highlight pay plans:

- Highlight pay plans in a given status. This algorithm is used to highlight pay plans in a given state (broken, kept, cancelled) that were started within the last X days.
- Highlight customer contacts of a given type. This algorithm would be used to highlight customer contacts of a given type that were created within the last X days. This would be useful if you create a specific type of customer contact when you deny a pay plan. Some utilities do this to prevent customers from shopping around.

In addition, you can define account-specific alerts to highlight customers that should never be allowed to have a pay plan (for whatever reason).

A Pay Plan Must Reference A Payment Method

When you create a pay plan, you must define how the customer will make the payments by referencing a payment method. Examples of payment methods include: In Person , Wire Transfer, By Post, Express Mail, etc.

The payment method is more than just documentation as it defines the number of grace days the customer has to make the pay plan's scheduled payments. For example, if you set up the payment method control table to indicate that payments made By Post have 3 grace days, then the customer has up to 3 days after each scheduled payment date to make the payment. If payment is not received by the scheduled payment date plus the grace days, the pay plan will be marked as broken (and the ADM will be triggered).

The Pay Plan Monitor

FASTPATH:

Please understand the concepts described in [The Lifecycle Of A Pay Plan](#) and [The Tendering Account May Differ From The Account Whose Debt Is Relieved](#) before reading this section.

The Pay Plan Monitor background process (referred to as PPM) is responsible for monitoring active payment plans. This process can cause a pay plan (PP) to become kept or broken (or being left as active).

NOTE:

When is a pay plan marked as broken / kept? It's important to understand that only the PPM can cause a pay plan to become kept or broken. This means that if a customer makes a payment that satisfies a pay plan, the pay plan will only be marked as kept when the pay plan monitor next runs. Analogously, if a payment is cancelled, nothing will happen to an active pay plan until the PPM next runs. When the PPM next runs, it will see that the scheduled payment was not kept and it will break the pay plan and schedule the ADM to be executed. When the ADM next executes, it will create a collection process (because the customer's debt will no longer be insulated by the pay plan's scheduled payments).

NSF Cancellations After A Pay Plan Is Kept. If a payment is cancelled due to non-sufficient funds (NSF) after a pay plan is marked as kept, the pay plan will remain kept. But keep in mind that the pay plan's account is scheduled for review by the ADM when a payment is cancelled due to NSF. When the ADM reviews the account's debt, it will no longer have an active pay plan to insulate it and the account's debt will likely trigger a new collection process. Refer to [How Pay Plans Affect The Account Debt Monitor](#) for more information.

The following points describe, at a high level, how the PPM monitors a pay plan (PP) for compliance.

- The system selects all frozen, non-cancelled payment segments associated with the PP's account and debt class where:
 - The payment date is after the start date of the pay plan, and
 - The payment's pay event has at least one tender that references the pay plan's payor.
- The system logically reduces / removes past and current scheduled payments (starting with the earliest scheduled payment) until the total amount of payment segments is exhausted (or there are no more historical / current scheduled payments).

NOTE:

Paying pay plans in advance. Scheduled payments with a future date are not logically removed / reduced. This means that if a customer makes advance payments on a pay plan, it will not be marked as kept until all scheduled payment dates are in the past.

- If all scheduled payments have been logically removed, the pay plan is marked as kept.
- If there exist scheduled payments where the pay date + grace days (grace days are defined on the pay plan's payment method) is before the current date (i.e., a payment doesn't exist for a scheduled payment):
 - The pay plan is marked as broken.

- The PP's break algorithm (if any) is called (note, for European / Australian pay plans, there are scenarios where the break algorithm can cause the pay plan to become unbroken - when there aren't at least two missed, historical scheduled payments).
- An ADM trigger is stored for the PP's account. This will cause the account to be reviewed by the ADM the next time it runs. And because the pay plan is broken, its scheduled payments will no longer insulate the account's arrearage.

IMPORTANT:

It's important that you schedule the PPM to run before the ADM so that it can break unpaid payment plans prior to the ADM subjecting the account's debt to collection criteria. Refer to [How Pay Plans Affect The ADM](#) for more information.

How Pay Plans Affect The Account Debt Monitor

As described under [A Pay Plan Insulates Overdue Debt From The Account Debt Monitor](#), a pay plan's scheduled payments insulate an account's debt from the ADM. This section describes how this is accomplished.

WARNING:

You should understand the concepts in [How Does The Account Debt Monitor Work](#) and [The Tendering Account May Differ From The Account Whose Debt Is Relieved](#) before reading the following.

NOTE:

The ADM will be triggered when a pay plan is broken. Refer to [The Pay Plan Monitor](#) for an explanation of how the ADM is triggered when a pay plan is broken.

Before the ADM subjects an account's debt to the collection criteria, it calls the debt's debt class's Override Arrears Algorithm (this is an optional plug-in spot on [Debt Class](#)). This algorithm is passed the debt class's aged debt and manipulates it as follows:

- First, a list of all past, present and future scheduled payments associated with the account and debt class's active pay plans is constructed.
 - If multiple payors are encountered (because the customer has multiple pay plans and these have different payors), a separate list of scheduled payments is maintained for each payor.
- Next, for each payor, retrieve the total amount of frozen, non-cancelled payment segments made on behalf of the pay plan's account and debt class.
 - Select all frozen, non-cancelled payment segments associated with the pay plan's account and debt class whose pay date is \geq pay plan's start date and the pay segment's event has at least one tendering account associated with the pay plan's payor.
- Next, logically reduce / remove past and current scheduled payments (starting with the earliest scheduled payment) until the payor's payment amount is exhausted (or there are no more historical / current scheduled payments). Future scheduled payments cannot be remove / reduced.
- Finally, reduce the passed in aged debt with any unpaid scheduled payments.

NOTE:

This logic is not "hard coded". Rather, the mechanism used to use a pay plan's scheduled payments to reduce debt is defined in an algorithm defined on the pay plan's debt class. The contents in this section describe how a base package algorithm works. Because it's an algorithm, you can introduce whatever logic you please.

The following is an example of how pay plans affect aged debt.

Date	Event	SA's Arrears	SA's Balances	Scheduled Payments
Prior to creation of the PP 1/18/2000		\$1,000 - 90 days old \$1,600 - 60 days old \$1,900 - 30 days old	Current: \$4,500 Payoff: \$4,500	
1/18/2000	Pay Plan created. The \$4,500 in future scheduled payments offsets the existing \$4,500 of aged debt.	\$1,000 - 90 days old \$1,600 - 60 days old \$1,900 - 30 days old De facto ADM debt: \$0	Current: \$4,500 Payoff: \$4,500	1/20/2001 \$1,500 2/01/2001 \$1,500 2/07/2001 \$1,500
1/20/2001	The customer pays \$1,500. There exists \$3,000 of future scheduled payments that offset the arrears	\$1,100 - 62 days old \$1,900 - 32 days old De facto ADM debt: \$0	Current: \$3,000 Payoff: \$3,000	1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 Future 2/07/2001 \$1,500 Future
1/20/2001	ADM runs. The \$3000 in future scheduled payments offsets the Current Balance of \$3000, so CC events not created.	\$1,100 - 62 days old \$1,900 - 32 days old De facto ADM debt: \$0	Current: \$3,000 Payoff: \$3,000	1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 Future 2/07/2001 \$1,500 Future
1/24/2001	A new bill is created for \$400	\$1,100 - 62 days old \$1,900 - 32 days old \$400 - 1 day old De facto ADM debt: \$400 - 1 day old	Current: \$3,400 Payoff: \$3,400	1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 Future 2/07/2001 \$1,500 Future
2/2/2001	Pay Plan Monitor runs. PP marked as Broken because the 2/1/2001 scheduled payment has not been paid (assuming no grace period on the pay plan's payment method)	\$1,100 - 74 days old \$1,900 - 44 days old \$400 - 8 days old	Current: \$3,400 Payoff: \$3,400	1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 "Late" 2/07/2001 \$1,500 Future
2/2/2001	ADM runs. There are no active pay plans and therefore there is nothing to insulate the customer's debt. Therefore the aged debt will be subjected to the collection criteria and an appropriate collection process will be created.	\$1,100 - 74 days old \$1,900 - 44 days old \$400 - 8 days old De facto ADM debt is the same as above (i.e., rather old)	Current: \$3,400 Payoff: \$3,400	Pay plan is broken and therefore its scheduled payments cannot be used.

Collection Process / Severance Process Cancellation

When a pay plan (PP) is created, the system determines if it can cancel active collection and severance processes associated with the pay plan's account and debt class. It does this because a pay plan's scheduled payments act as "pseudo payments" that relieve the account's debt (temporarily). The following points describe how this works:

- The system attempts to cancel collection processes by calling the [Collection Process Cancel Criteria Algorithm](#) defined on the debt class that is associated with the collection process. This algorithm is meant to cancel a collection process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see [How Pay Plans Affect The Account Debt Monitor](#) for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.
- It attempts to cancel severance processes by calling the [Severance Process Cancel Criteria Algorithm](#) defined on the debt class that is associated with the severance process. This algorithm is meant to cancel a severance process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see [How Pay Plans Affect The Account Debt Monitor](#) for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

If collection / severance processes still exist for the account / debt class associated with the pay plan, a warning is issued.

Interesting Pay Plan Facts

The following points describe a variety of interesting facts about pay plans (PP):

- An account may have many active pay plans. However, only 1 pay plan may be active for a given account / debt class / payor at any point in time.
- The existence of a pay plan has no impact on payment distribution.
- When a SA is stopped, if the SA's debt class has an active PP AND there are no other active SAs in the same debt class, the PP will be cancelled
 - The cancel reason will be "cancelled by system" (as opposed to "cancelled by user")
- If necessary, different collection / severance processes can be triggered if a broken PP is detected (via the override algorithms on CCC and write-off control - we do NOT provide such algorithms).

Setting Up Pay Plan Control Tables

This section describes the control tables needed to set up pay plans.

Setting Up Pay Plan Types

Pay plan types control what is done by a given pay plan. Open **Admin > Credit & Collection > Pay Plan Type** to define your pay plan types.

FASTPATH:

For more information refer to [The Big Picture Of Pay Plans](#) for more information.

Description of Page

To modify a pay plan type, simply move to a field and change its value. To add a new pay plan type, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Plan Type The name of the pay plan type.

Description A meaningful description of the pay plan type.

Broken Algorithm This algorithm is called when a pay plan is broken. Refer to [The Pay Plan Monitor](#) for more information about how pay plans are broken.

If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that breaks a pay plan. Click [here](#) to see the algorithm types available for this plug-in spot.

Debt Class The debt class covered by pay plans of this type. Refer to [Setting Up Debt Classes](#) for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_PP_TYPE](#).

Setting Up Payment Methods

Payment methods are used to describe how a customer intends to make their pay plan's scheduled payments. Open **Admin > Credit & Collection > Pay Method** to define your payment methods.

FASTPATH:

For more information refer to [A Pay Plan Must Reference A Payment Method](#) for more information.

Description of Page

To modify a pay method, simply move to a field and change its value. To add a new pay method, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Method The name of the payment method.

Description A meaningful description of the payment method.

Grace Days The number of days added to the scheduled payment date. The ADM will consider the pay plan to be broken if payment is not made by the scheduled date plus the grace days.

Auto Pay If the pay method is marked as being for **Auto Pay**, the PPAPAY background process will automatically create an automatic payment on the pay plan's scheduled payment dates IF the account has been set up for automatic payment.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_PAY_METH](#).

Setting Up Third Party Payors

Pay plans support optional third-party payors. Open **Admin > Credit & Collection > Third Party Payor** to define your third-party payors.

NOTE:

A third-party payor refers to an account. You must set up the account before you can create a third-party payor.

FASTPATH:

Refer to [A Pay Plan May Reference A 3rd Party Payor](#) for more information.

Description of Page

The following fields display for each third party payor:

Third Party Payor Provide a meaning id for the third-party payor that can be easily recognized when setting up a pay plan.

Description A meaningful description of the payor.

Account ID The account that is used for this payor. It is this account that is tracked as the "payee" of any payments made towards a third party payor's pay plan.

Active Check this box if the payor is currently available to participate in pay plans.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_THRD_PTY](#).

Creating Collection, Severance & Write-Off Procedures

Your collection procedures define how your organization collects overdue debt. Your severance procedures define how your organization severs service agreements when collection attempts fail. Your write-off procedures define how your organization writes off finalized debt. In this section, we describe how to set up the data that controls these procedures.

FASTPATH:

For more information about collection, severance and write-off procedures, see [The Big Picture Of Credit & Collections \(C&C\)](#).

WARNING:

There are innumerable ways to design your collection, severance and write-off procedures. Some designs will result in easy long-term maintenance, others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production collection, severance and write-off procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

Designing Your Collection Procedures

The design of your collection procedures is an iterative process. Over time, you will develop intuitive skills that will allow you to skip some iterations. However, when you're starting out, we recommend you use the following matrix as your guide. When the matrix is complete, you're ready to set up the collection process control tables.

SA's Debt Class	Account's Collection Class:	Account's Collection Class:

The topics discussed below will gradually complete this matrix using a simple case study.

FASTPATH:

For more information about how the information in this matrix is used to monitor your customers' debt, refer to [Different Collection Criteria For Different Customers And Different Debt](#).

Designing Your Debt Classes

Multiple debt classes are needed when you have different collection procedures for different types of service agreements. If all service agreement debt is collected the same way, then you'll have just one debt class (call it Generic). However, if you're like many organizations, you will have multiple debt classes. The following points will help you understand why:

- If you have both regulated and unregulated service, you probably have different debt classes for each type of service. Why? Because your local regulators control how you collect and cutoff overdue, regulated debt. For unregulated debt, your organization controls how overdue debt is collected.
- If your customers make charitable donations, you will have a charitable contribution debt class. Why? Because you probably send a different type of letter when the customer falls into arrears on their charitable contributions. You also can't cut off their water service if they don't make their charitable contributions.
- If you levy deposits, you will probably have a deposit debt class. Why? Because you probably respond differently if the customer doesn't pay their deposit (e.g., you may decide to cut off their electric service until the deposit is paid).
- If you allow customers to make payments on Non-Billed Budgets, you will probably have a Non-Billed Budget debt class. Why? Because you probably respond differently if the customer doesn't pay their Non-Billed Budget (e.g., you may decide to expire the Non-Billed Budget but not affect their other service since the Non-Billed Budget is a way for customers to prepay for upcoming bills).
- If you write-off uncollectable debt, you will need another debt class for write-off service agreements. Why? Because when you write-off debt in the system, you transfer the uncollectable debt from the original service agreement(s) to a write-off service agreement. The write-off service agreement holds this debt forever (or until it is paid). You need to use a different debt class for the write-off service agreements because they aren't subject to collection criteria.
- If you use the system to charge your organization's company usage, you'll need another debt class (we refer to it as the "N/A" debt class below). Why? Because all service agreements must have a debt class, even those that will never have debt.

SA's Debt Class	Account's Collection Class	Account's Collection Class
Regulated		
Unregulated		
Charitable Contribution		
Deposit		
Non-Billed Budget		
Write Off		
N/A		

Designing Your Collection Classes

Multiple collection classes are needed when any debt class has different collection rules depending on the type of customer. If all customers within all debt classes are collected the same way, then you'll just have a single collection class (call it Generic). However, if you're like many organizations, you will have multiple collection classes.

Consider unregulated debt. For commercial/industrial customers, you probably don't worry until they owe you more than, say, \$100 after 20 days. For residential customers, you probably don't worry until they owe you more than, say, \$5 after 20 days. In this situation, you will have at least two collection classes: one for large customers, the other for residential customers.

In our example, we are assuming you have two collection classes: Residential and Commercial/Industrial.

SA's Debt Class	Account's Collection Class:	Account's Collection Class:
	Residential	Commercial/Industrial
Charitable Contribution		
Regulated		
Unregulated		

Write Off

Company Usage

Designing Collection Class Controls

At this point we have the rows and columns defined in our matrix. Now it's time to work on the individual cells.

Each cell should have a "collection class control" that defines its collection criteria and what to do if the criteria are violated. If a cell doesn't have a collection class control, this means you don't have any debt associated with that combination of collection class and debt class. So, we'll mark each cell without debt with "N/A".

SA's Debt Class	Account's Collection Class:	
	Residential	Commercial/Industrial
Regulated		N/A
Unregulated		
Charitable Contribution		N/A
Deposit		
Write Off		
N/A		

Next, we'll mark each cell for debt classes whose debt isn't collectable (i.e., the write-off and N/A debt classes).

SA's Debt Class	Account's Collection Class:	
	Residential	Commercial/Industrial
Regulated		N/A
Unregulated		
Charitable Contribution		N/A
Deposit		
Write Off	N/A	N/A
N/A	N/A	N/A

NOTE:

If the Account Debt Monitor encounters debt associated with a non-existent collection class control, it will issue an error.

Determining the collection criteria in each remaining cell can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For charitable debt, if the customer is more than \$0 in arrears by more than 20 days, kick off the "charity reminder" collection process. We'll talk more about this collection process later.
- For regulated / residential debt, if the customer is more than \$15 in arrears by more than 20 days, kick off the Normal Regulated collection process. We'll talk more about this collection process later.
- For unregulated / residential debt, if the customer is more than \$5 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.

- For unregulated / commercial-industrial debt we have multiple criteria:
 - Highest priority. If the customer is more than \$10,000 in arrears by more than 20 days, kick off the Large Overdue Debt collection process. We'll talk more about this collection process later.
 - Lower priority. If the customer is more than \$100 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.
- For deposit debt (regardless of collection class) we have multiple criteria:
 - Highest priority. If the customer is more than \$5 in arrears by more than 50 days, kick off the Deposit Severely Overdue collection process. We'll talk more about this collection process later.
 - Lower priority. If the customer is more than \$15 in arrears by more than 20 days, kick off the Deposit collection process. We'll talk more about this collection process later.

Given the above, our matrix will look as follows:

SA's Debt Class	Account's Collection Class:	
	Residential	Commercial/Industrial
Charitable Contribution	If > \$0 is older than 20 days, start Charity Reminder collection process.	N/A
Regulated	If > \$15 is older than 20 days, start Normal Regulated collection process.	N/A
Unregulated	If > \$5 is older than 20 days, start Normal Unregulated collection process.	Highest priority: If > \$10,000 is older than 20 days, start Large Overdue Debt collection process. Lower priority: If > \$100 is older than 20 days, start Normal Unregulated collection process.
Deposit	Highest priority: If > \$5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > \$15 is older than 20 days, start Deposit collection process.	Highest priority: If > \$5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > \$15 is older than 20 days, start Deposit collection process.
Write Off	N/A	N/A
N/A	N/A	N/A

Designing Your Collection Class Control Overrides

WARNING:

Your collection needs may not require any overrides for your collection class control matrix and therefore this section may not be relevant.

The following matrix will help you design your collection class overrides. When the matrix is complete, you're ready to set up the collection class control tables.

Notice that the matrix has two dimensions: one is dependent on collection condition algorithms; the other is dependent on the collection class controls designed in the previous section. Collection condition algorithms are confusing. Think of them as optional conditions that, if met, will subject the collection class control's debt to different collection criteria.

Each cell in the matrix contains the collection criteria that will be applied to the account's debt when the collection condition is met (i.e., the same type of criteria - dollars and days and collection process - are defined in each cell).

We label the first collection condition as the Default. The collection criteria associated with this column will be used to analyze an account's debt when none of the other conditions applies. We'll start by indicating the Default collection criteria (this was defined in the previous section).

SA's Debt Class	Account's Collection Class:	Account's Collection Class:
	Default	Credit Rating < Threshold
Residential Charitable Contribution	See default collection criteria defined in previous section.	
Residential Regulated	See default collection criteria defined in previous section.	
Residential Unregulated	See default collection criteria defined in previous section.	
Commercial-Industrial Unregulated	See default collection criteria defined in previous section.	
Residential Deposit	See default collection criteria defined in previous section.	
Commercial-Industrial Deposit	See default collection criteria defined in previous section.	

If a different collection process OR criteria should be used when other conditions are met, you should indicate such by defining the collection criteria in the cell. For example, if we assume that all unregulated residential debt has a different collection process when the account's credit score is less than the threshold credit rating on the installation record or the account's CIS Division, our matrix will look as follows:

SA's Debt Class	Account's Collection Class:	Account's Collection Class:
	Default	Credit Rating < Threshold
Residential Charitable Contribution	See default collection criteria defined in previous section.	
Residential Regulated	See default collection criteria defined in previous section.	
Residential Unregulated	See default collection criteria defined in previous section.	Override: If Credit Rating is lower than the credit rating threshold: If > \$5 is older than 15 days, start Risky Unregulated collection process.
Commercial-Industrial Unregulated	See default collection criteria defined in previous section.	
Residential Deposit	See default collection criteria defined in previous section.	
Commercial-Industrial Deposit	See default collection criteria defined in previous section.	

Once the matrix is complete, you're ready to design your collection process and collection event types.

NOTE:

The collection conditions are limited by your imagination (and business requirements). We have provided the collection conditions you see above as an example; we don't expect you'll be able to use the exact conditions we supply. Your conditions will be based on any number of factors. For example, if you have different collection criteria that apply during winter months, you should add a new collection condition (called Winter Season). Or if you have different criteria based on years of service, you could have another condition.

New collection conditions may require programming. See [How To Add A New Algorithm](#) for more information.

Designing Collection Process Templates & Collection Event Types

The following table shows the collection process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Collection Process Template	Collection Event Template	Triggered X Days From Start Of Collection Process
Charitable Contribution Reminder	Charity courtesy reminder letter	0
	Start severance	15
Normal Regulated	Regulated courtesy reminder letter	0
	Regulated second notice letter	10
	Start severance	15
Large Overdue Debt	Large debt courtesy reminder letter	0
	To Do for large overdue debt	3
	Large debt second notice letter	10
	Start severance	15
Normal Unregulated	Unregulated courtesy reminder letter	0
	Unregulated second notice letter	5
	Start severance	10
Risky Customer Unregulated	Unregulated risky letter	0
	Start severance	5
Deposit	Deposit reminder	0
Deposit Severely Overdue	Create To Do entry	0

If we extract each unique event type from the above table, we end up with the following:

Collection Event Type	Event Type
Charity courtesy reminder letter	Send Letter - CHARIT REMIN
Start severance	Start Severance Process
Regulated courtesy reminder letter	Send Letter - REGUL REMIN
Regulated second notice letter	Send Letter - REGUL second
Large debt courtesy reminder	Send Letter - LARGE REMIN
Risky debt courtesy reminder	Send Letter - RISKY REMIN
To Do for large overdue debt	Issue To Do
Large debt second notice letter	Send Letter - LARGE second
Unregulated courtesy reminder letter	Send Letter - UNREG REMIN
Unregulated second notice letter	Send Letter - UNREG second
Deposit reminder	Send Letter - DEPOS REMIN

Now you're (almost) ready to set up your collection procedures.

Defining Cancellation Process Auto Cancellation Criteria

The topics in the section [How Are Collection Processes Cancelled](#) describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your [Debt Classes](#), and optionally, on your [Collection Process Templates](#).

Setting Up Collection Procedures

In the previous section, [Designing Your Collection Procedures](#), we presented a case study that illustrated a mythical organization's collection procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

Setting Up Collection Event Types

Collection event types control what is done by a given collection event. Open **Admin > Credit & Collection > Collection Event Type > Add** to define your collection event types.

Description of Page

Enter a unique **Collection Event Type** and **Description** for the collection event type.

Enter the **Collection Event Type**. Permissible values are: Affect Credit, Rating/Cash-Only, Cancel Budget, Generic Algorithm, Send Letter, Create To Do Entry, Start Severance Process. The following discussion describes the parameters that must be defined for each type of collection event.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Credit Rating Points** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account's CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Credit Rating Months** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

FASTPATH:

For more information, refer to [Account - Credit Rating](#).

The Send Letter collection event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.

- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

NOTE:

Letter creation is triggered via a customer contact. You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the collection event. Refer to [Setting Up Letter Templates](#) for more information.

The Cancel Budget collection event type cancel an account's budget plan (if the account is on such a plan). When a budget plan is cancelled, adjustments are issued to synchronize every service agreement's current balance with its payoff balance and each applicable SA's recurring charge amount (i.e., budget amount) is set to zero.

The Generic Algorithm collection event type causes the algorithm defined in the **Collection Event Alg** to be executed. You use this type of algorithm when the standard types of collection events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type of activated. Click [here](#) to see the algorithm types available for this plug-in spot.

The Create To Do Entry collection event type causes a To Do entry to be issued. A good example of where this is used is when the collection event requires that the customer be called on the phone. Refer to [The Big Picture of To Do Entries](#) for more information about To Do entries (refer to the To Do type TD-CEVT for the type of To Do entry that's created).

The Start Severance Process type will start a severance process for every service agreement linked to the collection process. No parameters are needed for this type of event.

Enter a **Long Description** to fully describe the collection event type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_COLL_EVT_TYP](#).

Setting Up Collection Process Templates

Collection process templates define the collection events that will be executed when a collection criteria rule is violated. Open **Admin > Credit & Collection > Collection Process Template > Add** to define your collection process templates.

Description of Page

Enter a unique **Collection Process Template** and **Description** for the collection process template.

Select a **Cancel Criteria Algorithm** if your organization allows individual service agreements to be "removed" from a collection process regardless of the debt associated with all service agreements in the debt class. In other words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM. If this algorithm is specified, it is executed by the collection process monitor when it detects that a credit has been applied to a service agreement linked to an active collection process. This algorithm will indicate if the specific service agreement that has been credited no longer has debt that warrants a collection process. Refer to [How Are Collection Processes Cancelled](#) for more information. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that "removes" a service agreement from a collection processes if the service agreement's debt so warrants. Click [here](#) to see the algorithm types available for this system event.

The **Response** grid contains an entry for every collection event that will be created when a collection process that references this template is created. The following information must be defined for each event:

Event Sequence controls the order in which the collection event types appear under the collection process template. The sequence number is system-assigned and cannot be changed. If you have to insert a collection event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Collection Event Type Specify the type of collection event to be generated.

Days After Process Creation Specify the number of days after the creation of the collection process that the related collection event will be triggered. Refer to [Calendar vs Work Days](#) for a description of how this system uses this information to set the trigger date on the respective collection events.

FASTPATH:

For more information about collection event types, see [Setting Up Collection Event Types](#). For more information about trigger dates, see [Collection Event Trigger Date](#).

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_COLL_PROC_TM](#).

Setting Up Collection Classes

Every account has a collection class. This class is one of several fields that control the collection method applied to the account's debt. Open **Admin > Credit & Collection > Collection Class** to define your collection classes.

FASTPATH:

For more information about collection classes, see [Designing Your Collection Classes](#).

Description of Page

Enter a unique **Collection Class** code and **Description** for each collection class.

Indicate which method is used to monitor the member accounts' unpaid debt:

- If you practice [balance-forward accounting](#) for accounts belonging to this collection class, select Collection, Severance & Write-Off. This method of collection is described throughout this chapter.
- If you practice [open-item accounting](#) for accounts belonging to this collection class, select Overdue. This method of collection is described under [Defining Overdue Processing Options](#).
- If accounts belonging to this collection class are not subject to either of the above collection methods, select Not Eligible For Collection. Please be aware that these accounts will NOT be reviewed for overdue debt.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_COLL_CL](#).

Setting Up Debt Classes

Every SA type has a debt class. This class is one of several fields that control the collection criteria applied to the service agreement's debt. Open **Admin > Credit & Collection > Debt Class > Add** to define your debt classes.

FASTPATH:

For more information about debt classes, see [Designing Your Debt Classes](#).

Description of Page

Enter a unique **Debt Class** and **Description** for the debt class.

Turn on **Eligible for Collection** if service agreements belonging to this debt class have their debt monitored by the collection process. This should only be turned off if this debt cannot be collected, e.g., write-off debt.

The grid that follows contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to an arbitrary number as only one algorithm for each system event is allowed in this case.

WARNING:

These algorithms are typically significant system processes. The absence of an algorithm may prevent the system from operating correctly.

You can define algorithms for the following **System Events**:

System Event	Optional / Required	Description
Collection Process Cancellation	Required if debt class is eligible for collection	<p>This algorithm determines if a collection process can be canceled, and if so, it cancels it. Refer to How Are Collection Processes Cancelled for more information.</p> <p>Click here to see the algorithm types available for this system event.</p>
Severance Process Cancellation	Required if debt class is eligible for collection	<p>This algorithm determines if a severance process can be canceled, and if so, it cancels it. Refer to How Are Severance Processes Cancelled for more information.</p> <p>Click here to see the algorithm types available for this system event.</p>
Override Arrears Due to Pay Plan	Required if you use Pay Plans	<p>This algorithm is called to temporarily override a customer's arrears using a pay plan's scheduled payments when the system looks at an account's debt from a credit & collections perspective (i.e., the ADM calls this algorithm before it subjects a customer's debt to the collection criteria and when a pay plan is created). It does not actually change any data, but overlays the current arrears with the pay plan scheduled payments.</p> <p>This algorithm is also called by the above algorithms when a pay plan is created in order to evaluate if the scheduled payments actually cover the arrears (if so, the collection / severance processes are cancelled). It is also called periodically by the ADM in order to establish if the current state of the pay plan still covers the arrears. Refer to How Pay Plans Affect The Account Debt Monitor.</p> <p>Click here to see the algorithm types available for this system event.</p>

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_DEBT_CL](#).

Setting Up Collection Class Controls

The topics in this section describe the windows on which you set up your collection class control information.

WARNING:

The information in this page is what controls how the system analyzes your customer's debt. The flexibility of this control information provides you with almost unlimited options. This is very powerful, but it requires careful analysis. Refer to [Designing Your Collection Procedures](#) for more information.

Collection Class Control - Main Information

The information on this transaction defines the conditions that will be checked by the [Account Debt Monitor](#) when it checks if an account has violated your debt criteria.

Open **Admin > Credit & Collection > Collection Class Control > Add** to define this information.

FASTPATH:

For more information about collection class control, refer to [Designing Collection Class Controls](#).

Description of Page

Enter a unique **Collection Class Control** code and **Description** for the collection class control (CCC).

Enter the **CIS Division** to which the CCC's criteria applies.

Enter the **Collection Class** to which the CCC's criteria applies.

Enter the **Debt Class** to which the CCC's criteria applies.

Enter the **Currency Code** in which the CCC's criteria are denominated.

Use **Long Description** to further describe the CCC.

FASTPATH:

The information in the following grid is not intuitively obvious. Refer to [Designing Collection Class Controls](#) and [Designing Your Collection Class Control Overrides](#) for more information.

The grid which follows contains the conditions that are checked by the [Account Debt Monitor](#) (ADM) to determine the type of criteria (defined on the next tab) that will be applied against an account's debt. In other words - the ADM will check each condition (from highest to lowest **Priority**). The first condition that returns a value of true will cause the system to compare the account's debt against the debt criteria defined on the next tab.

Multiple conditions may be defined if different conditions result in a different type of debt thresholds (or a different type of collection process). The following fields are required for each condition:

Collection Condition Priority The priority controls the order in which the ADM checks if a collection condition applies (the lower the number, the higher the priority). Higher priorities are checked before lower priorities.

NOTE:

The values for this field are customizable using the Lookup table. This field name is COLL_CAT_PRIO_FLG.

Condition Algorithm Define the algorithm used to check if an account should be subject to the collection criteria defined on the next tab. If the algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt

against the **Debt Criteria** (defined on the next tab) and start a collection process if the account has debt that violates these criteria.

You must have at least one collection condition; otherwise the system will not have criteria against which to compare the account's debt. This entry should have the lowest priority code and reference the "default" algorithm. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that references the "default" collection condition algorithm type ([COLL COND DF](#)).

If you have other conditions that should be checked before the default condition, you must create an entry for each in this grid. Each entry should have a priority consistent with your business requirements (and this priority should be higher than the default condition's priority). In addition, you should reference an algorithm that contains the conditions that will be checked to determine if the account should be subject to the debt criteria (defined on the next tab). The system is supplied with many additional algorithm types. In order to take advantage of them, you will need to create an algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that references one of the collection condition algorithm types. Click [here](#) to see the algorithm types available for this system event.

Where Used

Collection class controls contain the data that controls the Account Debt Monitor. Refer to [How Does The Account Debt Monitor Work?](#) for more information.

Collection Class Control - Debt Criteria

The information on this page defines the debt and age thresholds used by the [Account Debt Monitor](#) when it checks if an account has violated your acceptable levels of debt. Open **Admin > Credit & Collection > Collection Class Control > Search** and navigate to the **Debt Criteria** page to define this information.

NOTE:

The information on this page is not intuitively obvious. Refer to [Designing Collection Class Controls](#) and [Designing Your Collection Class Control Overrides](#) for more information.

Description of Page

The **Debt Criteria** scroll contains an entry for each collection criteria algorithm defined on the **Main** tab. The following information appears

The **Collection Condition Priority** controls the order in which the Account Debt Monitor (ADM) checks if a collection condition applies. Higher priorities are checked before lower priorities.

The **Condition Algorithm** is called by the ADM to determine which collection criteria should be applied to the account's debt. If this algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt against the **Debt Criteria** defined below. If the account violates any criteria, a collection process will be started (using the respective **Collection Process Template**).

The grid that follows contains the debt age and amount of debt that must be violated by the account in order for the ADM to create a collection process template. The following fields should be defined:

Arrears Priority controls the order in which the arrears criteria will be checked by the Account Debt Monitor (the lower the number, the higher the priority). The first criteria, if any, that is met will cause a collection process to be created (using the **Collection Process Template**).

Collection Process Template If the Account Debt Monitor determines that the account's debt violates the corresponding criteria, it creates a collection process using the specified collection process template.

Arrears Amount When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than "> Number of Days" (the next field) AND the debt exceeds "> Arrears Amount". If so, a collection process is started.

Days When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than **Days** AND the debt exceeds **Arrears Amount**. If so, a collection process is started.

Where Used

Collection class controls contains the data that controls the [Account Debt Monitor](#).

Designing Your Severance Procedures

The following matrix will help you design your severance procedures. When the matrix is complete, you're ready to set up the severance process control tables.

Notice that the matrix has two dimensions: one is dependent on severance criteria algorithms; the other is dependent on the SA type of the service agreement being severed. The number and type of SA types is dependent on how your organization sets up the SA type table (the SA types shown below are characteristic of those used by a simple utility).

SA Type	Severance Criteria Algorithm: Default	Severance Criteria Algorithm: Customer On Life Support
Electric Residential		
Electric Commercial		
Gas Residential		
Gas Commercial		
Charitable Contribution		

Once you know the values of each dimension, you fill in each cell with its respective severance events. We've completed the sample matrix with some characteristic events.

SA Type	Severance Criteria Algorithm: Default	Severance Criteria Algorithm: Customer On Life Support
Electric Residential	<p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p>	<p>Create a To Do entry asking a collection rep to call the customer.</p> <p>5 days later, create a 72-hour warning field activity.</p> <p>2 days after completion, create a To Do entry telling collection rep of impending life support cutoff.</p> <p>3 days after completion of warning, create a disconnect service field activity AND generate a To Do entry informing a collection agent of such.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection expire the service agreement.</p>
Electric Commercial	<p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p>	N/A

	Immediately after completion of the disconnect field activity, send a letter to the customer.	
	10 days after completion of disconnection, expire the service agreement.	
Gas Residential	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.
Gas Commercial	Create a 48-hour warning field activity. 2 days after completion, create a disconnect service field activity. Immediately after completion of the disconnect field activity, send a letter to the customer. 10 days after completion of disconnection, expire the service agreement.	N/A
Charitable Contribution	Expire service agreement	Expire service agreement

Once the matrix is complete, you determine the severance process templates needed to implement your severance procedures. The following table shows the severance process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Severance Process Template	Event Number	Severance Event Template	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Utility severance - default	10	Field activity - 48 hour disconnect for non-payment warning	N/A - first event	0
	20	Field activity - disconnect for non-payment	10	2
	30	'Service has been disconnected' letter	20	0
	40	Expire service agreement	20	10
Electric life support residential severance	10	Generate delinquent life support customer To Do entry	N/A - first event	0
	20	Field activity - 72 hour disconnect for non-payment warning	10	5
	30	Generate impending life support cutoff To Do entry to C&C rep	20	2

	40	Field activity - cut for non-payment	20	3
	50	Service has been disconnected letter	40	0
	60	Expire service agreement	40	10
Just expire severance	10	Expire service agreement	N/A - first event	

If we extract each unique severance event type from the above table, we end up with the following:

Severance Event	Event
Template	Type
48-hour warning	Generate Field Activity - Disconnect Warning
72-hour warning	Generate Field Activity - Disconnect Warning
Disconnect for non payment	Generate Field Activity - Cut For Non-Payment
Delinquent life support customer	Create To Do Entry - C&C Rep Role
Impending life support cutoff	Create To Do Entry - C&C Rep Role
Service has been disconnected letter	Send Letter - Customer Contact Type is Disconnect Letter
Expire service agreement	Expire Service Agreement

WARNING:

The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to [Setting Up Field Activity Type Profiles](#) for how to set up the specific disconnect field activity types for your various types of service points.

Now you're (almost) ready to set up your severance procedures.

Defining Severance Process Auto Cancellation Criteria

The topics in the section [How Are Severance Processes Cancelled](#) describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your [Debt Classes](#), and optionally, on your [Severance Process Templates](#).

Designing Your Reconnection Procedures

If a customer pays for a service agreement after the service has been cut for non-payment AND BEFORE THE SA HAS BEEN EXPIRED, they need to be reconnected. Counter-intuitively, you must set up a severance process to initiate the field activities to reconnect service.

NOTE:

Why do you use a severance process to reconnect service? Because a severance process is nothing more than a series of events that take place one after another. Some of the events create field activities, others send letters, others create

To Do entries. So, why not use a severance process? You just have to send different letters and perform different field activities.

WARNING:

The system will automatically create a reconnection process if a severance process is cancelled as a result of a payment (or other credits). Please note that this will only happen if you plug-in the appropriate post cancellation algorithm on your severance process templates. Refer to [What Happens When A Severance Process Is Cancelled?](#) for more information.

While you don't define the reconnect procedures for an SA type, we recommend you think about the reconnection steps for each of your SA types that can be disconnected for nonpayment. We've completed the sample matrix with some characteristic events.

SA Type	Steps
Electric Residential	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Electric Commercial	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Gas Residential	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.
Gas Commercial	Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer.

Once the matrix is complete, you determine the severance process templates needed to implement your reconnection procedures. Notice each SA type has the same reconnection steps. This means you just need one severance process. The following table shows this severance process template and its events.

Severance Process Template	Event Number	Severance Event Template	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Reconnect	10	Field activity - reconnect service	N/A - first event	0
	20	Service has been reconnected letter	10	0

If we extract each unique severance event type from the above table, we end up with the following:

Severance Event Template	Event Type
Reconnect	Generate Field Activity - Reconnect
Service has been reconnected letter	Send Letter

WARNING:

The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to [Setting Up Field Activity Type Profiles](#) for how to set up the specific disconnect field activity types for your various types of service points.

IMPORTANT:

If you want the system to automatically create a reconnection process if a customer pays after they have been cut, you must specify the appropriate post cancellation algorithm on your severance process templates.

And now you're ready to set up your severance (and reconnection) procedures.

Setting Up Severance Procedures

In the previous section, [Designing Your Severance Procedures](#), we presented a case study that illustrated a mythical organization's severance procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

Setting Up Severance Event Types

Severance event types control what is done by a given severance event. Open **Admin > Credit & Collection > Severance Event Type > Add** to define your severance event types.

FASTPATH:

For more information refer to [Designing Your Severance Procedures](#).

Description of Page

Enter a unique **Severance Event Type** code and **Description** for the severance event type.

Enter the Severance **Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Send Letter, Generic Algorithm, Create To Do Entry, Create Field Activities, Expire Service Agreement. The following discussion describes the parameters that must be defined for each type of severance event.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- account debt monitor.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.

The Send Letter severance event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Generic Algorithm severance event type causes the algorithm defined in the **Sev. Event Algorithm** to be executed. You use this type of algorithm when the standard types of severance events won't do what you need done.

The Create To Do Entry severance event type causes a To Do entry to be created. Refer to [The Big Picture of To Do Entries](#) for more information about To Do entries (refer to the To Do type TD-SEVT for the type of To Do entry that's created).

The Generate Field Activities severance event type causes one or more field activities to be generated. Enter the following **Parameters** for this type of event:

- Select the **Customer Event** associated with the field activity. Valid values are: Cut For Non-Payment (CNP), Disconnect Warning (Disc Warn), Reconnect for Payment (Reconn), Start Service (Start) , Start/Stop Service (Start/Stop), Stop Service (Stop), Reread (Reread).
- The system uses the **Customer Event** to select the appropriate field activity type(s) from the field activity type profile associated with the service points linked to the service agreement.

WARNING:

The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter off) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to [Setting Up Field Activity Type Profiles](#) for how to set up the specific disconnect field activity types for your various types of service points.

The Expire Service Agreement severance event type causes the service agreement to be moved to the pending stop state (it also populates the service agreement's stop date). Refer to [Finalizing Pending Stops](#) for how the system will eventually stop the service agreement (and then final bill it). There are no parameters for this type of event.

NOTE:

Cut for non-payment field activities are special. The Expire Service Agreement severance event type also makes any "cut for non-payment" field activities created by earlier severance events available to stop service. Specifically, it changes the linkage type of the field activities from Severance Activity to Stop Activity. You can see a service agreement's service points' field activities and their respective linkage type on [Service Agreement - Service Point](#).

Enter a **Long Description** to fully describe the severance event type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_SEV_EVT_TYPE](#).

Setting Up Severance Process Templates

Severance process templates define the severance events that will be executed when a service agreement is severed. Open **Admin > Credit & Collection > Severance Process Template > Add** to define your severance process templates.

Description of Page

Enter a unique **Severance Process Template** and **Description** for the severance process template.

If severance processes of this type should be automatically canceled when the customer pays the collection amount on the severance, turn on **Auto Cancel**. This switch would typically only be turned off for severance processes used to reconnect a cut service because you don't want such a reconnection process to be canceled when a payment is made. Refer to [Designing Your Reconnection Procedures](#) for more information.

In addition to turning on the **Auto Cancel** switch, specify a **Cancel Criteria Algorithm** if your organization allows a severance process to be cancelled regardless of the debt associated with all service agreements in the debt class. In other

words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM.

If the **Cancel Criteria Algorithm** is specified, it is executed when a credit is posted to the service agreement associated with a severance process. This algorithm will indicate if the service agreement no longer has debt that warrants a severance process. Refer to [How Are Severance Processes Cancelled](#) for more information. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants. Click [here](#) to see the algorithm types available for this plug-in spot.

If you wish to perform any special processes after a severance process is canceled, specify a **Post Cancel Algorithm**. This can be used to start a reconnection in case the severance process was canceled too late to stop the disconnection. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants. Click [here](#) to see the algorithm types available for this plug-in spot.

When a service agreement is to be severed due to non-payment, the system creates a severance process and links to it one or more severance events based on the **Event Types** entered here. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event:

Event Sequence controls the order in which the severance event types appear under the severance process template. The sequence number is system-assigned and cannot be changed. If you have to insert a severance event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Severance Event Type Specify the type of severance event to be generated.

Dependent On Other Events Turn this indicator on if the trigger date of the event can only be determined after earlier events are complete. For example, you would turn this switch on for the event that initiates the field activity to disconnect service. Why? Because you only want to disconnect service after the preceding event that warned the client of impending disconnection is complete.

Days After Prev Response Specify the number of days after the completion / cancellation of the dependent events on which the severance event will be triggered. If this event is not dependent on the completion of other events, this field contains the number of days after the creation of the severance process that the related severance event will be triggered. Refer to [Severance Event Dependencies and Trigger Date](#) and [Calendar vs Work Days](#) for a description of how the system uses this information to set the trigger date on the respective severance events.

When the **Dependent On Other Events** switch is on, use the grid to define the events on which this event is dependent. If multiple events are specified in the grid, all such events must be completed or cancelled before the event will be triggered.

Sequence is system-assigned and cannot be specified or changed.

Dependent On Sequence Specify the sequence number of the severance event on which the above severance event depends.

FASTPATH:

For more information about severance event types, see [Setting Up Severance Event Types](#). For more information about trigger dates, see [Severance Event Dependencies & Trigger Date](#).

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_SEV_PROC_TMP](#).

Designing Your Write-Off Procedures

The design of your write-off procedures is relatively straightforward. Simply follow the instructions in the following topics.

Designing Your Write-Off Debt Classes

Multiple write-off debt classes are needed when you have different write-off procedures for different types of service agreements. If all service agreement debt is written-off the same way, then you'll have just one write-off debt class (call it Generic). However, if you're like many organizations, you will have multiple write-off debt classes. The following points will help you understand why:

- If you bill for 3 rd parties, you probably have different write-off debt classes for the 3 rd party service agreements. Why? Because you probably treat 3 rd party uncollectable debt differently from your own debt.
- You will need a separate write-off debt class for service agreements whose debt cannot be written off. Why? Because there is a switch on the write-off debt class control table that controls if service agreements in the write-off debt class are eligible for write-off processing. Given that you will have some service agreements that hold debt that aren't eligible for write-off processing (e.g., service agreements that hold written-off debt and service agreements that overpayments), you will need at least one other write-off debt class.
- If you use the system to calculate charges for your organization's company usage, you'll need another write-off debt class (we refer to it as the "N/A" write-off debt class below). Why? Because all service agreements must have a write-off debt class, even those that will never have debt.

SA's Write-Off Debt Class	Account's Collection Class	Account's Collection Class
Normal W/O		
N/A		

Designing Write-Off Controls

Set up a matrix using the collection classes you designed when you were designing your collection procedures ([Designing Your Collection Procedures](#)).

SA's Write-Off Debt Class	Account's Collection Class	Account's Collection Class
	Residential	Commercial/Industrial
Normal Write Off		
N/A		

Each cell should have a "write-off control" that defines what to do when the system detects finalized debt that hasn't been paid. This is true even of the "N/A" write-off debt class. Why? Because you may want the system to write-down these stopped SAs when they have a small balance. For example, if you have a write-off service agreement that subsequently receives a partial payment that leaves a small amount owing, you probably want the system to generate a write-down adjustment (so that the write-off service agreement will close). We'll initially fill in the matrix for the "N/A" write-off debt class.

SA's Write-Off Debt Class	Account's Collection Class	Account's Collection Class
	Residential	Commercial/Industrial
Normal Write Off		
N/A	Attempt to reduce the SA's balance to zero using the following methods:	Attempt to reduce the SA's balance to zero using the following methods:

Synchronize current balance with payoff balance.

If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.

Synchronize current balance with payoff balance.

If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.

NOTE:

If the Write Off Monitor encounters debt associated with a non-defined collection class and write-off debt class, it will issue an error.

For each cell that isn't designated as N/A, you need to answer the following questions:

- Are you allowed to transfer debt to other non-closed service agreements linked to the account? If so, you need to define the algorithm used to do such. Refer to [Setting Up Write-off Control](#) for more information about this algorithm.
- Are you allowed to write-down small amounts of debt (or small credits)? If so, you need to define the algorithm used to do such. Refer to [Setting Up Write-off Control](#) for more information about this algorithm.
- Should you refund credit balances with a check? If so, you need to define the algorithm to do such. Refer to [Setting Up Write-off Control](#) for more information about this algorithm.
- If debt remains after doing the above, how do you write it off (e.g., do you first refer the debt to a collection agency and only write it off after waiting 30 days)?

We'll fill in the above matrix with our assumptions:

SA's Write-Off Debt Class	Account's Collection Class	Account's Collection Class
	Residential	Commercial/Industrial
Normal Write-Off	<p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Attempt to transfer debt to another active service agreement linked to the account.</p> <p>If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.</p> <p>If the debt is <= \$-1, create an A/P adjustment to refund the credit to the customer.</p> <p>If debt remains:</p> <p>Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process.</p> <p>Otherwise, create the default write-off process for residential debt.</p>	<p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Attempt to transfer debt to another active service agreement linked to the account.</p> <p>If the debt / credit is < \$10 and > \$-10, write down the debt using a write-down adjustment.</p> <p>If the debt / credit is <= \$-10, create an A/P adjustment to refund the credit to the customer.</p> <p>If debt remains:</p> <p>Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process.</p> <p>Otherwise, create the default write-off process for commercial debt.</p>
N/A	<p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Synchronize current balance with payoff balance.</p> <p>If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.</p>	<p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Synchronize current balance with payoff balance.</p> <p>If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.</p>

Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.

Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.

We can now use the information in the above matrix to design the necessary Write Off Process Templates and Write Off Event Types.

Designing Write Off Process Templates & Write Off Event Types

The following table shows the write-off process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

Write Off Process Template	Write Off Event Type	Triggered X Days From Start Of Write Off Process
Residential	Refer to collection agency	0
	Letter notifying customer of referral	0
	Cancel collection agency referral	60
	Write off	60
Non-Cash Deposit Exists	To Do for non-cash deposit redemption	0
	To Do to highlight unpaid SA(s) still exist (and they will be reconsidered for write-off processing)	10
Commercial	Refer to collection agency	0
	Letter notifying customer of referral	0
	To Do to check up on collection agency's efforts	30
	Cancel collection agency referral	60
	Write off	60

If we extract each unique event type from the above table, we end up with the following:

Write Off Event Type	Event Type
Notification of write-off referral	Send letter - Debt referred to a collection agency
Refer to collection agency	Refer to collection agency
Cancel collection agency referral	Cancel collection agency referral
Write off	Write off
To Do for non-cash deposit redemption	Generate To Do - Redeem non-cash deposit
To Do to highlight unpaid SA(s) still exist	Generate To Do - SA(s) linked to a non-cash deposit remain unpaid (and will be reconsidered for write-off processing)
To Do to check up on collection agency's efforts	Generate To Do - Check up on collection agency's efforts

And now you're ready to set up your write-off procedures.

Setting Up Write-Off Procedures

In the previous section, [Designing Your Write-Off Procedures](#), we presented a case study that illustrated a mythical organization's write off procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

Setting Up Write Off Debt Classes

Every SA type has a write-off debt class. This class is one of several fields that control the write off criteria applied to the service agreement's debt. Select **Admin > Credit & Collection > Write Off Debt Class** to define your debt classes.

FASTPATH:

For more information about debt classes, see [Designing Your Write-Off Debt Classes](#).

Panel controls

To modify a write-off debt class, simply move to a field and change its value. To add a new write-off debt class, click + to insert a row, then fill in the information for each field. The following fields display:

Write Off Debt Class Code The unique identifier of the write off debt class.

Eligible for Write Off Indicates if service agreements belonging to this write off debt class are eligible for write-off processing. This should only be turned off if this debt cannot be written off, e.g., write off debt.

Description The description of the write off debt class.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_WO_DEBT_CL](#).

Setting Up Write Off Event Types

Write-off event types control what is done by a given write-off event. Select **Admin > Credit & Collection > Write Off Event Type > Add** to define your write-off event types.

Description of Page

Enter a unique **Write Off Event Type Code** and **Description** for the write-off event type.

Enter the **Write Off Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Cancel Agency Referral, Generic Algorithm, Refer to Agency, Send Letter, Create To Do Entry, Write Off using Distrib Code, and Write Off using SA Type. The following discussion describes the parameters that must be defined for each type of write-off event.

The Affect Credit Rating/Cash-Only write-off event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Affect Credit Rating By** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account's CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Affect Cash-Only Score By** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.

- Use **Months Affecting Credit Rating** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

FASTPATH:

For more information, refer to [Account - Credit Rating](#).

The Cancel Agency Referral event type will cancel previous collection agency referrals. No parameters are needed for this type of event.

The Generic Algorithm write-off event type causes the algorithm defined in the **Generic Algorithm** to be executed. You use this type of algorithm when the standard types of write off events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type are activated. Click [here](#) to see the algorithm types available for this plug-in spot.

The Refer to Agency event type will refer the debt associated with the process' SAs to a collection agency. You must supply the **Agency Selection Algorithm** that is used to determine the collection agency associated with the referral. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the collection agency to which bad debt should be referred. Click [here](#) to see the algorithm types available for this plug-in spot.

NOTE:

Letters. You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the write off event type. Refer to [Setting Up Letter Templates](#) for more information.

The Send Letter write-off event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following parameters for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Create To Do Entry write-off event type causes a To Do entry to be issued. Refer to [The Big Picture of To Do Entries](#) for more information about To Do entries (refer to the To Do type TD-WOEV for the type of To Do entry that's created).

The Write Off using Distrib Code event type causes bad debt to be written off in accordance with the distribution codes associated with the financial transactions that caused the debt in the first place. Use this method if, for example, you want to write-off revenue differently than you write-off liabilities. When this type of event is activated, the system accumulates the distribution codes from GL details associated with recent financial transactions linked to each write-off service agreement. When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreements. The type of service agreements to which the debt is transferred is defined on the distribution codes. Refer to [Setting Up Distribution Codes](#) for more information.

The Write Off using SA Type event type causes all debt associated with the process' SAs to be transferred to a write-off service agreement linked to the account. Enter the following **Parameters** for this type of event:

- **CIS Division / SA Type** is the type of write-off service agreement to which the debt will be transferred. Note well,
 - The system will reuse an existing service agreement if an active SA of this type is already linked to the account; otherwise the system will create a new service agreement of this type.
 - The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on the write-offable SA Type. Refer to [SA Type - Main Information](#) for more information.

- The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write off SA type. Refer to [SA Type - Detail](#) for more information.

Enter a **Comment** to fully describe the write-off event type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_WO_EVT_TYP](#).

Setting Up Write Off Process Templates

Write-off process templates define the write-off events that will be executed when a write-off criteria rule is violated. Select **Admin > Credit & Collection > Write Off Process Template > Add** to define your write-off process templates.

Description of Page

Enter a unique **Write Off Process Template** code and **Description** for the write-off process template.

The rows in the following grid define the events that will be created when a write off process is created using this template. The following fields display:

Event Sequence controls the order in which the write-off event is executed. The sequence number is system assigned and cannot be changed. If you need to insert a write-off event between two existing events, you must remove the latter events, insert the new event, and then re-enter the removed events.

Write-off Event Type Code Specify the type of write-off event to be generated. The event type's description is displayed adjacent.

Days After Process Creation Specify the number of days after the creation of the write-off process that the related write-off event will be triggered. Refer to [Calendar vs Work Days](#) for a description of how this system uses this information to set the trigger date on the respective write-off events.

FASTPATH:

For more information about write-off event types, see [Setting Up Write Off Event Types](#). For more information about trigger dates, see [Write-off Event Trigger Date](#).

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_WO_PROC_TMPL](#).

Setting Up Write Off Control

Write-off controls define how the system handles finalized, unpaid debt belonging to a given collection class and write off debt class.

Write Off Control - Main

Select **Admin > Credit & Collection > Write Off Control > Add** to define basic information about a write-off control. After entering basic information, navigate to the **Criteria** tab to define the type of write-off process to start when given criteria are met.

FASTPATH:

For more information about write-off control, refer to [Designing Write-Off Controls](#).

Panel controls

Enter a **Write Off Control** code and **Description** for the write-off control (WOC).

Enter the **Collection Class** to which the WOC applies.

Enter the **Write Off Debt Class Code** to which the WOC applies.

Enter general **Comments** to further describe the WOC.

Define the **Synch All Algorithm** used by the system to generate adjustments that cause current balance to equal payoff balance on the service agreements to be written off. This type of algorithm is issued before you actually start a write-off process as current balance is meaningless at write-off time (the customer owes you the payoff balance). If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that synchronizes current and payoff balances. Click [here](#) to see the algorithm types available for this plug-in spot.

Define the **Debt Transfer Algorithm** used by the system when it attempts to transfer the unpaid debt to another active service agreement linked to the stopped SA's account. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that transfers unpaid balances. Click [here](#) to see the algorithm types available for this plug-in spot.

Define the **Write Down Algorithm** used by the system when it attempts to write-down small debt and/or credit balances. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that writes down small amounts. Click [here](#) to see the algorithm types available for this plug-in spot.

Define the **Credit Refund Algorithm** used by the system when it refunds a credit balance to a customer. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that refunds credit balances. Click [here](#) to see the algorithm types available for this plug-in spot.

Write Off Control - Criteria

Select **Admin > Credit & Collection > Write Off Control > Search** and navigate to the **Criteria** page to define the type of write-off process to start when given criteria are met.

FASTPATH:

The following information is not intuitively obvious. Refer to [Designing Write-Off Controls](#) for more information.

Panel controls

The information in the grid defines the write-off process to be executed for debt belonging to the previously defined collection class and write off debt class. The type of write-off process may differ depending on some condition. For example, you may have a different write-off process if the customer has a non-cash deposit. You must have at least one entry in this collection otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **Write Off Criteria Algorithm** that references the WO CRIT DFLT the algorithm type.

The following fields display:

Priority controls the order in which the criteria will be checked by the Write Off Monitor (higher priorities are checked before lower priorities). The first criteria algorithm that is met (i.e., returns a value of *True*) will cause the associated write-off process to be initiated.

NOTE:

The values for this field are customizable using the Lookup table. This field name is CRIT_PRIO_FLG. Be aware that this field is used for multiple tables: [Collection Class Control](#), [Severance Criteria](#), [Write Off Control](#).

Write Off Criteria Algorithm The Write Off Monitor checks if the condition defined by the W/O Condition Algorithm applies to the account whose debt is being analyzed. If a condition is met, a write-off process is created using the associated write-off process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines if a customer's bad debt should be processed using the associated **Write Off Process Template**. Click [here](#) to see the algorithm types available for this plug-in spot.

IMPORTANT:

You must have at least one entry in this grid otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **W/O Criteria Algorithm** that references the [WO CRIT DFLT](#) algorithm type.

Write Off Process Template If the Write Off Monitor determines the condition defined by the w/o condition algorithm applies, a write-off process is created using the associated write-off process template.

Where Used

Write-off controls contain the data that controls the Write Off Monitor. Refer to [How Does The Write-Off Monitor Work?](#) for more information.

Setting Up Collection Agencies

You must set up a collection agency for each such organization to which you refer delinquent debt. To define a collection agency, select **Admin > Credit & Collection > Collection Agency**.

Description of Page

Enter an easily recognizable **Collection Agency** code and **Description** for each collection agency.

A collection agency must be associated with a Person. Choose the **Person ID** of the organization from the prompt.

FASTPATH:

Information about how to set up persons is discussed in [Maintaining Persons](#).

Turn on the **Active** switch if the collection agency is actively receiving referrals.

Specify the **Batch Control** that's used to route new and cancelled referrals to the collection agency. The batch control's description is displayed adjacent.

Where Used

Collection agencies get assigned to collection agency referrals when the collection agency referral background process executes. Refer to [How Do Collection Agency Referrals Work?](#) for more information.

Setting Up Feature Configuration

You must set up a [Feature Configuration](#) if you use the [champion / challenger](#) functionality.

The following describes the various **Option Types** that must be defined:

Champion Template\$Challenger Template\$Percentage(1-100). You need only set up options of this type if your implementation implements [Champion / Challenger](#) functionality. Options of this type are entered in the format A\$B\$nnn where A is the collection process template of the champion template, B is the collection process template of the challenger template, and C is the percent of the time that the system should create the challenger template. The collection monitor uses this option to override the champion collection process template X% of the time with the challenger template. You may enter any number of these options (but only one per Champion Template).

How To

The contents of this section describe how to set up various credit and collections scenarios.

How To Nominate A Single Service To Sever (Rather Than Sever Everything That's In Arrears)

Some organizations that offer multiple services do not sever all services when the customer falls into arrears. Rather, they nominate a single service agreement to sever in the hopes that the lack of service will cause the customer to remit payment. The following diagram illustrates the control tables values required to implement this type of requirement.

The following important concepts are illustrated above:

- The collection process's last event does NOT sever all services. Rather, it calls an algorithm that selects a single service to sever. A base package algorithm allows you to define the primary service to sever and a secondary service to sever (if the customer does not have the primary service). If you sold electricity and gas, you would probably define the primary service as electricity and the secondary as gas (because electricity is easier to cutoff than gas).
- The severance process that is started for the primary service cuts service. If the customer doesn't remit what is owed, the second severance event calls an algorithm that severs all other service agreements in the debt class.
- Because you are nominating a single service to sever, you must set up a special value in collection class control to force the ADM to ignore all service agreements in a debt class when one of the SAs in the debt class is being severed. Notice that the age / amount in the criteria is so large that it could never be violated.
- In addition, because the entire debt class must no longer be in arrears to stop the collection and severance processes, you must plug-in the appropriate collection process and severance process cancellation criteria on the debt class. Refer to [How Are Collection Processes Cancelled](#) and [How Are Severance Processes Cancelled](#) for more information about how these algorithms are used. Also note, you do not need service agreement cancellation criteria defined on your collection process templates and severance process templates (because cancellation is controlled at the debt class level).

Defining Asset Options

NOTE: The asset management functionality described in this section is available only to cloud implementations using Oracle Utilities Customer Cloud Service or Oracle Utilities Meter Solution Cloud Service.

Asset Activity Types

Understanding Asset Activity Types

Activity types define the main attributes broad range of activities, such as maintenance, repairs, inspections, field work etc. The base package includes an asset activity type business object (W1-SOMActivityType) that should be used when created asset activity types.

Activity types are defined by:

- **Activity Business Object:** The business object used for asset activities of this type
- **Activity Schedule Information:** Default scheduling information for asset activities of this type, including Activation Lead Days, Work Lead Days, and Activity Disposition.
- **Attachments:** One or more attachments associated with asset activities of this type, such as procedures or checklists.
- **Exception Handling:** Details regarding exception handling for asset activities of this type, including default To Do Type, To Do Role, and retry options.
- **Completion Event Types:** One or more completion event types associated with asset activities of this type. See [Understanding Completion Event Types](#) for more information.
- **Object To Create:** The service history type to be created by asset activities of this type. Service history records are created by Create Activity Type's Service History completion events.

Refer to [Defining Asset Activity Types](#) for more information about setting up asset types.

NOTE: Asset activity types are created by the system when [field task types](#) are created in Service Order Management.

Defining Asset Activity Types

You use the **Activity Type** portal to display and maintain asset activity types.

Refer to [Understanding Asset Activity Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Activity Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type:** This zone displays basic information about the activity type.
- **Attachments:** This zone attachments associated with the activity type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [W1_ACTIVITY_TYPE](#).

Asset Completion Event Types

Understanding Asset Completion Event Types

Asset completion event types are used to define various processes or events to be executed when completing an asset activity such as asset replication, service history creation, attachment creation, and activity creation.

Asset completion event types are referenced on activity types to indicate which completion events should be included as part of the lifecycle of activities of that type. For example, this affects when service history is created for an activity, and the disposition of the assets on an activity as the activity is processed. Asset completion events can be configured as optional or required for activities of different types.

Asset completion event types are defined by:

- **Completion Event Business Object:** The business object used for asset completion events of this type
- **Identifiers:** One or more identifiers that can be used to characterize asset completion events of this type
- **Inbound Communication:** Information used to create asset completion events of this type using information defined within an inbound communication business object, or within its raw message
- **UI Payload Create Data Mover:** XPath statements executed when creating asset completion events of this type online. These statements are used to populate elements within the payload from the completion event business object.

Refer to [Defining Completion Event Types](#) for more information about setting up completion event types.

Defining Asset Completion Event Types

You use the **Completion Event Type** portal to display and maintain asset completion event types.

Refer to [Understanding Asset Completion Event Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Completion Event Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Completion Event Type :** This zone provides information about the selected completion event type, including as inbound communications and attachments.
- **Unlink Activity Types:** This zone enables the removal of an activity type from the completion event type. To remove an activity type select the activity type(s) to remove and click **Remove**. The selected activity types will no longer appear in the **Unlink Activity Types** zone.
- **Link Activity Types:** This zone enables adding an activity type to the completion event type. To link an activity type:
 1. Enter search criteria in the **Activity Type Description** field and click **Search**. The zone will display a list of activity types matching your search criteria.
 2. Select the activity type(s) to add and click **Link**. The selected activity types will now appear in the **Unlink Activity Types** zone.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [WI_CMPL_EVT_TYPE](#).

Asset Inbound Communication Types

Understanding Asset Inbound Communication Types

Asset inbound communication types define the information required for the system to receive messages from external systems. These typically hold value mappings of the inbound communication elements to an xpath element in the completion message.

Asset inbound communication types are defined by:

- **Inbound Communication Business Object:** The business object used for asset inbound communications of this type
- **Exception Handling:** Details regarding exception handling for asset inbound communications of this type, including default To Do Type, To Do Role, and retry options.
- **Message Validation:** Source elements within the inbound communication business object or raw message used for validation of asset inbound communications of this type
- **Communication Data Mapping:** Information used to populate communication business object elements from information within the communication's raw message
- **Attachment Suppression:** Substitution text used in place of large data attachments in the completion event list on the inbound communication. Used when messages received from an external system contain attachment data that are very large.

Refer to [Defining Asset Inbound Communication Types](#) for more information about setting up asset inbound communication types.

Defining Asset Inbound Communication Types

You use the **Communication Type** portal to display and maintain asset inbound communication types.

Refer to [Understanding Asset Inbound Communication Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Inbound Communication Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Communication Type List:** This zone lists all asset inbound communication type records. Broadcast a record to display the details of the selected record.
- **Communication Type:** This zone provides information about the selected communication type, such as attachment suppression, communication data mapping, message validation and exception handling.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [W1_COMM_TYPE](#).

Asset Types

Understanding Asset Types

Asset types define the attributes for assets and components of a certain type including information such as the valid location types and service history types for the assets and whether or not such assets can have attached components.

Asset types are defined by:

- **Component Relationship:** A flag that indicates if components can be installed on assets or components of this type
- **Asset Business Object:** The business object used for assets or components based on this asset type
- **Valid Location Types:** A list of location types where assets or components of this type can be located
- **Valid Attached To Asset Types:** A list of valid asset types where components of this type can be attached (applicable to components only)
- **Valid Service History Types:** A list of valid service history types that can apply for assets or components of this type

Refer to [Defining Asset Types](#) for more information about setting up asset types.

Asset Classes

Assets are defined by classes, each of which is based on a specific business object, and determines the type of asset: an asset or a component.

The table below lists the asset classes and the business object for each.

Asset Class	Business Object
Asset	W1-AssetType (Operational Device Asset Type)
Component	W1-ComponentType (Operational Device Component Type)

Defining Asset Types

You use the **Asset Type** portal to display and maintain asset types.

Refer to [Understanding Asset Types](#) for more information.

You can access the portal from **Admin > Asset Management > Asset Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Asset Type** : This zone provides information about the asset type.
- **Asset Type Statistics:** This zone displays statistics for the asset type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [WI_ASSET_TYPE](#).

Service History Types

Understanding Service History Types

Service history types define the main attributes for service history of a certain type. Types might include maintenance, inspection, service, test, measurement, and so on.

Service history types are defined by the following:

- **Service History Business Object:** The business object used to create service history records of this type.

- **Category:** The category to which service history records of this type belong. The base package includes the following categories:
 - Downtime
 - Failure
 - Inspection
 - Maintenance
 - Repair
- **Service Schedules:** One or more template work orders and time intervals that should be used to schedule work order generation for service history records of this type

If service histories of a certain service history type need follow-up actions, such as work orders or work order activities, users can configure those follow-up actions on the service history type. Note that you will need to specify a compliance type if a regulatory compliance requirement is associated with your follow-up action.

For example, if you have a Service History Type of “Grade 2 Gas Leak”, users could define a follow-up action of “Recheck” which could be configured with a “30 day” Compliance Type and a follow-up action of “Repair” which could be configured with a “1 year” Compliance Type.

Defining Service History Types

You use the **Service History Type** portal to display and maintain service history types.

Refer to [Understanding Service History Types](#) for more information.

You can access the portal from **Admin > Asset Management > Service History Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Service History Type** : This zone provides information about the service history type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [WI_SVC_HIST_TYPE](#).

Configuration Types

Understanding Configuration Types

Configuration types define the information required for various asset configurations with other assets, components, firmware, and other data.

Configurations are referenced on specifications which are then referenced on assets and components to indicate the best way that these entities can work with the other entities that they are connected to in the field.

Configuration types are defined by the following:

- **Configuration Class:** The class for configurations of this type
- **Configuration Category:** The category of configurations of this type
- **Configuration Business Object:** The business object used for configurations of this type

Configuration Classes

In general configuration classes define the types of connections that are being configured. Each configuration class is based on a specific business object, which is the business object used for configurations of each class and type.

The table below lists the configuration classes and the business object for each.

Configuration Class	Business Object
Single Asset	W1-SingleAssetConfig (Single Asset Configuration)
Asset/Component	W1-AssetCompConfig (Asset/Component Configuration)
Asset to Asset	W1-AssetToAssetCompConfig (Asset to Asset/Component Configuration)
Asset/Component to Asset	W1-AssetCompToAssetConfig (Asset/Component to Asset Configuration)
Asset to Asset/Component	W1-AssetToAssetConfig (Asset to Asset Configuration)
Asset/Component to Asset/Component	W1-AssetCompToAssetCompConfig (Asset/Component to Asset/Component Config)

Defining Configuration Types

You use the **Configuration Type** portal to display and maintain configuration types.

Refer to [Understanding Configuration Types](#) for more information.

You can access the portal from **Admin > Asset Management > Configuration Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration Type:** This zone lists all configuration type records. Broadcast a record to display the details of the selected record.
- **Configuration Type :** This zone provides information about the selected configuration type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [W1_CONFIG_TYPE](#).

Configurations

Understanding Configurations

Configurations document and manage valid setups for assets and components. This includes a specification for each asset or component in the configuration as well as the valid value for each parameter, such as the firmware version of each asset.

Configurations are defined by the following:

- **Configuration Type:** The [configuration type](#) upon which the configuration is based
- **Status:** The current status of the configuration
- **Configuration Detail:** Specific information related to the configuration such as the assets and components involved, the firmware, characteristics, identifiers and other important information

Defining Configurations

You use the **Configuration** portal to display and maintain configurations.

Refer to [Understanding Configurations](#) for more information.

You can access the portal from **Admin > Configuration Report > Configuration**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration:** This zone provides information about the selected configuration.
- **Configuration Attachments:** This zone lists any attachments defined for the configuration.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [WI_CONFIG](#).

Configuration Reports

Understanding Configuration Reports

Configuration reports provide a summary of any currently installed configurations.

These reports show whether the configuration in an installation is valid or invalid, the identifiers and values being used, and display all of the assets/components and other elements that make up the installed configuration.

Configuration reports are defined by the following:

- **Reporting Mode:** The mode in which the report is run (One Time or Recurring)
- **Status:** The current status of the report (Pending or Submitted)
- **Report Criteria:** Specific information used to establish the filter criteria when generating the report, such as the assets and components involved, the firmware, characteristics, identifiers and other important information.
- **Report Result:** Specific information for each configuration, including the number of configurations, the assets and components involved, and the specifications and firmware versions of each. If the configuration is invalid, the **Configuration** column is blank in the report results. Users can navigate to specific valid configurations to review and edit the setup as needed. In addition, users can generate a work order to correct, reconfigure, or otherwise maintain any of the configurations by clicking **Generate Activity**.

Base Package Configuration Reports

The base package includes a number of configuration reports, each based on one of the support configuration classes (see [Understanding Configuration Types](#)).

The table below lists the configuration reports and the business object for each.

Configuration Report	Business Object
Single Asset Configuration Report	W1-SingleAssetCfgRpt
Asset/Component Configuration Report	W1-AssetCompCfgRpt
Asset to Asset Configuration Report	W1-AssetToAssetCfgRpt

Configuration Report	Business Object
Asset/Component to Asset Configuration Report	W1-AssetCompToAssetCfgRpt
Asset to Asset/Component Configuration Report	W1-AssetToAssetCompCfgRpt
Asset/Component to Asset/Component Configuration Report	W1-AssetCompToAssetCompCfgRpt

Defining Configuration Reports

You use the **Configuration Report** portal to display and maintain configuration reports.

Refer to [Understanding Configuration Reports](#) for more information.

You can access the portal from **Admin > Configuration Report > Configuration Report**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration Report:** This zone provides information about the selected configuration report.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [W1_CONFIG_RPT](#).

Defining Location Options

Asset Location Types

Understanding Asset Location Types

Asset location types define the details of asset or component locations of a certain type. Valid types of asset locations can include service points, other locations for installed assets, or any other location as defined by your organization.

Asset location types are defined by the following:

- **Class:** The general class for asset locations of this type, such as commercial or residential, a shop or warehouse, etc.
- **Location Business Object:** The business object used for asset locations of this type
- **Number of Assets Allowed:** A flag that indicates whether or not asset locations of this type can accommodate a single or multiple assets
- **Service Type:** The type of service (electric, water, etc.) that asset locations of this type support
- **Allow Related Work Locations:** A flag that indicates whether asset locations of this type should be allowed to be connected to a work location
- **Valid Parent Location/Organization Types:** One or more valid parent locations and parent organizations that can be referenced on asset locations of this type. Used primarily for reporting.
- **Valid Communicate-To Location Types:** One or more asset location types to which asset locations of this type can communicate. The **Tree View** tab of any asset or location will display other related assets with a visual indication of their relationship.

Defining Asset Location Types

You use the **Asset Location Type** portal is used to display and maintain asset location types.

Refer to [Understanding Asset Location Types](#) for more information.

You can access the portal from **Admin > Location > Asset Location Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Asset Location Type List:** This zone lists all asset location type records. Broadcast a record to display the details of the selected record.
- **Asset Location Type:** This zone provides information about the selected asset location type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [WI_NODE_TYPE](#).

Organization Types

Understanding Organization Types

Organization types define the main attributes for organizations of a certain type.

Organization types are defined by the following:

- **Class:** The general class organization. Parent organizations have a class of “Parent”.
- **Organization Business Object:** The business object used for organizations of this type
- **Valid Parent Organization Types:** One or more valid parent organizations that can be referenced on organizations of this type. Used primarily for reporting.

Defining Organization Types

You use the **Organization Type** portal is used to display and maintain organization types.

Refer to [Understanding Organization Types](#) for more information.

You can access the portal from **Admin > Location > Organization Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Organization Type List:** This zone lists all organization type records. Broadcast a record to display the details of the selected record.
- **Organization Type:** This zone provides information about the selected organization type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [WI_NODE_TYPE](#).

Organizations

Understanding Organizations

Organizations are used for categorization and reporting for locations.

For example, your reporting may include a hierarchy that groups locations by a structure of parent and child organizations.

Organizations are defined by the following:

- **Organization Type:** The organization's type. [Understanding Organization Types](#) for more information.
- **Organization Disposition:** The current status of the organization (Active or Inactive)
- **Parent Organization:** The parent organization, if applicable.
- **Main Contact:** A contact for the organization

Defining Organizations

You use the **Organization** portal to display and maintain organizations.

Refer to [Understanding Organizations](#) for more information.

You can access the portal from **Admin > Location > Organization**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Organization:** This zone provides information about the organization.
- **Child Locations / Organizations:** This zone lists any child locations and/or organizations for the current organization.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [W1_NODE](#).

Out of Service Location Types

Understanding Out of Service Location Types

Out of service location types define attributes of types of locations where assets that are out of service are stored and maintained. Examples of out of service locations include warehouses, storerooms, and repair shops.

Out of service location types are defined by the following:

- **Class:** The general class (storeroom, meter shop, etc.) of out of service locations of this type
- **Location Business Object:** The business object used for out of service locations of this type
- **Valid Parent Location/Organization Types:** One or more valid parent locations and parent organizations that can be referenced on out of service locations of this type. Used primarily for reporting.

Defining Out of Service Location Types

You use the **Out of Service Type** portal is used to display and maintain out of service location types.

Refer to [Understanding Out of Service Location Types](#) for more information.

You can access the portal from **Admin > Location > Out of Service Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Out of Service Location Type List:** This zone lists all out of service location type records. Broadcast a record to display the details of the selected record.
- **Out of Service Location Type:** This zone provides information about the selected out of service location type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [WI_NODE_TYPE](#).

Out of Service Locations

Understanding Out of Service Locations

Out of service locations are physical locations where assets are stored or repaired such as a storeroom, warehouse, or service facility. When assets are changed to statuses such as “In Repair” or “Pending Disposition” the asset location is typically moved to an out of service location.

Out of service locations are defined by the following

- **Location Type:** The out of service location’s type. See [Understanding Out of Service Location Types](#) for more information.
- **Location Disposition:** The current status of the out of service location (Active or Inactive)
- **Parent Location/Organization:** The out of service locations’ parent location or organization (if applicable)
- **External ID:** An ID used to identify the out of service location in external systems
- **Address Information:** The physical address of the out of service location
- **Contacts:** The primary contact for the out of service location. See [About Contacts](#) and [Maintaining Contacts](#) for more information about creating and maintaining contacts used with out of service locations.
- **Field Information:** Additional information about the physical location, such as GPS coordinates

Defining Out of Service Locations

You use the **Out of Service Location** portal to display and maintain out of service locations.

Refer to [Understanding Out of Service Locations](#) for more information.

You can access the portal from **Admin > Location > Out of Service Location**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Out of Service Location:** This zone provides information about the out of service location.
- **Current Activities:** This zone provides a summary of the activities that are currently associated to the location.
- **Asset Summary:** This zone provided statistics about the number of assets, by asset type, that are currently associated with the location.
- **Owned Attachments:** This zone lists attachments owned by the location.
- **Referenced Attachments:** This zone lists attachments related to the location.

NOTE: See [About Contacts](#) and [Maintaining Contacts](#) for more information about creating and maintaining contacts used with out of service locations.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [W1_NODE](#).

Defining Device Options

Command Sets

Understanding Command Sets

Command sets are used to define a group of commands that are not eligible for a particular device. For instance, if Commission or Decommission commands should be considered ineligible for a particular device model, a command set that references the Device Commission and Device Decommission business objects could be created and associated with that device model.

Command sets are specified for individual device models via the Manufacturer portal.

Individual devices of a particular model can be configured to override ineligibility if needed.

Configuring Command Sets

This portal is used to display and maintain a Command Set.

Refer to [Understanding Command Sets](#) for more information.

You can access the portal from the **Admin > Device > Command Set**.

The following zones may appear as part of the portal's **Main** tab page:

- **Command Set List:** This zone lists all Command Set records. Broadcast a record to display the details of the selected record.
- **Command Set:** This zone provides information about the selected Command Set.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_COMMAND_SET](#).

Head End Systems

Understanding Head End Systems

Head end systems are systems that collect measurement data and meter events for eventual submission to the application. Many devices can communicate to the application through a single head-end system, but a utility may have numerous head-end systems through which they communicate with devices.

Head end systems utilize processing methods that specify the type of initial measurement data and device events to create for devices (and their related measuring components) based on measuring component type. Head end systems also utilize processing methods that specify how smart meter commands are processed.

Refer to [Understanding Process Methods](#) for more information about processing methods.

Head End Systems Impact Data Import and Export

Head end systems are configured to identify how a particular external system communicates data with Oracle Utilities Meter Data Management. This includes:

- The identifier type used to locate devices and measuring components. These are used both on import and export of data.
- The date/time format used in various data imports (i.e. whether or not the date/time format includes time zone information).

Please refer to the embedded help for more information about these fields.

Each head end system can be associated to an [external system](#) which is used to define the messages that can be sent to that service provider and how each message is sent.

Understanding Processing Methods

Head end systems, external applications, and market participants can have one or more associated processing methods that define the format or means by which it receives or sends data from or to the application, such as bill determinants, interval data, or meter events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and usage transactions. Processing methods can also be used to define the information an external system wishes to subscribe to receive from our application.

At the lowest level processing methods are used to identify an outbound message type, business object, batch control, or message category and number.

Each processing method is comprised of a business object that defines what is being mapped as well as how it should be mapped.

Important Processing Method System Events

The actual logic to determine the appropriate output for a given head end system, external application, or market participant and processing role for a processing method is executed by the following system event:

- **Determine Processing Method(s):** is a business object algorithm system event that takes in a head end system, external application, or market participant, a processing role, and a list of relevant input data aka related object (e.g. a measuring component, device, etc). For the head end system or external application and the input data it will analyze the selection criteria to determine the appropriate output.

How Processing Methods Work

Processing methods perform two basic tasks:

- They define the criteria for selecting the appropriate output. This can be as simple as providing a single object in return without qualification or in more involved situations it could support determining the appropriate return object based on characteristics of the data being processed. This is accomplished through the data structure defined on the processing method business object.
- They evaluate the criteria for selecting the appropriate output given a specific head end system, external application, or market participant. This is accomplished through the Determine Processing Method system event on the processing method business object.

Each processing method business object can be associated to one or more processing roles. This is done by adding the Applicable Processing Role business object option. It is these processing roles that actually create the association between a head end system, external application, or market participant, the processing method, and the functional event that is being

executed. For example, when initial measurement data is processed through the IMD Seeder the processing role Initial Measurement Creation is used to identify the processing method "How to Create MC Related Information" which maps a particular measuring component type to the appropriate initial measurement business object to be used for processing.

When system logic requires the results of a processing method the service Determine Service Providers and Methods is used. This service is available to call via Java or from within scripting through the business service of the same name. It can be called in one of two ways:

With a head end system, external application, or market participant: identifies the appropriate output for a single head end system, external application, or market participant being processed for the input processing role and related objects

Without a head end system, external application, or market participant: used to identify subscribing systems. This will provide a list of any head end system, external application, or market participant that has the input processing role and an appropriate output given the related objects.

Processing Methods Available

There are the following processing methods provided by the base package:

Name	Details	Business Object
How to Create OB COMM/Send OB Message	Identifies Message Number/Category, Business Object, Outbound Message Type and allows for an override by a device type.	D1-HowToCreateActivityOBComm
How to Create MC Related Information	Identifies a business object and allows for an override by measuring component type.	D1-HowToCreateMCInformation
How to Process Device Event Related Info	Identifies a business object, outbound message type, and batch control by device event category allowing for an override by device event type.	D1-HowToProcDvcEvtsInformation
How to Process Device Related Information	Identifies a business object and allows for an override by device type.	D1-HowToProcessDeviceInfo
How to Send Activity Related Information	Identifies a batch control and business object by activity type and allows for an override by device type.	D1-HowToSendActInformation
How to Send Activity Related O/B Messages	Identifies an outbound message type, message category, and message number and allows for override by activity type.	D1-HowToSendActivityResponse
How To Create US Related Information	Identifies a business object and allows for override by usage subscription type.	D2-HowToCreateUSInformation
How To Send US Related Information	Identifies a batch control, business object, and outbound message type and allows for override by usage subscription type.	D2-HowToSendUSInformation
How to Process Service Point Related Info	Identifies a business object and allows for override by service point type.	D1-HowToProcSPRelatedInfo
How to Send Field Activity Related Info	Identifies a outbound message type and allows for an override by field task type.	D1-HowToSendFARelatedInfo
How to Send Field Activity Remark Info	Identifies an outbound message type for an activity remark type.	D1-HowToSendActivityRemarkInfo
How to Translate External Value	Identifies a business object and allows for override by identifier.	D1-HowToTranslateExternalValue
How to Request Customer Notification	Identifies a list of outbound message types.	D1-HowToRequestCustomerNotific

Understanding SGG Adapter Configuration

This section describes how to use a head end system's SGG Adapter Configuration portal.

You can use the SGG Adapter Configuration portal to view configuration information and access configuration components for an SGG adapter head end system.

Note: This portal displays configuration information for head-end systems that reference an SGG Adapter Configuration Sheet extendable lookup..

To use the configuration information portal for an SGG adapter head end system:

Select **Admin > Device > Head End System**.

In the Head End system List zone, click the Broadcast icon for the head-end system you wish to view.

Click the SGG Adapter Configuration tab to view the configuration information.

The SGG Adapter Configuration portal contains the following zones:

- **SGG Adapter Configuration Tracker:** This zone displays the configuration details of the adapter, as defined by the SGG Adapter Configuration Sheet extendable lookup referenced on the head end system. The configuration details include:

The components required for usage and event processing and command processing. To view more details about the components, you can click the component name to go to the business object for the component. For example, you can click the business object "SSN - Connect or Disconnect" to go to the business object portal for the SSN - Connect or Disconnect business object.

Status messages describing the configuration status of components. The following table lists the status messages that may be displayed and the possible actions you can take:

If the status message is...	You can...
Set up this processing method	Click the processing role to set up the processing method.
This processing method has been configured	Click the processing role to view the configured processing method.
Update your processing method with a communication BO	Click the status message to set up the processing method.
Update your external system / outbound message type with an Message sender	Click the status message to go to the external system.
Update your processing method with an outbound message type	Click the status message to set up the processing method.
Add a value to get started	Click the status message to go to the extendable lookup.
Values Existing: (number)	Click the status message to go to the extendable lookup.
Add a communication type	Click the status message to go to the communication type portal.
Add a device event type	Click the status message to go to the device event type business object for the communication type. This message appears only for Echelon type adapters.
Master Configuration has been added	Click the status message to view the Master Configuration portal.
Add Master Configuration for this adapter	Click the status message to view the Master Configuration portal.

Upload Statistics Aggregators: This zone lists the IMD Upload Statistics Aggregator measuring components associated with the head-end system.

Configuring Head End Systems

This portal is used to display and maintain Head End Systems.

Refer to [Understanding Head-End Systems](#) for more information.

You can access the portal from the **Admin > Device > Head End System**.

The following zones may appear as part of the portal's **Main** tab page:

- **Head End System List:** This zone lists all Head End System records. Broadcast a record to display the details of the selected record.
- **Head End System:** This zone provides information about the selected Head End System.
- **Processing Method List:** This zone provides the list of processing methods defined for the Head End System.
- **Translation Methods List:** This zone provides the list of translation methods defined for the Head End System.
- **Inbound BOs Sent By Service Provider:** This zone lists inbound Business Objects that are sent by this Head End System. The identification is driven by the Business Object having a Business Object Option of type "Sent By Service Provider" that references the current Head End System.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_SPR](#).

Measuring Component Types

Understanding Measuring Component Types

Measuring component types define the most important properties of a measuring component.

Measuring component types define what a measuring component measures (KWH, temperature, etc.), how regularly it measures it, and whether it should be connected to a physical device, or if it's used as a scratchpad measuring component or an aggregator measuring component. Measuring component types also specify how the measuring component's final measurements should be stored, how the measuring component's user-defined values should be calculated, and specific rules governing validation, editing, and estimation (VEE) for measuring components of the type. In addition, measuring component types define display properties and valid attribute values for measuring components belonging to the type.

The following configurable items are available for most measuring component types:

- **Value Identifiers:** These store the values of UOM, TOU, and SQI that identify the measured amounts for measuring components of this type. Value identifiers specify the quantities stored on the measurement records for measuring components of this type. Please refer to the Measuring Component Type Value Identifiers topic later in this section for more information.
- **Valid VEE Groups:** These define the VEE groups considered valid for measuring components of this type. Each group supplied here will be available to be selected on measuring components of this type and act as an override to the Fallback VEE Groups.
- **Fallback VEE Groups:** These define default VEE groups for a specific VEE Group Role that can be used with all measuring components of this type. This alleviates the need to specify the same VEE groups on multiple measuring components of the same type. Changes made to these groups will automatically apply to all measuring components of this type unless they have specified their own VEE groups for that particular VEE Group Role. Each VEE group is designated a VEE group role that indicates when and how the VEE group is used (for initial load, manual override, estimation, etc.).
- **Eligible Profile Factors (interval only):** These define the profile factors that are considered to be eligible for interval measuring components of this type. One profile factor can be identified as the default. The default profile factor will be automatically selected in system processing when a profile factor is required.
- **Valid Profile Factors for Conversion from Scalar to Interval (scalar only):** These define the profile factors that are considered to be eligible for scalar measuring components of this type when converting scalar measurements to interval

measurements. These profile factors are used to produce a curve of interval data from a scalar value. Without one of these factors defined scalar to interval conversion will use a flat line method (i.e. evenly divide the scalar value across the intervals). One profile factor can be identified as the default. The default profile factor will be automatically selected in system processing when a conversion profile factor is required.

- **Valid Scratchpad Measuring Component Types:** These define the scratchpad measuring component types considered valid for measuring components of this type.
- **Related Statistics Measuring Component Types:** These define the measuring component types that will be used to store statistical information about the historical usage of measuring components of this type. Please refer to [Configuring Measuring Component Statistics](#) for more information on how this list is used.
- **Display Properties:** Defines how measurement data for measuring components of this type is displayed, including:
 - *Display Configuration:* Details related to how measurements are displayed, including the 360 chart rendering method, number of hours of data to display, the maximum days to search for measurements, the default TOU map used, the TOU by Day Profile factor used, and default measurement condition.
 - *Event Bar Profiles:* The event bar profiles used when displaying measurement data for measuring components of this type. Event bar profiles are defined as values for the 360 View Event Bar Profile extendable lookup.
 - *Final Values Overlay Profiles:* The final values overlay profiles used when displaying measurement data for measuring components of this type. Final values overlay profiles are defined as values for the Final Values Overlay Profile extendable lookup.
 - *Measurement Conditions Not Shown on Chart:* The measurement conditions that should be omitted from rendering onto 360 Degree charts. Measurements whose conditions match these values will be rendered as gaps. For example, many 360 Degree charts use the condition "No Read - System" to represent the lack of a measurement, by adding this condition to this list it a gap will be rendered instead of a line with a 0 quantity measurement and a condition of "No Read - System".

When creating a measuring component type the following options are available:

Name	Details	Business Object
Interval Channel Type - Physical	Provides the configuration for a physical interval channel (e.g. interval size). This is recommended for measuring components that measure consumptive usage.	D1-IntervalChannelTypePhysical
Interval Channel Type - Scratchpad	Provides the configuration for a scratchpad interval measuring component.	D1-IntervalChannelTypeScratchp
Interval Channel Type - Physical Subtractive	Provides the configuration for a physical subtractive interval channel. In addition to standard interval configuration (e.g. interval size) it also provides additional subtractive specific configuration (e.g. rollover validation, estimate reevaluation, etc). This is recommended for measuring components that measure subtractive usage.	D1-IntrvlChanTypPhysSubtractiv
Register Type	Provides the configuration for a physical register that is manually read (e.g. rollover validation). These can be either consumptive or subtractive but are expected to be read infrequently (e.g. once a month).	D1-RegisterTypePhysical
Auto-Read Register Type	Provides the configuration for a physical register that is automatically read. In addition to the standard register configuration (e.g. rollover validation) it also provides details around the schedule of expected readings (e.g. first daily measurement time and expected hours between measurements). These can either be consumptive or subtractive but are expected to be read frequently (e.g. at least once per day). Note: these measuring component types can also be used to model interval data that is	D1-AutoReadRegisterType

received with a large interval size (e.g. 24 hours).

Aggregator Type	Provides the configuration for an aggregation measurement.	D2-AggregatorType
-----------------	--	-------------------

Refer to [Configuring an Out-of-the-box Aggregation](#) for more information about aggregation configuration

Measuring Component Type Value Identifiers

Measuring components are configured to measure specific types of quantities this is defined by the list of value identifiers on the measuring component type. Up to eleven value identifiers can be specified. The primary measured quantity should be identified using the Value Identifier Type of Measurement. An additional ten derived values can be computed based on the primary measurement, these are identified with the Value Identifier Type of Value 01 through Value 10. Each value identifier is constructed of:

- **Unit of Measure:** The unit of measure for the quantity being recorded. Examples include kilo-watt hours (kWh), kilowatts (kW), therms, cubic feet (CCF), temperature (Fahrenheit or Celsius), etc. Refer to [Understanding Units of Measure](#) for more information.
- **Time of Use:** Modifiers for a given unit of measure that indicate a period of time during which a quantity has been used, such as On-Peak (meaning during a time when the greatest quantity of some consumable is being used), Off-Peak (meaning during a time when the least amount of some consumable is being used), etc. Refer to [Understanding Time of Use](#) for more information.
- **Service Quantity Identifiers:** Used to further distinguish between measured quantities that have identical UOM/TOU combinations, including situations in which the distinguishing identifier of a UOM is not accurately described as a TOU. Generally, SQI is only used when multiple measuring components measure the same thing, but in different ways. A meter that measures both generation KWH and consumption KWH could use SQIs to differentiate between the two. Refer to [Understanding Service Quantity Identifiers](#) for more information.
- **Value Derivation Algorithm:** Unlike UOM, TOU, and SQI this is not used in the identification of what is measured but rather is used to calculate a derived value based on the primary measurement. An algorithm from the list should be selected that contains the appropriate logic for calculating the derived value. This is applicable for those value identifiers with a Value Identifier Type of Value 01 through Value 10. More information on how derived values are calculated can be found in the Important Measuring Component Type System Events topic in this chapter. For more functional information about derived values please refer to [About Final Measurements](#).

The combination of UOM, TOU and SQI define what a measuring component measures. TOU and SQI are optional, but UOM must be defined for all value identifiers. For example, consider a meter (as illustrated in the image below) with two measuring components, both measuring the same unit of measure (kWh), but each measuring component measures consumption in different time of use (TOU) periods (peak and off-peak).

Another example might be a meter that records both generated KWH and consumed KWH. This meter would be configured to measure both UOM and SQL.

A measurement is recorded each time a measuring component is read. This means that for a meter with two measuring components that is read once a month, two measurements, one for each measuring component, would be recorded each month.

Important Measuring Component Type System Events

The measuring component type supports several business object algorithm system events that relate to calculating the consumption for measuring components of that type:

- **Calculate Interval Consumption:** receives the interval list and performs any necessary calculations on that interval data to compute consumption. Since interval data is already received as consumption data algorithms for this system event are typically limited to application of the appropriate multipliers. Refer to the algorithm type Calculate Interval Consumption ([D1-IN-CNSUMP](#)) as an example.
- **Calculate Scalar Consumption:** receives information about the scalar reading and calculates the consumption as appropriate. Algorithms for this event typically support calculating the consumption using a stop and start reading or backing into a reading using consumption and a start reading. Much like the interval counterpart it will apply the appropriate multipliers. Refer to algorithm type Calculate Scalar Consumption ([D1-SC-CNSUMP](#)) as an example.
- **Calculate Subtractive Interval Consumption:** receives the interval list and supporting information (e.g. the start reading for the first interval) and either calculates the consumption by subtracting the interval's reading from the prior interval's reading or calculates the reading by adding the current interval's consumption to the prior interval's reading. Refer to algorithm type Calculate Subtractive Interval Consumption ([D1-SIN-CNSUM](#)) as an example.
- **Condition Mapping:** receives the details of a single subtractive interval along with the details for its start reading and computes the applicable final condition and reading condition. This is leveraged solely for subtractive interval measuring component types. Refer to algorithm type Subtractive Interval - Condition Mapping ([D1-SIN-CNMAP](#)) as an example.

These system events are typically called from within initial measurement processing during the initial stages of the initial measurement lifecycle (e.g. the Pre VEE status of most initial measurement business objects).

In addition to the measuring component type business object algorithms there is an additional system event provided on measuring component type itself:

- **Value Derivation:** receives details of an initial measurement and an associated final measurement. Using these inputs it can compute a value derived either from the primary measurement or one of the other derived values. Refer to algorithm type Derive a quantity using a formula ([D1-DERIVAQTY](#)) as an example.

Important Measuring Component System Events

The measuring component business object that is associated to a given measuring component type supports a special system event that is used in the periodic estimation process:

- **Periodic Estimation:** this system event will scan the measuring component's final measurement history to identify missing measurements and create either a To Do, or an estimation initial measurement, or both. More detail about this system event can be found by visiting the following algorithm types: Refer to algorithm type Create Interval IMD and To Do Based Upon Install History ([D1-CIITBIH](#)) and Auto-Read Scalar Periodic Estimation ([D1-ARSPE](#)) as an example.

Measuring Component Business Object Options Drive Functionality

The device business object that is associated to a given device type plays an important role in how a device is processed in a system beyond defining the data associated to that device. Below are a list of business object options that are defined on the device business object and their impact on system processing:

- **Estimation Initial Measurement Data BO:** Is used to identify the appropriate estimation IMD to create.
- **Manual Override IMD BO:** Is used to identify the appropriate manual override IMD to create.
- **System IMD BO:** Is used to identify the appropriate system IMD to create.
- **Measuring Component Consumption Function:** identifies a function that can be executed from any compatible measuring component 360 Degree zone. Each measuring component can support 0 to many of these functions.

- **Interval Initial Measurement Function:** identifies a function that can be executed from any compatible initial measurement zone. Each measuring component can support 0 to many of these functions.

More detail about these options can be found by visiting a measuring component business object and inspecting the business object options.

Configuring Measuring Component Types

This portal is used to display and maintain a Measuring Component.

Refer to [Understanding Measuring Component Types](#) for more information.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Type:** This zone provides information about the selected Measuring Component Type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_MEASR_COMP_TYPE](#).

Measuring Component Comparison Types

Understanding Measuring Component Comparison Types

Measuring component comparison types define the details by which measuring component data can be compared to determine the days that most closely resemble a specific day being evaluated. For example, measuring component comparison types can be used on measuring components that store weather data so that comparisons can be made based on temperature. These are used when performing “proxy day” estimations, allowing the application to search for days that are similar to historical data (for instance, the same date from the previous month or previous year) to use as the basis for estimation.

Measuring component comparison types use the following parameters:

- A specific metric to be calculated to enable data comparisons. The “Calculate Comparison Coefficient - Pearson Correlation Coefficient” algorithm, included with the base package can be used to calculate a coefficient based on the linear correlation between two data sets (specifically between weather data stored on a measuring component and on the comparison object).
- The specific object to be compared. This can be either the same measuring component (to compare against historical data for the same measuring component), or a factor profile (to compare against profile data).
- The date range for the comparison period, including the start of the comparison period (current date, same date last year, or both), the time each day through which the comparison will be calculated, and the number of days prior to and after the start date that will be compared with the comparison object.
- Average Difference Eligibility: An average value either above or below the average for the current date that will be eligible for comparison. For example, assume the current date’s average is 75, and the prior day’s average is 72. If the Average Difference Eligibility is set to 3 then the prior day value of 72 will be eligible for comparison to the current day average of 75.
- The maximum number of resulting calculations that should be stored as measuring component comparable periods.
- A template that defines which days are considered like each day of the week (for example, weekdays are like other weekdays, weekend days are like other weekend days). This template is defined as a record for the “Like Day Eligibility Template” extendable lookup.
- Work calendars used to determine if specific data should be compared to other weekend days or to the same date in prior years, and which dates, if any, should be excluded from historical data used for comparison.

Configuring Measuring Component Comparison Types

Refer to [Understanding Measuring Component Comparison Types](#) for more information.

You can access the portal from **Admin > Device > Measuring Component Comparison Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Comparison Type List:** This zone lists all measuring component comparison type records. Broadcast a record to display the details of the selected record.
- **Measuring Component Comparison Type:** This zone displays details for the selected measuring component comparison type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_MC_COMPAR_TYPE](#).

Device Configuration Types

Understanding Device Configuration Types

Device Configuration types define the measurements a given device can record. It should be noted that the device configuration type itself does not specify this information but rather the device configuration type will identify the valid list of measuring component types that can be referenced associated to a device.

When creating a new device configuration type there are the following options:

Name	Details	Business Object
Device Configuration Type	This represents configurations for physical meters and communication components. It identifies a list of valid measuring components types.	D1-DeviceConfigurationType
Item Configuration Type	This represents badged items that are installed at a particular service point. Given the nature of items there are no measuring component types associated to this type.	D1-ItemConfigurationType

Refer to [Configuring Consumption Synchronization](#) for more information on how a device configuration type can be set up to synchronize consumption between two related channels of measurement data.

Configuring Device Types

This portal is used to display and maintain a Device Type.

Refer to [Understanding Device Types](#) for more information.

You can access the portal from the **Admin > Device > Device Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Type List:** This zone lists all Device Type records. Broadcast a record to display the details of the selected record.
- **Device Type:** This zone provides information about the selected Device Type.
- **Device Type Service Quantity:** This zone displays the list of effective dated service quantities supported by the selected Device Type. This applies only to Items.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_DVC_TYPE](#).

Device Types

Understanding Device Types

Device types define information about a class of devices, including properties that apply to all devices of a type. Properties defined for a device type can be overridden for an individual device

Specifically, device types provide information about:

- How a device can be configured by defining the valid list of device configuration types
- How a device communicates by defining a fallback head end system and a list of valid head end systems.
- How a device records measurement data through the fallback incoming data shift which plays an important role in daylight savings processing. Refer to [Daylight Savings Time Support](#) for more information.
- The consumption profile of an item: the unit of measure consumed and method of calculation (profile or straight line)

When creating a new device type there are the following options:

Name	Details	Business Object
Smart Meter Device Type	These devices measure consumption for a given service point, support remote commands, and remote collection of measurement and event data. These devices are associated to a head end system.	D1-SmartMeterType
Manual Meter Device Type	These devices measure consumption for a given service point but require a visit to the service point to collect the measurement data. They are not associated to head end systems.	D1-ManualMeterType
Item Device Type	These devices represent various items that consume consumption at a constant rate which are not directly metered. As consumption is calculated rather than measured so there is no need for an association to a head end system. Devices of this type can either be created individually for "badged" items or can be listed directly on a service point for "unbadged items."	D1-ItemType
Communications Component Device Type	These devices provide remote collection of consumption data measured by a manual meter to which they are attached. These devices are associated to a head end system.	D1-CommunicationCompMeterType

Device Business Object Options Drive Functionality

The device business object that is associated to a given device type plays an important role in how a device is processed in a system beyond defining the data associated to that device. Below are a list of business object options that are defined on the device business object and their impact on system processing:

- **Device Category:** This defines the type of device and correlates to the core device types that are supported (i.e. smart meter, AMR meter, manual meter, item, or communication component). This value is used by smart meter commands, service order management, and other system processes to make processing decisions.

- **Install Event BO:** This identifies the appropriate install event business object to use when this device is being installed at a service point. Refer to [About Install Events](#) for more information about install events.
- **Valid Command Request BO:** This identifies the commands that are valid for any device of this type. This option can be repeated for as many commands as the device supports. Note: the combination of the device and service provider (aka head end) define the true list of available commands by device.
- More detail about these options can be found by visiting a device business object and inspecting the business object options.

Device Type - Service Quantity

For "badged" and "unbadged" items consumption is not directly measured. Instead, for each item type, the average daily consumption amount is provided. The commodity represented by the daily consumption amount is defined by the item type's unit of measure.

The average daily consumption amount can be effective dated over time to support changes in the consumption profile. This is used in conjunction with the item's calculation method to derive the consumed amount per interval.

Refer to [Multiple Time Zone Support](#) for additional information on how device type service quantities are impacted by multiple time zones.

Configuring Device Types

This portal is used to display and maintain a Device Type.

Refer to [Understanding Device Types](#) for more information.

You can access the portal from the **Admin > Device > Device Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Type List:** This zone lists all Device Type records. Broadcast a record to display the details of the selected record.
- **Device Type:** This zone provides information about the selected Device Type.
- **Device Type Service Quantity:** This zone displays the list of effective dated service quantities supported by the selected Device Type. This applies only to Items.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_DVC_TYPE](#).

Defining Device Installation Options

Service Point Types

Understanding Service Point Types

Service point types define a specific type of point at which service is delivered.

Specifically, service point types define how the application manages many aspects of the service point's behavior. A service point type may have one or more valid device types defined that limit the types of devices that can be installed at service

points of this type. A service point type may also have one or more service agreement types (SA Types) that define the types of service agreements that may be linked to service points of this type.

The **Service Point Business Object** field defines the business object used for service points of this type. Service points in Customer To Meter should be created using the “Service Point — MDM” (X1D-ServicePoint) business object.

The **Service Point Category/Sub Type** field defines the types of devices that can be installed at service points of this type. Valid values include:

- **Meter:** Indicates that a single meter can be installed at service points of this type.
- **Item:** Indicates that a single "badged" item can be installed at service points of this type.
- **Multi-Item:** Indicates that one or more "unbadged" items can be installed at service points of this type.

The **Characteristics** section defines characteristics common to all service points of this type.

NOTE: In Oracle Utilities Customer To Meter, Service Point Types are maintained via [Merged Maintenance](#).

Valid Service Point Characteristic Types

The **Valid SP Characteristic Types** zone lists the valid characteristic types that may be instantiated on service points of this type. Only characteristic types defined for both the “Service Point — MDM” **and** “Service Point — CCB” characteristic entities can be selected in this zone. Characteristics of these types are maintained using the **SP Characteristics** zone in the **Service Point** portal.

Other Service Point Characteristic Types

Though not recommended, it's possible to create characteristic types defined for **either** the “Service Point — MDM” characteristic entity **or** the “Service Point — CCB” characteristic entity. In these instances, the following considerations should be taken into account:

- Characteristic types defined for the “Service Point — MDM” characteristic entity, but **not** the “Service Point — CCB” characteristic entity, must be defined as flattened characteristics on the service point business object and maintained through the service point maintenance portal.
- Characteristic types defined for the “Service Point — CCB” characteristic entity, but **not** the “Service Point — MDM” characteristic entity) are not supported in Customer To Meter.

Configuring Service Point Types

This portal is used to display and maintain a Service Point Type.

Refer to [Understanding Service Point Types](#) for more information.

You can access the portal from **Admin > Geographic > Service Point Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Point Type List:** This zone lists all service point type records. Broadcast a record to display the details of the selected record.
- **Service Point Type:** This zone provides information about the selected service point type.
- **Valid SP Characteristic Types:** This zone lists the valid characteristic types that may be instantiated on service points of the service point type. To add or edit valid characteristic types, click **Edit**.

NOTE: Only characteristics types defined for both the “Service Point — MDM” **and** “Service Point — CCB” characteristic entities can be selected in this zone.

NOTE: In Oracle Utilities Customer To Meter, Service Point Types are maintained via [Merged Maintenance](#).

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_SP_TYPE](#).

Service Point Quantity Types

Understanding Service Point Quantity Types

Service point quantity types define types of quantities that can be stored for a service point. These quantity types are often infrequently calculated descriptors of a given customer and how they relate, at an aggregate level, to either the customer base as a whole or their particular rate class. For example, a customer quantity may be used to store a scaling factor that describes how a given customer's usage compares to the profiled usage for their rate class.

In a settlement implementation, service point quantity types can be used to define values calculated monthly, annually, etc., such as annual peak load contribution (PLC).

Service quantity types use the following parameters:

- The service type (electric, gas, water, etc.) for service point quantities of this type
- Quantity identifiers related to the current service point quantity type (used to provide shorthand descriptions of the various types of values measured by service point quantities of this type)

Configuring Service Point Quantity Types

Refer to [Understanding Service Point Quantity Types](#) for more information.

You can access the portal from **Admin > Device Installation > Service Point Quantity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Point Quantity Type List:** This zone lists all service point quantity type records. Broadcast a record to display the details of the selected record.
- **Service Point Quantity Type:** This zone displays details for the selected service point quantity type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_SP_QTY_TYPE](#).

Divisions

Understanding Divisions

Divisions are used to delineate between different operating companies within a large conglomerate of utilities.

Divisions can have one or more characteristics defined.

Divisions can be defined on several other objects and entities in the system, including:

- Service Point
- Usage Subscription/Usage Subscription Type
- Usage Calculation Group

- Settlement Calculation Group
- Aggregation Group
- Data Source
- Market Product Type
- Market Product Set
- Measurement Data Snapshot Type
- Attribute Data Snapshot Type

Configuring Divisions

You use the **Divisions** portal to display and maintain divisions.

Refer to [Understanding Divisions](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Division**.

The following zones may appear as part of the portal's **Main** tab page:

- **Division List:** This zone lists all division records. Broadcast a record to display the details of the selected record.
- **Division:** This zone provides information about the selected division.
- **Characteristics:** This zone displays a list of characteristics defined for the selected division.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_DIVISION](#).

Measurement Cycles

Understanding Measurement Cycles

Measurement cycles define the schedule for manual meter reading of devices at Service Points in that cycle. Measurement cycles can have one or more associated routes used to collect measurements.

Measurement cycles can also be configured to define when to [create usage transactions](#) for Usage Subscriptions associated to Service Points in the cycle.

For a deeper functional understanding, refer to the [About Route Management](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Measurement Cycles

This portal is used to display and maintain a Measurement Cycle.

Refer to [Understanding Measurement Cycles](#) for more information.

You can access the portal from the **Admin > Device Installation > Measurement Cycle**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measurement Cycle List:** This zone lists all Measurement Cycle records. Broadcast a record to display the details of the selected record.

- **Measurement Cycle Type:** This zone provides information about the selected Measurement Cycle.
- **Measurement Cycle Route List:** This zone lists the measurement cycle routes related to the measurement cycle.
- **Measurement Cycle Schedule List:** This zone lists the measurement cycle schedules related to the current measurement cycle.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_MSRMT_CYC](#).

Measurement Cycle and Bill Determinants

The system can be configured to periodically push bill determinants to subscribing systems. In this case, measurement cycles can be configured to define when to create usage transactions for Usage Subscriptions associated to Service Points in the cycle. Even Service Points whose meters are read automatically may reference measurement cycles.

Creating bill determinants (by creating a usage transaction) is performed by an algorithm on the "Complete" state of the SP/Measurement Cycle Schedule Route business object (similar to creating activities as described above).

When the Pending SP/Measurement Cycle Schedule Route records are processed by the D1-PSPSR batch, rather than create a handheld download activity, the algorithm can create a usage transaction (usage transactions are transactions that cause bill determinants to be calculated for the Service Point's Usage Subscription).

If the implementation needs to both manually read the meter and push bill determinants, both algorithms would be plugged in on the SP/Measurement Cycle Schedule Route business object.

Measurement cycle processing is managed by the following three batch processes:

- **Create Pending Measurement Cycle Schedule Routes (D1-CMCS):** This batch process creates Schedule Routes for Measurement Cycle Schedules whose schedule selection date is on or before the batch business date. This process is used if routes have the same schedule each month, quarter, etc. This process simply copies the routes from the Measurement Cycle to the Measurement Cycle Schedule on/after the scheduled selection date.
- **Create Pending SP / Measurement Cycle Schedule Route Records (D1-CSPSR):** This batch process creates a "SP/Measurement Cycle Schedule Route" transaction for every Service Point in the Measurement Cycle Schedule Route that is ready for processing.
- **Process Pending SP / Measurement Cycle Schedule Route Records (D1-PSPSR):** This batch process transitions the Pending "SP/Measurement Cycle Schedule Route" transactions to their Complete state. Custom algorithms can be configured to do any additional necessary work, such as creating a "Meter Read Download" activity. This custom algorithm would be configured as an Enter algorithm on the "Complete" state of the SP/Measurement Cycle Schedule Route business object.

For a deeper functional understanding, refer to the [About Route Management](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Measurement Cycle Schedules

Understanding Measurement Cycle Schedules

Measurement cycle schedules define the dates on which devices are scheduled to be read for a given measurement cycle and the routes used to collect measurements for the measurement cycle.

For a deeper functional understanding, refer to the [About Route Management](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Measurement Cycle Schedules

This portal is used to display and maintain a Measurement Cycle Schedule.

Refer to [Understanding Measurement Cycle Schedules](#) and [Understanding Measurement Cycles](#) for more information.

You can access the portal from the **Admin > Device Installation > Measurement Cycle Schedule**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measurement Cycle Schedule Query:** This zone allows you to query for Measurement Cycle Schedules based on Measurement Cycle and select the desired record.
- **Measurement Cycle Schedule:** This zone provides information about the selected Measurement Cycle Schedule.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_MSRMT_CYC_SCHED](#).

Setting Up Metered Premise Options

This section describes tables that must be set up before you can define premises.

Setting Up Meter Read Instructions

When you set up a premise you may define instructions to be supplied to the individuals who read the meters located at the premise. To define meter read instruction codes, open **Admin > Geographic > Meter Read Instruction**.

Description of Page

Enter a unique **Meter Read InstructionCode** and **Description** for every meter read instruction.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_MR_INSTR](#).

Setting Up Meter Read Warnings

When you set up a premise you may define warnings to be supplied to the individuals who read the meters located at the premise. To define meter read warning codes, open **Admin > Geographic > Meter Read Warning**.

Description of Page

Enter a unique **Meter Read Warning** and a **Description** for every meter read warning.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_MR_WARN](#).

Setting Up Consumption Estimation Parameters

The system estimates consumption under the following situations:

- At billing time, when "real" consumption cannot be computed due to the lack of a meter read, the system estimates how much the customer used assuming the following conditions are true:
 - The service agreement allows estimation.
 - The rate schedule allows estimation.
 - The bill cycle schedule (if one is being used) allows estimation.
 - The register is not a peak register (this is an artificial constraint, but most organizations do not estimate peak consumption). Note that the base product estimation algorithms may attempt to estimate peak registers.
 - The register is subtractive. This is because only subtractive registers are self-correcting. For example, assume we estimate a reading of 100 and the next real read is 102, the customer will only be charged for 2 units. But consider what would happen if we estimated a consumptive register, the consumption associated with the next real read will be billed in its entirety.
- When a meter read is added, the system verifies that the resultant consumption is congruous with historical consumption trends (i.e., high / low checks are performed).

This section describes the tables that must be set up to estimate consumption.

Defining Device Measurement Options

Units of Measure

Understanding Units of Measure

Units of Measure (UOM) identify quantities measured and recorded, such as KWH, KW, cubic feet, degrees Celsius, etc. UOMs are based on a specific service type.

NOTE: In Oracle Utilities Customer To Meter, Units of Measure are maintained via [Merged Maintenance](#).

Important Unit of Measure System Events

Unit of Measure supports the following business object algorithm system events:

- **Axis Conversion:** this event receives a list of measurements along with a source UOM and interval size and a target UOM and interval size. It should then perform the necessary actions to convert the source UOM and interval size into the target UOM and interval size. Refer to the algorithm Axis Conversion algorithm ([DI-AXIS-CONV](#)) as an example.

Configuring Units of Measure

This portal is used to display and maintain a Unit of Measure.

Refer to [Understanding Units of Measure](#) for more information.

You can access the portal from the **Admin > Rates > Units of Measure**.

The following zones may appear as part of the portal's **Main** tab page...

- **Unit of Measure List:** This zone lists all units of measure. Broadcast a record to display the details of the selected record.
- **Unit of Measure:** This zone provides information about the selected unit of measure.

NOTE: In Oracle Utilities Customer To Meter, Units of Measure are maintained via [Merged Maintenance](#).

Where Used

Follow this link to open the Application Viewer data dictionary where you can view the tables that reference [D1_UOM](#) and [UOM](#).

Service Quantity Identifiers

Understanding Service Quantity Identifiers

Service Quantity Identifiers (SQI) are used to further distinguish between measured quantities that have identical UOM/TOU combinations, including situations in which the distinguishing identifier of a UOM is not accurately described as a TOU. Some examples include: Generated, Consumed, etc.

SQIs can also be used as a stand-alone representation of a service quantity that is not measured (one that is not properly described as a UOM) within a usage service quantity collection (such as a billing determinant).

NOTE: In Oracle Utilities Customer To Meter, Service Quantity Identifiers are maintained via [Merged Maintenance](#).

Configuring Service Quantity Identifiers

This portal is used to display and maintain a Service Quantity Identifier.

Refer to [Understanding Service Quantity Identifiers](#) for more information.

You can access the portal from **Admin > Rates > Service Quantity Identifier**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Quantity Identifier List:** This zone lists all Service Quantity Identifiers. Broadcast a record to display the details of the selected record.
- **Service Quantity Identifier:** This zone provides information about the selected Service Quantity Identifier.

NOTE: In Oracle Utilities Customer To Meter, Service Quantity Identifiers are maintained via [Merged Maintenance](#).

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_SQI](#) and [SQI](#).

Time of Use

Understanding Time of Use

Time of Use (TOU) periods are modifiers for a given unit of measure that indicate a period of time during which a quantity has been used, such as On-Peak (meaning during a time when the greatest quantity of some consumable is being used), Off-Peak (meaning during a time when the least amount of some consumable is being used), etc.

NOTE: In Oracle Utilities Customer To Meter, Time of Use periods are maintained via [Merged Maintenance](#).

Configuring Time of Use

This portal is used to display and maintain a Time of Use.

Refer to [Understanding Time of Use](#) for more information.

You can access the portal from **Admin > Rates > Time of Use**.

The following zones may appear as part of the portal's **Main** tab page:

- **Time Of Use List:** This zone lists all Time Of Use records. Broadcast a record to display the details of the selected record.
- **Time Of Use:** This zone provides information about the selected Time Of Use.

NOTE: In Oracle Utilities Customer To Meter, Time of Use periods are maintained via [Merged Maintenance](#).

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_TOU](#) and [TOU](#).

Service Types

Understanding Service Types

Service Types define specific types of service for which usage can be recorded and captured, such as electric, gas, steam, etc.

NOTE: In Oracle Utilities Customer To Meter, Service Types are maintained via [Merged Maintenance](#).

Configuring Service Types

This portal is used to display and maintain a Service Type.

Refer to [Understanding Service Types](#) for more information.

You can access the portal from **Admin > General > Service Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Type List:** This zone lists all Service Type records. Broadcast a record to display the details of the selected record.
- **Service Type:** This zone provides information about the selected Service Type.

NOTE: In Oracle Utilities Customer To Meter, Service Types are maintained via [Merged Maintenance](#).

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_SVC_TYPE](#) and [SERVICE TYPE](#).

Factors

Understanding Factors

Factor are a centrally stored set of values for use in validation rules, bill determinants calculations, and other processes.

A factor can have different values depending upon some definable attribute of a system object, such as customer size associated with a service point. Examples of factors can include minimum and maximum thresholds, loss factors, etc. Classes of factors are defined that can have numeric values (as in the above examples), or values pointing to profile measuring components, or VEE groups.

A factor's values are effective-dated values - either a number, a profile measuring component, a temperature profile measuring component, a VEE group, or some custom-defined value - assigned to a factor and associated to the value of some attribute of a system object. For example, consider a service point that can be classified as residential, commercial, or industrial. The tolerance percentage by which a customer's consumption can exceed last month's consumption can be based on the service point category.

For this example, factor values for a single factor called "tolerance percentage" could be:

- Residential - 20%
- Commercial - 10%
- Industrial - 5%.

Configuring Factors

This portal is used to display and maintain Factors and Factor Values.

Refer to [Understanding Factors](#) for more information.

Prerequisites: You must define factor characteristic source algorithms, factor characteristic types, and factor characteristic values before you can create a factor. Refer to the Oracle Utilities Application Framework online help for more information about algorithms, characteristic types, and characteristic values.

The following zones may appear as part of the portal's **Main** tab page:

- **Factor List:** This zone lists all factor records. Broadcast a record to display the details of the selected record.
- **Factor:** This zone provides information about the selected factor.
- **Factor Char Value and Factor Value List:** This zone lists the characteristic values associated to the factor characteristic. For each characteristic value it will display the related factor values. From this zone you can click the **Factor Value** link to see the factor value in more detail on the **Factor Value** portal.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_FACTOR](#).

Processing Timetable Types

Understanding Processing Timetable Types

Processing timetable types define types of schedules that can be referenced by different processes and objects in Oracle Utilities applications such as Oracle Utilities Meter Data Management and Oracle Utilities Market Settlements Management. For example, if a process requires requesting data from an external system on a daily basis, a daily processing timetable type could be used to define the details of this schedule.

Processing timetable types are used by standalone data request measuring components to control the schedule by which requests for data are processed (for example, in a settlement process in which zonal load is requested on a daily basis). They are also used in the attribute data snapshot creation process.

The base package includes two processing timetable type business objects used with specific scheduling patterns:

- **Daily Processing Timetable:** Used for daily schedules
- **Defined Dates Processing Schedule:** Used for schedules that should execute on specific dates.

Parameters used to define processing timetable types include:

- **Execution Frequency Class:** Designates the type of processing timetable, Daily or Defined Dates (based on the business object)
- **Scheduling Information:** Details about how the schedule is executed, including:
 - **Period Cut-Off Time:** The time of day that represents the end of a period. In many instances this will be 12:00 AM. However, for something like a "Gas Day" this might be set to 09:00 AM.
 - **Earliest Execution Time:** Used to prevent records from being processed until after this time each day. This time relates to the processing time.
 - **Lag / Lead:** A flag that indicates whether periods in the past (Lag) or future (Lead) should be processed (applies to Daily schedules only)
 - **Lag Days / Lead Days:** The number of days in the past (Lag) or future (Lead) that should be processed (applies to Daily schedules only)
 - **Restrict Processing by Work Calendar:** Used to restrict processing to only the work days configured in the Work Calendar and will exclude any holidays added to the calendar (applies to Daily schedules only)
- **Workflow Information:** Details about how the processing timetable aligns with process workflows, including warning time and target due time
- **Processing Dates:** A list of specific dates on which the process should be executed (used with Defined Dates Processing Schedule only)

Configuring Processing Timetable Types

Refer to [Understanding Processing Timetable Types](#) for more information.

You can access the portal from **Admin > General > Processing Timetable Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Processing Timetable Type List:** This zone lists all processing timetable type records. Broadcast a record to display the details of the selected record.
- **Processing Timetable Type:** This zone displays details for the selected processing timetable type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_PROC_TIMETABLE_TYPE](#).

Initial Measurement Data

Configuring the Initial Measurement Algorithms

The behavior of initial measurement data processing can be adjusted by updating parameters in several key algorithms in the lifecycle.

NOTE: This is not a list of all algorithms and algorithm parameters that can be customized in the initial measurement processing lifecycle. Rather, it is a selection of some of the more impactful parameters.

Initial Measurement Data Seeder Algorithms

- Derive Service Provider and Measuring Component ([D1-DER-SPRMC](#)):
 - Enabling a standalone measuring component search allows initial measurement data to be processed without a device identifier. This is useful when profile or temperature data is loaded through the IMD Seeder and a match must be made on measuring component identifiers alone.
 - If measuring component identifiers can be repeated across measuring components for the same device then the error for duplicate measuring components being found can be turned off. This is useful for certain head end systems that will have multiple channels with the same channel identifier. When a duplicate is found the search will fall back on other means for identifier the correct measuring component.
- Perform Date/Time Adjustments and Undercount/Overcount Check ([D1-DODTTMADJ](#)):
 - Undercount validation can be turned off completely or left enabled. When left enabled the automatic filling of gaps can be turned off separately.
 - The overcount check can be turned off.
 - The automatic adjustment of the individual interval date/times to an interval boundary can be turned on.

NOTE:

If your implementation receives initial measurement data with date/times that do not include an explicit time zone and the devices report date/times in standard time, you may need to add the following configuration:

- Navigate to **Admin > Integration > Message Option**
- In the **XAI compliance** option, ensure that the following text is provided:
`xsd:strict:dstGapInStandardTime`

This will prevent a date/time reported in standard time that falls on the missing hour of the day Daylight Savings Time is entered from being misinterpreted.

Specific Initial Measurement Data Algorithms

- Normalize measurements (overwrite identical existing Measurements) ([D1-NORM-IMD](#)):
 - When the initial measurement data includes measurements that match exactly with the existing final measurements they can either be overwritten or skipped.
 - If logging of changes to final measurements is desired then it must be indicated as such in this algorithm. It is suggested to keep this turned off for high volume initial measurement data such as initial load. See [Configuring Measurement Logging](#) for more details.

NOTE: Refer to [Configuring Consumption Synchronization](#) for additional parameters that can be adjusted on specific initial measurement data algorithms.

Configuring Measurement Logging

There are two components to logging changes to final measurements:

- **Initial Measurement Finalization:** the "normalization" algorithm on a particular initial measurement data business object will determine how final measurements are updated. For performance reasons certain types of initial measurement data (e.g. initial load) are delivered with a final measurement update method that will skip any logging. This can be controlled by parameters on the algorithm that implements the algorithm type Normalize Measurements for Initial

Measurement Data ([D1-NORM-IMD](#)). Specifically the "Create Measurement Log on Update (Y/N)" parameter should be set to "Y". As mentioned creating these logs has a performance impact and it is not recommended for use on initial load.

- **Measurement Business Object:** there must be an algorithm for the audit system event configured. The base package delivers the algorithm type Add Measurement Log Record ([D1-AMSRMTLOG](#)). It is this algorithm that actually records the log entries.

Logging User Updates to Manual Initial Measurements

By default, manual edits made by users of these zones are not logged on the Log tab. Logging of manual edits to manual initial measurements can be enabled by adding a logging algorithm on an appropriate lifecycle state of the manual initial measurement business objects. The Log User Transaction ([D1-LOGUSRTRN](#)) base package algorithm can be used for this. This Enter algorithm is designed to be defined on the Initial state of the manual initial measurement business objects, but it can also be defined on any (non-transitory) Interim or Final state as well.

To ensure logging of any or all manual edits made to manual initial measurements, this algorithm should be specified on any state in which users will make manual edits. This will most often be the Pending or VEE Ready states, but could also include the Error, Exception, or Finalized states.

CAUTION: When defining this algorithm, the user should exercise caution and determine if previous algorithms in the sequence within the state contain any form of transitioning logic that may inadvertently cause this algorithm to be bypassed.

Defining VEE Options

Exception Types

Understanding Exception Types

Exception Types define the groupings of exceptions for an IMD based on their functional similarity. This provides a way to define VEE Exceptions in a distinct enough way to understand the root issue that was generated from the VEE Rule.

For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Exception Types

This portal is used to display and maintain an Exception Type.

Refer to [Understanding Exception Types](#) for more information.

The following zones may appear as part of the portal's **Main** tab page:

- **Exception Type List:** displays all of the Exception Types so you can choose the one you want to display in more detail
- **Exception Type:** shows the specific configuration for the selected Exception Type

There are two different options to use when creating an Exception Type:

Name	Details	Business Object
VEE Exception	This will create a "normal" VEE Exception that is attached to an IMD for tracking of conditions triggered in the VEE process.	D1-VEEException

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_EXCP_TYPE](#).

VEE Groups

Understanding VEE Groups

VEE groups are collections of VEE Rules that are applied to initial measurement data. During the VEE process, the system executes the VEE Rules defined in each VEE group. The rules within a VEE group are defined in a specific sequence, allowing control over the order in which the rules are executed.

VEE groups can be associated to a specific measuring component, or to a measuring component type (or both). VEE groups associated with a measuring component type are applied to all measuring components of that type, while those associated to a specific measuring component are applied only to that measuring component. VEE groups associated to a measuring component override those assigned to a measuring component type.

VEE groups can also be referenced by the [Execute VEE Group](#) VEE Rule.

For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring VEE Groups

This portal is used to display and maintain a VEE Group.

Refer to [Understanding VEE Groups](#) for more information.

You can access the portal from the You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **VEE Group:** Defines basic information about VEE group
- **VEE Rules List:** lists the VEE Rules belonging to the group
- **Referencing VEE Rules List:** lists the VEE Rules that reference the group
- **Referencing VEE Group Factors List:** lists the VEE group factors that reference the group
- **Referencing Measuring Component Type List:** lists the measuring component types that reference the group
- **Referencing Measuring Component List:** lists the measuring components that reference the group

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_VEE_GRP](#).

VEE Rules

Understanding VEE Rules

VEE Rules are standard and custom Validation and Estimation rules that perform checking and/or manipulation of initial measurement data. VEE Rules are created for a specific VEE group. For example, if you were configuring two VEE groups and both included a specific VEE Rule, you would need to create two instances of the VEE Rule, one for each group.

The specific validation and estimation processing performed on initial measurement data is defined in individual VEE Rules, each performing a specific set of targeted logic. The base product contains many VEE Rules you can use in your implementation, but you can also create your own custom VEE Rules.

Some VEE Rules generate VEE Exceptions if the initial measurement data fails the conditions specified for the rule. Other rules override measurements, changing measurement values as dictated by the rule's parameters. Some rules can both create exceptions and override the measurement as part of a single process. By convention, VEE Rules change the Post-VEE quantities of initial measurement data, but VEE Rules can change anything on an initial measurement.

Every VEE Rule has an effective period. Rules will only be applied if the initial measurement's start date is within the rule's effective period. For example, an Interval Spike Check rule with a Start Date of 11/15/2010 will only be applied if the start date of the initial measurement is on or after 11/15/2010.

This allows you to update the specifics of a rule without removing the previous version of the rule. For example, you might change the tolerance of an Interval Spike Check rule from 1.2 to 1.5 as of a certain date. However, for initial measurement data for the period prior to the change, you would want to use the tolerance for the original version of the rule (1.2) instead of the new tolerance (1.5).

On almost every VEE Rule, the failure of the rule results in a VEE Exception and the [Exception Type](#) for the failure can be configured on the rule. These Exception Types can also be set to a specific Exception Severity:

- **Information:** Used to highlight minor issues, but not sufficient to cause the initial measurement data to be put into the exception state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues:** Used to report a problem that will prevent the initial measurement data from being finalized. Multiple "issue exceptions" can be created during VEE processing. If at least one issue exists after all rules have been applied, the initial measurement data is transitioned to the exception state
- **Terminate:** Used to report a severe issue that will cause the VEE process to stop and the initial measurement data to be transitioned immediately to the exception state. Only one terminate exception can be issued (as the first one causes VEE processing to stop on an initial measurement data).

For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring VEE Rules

This portal is used to display and maintain a VEE Rule. Also, a list of the specific out-of-the-box rules is included below the instructions for using the portal.

Refer to [Understanding VEE Rules](#), [Understanding VEE Groups](#), and [Understanding Exception Types](#) for more information. For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

You can access the portal from . You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **VEE Rule:** this zone displays all of the configuration items specific to this instance of a VEE Rule.
- **Eligibility Criteria List:** this zone displays any VEE Rule Eligibility Criteria that have been setup. These eligibility criteria determine conditionally whether the VEE Rule should be executed or not. Use the Add button to create a new eligibility criteria for the rule you're viewing.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_VEE_RULE](#).

Validation VEE Rules

Below is a list of the validation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Applicable Data Type(s)	Purpose
Consecutive Interval Check	Interval	This validation rule flags any combination of consecutive intervals within Initial Measurement Data based on the values of the data or the condition codes of the data.
Duplicate IMD Check	Interval or Scalar	This rule allows for a duplicate IMD to be flagged.
Dynamic Comparison Validation	Interval or Scalar	This powerful, flexible validation rule compares measurements to historical statistics for the related Service Point. The system will maintain statistics such as the following: sum, min, max, average, median, zero value count, outage count, and standard deviation. Then you define formulas (no programming required) for the comparison of current measurements to these statistics.
Ensure IMD Exists for Sibling MCs	Interval or Scalar	This rule validates that an IMD exists for all of the other measuring components associated to the same Device Configuration as the current measuring component, for the same period of time.
Final Measurement Replacement	Interval or Scalar	This validation rule allows you to define a variety of configuration options to decide if new data should replace existing measurements. The options include value change thresholds, percentage change thresholds, as well as condition code ranking.
High/Low Check	Interval or Scalar	This validation rule compares the total consumption of the current IMD to historical values. The comparison is normalized based on average daily usage (ADU). If the current IMD is too high or too low compared to historical data then an exception is thrown.
Inactive Measurement Check	Interval or Scalar	This validation rule flags any Initial Measurement Data received on a device that is either disconnected, uninstalled, and/or not connected to a Usage Subscription.

Interval Size Validation	Interval	This rule validates that the interval size (in seconds) supplied with the Initial Measurement is equal to the interval size defined on measuring component's type.
Interval Spike Check	Interval	This rule checks for spikes within an IMD and generates an exception if one is found.
Multiplier Check	Interval or Scalar	This rule validates that the register multiplier supplied with the IMD is equal to the multiplier stored on the measuring component. If not, an exception is created using the register multiplier exception type and severity configured on the rule.
Negative Consumption Check	Interval or Scalar	This rule flags any IMD where the total consumption is negative.
Prolonged Estimation Check	Interval or Scalar	This validation rule creates an alert when a device has been estimated for an extended period of time.
Raise Missing Quantity Exception	Interval	This rule flags any missing interval data.
Sum Check	Interval or Scalar	This rule is used to compare the difference between interval data to scalar data for a period of time, or between a set of TOU scalar reads to a "Sum" scalar reading.
Unit of Measure Check	Interval or Scalar	This rule checks the unit of measure (UOM) passed in with the Initial Measurement against the primary unit of measure configured on the measuring component's type.
Zero Consumption Check	Interval or Scalar	This rule checks if the total consumption for the IMD is zero. There is also a check for whether an outage occurred during the same time as the zero consumption to provide ways to avoid exceptions in that case.

Estimation VEE Rules

Below is a list of the estimation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Applicable Data Type(s)	Purpose
Interval Adjustment From Scalar	Interval	This rule performs adjustments to interval values based on the values from the associated scalar data on the same device.
Interval Averaging Estimation	Interval	This rule finds historical interval data from the same measuring component based on a variety of configuration options to use for estimating any missing data within an IMD.
Interval Create Estimation IMD for Gap	Interval	This estimation rule creates a new Estimation IMD to fill gaps between the interval data received from the Head End.

Note: this estimation rule acts differently from the other rules as it creates a new IMD rather than filling in missing values in an estimation IMD created from periodic estimations.

Interval Interpolation Estimation	Interval	This rule attempts to interpolate gaps within an IMD using prior and subsequent intervals as starting points for linear interpolation.
Interval Profile Estimation	Interval	This rule estimates any missing interval data for the IMD based on a referenced Profile Factor.
Interval Proxy Day Estimation	Interval	This rule checks for days with similar temperature and uses the measurement data from those days as the basis of interval estimation for the in-flight initial measurement.
Scalar Calculation From Interval	Scalar	This rule performs adjustments to scalar values based on the values from the associated interval data on the same device.
Scalar Estimation	Scalar	This rule finds historical scalar data from the same measuring component based on a variety of configuration options to use for estimating any missing data within an IMD.
Scalar Profile Estimation	Scalar	This rule estimates any missing scalar data for the IMD based on a referenced Profile Factor.
Scalar Proration	Scalar	This rule prorates the value of a scalar reading that has two valid scalar readings on either side as boundaries. It will also take into account any related interval data within the same period to exclude from the calculation.
Subtractive Interval Adjustment Rule	Subtractive Interval Adjustment Rule	This rule performs adjustments to qualifying interval consumption values for subtractive interval measuring components based on an adjustment target calculated using a start and stop reading for the period that encapsulates the intervals to adjust.

Decision-Making VEE Rules

There are VEE Rules delivered as part of the base product that help with decision-making when executing VEE (listed below). For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Purpose
Exception Handler	This rule allows for termination of the VEE process based on a configurable set of exceptions being present for the IMD. This rule also allows a unique To Do Type to be generated based on a group of exceptions.
Execute VEE Group	This rule performs a call to execute a separate VEE Group which includes execution of all VEE Rules within that group.

Successful Termination

This rule allows VEE to be successfully terminated based on a list of exceptions.

VEE Group Matrix (Factor)

This rule provides a way to choose different instances of a VEE Rule using a Factor. This factor leverages characteristics that are defined on Service Point, Device, or Measuring Component.

Validation VEE Rules

Consecutive Interval Check

Overview

This rule flags any combination of consecutive intervals within Initial Measurement Data based on the values of the data or the condition codes of the data. It can be used to find faulty meters that are reporting consecutive outage codes, zero measurements, or negative values. It can also be used by water utilities to identify leaks based on the interval never reaching zero.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-CONSINTRV](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

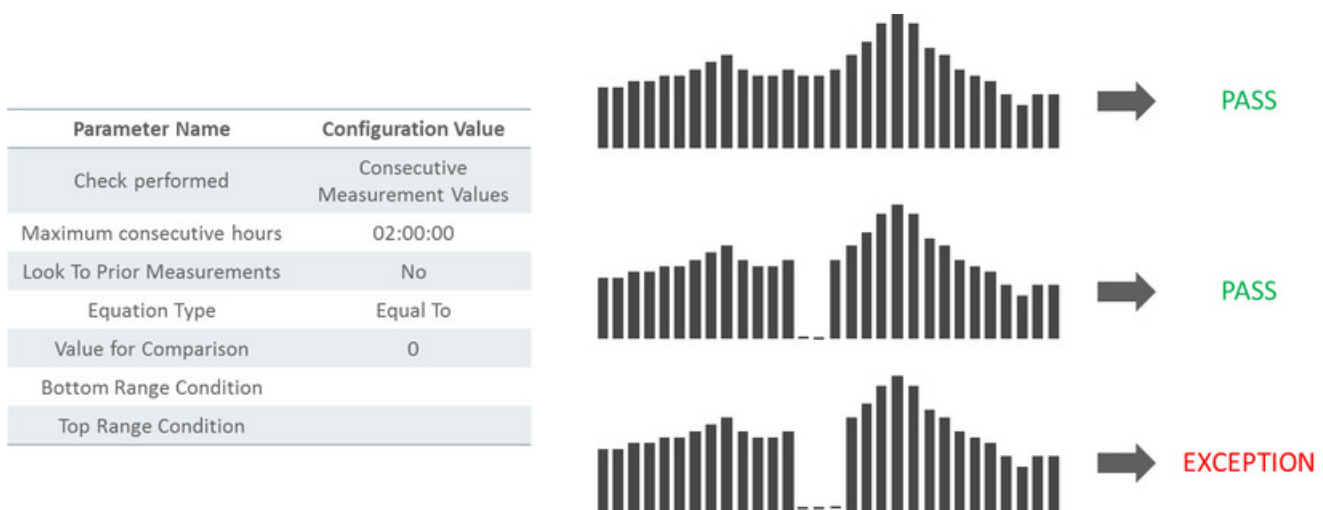

Business Object

D2-ConsecutiveIntervalCheck

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Rule configured to fail for zero values

Scenario 2: Rule configured to fail for negative values

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Less Than
Value for Comparison	0
Bottom Range Condition	
Top Range Condition	

Scenario 3: Rule configured to fail for missing condition codes

Parameter Name	Configuration Value
Check performed	Consecutive Condition Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	
Value for Comparison	
Bottom Range Condition	Missing
Top Range Condition	Missing

KEY
 = Regular data
 = Missing data

Scenario 4: Rule configured to fail for outage condition codes only if its zero

Parameter Name	Configuration Value
Check performed	Both
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Equal To
Value for Comparison	0
Bottom Range Condition	Outage
Top Range Condition	Outage

Scenario 5: Rule configured to fail if a long period of consecutive water values are greater than 0.1

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	20:00:00
Look To Prior Measurements When First Interval Matches Criteria	No
Equation Type	Greater Than
Value for Comparison	0.1
Bottom Range Condition	
Top Range Condition	

Scenario 6: Look back at prior measurements when the first interval matches criteria

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	Yes
Equation Type	Equal To
Value for Comparison	0
Bottom Range Condition	
Top Range Condition	

Duplicate IMD Check

If the current Initial Measurement Data (IMD) being validated is determined to be a duplicate of an existing IMD for the same measuring component, this rule will produce a VEE exception of the type and severity configured on the VEE Rule. The algorithm logic looks for duplicate IMDs using the following criteria:

- associated to the same measuring component as the current IMD
- utilizes the same IMD business object as the current IMD (for example, Initial Load Scalar)
- references the same To Date/Time (ends on the same date) as the current IMD
- exists in a "Finalized" state
- the contents of pre-VEE are identical to the pre-VEE of the current IMD

If any IMDs are found that meet all of the above criteria, the current IMD is deemed to be a duplicate.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D1-DUPIMDCHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-DuplicateIMDCheck

Dynamic Comparison Validation

This validation rule compares measurements to historical statistics for the related Service Point. The system will maintain statistics such as the following: sum, min, max, average, median, zero value count, outage count, and standard deviation. Setting up these [Measuring Component Statistics](#) is a prerequisite to using the rule.

Users can define formulas (no programming required) for the comparison of current measurements to these statistics. This is powerful rule will allow utilities to look for unusual usage patterns. For example:

- Lowest/highest usage ever
- Current usage is more than three standard deviations from the mean
- Detect unexpected zero usage
- Detect negative usage while ruling out known cases
- Abnormal usage
- Voltage threshold monitoring
-

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-DYNCOMCHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-DynCompValidation

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Example 1: Detect new "high water mark"

Historical Statistics			
Statistics MC Type: MC_STATS_13MONTHS			
Max	15 min	4.320	

Dynamic Values	
Variable Name: IMD1	<ul style="list-style-type: none"> Source Type: IMD Set Function: Max
Variable Name: CS1	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_13MONTH Value: Max

Equation

$$IMD1 > CS1 * 1.1$$

This equation is comparing the max interval in the new IMD to the max interval from the last 13 months of history from the MC. If greater than 110% of max then fail.

Example 2: High Usage

Historical Statistics			
Statistics MC Type: MC_STATS_LASTMONTH			
Average	15 min	1.630	
Standard Deviation	15 min	0.519	
Statistics MC Type: MC_STATS_LASTYEAR			
Average	15 min	1.893	
Standard Deviation	15 min	0.851	

Dynamic Values			
Variable Name: IMD1	<ul style="list-style-type: none"> Source Type: IMD Set Function: Max 	Variable Name: CS3	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTYEAR Value: Average
Variable Name: CS1	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTMONTH Value: Average 	Variable Name: CS4	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTYEAR Value: Standard Deviation
Variable Name: CS2	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTMONTH Value: Standard Deviation 		

Equation

$$(IMD1 - CS1) / CS2 > 3$$

$$AND (IMD1 - CS3) / CS4 > 3$$

This equation checks that the standard score of the current max interval is within 3 standard deviations of historical data from last month and last year. If greater than 3 standard deviations, an exception is thrown.

Example 3: Detect unexpected zero usage (method 1)

Historical Statistics			
Statistics MC Type: MC_STATS_LASTMONTH			
Total Count	15 min	2880	
Zero Count	15 min	3	
Statistics MC Type: MC_STATS_LASTYEAR			
Total Count	15 min	2880	
Zero Count	15 min	0	

Dynamic Values			
Variable Name: IMD1	<ul style="list-style-type: none"> Source Type: IMD Calc Function: Sum 	Variable Name: CS_T2	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTYEAR Value: Total Count
Variable Name: CS_T1	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTMONTH Value: Total Count 	Variable Name: CS_Z2	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTYEAR Value: Zero Count
Variable Name: CS_Z1	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTMONTH Value: Zero Count 		

Equation

$$IMD1 = 0$$

$$AND CS_Z1 / CS_T1 < 0.01$$

$$AND CS_Z2 / CS_T2 < 0.01$$

This equation finds zero intervals in the current IMD that seem to not fit with historical trends for the customer based on prior counts of zero intervals.

Example 4: Detect unexpected zero usage (method 2)

Historical Statistics			
Statistics MC Type: MC_STATS_LASTMONTH			
Min	15 min	0.43	
Statistics MC Type: MC_STATS_LASTYEAR			
Min	15 min	0.52	

Dynamic Values			
Variable Name: IMD1	<ul style="list-style-type: none"> Source Type: IMD Calc Function: Min 	Variable Name: CS1	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTMONTH Value: Min
		Variable Name: CS2	<ul style="list-style-type: none"> Source Type: Channel Statistics MC Type: MC_STATS_LASTYEAR Value: Min

Equation

$$IMD1 = 0$$

$$AND CS1 > 0$$

$$AND CS2 > 0$$

This equation finds zero intervals in the current IMD that seem to not fit because the minimum values for the meter historically have never reached zero during comparable periods.

Example 5: Detect negative usage while ruling out known cases

Historical Statistics

Statistics MC Type: MC_STATS_13MONTHS		
Negative Count	15 min	0

Dynamic Values

Variable Name: V1

- Source Type: IMD
- Calc Function: Min

Variable Name: V2

- Source Type: Channel Statistics
- MC Type: MC_STATS_13MONTHS
- Value: Negative Count

Equation

$$V1 < 0 \text{ AND } V2 = 0$$

This equation detects negative usage on the current IMD while the prior 13 months shows no cases of negative usage.

Example 6: Abnormal usage

Historical Statistics

Statistics MC Type: MC_STATS_LASTMONTH		
Average	15 min	1.630
Standard Deviation	15 min	0.519

Statistics MC Type: MC_STATS_LASTYEAR		
Average	15 min	1.893
Standard Deviation	15 min	0.851

Dynamic Values

Variable Name: IMD_STD

- Source Type: IMD
- Calc Function: Standard Deviation

Variable Name: LM_STD

- Source Type: Channel Statistics
- MC Type: MC_STATS_LASTMONTH
- Value: Standard Deviation

Variable Name: IMD_AVG

- Source Type: IMD
- Calc Function: Average

Variable Name: LY_AVG

- Source Type: Channel Statistics
- MC Type: MC_STATS_LASTYEAR
- Value: Average

Variable Name: LM_AVG

- Source Type: Channel Statistics
- MC Type: MC_STATS_LASTMONTH
- Value: Average

Variable Name: LY_STD

- Source Type: Channel Statistics
- MC Type: MC_STATS_LASTYEAR
- Value: Standard Deviation

Equation

$$\text{IMD_AVG} \leftrightarrow 0$$

$$\text{AND ABS(IMD_AVG - LM_AVG)} < 0.5$$

$$\text{AND ABS(IMD_AVG - LY_AVG)} < 0.5$$

$$\text{AND ABS(IMD_STD - LM_STD)} > 1.5$$

$$\text{AND ABS(IMD_STD - LY_STD)} > 1.5$$

This equation determines that the average of the current IMD is close to the historical average but that the standard deviation is far off. This points to abnormal usage.

Example 7: Voltage threshold monitoring

Historical Statistics

None

Dynamic Values

Variable Name: VOLT_MAX

- Source Type: IMD
- Calc Function: Max

Variable Name: VOLT_MIN

- Source Type: IMD
- Calc Function: Min

Equation

$$\text{VOLT_MIN} < 117$$

OR

$$\text{VOLT_MAX} > 127$$

This equation determines if the voltage data in the current IMD has fallen below or exceeded the bounds that a utility needs to keep customer voltage within. This is usually set to values that catch incorrect voltage before the value drops below the regulatory requirement.

Ensure IMD Exists for Sibling MCs

This rule validates that an IMD exist for all of the other measuring components associated to the same Device Configuration as the current measuring component, for the same period of time.

A check is also performed that all of the Initial Measurements have the same External Source ID (indicating that they all came from the same usage file).

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-ENSIMDMC](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-EnsureIMDExistsForSibling

Final Measurement Replacement

This validation rule allows you to define a variety of configuration options to decide if new scalar or interval data should replace existing measurements. The options include value change thresholds, percentage change thresholds, as well as condition code ranking. One common use for this rule is rejecting trivial measurement changes to prevent very small changes for a bill from being sent to a customer.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-VLMSRCOND](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-FinalMeasurementValidation

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Example 1: Replacement of measurements based solely on value difference

KEY

- = Regular
- = System Estimated
- = No Read – System
- = No Read – Outage
- = Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Value Change
Value Change Tolerance	0.1
Percentage Change Tolerance	
Condition Code Prioritization by Groups	

Example 2: Percentage change to replace measurement

KEY	
■	= Regular
■	= System Estimated
■	= No Read – System
■	= No Read – Outage
■	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Percentage Change
Value Change Tolerance	
Percentage Change Tolerance	50
Condition Code Prioritization by Groups	

Example 3: Partial replacement of estimated data with regular data based on condition range prioritization

KEY	
■	= Regular
■	= System Estimated
■	= No Read – System
■	= No Read – Outage
■	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Value Change
Value Change Tolerance	0.1
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

Example 4: Partial replacement of regular data with outage data based on condition range prioritization

KEY	
■	= Regular
■	= System Estimated
■	= No Read – System
■	= No Read – Outage
■	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Value Change
Value Change Tolerance	0.1
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

Example 5: Super not replaced by regular (retain a smoothed spike)

KEY	
■	= Regular
■	= System Estimated
■	= No Read – System
■	= No Read – Outage
■	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System

Replacement Condition Value	No Read – System
Replace Manually Edited Data?	No
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	
Value Change Tolerance	
Percentage Change Tolerance	
Condition Code Prioritization by Groups	

Example 7: Allow replacement of manually edited data if the condition group is lower than new data

KEY	
■	= Regular
■	= System Estimated
■	= No Read – System
■	= No Read – Outage
■	= Super
⚙	= User Edited data

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	No
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	
Value Change Tolerance	
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

High/Low Check

This validation rule compares the total consumption of the current IMD to historical values. The comparison is normalized based on average daily usage (ADU). If the current IMD is too high or too low compared to historical data then an exception is thrown.

Numerous configuration options are provided including:

- A Historical Pre-Window and Post-Window that determines the number of days to check before and after the period being examined.

- Percentages to control how much of the historical data can be user edited, estimated, or non-normal data.
 - What type of historical data to look at first
 - What to do when an outage has occurred
-

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-HILO-CHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-VEERuleHighLowCheck

Inactive Measurement Check

This validation rule flags any Initial Measurement Data received on a device that is either disconnected, uninstalled, and/or not connected to a usage subscription.

- When the 'Check Measurements on Disconnected Device' flag is set to "Yes", the logic will compare the IMD measurements total to the threshold configured. If the total measurements are above the threshold, then logic compares the IMD dates to two things: 1) On/Off Dates related to the Install Event and 2) the Installation and Removal Dates of the Install Event. If the On or Off falls within the dates for an interval IMD, then the logic will only sum intervals that fall during the disconnected periods.
 - When the 'Check for Uninstalled Device' flag is set to "Yes", the logic will check for a valid Install Event based on the IMD dates.
 - When the 'Check for Missing Usage Subscription' flag is set to "Yes", the logic will check for an active Usage Subscription based on the IMD dates.
-

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-INACTVCHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-InactiveMeasurementCheck

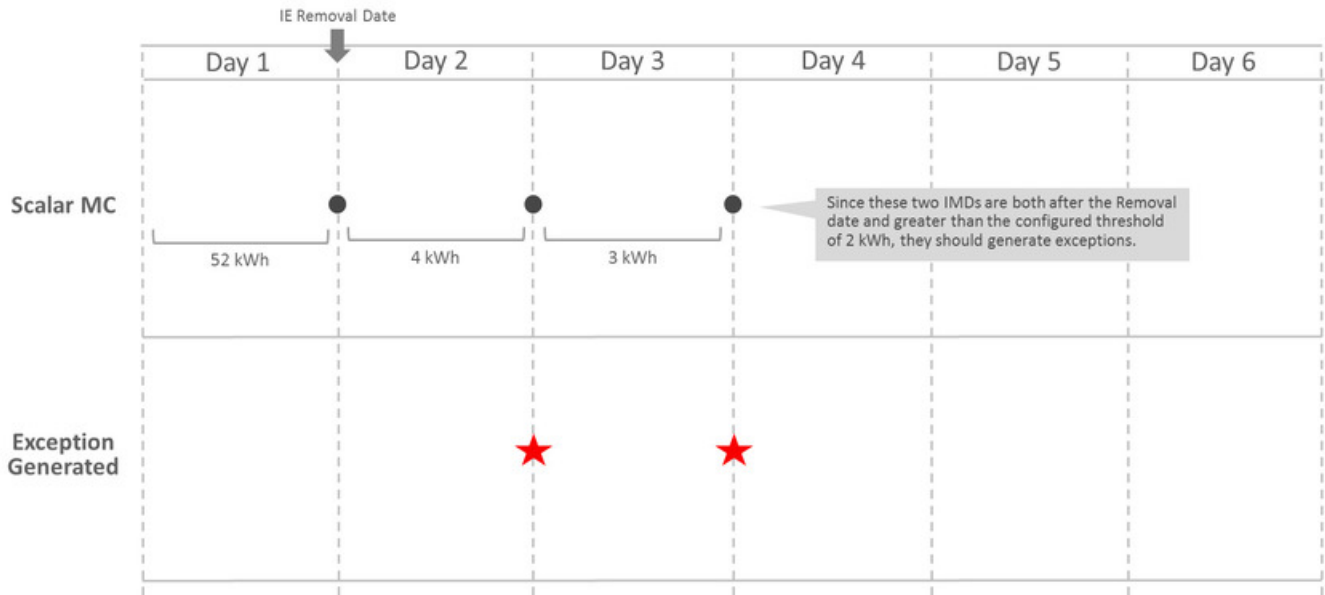

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Example 1: Non-zero data during disconnected period

Example 2: Non-zero data after removal date with no new install

Example 3: Data received when device has no Install Event records

Example 4: Data received when not connected to a Usage Subscription record

Interval Size Validation

This rule validates that the interval size (in seconds) supplied with the Initial Measurement is equal to the interval size defined on measuring component's type.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-INTSIZVAL](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalSizeValidation

Interval Spike Check

This rule looks for spikes by taking the highest interval and the third-highest interval, and determining the percent difference between the two. If the percent difference is larger than the tolerance configured on the rule, the algorithm logs an exception of the type and severity configured on the rule.

The rule can be executed in one of two modes (as configured on the rule):

- The spike check is performed for every 24-hour chunk of data in the initial measurement data set
- The spike check is performed for the entire initial measurement data set

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-INTSPKCHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalSpikeCheck

Multiplier Check

This rule validates that the register multiplier supplied with the Initial Measurement is equal to the multiplier stored on the measuring component.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-REGMULCHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RegisterMultiplierCheck

Negative Consumption Check

This rule checks if the total consumption of the IMD is less than zero. If the rule encounters negative consumption, an exception will be logged only if the related Measuring Component Type is not configured to "allow negative consumption".

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-NCON-CHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-NegativeConsumptionCheck

Prolonged Estimation Check

This validation rule can be used on either interval or scalar and will alert you when a device has been estimated for an extended period of time. The IMD must first fall within the condition code range configured on the rule for this to execute. Next the validation finds the 'Most Recent Non-Estimated Read Date Time' from the Measurement Component. If this date plus the 'Days of Estimation Allowable' from the VEE Rule is less than the IMD End Date then a Prolonged Estimation Exception is created.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-PROESTCHK](#) Algorithm Type.

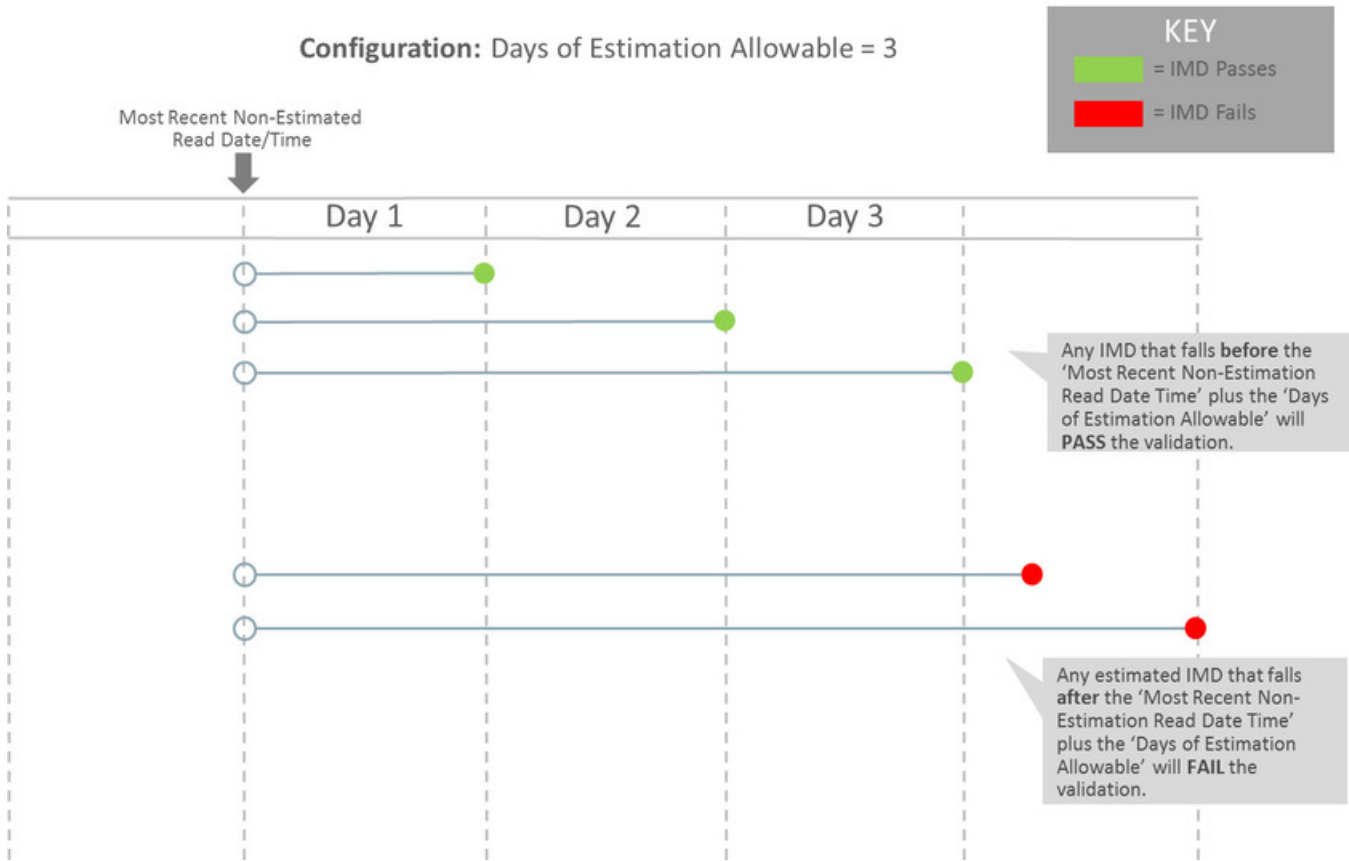

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProlongedEstimationCheck

Example Scenario

Below is an example scenario that can be achieved based on configuration of this rule.

Raise Missing Quantity Exception

This rule flags any missing interval data while providing a soft parameter on the algorithm to exclude a condition range if desired.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-RAIMISQTY](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RaiseMissingQuantityExcp

Sum Check

This rule evaluates whether consumption for the current Initial Measurement Data is within a tolerance of the sum of the consumption during the same period for any measuring components related to the current one. If the values are not within the defined tolerance of each other, and exception is logged.

The rule can be used to evaluate consumption totals for an interval measuring component that has a related scalar measuring component with the same UOM to ensure that the total consumption of the interval measuring component is within a tolerance of that of the scalar value. It can also be used to evaluate consumption totals for scalar TOU meters that have a "check" register (for example, three registers that measure ON-PEAK, OFF-PEAK, and SHOULDER, with a fourth check register that measures the total consumption).

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-SUM-CHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-SumCheck

Unit of Measure Check

This rule checks the unit of measure (UOM) passed in with the Initial Measurement against the primary unit of measure configured on the measuring component's type.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-UOMCHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-UOMCheck

Zero Consumption Check

This rule checks if the total consumption for the IMD is zero. There is also a check for whether an outage occurred during the same time as the zero consumption to provide ways to avoid To Dos by having a different exception type.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-ZEROCNCHK](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ZeroConsumptionCheck

Estimation VEE Rules

Interval Adjustment From Scalar

This rule adjusts interval Initial Measurement Data based on scalar values using one of two options configured on the VEE Rule. Both options require that a scalar measuring component be related to the current interval measuring component using the Consumption Reference Measuring Component, and that one or more final measurements be present for the related measuring component between the start and end date/times of the current Initial Measurement Data set.

1. Adjust all intervals. In this case, the scalar consumption provides a value that is then used to proportionally adjust all of the intervals in the set. The formula used is $(\text{Scalar Consumption} / \text{Total Initial Measurement Consumption}) * \text{Interval Amount}$. If the total of all of the intervals had been equal to zero originally, the rule adjusts all of the intervals to the same value.
 2. Adjust intervals based on condition. For this option, a range of conditions is configured on the VEE Rule, and the rule adjusts only those intervals with conditions that lie within the configured range. The adjustment is done by applying an adjustment factor to each of the intervals within range.
-

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-INTADJSCA](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalAdjustmentFrmScalar

Interval Averaging Estimation

The algorithm estimates when the current Measuring Component is eligible. Estimation is performed only if all these conditions are satisfied:

- The Measuring Component is interval.

- The Measuring Component is linked to a Service Point or the VEE Rule's Estimate If Not Attached to SP field is set to "Estimate".
- The Percentage of Missing Intervals is less than the VEE Rule's Maximum Percentage Missing Intervals Threshold.

The algorithm will compute the Total Accumulated Consumption and the Total Number of Intervals using a variety of methods including scanning holidays, similar days of the week, or neighboring days. Once a set of valid comparison days are found then these are used as the basis of creating estimated intervals for the current IMD.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-INTAVGEST](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalAveragingEstimation

Interval Create Estimation IMD for Gap

This rule is very different from other VEE rules in that it does not examine the current initial measurement but rather looks to see if there are any missing measurements prior to the initial measurement being processed (i.e. a gap exists). If so and the scenario meets the configured options it will generate an estimation initial measurement to fill in that gap.

This rule is intended to provide more real-time filling of missing measurements as opposed to running periodic estimation. However, it is still expected that periodic estimation will be used in conjunction with this rule such that any gaps that are not filled in by this rule would eventually be filled in by periodic estimation.

This rule can be configured to perform minimal validation of that gap that is identified and defer to the estimation initial measurement to validate against other initial measurements and final measurements that may overlap the gap. Conversely, it can also be configured to validate the gap and exclude any periods where a final measurement or in progress initial measurement overlaps the gap's duration.

NOTE:

This estimation rule acts differently from the other rules - it creates a new IMD rather than filling in missing values in an estimation IMD created from periodic estimations.

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-CREESTIMD](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-CreateEstimationIMDRule

Example Scenarios

The following are sample scenarios that can be achieved based on configuration of this rule.

Example 1: A 4-hour gap exists and the rule is configured to always fill gaps. Maximum hours are set to 4 and the gap fill is set to "always".

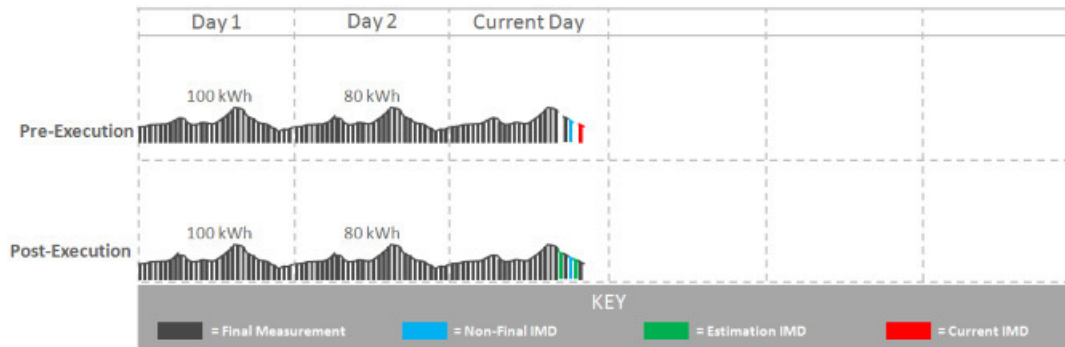

Since the maximum hours has not been exceeded and the rule is configured to always fill the gap, a 4-hour estimation IMD is created to fill the gap.

Example 2: A 4-hour gap exists and the rule is configured to always fill gaps. However, the maximum number of hours to fill is 3.

Since the gap is 4 hours long and the maximum hours to gap fill is 3 hours, no estimation has been created. An exception would be created if the rule were configured this way.

Example 3: A non-contiguous gap exists and the rule is configured to "Skip In-Progress IMDs and Final Measurements" with a maximum number of IMDs set to 2.

In this scenario:

- One interval in the 4-hour gap is covered by a final measurement.
- One interval in the 4-hour gap is covered by an in-progress IMD.
- Two estimation IMDs are generated one to fill each hour not covered by a final measurement or in-progress IMD.

Interval Interpolation Estimation

This rule attempts to interpolate gaps in Initial Measurement Data sets using prior and subsequent intervals as starting points for linear interpolation. A configuration parameter determines the maximum number of consecutive intervals within a gap before that gap can no longer be interpolated.

If a given gap lies at the beginning or end of the Initial Measurement Data set, this algorithm seeks out final measurements immediately before or after the set in an attempt to find two reference measurement values for interpolation. In this situation, assuming that the condition of the measurement retrieved lies in NEITHER of the algorithm parameter ranges you have configured (the measurement is neither "missing" nor an "outage"), this measurement value is then used as the basis for interpolation.

In the event that the gap is the entire length of the Initial Measurement Data set (and the VEE Rule is configured such that this is not too large of a gap), the routine attempts to find final measurements as described above.

If a valid measurement can be found for only one side of a given gap, the interpolation logic assigns each interval in the gap the same value - the value of the measurement retrieved. This is referred to as applying a "flat load".

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-INTINTEST](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalInterpolationEst

Interval Profile Estimation

This rule uses a profile measuring component's interval consumption as a source of values to assign to intervals in the current Initial Measurement Data set that are marked "missing" via the interval's condition. If the interval is marked with a condition indicating "outage", the algorithm skips it.

If a measurement is not available for the profile measuring component on the date/time, the interval is left unchanged.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-INTPROEST](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalProfileEstimation

Interval Proxy Day Estimation

This rule checks for days with similar temperature and uses the measurement data from those days as the basis of interval estimation for the in-flight initial measurement. [Measuring component comparison periods](#) are used as the main driver for determining similar temperature days.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-INTPROXY](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalProxyDayEstimation

Scalar Calculation From Interval

This rule calculates a single consumption amount for a scalar measuring component's Initial Measurement using the total consumption for the same date/time range for a related interval measuring component.

The scalar value replaces any existing value within the Initial Measurement (in the post-VEE list) and updates the condition to the value configured on the VEE Rule. This VEE Rule updates the condition to the value defined in "Condition Value for High Quality Condition" when the measurement condition value for all underlying interval data and the previous scalar measurement (when Evaluate Condition Of Previous Scalar Measurement is configured as "Yes") is greater than or equal to the "Minimum Condition Quality to Override" (If "Minimum Condition Quality to Override" is defined) otherwise it updates the measurement condition of the Initial Measurement Data to the condition defined in "IMD Created Condition Value".

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-SCACALINT](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarCalcFromInterval

Scalar Estimation

This rule uses historical data for the same measuring component to derive an estimated value for a scalar Initial Measurement. Depending upon a VEE Rule configuration parameter, the routine uses historical data from a month ago followed by a year ago, or vice-versa. If the data for the first historical period turns out to be usable, the second historical period will not be evaluated. Whether historical data qualifies for use in estimation is configured via the rule parameters in conjunction with the below algorithm parameters.

The rule rejects consumption from a historical period as unusable for estimation if too great a portion of the period is covered by final measurements that are not high-quality. The first pair of parameter values are used when evaluating the acceptable System-Estimated Percentage for historical periods as configured on the VEE Rule. Once an estimated value is calculated, the routine backs into a reading (which involves backing out multipliers and, if the measuring component is subtractive, adding the result to the prior reading).

An interim High/Low can also be configured on this rule.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-SCALAREST](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarEstimation

Scalar Profile Estimation

This VEE rule arrives at a scalar estimate by looking at final measurements for a profile measuring component covering the same date range as the current Initial Measurement. The profile measuring component to be used as a source of measurement data is defined via a profile factor on the rule. This rule is meant primarily for a configuration in which the profile measuring components are interval, although the profile could be scalar as well.

If a measurement already exists in the current Initial Measurement with a condition that lies within the ranges specified in the pairs of algorithm parameters for "system estimate" and "regular", the routine does not attempt to estimate.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-SCAPROEST](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarProfileEstimation

Scalar Proration

This rule prorates the value of a scalar reading that has two valid scalar readings on either side as boundaries.

If the scalar MC does have a related interval MC and 'Minimum Related Measurement Condition' is defined the algorithm will take into consideration any intervals during the proration period that meet a minimum condition quality defined by the 'Minimum Related Measurement Condition' when performing the proration. This is to keep the prorated scalar estimates in sync with any existing interval measurements. To do this the algorithm will augment the total duration and total quantity being prorated by the related interval MC's qualifying measurements. For example, take the following scenario:

- Scalar proration is executing for a scalar IMD for 01/01 12:00 AM - 01/02 12:00 AM (24 hours)
- The subsequent measurement is for 150 kWh and has a measurement date/time of 01/04 12:00 AM (72 hours)
- The related interval MC has measurements on 01/03 12:00 AM to 01/04 12:00 AM totally 100 kWh (24 hours)

Therefore the result of the calculation for the scalar IMD from 01/01 12:00 AM to 01/02 12:00 AM would be 25 kWh. Since the interval measurements covered 24 of the 72 total hours of the 150 kWh that would leave 50 kWh to be split among the remaining 48 hours. Which leaves 25 kWh for 01/01 12:00 AM to 01/02 12:00 AM and 25 kWh for 01/02 12:00 AM to 01/03 12:00 AM.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-SCLRPRORT](#) Algorithm Type.

Business Object

D2-ScalarProration

Subtractive Interval Adjustment Rule

This rule adjusts qualifying consecutive intervals for a subtractive interval initial measurement (IMD) based on the known consumption between a set of actual readings. The readings can either be leveraged from other intervals within the IMD or from the final measurements when there are no suitable readings within the IMD. The adjustment is done by applying an adjustment factor to each of the qualifying intervals.

The rule supports adjusting multiple sets of qualifying consecutive intervals by calculating a consumption adjustment target and adjustment factor specific to each set of consecutive qualifying intervals.

Intervals are considered to be qualified for adjustment based on condition. A range of conditions is configured on the VEE Rule, and the rule adjusts only those intervals with conditions that lie within the configured range.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-SUBINADJV](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Decision-Making VEE Rules

Exception Handler

This rule allows you to terminate the VEE process based on a configurable set of exceptions being present for the IMD. This rule also allows a unique To Do Type to be generated based on a group of exceptions.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D1-AVEER-EEH](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleExceptionHandler

Execute VEE Group

Many implementations need to execute a group of validations for any data being received. For example, you might want to perform device identifier validations, multiplier checks, and UOM checks on all measuring components. One inefficient way to meet this requirement would be to repeat these three rules in multiple VEE groups. However, this solution becomes hard to maintain if changes to the rules are required (or if new "global rules" are introduced) as each group would have to be updated. Instead of this, you can use the "Execute VEE Group" rule to execute a referenced VEE Group. Using the example

above, you could create a group called "Rules for All MCs" that contains a device identifier validations rule, a multiplier check rule, and a UOM check rule, and then reference the "Rules for All MCs" group in a Execute VEE Group rule.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D1-AVEER-RFG](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleReferredVEEGroup

Successful Termination

This rule allows VEE to be successfully terminated based on a list of exceptions.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D1-AVEER-EST](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleSuccessTermination

VEE Group Matrix (Factor)

Another situation likely to occur in many implementations is where specific rules may need to be applied to measurement data based on specific criteria, such as geography. For example, some geographic territories may have unique VEE Rules in addition to rules that are applied to all geographic territories. The "VEE Group Matrix (Factor)" rule allows for a Factor to determine which VEE Rule gets executed based on defined characteristics.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D1-AVEER-FCT](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleGroupFactor

Prerequisite Setup

Since the prerequisite setup items for this rule are more involved, the following procedure describes these in detail:

1. Create the Characteristic Type and Values to be used by the factor that will be referenced by the rule.
 2. Create the Characteristic Source Algorithm to be used by the factor that will be referenced by the rule.
 3. Create the VEE Groups to be associated to the characteristic values.
 4. Create the Factor that will be referenced by the rule.
-

5. Create the Factor Values for the factor, each referencing an effective-dated characteristic value/VEE group pairings.
6. Create the rule, referencing the factor

Measuring Component Statistics

Understanding Measuring Component Statistics

Oracle Utilities Meter Data Management provides a way to stage statistics for Measuring Components in order to speed up VEE processing. These statistics are primarily meant for use in conjunction with the [Dynamic Comparison Validation](#) VEE Rule, but could also be generated for other analytics or reporting.

Some of the potential benefits of using Measuring Component Statistics are:

- Reduce the data volume for VEE queries by up to 1000 times (this is most beneficial when replacing VEE Rules that query historical data such as High/Low)
- Offload heavier processing of historical data to "system downtimes" - potentially nights or weekends

Below is an overview example of how Measuring Component Statistics can be implemented along with the Dynamic Comparison Validation:

The steps for pre-staging Measuring Component Statistics are detailed below:

1. A Physical Measuring Component is created. The algorithm to trigger the creation of Statistics Measuring Components is only set on Interval or Auto-Read Scalar BOs as part of base product.
2. New Statistics Measuring Component are created and linked to the Physical Measuring Component.
3. The Measuring Component Historical Statistics Batch ([DI-MCHS](#)) is run based on the schedule you've defined. The suggestion is to run this either nightly or on the weekends during quieter times for overall system processing.
4. A measurement is created for the Statistics Measuring Component that holds historical statistics related to the Physical Meter for a specific period of time (in this example it's set for 13 months).

The steps for how VEE can take advantage of Measuring Component Statistics are detailed below:

1. IMDs are received from the Head End.
2. The [Dynamic Comparison Validation](#) VEE Rule is configured to execute for the meter. This validation uses the historical statistics from the Statistics Measuring Component in order to perform its validation logic.
3. An exception and potentially a To Do is generated based on the failure of the VEE rule.

Storage Impact from Statistics

Much consideration was given to the storage implications when designing Measuring Component Statistics. Below is an outline of the storage impact to customers who choose to calculate and store Channel Statistics. An example impact to a utility with 1 million Physical Meters (each with 4 channels of information) is shown in the far right column:

Area	Additional Data in MDM	Example Impact <small>(assuming utility has 1 million Physical Meters)</small>
Additional MCs <i>Assumption: Statistics are only configured on the primary billing channel MC Type for the majority of your Physical Meters.</i>	1-3 extra MCs per Physical Meter <i>Assumption: customers will only configure Statistics on their primary billing channel MC Type for the majority of their Physical Meters.</i>	1 - 3 million extra MCs <i>This increases the Measuring Component table by an extra 25% to 75% from its size without statistics.</i>
Additional Measurements <i>If 'Statistics Retention Mode' configured as "Only Retain Most Recent Record".</i>	1 extra Measurement per Physical Meter	1 - 3 million extra Measurements for the life of MDM <i>This data is a minuscule fraction compared to the overall AMI data footprint.</i>
Additional Measurements <i>If 'Statistics Retention Mode' configured as "Retain Historical Records".</i>	1 extra Measurement per Physical Meter per week	1 - 3 million extra Measurements per week (52-156 million per year) <i>This data is 0.2-0.5% of the size of the AMI data collected in that same week.</i>

Configuring Measuring Component Statistics

Measuring Component Types

In order to start generating Measuring Component Statistics, two different configurations must occur for [Measuring Component Types](#):

- New Measuring Component Types must be configured that leverage the **Channel Statistics Type** business object. These should be setup as the periods for which Measuring Component Statistics should be calculated. For example, if you would like to be able to reference both last month, last year, as well as the past 13 months as statistics periods, then 3 different Channel Statistics Types must be setup for this. These could be setup as follows:
 - "Last Month" Channel Statistics Type:
 - Period End Lag Days = 0
 - Period Start Lag Days = 30
 - "Same Month Last Year" Channel Statistics Type:
 - Period End Lag Days = 365
 - Period Start Lag Days = 395
 - "Prior 13 Months" Channel Statistics Type:

- Period End Lag Days = 0
- Period Start Lag Days = 395

NOTE: *it's recommended to set the Statistics Retention Mode to "Only Retain Most Recent Record" on the Channel Statistics Type to reduce the amount of data being stored in Oracle Utilities Meter Data Management.*

- For a Physical Measuring Component Type leveraging either "Interval Channel Type" or "Register - Auto-Read Type", the **Related Statistics Measuring Component Types** section must be filled in with the appropriate types that should be created for the Physical Measuring Component.

VEE Rule

If you have a desire to leverage Measuring Component Statistics for VEE, the [Dynamic Comparison Validation VEE Rule](#) section should be referenced. A number of detailed examples of how to implement this rule are provided in this section as well.

Related Batch Controls

There are a few batches directly involved with Measuring Component Statistics:

- **Measuring Component Historical Statistics (D1-MCHS)**: this batch monitors any active Statistics Measuring Components to execute the logic for calculating a new set of historical statistics.
- **Statistics Measuring Component Creation (D1-STMCC)**: this batch is used to create Statistics Measuring Components on any Physical Measuring Components that were created prior to configuring this module. This is especially useful for existing customers that want to implement Statistics Measuring Components for all of their devices.

NOTE: Refer to [Understanding Measuring Component Statistics](#) for more information.

Defining Usage Options

This section describes concepts and common tasks related to usage administration.

The Big Picture of Usage Requests

Oracle Utilities Meter Data Management is used by some organizations who use a meter data management (mdm) system to record meter reading information. Since meter reads are not available in Oracle Utilities Customer Care and Billing to calculate consumption during the billing process, usage (or bill determinants) must be requested by Oracle Utilities Customer Care and Billing from the mdm system, Oracle Utilities Meter Data Management.

The following sections describe how the base-package usage request process works.

Requesting Bill Determinants

The term bill determinant request is another way to refer to a usage request. These usage requests are created during the batch billing process, and also when a user generates an online bill segment or performs cancel / rebill. The get consumption algorithm specified on the SA Type's Bill Segment Type is responsible for creating the usage request.

Online Billing Usage Requests

Usage Request Lifecycle

The usage request business object (BO) contains the rules that govern the processing of a usage request. The base product provides the BO C1-UsageRequest which serves as a parent BO and contains the following lifecycle:

- All usage requests are created in the initial Pending state. If the usage request was created from the batch billing process, the batch Usage Scheduled Monitor Process must be executed to transition the usage request.
- If there are pending sync requests for the usage request's service agreement, the usage request is held in the Awaiting Data Sync state until the sync is processed.
- Once all pending sync requests related to the usage request have been processed, the usage request transitions to the Send Request state. An enter algorithm on this transitory state is responsible for sending the usage request to Oracle Utilities Meter Data Management (MDM).
- usage request sits in the Awaiting Bill Determinants state until a response is received from MDM, or a time out is encountered.
- When a response is received from , the usage request is transitioned to either the Bill Determinants Received state, or the Error state. In the case of an error, the following occurs:
 - If the usage request was created from the batch billing process and the billing window is still open, a new usage request will be created the next time billing runs and the process is repeated. If however, the billing window is no longer open, a to do entry is created for manual follow up.
 - If the usage request was created from an online billing process, the user will be notified. The bill segment remains in the error state and the user can either delete the bill segment, or attempt to generate it again. If the bill segment is regenerated, a new usage request is created and the process is repeated.
 - The system transitions usage requests in the Bill Determinants Received state to the Bill Determinants Processed state. An enter algorithm on this final state is responsible for generating the bill segment. If the usage request was created from the batch billing process, the bill segment is frozen and the bill is completed. For online billing usage requests, the user is responsible for freezing the bill segment and completing the bill.

Summary Billed Accounts and Usage Requests

A "summary" account refers to an account with service agreements that cover more than one premise. If these premises are linked to service points that span different routes scheduled for reading on different dates, there's no guarantee that all the account's SAs will be billed at the same time. This is because batch billing for manually read meters is based on the meter's scheduled reading date.

For example, assume a summary account has two SAs each linked to a different premise. One is on route X, scheduled for reading every first of the month and the other is on route Y, scheduled for reading every 20th of the month. Assume that the account's bill cycle is cycle X (which matches the schedule of premise/SP on route X). When billing runs on the first of the month, the service agreements tied to route Y won't have any reads. And because route Y is not scheduled for reading, the system will not estimate the consumption. Instead, it will skip billing the route Y SAs until the next month. This means some SAs are always one billing cycle behind.

Requesting Bill Determinants for Summary Billed Accounts

Usage requests for summary billed accounts are handled as follows:

- On the first night of the billing window usage requests are created for each SA and sent to Oracle Utilities Meter Data Management (MDM). MDM then checks what the next schedule read date is for each service point.

- Assuming Oracle Utilities Meter Data Management owns meter read schedules; when batch billing executes Oracle Utilities Customer Care and Billing (CCB) cannot determine whether a summary account's service agreement should be included on the bill or not.
- If MDM determines that an SA/usage subscription should be skipped from billing, it notifies CCB by including a skip indicator and reason on the usage response, as well as the SA's next scheduled read date. This date is captured as a **MDM Next Scheduled Read Date** characteristic on the SA, and the usage request is cancelled. The system still attempts to complete the bill since this might be the last outstanding usage request for the bill
- When billing next runs, the base *Get bill segment consumption using a usage request* algorithm first checks if the SA should be skipped as follows (Note that this check is also performed in first billing run):
- Get the **MDM Next Scheduled Read Date** characteristic on the SA. If this date is after the bill segment end date, we'll skip the SA from billing

If your implementation would like to wait until the bill cycle window end date before attempting to complete summary account's bills, ensure that the **Complete Bill at End of Bill Cycle** pre-bill completion algorithm is defined on customer class. This is useful if scheduled reads are expected in the bill cycle window, but not necessarily on the window start date.

Corrected Read Notifications

If a read that was used for bill determinant calculations is modified in the mdm system, notification is sent to Oracle Utilities Meter Data Management.. Resulting in the creation of an off cycle bill generator. The system uses the business object defined as the OCBG Corrected Read BO MO option on the Off Cycle Bill Generator maintenance object to create the OCBG.

What happens next depends on the lifecycle that your implementation has configured for the OCBG Corrected Read BO. Here are examples of what might occur:

- Create a To Do entry for manual follow up.
- Find any frozen bill segments that might be affected by the corrected read and perform cancel/rebill.

Configuring The System For Usage Request Integration

Oracle Utilities Customer Care and Billing sends usage requests to Oracle Utilities Meter Data Management (MDM) in the form of an xml message. MDM sends responses back to Oracle Utilities Customer Care and Billing.

The following sections describe at a high level the data setup required to send usage requests to

Start and End Times for Billing

As you know, there is logic in billing to determine the start date and end date for a bill segment. Refer to [Ways To Control The Start Date Of A Bill Segment](#) and [Ways To Control The End Date Of A Bill Segment](#) for more information. When billing for a customer with interval data, the system also needs to know the time.

The time used by billing, referred to as the cutoff time, is stored on the service agreement. There is also a control on the service agreement called Start Day Option that determines which day to use for the start time. Billing uses the billing date, the cutoff time, and the start day option to determine the correct interval data to process.

Oracle Utilities Customer Care and Billing lacks knowledge of the type of meter installed at a service point. Thus, both interval processing period as well as scalar processing information is captured on a usage request. Oracle Utilities Meter Data Management (MDM) then uses the appropriate period to calculate bill determinants based on the type of meter installed.

MDM returns the true usage period used to calculate bill determinants on the usage response. This usage period is captured on the bill segment.

The Big Picture of Time of Use Mapping and Pricing

This section provides an overview of the concepts related to setting up your control tables to support time of use mapping and pricing with the rates.

NOTE: Time of use mapping is supported to enable low volume interval data manipulation (for example, for mapping electric vehicle charging events into time of use quantities). A meter data management application, such as Oracle Utilities Meter Data Management, must be used to manipulate high volumes of interval data and calculating bill determinants for billing purposes.

Mapping to Time of Use (TOU) Periods

Many customers choose not to price their interval data using interval prices. Customers may choose for their interval data to be mapped into time of use (TOU) periods. This option for interval data might be preferred because:

- Typically it involves fixed prices for the use periods
- It is more manageable than direct billing
- It is easier for a customer to forecast and budget

A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times). The TOU Map has a TOU Map Type, which defines the interval size between TOU map data rows.

Time of use periods can (and often do) change during the year.

Map #123 (TOU Group 2)	
Effective 1 Jan 2000	
Interval Date/Time	
30/Apr/00 16:30	On Peak/Winter
30/Apr/00 16:45	On Peak/Winter
30/Apr/00 17:00	Off Peak/Winter
30/Apr/00 17:15	Off Peak/Winter

01/May/00 7:45	Off Peak/Summer
02/May/00 8:00	On Peak/Summer
02/May/00 8:15	On Peak/Summer

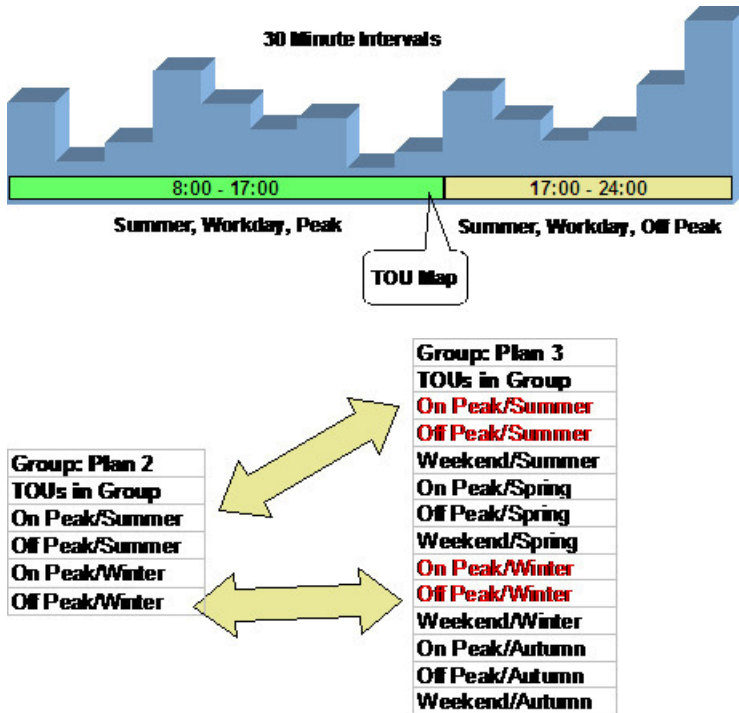

All the possible TOU codes for a given map are grouped together in a TOU group. Refer to [Grouping of TOU Codes for TOU Mapping](#) for more information.

Grouping of TOU Codes for TOU Mapping

This section describes the relationship between TOU Codes and TOU Mapping.

Overview of TOU Codes and TOU Mapping

A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times).

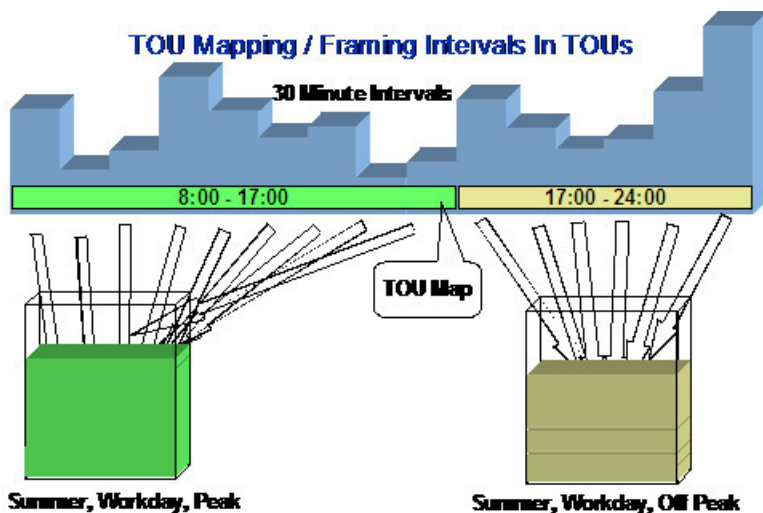

TOU Sequence for TOU Mapping and Pricing

If desired, you may use sequence number to indicate the relative position or relative priority of each TOU code within a TOU group. This sequence number is not used by any system functionality, but is available for you to use in a plug-in algorithm.

Time of Use (TOU) Mapping and Pricing

The following section describes the logic used by the system to map an interval data curve to TOU periods using a TOU map, and subsequently apply prices to these mapped quantities.

At some point during billing, the system will take an interval data curve and will map the interval values to TOU periods based on a TOU Map. The interval data curve is retrieved from either a specific usage request or from the new rate engine buffer populated prior to calling the rate engine.

This type of data manipulation is typically handled using a calculation rule based on the 'math' calculation rule type.

Once the interval data curve values have been mapped to TOU periods, prices can be applied to the time of use period quantities using calculation rules based on the 'service quantity' calculation rule type.

Calculation Rules for TOU Mapping & Pricing

Calculation Rules are used to perform time of use mapping and time of use pricing.

Time of Use Mapping

Time of use mapping will be typically handled using a calculation rule based on the 'math' calculation rule type. Calculation rules of this type can perform many functions. Two examples include:

- Applying a TOU map to an interval data curve to produce service quantities that will be added to the bill segment's SQ collection.
- Applying a TOU map to a derived interval data curve. For example, after deriving the power factor curve, perform TOU mapping on the resultant curve.

For further details on the 'math' calculation rule type, refer to [Base Package Math Calculation Rule](#) for more information.

Time of Use Pricing

Time of use pricing will be typically handled using calculation rules based on the 'service quantity' calculation rule type. Calculation rules of this type can perform many functions. For example:

- Add or update a service quantity in the bill segments SQ collection
- Create bill calculations lines that levy charges based on some type of consumption. For example, applying a price to a specific service quantity in the bill segment's SQ collection

For further details on the 'service quantity' calculation rule type, refer to [Base Package Service Quantity Calculation Rule](#) for further information.

NOTE: Calculation rules are implemented using algorithms that contain the logic to be performed. If your implementation requires a new type of calculation rule, you can configure a new calculation rule type and reference the appropriate algorithm on it.

TOU Map Used For Mapping

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule.

Attributes of TOU Maps

TOU map types define attributes shared by TOU maps of a given type. The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting.

Designing Your Time of Use (TOU) Mapping and Pricing Options

This section provides an overview for designing your control tables to support time of use (TOU) mapping and pricing with the new rating engine.

Designing Your Time Of Use (TOU) Mapping and Pricing Calculation Rules

As you know from the rates chapter, the system can handle mapping of interval data curve values into different time of use periods and pricing these quantities using the 'math' and 'service quantity' calculation rule types respectively. Refer to [Base Package Calculation Rule Descriptions](#) for more information.

The following guidelines provides a high level outline on how you should go about designing a rate schedule that involves time of use mapping and pricing.

- Obtain copies of existing bills that use the rate in question. If the rate is new, then write up exactly how the information should appear on the customers' printed bills.
- Identify all the lines that represent charges for individual time of use periods.
- Determine how the quantities for the time of use periods are calculated. Which time of use map is used to define the time periods?
- In order to perform time of use mapping and pricing, calculation rules need to be designed
 - A calculation rule based on the 'math' calculation rule type may be used to map an interval data curve into time of use periods. This calculation rule must know the TOU map to apply to the interval data curve to map into the relevant time of use periods. The time of use period quantities are populated in the bill segments SQ collection.
 - Calculation rules based on the 'service quantity' calculation rule type may be used to apply prices to each mapped time of use period quantity. These calculation rules each require either a price or regular bill factor for pricing each time of use period quantity. The bill factor may contain the price directly, or may indicate that the price is customer specific and can be found as contract quantities for the service agreement.

Once you have your calculation rules designed, you will be able to design the other control tables needed to set up your time of use billing customer.

Designing Your TOU Codes for TOU Mapping

The next most logical step in designing your time of use mapping controls is to define your time of use codes. To do this, look at the time of use periods to which your usage needs to be mapped. These values will likely correspond to the time of use quantities that your rate bills for. It should be noted that it's possible that will not bill for every time of use period.

Designing Your TOU Groups for TOU Mapping

To further aid in designing time of use mapping, the TOU Group enables you to group together all the time of use codes that are available to be used in a single map. You must also decide if you want to use a sequence number to define the relative order of a TOU code within a TOU group.

When TOU data is created for a TOU map, only TOU periods defined on a specified TOU group can be specified.

Designing Your TOU Map Types for TOU Mapping

Now that you have your TOU groups defined, you can begin defining TOU map types. Recall that the TOU map type defines the attributes that may be shared by TOU maps of the same type.

The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting. Refer to [Designing Your Time Options](#) for more information.

TOU Map Type Interval Size

The interval size of a TOU map must divide evenly into the interval size of the interval data curve that uses the map (because the system joins the date/time of the interval data curve values to the date/time of the TOU data). This means that it is possible to use a 15 minute TOU map with a 60 minute interval data curve. However, it is not OK to have a 60 minute TOU map used with a 15 minute interval data curve because the join will miss 3 out of 4 interval data curve values.

TOU Map Type Override Template

While most TOU maps will use the TOU map template defined on the TOU map type, TOU maps also support override templates. Refer to [Designing Your TOU Map Templates](#) for TOU Mapping for more information.

- A TOU map's TOU map type defines the default TOU map template that's used to generate its TOU data.
- A TOU map's type defines the TOU map templates that can be referenced on individual TOU maps to override the default template.
- An individual TOU map can have override templates. If the TOU map doesn't have an override template, the default template defined on the TOU map type is used to generate the map's TOU data.

Refer to [Creating TOU Map Types](#) for further information.

Designing Your TOU Map Templates for TOU Mapping

In order to help your users to create and maintain data for TOU maps, you may define TOU map templates, which can be used to generate data for a TOU map. The templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates.

Every TOU map references a TOU map template that defines the rules for generating TOU data from that TOU map. Specifically, TOU map templates define:

- The TOU group (defines the valid TOU periods for the template) used for the TOU map
- The default TOU period used for periods not explicitly defined. (This means you don't have to specify dates and times for all periods. For example, if your default TOU period is "Off Peak" you only need to define dates and days and times for On Peak or other TOU periods.)
- The specific date ranges, days of the week, and time periods designated for each TOU period. The system periodically generates TOU map data for TOU maps by interpreting the rules defined in the template.

Holidays

Many utilities categorize consumption on holidays differently than on the day of week on which the holiday falls. For example, holiday consumption might be categorized as Off-Peak regardless of the day it falls on. TOU map templates can define rules for different TOU periods for holidays by specifying the following:

- A Work Calendar that defines when holidays start and end
- Either:
 - A Holiday TOU period for consumption on holiday
 - A Holiday TOU Map Template that defines the TOU codes to use for different times in the year

TOU Map Template Interval Size

TOU map templates can also specify an interval size. This value specifies the duration of the individual TOU map data records, and also controls the values allowed in the Start and End Times. For example, if a TOU map template sets the interval size at 15 minutes, Start and End times must be in units of the interval size (10:00, 10:15, 10:30, etc.).

A TOU map template can be used to generate TOU map data for TOU maps whose interval size is divisible by the template's interval size. For example, a 60 minute template can be used to generate TOU data for TOU maps with an interval size of 60 minutes, 15 minutes, 5 minutes, etc. This means separate map templates are not needed for every interval size.

Refer to [Creating TOU Map Templates](#) for further information.

Setting Up Time of Use (TOU) Mapping and Pricing Control Tables

This section provides an overview of setting up your control tables to support time of use mapping and pricing with rates.

Creating TOU Map Templates

TOU map templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates and used for TOU map data generation.

Prerequisites: You must define TOU groups and work calendars before you can create TOU map templates. Refer to the Oracle Utilities Application Framework online help for more information about creating work calendars.

To define a new TOU map template, follow these steps:

1. Select If your system supports more than one TOU map template business object, you will be prompted to select a business object for this TOU map template.
2. Enter a name and a meaningful description for the TOU map template.
3. Select the TOU group to be used by the TOU map template.
4. Select the default TOU for the TOU map template (from the TOU Group). This is the TOU used when creating TOU map data for dates not accounted for in the TOU Schedules section.
5. Select the work calendar for the TOU map template. Work calendars define the days of the week on which work is performed, and specify holidays.
6. Select the holiday TOU for the TOU map template (from the TOU Group).
7. Select the TOU map template used for holidays (if applicable).
8. Specify the interval size for TOU map data created from the map template. Interval size is designated as hours:minutes:seconds (HH:MM:SS)

9. To specify TOU schedule's date ranges and which TOUs should be used for this TOU map template, click the + or - sign in the TOU Schedule Section and enter or select the following:
 - Start and End Dates for a specific date range
 - Start and End Days of the Week: To add or remove Start and End Days of the Week pairs, click the + or - sign and select the appropriate weekdays
 - Start and End Times: To add or remove Start and End Times within a Start and End Days of the Week pair, click the + or - sign and enter the appropriate times
 - TOU
10. Click **Save**.

Now you can use the TOU map template when creating TOU types.

Creating TOU Map Types

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule. TOU map types define attributes shared by TOU maps of a given type.

Prerequisites: You must define TOU map templates and time zones before you can create TOU map types. Refer to the Oracle Utilities Application Framework online help for more information about creating time zones.

To maintain existing TOU map types, select then use standard actions to edit, duplicate, or delete a TOU map type.

To define a new TOU map type, follow these steps:

1. Select

NOTE: If your system supports more than one TOU map type business object, you will be prompted to elect a business object for this TOU map type.

2. Enter a name and a meaningful description for the TOU map type.
3. Select the business object to use when creating TOU maps of this type
4. Select the time zone for the TOU map type.
5. Specify the interval size for TOU map data created from the map type. Interval size is designated as hours:minutes:seconds (HH:MM:SS)
6. Select the default TOU map template for the TOU map type
7. To add or remove override TOU map templates for this TOU type, click the + or - sign in the Override TOU Map Templates section and select the TOU map template.
8. Click **Save**.

Now you can use the TOU map type when creating TOU maps.

Usage Subscription Types

Understanding Usage Subscription Types

Usage Subscription Types define a collection of properties defining a class of Usage Subscriptions. Usage Subscription types also control valid values for various attributes of Usage Subscriptions.

For a deeper functional understanding, refer to the [About Usage Subscriptions](#) or [About Usage Calculation](#) sections .

Configuring Usage Subscription Types

This portal is used to display and maintain a Usage Subscription Type.

Refer to [Understanding Usage Subscription Types](#) for more information.

You can access the portal from the .

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Subscription Type List:** displays all of the Usage Subscription Types so you can choose the one you want to display in more detail
- **Usage Subscription Type:** shows the specific configuration for the selected Usage Subscription Type

The Usage Subscription Type defines a number of lists for "valid" objects that can be used in conjunction with the overall usage calculation process:

- Valid Service Point Types
- Valid Usage Recipients
- Valid Usage Calculation Groups
- Valid Dynamic Option Types

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_US_TYPE](#).

Integrating Usage Transactions

Requesting Usage Transactions

Usage transactions can be created via a request from the billing process.

To invoke a usage transaction request, the billing process invokes a Usage Transaction Request Inbound service script which invokes the Usage Transaction Seeder (D2-UsgTranSeeder) business object. This business object does the following:

- Determines the usage subscription ID based on an external usage subscription ID
- Determines the appropriate usage transaction business object to create. This uses the "How To Create Usage Subscription Related Information" processing method defined for the "Usage Transaction Creation" processing role on the service provider that represents the external system.

For a deeper functional understanding of Usage Transactions, refer to the [About Usage Transactions](#) section.

Processing Usage Transactions

In Oracle Utilities Customer To Meter, usage transaction information, including bill determinants and other data is requested and "sent" to the billing process.

Usage transactions are sent when they enter the "Sent" state via a number of Enter algorithms on the base package usage transaction business object (D2-UsageTransaction) .

- The "Send Usage" (D2-SEND-USG) algorithm determines the method used to send the information, based on the Usage Recipient (service provider) defined on the usage transaction's Usage Subscription (in most cases, Customer To Meter).

- The “Send Usage Response” (X1–SENDUSGRP) algorithm sends a response to the billing process, and transitions the related usage request to its next state.
- The “Transition Related Usage Request from UT” (X1-TRNUSGREQ) algorithm transitions the related usage requests in the “Awaiting BD” state to its next state (if the usage transaction had been previously stopped at a non-final status (such as Approval In Progress)).

Usage transactions can be sent via either online real-time processing or periodically via batch processing.

Online Real-Time Processing

To set up the service provider to support online real-time notification of usage transactions, do the following:

- Create one or more Outbound Message Types that reference the outbound message business object to be used to send usage transaction information to the billing system. The base package include the following business object for Usage Transaction Outbound Message (X1-UsageTranOutboundMesg).
- Define a Message Sender that will be used to send the message to the external system.
- Add the outbound message type to the service provider's External System and reference the Message sender created above.
- Add a processing method to the service provider as follows:
 - **Processing Role:** Usage Transaction Notification - Online
 - **Processing Method:** How To Send US Related Information
 - **Status:** Active
 - **Default Processing Method:**
 - **Outbound Message Type:** the outbound message type created above
 - **Override Processing Method:** outbound message types for specific usage subscription types if applicable

For a deeper understanding of integrating usage transactions with , refer to the [Configuring the Bill Determinant Interface](#) in the Interface section.

Batch Processing

Requests from the billing process that have been indicated as "batch requests" (such as those produced by Oracle Utilities Customer Care and Billing batch billing process) accumulate in a "calculation deferred" state to be processed specially by the **Usage Transaction Calculate Defer Monitor** batch control (D2-UTCD).

To set up the service provider to support periodic batch processing of usage transactions, use a periodic monitor batch control. These batch programs should invoke the business objects that will contain the usage transaction information. The base package includes the following business object for this: Usage Transaction Outbound Message (D2-UsageTranOutboundMesg).

Next, setup the following configuration:

- Add a processing method to the service provider as follows:
 - **Processing Role:** Usage Transaction Notification - Batch
 - **Processing Method:** How To Send US Related Information
 - **Status:** Active
 - **Default Processing Method:**
 - **Batch Control:** the batch control created above
 - **Override Processing Method:** batch controls for specific usage subscription types if applicable

Errors encountered when processing Usage Transactions can be reprocessed with the following batches:

- Reprocessing usage transaction "seeders" in error ([D2-UTSED](#))
- Reprocessing usage transactions in error ([D2-UTID](#))

If unexpected errors occur that leave usage transactions in an unmonitored state, the **Usage Transaction Monitor** batch control ([D2-UT](#)), or one based on this batch control with parameter values tailored to any specific requirements, can be used to process those usage transactions.

For a deeper functional understanding of Usage Transactions, refer to the [About Usage Transactions](#) section.

Generating Usage Transactions in Oracle Utilities Meter Data Management

There may be some cases where Usage Transactions should be generated in Oracle Utilities Meter Data Management rather than requested from an external system. Generation of these usage transactions are scheduled around the time when the meter installed on the service point is read.

Base product delivered a batch program that reads all pending measurement cycle schedule routes with selection date on or before the business date and creates as SP measurement cycle schedule route business object instance that stages the creation of these usage transactions.

For additional details refer to the batch control ([D1-CSPSR](#)) and business object ([D1-SPMsrmtCycScheduleRoute](#)).

Usage Transaction Exception Types

Understanding Usage Transaction Exception Types

Usage Transaction Exception Types define the groupings of exceptions for a Usage Transaction based on their functional similarity. This provides a way to define Usage Transaction Exceptions in a distinct enough way to understand the root issue that was generated from the usage calculation rule.

For a deeper functional understanding of Usage Calculation, refer to the [About Usage Calculation](#) section.

Configuring Usage Transaction Exception Types

This portal is used to display and maintain a Usage Transaction Exception Type.

Refer to [Understanding Usage Transaction Exception Types](#) for more information.

You can access the portal from the .

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Transaction Exception Type List:** displays all of the Usage Transaction Exception Types so you can choose the one you want to display in more detail
- **Usage Transaction Exception Type:** shows the specific configuration for the selected Usage Transaction Exception Type

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_USAGE_EXCP_TYPE](#).

Usage Calculation Groups

Understanding Usage Calculation Groups

Usage calculation groups are collections of usage calculation rules that are used to either calculate bill determinants or validate bill determinants. During the usage transaction process, the system executes the usage calculation rules defined in the usage calculation group referenced on the usage subscription. The rules within a usage calculation group are defined in a specific sequence, allowing control over the order in which the rules are executed.

Usage calculation groups are associated with specific usage subscriptions and usage subscription types (or both). When assigned to usage subscriptions, usage calculation groups contain the usage calculation rules to be used to calculate usage / bill determinants. Usage calculation groups associated with usage subscription types are those groups considered valid for usage subscriptions of that type.

Usage calculation groups can also specify a list of device donfiguration types that are considered valid. Usage calculation groups should only be associated with usage subscriptions for service points related to device configurations of a valid device configuration type.

Usage calculation groups can also be referenced by the [Execute Usage Calculation Group](#) usage calculation rule.

For a deeper functional understanding of usage calculation, refer to the [About Usage Calculation](#) section.

Configuring Usage Calculation Groups

This portal is used to display and maintain a usage calculation group.

Refer to [Understanding Usage Calculation Groups](#) for more information.

You can access the portal from You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Group:** Defines basic information about usage calculation group
- **Usage Calculation Rules List:** lists the usage calculation rules belonging to the group
- **Referencing Usage Calculation Rules List:** lists the usage calculation rules that reference the group
- **Referencing Usage Subscription Type List:** lists the usage subscription types that reference the group
- **Referencing Usage Subscriptions List:** lists the usage subscriptions that reference the group

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_USG_GRP](#).

Usage Calculation Rules

Understanding Usage Calculation Rules

Usage calculation rules are standard and custom rules that perform calculations on measurement data to generate bill determinants and other values used by external systems, such as billing systems, customer information systems, etc.

Usage calculation rules are created for a specific usage calculation group. For example, if you were configuring two usage calculation groups and both included a specific usage calculation rule, you would need to create two instances of the usage calculation rule, one for each group.

The base package includes rules that calculate common bill determinants including:

- Scalar reads
- Time-of-use consumption (by applying a time-of-use map to an interval channel)
- Interval curves (either real or derived)
- Virtually anything else that can be calculated from the information in the system

For a deeper functional understanding of usage calculation, refer to the [About Usage Calculation](#) section.

Usage Transaction Exceptions

On almost every usage calculation rule, the failure of the rule results in a usage transaction exception and the [Usage Transaction Exception Type](#) for the failure can be configured on the rule. These usage transaction exception types can also be set to a specific Exception Severity:

- **Information:** Used to highlight minor issues, but not sufficient to cause the usage transaction to be put into a failure state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues:** Used to report a problem that will prevent the usage transaction from being sent. Multiple "issue exceptions" can be created during usage transaction processing. If at least one issue exists after all rules have been applied, the usage transaction is transitioned to a failure state requiring review and approval.
- **Terminate:** Used to report a severe issue that will cause the usage calculation process to stop and the usage transaction to be transitioned immediately to a failure state requiring review and approval. Only one terminate exception can be issued (as the first one causes calculation processing to stop on for a Usage Transaction). This should be used for cases where manual override / approval isn't accurate. For example, a "Curve Not Continuous" error that says the interval data doesn't cover the full usage period should always be set to Terminate as an Exception Severity.

Rounding Usage Transaction Service Quantities

Several usage calculation rules provide a means for defining the manner in which service quantities are rounded during usage calculations. Service quantity rounding can be defined using the **SQ Rounding Details** which allow configuration of the method by which quantities are rounded (Up, Down, or Nearest) and the number of decimal positions retained after rounding.

Creating Measurement Data Snapshots

Daily Scalar Calculation Rule, Get Interval, Get Item Counts and Consumption, and Get Scalar Details usage calculation rules can be configured to create measurement data snapshots during usage transaction processing. Measurement data snapshots are used by data aggregation in Market Settlements Management.

Measurement data snapshot configuration is done in the **Extract To Measurement Data Snapshots** section, and includes the following options:

- **Measurement Data Snapshot Type:** The measurement data snapshot type for measurement data snapshots created by the usage rule.
- **Usage Transaction ID To Use:** A flag that designates the type of ID to use to identify the usage transaction on the measurement data extract. Options include:
 - **Usage Transaction ID:** The usage transaction's ID
 - **Usage Transaction External ID:** The external ID for the usage transaction. Used when the usage transaction is triggered by external system such as a CIS (or by the billing functionality in Customer To Meter)
- **Extract To Different Usage Subscription:** A flag that designates whether or not the measurement data snapshot should be extracted to a different usage subscription, such as one used by Market Settlements Management. Options include:
 - **No:** The extract will reference the usage subscription for which usage calculations are being processed. This option is used when Meter Data Management and Market Settlements Management are installed in different application environments. In this case, the extract can be exported from Meter Data Management for subsequent import into Market Settlements Management.

- **Yes:** The extract will reference a different usage subscription such as one used by Market Settlements Management. This option is used when Meter Data Management and Market Settlements Management are installed in the same application environment. In this case, the measurement data snapshot is “exported” within the system to the Settlement Item, where it can be used in data aggregation processing. When this option is selected, the **Source Identifier Type** and **Target Identifier Type** fields must be configured to define how the system will determine the correct settlement usage subscription to use.
- **Irregular Data Flag Mapping:** Ranges of condition codes used to flag data as “irregular”. The value of the **Irregular Data Flag** (based on the IRREGULAR_DATA_FLG lookup) is used to flag data that falls with each range configured. A blank **Irregular Flag** value denotes that the condition range is considered to be "Regular".

See [About Measurement Data Snapshots](#) for more information about measurement data snapshot creation and processing.

Configuring Usage Calculation Rules

This portal is used to display and maintain a usage calculation rule.

Refer to [Understanding Usage Calculation Rules](#), [Understanding Usage Calculation Groups](#), and [Understanding Usage Transaction Exception Types](#) for more information.

You can access the portal from . You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Rule:** Defines the usage calculation rule, including parameters used when executing the rule
- **Eligibility Criteria List:** Lists the eligibility criteria defined for the rule

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_USG_RULE](#).

Pre-Calculation Usage Calculation Rules

The following is a list of the pre-calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
Alignment and Delay Usage Calculation Rule	Interval or Scalar	This rule can be used to handle two main needs: 1) aligns all measuring components for a Usage Subscription to the same date (whether on the same device or separate devices) 2) delays the usage transaction until the end of the retry window based on the quality of available data and other configured parameters.
Check Existence of Installed Device	Interval or Scalar	This rule checks for the existence of a device installed on the Usage Subscription's Service Point for the usage period. In the case of multi-items this rule also checks that they are effective for the usage period.

Calculation Usage Calculation Rules

The following is a list of the calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
Apply Math (Interval Data)	Interval	<p>This rule is used to perform calculations on interval data and stores the results in the usage transaction's service quantities. A variety of options are available on this rule that include defining the calculation type, variables to use, as well as the equation to use (math functions and expressions).</p> <p>This rule provides aggregated usage for all selected interval measuring components (filter by TOU, SQI & UOM) associated to a usage subscription.</p> <p>This rule can also multiply total usage by a factor using a custom formula.</p>
Daily Scalar Usage Calculation Rule	Scalar	<p>This rule is used to calculate usage of daily scalar measuring components installed in the Service Points associated with a Usage Subscription for the specified usage period. It creates bill determinants by taking the difference between the beginning and ending reading for the bill period.</p> <p>This rule can also be used to provide register readings by measuring component.</p> <p>For consumption values, only the beginning and ending readings are exported</p> <p>This rule supports date breaks (the normal Get Scalar Data rule does not).</p>
Get Interval Data	Interval	<p>This rule is used to get interval quantities from interval measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Interval' usage period.</p> <p>This rule retrieves the interval data for measuring components associated to a usage subscription by TOU, SQI and UOM.</p> <p>This rule converts the interval data to another interval length or unit of measure.</p>
Get Item Counts and Consumption	Interval or Scalar	<p>This rule finds item-based and multi-item-based Service Points linked to the Usage Subscription for the current usage transaction, summarizes the item counts by item type and Service Point, and calculates item-based consumption.</p>
Get Scalar Details	Scalar	<p>This rule is used to get usage from scalar measuring components installed in</p>

the Service Points linked to the Usage Subscription for the specified 'Scalar' usage period.

This rule creates bill determinants by summing all scalar readings for the bill period. This rule can also be used to provide register readings by measuring component. All readings are exported by this rule.

Note: This rule is used for traditional monthly read meters.

Get Subtractive Interval Details	Get Subtractive Interval Details	<p>This rule is used to get interval quantities from subtractive interval measuring components installed on the service points linked to the usage subscription for the specified 'interval' usage period.</p> <p>It also identifies the start and stop readings for each usage period using subtractive interval readings.</p>
Get TOU Mapped Usage	Interval	<p>This rule is used to get time of use quantities from interval measuring components for devices installed at the Service Points linked to the Usage Subscription for the specified 'Interval' usage period.</p>
Interval Tier Calculation	Interval	<p>This rule calculates the difference between a source and reference vector.</p> <p>This rule loops through each tier that is configured and calculates the imbalance amount associated to that tier level.</p> <p>This rule breaks down that difference into one to many positive or negative tiers, and create a service quantity for each tier calculated.</p>
Profile Accumulation	Interval	<p>This rule is used to manipulate a customer's interval data by adding other vectors to it. Those other vectors are derived from a list of profile factors and corresponding characteristic values stored in a list on the usage transaction.</p>
Round and Adjust Usage	Interval or Scalar	<p>This rule copies identified source and target Service Quantities and inserts these as Service Quantities that are rounded and adjusted.</p>
Vector and Service Quantity Math	Interval	<p>This rule is designed to facilitate configuration of complex vector calculations. It is based on a series of underlying services with vectors configured as input to the calculations.</p> <p>Typical uses:</p> <p>Perform math using interval data, e.g., take the difference between two curves, find max values, find coincident peaks, multiply a curve by a value, apply TOU maps, etc.</p>

Define complex formulas using various interval curves, profile factor values or calculated service quantities (bill determinant values).

Support math functions: sin, cos, square root, etc.

Store derived curves in memory that can be used in subsequent calculations

Please note, this rule is not as efficient as other rules.

Post-Calculation Usage Calculation Rules

Below is a list of the post-calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
Usage High/Low Rule	Interval or Scalar	This rule compares the Service Quantities of the Usage Transaction to historical values. If the current value is too high or too low compared to historical data then an exception is thrown.
Validate Against Tolerance	Interval or Scalar	This rule is used to validate the calculated usage against a tolerance value. The tolerance value may either come from the specified value or tolerance factor defined in the usage calculation rule.
Business Flag Hold	Interval or Scalar	This rule can stop a usage transaction from proceeding when there have been business flags for the applicable service points. The hold can either be indefinite or set to expire a configurable amount of time prior to the calculation window ending.

Decision-Making Usage Calculation Rules

There are usage calculation rules delivered as part of the base product that help with decision-making when executing running the usage calculation process. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Purpose
Execute Usage Calculation Group	This rule performs a call to execute a separate usage calculation group which includes execution of all usage calculation rules within that group.
Exception Handler	This rule is used to terminate execution of the usage processor if exception count criteria specified in the rule is met.

Advanced Aside: Using Factors For Variables

A situation common in some implementations involves converting one unit of measure (UOM) to another. However, the conversion factor used in conversions of this can differ based on many different types of criteria, such as the location of the service point or other characteristics. This sort of calculation can be implemented as a usage calculation rule that accumulates consumption for one UOM and converts the consumption to a different UOM by applying a factor to it.

Factors used for this purpose have a Factor Class of "Number," and use some unique rules:

- Number factors reference a characteristic type (with pre-defined values).
- Number factors reference an algorithm that retrieves or derives the value of the characteristic type at runtime.

Factor values for a Number factor are effective-dated pairings of a characteristic value and a corresponding value. Because these pairings are effective-dated, the value returned from the factor can change over time for each characteristic value. At run time, the rule retrieves / derives the characteristic value for the factor's characteristic type and then finds the value associated with the respective characteristic value. Factors can be related to any real or dynamic attribute, so rules of this type are very flexible. For example:

- **Real Attribute:** you could create a rule that retrieves a specific value based on the location of a service point.
- **Dynamic Attribute:** you could create a rule that retrieves a percentage value based on the amount the customer conserved as compared to the same period in the prior year, returning one value if the amount conserved is between 5% and 10%, another value if the amount conserved is between 10% and 20%, and yet a third value if the amount conserved is greater than 20%. The amount conserved is dynamically calculated at execution time and is compared to the characteristic values defined for the factor, and returns the appropriate value. In this example, if the amount conserved was anything less than 5%, no percentage value would be returned.

Pre-Calculation Usage Calculation Rules

Alignment and Delay Usage Calculation Rule

This rule attempts to delay usage calculation until high quality data for calculating bill determinants have become available. It is especially useful for usage subscriptions having multiple sources of usages such as multiple service points or multiple measuring components on the installed meter. The rule ensures that the usage calculated is based on a common date or alignment date, identified for these sources.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-ALGNDELAY](#) Algorithm Type.

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Get the total KWH for the period

Calculation Type = Single Variable

Variable Name = V1, where the following is configured:

- Variable Type = Channel Accumulation
 - UOM = KWH
 - Set Function = Sum
-

Scenario 2: Get the higher value between the total KWH or total KVARH

Calculation Type = Math Function

Math Function = Max

Variable Name = V1, where the following is configured:

- Variable Type = Channel Accumulation
 - UOM = KWH
 - Set Function = Sum
-

Variable Name = V2, where the following is configured:

- Variable Type = Channel Accumulation
 - UOM = KVARH
 - Set Function = Sum
-

Scenario 3: Total KWH multiplied with a factor value

Calculation Type = Mathematical Expression

Mathematical Expression = $V1 * V2$

Variable Name = V1, where the following is configured:

- Variable Type = Channel Accumulation
 - UOM = KWH
 - Set Function = Sum
-

Variable Name = V2, where the following is configured:

- Variable Type = Factor
 - Factor = factor code that holds the multiplier
-
-

Daily Scalar Usage Calculation Rule

This rule is used to calculate usage of daily scalar measuring components installed in the Service Points associated with a Usage Subscription for the specified 'Interval' usage period. Only automatically read scalar measuring components with value identifier that matches usage calculation rule's UOM/TOU/SQI will be processed.

If configuring this rule with interval and scalar usage calculation rules under a usage calculation group, it should be executed after interval usage calculation rule and before the scalar usage calculation rule.

This rule calculates usage based on the beginning and ending reading values -- ignoring intermediate readings. This rule will not estimate data based on the usage transaction estimate flag. Frequently read scalar devices must use periodic estimation processes.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-GETFRESCR](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-CalFrequentlyReadScalar

Get Interval Data

This rule is used to get interval quantities from interval measuring components installed in the service points linked to the usage subscription for the specified 'Interval' usage period. Only measuring components that match the UOM/SQI defined in the usage calculation rule are processed. Measurements within the period are stored in the usage transaction's service quantities' interval data list. The SQ entry's quantity is calculated based on the **Calculate Function** defined in the usage calculation rule. This is done for every entry in the usage period list. Each service quantity recorded by this rule is linked to a service point and measuring component.

By supplying the Axis Conversion parameters on the usage calculation rule, this algorithm will convert the identified measuring component's consumption into the supplied UOM and interval size prior to storing the consumption into the service quantity's interval data list.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-GETINTDAT](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetIntervalData

Get Item Counts and Consumption

This rule finds item-based and multi-item-based Service Points linked to the Usage Subscription for the current usage transaction, summarizes the item counts by item type and Service Point, and calculates item-based consumption. Once the item detail entries are created, the rule processes goes through them to create usage period SQs.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-GETITEMCC](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetItemCountsConsumption

Get Scalar Details

This rule is used to get usage from scalar measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Scalar' usage period. By default all scalar measuring components are processed but if specific UOMs/TOUs/SQIs are defined in the usage calculation rule then only applicable measuring components are processed. Measurements within the period are retrieved. The usage transaction request may indicate whether or not 'Estimate' measurements are allowed.

The measurement details are stored in the usage transaction's scalar details. The usage is also stored in the usage transaction's service quantities unless otherwise specified in the usage calculation rule (using Build Service Quantity indicator).

This rule can be configured to perform measurement quality assessment, which will result in the population of the measurement quality list with the quantities and corresponding conditions of those measurements (regular, estimated, etc.).

Please note: this rule should not be used with readings occurring daily or more frequently as it will retrieve all of the readings to store in the Usage Transaction. The [Daily Scalar usage calculation rule](#) may be a better option for this use case.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-GETSCALAR](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetScalar

Get Subtractive Interval Details

This rule is used to calculate the usage for a subtractive interval measuring components. This differs from the Get Interval Data usage calculation rule in that it also retrieves a start and stop reading for each usage period it calculates. The start and stop readings are then used to provide entries into the usage scalar details table which are then made available in the usage transaction sent to the billing system for bill presentment.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-SUBINTADJ](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetSubtractiveInterval

Get TOU Mapped Usage

This rule is used to get time of use quantities from interval measuring components for devices installed at the Service Points linked to the Usage Subscription for the specified 'Interval' usage period. Only measuring components that match the UOM/SQI defined in the usage calculation rule instance are processed.

Measurements within the period are mapped to time of use quantities based on the TOU map defined on the usage calculation rule. If dynamic options are specified in the referenced TOU map and if there are dynamic option events in effect within the usage period then the TOU map associated with the dynamic option is used for the entire dynamic option event period. This calculation is performed for every usage period requested.

The calculated time of use quantities are stored in the usage transaction's service quantities per Service Point and measuring component.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-GETTOUUSG](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetTOUUsage

Interval Tier Calculation

This rule calculates the difference between a source and reference vector. It then breaks that difference into one to many positive or negative tiers. For each tier calculated it will create a service quantity with the optional ability to create additional service quantities for the total of all positive tiers and the total of all negative tiers. This rule will loop through each tier that is configured and calculate the imbalance amount associated to that tier level.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-GETINTIER](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalTierCalculation

Profile Accumulation

This rule is used to manipulate a customer's interval data by adding other vectors to it. Those other vectors are derived from a list of profile factors and corresponding characteristic values stored in a list on the usage transaction.

The typical application of this rule is for customer self-service rate compare, in which a self-service user has selected a set of usage adjustments to apply to his/her historical consumption to assess the effect on the amount consumed.

This rule algorithm retrieves the customer's usage (the source UOM) for the usage period using one of two options:

- A channel linked to a Usage Subscription
- A usage transaction service quantity

Then it takes each entry in the usage transaction's profile factor list, finds the profile measuring component for each, retrieves the measurement data for the profile, applies axis conversion to align it to the source UOM and target interval size, and adds it to the source vector. Each profile's data is added progressively to arrive at a final vector. The final vector may then be TOU-mapped, and the vector itself may be preserved or discarded.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-DYNPRFLAC](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProfileAccumulation

Profile Service Quantity

This rule intervalizes scalar service quantity values based on a profile measuring component.

This rule first retrieves scalar service quantities, identified by the rule's UOM/TOU/SQI. If multiple service quantities exist for the service point they will be summarized at the service point level. In the case of a split or broken usage period for a service point, the usage period is merged and the quantities are summarized. Each service quantity is subject to intervalization. The profile measuring component is then derived using the profile factor supplied with either the usage subscription or service point as characteristic sources. If the profile is not available, an exception will be created using the exception details on the rule.

If a dynamic option type is provided, the events associated with it are retrieved for the usage transaction period. Any intervalized quantities that coincide with the dynamic option events start/end date time are then recorded in a new usage period service quantity of usage type "Correlated SQ".

If no dynamic option type provided, the intervalized quantities are recorded in a new usage period service quantity of usage type "Profile SQ".

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-PRFSVCQTY](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProfileServiceQuantity

Round and Adjust Usage

This rule copies identified source and target Service Quantities and inserts these as period Service Quantities that are rounded and adjusted. This rule captures the source and target Service Quantity identifiers, rounding method, and Service Quantity bucket to hold the adjustment. The usage calculation rule also has an option to validate the difference between the source and target service quantities.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-RNDADJUSG](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RoundAndAdjustUsage

Vector and Service Quantity Math

This rule is designed to facilitate configuration of complex vector and scalar quantity calculations. It is based on a series of underlying services, including Axis Conversion, Apply Formula (most importantly), and Apply TOU Map. It can be configured to accept as input up to five vectors - where a single vector can represent the combination of all measuring components with linkages to the Usage Subscription with the configured UOM/SQI. It can also accept a list of scalar variables that can be taken in as factor values, usage transaction service quantities, set functions on a vector, or numeric values.

Vectors can be combined using a simple formula expression, or using condition formula expressions. Both interval values and interval conditions can be referenced. The result is interval-by-interval processing of the vector formula. The resulting final vector can be stored, TOU mapped, and/or subjected to a final set function (such as sum or max).

This rule stores service quantities of type "other" - meaning that the service quantities created by this rule do not have linkages to a specific Service Point or measuring component, given the potentially diverse sources of the data taken as input by this rule that lead to the final quantity.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-MATH](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-Math

Post-Calculation Usage Calculation Rules

Usage High/Low Rule

This rule is used to validate the current usage against historical usage - previous year usage or previous usage. It ensures that any increase or decrease of the current usage relative to historical usage is within a tolerance.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-USGHIGLOW](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-UsageHighLowRule

Validate Against Tolerance

This rule is used to validate the calculated usage against a tolerance value. The tolerance value may either come from the specified value or tolerance factor defined in the usage calculation rule.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-VALUSGTOL](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ValAgainstTol

Business Flag Hold

This rule can be used to place a hold on a usage transaction until the business flags related to the usage transactions service points can be investigated. The hold can be placed in one of two ways:

- **Calculation Window Based:** holds will remain until either a user manually bypasses the usage exception error or the current date is within a configurable tolerance of the calculation window end (aka the retry until date time).
- **Indefinite:** holds require a user to manually bypass the usage exception that is generated.

Defining which business flags should result in a usage transaction is a matter of identifying which business flag types, priorities, and confidences should be included.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-AUR-IBFH](#) algorithm type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-BusinessFlagHold

Decision-Making Usage Calculation Rules

Execute Usage Calculation Group

This rule performs a call to execute a separate usage calculation group which includes execution of all usage calculation rules within that group. It is especially useful in cases where repeating the same rule over and over would be hard to maintain.

For example, you may want to calculate a straightforward kWh sum for every usage calculation group. Creating a separate CALC_KWH_SUM usage calculation group for this one calculation allows you to isolate the configuration points. Then the CALC_KWH_SUM usage calculation group can be referenced in every other usage calculation group that needs this sort of service quantity.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D1-AUSGR-RFG](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-UsageRuleReferredUsageGroup

Exception Handler

This rule evaluates the exception list that was accumulated during the execution of the calculation rules against exception criteria configured on this rule. This used to terminate the execution of usage calculation group processor if there are far too many exceptions hit during the execution.

NOTE:

Additional detail on the logic of this rule can be found in the Detailed Description of the [D2-UREXPCHAN](#) Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-UsageRuleExceptionHandler

Detailed Configuration Examples

Demand Calculation Options Using Interval Data

There are a number of ways to calculate a demand value from interval data when retrieving bill determinants for CIS. A few examples of demand calculations are listed below:

Scenario1: Use interval data for demand at a common block size: the [Vector and Service Quantity Math](#) usage calculation rule can be used to calculate demand from the interval data. Below is one example of configuration to handle demand calculation based on 30 minute blocks:

Usage Calculation Rule field	Value	Notes
------------------------------	-------	-------

Vector 1 // Type	Physical Channels Links to Usage Subscription	
Vector 1 // Unit of Measure	Kilowatt-Hours	Use your own UOM here - this is just as example.
Vector 1 // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Vector Processing // Common Interval Size	00:30:00	This configuration rolls up all channels (whether 5 minute, 15 minute, or 30 minute interval data) into a common interval size.
Vector Processing // Vector Formula Source	Simple Vector Formula	
Vector Processing // Simple Vector Formula	IV1*2	This is multiplying the common 30 minute interval size by 2 to achieve an hourly value.
Result // Unit of Measure	Kilowatts	Use your own UOM here - this is just as example.
Result // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Result // Insert Primary SQ Entry	Yes	
Result // SQ Entry Quantity Source	Set Function Against Derived Vector	
Result // Set Function Against Derived Vector	Max	This function pulls the max value based on the configuration in the "Vector Processing" section.

Scenario 2: Use interval data for demand by TOU period: This example is very similar to the last and again leverages the [Vector and Service Quantity Math](#) usage calculation rule. However, instead of calculating a single demand value for the entire period it will calculate a demand value for each TOU period:

Usage Calculation Rule field	Value	Notes
Vector 1 // Type	Physical Channels Links to Usage Subscription	
Vector 1 // Unit of Measure	Kilowatt-Hours	Use your own UOM here - this is just as example.
Vector 1 // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Vector Processing // Common Interval Size	00:30:00	This configuration rolls up all channels (whether 5 minute, 15 minute, or 30 minute interval data) into a common interval size.
Vector Processing // Vector Formula Source	Simple Vector Formula	
Vector Processing // Simple Vector Formula	IV1*2	This is multiplying the common 30 minute interval size by 2 to achieve an hourly value.
Result // Unit of Measure	Kilowatts	Use your own UOM here - this is just as example.
Result // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Result // Insert Primary SQ Entry	No	
Result // Apply TOU Map To Derived Vector	Yes	
Result // TOU Map	(your TOU Map)	Select the TOU Map you'd like to apply.

Usage Calculation Types

Understanding Usage Calculation Types

Usage calculation types define calculations executed at a customer level where there may be more than one calculation per usage subscription. For example, a customer may have a usage subscription for producing billing determinants but there may be additional calculations that will be executed on a much less frequent basis (annually, quarterly, etc). Usage calculation types provide a way to leverage a single usage subscription to drive multiple different calculations.

Usage calculation types use the following parameters:

- **Request Type:** Used to drive the creation and processing of the usage transactions for all usage subscriptions that are valid for the usage calculation type.

NOTE: Request types for usage calculation types should be based on the Usage Calculation Request Type business object (D2-UsageCalculationReqType)

- **Service Point Quantity Creation:** Details of the quantities created by usage calculations of this type, including service point quantity type, and UOM, TOU, and SQL.
- **Applicable Usage Subscription Types:** A list of usage subscription types for which this usage calculation type is applicable. Each usage subscription type is defined by an effective date range, the usage transaction business object used for the usage calculation, the result UOM/TOU/SQL, and the usage calculation group used to perform the calculations.

Configuring Usage Calculation Types

You use the **Usage Calculation Type** portal to maintain and view usage calculation types.

Refer to [Understanding Usage Calculation Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Calculation Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Type List:** This zone lists all usage calculation type records. Broadcast a record to display the details of the selected record.
- **Usage Calculation Type:** This zone displays details for the selected usage calculation type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_USG_CAL_TYPE](#).

Usage Subscription Quantity Types

Understanding Usage Subscription Quantity Types

Usage subscription quantity types define types of quantities that can be stored for a usage subscription. These quantity types are often infrequently calculated descriptors of a given customer and how they relate, at an aggregate level, to either the customer base as a whole or their particular rate class. For example, a customer quantity may be used to store a scaling factor that describes how a given customer's usage compares to the profiled usage for their rate class.

In a settlement implementation, usage subscription quantity types can be used to define values calculated monthly, annually, etc., such as annual peak load contribution (PLC).

Usage subscription quantity types use the following parameters:

- **Service Type:** The service type (electric, gas, water, etc.) for service point quantities of this type.
- **Usage Subscription Quantity Business Object:** The business object used for usage subscription quantities of this type.
- **Usage Subscription Quantity Identifiers:** Value identifiers related to the current usage subscription quantity type (used to provide shorthand descriptions of the various types of values measured by usage subscription quantities of this type).

Configuring Usage Subscription Quantity Types

You use the **Usage Subscription Quantity Type** portal to display and maintain usage subscription quantity types.

Refer to [Understanding Usage Subscription Quantity Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Subscription Quantity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Subscription Quantity Type List:** This zone lists all usage subscription quantity type records. Broadcast a record to display the details of the selected record.
- **Usage Subscription Quantity Type:** This zone displays details for the selected usage subscription quantity type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_US_QTY_TYPE](#).

Dynamic Option Types

Understanding Dynamic Option Types

Dynamic options specify terms that override how usage is normally calculated, such as a critical peak period that affects the TOU mapping of interval consumption. Dynamic option types store information common to dynamic options of a specific type.

There are two classes of dynamic options:

- **Interval Set:** Used to represent dynamic option types that provide a set of intervals that will be included in a calculation.
- **Usage Event:** Used to represent dynamic option types that provide a specific period of time during which a dynamic option is applicable.

Interval Set dynamic option types also define key information about the interval data they represent, including:

- **Unit of Measure:** Identifies the quantity that Interval Set dynamic options and Interval Set dynamic option events based on this type are measuring.

- **Interval Size:** Defines the size of the intervals for Interval Set dynamic option events of this type, represented as hours:minutes:seconds (HH:MI:SS).

Configuring Dynamic Option Types

This portal is used to display and maintain a Dynamic Option Type.

Refer to [Understanding Dynamic Option Types](#) for more information.

You can access the portal from **Admin > Usage > Dynamic Option Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Dynamic Option Type List:** displays all of the Dynamic Option Types so you can choose the one you want to display in more detail
- **Dynamic Option Type:** shows the specific configuration for the selected Dynamic Option Type

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_DYN_OPT_TYPE](#).

Bill Cycle

Understanding Bill Cycles

Bill cycles identify when a customer is going to be billed and when bill determinants are going to be calculated.

NOTE: Meter Data Management bill cycles are created from Customer Care and Billing bill cycles via [Customer To Meter Master Data Synchronization](#).

Configuring Bill Cycles

This portal is used to display and maintain a Bill Cycle.

Refer to [Understanding Bill Cycles](#) for more information.

You can access the portal from other objects such as Measurement Cycles.

The following zones may appear as part of the portal's **Main** tab page:

- **Bill Cycle List:** displays all of the Bill Cycles so you can choose the one you want to display in more detail.
- **Bill Cycle:** shows the specific configuration for the selected Bill Cycle.
- **Bill Cycle List:** lists the bill cycle schedules of the current bill cycle.

NOTE: Meter Data Management bill cycles are created from Customer Care and Billing bill cycles via [Customer To Meter Master Data Synchronization](#). Bill cycles should only be updated via the Customer Care and Billing Bill Cycle portal.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_BILL_CYC](#).

Defining Time of Use Options

Time of Use Groups

Understanding Time of Use Groups

Time of Use (TOU) Groups are groups of TOUs that are associated to TOU templates that limit the TOUs available for use in a TOU schedule. These TOUs will be available as the default, holiday, and schedule TOUs within the template.

Each TOU in the group is given a priority. The priority is important in a few ways:

- The [TOU Overlay](#) 360 Degree zone uses these priorities to decide which TOUs will be rendered as a unique shade and which will fall into a category of "other" when the maximum number of distinct TOUs to graph has been reached.
- These priorities are available for use in customized logic.

Configuring Time of Use Groups

This portal is used to display and maintain a TOU Group.

Refer to [Understanding Time of Use Groups](#) for more information.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Group List:** This zone lists all TOU Group records. Broadcast a record to display the details of the selected record.
- **TOU Group:** This zone provides information about the selected TOU Group.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_TOU_GRP](#).

Time of Use Map Templates

Understanding Time of Use Map Templates

Every TOU map references a TOU map template that defines the rules for generating TOU data from that TOU map. Specifically, TOU map templates define:

- The TOU group (defines the valid TOU periods for the template) used for the TOU map
- The default TOU period used for periods not explicitly defined. (This means you don't have to specify dates and times for all periods. For example, if your default TOU period is "Off Peak" you only need to define dates and days and times for On Peak or other TOU periods.)
- The specific date ranges, days of the week, and time periods designated for each TOU period.

The system periodically generates TOU map data for TOU maps by interpreting the rules defined template.

Attributes used to define TOU map templates include the following:

- **TOU Group:** the TOU group used by the map template Default TOU: the default TOU for the map template (from the TOU Group). This is the TOU used when creating TOU map data for dates not accounted for in the TOU Schedules section.
- **Work Calendar:** the work calendar used to identify holidays. On each holiday the Holiday TOU will be used. For additional information see [Defining Work Calendar](#) in the Oracle Utilities Application Framework *Administrative User Guide*.
- **Holiday TOU:** the TOU used for holidays (from the TOU Group)
- **Holiday Template:** the TOU map template used for holidays (if applicable)
- **Interval Size:** the size of the intervals for TOU map data created from the map template, represented as hours:minutes:seconds (HH:MI:SS).
- **TOU Schedules:** date ranges (including month, day, and time ranges) and which TOUs

Refer to [Understanding Referencing Master Data by Identifiers](#) for information on how admin configuration can reference a TOU map by a TOU template to ease migration of data between environments.

TOU Map Template Interval Size

TOU map templates can also specify an interval size (in seconds-per-interval, or SPI). This value specifies the duration of the individual TOU map data records, and also controls the values allowed in the Start and End Times. For example, if a TOU map template sets the interval size at 15 minutes, Start and End times must be in units of the interval size (10:00, 10:15, 10:30, etc.).

A TOU map template can be used to generate TOU map data for TOU maps whose SPI is divisible by the template's SPI. For example, a 60 minute template can be used to generate TOU data for TOU maps with SPIs of 60 minutes, 15 minutes, 5 minutes, etc. This means separate map templates are not needed for every SPI.

Holidays

Many utilities categorize consumption on holidays differently than on the day of week on which the holiday falls. For example, holiday consumption might be categorized as Off-Peak regardless of the day it falls on. TOU map templates can define rules for different TOU periods for holidays in two ways. Both options require that the template references a Work Calendar that identifies each of the holidays throughout the year. In addition they require either:

- A Holiday TOU that will be used for each holiday for the duration of that holiday (e.g. Off Peak)
- A Holiday TOU Map Template that defines the TOUs that should be used for holidays that fall during different seasons within the year (e.g. Off Peak Summer, Off Peak Winter)

Important Time of Use Template System Events

The time of use template supports the following business object algorithm system events:

- **Derive TOU:** receives a date time and determines the TOU code for that date time based on the configuration of the time of use template schedule. See algorithm type Derive Time Of Use For Date Time ([D2-DERTOU-DT](#)) as an example.

Configuring Time of Use Map Templates

This portal is used to display and maintain a TOU Map Templates.

Refer to [Understanding Time of Use Map Templates](#) for more information.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Map Template List:** This zone lists all TOU Map Template records. Broadcast a record to display the details of the selected record.
- **TOU Map Template:** This zone provides information about the selected TOU Map Template.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_TOU_MAP_TMPLT](#).

Time of Use Map Types

Understanding Time of Use Map Types

TOU Map Types define important properties of TOU maps of the type, including the interval size and the valid TOU map templates.

Attributes used to define TOU map types include the following:

- **Time Zone:** the time zone to be used when generating the TOU map data. Refer to [Multiple Time Zone Support](#) for more information about how time zones impact TOU map data in multiple time zone environments.
- **Interval Size:** the size of the intervals for TOU map data created from maps of this type, represented as hours:minutes:seconds (HH:MI:SS). The interval size cannot be larger than the interval size defined on the Default TOU Map Template or any of the Override TOU Map Templates.
- **Default TOU Map Template:** the default TOU map template used by maps of this type
- **Override TOU Map Templates:** one or more TOU map templates that can be used as an override on TOU maps of this type.

TOU Map Type Interval Size

The SPI of a TOU map must divide evenly into the SPI of any measuring component that uses the map (because the system joins the date/time of the measurement to the date/time of the TOU data). This means that it is possible to use a 15 minute TOU map with a 60 minute measuring component. However, it is not OK to have a 60 minute TOU map used with a 15 minute measuring component because the join will miss 3 out of 4 measurements.

However, it is important to note that the TOU mapping process is at its most efficient when the measurement data that is being mapped is of the same interval size as the TOU schedule it is being mapped against. When there are differences in the interval size the process must first convert the measurement data into the appropriate interval size for the TOU Map prior to applying the TOU Map.

This means that for each TOU Map Template you should have sufficient TOU Map Types to cover the various interval sizes that will be supported by your measurement data. For example, if you have measuring components with interval sizes of 15 minutes, 30 minutes, and 60 minutes then for each TOU Map Template there should be TOU Map Types with interval sizes of 15 minutes, 30 minutes, and 60 minutes.

Default and Override TOU Map Templates

While most TOU maps will use the TOU map template defined on the TOU map type, TOU maps also support a fallback/override pattern used in other areas of the system.

- A TOU map's TOU map type defines the default (or "fallback") TOU map template that's used to generate its TOU data.
- A TOU map's type defines the TOU map templates that can be referenced on individual TOU maps to override the "fallback" template.
- An individual TOU map can have an override template. If the TOU map doesn't have an override template, the fallback template defined on the TOU map type is used to generate the map's TOU data.

Important Time of Use Map System Events

The TOU Map business object that is associated to a given TOU map type supports a special system event that is used in the generation of TOU map data:

- **Create TOU Map Data:** receives a date range and for that date range it will create the appropriate TOU map data for the TOU map. See algorithm type Create TOU Map Data ([D2-CRETMD-CT](#)) as an example.

Configuring Time of Use Map Types

This portal is used to display and maintain a TOU Map Types.

Refer to [Understanding Time of Use Map Types](#) for more information.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Map Type List:** This zone lists all TOU Type records. Broadcast a record to display the details of the selected record.
- **TOU Map Type:** This zone provides information about the selected TOU Map Type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_TOU_MAP_TYPE](#).

Defining Premise and Service Point Options

A premise is where a customer consumes the services supplied by your company. Located at a premise are the various devices that consume energy and measure consumption. Before you can define premises and devices, you must set up the control tables defined in this section.

WARNING:

The topics in this section do not describe every table that must exist in order to set up premises and service points. Many premise and service point control tables are described in , and . The tables described in this section are those that must be set up regardless of the type of service.

An Illustration Of A Premise

The following picture illustrates a premise with 2 service points, 2 meters, and 2 badged items:

The following concepts are illustrated above:

Premise A premise describes a location at which your company supplies some type of service. In addition to the obvious address information, a premise also contains geographic coordinates, meter read instructions, and taxation jurisdiction information.

FASTPATH:

For more information about the control tables that must be set up before you can define a premise see [Setting Up Premise Options](#).

Service Point A service point (SP) is a geographic location at which service(s) are delivered to a premise. The SP record maintains information about the type of service, the (if the service is metered), the field office responsible for maintaining the service, the distribution company that supplies the service, etc.

There are three major categories of service points:

- Those where the rate of consumption and the total amount of consumption is measured (e.g., electricity, gas, water) by a meter. You can think of this type of service point as a "socket" into which a meter can be plugged. Over time, many meters may be plugged into the socket. We refer to these types of service points as metered.
- Those that hold badged items. A badged item is a physical device with a unique identity (e.g., a specific street light, a specific hydrant). You can think of this type of service point as a "socket" into which a badged item can be plugged. Over time, many items may be plugged into the socket. We refer to these types of service points as item-based.
- Those used to hold one or more non-badged items. For example, if your organization doesn't badge street lamps, you can use a single service point to hold an infinite number of lamps. We refer to these types of service points as non-badged.

FASTPATH:

Refer to [Service Points \(SPs\)](#) for more information about non-badged items.

An unlimited number of SPs may exist at a premise. However in reality, the number of SP's is related to the number of services supplied by your company. For example, an electric and gas company will typically have two SPs per premise.

FASTPATH:

For more information about the control tables that must be set up before you can define service points refer to [Setting Up Generic Service Point Options](#), .

Field activities may be dispatched to all types of service points.

Meter A meter is a physical device used to measure the amount of gas, water, or electricity used by a customer. While most meters measure consumption in a single unit of measure (e.g., gallons, cubic feet, kilowatt-hours), some electric meters are extremely sophisticated and measure several different factors. For example, some electric meters measure how much was used, when it was used, the efficiency of consumption, the maximum amount used, and a few other unusual things.

FASTPATH:

For more information about the control tables that must be set up before you can define a meter, refer to , and [Setting Up Consumption Estimation Parameters](#).

FASTPATH:

For more information about the control tables that must be set up before you can define an item, refer to .

For more information about premises and service points, refer to [Understanding The "V"](#).

Setting Up Premise Options

This section describes tables that must be set up before you can define premises.

Defining Premise Types

Open **Admin > Geographic > Premise Type** to define the premise types used to categorize your premises.

Description of Page

Enter a unique **Premise Type** and a **Description** for every premise type.

Allow CIS Division controls whether premises of this type can use the CIS Division on the premise page. Valid values are Not Allowed, Optional, and Required.

If your implementation requires restricting data by CIS Division, it is recommended that Allow CIS Division be set to Required.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_PREM_TYPE](#).

Implementing Address Validation

In order to set up address validation, you must ensure that the following Option Types are defined with their corresponding values on the General System Configuration – Feature Configuration page:

Option Type	Description
Address Validation Script	Indicates the name of the BPA script to invoke when a user clicks on the validate address button. This option is required if the Allow Address Validation option is set to Y. The base product includes sample script C1-ValAddr that uses Oracle Spatial procedures and functions to geocode an address and return its matching quality code.
Allow Address Validation	Indicates whether an integration with address validation software is implemented. If set to Y, the system will render a validate button along with the address fields displayed throughout the application to trigger address validation. Valid values are 'Y' and 'N'. If set to Y, the Address Validation Script to invoke must be specified.

As described in the above table, the base product includes sample script C1-ValAddr uses Oracle Spatial procedures and functions to geocode an address and return a matching quality code. To use this script, ensure that the Oracle Spatial Geocoding (F1-ORAGEOCD) algorithm is plugged in on installation options for the geocoding service system event. A data source containing the geocoding data must also exist on the database.

If your implementation uses something other than Oracle Spatial for address validation, you'll need to create a new address validation BPA script to specify on the General System Configuration feature configuration. For additional information about creating this script, see the steps descriptions for the C1-ValAddr script in the application. The new script should contain the following move step to update the page:

- If the calling page is an old style page, the move from the BPA to the page can be achieved by specifying a move step from a source field to a User Interface Field.
- If the calling page is a display map, the move from the BPA to the page can be achieved by specifying a step to read the Business Object, modify the values as returned by the validation software, and then update the BO.

Setting Up Generic Service Point Options

This section describes tables that must be set up before you can define service points.

Setting Up Service Point Types

Every service point must reference a service point (SP) type. The SP type controls almost all aspects of the service point's behavior (e.g., the type of field activity that may be dispatched to it, the type of service agreement that may be linked to it, the type of that may be installed at it).

The topics in this section describe the windows used to set up your SP types.

WARNING:

Setting up SP types requires careful analysis of your company's SA types, field activities, and its consumption estimation philosophy. Refer to [Designing SP Types](#) for more information about this design process.

Setting Up Premise & Service Point Postal Defaults

You set up postal defaults if your company is able to default field values onto new premises and service points based on the premise's postal code. The topics in this section describe how to maintain postal defaults.

FASTPATH:

For more information about where these default values are used, refer to [Maintaining Premises](#) and [Maintaining Service Points](#).

Postal Defaults - Main

To define premise postal defaults, open **Admin > Geographic > Postal Code Default > Add**.

Description of Page

Enter the **Country Code** and range of postal codes to which the default values apply using the **From Postal Code** and **To Postal Code**.

NOTE:

You may not have postal defaults whose from / to postal codes overlap.

Enter the **County** to be defaulted onto new premises located in this postal code range.

Enter the **City** to be defaulted onto new premises located in this postal code range.

Enter the **CIS Division** to be defaulted onto new premises located in this postal code range.

Enter the **State** to be defaulted onto new premises located in this postal code range.

Enter the **Time Zone** to be defaulted onto new premises located in this postal code range.

Use the **Characteristic Types and Values** collection to define the **Characteristic Types** and their respective **Characteristic Values** to be defaulted on premises located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a premise.

FASTPATH:

For more information about characteristics, see [Setting Up Characteristic Types & Their Values](#) and [An Illustration Of A Bill Factor And Its Characteristics](#).

Use the **Geographic Types and Values** collection to define the **Geographic Types** and their respective **Values** to be defaulted on premises located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Where Used

This information is defaulted when a new Premise is added. Characteristics and geographic values are also defaulted when the postal code for a Premise is changed. Refer to [Maintaining Premises](#) for more information.

Postal Defaults - Service Default

To define values to be defaulted for a service point located in a postal range, open **Admin > Geographic > Postal Code Default > Search** and navigate to the **Service Defaults** page.

FASTPATH:

For more information about where these default values are used, refer to [Maintaining Service Points](#).

Description of Page

Use the **Service Defaults** collection to define values to be defaulted on service points located in a given postal code range belonging to a given **Service Type** (note, a service point's Service Type comes from its SP Type).

- Use the **Characteristic Types and Values** collection to define the **Characteristic Types** and their respective **Characteristic Values** to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a service point.
- Use the **Geographic Types and Values** collection to define the **Geographic Types** and their respective **Values** to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Designing SP Types

Every service point must reference an SP type. When you set up an SP type, you define how the system manages many aspects of its service points' behavior.

NOTE:

Perfect foresight. In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SP types. In reality, setting up your SP types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

Designing your SP types is an iterative process. To minimize the number of iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SP types.

SP Type	Service Type
---------	--------------

Service Segmentation

At a minimum, you will have one SP type for every different type of service that exists at your premises. If we assume that your organization sells gas, water, waste water and electricity services, you will need four SP types.

SP Type	Service Type
GAS	Gas service
WATER	Water service
WASTE WATER	Waste water service
ELECTRIC	Electric service

Device Segmentation

For each service, determine if there exist meters, badged items, or non-badged items at the service points. For example, if we assume:

- Electric service has service points with meters, badged lamps, and parking lots.
- Gas and water services just use meters.
- Waste water service doesn't actually have a meter installed at it (it uses the water consumption measured by the water service point's meter)

Then your SP types will be:

SP Type	Service Type	SP Sub Type
GAS - METERED	Gas service	Meter
WATER - METERED	Water service	Meter
WASTE WATER	Waste water service	Unbadged

ELECTRIC - METERED	Electric service	Meter
ELECTRIC - BADGED LAMP	Electric service	Item
ELECTRIC - PARKING LOT	Electric service	Unbadged

SA Type Segmentation

Every SP Type whose service points can be linked to a service agreement has one or more SA types. These define which type of service agreements can pay for the service point's service. If different service points have different valid SA types, you will need to split the SP types accordingly.

The SA Type segmentation of SP Types is the most complicated design decision you'll have to make. Unfortunately, the decision making process is subjective and iterative. The iterations are caused by the fact that the number of SA types is dependent on the number of SP types (and vice versa). We recommend the following to help work your way through this conundrum:

- Design your SA types using the information in [Defining Service Agreement Types](#).
- Return to your SP types and determine if, given the proposed SA types, you can define a list of valid SA types for each SP type. If you find the population of SA types (and their valid rates) could result in invalid rates paying for service at a service point, divide your SA types further.

Defining Bill and Measurement Cycles

This chapter is dedicated to issues related to defining cycles, routes and schedules in the system.

Defining Bill and

Every account references a bill cycle. An account's bill cycle controls when it is billed.

In this section, we describe how to design and set up these cycles. In addition, we discuss how to set up bill period schedules. These are used to define the bill segment end date for special types of non-metered service agreements.

NOTE:

Recommendation. We recommend reviewing [Bill Frequency - Bill Cycle vs Bill Segment Duration](#) before setting up this information.

The Big Picture of Bill Cycles, Measurement Cycles, and Bill Periods

The topics in this section provide background information about a variety of bill cycle, , and bill period issues.

Designing Cycles for Metered Services

The topics in this section provide background information about a variety of issues.

A Description of the Cyclical Meter Read Process

Manual meter readers using handheld devices record most meter reading measurements in the field. These meter reads are uploaded into the system for use by Oracle Utilities Meter Data Management.

A service point's installed meter device is measured due to the following data relationships:

- Every metered service point references a schedule route.
- A route references a measurement cycle.
- A measurement cycle has measurement cycle schedules that define when the service points in the cycle are measured.
- Every measurement cycle schedule contains two dates:
 - **Scheduled selection date.** This is the date Meter Data Management could use to select the service points in the cycle for download to your handheld software via custom algorithms to create handheld activities when pending measurement cycle schedules are proposed (refer to [Measurement Cycle and Bill Determinants](#) for more information).
 - **Expected work date.** This is the date the meter is expected to be read.

NOTE:

Overriding a route within a specific schedule. Rather than downloading all routes within a cycle, you can set up the system so that only specific routes are downloaded on any given date. This is a very powerful feature. You can use it, for example, to estimate specific cycles every other month or indicate the customer reads the meter every third month. Refer to [Designing Measurement Cycles, Routes, And Schedules](#) for more information.

-
- On the scheduled selection date, Meter Data Management could create a download file, via custom algorithms, containing information to be sent to your handheld software. This download file should contain information about every register or measuring component on every meter in the routes being downloaded.
 - Your handheld software distributes this information to the handheld devices and then your meter readers do their job. When they finish, the resultant measurements are uploaded into the system for subsequent use by other processes such as usage transactions for billing.

WARNING:

It is very important to create a measurement cycle schedule for every expected read date regardless of whether the cycle's routes are downloaded. Why do you have to do this? Because Meter Data Management uses the expected work date on the measurement cycle to know when to look for a measurement during usage calculations. If it can't find a reading on or near this date, Oracle Utilities Meter Data Management may estimate consumption. Without a measurement cycle schedule, MDM wouldn't know when to look for readings. So, for example, if you estimate a given cycle's consumption EVERY OTHER MONTH, you must create a measurement cycle schedule for EVERY month. On each month's schedule, you must define if the routes should be downloaded.

FASTPATH:

For more information about the how to control when a cycle is read, refer to [Setting Up Measurement Cycle Schedules](#).

Designing Measurement Cycles, Routes, And Schedules

The topics in this section provide information describing how to design your measurement cycles, routes, and schedules.

- [Designing Measurement Cycles For Meter Reading](#)
- [Designing Schedule Routes For Meter Reading](#)

- [Designing Metered Measurement Cycle Schedules](#)

Designing Measurement Cycles for Meter Reading

The criterion that affects the number of measurement cycles has nothing to do with when meter readers physically read your meter devices. Rather, the frequency that you bill the meter's consumption (real or estimated) is what controls the number of measurement cycles.

So, for example, if you bill every month, but read every OTHER month, you'll have 20 measurement cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 measurement cycles. If you bill quarterly, you'll have 60 measurement cycles. Etc.

NOTE:

Different billing frequencies are possible for different service points. If you have different billing frequencies for your different types of metered service, you'll need a different set of cycles for each billing frequency. For example, if you bill water quarterly and electricity monthly, you'll have 20 bill cycles (one for each bill day during a month), but you'd need 60 quarterly measurement cycles for your water service points, and 20 monthly measurement cycles for your electric service points. This would result in a customer getting billed every month. However, four times a year, their bill would contain a charge for both electricity and water.

[Top of the Page](#)

Designing Service Routes For Meter Reading

The following points describe the relationship between a meter read, a route and a measurement cycle:

- A measurement cycle contains one or more routes.
- A route has one or more service points.
- A service point holds an installed meter device.
- And a device is what is measured.
- Therefore, the number of devices a person can read in a day limits the number of service points in a route.

WARNING:

If your company supplies electric service and uses MV90's, you will need to take advantage of "notional" routes. A "notional" route's service points are never actually read by a human. Rather, the service points' consumption is fed to the system by a sophisticated device (e.g., an MV90). These service points still need to be linked to a route because usage calculation is dependent on the route's cycle to determine the expected meter read date.

[Top of the Page](#)

Designing Metered Measurement Cycle Schedules

The process of designing your measurement cycle schedules is either easy or complicated. It will be easy if all routes within a cycle are downloaded when the measurement cycle is scheduled for download. It will be complicated if you download a subset of routes within a cycle on any given download date. We'll provide a few examples to help explain why.

If you download all cycles in a route whenever the cycle is downloaded, your measurement cycle schedule will look as follows.

NOTE:

Bill cycles. We've included each measurement cycle's related bill cycle to help you understand when the measurement cycle's consumption will be billed. Bill cycles are discussed in [Bill Cycles](#).

Measurement Cycle	Download Date	Expected Work Date	Which Routes To Download	Bill Cycle	Bill Window	Estimation Date
-------------------	---------------	--------------------	--------------------------	------------	-------------	-----------------

1	28-May-99	31-May-99	All	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	All	2	1-Jun-99 to 3- Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	All	3	2-Jun-99 to 4- Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	All	4	3-Jun-99 to 7- Jun-99	7-Jun-99

Etc. to 20

Now let's complicate life. If we assume you physically read your routes every other month (but bill monthly using estimated consumption), then you'll need the following measurement cycle schedule.

Measurement Cycle	Download Date	Expected Work Date	Which Routes	Bill Cycle	Bill Window	Estimation Date
1	30-May-99	31-May-99	1, 2, 3 - Download 4, 5, 6 - Estimate	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	2	1-Jun-99 to 3- Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	3	2-Jun-99 to 4- Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	1, 2, 3 - Download 4, 5, 6 - Estimate	4	3-Jun-99 to 7- Jun-99	7-Jun-99

Etc. to 20

1	29-Jun-99	30-Jun-99	1, 2, 3 - Estimate 4, 5, 6 - Download	1	30-Jun-99 to 2-Jul-99	2-July-99
2	30-Jun-99	1-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	2	1-July-99 to 3- Jul-99	3-July-99
3	1-July-99	2-July-99	1, 2, 3 - Estimate 4, 5, 6 - Download	3	2-July-99 to 4- July-99	4-July-99
4	2-July-99	3-July-99	1, 2, 3 - Estimate	4	3-July-99 to 7- July-99	7-July-99

Etc. to 20

Notice the following:

- You still have 20 measurement cycles even though you only read the meters every other month. Why? Because Oracle Utilities Meter Data Management uses the expected work date on the measurement cycle to know when to look for a measurement. If it can't find a reading on this date, Meter Data Management estimates consumption. Without a measurement cycle schedule, Meter Data Management wouldn't know when to look for readings.
- Every other month you download half the routes in each cycle and estimate consumption for the other half.
- If you don't download all routes when a measurement cycle is scheduled, you have to indicate how to handle every route in the cycle.

The above design is infinitely flexible. You can use it to handle any number of requirements:

- Estimate consumption every seventh month.
- Bill every month, but only read once a quarter.
- Etc.

Bill Cycles

The topics in this section provide background information about a variety of bill cycle features.

The Cyclical Billing Process & Window Billing

The cyclical bill creation process creates most bills. This process works as follows:

- Every account references a bill cycle. The bill cycle's schedule controls WHEN the system attempts to create bills for the account.
- Every bill cycle has a bill cycle schedule that defines the dates when a cycle's accounts are to be billed. Rather than attempt to create bills on one evening, most bill cycles use a concept of "window billing" where the system attempts to produce bills for accounts over a few nights. The first night (i.e., the day the window opens) should be the earliest day on which meter reads for the account can enter the system. The last night (i.e., the day the window closes) should be the last possible day in which a meter read can enter the system. This concept of window billing allows you to start billing accounts on the earliest possible day and then bill the stragglers over successive evenings. This results in much better cash flow.
- When the bill cycle creation process runs, it looks for bill cycles with open bill windows. It then attempts to create bills for the accounts in each such cycle. If a bill is created, it will send it out that evening. If a bill cannot be created, the system will create a bill in the "error" state with a message that can be analyzed by your billing staff. The next day, your staff can either correct the problem or not. When the bill cycle creation process next runs, it deletes all "error" bills and attempts to recreate them. It continues this throughout the bill window. If bills are in error at the end of the window, they will remain in this state until a user fixes them. If the bills are still in error when the cycle's next window opens, a billing error will be generated.

The following diagram should help clarify the above.

FASTPATH:

For more information about the how to control when bills are produced for a cycle, refer to [Bill Cycle - Bill Cycle Schedule](#).

Designing Your Bill Cycle

The number of bill cycles is determined by the frequency that you bill your customers. So, for example, if you bill every month, you'll have 20 bill cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 bill cycles. If you bill quarterly, you'll have 60 bill cycles. Etc.

Keep in mind the following:

- You may need additional bill cycles if you allow customers to be billed off-cycle. For example, you could create a bill cycle called "Seniors" and link this to every senior citizen. You would set up this bill cycle's schedule to create bills shortly after social security checks are issued.
- You may need other bill cycles for customers with non-metered services (e.g., land leases, one time invoices).

IMPORTANT:

An account's bill cycle should attempt to create bill segments at least as often as the shortest service agreement duration. For example, if an account has both monthly and quarterly service agreements, the account should be placed on a monthly bill cycle. Refer to [Bill Frequency - Bill Cycle vs Bill Segment Duration](#) for more information.

The Relationship Between Metered Measurement Cycles and Bill Cycles

As you can deduce, a service point's measurement cycle is related to an account's bill cycle.

The following table is an example of how you would set up the various dates on the various schedules that control meter reading and billing.

Measurement Cycle	Download Date	Expected Work Date	Bill Cycle	Bill Window	Estimation Date
1	28-May-99	31-May-99	1	31-May-99 to 2-Jun-99	2-Jun-99
2	31-May-99	1-Jun-99	2	1-Jun-99 to 3-Jun-99	3-Jun-99
3	1-Jun-99	2-Jun-99	3	2-Jun-99 to 4-Jun-99	4-Jun-99
4	2-Jun-99	3-Jun-99	4	3-Jun-99 to 7-Jun-99	7-Jun-99
Etc.					

Notice the following about this example:

- The bill cycle code is the same as the measurement cycle. This is not necessary, it's just good practice.
- The bill window starts on the first date on which a meter read could be uploaded.
- The bill window ends on the day after the last possible day a read could be uploaded for the bill cycle.
- Oracle Utilities Meter Data Management only estimates consumption on the last day of the bill window.

FASTPATH:

For more information about the bill cycle schedule, refer to [Setting Up Bill Cycles](#).

How Does An Account Get Its Bill Cycle?

Most accounts are created behind-the-scenes when a user uses the "add account" option on [Person - Main Information](#). An account created like this doesn't have a bill cycle. Rather, it sits in limbo awaiting the activation of its first service agreement. When a service agreement is activated, the system populates the account's bill cycle using the following algorithm:

- If an account's bill cycle is protected, the activation of a service agreement will not affect an account's bill cycle. Refer to [Protecting An Account's Bill Cycle](#) for more information.
- If the service agreement being activated is for metered service, the account is given a bill cycle that will generate bills shortly after the service point is read. The route the system follows to get this bill cycle is a bit indirect:
 - A metered service agreement references one or more metered service points.
 - Every metered service point references a measurement cycle (the measurement cycle controls when the meter at the service point is read).
 - Every measurement cycle references a default bill cycle. It is this bill cycle that is populated on the account paying for service at the service point.
- If the service agreement being activated is not metered, the system cannot populate the account's bill cycle because there is no measurement cycle from which to default the bill cycle. This means the account's bill cycle will be blank until a user specifies a bill cycle for the account (using the Account page).

NOTE:

A To Do entry highlights accounts without a bill cycle. A To Do entry highlights those accounts that require a user to specify a bill cycle. This entry is generated for accounts without a bill cycle that have active service agreements.

When the last service agreement linked to an account is stopped, the account's bill cycle will be changed so that the account will be final billed when billing next executes. Refer to [What Happens At Finalization Time?](#) for more information.

When a service point's measurement cycle is updated, and the account's bill cycle is not protected, the system automatically updates the account's bill cycle to be in sync with the measurement cycle. Note that this will only take place if the Allow Bill Cycle Synchronization **Option Type** on the General System Options [Feature Configuration](#) is set to Y.

Protecting An Account's Bill Cycle

Over time, as a customer moves from premise to premise, their bill cycle is changed behind-the-scenes to be in sync with the latest service point's measurement cycle (as described in the previous section). If you do not want the system to change an account's bill cycle when a metered service agreement is activated, you need to turn on the account's **protect bill cycle** flag. You would do this if a customer liked to be billed at the start of the month regardless of when their device was read.

When the last service agreement for an account is stopped, the protect bill cycle flag is reset. This is to ensure that if the customer returns to start new service again, the bill cycle can be set based on [How Does An Account Get Its Bill Cycle](#).

What Happens If An Account Has Service Agreements Spanning Metered Measurement Cycles?

A single account can have service agreements that are in several measurement cycles. The bill cycle on such an account will default based on the last activated metered service agreement.

It's important to be aware that an account will only have bills created when its bill cycle schedule so indicates. This means that the consumption for some service points could remain unbilled for a few weeks.

Designing Bill Periods

Bill periods are used by non-metered service agreements whose bill end dates need to fall on strict dates. You need only set up this information if you have this type of service agreement.

FASTPATH:

Refer to [Ways To Control The End Date Of A Bill Segment](#) for more information.

Every bill period has a calendar that defines when bill segments are created for service agreements that use the bill period. Examples of bill periods include:

- Quarterly Bill - Last Day Of Quarter
- Quarterly Future Bill - Last Day Of Quarter
- Monthly - 15th Day Of Month.
- Monthly Future Bill - Last Day Of Month.

The Quarterly Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

Earliest Date On Which To Create A Bill Segment	Bill End Date
1-Oct-1998	30-Sep-1998
1-Jan-1999	31-Dec-1998
1-Apr-1999	31-Mar-1999
1-Jul-1999	30-Jun-1999

...

The Quarterly Future Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

Earliest Date On Which To Create A Bill Segment	Bill End Date
15-Dec-1998	31-Mar-1999
15-Mar-1999	30-Jun-1999

...

The remainder of this section provides examples using the above calendars.

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.
- The service agreement's SA type references the Quarterly Future Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempt to create segments as soon as possible) for several bill periods:

Earliest Date Segment Will Be Produced	Bill Period
18-Dec-1998	18-Dec-1998 thru 31-Mar-1999
15-Mar-1999	1-Apr-1999 thru 30-Jun-1999

...

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.
- The service agreement's SA type references the Quarterly Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempts to create segments as soon as possible) for several bill periods:

Earliest Date Segment Will Be Produced	Bill Period
1-Jan-1999	18-Dec-1998 thru 31-Dec-1998
1-Apr-1999	1-Jan-1999 thru 31-Mar-1999

...

FASTPATH:

Refer to [Setting Up Bill Periods](#) for information about how to define this information.

Setting Up Bill Cycles

An account references a bill cycle. The bill cycle defines when the account is billed and when the account's debt is checked to determine if it's overdue. To define a bill cycle and its bill cycle schedule, open **Admin > Billing > Bill Cycle > Add.**

Description of Page

Enter a unique **Bill Cycle** and **Description** for every bill cycle.

If your implementation requires restricting bill cycles to accounts by CIS Division, specify a **CIS Division** on the bill cycle.

Use the **Bill Cycle Schedule** collection to define when bills are produced for the accounts in a given bill cycle. The following fields are required for each instance:

Window Start Date Specify the date on which the system should start trying to create bills for accounts in the cycle.

Window End Date Specify the last day on which the system will create bills for accounts in the cycle. This should be the last possible date on which a meter read could be loaded into Oracle Utilities Meter Data Management for the account.

Accounting Date Specify the financial date associated with the bills' financial transaction. The accounting date defines the financial period(s) to which the bills will be booked in your general ledger.

Estimate Date The date on which Oracle Utilities Meter Data Management may start estimating consumption if a real measurement cannot be found. When specified, this date is typically on or shortly before the window end date.

Freeze and Complete Turn on this switch if the system should freeze and complete any bill that is created without errors. If this switch is turned off, all bills created by the billing process will be left in the unfinished state. You would only turn this switch off if you want to verify an entire bill run prior to freezing it (e.g., if you are introducing a new version of a rate). If you turn this off, you will need to return to this page after verifying a bill run and turn it back on for the customers to receive bills. When the system next runs, it deletes all unfrozen bills and recreates them as per the instructions on the bill cycle schedule.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_BILL_CYC](#).

The batch bill creation process uses this schedule to define the bill cycles for which it should create bills.

NOTE:

Don't forget. After you set up the bill cycles that correspond with measurement cycles, go to [Setting Up Measurement Cycle Schedules](#) and update the measurement cycles accordingly.

Setting Up Service Cycles And Measurement Cycle Schedules

Refer to [Measurement Cycles](#), [Measurement Cycle and Bill Determinants](#), and [Setting Up Measurement Cycle Schedules](#) sections for more information

Setting Up Measurement Cycle Schedules

FASTPATH:

Refer to [Designing Cycles for Metered Services](#) for more information about . Refer to [The Relationship Between Metered Service Cycles and Bill Cycles](#) for more information about how s are linked to bill cycles.

Description of Page

When you want to add a new schedule, you must specify the following information:

Service Cycle Enter the ID of the cycle whose routes will be downloaded.

Scheduled Selection Date Specify the date on which the system is meant to download information about the cycle's meters. This date should be a day or two before the scheduled work date.

Define the date the meters in the route are scheduled to be read using **Scheduled Work Date**. This date is extremely important as billing uses it when it looks for meter reads for service points in this cycle. If billing can't find a reading, consumption will be estimated as of this date (assuming the service agreement allows estimation).

Click **Pre-Generate Routes** if you need to finesse the cycle's routes on this Scheduled Selection Date (e.g., because some of the routes shouldn't be downloaded on a given date because the system is meant to estimate consumption). If you don't

click this button, the system will create the routes on the scheduled selection date. It does this by creating a route extract for each downloadable route within the cycle (as defined by the route type). If you click this button, the system shows all routes within the cycle in the grid below. You must then define how the system is supposed to download each route on the scheduled selection date.

Click **Delete Routes** if you have pre-generated the routes and you want to remove them and allow the system to create the routes on the scheduled selection date.

Use the **Service Schedule Routes** to define how individual routes within the cycle should be handled during the download. The following fields are required for each schedule read date:

Service Route The unique ID of the service route. The route's route type is displayed adjacent.

Schedule Type This defines if and how the system is supposed to download the route's meter reads. Valid values are: Cust Read, Download, Estimate. Only those routes defined as Download will have meter reads downloaded. The other values are used to document why the route won't be downloaded.

Schedule Status This defines the download status of the route. Valid values are Pending and Complete. This value is only displayed for routes with a schedule type of Download.

Where Used

This information is used by the meter read download process to determine which meter reads to download.

This information is used by the billing process to determine the date on which it expects to find a read. If it cannot find a read on or around this date, and it's OK to estimate consumption, consumption will be estimated as of the scheduled work date. The system uses the service agreement's rate schedule's frequency to determine the period of time around the scheduled work date in which it looks for a read. Refer to [Defining Frequency Codes](#) for more information.

Setting Up Bill Periods

Some SA types reference a bill period. The bill period defines when the service agreement's bill segments are produced and the respective end date of each bill segment.

FASTPATH:

Refer to [Designing Bill Periods](#) for more information.

To define a bill period and the bill period schedule, open **Admin > Billing > Bill Period > Add**.

Description of Page

Enter a unique **Bill Period** and a **Description** for every bill period.

Use the **Bill Period Schedules** collection when the system should create bill segments for service agreements that use a given bill period. It also defines the end date of each respective bill segment. The following fields are required:

Bill Date Specify the earliest date on which the system is allowed to create a bill segment for service agreements using this bill period.

Bill Seg End Date Specify the end date of the bill segment. For future bills, this will be after the bill date. For retro bills, this will be before the bill date.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_BILL_PERIOD](#).

This information is used by the bill segment creation process to determine the end date of service agreements that use a bill period.

Defining Statement Cycles

If you have persons set up in the system to receive statements with financial information, you will need to assign them to a statement cycle and define a schedule for the statement cycle.

FASTPATH:

Refer to [The Big Picture of Complex Statements](#) for more information about statements.

The Big Picture Of Statement Cycles

A statement cycle has a similar purpose to that of a bill cycle. It controls when statements will be produced.

The Cyclical Statement Process

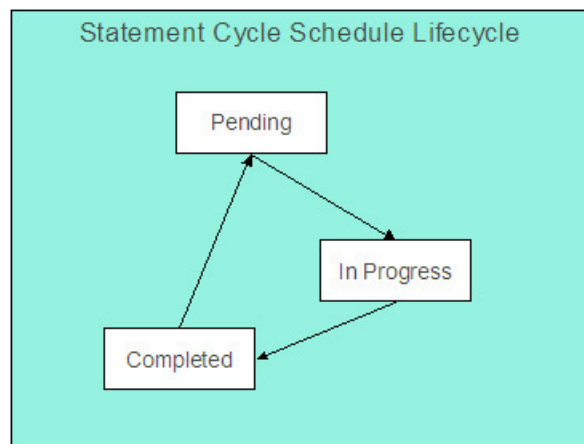

Persons who wish to receive statements will work with you to determine how often these statements should be produced. Some persons may want a monthly statement, some a quarterly and some annually. For each unique schedule that is designed for your various statement persons, you will set up a Statement Cycle and its schedule.

Designing Your Statement Cycles

The number of statement cycles is determined by a combination of the frequency that you will send statements to the statement persons and how many statement cycles you wish to manage within the same frequency.

So, for example, for all the statement persons who wish to receive a monthly statement, will you create only one monthly Statement Cycle so that all monthly statements are produced the same day? Or will you have several monthly statement cycles scheduled throughout the month? The answer will depend on the volume of statements being produced and on how you want to manage the statement production.

Lifecycle of a Statement Cycle Schedule

Pending The statement cycle schedule is added in this state. The Create Statements background process find records in this state to process on the appropriate date.

FASTPATH:

Refer to [Create Statements Background Process](#) for more information.

In Progress Records in this state are currently being processed by the Create Statements background process.

Completed Records in this state have already been processed by the Create Statements background process. If a problem occurs with the Create Statements background process and it needs to be rerun, simply change the status back to pending and rerun the process.

Setting Up Statement Cycles

A Statement Construct references a statement cycle. The statement cycle defines when the statement person will receive statements with financial information related to the accounts and service agreements linked to the statement construct. To define a statement cycle and its statement cycle schedule, open **Admin > Billing > Statement Cycle > Add**.

Description of Page

Enter a unique **Statement Cycle** and **Description** for every statement cycle.

Use the **Statement Cycle Schedule** collection to define when statements are produced for the persons with statement construct records in the given statement cycle. The following fields are required for each instance:

Processing Date Specify the date on which the system should create statements for persons with statement construct records in the cycle.

Status Indicates the status of the cycle schedule. Refer to [Lifecycle of a Statement Cycle Schedule](#) for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CL_STM_CYC](#).

The batch statement creation process uses this schedule to determine which statement cycles for it should create statements for the statement construct records. Refer to [Create Statements Background Process](#) for more information.

Defining Service Agreement Type (SA Types)

Every service agreement must reference a SA type. The SA type defines what you sell, how much you sell it for, to whom you sell it, how overdue debt is collected, and how sales will be booked in your general ledger.

NOTE:

Perfect foresight. In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SA types. In reality, setting up your SA types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

Designing SA Types For Service Agreements With Service Points

Designing your SA types is an iterative process. To minimize some iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SA types.

Division/SA Type	Service Type
------------------	--------------

The topics in this section provide guidelines describing how to fill in this table for SA types associated with service agreements that charge for service point-oriented services.

CIS Division Segmentation

A CIS division is typically associated with a jurisdiction. The definition of a jurisdiction is a geographic-oriented entity with unique business rules. For example, if you conduct business in California and Nevada, and each state has different collection rules, you will need a separate jurisdiction for each state. You must set up a CIS division for each jurisdiction in which you conduct business.

If we assume that you are located in a single jurisdiction - say California - we will need a single CIS division for all of our SA types.

CIS Division/SA Type
CA

Service Segmentation

At a minimum, you will have one SA type for every different type of utility service offered by your organization. If we assume you sell electricity, gas, water, wastewater and cable; your SA Types will be as follows:

CIS Division/SA Type	Service Type
CA/G	Gas service
CA/W	Water service
CA/E	Electric service
CA/WW	Waste water service
CA/CABLE	Cable

Receivable Segmentation

Many organizations segregate their receivable balances in the general ledger. For example, the receivable amount associated with gas and water service may be maintained in separate GL accounts.

If your organization does this, you will probably have at least one SA type for each such receivable account because each SA type references a distribution code that typically contains the receivable account.

- The word *probably* is underlined because this is a rule of thumb. There are situations where the number of receivable accounts isn't directly related to the number of SA types. This happens when an organization maintains very detailed receivable accounts in the general ledger and maintaining a one-to-one relationship between SA types and distribution codes would lead to a massive proliferation of SA types (and you don't want this!). If your organization maintains very detailed receivable accounts, please speak to your implementers, they should be able to introduce a small customization to generate the appropriate receivable account rather than extract it from the distribution code.
- The word *typically* is underlined because there are several SA types that don't book to a receivable account when bill segments are generated. For example, company usage and charitable contributions. Refer to [Company Usage](#)

[Segmentation](#) and [Charitable Contribution Segmentation](#) for examples of SA types that don't book to receivable accounts.

We'll simplify our example and assume your organization has one receivable account for all types of utility service. Given this, we won't need additional SA types to support receivable segmentation:

CIS Division/ SA Type	Service Type	Distribution Code
CA/G	Gas service	A/R-UTIL
CA/W	Water service	A/R-UTIL
CA/E	Electric service	A/R-UTIL
CA/WW	Waste water service	A/R-UTIL
CA/CABLE	Cable service	A/R-UTIL

Revenue Segmentation

Look at your rates and determine which rates can be used by each SA type. The following table shows the sample rates that can be used for each service:

CIS Division/ SA Type	Service Type	Distribution Code	Rates
CA/G	Gas service	A/R-UTIL	GALL-1
CA/W	Water service	A/R-UTIL	WALL-1
CA/E	Electric service	A/R-UTIL	ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1
CA/WW	Waste water service	A/R-UTIL	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	CABLE

Now, look at the rates' calculation rule GL Distribution window. You're looking for calculation rules whose GL distribution is affected by revenue class. If there are no revenue classes referenced on the calculation rules, this means that the revenue associated with the rate will be booked to a single GL account regardless of the type of customer. If you see revenue classes, this means that the revenue account associated with the calculation rule(s) differs depending on the SA type's revenue class. If revenue classes are used in the rates, you must create a different SA Type for every revenue class.

Let's assume the following:

- The gas rate (GALL-1) references the RESIDENTIAL, COMMERCIAL and INDUSTRIAL revenue classes in order to differentiate revenue based on the type of customer.
- None of the other rates differentiate revenue based on customer class.

Our SA types will now look as follows:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1

CA/W	Water service	A/R-UTIL	N/A	WALL-1
CA/E	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1
CA/WW	Waste water service	A/R-UTIL	N/A	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE

Notice that we created new SA types for gas in order to specify the respective revenue class. We didn't do this for the other services because it isn't necessary. However, you should feel free to do this if it feels right or if you need it for reporting purposes. For example, if you want to report on all *residential* service agreements, but you differentiate only gas by residential versus commercial, you'll be in trouble.

Rate Segmentation

Every SA Type whose service agreements have their charges calculated with a rate must have one or more rates linked to it. These define which rates can be linked to the SA type's service agreements. If different service agreements have different valid rate combinations, you will need to split the SA types accordingly.

For example, look at the electric rates. If we assume:

- the RES rates can only be used for residential customer,
- the IND rates can only be used for industrial customers,
- the COM rates can only be used for commercial customers,
- the LAMP rates can only be used for lamp customers

Then you might want to set up a new SA type to indicate such. The advantage of doing this is that you get more control over which rates can be used on a given SA type. The disadvantage is that you proliferate SA types. Unfortunately, it's really a question of taste.

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1
CA/W	Water service	A/R-UTIL	N/A	WALL-1
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1
CA/LAMP	Electric service	A/R-UTIL	N/A	ELAMP-1
CA/WW	Waste water service	A/R-UTIL	N/A	WWALL-1
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE

WARNING:

Don't be too specific in your analysis in respect of rate segmentation because you could end up with a separate SA type for every rate (and you don't want this). We understand this is a very subjective warning, but we recommend that you start out with broad bands of rates that can be used on a SA type and narrow it down if you end up unhappy with the

results. For example, you don't have to set up a separate SA type for low-income residential gas customers just because they have a special rate. Rather, you can leave your SA types as they are and treat low-income gas customers as a subset of your residential gas customers. **For more information**, refer to [Setting Up Start Options](#).

NOTE:

Rate override. If a service agreement of this type may be linked to a terms of service record, you must also consider whether or not the [rate schedule could be overridden](#) by a template SA linked to the terms of service record. Refer to [SA Type - Rate](#) for information about the possible values for this field.

Service Point (SP) Type Segmentation

Every SA Type whose service agreements exist to bill for service point-oriented service has one or more SP types. These define which type of service points can be linked to the SA type's service agreements. If different service agreements have different valid SP types, you will need to split the SA types accordingly.

For each service point-oriented SA type, determine if there are any restrictions in respect of the types of service points that can use the SA type's rates. For example, if we assume that only commercial SP types can be used by commercial customers, industrial SP types by industrial customers, residential SP types by residential customers, your SA types will be:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates	SP Type
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1	G-RES
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1	G-COM
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1	G-IND
CA/W-RES	Water service	A/R-UTIL	N/A	WALL-1	W-RES
CA/W-COM	Water service	A/R-UTIL	N/A	WALL-1	W-COM
CA/W-IND	Water service	A/R-UTIL	N/A	WALL-1	W-IND
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1	E-COM
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1	E-IND
CA/WW-RES	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES
CA/WW-COM	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM
CA/WW-IND	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE	CABLE

Notice the wastewater SA types reference both water and waste water service points. This is intentional as wastewater service uses the consumption from the water service to calculate some part of the wastewater charge.

Company Usage Segmentation

Up to now, we've discussed SA types associated with service agreements linked to your customers. The system has also been designed to keep track of the expenses associated with your company's use of power. If you want the system to do this, you must create at least one SA type for each service consumed by your organization.

For example, if we assume your organization consumes electric, gas, and water service; your SA types will now be as follows:

CIS Division/ SA Type	Service Type	Distribution Code	Revenue Class	Rates	SP Type	Bill Seg Type
CA/G-RES	Gas service	A/R-UTIL	R - residential	GALL-1	G-RES	
CA/G-COM	Gas service	A/R-UTIL	C - commercial	GALL-1	G-COM	
CA/G-IND	Gas service	A/R-UTIL	I - industrial	GALL-1	G-IND	
CA/W-RES	Water service	A/R-UTIL	N/A	WALL-1	W-RES	
CA/W-COM	Water service	A/R-UTIL	N/A	WALL-1	W-COM	
CA/W-IND	Water service	A/R-UTIL	N/A	WALL-1	W-IND	
CA/E-RES	Electric service	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES	
CA/E-COM	Electric service	A/R-UTIL	N/A	ECOM-1	E-COM	
CA/E-IND	Electric service	A/R-UTIL	N/A	EIND-1	E-IND	
CA/WW-RES	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES	
CA/WW-COM	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM	
CA/WW-IND	Wastewater service	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND	
CA/CABLE	Cable service	A/R-UTIL	N/A	CABLE	CABLE	
CA/E-COY	Electric service	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG
CA/G-COY	Gas service	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG
CA/W-COY	Water service	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG

Notice the three company usage SA types do not reference an A/R account as their distribution code. This is because when bill segments are created for these types of service agreements, the system must debit an expense account (or contra-revenue account) rather than a receivable account.

FASTPATH:

For more information, refer to [Designing and Defining Bill Segment Types](#).

Debt Class Segmentation

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you will have to split the SA Type.

FASTPATH:

For more information about debt class, refer to [Designing Your Collection Procedures](#).

If we assume that your residential services are regulated and your commercial and industrial services are deregulated, we won't have to introduce additional SA types.

CIS Division/	Distribution Code	Revenue Class	Rates	SP Type	Bill Seg Type	Debt Class
---------------	-------------------	---------------	-------	---------	---------------	------------

SA Type

CA/G-RES	A/R-UTIL	R - residential	GALL-1	G-RES		REGU
CA/G-COM	A/R-UTIL	C - commercial	GALL-1	G-COM		UNRE
CA/G-IND	A/R-UTIL	I - industrial	GALL-1	G-IND		UNRE
CA/W-RES	A/R-UTIL	N/A	WALL-1	W-RES		REGU
CA/W-COM	A/R-UTIL	N/A	WALL-1	W-COM		UNRE
CA/W-IND	A/R-UTIL	N/A	WALL-1	W-IND		UNRE
CA/E-RES	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES		REGU
CA/E-COM	A/R-UTIL	N/A	ECOM-1	E-COM		UNRE
CA/E-IND	A/R-UTIL	N/A	EIND-1	E-IND		UNRE
CA/WW-RES	A/R-UTIL	N/A	WWALL-1	W-RES, WW-RES		REGU
CA/WW-COM	A/R-UTIL	N/A	WWALL-1	W-COM, WW-COM		UNRE
CA/WW-IND	A/R-UTIL	N/A	WWALL-1	W-IND, WW-IND		UNRE
CA/CABLE	A/R-UTIL	N/A	CABLE	CABLE		UNRE
CA/E-COY	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG	No debt
CA/G-COY	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG	No debt
CA/W-COY	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG	No debt

Notice the three company usage SA types do not have a debt class. This is because their bill segment type's FT algorithm doesn't cause debt to be created and therefore there is no reason to have a debt class. However, you'll need to create a "dummy" debt class - call it N/A - for these SA types because every SA type must reference a debt class.

Budget Billing Segmentation

Many utilities offer their customers levelized payment plans to smooth out the seasonal bill variations. We call this levelized amount the *budget amount*.

FASTPATH:

Refer to [Budget Billing](#) for more information about budgets in general. Refer to [Billing - Current Balance versus Payoff Balance](#) for an example of budget billing accounting.

If we assume that you only allow budget billing on the electric and gas residential services, then you'll need to update your CA/G-RES and CA/E-RES SA types:

CIS Division/ SA Type	Dist Code	Rev Class	Rates	SP Type	Bill Seg Type	Debt Class	Recurring Charge Control Info
CA/G-RES	A/R-UTIL	R	GALL-1	G-RES		REGU	Amount to bill is Not Allowed Amount is Optional Frequency is Monthly

						Recurring Amount Label is Budget Amount:
CA/G-COM	A/R-UTIL	C	GALL-1	G-COM		UNRE
CA/G-IND	A/R-UTIL	I	GALL-1	G-IND		UNRE
CA/W-RES	A/R-UTIL	N/A	WALL-1	W-RES		REGU
CA/W-COM	A/R-UTIL	N/A	WALL-1	W-COM		UNRE
CA/W-IND	A/R-UTIL	N/A	WALL-1	W-IND		UNRE
CA/E-RES	A/R-UTIL	N/A	ERES-1, ERES-2	E-RES		REGU
						Amount to bill is Not Allowed Amount is Optional Frequency is Monthly Recurring Amount Label is Budget Amount:
CA/E-COM	A/R-UTIL	N/A	ECOM-1	E-COM		UNRE
CA/E-IND	A/R-UTIL	N/A	EIND-1	E-IND		UNRE
CA/WW-RES	A/R-UTIL	N/A	WWALL-1	W-RES, WW- RES		REGU
CA/WW-COM	A/R-UTIL	N/A	WWALL-1	W-COM, WW- COM		UNRE
CA/WW-IND	A/R-UTIL	N/A	WWALL-1	W-IND, WW- IND		UNRE
CA/CABLE	A/R-UTIL	N/A	CABLE	CABLE		UNRE
CA/E-COY	EXP-COMP	N/A	E CO USE	E-CO USE	COMPUSAG	No debt
CA/G-COY	EXP-COMP	N/A	G CO USE	G-CO USE	COMPUSAG	No debt
CA/W-COY	EXP-COMP	N/A	W CO USE	W-CO USE	COMPUSAG	No debt

Notice the following:

- We updated the two SA types to allow recurring charge information.
- The Recurring Charge Amount is Optional. Why? Because those customers who aren't on a budget plan won't have a recurring charge amount. Those customers on a budget will have a recurring charge amount.

NOTE:

Turn on Eligible for Budget. Besides indicating that these SA types use recurring charges, you also need to turn on the Eligible for Budget switch on the SA type to indicate that this type of SA participates in budget processing.

Override Budget Eligibility. You may plug in an override budget eligibility algorithm on an SA type that is configured to be Eligible for Budget if certain service agreements of this type are not eligible.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes.

Designing SA Types For SAs Without Service Points

The topics in this section provide guidelines describing how to design the SA types associated with your service agreements that don't have service points.

Overpayment Segmentation

When a customer pays more than they owe, you must decide what to do with the excess money. The following points describe two possibilities:

- You could create a new service agreement to hold the excess (let's call it an overpayment SA). The credit would be transferred from this service agreement to the billable service agreements when the next bill is completed. This means that all billable service agreements have the same opportunity to receive the overpayment when they are billed in the future.
- You could amalgamate the excess payment on one of the existing, billable service agreements. For example, if a customer has both electric and gas service, the excess funds could be kept on either the gas or the electric SA. This would result in the following:
 - The service agreements that do NOT receive the overpayment will have debt when they are next billed.
 - The service agreement that receives the overpayment could have its future debt offset by the overpayment (meaning that it could have a credit balance until the service agreement's future bill segments offset the overpayment amount).
- The above situation is not desirable unless the customer intentionally overpaid one service agreement. The first method (keeping the overpayment on a separate service agreement) obviates this potential problem. Obviously, if your organization sells a single service (and therefore your customers have a single service agreement) you would choose the second method.

You control which method is used by plugging in the appropriate Overpayment Distribution algorithm on each [Customer Class](#) (i.e., you can choose a different method for different customer classes). If you choose to hold overpayments on a separate SA, then you must set up an SA Type as described in the following table:

CIS Division/ SA Type	Service Type	Distrib. Code	Eligible for Billing	Debt Class	Pay Seg Type	Do Not Overpay	One-time
CA/OVERPAY	Other	A/P - OVER	Not billed	N/A	Normal	No	Yes

Notice the following about the new overpayment SA type:

- It has an interesting distribution code. This is because when a payment segment is created for this type of service agreements, the system must credit a liability (an overpayment is a liability).
- It's important to indicate that the overpayment SA is a one-time service agreement. Why? Because this means that the system will automatically close the SA when it's balance falls to zero (i.e., when all of the overpayment has been used to satisfy future bills).
- A bill segment type is not needed because the system never creates bill segments for such service agreements (they exist only to hold excess credits).
- You may also want to turn on the alert message

- You must plug-in a bill completion algorithm on this SA type. This bill completion algorithm will transfer the credit balance to the account's other service agreements when the bill is completed. Refer to [The Credit Transfer Algorithm](#) for more information about this algorithm.
- You must also reference this overpayment SA type as the parameter value on your overpayment algorithm (this algorithm is plugged in on the desired customer classes). Refer to [Overpayment Algorithm](#) for more information about this algorithm.

NOTE:

If overpayment means charitable contribution. Some organizations sponsor a program that works as follows - if a customer overpays a bill by a given amount (say \$5), this amount is assumed to be a charitable contribution. If you have this requirement, you will create another SA type to hold a customer's charitable contributions. This SA type will look similar to the one described below (see [Charitable Contribution Segmentation](#)) except it is not billable. The funds will be credited to this service agreement by creating a new overpayment algorithm that is similar to the base package [Overpayment Algorithm](#). This new algorithm will be very similar to the existing algorithm. The main difference will be that it will have to check if the overpayment amount is an exact value (say \$5). If so, it will create a payment segment for the charitable contribution SA type; otherwise it will create a payment segment for the overpayment SA.

Write Off Segmentation

When you write off non-collectable debt, you transfer the receivable from a "normal" service agreement onto one or more write-off service agreements. When the debt is transferred to a write-off service agreement, the distribution code on the "normal" service agreement is credited (typically an A/R GL account), and the distribution code on the write-off service agreement is debited.

You will almost always need a write-off service agreement whose distribution code is the write-off expense. However, you probably don't book all of the write-off amount to a write-off expense account. Why? Because the debt that you're writing off typically contains both revenue and liabilities. At write-off time, you want to book the written off revenue to a write-off expense account and you want to reduce the liabilities (you don't owe the liability if you don't get paid). This means you'll need another SA type for the liabilities. Refer to [The Ramifications of Write Offs in the General Ledger](#) for a complete explanation.

The following table contains the minimum number of SA Types that you'll need to hold your write-offs.

CIS Division/ SA Type	Service Type	Distrib. Code	Bill Seg Type	Debt Class	Pay Seg Type	Do Not Overpay
CA/WO-STD	Other	EXP-W/O	Not billed	WO	Normal	Yes
CA/WO-LIA	Other	LIA-General	Not billed	WO	Normal	Yes

Notice the following about the new write-off SA types:

- They have interesting distribution codes. This is because when debt is transferred to these types of service agreements, the system must debit either an expense account (i.e., write-off expense) or a liability account. It's important to note that in [The Ramifications of Write Offs in the General Ledger](#) we explain how this liability account may be overwritten with the liability account that was originally booked.
- Neither needs a bill segment type because the system never creates bill segments for such service agreements (they exist only to hold uncollectable debt)
- Even though the debt is not collectable, it still has a debt class. Why? Because the system shows a customer's debt on many inquiries by debt class and it's important to show write-off debt on these queries.
- The combination of Payment Segment Type and Do Not Overpay are important. Refer to [The Ramifications of Write Offs in the General Ledger](#) for a complete explanation.

NOTE:

The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on each write-offable SA type. The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write-off SA type.

An Alternative. If you have a limited number of liability accounts, you may decide to have a separate write-off service agreement for each liability account. Doing this would proliferate the number of service agreements created at write-off time. However, it would simplify the remittance of payment to the taxing authority if the reversed liability is ever paid.

Connection Charge Segmentation

If you levy connection charges, you have two options:

- You can create a SA type that exists purely to handle connect charge debt. After doing this, you'd create a start option for this SA type that causes an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had multiple services (e.g., a combined electric, gas, water utility) that only levies a single connection charge regardless of the number of services started. If you use this approach, make sure to indicate the SA type is non billable.
- You can levy a start adjustment on one of your existing SA types (e.g., CA/E-RES). The easiest way to do this is with a start option. On the start option you'd indicate an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had a single service offering (e.g., an electric-only utility). Refer to [Setting Up Start Options](#) for more information.

In the table below, we show what would be necessary if you want to have a separate service agreement for the connection charge.

CIS Division/ SA Type	Service Type	Distrib. Code	Bill Seg Type	Debt Class
CA/CONNECT	Other	A/R-UTIL	Not billed	REGU

Notice the following about the new connection charge SA type:

- It has a normal receivable distribution code.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (its charged via an adjustment).
- The debt class is interesting - REGU (for regulated). We are intentionally linking the connection charge debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the connection charge debt the same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).

Charitable Contribution Segmentation

If your organization accepts charitable contributions made by your customers, you must create a SA type to hold these contributions.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/CHARITY	Other	A/P-CHAR	CHAR	RECUR	Amount to bill is Not Allowed

Amount is Required
 Frequency is
 Monthly
 Recurring Amount
 Label is Contrib.
 Amount

Notice the following about the new charitable contribution SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., charitable contribution payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the charitable contribution is created.
- It uses an interesting bill segment type - RECUR. This bill segment type was set up to create recurring charges that don't automatically stop at some point in time.
- The debt class is interesting - CHAR (for charity). This is done so that past due charitable contribution debt is treated separately from other types of debt.
- The recurring charge control information is set up as defined.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

WARNING:

It's important that you assign the charitable contribution SA type with a payment segment type that only affect current balance (as opposed to affecting current AND payoff balance). This is because there is no receivable recognized when the contribution is billed and therefore there is no payoff balance to relieve when it's paid.

Payment Arrangement Segmentation

If your organization allows customers to payoff outstanding debt using payment arrangements (e.g., current bill plus \$X), you will need a new SA type for every debt class that can have a payment arrangement. If we assume you can have payment arrangements for both regulated and unregulated debt, then you'll need at least two more SA types (you may have more SA types if you need to segregate the payment arrangement receivable amount by utility type (or some other type)).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/PA-REGU	Other	A/R-ARRG	REGU	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Arrange Amount
CA/PA-UNRE	Other	A/R-ARRG	UNRE	RECUR-AS	Amount to bill is Not Allowed

Amount is Required
 Frequency is
 Monthly
 Recurring Amount
 Label is Arrange
 Amount

Notice the following about the new payment arrangement SA types:

- They have an interesting distribution code. This is because when funds are transferred to these types of service agreements, the system must debit a receivable (i.e., payment arrangement receivable).
- They use an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- Each new SA type references the debt class whose debt it will pay off. We are intentionally linking the payment arrangement debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the arrangement debt as the same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).
- The recurring charge control information is set up as defined.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use Start Options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Merchandise Segmentation - Installment Billing

If your organization allows customers to purchase merchandise using an installment plan, you must create a SA type for this.

NOTE:

No installments. If the customer must pay for the merchandise in one lump amount, you'd create an SA type similar to the [Connection Charge Segmentation](#) example.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/MERCH-I	Merch	A/R-MRCH	UNRE	RECUR-AS	Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount

Notice the following about the new merchandise SA type:

- It has a normal receivable distribution code.

- It uses an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- The recurring charge control information is set up as defined.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started. Refer to [Start Option Considerations For SA Types That Use Initial Adjustments](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Deposit Segmentation - Installment Billing

If your organization allows customers to pay deposits using an installment plan, you must create an SA type for this.

NOTE:

No installments. If the customer must pay for the deposit in one lump amount, you'd create an SA type similar to the [Connection Charge Segmentation](#) example. Just make sure the adjustment that's levied to charge for the deposit amount doesn't affect payoff balance (when you bill a deposit, the customer doesn't really owe anything because it's not a true receivable from an accountant's perspective).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type	Recurring Charge Control Info
CA/DEP-I	Other	A/P-DEPO	DEP	RECURATB	Amount to bill is Required Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount

Notice the following about the new deposit SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., deposit payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the deposit is created.
- It uses an interesting bill segment type - RECURATB. This bill segment type was set up to create recurring charges that stop when the system has billed the Total Amount to Bill.
- The debt class is interesting - DEP (for deposit). This is done so that past due deposit "debt" is treated separately from other types of debt.
- The recurring charge control information is set up as defined. Note well, the Amount to bill is Required.

FASTPATH:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

NOTE:

Bill messages on receipt of deposit in full. The base package includes a special FT Freeze algorithm that can be specified on deposit SA Types. It recognizes when a deposit has been paid in full, and creates a bill messages to inform the customer. Refer to algorithm DEP PIF MSG in [Algorithm Types](#) for more information.

Billable Charge Segmentation

You create a billable charge whenever a customer should be charged for a service that occurs outside the normal course of business. For example, you would create a billable charge to charge a contractor for the repair of a ruptured gas line. You can also use billable charges to "pass through" other bill ready charges generated outside the system, by another application, or by a 3rd party supplier.

A billable charge must reference a service agreement. This service agreement behaves just like any other service agreement:

- **Bill segments are created for the service agreement.** Whenever billing is performed for an account with billable charge service agreements, the system creates a bill segment for each service agreement with unbilled charges. If multiple unbilled charges exist for a given service agreement, only one bill segment will be created and it will contain details about all of the billable charges.
- **Payments are distributed to the service agreement.** Payments made by an account are distributed to its billable charge service agreements just like any other service agreement.
- **Overdue debt is monitored.** The credit and collections process monitors billable charge service agreements for overdue debt and responds accordingly when overdue debt is detected.

Therefore, you must set up at least one SA type to hold your billable charge debt. You may have multiple charges based on billing frequencies, A/R booking, debt monitoring, etc. It's really up to you.

The easiest way to determine how many billable charge SA types you'll need is to define every conceivable billable charge (which you should have done when you designed your [billable charge templates](#)). Then ask yourself if they have the same billing and payment behavior, if so, you'll have one SA type. If not, you'll need one SA type for each combination.

We will assume your billable charges are all used to levy unusual one-off charges that can be collected in the same way, therefore we'll need one SA type.

CIS Division/ SA Type	Service Type	Distrib Code	Debt Class	Bill Seg Type	Billable Charge Templates	Rate
CA/ONETIME	Other	A/R-UTIL	UNRE	BILLCHRG	TREETRIM DAMAGE	None
CA/PASSTHRU	Electricity	A/R-OTHER	UNRE	BILLCHRG	None	None
CA/ADDON	Electricity	A/R-OTHER	EXTERNAL	BILLCHRG	None	TAXES

Notice the following about the new one time SA type:

- It has a normal receivable distribution code.
- Its debt class is unregulated.
- It uses an interesting bill segment type - BILLCHRG. This bill segment type was set up to create bill segments using billable charges.

- It references the valid billable charge templates that can be used on this SA type.

NOTE:

One Time Charge. The ONE TIME example shown above implies this SA type exists to hold one-time charges.

Because of this, you should turn on the One Time Charge switch on the SA type so that service agreement's of this type are automatically closed when final payment is received. You don't have to do this because a customer could have a single billable charge service agreement that is perpetually active for pass through charges (i.e., it doesn't have a stop date). If you do this, the system will create a bill segment for this service agreement whenever it finds an unbilled billable charge linked to the service agreement.

Notice the following about the pass through SA Type:

- It doesn't use the normal distribution code or debt class. This is done so that the debt and receivable can be tracked separately. If these charges were being pass through from another system, you might want to track these financial values separately.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.
- Templates are not relevant - these charges are not created on-line using templates, but are loaded via the [Billable Charge Upload Staging](#).

Notice the following about the add on charges SA Type:

- This is an example of bill-ready charges (similar to pass through) to which the system adds on other charges, for example, taxes.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.
- It also uses a Rate. In this case, the bill creation algorithm (specified on the bill segment type) will take any billable charge lines and attach them to a bill. In addition, these billable charges will include billable charge service quantities (SQs). These service quantities will also be swept onto the bill segment, and the Rate (TAXES in this example) will be applied. In order for taxes to be calculated, the billable charge SQs must include the total taxable amount - the system is not able to apply the rate on top of the other billable charges. But, it can apply the tax rate to the SQs that are supplied.
- You can also use this technique to bill other rate-ready service quantities, like kWh, CCF, *etc.* This is a way to process rate-ready data for which you have a contract, but you do not know the meter (and therefore, cannot collect real meter reads).
- If the rate has pre-processing calculation groups, these will be applied as well.

FASTPATH:

For more information about billable charge templates, refer to [Setting Up Billable Charge Templates](#).

Over/Under Cash Drawer Segmentation

In order to balance a tender control that is out-of-balance, your organization must set up an account with a service agreement whose SA type references the over/under expense account. You will probably only have one service agreement that references this SA type, but you still must have it if you remit funds via a cash drawer.

FASTPATH:

For more information about over/under processing, refer to [How To Get An Unbalanced Tender Control In Balance \(Fixing Over/Under\)](#).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type
CA/OVR UNDR	Other	EXP-OV/UND	N/A	Not billed

Notice the following about the new SA type:

- It has an interesting distribution code. This is because when a payment segment is applied to this type of service agreement, the system must debit an expense account for under amounts (and credit it for over amounts).
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has over/under payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

Payment Upload Error Segmentation

If the payment upload process detects an invalid account on a payment upload record, it will create a payment for the suspense service agreement defined on the upload process' tender source (see [Setting Up Tender Sources](#)). You should create a special SA type for this service agreement.

FASTPATH:

For more information about the payment upload process, refer to [Phase 3 - Create Payment Events, Tenders, Payments, and Payment Segments](#).

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	Bill Seg Type
CA/SUSPENSE	Other	EXP-MISC	N/A	Not billed

Notice the following about the new SA type:

- It has an interesting distribution code. This code should probably be a suspense account. All payment segments that are created for this service agreement will eventually be transferred to a "real" service agreement and therefore this GL account's balance should be zero when no payments are in suspense.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has invalid account payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

CIAC Segmentation

If your company bills and refunds Contribution In Aid of Construction (CIAC) contracts, you must create one or more SA types. CIAC contracts are typically used to levy charges associated with line extensions. These types of service agreements are different from other service agreements because the initial amount charged is refunded to the original payee when new properties (or extensions) are added to the extension (or when the new properties are subsequently billed for service).

NOTE:

Billable charges are used for the original CIAC service agreement. CIAC SA types are always Billable Charge SA types because an operator must specify the exact amount to charge the contractor using a billable charge. Refer to [Billable Charge Segmentation](#) for more information.

The following points describe how CIAC processing is implemented in the system:

- When a new line extension is build, you will create a new service agreement that references your CIAC SA type. This service agreement should be linked to a service point associated with the extension. The easiest way to create this service agreement and link it to the service point is by using the Start Account transaction. It's important to remember to define your CIAC SA type as a valid SA type for the SP type used to represent the line extension.
- When a new premise / service point is built that "hangs" off the original extension, the new service point should be linked to the original service point. This can be done by referencing the original service point as the "parent" service point of the new service point using a [foreign key value characteristic](#).
- The system periodically monitors the original CIAC service agreement. The process that performs this monitoring is referenced on the original CIAC service agreement's SA type. The exact processing that takes place during this monitoring is up to your organization's specific business requirement. For example, if you refund 10% of every bill produced for the "downstream" service points to the original contractor, you would have logic in your CIAC monitoring process that looks for recent bill segments produced for the "downstream" service agreements and then creates an adjustment for the master service agreement.

NOTE:

CIAC refunds are idiosyncratic. Because CIAC refund processing is idiosyncratic, we do not supply any CIAC monitoring processes in the base package. This is because the likelihood that they could be used is extremely low because of your organization's unique requirements.

Therefore, if your organization performs CIAC processing, you should create a special SA type.

CIS Division/ SA Type	Service Type	Distrib. Code	Debt Class	CIAC Process	Bill Seg Type
CA/CIAC	Other	A/R - CIAC	UNRE	Refund based on percent of future bills	Billable Charge

Loan Segmentation

If you loan money to customers that is recouped using an amortization schedule, you need to set up an SA type for the loan service agreement.

CIS Division/ SA Type	Service Type	Distrib. Code	Loan A/R Distrib. Code	Debt Class	Bill Seg Type
CA/LOAN	Other	A/R - LOAN	A/R - STLN	UNRE	LOAN

FASTPATH:

Refer to [Setting Up The System To Enable Loans](#) for more information.

Non-Billed Budget Segmentation

If you allow your customers to pay set amounts at specified intervals (e.g. every two weeks), you need to set up SA types for Non-Billed Budget service agreements. Non-billed budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. You may implement two types of Non-Billed Budgets monitored and unmonitored, each type requiring a different SA type. You may also implement different renewal options for Non-Billed Budgets.

CIS Division/ SA Type	Service Type	Distrib. Code	Non Billed Budget Monitoring	Debt Class	Renewal	Bill Seg Type
CA/NBB-MON	Other	A/P - OVPY	Monitored	NBB	Optional	Not billed
CA/NBB- UNMON	Other	A/P - OVPY	Unmonitored	N/A	Optional	Not billed

FASTPATH:

For more information about monitored and unmonitored Non-Billed Budgets, refer to [Defining Non-Billed Budget Options](#).

Designing SA Type For Other Segmentations

The earlier parts of this discussion described the most common factors that cause the creation of SA Types. However, many obscure factors could cause the introduction of more SA Types. In this section, we explain these more obscure factors.

WARNING:

We strongly recommend not being too pedantic when considering the factors described in this section. If you can only think of a few strange situations that would necessitate a SA type, think carefully before you introduce it. It's better to be a little less than perfect than end up with large number of obscure SA types.

Cash Distribution Segmentation

Every SA Type has a payment segment type. The payment segment type defines the cash account to which the SA type's payments should be booked. If different service agreements have different cash accounts, you will need to split the SA types accordingly.

Adjustment Profile Segmentation

Every SA Type has one or more adjustment profiles. These profiles define the valid adjustment types that can be booked to the SA type's service agreements. If different service agreements within an SA type have different mixtures of valid adjustment types, you must split the SA types accordingly.

Late Payment Charge Segmentation

An option exists on SA Type that causes the system to generate a late payment charge if payment is not received on time. If you don't levy late payment charges on all service agreements, you will need to determine when you do and design your SA types accordingly.

In addition, if you levy late payment charges, the percentage levied and the algorithm that defines the amount of the outstanding balance subject to the charge is defined on the SA type.

Debt Classification Segmentation

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you must split the SA Type.

FASTPATH:

For more information about debt class, refer to [Designing Your Collection Procedures](#).

NOTE:

Write Off Debt Class vs. Normal Debt Class. An SA type references both write off debt class and normal debt class. An SA type's write-off debt class controls the write-off rules imposed on service agreements of a given type. An SA type's normal debt class controls the collection rules imposed on service agreements of a given type. Refer to [Different Collection Criteria For Different Customers And Different Debt](#) for more information about collection rules. Refer to [Different Write-Off Criteria For Different Customers And Different Debt](#) for more information about write-off rules.

Allow Estimates Segmentation

Every SA Type has a switch that controls whether the system consumption if meter reads are missing at billing time. If a given SA Type has different situations when the system should and should not estimate, you will have to split the SA Type.

NOTE:

Override. You can override the value of the SA Type's estimation switch on an individual service agreement. This means that if only a few service agreements don't abide by the SA Type's estimation switch, you can change the switch value of these service agreements.

Severance Criteria Segmentation

Every SA Type has severance criteria. The severance criteria define the severance process used to sever service if the customer doesn't pay. You can have multiple severance processes if different conditions warrant a different process. For example, you may have a different severance process if the customer has life support.

If you have a SA Type that requires different severance conditions other than those currently supported, you can make a programmatic change to introduce the additional conditions OR you can split the SA Type.

FASTPATH:

For more information about severance, refer to [Designing Your Severance Procedures](#).

Deposit Class Segmentation

Every SA Type that exists to hold a cash deposit will reference a deposit class. The deposit class defines the business rules that control various functions including interest calculation and refund criteria. You will need multiple deposit SA Types if any of the deposit class' rules / conditions differ for different types of deposits. For example, if residential customers use a different recommended deposit algorithm as compared to commercial customers, you'd need one SA type for residential deposits and another for commercial deposits (where the residential deposit SA type will reference the residential deposit class and the commercial deposit SA type will reference the commercial deposit class).

You will need additional deposit SA types if your customers can have multiple deposits where each deposit is restricted to a specific type of debt. For example, if separate deposits are held for regulated and unregulated debt (and a customer could hold a combination of regulated and unregulated debt), you'd need one SA type for regulated deposits and another for unregulated deposits.

FASTPATH:

For more information about deposit class, refer to [Designing and Defining Deposit Classes](#).

Sub SA Types

If you operate in a deregulated environment AND if you provide billing services for other service providers, you will need to create SA types to handle the billing of the service providers' charges.

FASTPATH:

Refer to [Designing Your SA Types And Start Options For Sub SAs](#) for more information.

Financial Settlement SA Types

If you operate in a deregulated environment, you may have to create financial settlement service agreements for the service providers. As explained in [Service Providers Have Service Agreements Too, We Bill For Them and They Bill For Us](#) service providers require a service agreement to hold adjustments used to increase how much you owe the service provider (or how much they owe you).

FASTPATH:

Refer to [Designing SA Types For Service Provider Financial Settlements](#) for more information.

Usage Request SA Types

FASTPATH:

For more information about usage requests, refer to [The Big Picture Of Usage Requests](#).

Initial Consumption Period Considerations

Bill segments produced for a service agreement have two time periods:

- The bill segment period. The bill segment period defines the entire period of time covered by a bill segment's charges.
- The consumption period. The consumption period defines the period of time used to calculate the number of days for daily charges.

The consumption period almost always starts one day after the bill segment period. The consumption period always ends on the bill segment's end date. For example, a bill segment period that spans 5-Jan-2002 through 6-Feb-2002 will almost always have a corresponding consumption period of 6-Jan-2002 through 6-Feb-2002. The reason that the start dates don't match is because a bill segment's start date equals the end date of the prior bill segment (i.e., the start date was already counted in the previous bill segment's consumption period and we don't want to count it twice).

The only time when the previous paragraph isn't true is the first bill segment that's produced for a new service agreement. This is because different utilities count the first day of a new service agreement differently than others. Because of this, a flag exists on SA Type called **Initial Start Date Option**. This flag controls whether the service agreement's start date is included in the consumption period in a service agreement's first bill segment.

The following table describes the ramifications of the options you can set for this flag.

Flag Value	Consumption Period Calculation	Use This Option When
Add 1 Day Always	The consumption period's start date is calculated by adding 1 day to the service agreement's start date. (The SA start date is never included in the consumption period for the first bill segment.)	You want the initial bill and all subsequent bills to have a consistently calculated consumption period (i.e., the consumption period for the first and all other bills is always one day less than the bill segment's period).
Add 1 Day for Back-to-back	A back-to-back occurs when any service point for this service agreement was previously linked to a different service agreement that was stopped on the same date that the new service was started (i.e., there is no gap in the service). If a back-to-back is detected, the consumption period start date is calculated by adding 1 day to the SA start date. If no back-to-back is detected, the start date of the consumption period is the SA start date.	You want to flexibly handle consumption period calculation. If you start customers on the same date as the stop date of the previous customer, billing does not include the SA start date in the consumption period. However, if you start a new customer one day (or more) after the stop date of the previous customer, billing includes the first day of the service agreement in the consumption period.
Include First Day	The start date of the consumption period is the service agreement start date. (The SA start date is always included in the consumption period.)	You want to always include the first day AND you will never encounter a back-to-back situation.

The example below shows how the consumption period would be calculated with the various options for a customer who starts service on January 1.

First Bill	Second Bill	Third Bill
Meter Read: Jan 31	Meter Read: Feb 28	Meter Read: Mar 31
Bill Segment Period: Jan 1 to Jan 31	Bill Segment Period: Jan 31 to Feb 28	Bill Segment Period: Feb 28 to Mar 31

Consumption period using Add 1 Day Always	Jan 2 to Jan 31 (30 days)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Add 1 Day for Back-to-back when back-to-back is detected	Jan 2 to Jan 31 (30 days)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Add 1 Day for Back-to-back when back-to-back is NOT detected	Jan 1 to Jan 31 (31 days)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)
Consumption period using Include First Day	Jan 1 to Jan 31 (31 days)	Feb 1 to Feb 28 (28 days)	Mar 1 to March 31 (31 days)

There may be SA types for which the value of this flag does not affect the consumption period calculation and still other SA types where this flag is never used. For example,

- For billable charge service agreements, the consumption period is equal to the start and end dates on the billable charge and therefore this flag is not applicable.
- A sub SA either inherits the consumption period from the master SA or it uses billable charges. As a result, billing does not use this flag.
- For some service agreements, the charges on the rate are not affected by the consumption period. For example, if you have a customer with a simple meter and a simple usage-based charge, billing calculates the amount of consumption between the start reading and end reading and applies the rate (i.e., the number of days in the consumption period doesn't impact the charges in some rates).
- Some service agreements are not billed, for example, [overpayment service agreements](#). For this type of service agreement and other types of service agreements that are not billed, this flag is not applicable. However, the system does not prevent a value from being entered in these cases to allow for an implementation process to use the flag if needed.

Setting this flag to an appropriate value is significant for certain types of service agreements.

- For services whose rate includes daily charges, the configuration of this flag may impact the first bill segment for the service agreement. For example, if the first bill period is October 1st through October 31st, do you consider consumption period to be 31 days or 30 days? How you want to bill the customer on the first bill determines how you set this flag.

Processing Sequence Considerations

You may have customers with a complex collection of contracts such that the calculation for one bill segment relies on information calculated by another bill segment for the same account. For example, perhaps you need to process your bill segments as follows:

- Step 1: Calculate bill segments for all the account's "single site" service agreements (i.e., each service agreement related to a single premise)
- Step 2: Calculate the bill segment for additional charges for the "head office" service agreement where the charges are based on the aggregated consumption of all premises from all bill segments (calculated in the first step).

To create the "head office" bill segment for the account, you must control the order in which the system creates the bill segments for each service agreement.

The SA type allows you to indicate a billing processing sequence that controls the order in which the service agreements are processed. The processing sequence is optional and service agreements are processed in ascending order of their SA type's billing processing sequence. As a result, SA Types with a processing sequence of zero are processed first, then 1, then 2, etc.

NOTE:

If you have sub SAs linked to a master SA, the billing processing sequence is used first to order the creation of bill segments for the master SAs. If you populate a processing sequence on an SA type for a sub SA, it is used to control the order in which the sub SAs for a given master SA are processed relative to each other. Refer to [Designing Your SA Types And Start Options For Sub SAs](#) for more information.

The billing processing sequence also controls the order of service agreements in the following other processes:

- Execution of pre bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the pre bill completion algorithms on its [SA type](#) are processed in the order of the algorithm's sequence.
- Execution of bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the completion algorithms on its [SA type](#) are processed in the order of the algorithm's sequence.

Designing Prepayment Billing Options

This section provides guidelines describing how to design service agreements that handle smart meter prepaid billing.

When a customer is subject to prepayment, normal cycle-based billing is not used to calculate the bill segments for their service. Rather, a prepay billing (PPB) process creates bill segments frequently (for example, daily) and periodically requests funds to maintain an adequate payoff balance. Bills will only be used to periodically inform the customer of the various financial transactions that have occurred since the last bill was produced.

Implementing prepayment billing requires the configuration of the following objects:

- SA Type
- Adjustment Types
- Bill Segment Type
- Service Task Type

These configuration tasks are described below.

NOTE: For additional information, see the detailed descriptions in the application for the C1-PrepayBillerTaskType and C1-PrepayBillerTask business objects.

SA Type for Prepay Billing

To configure a prepay billing SA Type, create a new SA type with the following attributes:

- Set the Special Role flag to **Bill Determinants Required**. The Prepay Option should be set to **Prepaid Smart Meter**.
- Specify the SA Creation system event with the algorithm CI_CREATEPPB to create the service agreement's prepay biller.
- Specify the Payment Freeze system event with the algorithm STPZ-RMVC to set current amount to zero on a payment.
- If required, specify the Bill Completion system event with an algorithm of the type C1-CREPPBBM to add a bill message that informs an end customer of their prepaid charges for the period. You may need to create an algorithm of this type if it does not exist in your system.
- **Eligible for Budget** should be set to false.
- Reference a new **Prepay Bill Segment Type**, which is described below.

The following adjustment types must also be defined on the prepay SA type:

- **Adjustment Type (Xfer)** specifies the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement

- **Adjustment Type (Current=0)** specifies the type of adjustment used to set the prepaid current balance to zero after debt has been transferred
- **NSF Adjustment Type** specifies the type of adjustment used to levy an NSF charge. The NSF Adjustment Type is described in greater detail below.

The new SA types must be added to the data value mapping between CCB and MDM. This is to enable the synchronization of SAs of this type to MDM. The new CCB SA types can be mapped to existing US types in MDM. For additional information about this configuration, please see the integration documentation.

Adjustment Types for Prepay Billing

- **Funds Request Adjustment Type:** This adjustment type captures the type of adjustment used to request more prepaid funds. This adjustment type is specified on the prepaid biller task type. Specify the following algorithms on this adjustment type:
 - **Adj. Financial Algorithm** should reference the Adjustment FT creation algorithm ADJT-CA (Payoff=0/Current=Adj Amount (No GL)).
 - **Adjustment Freeze Algorithm** should reference an algorithm of the type C1-PPBADJFRZ (Set Prepaid Funds Request FT Details). You may need to create an algorithm of this type if it does not exist in your system.
- **NSF Adjustment Type:** For prepaid customers on autopay, when a user cancels an autopay tender the cancel reason must indicate that an NSF charge should be levied. The system invokes the NSF Charge algorithm specified on the tender's account's customer class which creates the NSF adjustment on the appropriate SA. The charge is levied using the NSF Adjustment Type specified on the SA's SA type. This adjustment type must reference the new adjustment freeze algorithm that will disable automatic payments on the PPB. This algorithm must be based on the algorithm type C1-DISPPBAP (Disable PPB's Automatic Payment). You may need to create an algorithm of this type if it does not exist in your system.

Bill Segment Type Required for Prepay Billing

Configure a new bill segment type for prepaid service agreements. This bill segment type should have the following attributes:

- **Create Algorithm** should be set to C1-BSBS-UR to create bill segment using a usage request.
- **Financial Algorithm** should be set to a new algorithm with algorithm type C1-NEM-GL (Payoff Amt = Bill Amt / Current Amt = 0 (GL affected)). You may need to create an algorithm of this type if it does not exist in your system.
- **Get Consumption Algorithm** should be set to C1-BSGC-USG to get bill segment consumption using a usage request.

Service Task Type for Prepay Billing

Configure a new service task type for prepay billing. This task type should reference the Prepay Biller (PPB)Task Type Business Object (C1-PrepayBillerTaskType). The task type must be specified on the new prepay billing SA creation algorithm. The task type captures the adjustment type used when an adjustment is created to request additional funds from the customer. Ensure that this adjustment type references the adjustment freeze algorithm (C1-PPBADJFRZ) that populates the financial transaction's arrears date.

SA Types And The Financial Design

In this section, we provide an example of how our SA Types map to Bill Segment Types, Payment Segment Types, and Adjustment Profiles. This example is meant to help solidify the power of the financial model, it is not necessarily indicative of how your specific implementation will look.

WARNING:

If you are not comfortable with the topics described in [Defining Financial Transaction Options](#), the following table will not make sense.

Division/SA Type	Distribution Code	Bill Segment Type	Payment Segment Type	Adjustment Profiles
CA/G-RES	A/R-UTIL		NORMAL	BALXFER, MISCFEES, BUDGET
CA/G-COM	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/G-IND	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/W-RES	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/W-COM	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/W-IND	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/E-RES	A/R-UTIL		NORMAL	BALXFER, MISCFEES, BUDGET
CA/E-COM	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/E-IND	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/WW-RES	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/WW-COM	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/WW-IND	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/CABLE	A/R-UTIL		NORMAL	BALXFER, MISCFEES
CA/E-COY	E-COMP	COMPUSAG		
CA/G-COY	E-COMP	COMPUSAG		
CA/W-COY	E-COMP	COMPUSAG		
CA/VO-STD			NORMAL	BALXFER
CA/VO-LIA			NORMAL	BALXFER
CA/CONNECT			NORMAL	BALXFER, MISCFEES
CA/CHARITY	A/P-CHAR	RECUR	CHARITY	CHARITY
CA/PA-REGU	A/R-ARRG	RECUR-AS	NORMAL	BALXFER, MISCFEES, DPA
CA/PA-UNRE	A/R-ARRG	RECUR-AS	NORMAL	BALXFER, MISCFEES, DPA
CA/MERCH-I	A/R-MRCH	RECUR-AS	NORMAL	BALXFER, MISCFEES, MERCH
CA/DEP-I	A/P-DEPO	RECUR-AS	NORMAL	BALXFER, MISCFEES, DEPOSIT
CA/ONETIME	A/R-UTIL	BILLCHRG	NORMAL	BALXFER, MISCFEES
CA/OVR UNDR	EXP-OV/UND		NORMAL	
CA/OVERPAY	A/P-OVER		NORMAL	BALXFER
CA/SUSPENSE	A/R-SUSP		NORMAL	
CA/NBB	A/P-OVPY		NORMAL	BALXFER, MISCFEES, NBB

If you operate in a deregulated environment, you will also have additional SA types as described under [Designing Your SA Types And Start Options For Sub SAs](#) and [Designing SA Types For Service Provider Financial Settlements](#) you may have additional SA types.

Setting Up SA Types

In the previous section, Designing SA Types, we presented a case study that illustrated a mythical organization's SA types. In this section, we explain how to use the windows on the SA Type window group to maintain your SA Types.

SA Type - Main Information

Open **Admin > Customer > SA Type > Add** to define core information about your SA Types.

WARNING:

Every SA Type is owned by a CIS Division. This Division controls many values that can be referenced on the SA Type. If you don't understand Divisions and their place in the application, do NOT attempt to set up your SA Types. Rather, refer to [CIS Division Portal](#) before proceeding.

Description of Page

Enter a unique combination of **CIS Division** and **SA Type** for every service agreement type.

Enter a **Description** for the SA type.

Service Type defines the type of service associated with the SA type. If the SA type has rates, only rates belonging to this service type may be linked to the SA type.

Select the **Distribution Code** and **GL Division** that defines the receivable account for receivable-oriented service agreements. For non-receivable oriented service agreements, this distribution code is typically as follows:

- Charitable contributions. The distribution code is a charity payable account.
- Deposits. The distribution code is a deposit payable account.
- Non-Billed Budgets. The distribution code is an overpayment payable account.
- Company usage. The distribution code is a company usage expense account.
- Write off. The distribution code is a write-off expense account.
- Payment arrangements. The distribution code is a payment arrangement receivable account.

FASTPATH:

For more information about GL accounts, refer to [The Source Of GL Accounts On Financial Transactions](#).

Select the **Revenue Class** associated with the SA Type (and its service agreements). The revenue class may affect the revenue account(s) generated by the service agreement's rate.

FASTPATH:

Refer to [Designing Calculation Groups and Rules](#) for more information about revenue class.

Turn on **Start Options Required** if you want to force a customer service rep to choose a start option when they start service for this SA Type (on the Start Account window). If this switch is off and a rate is required for the SA Type, the system defaults the SA type's default rate on new service agreements. The default rate is defined on the SA Type - Rate page.

FASTPATH:

Refer to [Setting Up Start Options](#) for more information about the pros and cons of requiring start options.

Select the **Pay Segment Type** that defines how payment segments linked to service agreements of this type affect:

- The service agreement's payoff and current balances

FASTPATH:

For more information about payment segment types, refer to [Setting Up Payment Segment Types](#).

When a tender is canceled, a cancellation reason must be supplied. If the cancellation reason indicates a NSF (non sufficient funds) charge should be levied, the system invokes the Levy an NSF Charge algorithm specified on the tender's account's [customer class](#). Because adjustments must be linked to a service agreement, the algorithm must determine the appropriate service agreement to use to levy the adjustment based on business rules. The charge is levied using the **NSF Adjustment Type** of the appropriate service agreement's SA type.

WARNING:

You must specify adjustment type profiles on the SA type (on the Adjustment Type window) before adjustment types will appear in the above drop downs.

FASTPATH:

For more information about adjustment types, refer to [Setting Up Adjustment Types](#). For more information about cancellation reasons, refer to [Setting Up Payment Cancellation Reasons](#).

Select the **Payment Priority**. This field is available for use by the algorithms that distribute partial payments amongst an account's service agreements. Higher priority service agreements will have their debt relieved before lower priorities. Refer to [Distribution Based on Payment Priority](#) and [Delinquent Payment Distribution Algorithm](#) for information about payment distribution algorithms that use this field.

NOTE:

The values for this field are customizable using the Lookup table. This field name is PAY_PRIORITY_FLG.

FASTPATH:

For more information about distribution priority, refer to [Distributing A Payment Amongst An Account's Service Agreements](#).

Select the **Delinquent Payment Priority**. This field is available for use by the algorithms that distribute partial payments amongst an account's service agreements. Higher priority service agreements will have their debt relieved before lower priorities. Refer to [Delinquent Payment Distribution Algorithm](#) for information about a payment distribution algorithm that uses this field.

NOTE:

The values for this field are customizable using the Lookup table. This field name is DEL_PRIORITY_FLG.

Turn on **Do Not Overpay** if the system is not allowed to distribute an overpayment to this type of service agreement (i.e., the service agreement is not allowed to have a system-created credit balance). This field is available for use by algorithms that distribute overpayments. Refer to [Overpayments Held On Highest Priority Service Agreement](#) for information about an overpayment algorithm that uses this field.

Turn on **Late Payment Charge** if the system should generate a late payment charge for this type of service agreement if payment is not received on time. If this is turned on, you must define the **LPC Calc. Algorithm** used to calculate the late payment charge amount. Refer to [Defining Late Payment Charge Options](#) for more information about late payment charges. Examples of algorithm types used for calculating late payment charges are [BILPC-SPRC](#) and [BILPC-TOTAL](#).

Define the **Adjustment Type (Synch Curr)** that will be used to synchronize (make equal) the current amount with the payoff amount on a service agreement of this type. This type of processing happens as follows:

- Most **write-off** algorithms that perform financial efforts (e.g., writing off debt), will issue an adjustment of this type if the service agreement's current and payoff balances are not equal.
- If a user stops a customer on a **budget plan**, the system issues adjustments of this type to synchronize the customer's current and payoff balances.
- If a user stops a service agreement covered by a **Non-Billed Budget**, the system issues adjustments of this type to synchronize the customer's current and payoff balances.
- If a **cancellation of a bill segment** occurs after a customer has stopped participating in a budget plan, an adjustment of this type is issued to synchronize the imbalance created when the bill segment's financial transaction is canceled.

Turn on **CIAC SA Type** and specify an appropriate **CIAC Refund Process** if service agreements of this type are used to bill for Contribution In Aid of Construction (CIAC) charges. Refer to [CIAC Segmentation](#) for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_SA_TYPE](#).

SA Type - Detail

Open **Admin > Customer > SA Type > Search** and navigate to the **Detail** page to define additional details about a given SA type.

Description of Page

Turn on **Display As Alert** if Control Central should display an alert if an account has a service agreement of this type that isn't Closed or Canceled. If this switch is on, also enter the **Alert Information** to appear on Control Central. We recommend only using this feature on unusual SA types (e.g., payment arrangements, write-offs) so that a CSR is not presented with an alert for every SA type.

If this SA Type is used for any of the **Special Roles**, defined in the dropdown, indicate which one. Valid values are: Billable Charge, Cash Deposit, Loan, Non-Billed Budget, Payment Arrangement, Write Off, Bill Determinants Required. This information is used on windows with functionality that can only be used by service agreements used for specific roles. For example, the Billable Charge window group can only reference Billable Charge service agreements.

If Special Role is Cash Deposit, you must define the **Deposit Class** of the deposit. You should also define a **Deposit Class** on every SA type to which a given deposit can be distributed.

FASTPATH:

Refer to [What Do Deposit Classes Do?](#) for more information.

If the Special Role is Loan, you must also define the following fields:

- Use the **Interest Bill Factor** to define the bill factor code for the loan interest rate.
- Use **Override Interest Flag** to indicate whether the interest rate defined on the interest bill factor may be overridden at the SA level. If you select Allowed, the interest rate may be overridden by a contract value on a start option or the SA.
- Use the **Loan A/R Distribution Code** to define the distribution code to be used when posting the short-term receivable amount to the general ledger (the normal distribution code is used for the long-term receivable). If the normal distribution code is the same as the **Loan A/R Distribution Code**, the SA type does not differentiate between long- and short-term receivables. If the two distribution codes are different, the SA type differentiates between long- and short-term receivables.

FASTPATH:

Refer to [Defining Loan Options](#) for more information about **Interest Bill Factor**, **Override Interest Flag** and **Loan A/R Distribution Code**.

If the Special Role is Non-Billed Budget , you must also define the following:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to the transfer accumulated credit from the Non-Billed Budget SA to the SAs covered by the Non-Billed Budget when the account is billed or the Non-Billed Budget SA is stopped.
- Use the **Non-Billed Budget Monitoring** to specify whether the Non-Billed Budget is monitored by the account debt monitor.

If the SA type is defined as Eligible for Non-billed Budget, you must also define the following:

- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the service agreement's current balance to zero when a service agreement of this type is linked to an active, monitored Non-Billed Budget.

If the Special Role is Payment Arrangement, you must also define two adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the payment arrangement service agreement.
- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the payment arrangement's current balance to zero after funds have been transferred.

If the Special Role is Write Off, you must also define the following adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the uncollectable service agreements to the write off service agreement.

NOTE:

It may be important to your organization to track the original source of debt that is being written off. The system is delivered with three characteristic types: C1-WODST, C1-WOCHT, and C1-WOCHV that can record the distribution code, characteristic type and characteristic value from the FT GL(s) being written off onto the write off adjustment. To enable this logic, specify these characteristic types as allowable characteristic types on your write off transfer adjustment type.

If the Prepay Option is **Prepaid Smart Meter**, you must also define two adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement.
- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the prepaid current balance to zero after debt has been transferred.

WARNING:

You must specify adjustment type profiles on the SA type (on the Adjustment Type window) before adjustment types will appear in the above drop downs.

The **Stop Option Flag** can be used to automatically stop a service agreement when all other service agreements of an account are stopped. Valid values are: Automatically Stop SA. When all service point related service agreements of an account are stopped then all additional service agreements where the **Stop Option** is set to Automatically Stop SA will also be stopped. This is useful, for example, with charitable contribution service agreements. The charity service agreement should be stopped when all utility related services are stopped.

FASTPATH:

Refer to [The Lifecycle of a Service Agreement](#) for more information on the **Stop Option**.

Turn on **One Time Charge** if this SA type is used for one-time invoices. When a one-time invoice service agreement is created, the system sets the stop date of the SA to be equal to the start date.

Turn on **Sub SA** if this SA type is used to define the business rules for sub service agreements.

FASTPATH:

Refer to [Sub Service Agreements](#) for more information about sub service agreements.

Renewal of SAs of this type may be Optional, Not Allowed or Required depending on your business processes. If renewal is not allowed, the SA expires on the expiration date. Renewal treatment is an important consideration for SAs that require an expiration date, such as [non-billed budget SAs](#).

If renewal is required or optional, specify the **Days Before Expiration for Renewal**. Note that currently this is only used by Non-Billed Budgets to calculate the renewal date based on the expiration date.

If the Special Role is Non-billed Budget, **Non-Billed Budget Monitoring** must indicate whether the Non-Billed Budget is monitored by the account debt monitor.

FASTPATH:

Refer to [Credit and Collections and Non-Billed Budgets](#) for more information about monitoring Non-Billed Budgets.

Set the **Eligible for Payment Arrangement** flag to Eligible if this SA type can be included in a payment arrangement.

NOTE: This flag is automatically set to Ineligible on SA types with a Special Role of Payment Arrangement.

Where Used

The alert information is used by Control Central to alert a CSR when unusual service agreements exist for an account. Refer to [Control Central - Main](#) for more information.

Only SA types designated as being Billable Charge may have billable charges linked to them. Refer to [Maintaining Billable Charges](#) for more information.

Only SA types designated as being Cash Deposit are processed by the various deposit-related background processes (e.g., interest calculation, automatic refund, etc.). Refer to [The Big Picture Of Deposits](#) for more information.

Only SA types designated as Loan are used to define the loan terms for a loan SA. Refer to [Loans](#) for more information.

Only SA types designated as Non-billed Budget may be used to set up Non-Billed Budgets. Refer to [Non-Billed Budgets](#) for more information.

Only SA types designated as being Payment Arrangement may be used on the payment arrangement window group. Refer to [Setting Up Payment Arrangements](#) for more information.

Only SA types designated as being Write Off may be specified as the write off SA type on distribution codes. Refer to [Setting Up Distribution Codes](#) for more information.

Only service agreements whose SA type is designated as being Write Off appear on the Write Off SAs query. Refer to [Write Off - Write Off SAs](#) for more information.

SA Type - Billing

Open **Admin > Customer > SA Type > Search** and navigate to the **Billing** page to define how the system manages bill segments for service agreements of a given SA type.

Description of Page

Turn on **Eligible for Billing** if the system should create bill segments for service agreements of this type. This will typically be turned on for all service agreements except for those used to hold write-off amounts or to levy one-off adjustments.

Define the minimum number of days a bill segment (other than the final segment) must span using **Minimum Days for Billing**. This is useful to prevent initial bill segments that span only a few days.

FASTPATH:

For more information about minimum days, refer to [Preventing Short Bill Segments](#).

Select the **Bill Segment Type** that controls both how bill segments for this SA Type will be created and how the related financial transaction affects the general ledger and the customer's debt.

FASTPATH:

For more information about bill segment types, refer to [Setting Up Bill Segment Types](#).

Use **Default Description on Bill** to define the verbiage that should print on the customer's bill.

NOTE:

Rates overwrite this description. The Default Description on Bill is not applicable for service agreements whose charges are calculated using a rate. Why? Because the description that appears on the bill segment is defined on the rate schedule's rate version calculation group.

Billable charges overwrite this description. The Default Description on Bill is not applicable for service agreements whose charges are calculated using a billable charge. Why? Because the description that appears on the bill segment is defined on the billable charge.

Use the **Billing Processing Sequence** if you need to control the order in which service agreements linked to this SA type are processed by billing.

FASTPATH:

Refer to [Processing Sequence Considerations](#) for more information.

Use **Bill Print Priority** to define the order in which the SA type's bill segments should appear on bills (relative to the other SA types that appear on a bill).

NOTE:

The values for this field are customizable using the Lookup table. This field name is BILL_PRT_PRIO_FLG.

Use **Max Bill Threshold** if you want the system to generate a bill error when a bill segment is produced in batch that exceeds a given value. These bill errors will appear on the standard billing queries and To Do lists. If, after reviewing the high value bill segment, an operator truly intends to send the bill out, they should regenerate the bill. Refer to [How To Correct A Bill Segment That's In Error](#) for more information.

WARNING:

The value entered in this field will DEFAULT onto service agreements of this type when they are first created. An operator may change the default value on a service agreement in case a specific customer has unusually high bills that continually error out. It's important to be aware that if you change the value of High Bill Amount on an SA type and there already exist service agreements of this type, the existing service agreements will contain the original value (the new value on the SA type will not be propagated on the existing service agreements).

Use **Graph Unit Of Measure** to define the unit of measure of the graphed consumption on the bill (if any).

Turn on **Characteristic Premise Required** if a characteristic premise must be linked to the service agreement when the service agreement is activated. The characteristic premise is used to define the taxing authorities associated with the service agreement's bill segments. It is also used to identify where the service agreement's service is located on various windows.

FASTPATH:

For more information about how characteristic premise is used, refer to [An Illustration Of A Bill Factor And Its Characteristics](#).

Use the **Initial Start Date Option** to control how billing should calculate the consumption period for the very first bill for service agreements of this type. This field is not applicable for sub SA types or SA types with a special role of Billable Charge. Valid values are Include First Day, Add 1 Day Always and Add 1 Day for Back-to-back. Refer to [Initial Consumption Period Considerations](#) for more information.

Non-metered service agreements may have the end date of their bill segments defined on a user-maintained bill period schedule. This option is used when bill segments must fall on strict calendar boundaries (e.g., quarterly bills that end on the last day of the quarter). If this SA type should be billed like this, select Use Bill Period in the **Use Calendar Billing** field. When this option is used, you must define the **Bill Period** whose schedule defines the bill segment end dates.

FASTPATH:

For more information about bill period schedules, refer to [Designing Bill Periods](#). For more information about other bill end date methods, refer to [Ways To Control The End Date Of A Bill Segment](#).

Instead of the Use Bill Period method, non-metered service agreements may have their bill segment end date based on the first day of service. For example, if service started on the 16th of some month, the ongoing bill segments will start on roughly the 16th of each month. This option is frequently used to bill for garbage or cable service. If this SA type should be billed like this, select Anniversary Future Billing or Anniversary Past Billing in the **Use Calendar Billing** field. When either option is used, you must define the **Anniversary Bill Frequency**. This frequency defines the amount of time between bill segments.

FASTPATH:

For more information about anniversary billing, refer to [Using The Anniversary Method](#). For more information about other bill end date methods, refer to [Ways To Control The End Date Of A Bill Segment](#).

Total Bill Amount indicates whether service agreements of this type can use the total amount to bill field on the service agreement page. Valid values are Not Allowed and Required. Only SA types used to bill for deposits or loans should have this field set to Required.

If Required is selected, you must enter the **Total Amount To Bill Label**. The **Total Amount To Bill Label** defines the label that prefixes the total bill amount on the service agreement page for service agreements of this SA type.

FASTPATH:

For more information about total amount to bill and deposit service agreements, refer to [Total Amount To Bill](#). For more information about total amount to bill and loan service agreements, refer to [Setting Up The System To Enable Loans](#).

Recurring Charge indicates whether service agreements of this type can use the recurring charge field on the service agreement window. Valid values are Not Allowed, Optional and Required. If either Optional or Required are used, you must enter:

- **Recurring Chg Amt Label**. This defines the label that prefixes the recurring charge amount on the service agreement window for service agreements of this SA type.
 - **Recurring Charge Frequency**. This defines the following:
 - Specifies the frequency at which the Recurring Charge Amount specified on service agreements of the SA Type is to be billed.
 - Serves as the basis for proration of the Recurring Charge Amount.
 - Specifies the frequency at which service agreements of the SA Type without a rate and/or meters will be billed.
-

FASTPATH:

For more information about how to use the recurring charge information, refer to [Charitable Contribution Segmentation](#), [Merchandise Segmentation - Installment Billing](#), [Deposit Segmentation - Installment Billing](#), [Payment Arrangement Segmentation](#), [Budget Billing Segmentation](#), [The Terms Of A Loan Are Stored On A Service Agreement](#).

Turn on **Eligible for Budget** if service agreements of this type can participate in budget billing. If this switch is turned on, then you must define the **Adjustment Type (Synch Current)** that will be used to synchronize (make equal) the current amount with the payoff amount on a service agreement of this type when a budget is cancelled. (The Adjustment Type (Synch Current) field is on the main page.)

FASTPATH:

Refer to [Budget Billing](#) for more information about budgets in general. Refer to [Budget Billing Segmentation](#) and [Designing and Defining Budget Plans](#) for more information.

Set the **Eligible for Non-Billed Budget** flag to Eligible for Non-Billed Budget if you want SAs of this type to be eligible to be covered by a Non-Billed Budget. If this flag is set to Eligible for Non-Billed Budget, you must also define the **Adjustment Type (Current = 0)** field (on [SA Type - Detail](#)).

FASTPATH:

Refer to [Current Amount For SAs Covered By A Non-Billed Budget](#) and [SA Types for SAs Covered by Non-Billed Budgets](#) for more information.

Require Total Amount Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's required total amount switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

Bill Segment Create Algorithm	SA Type Require Total Amount Switch:	SA Type Require Total Amount Switch:
	Not allowed	Required
	Metered services. Lamp services. Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable.	N/A
Recurring Charge With Auto Stop	Payment arrangements. Merchandise installment plans. Zero-interest loans.	N/A
Recurring Charge For Amount To Bill	N/A	Deposit installment plans.
Recurring Charge	Charitable contributions.	N/A
Billable Charge	One time invoices. Pass through charges	N/A
Loan	N/A	Loans.

Allow Recurring Charge Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's allow recurring charge switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

Bill Segment Create Algorithm	SA Type Recurring Charge Switch:	SA Type Recurring Charge Switch:	SA Type Recurring Charge Switch:
	Not allowed	Optional	Required
	Metered services - no budget Lamp services Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable.	Metered services - budget optional	Metered services - budget required
Recurring Charge With Auto Stop	N/A	Payment arrangements. Merchandise installment plans. Zero-interest loans. SEE NOTE!	Payment arrangements. Merchandise installment plans. Zero-interest loans. SEE NOTE!
Recurring Charge For Amount To Bill	N/A	Deposit installment plans. SEE NOTE!	Deposit installment plans. SEE NOTE!
Recurring Charge	Charitable contributions	N/A	N/A
Billable Charge	One time invoices. Pass through charges	N/A	N/A
Loan	N/A	N/A	Loans.

NOTE:

Most recurring charge SA types require a recurring charge amount on their service agreements. However, the above matrix indicates you can have recurring charge SA types where this value is optional. Why? A special algorithm exists in billing that says if the recurring charge amount is 0 (zero) the system will bill the remaining payoff balance or total amount to bill. This algorithm exists so that you can easily bill the amount in one lump sum (i.e., don't bill it in installments).

Where Used

The billing information is used when the system creates a bill segment for service agreements of this type.

SA Type - Rate

Open **Admin > Customer > SA Type > Search** and navigate to the **Rate** page to define the rates that may be referenced on service agreements of a given type.

Description of Page

Turn on **Rate Required** if the bill segment creation algorithm for the SA type expects a rate schedule to be referenced on service agreements of this type.

FASTPATH:

For more information, refer to [Rates](#).

This feature is possible if the usage subscription type is configured with the base Dynamic Usage Group Determination algorithm, which determines the applicable usage group for each effective rate schedule. This algorithm requires that the CCB rate schedule has usage group extendable look-ups configured for the rate schedule and device configuration type combinations.

A typical use case is when there is a smart meter rollout in the middle of billing period and there are rate schedule changes that coincide with the meter exchange date. The usage group that is tied to the old meter will have rules that calculate scalar consumption, and the usage group that is tied to the new meter will have rules that calculate interval consumption. The end result is that the customer is billed with scalar consumption for the period where old meter was installed, and billed with interval consumption for the period where new meter is installed.

If the Contract Management module is not [turned off](#), which includes [umbrella agreement management](#), indicate the **Rate Source**. Check SA Only indicates that the rate schedule currently in effect for the service agreement should always be used. Check TOS First, then SA indicates that if the service agreement is linked to a terms of service record, the service agreement's rate could be [overridden by one linked to the terms of service](#) record.

The information in the **Rate Schedules** collection defines the rates that may be referenced on service agreements of this type. The following fields are required for each SA Type:

Rate Schedule Specify the rate schedule; its description is displayed adjacent.

Use As Default Turn on this switch for the rate to be defaulted on new service agreements.

Rate Required versus Bill Segment Algorithm

The following table shows appropriate combinations of the SA type's rate required switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not applicable. Otherwise, we list typical types of service agreements that will use a combination. Be aware that no cross validation exists between the rate required switch and the bill segment creation algorithm when setting up the SA type.

Bill Segment Create Algorithm	SA Type Rate Required Switch:	SA Type Rate Required Switch:
	Not allowed	Rate required on SA
	N/A	Metered services. Lamp services. Misc item services. Company usage.
Recurring Charge With Auto Stop	Payment arrangements. Merchandise installment plans. Zero-interest loans.	N/A
Recurring Charge For Amount To Bill	Deposit installment plans.	N/A
Recurring Charge	Charitable contributions.	N/A
Billable Charge	One time invoices.	Billable charges that require a rate to add-on extra charges (like taxes) or billable charges where the consumption is interfaced and

the system is responsible for calculating the charges.

Loan

Loans.

N/A

Where Used

This information is used to default and validate the rate specified on a service agreement. Refer to [Service Agreement - Rate Info](#) for more information.

SA Type - SP Type

Open **Admin > Customer > SA Type > Search** and navigate to the **SP Type** page to define the service point types that may be referenced on service agreements of a given type.

Description of Page

Turn on **Service Points Required** if at least one service point should be linked to service agreements of this type in order to properly bill the service agreements.

The information in the **SP Types** collection defines the service point (SP) types that may be referenced on this SA type's service agreements. The following fields are required for each SA Type:

SP Type Specify the SP type; its description is displayed adjacent.

FASTPATH:

For more information about SP types, refer to [Designing SP Types](#).

Where Used

This information is used to validate the types of service points linked to a service agreement. Refer to [Service Agreement - SA / SP](#) for more information.

SA Type - Adjustment Profiles

Open **Admin > Customer > SA Type > Search** and navigate to the **Adj Profile** page to define the adjustment profiles that define adjustment types that may be referenced on service agreements of a given type.

Description of Page

Define the **Adjustment Type Profiles** that, in turn, define adjustment types that may be referenced on service agreements of a given type.

FASTPATH:

For more information about adjustment type profiles, refer to [Setting Up Adjustment Type Profiles](#).

Where Used

This information is used to validate the adjustments linked to the service agreement. Refer to [Adjustment - Main Information](#) for more information.

SA Type - C&C

Open **Admin > Customer > SA Type > Search** and navigate to the **C&C** page to maintain attributes that affect how the system severs the service agreement when collection attempts fail.

FASTPATH:

Refer to [Designing Your Severance Procedures](#) for more information.

Description of Page

Select the **Debt Class** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class.

Select the **Write Off Debt ClassCode** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class during write-off processing.

NOTE:

Write Off Debt Class vs. Regular Debt Class. It's important to be aware that a SA type references both a regular debt class and a write-off debt class. The regular debt class controls the collection criteria applied against an account's service agreements. The regular debt class is also used to segregate an account's outstanding balance on several queries in the system. The write-off debt class controls the write-off criteria applied against an account's stopped service agreements. The reason the system supports two different debt classes is because you may categorize your service agreements differently when you try to collect overdue debt versus when you write-off debt. Refer to [The Big Picture Of Write Off Processing](#) for more information.

The information in the **Severance Criteria** collection defines the SA Type's severance criteria. Severance criteria define the severance process to be executed for service agreements of a given SA type. The severance process may differ depending on some attribute of the customer or premise. For example, you may have a different severance process if the customer has life support equipment.

FASTPATH:

The following information is not intuitively obvious. Refer to [Designing Your Severance Procedures](#) for more information.

The following fields are required for each instance:

Priority The priority controls the order in which the system determines if the severance process should be applied (the first severance process whose algorithm applies is used). Higher priorities are checked before lower priorities.

Severance Criteria Algorithm Select the algorithm to be used to check if the severance process should be initiated for service agreements of this type. If a condition is met, a severance process is created using the associated severance process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines if the severance of a service agreement should be processed using the associated **Severance Process Template**. Click [here](#) to see the algorithm types available for this plug-in spot.

IMPORTANT:

You must have at least one entry in this collection otherwise the system will not start a severance process when a service agreement of this type needs to be stopped due to non payment. This entry should have the lowest priority code and should reference a **Severance Criteria Algorithm** that references the **SV CRIT DFLT** algorithm type.

Severance Process Template Specify the severance process template to use to sever the service agreement; its description is displayed adjacent.

Where Used

The debt class has multiple uses:

- The system summarizes an account's debt by debt class on [Account - Main Information](#) and [Account - Financial Balances](#).
- Debt class is one component that controls how the system analyzes an account's overdue debt (the others are the account's collection class and currency). Refer to [Different Collection Criteria For Different Customers And Different Debt](#) for more information.
- Write off debt class is one component that control how the system writes off an account's stopped service agreements. Refer to [Different Write-Off Criteria For Different Customers And Different Debt](#) for more information.

The severance criteria are used when a collection event is activated that indicates that service should be severed.

SA Type - Billable Charge Template

Open **Admin > Customer > SA Type > Search** and navigate to the **BC Template** page to define the billable charge templates that can be used on service agreements of a given type.

NOTE:

Only billable charges have billable charge templates. Only service agreements that are defined as Billable Charges (in the Special Role on the Details window) may use the grid on this window.

Description of Page

The information in the **Billable Charge Template** collection defines the SA Type's permissible billable charge templates. A billable charge template contains the default bill lines, amounts and distribution codes used to levy a one-off charge. The following fields are required for each template:

Billable Charge Template Specify the billable charge template. Its description is displayed adjacent.

Use As Default Turn on this switch for the template to be defaulted on new billable charges linked to service agreements of this type (if any).

FASTPATH:

For more information about billable charge templates, refer to [Setting Up Billable Charge Templates](#).

Where Used

This information is used to limit the billable charge templates that can be used for a given SA type.

SA Type - Characteristics

To define characteristics common to all service agreements of a given type, open **Admin > Customer > SA Type > Search** and navigate to the **Characteristics** page.

Description of Page

Use the characteristics collection to define a **Characteristic Type**, **Sequence**, and **Characteristic Value** common to all service agreements of this type.

NOTE:

You can only choose characteristic types defined as permissible on a SA Type record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

SA Type - Algorithms

Open **Admin > Customer > SA Type > Search** and navigate to the **Algorithm** page to define the algorithms that should be executed for service agreements of a given type.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

WARNING:

These algorithms are typically significant processes. The absence of an algorithm may prevent the system from operating correctly.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description
Bill Completion	Optional	<p>These algorithms are executed whenever a bill is completed for an account that contains a non-canceled service agreement of this type. The following situations necessitate the definition of a completion algorithm on an SA type:</p> <ul style="list-style-type: none">- As explained under Technical Implementation of A/R Transfer and Technical Implementation of Routing Billable Charges To Service Providers, when a bill is completed, the system needs to set up the data necessary to interface any "master" SA's charges to the service provider and to transfer the receivable balance from the customer to the service provider. The system will only do this if you specify an appropriate algorithm on the master SA types.- As explained under Billing For SAs Covered By The Non-Billed Budget, when a bill is completed for accounts that have a Non-Billed Budget SA, the system needs to distribute the Non-Billed Budget's credit balance to the covered SAs. The system will only do this if you specify an appropriate algorithm on the NBB SA types.

- As explained under [Overpayment Segmentation](#), when a bill is completed, the system may apply an excess credit from a prior overpayment to an account's service agreements.

Note. Algorithms of this type are called for all non- Canceled service agreements, regardless of whether or not they are billed. If your algorithms should only be processed under certain conditions (for example, only process this algorithm for Active service agreements), then it is the responsibility of the algorithm to check the conditions before continuing.

Click [here](#) to see the algorithm types available for this system event.

Bill Eligibility	Optional	<p>These algorithms are executed during billing and allow logic to be introduced to check additional criteria to determine if an SA is eligible for billing.</p> <p>Click here to see the algorithm types available for this system event. The algorithm type delivered with the system provides an example of how plug-ins of this type can be used</p>
Break NBB SA	Optional	<p>These algorithms are executed when a Non-Billed Budget is manually stopped via the Non-Billed Budget maintenance page.</p> <p>Click here to see the algorithm types available for this system event.</p> <p>Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.</p>
Break Pay Arrangement	Optional	<p>These algorithms are by executed by severance events when the event is created for payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place when a customer breaks a payment arrangement. Refer to Monitoring Payment Arrangements for more information about breaking payment arrangements.</p> <p>Click here to see the algorithm types available for this system event.</p>
Budget Eligibility	Optional	<p>These algorithms are executed when determining in a service agreement is eligible for budget. Algorithms of this type are only applicable on SA types that are marked as eligible for budget and may be used to</p>

override that setting and indicate that the service agreement is not eligible.

For example, maybe service agreements in a certain rate are not eligible. Or perhaps service agreements with a given characteristic value are not eligible.

Click [here](#) to see the algorithm types available for this system event.

Cut Process Rule

Optional

These algorithms are executed to create a cut process for service agreements of this type. Refer to [The Big Picture Of Cut Processes](#) for more information.

Click [here](#) to see the algorithm types available for this system event.

FT Freeze

Optional

These algorithms are executed whenever a financial transaction is frozen that is linked to a service agreement of this type. The following situations necessitate the definition of an FT freeze algorithm:

- As explained under [Technical Implementation of Routing Consumption To Service Providers](#), when a master SA's bill segment is frozen, the system must check if there are any service providers who need the bill segment's consumption. If so, it sets up the data necessary to interface the master SA's consumption (snapshot on the bill segment) to the service provider(s). The system will only do this if you specify an appropriate FT Freeze Algorithm on the master SA types.

- As explained under [Technical Implementation of Paying The Service Provider](#), when a financial transaction (FT) is frozen that is associated with a sub SA, the system must check if this FT should trigger the "payment" of a service provider. If so, it has to create an adjustment to increase how much we owe the service provider. The system will only do this if you specify an appropriate FT Freeze Algorithm on the sub SA types.

Click [here](#) to see the algorithm types available for this system event.

High Bill Amount

Optional

This algorithm type checks for high bill amounts during batch billing. A bill threshold amount can be defined on a service agreement. By default the system compares this threshold amount to the bill segment amount during batch billing. If the bill segment amount exceeds the given threshold value,

a bill error is generated. No proration takes place on the threshold amount if the bill segment's consumption period falls outside of the rate frequency's normal period.

This algorithm may be used to override the default system behavior. It will prorate the SA's bill threshold amount before comparing it to the batch bill segment amount if the consumption period falls outside of the rate frequency's normal period.

Click [here](#) to see the algorithm types available for this system event.

Landlord Reversion	Optional	<p>These algorithms are used to create, update or cancel a service agreement for a landlord when service is started, stopped or updated for a premise that references a landlord agreement.</p> <p>Algorithms of this type are called:</p> <ul style="list-style-type: none">- When starting a new SA (start initiation)- When stopping an SA (stop initiation)- When canceling a pending start SA- When changing the stop / start dates of back-to-back service agreements <p>Click here to see the algorithm types available for this system event.</p>
Loan Interest Charge	Optional	<p>These algorithms are executed whenever the interest charge needs to be calculated for a loan, such as when the loan amortization schedule is created and when a bill segment is created for a loan SA. This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.</p> <p>Click here to see the algorithm types available for this system event.</p>
Loan Periods and Amount	Optional	<p>These algorithms are executed whenever a user clicks the Calculate button on Loan - Main or on the Start SA Confirmation dialog for a loan SA. It calculates either the number of periodic payments or the payment amount (depending on whether the user specifies the number of payments or the payment amount as input). This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.</p> <p>Click here to see the algorithm types available for this system event.</p>
Loan Schedule	Optional	<p>These algorithms are executed whenever the system needs to create a loan amortization schedule for a loan, such as when you</p>

renegotiate the terms of a loan on [Loan - Main](#). This algorithm should be specified on SA types with a special role of Loan. Refer to [Defining Loan Options](#) for more information.

Click [here](#) to see the algorithm types available for this system event.

Override Proration Days	Optional	<p>This algorithm is invoked from rate application, right after base has determined if proration applies. It is used to override base days, normal days and "is within proration window" indicator, which were determined by base logic. Only one algorithm may be plugged-in to this system event. This is available only in the calculation rule based rating engine.</p> <p>Click here to see the algorithm types available for this system event.</p>
Payment Arrangement	Optional	<p>These algorithms are by executed to handle the creation, breaking and canceling of payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place during the lifecycle of a payment arrangement. Refer to Monitoring Payment Arrangements for more information about payment arrangements.</p> <p>Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.</p>
Payment Freeze	Optional	<p>These algorithms are executed whenever a payment is frozen. The following situations necessitate the definition of such an algorithm:</p> <ul style="list-style-type: none">- For a loan SA, such an algorithm is required to create a frozen adjustment that transfers any credit balance resulting from an overpayment to the loan's principal balance. Refer to Defining Loan Options for more information. <p>Click here to see the algorithm types available for this system event.</p>
Pre-Bill Completion	Optional	<p>These algorithms are executed immediately prior to bill completion when a bill contains a bill segment for a service agreement whose SA type has such an algorithm. The following situations necessitate the definition of such an algorithm:</p> <ul style="list-style-type: none">- If you want to delete a bill segment that's in error on the last night of a bill cycle when there are other bill segments that aren't in error, use such an algorithm.

		Click here to see the algorithm types available for this system event.
Process NBB Scheduled Payment	Optional	<p>These algorithms are executed by the NBB Scheduled Payment Processing background process whenever a scheduled payment is due. If the Non-Billed Budget SA is unmonitored, this algorithm is not called. This algorithm should be specified on Non-Billed Budget SA types to create the necessary adjustments for the Non-Billed Budget SA.</p> <p>Click here to see the algorithm types available for this system event.</p>
Proposal SA Acceptance	Optional	<p>These algorithms are executed when a proposal service agreement is accepted. Refer to Enabling The Creation Of A Real Service Agreement for more information.</p> <p>Click here to see the algorithm types available for this system event.</p>
Proposal SA Bill Segment Generation	Optional	<p>These algorithms are executed to generate simulated bills segments for a proposal service agreement. Refer to Enabling The Generation Of Simulated Bill Segments for more information.</p> <p>Click here to see the algorithm types available for this system event.</p>
Proposal SA Creation	Optional	<p>These algorithms are executed when a proposal service agreement is created. Refer to Enabling The Automatic Generation Of Billing Scenarios for more information.</p> <p>Click here to see the algorithm types available for this system event.</p>
SA Activation	Optional	<p>These algorithms are executed when a service agreement status changes from Pending Start to Active. It performs any additional activities that are necessary to activate an SA. The following situations necessitate the definition of such an algorithm:</p> <ul style="list-style-type: none"> - If you want to create a customer contact to indicate that a non-billed budget has been activated, use such an algorithm. <p>Click here to see the algorithm types available for this system event.</p>
SA Cancel	Optional	<p>These algorithms are executed when a service agreement status changes to Canceled. It performs any additional activities that are necessary to cancel an SA.</p> <p>An example of when you may use this algorithm is that perhaps your business</p>

rules dictate that the creation of a payment arrangement should create a credit rating history transaction. When a payment arrangement SA is canceled, the credit rating should be updated with an end date.

Click [here](#) to see the algorithm types available for this system event.

SA Creation	Optional	<p>These algorithms are executed when a service agreement is created. The following situations necessitate the definition of such an algorithm on an SA type:</p> <ul style="list-style-type: none">- If you want to create a To Do entry whenever a new service agreement of a given type is added, specify such an algorithm.- If you want to automatically activate SAs of a given type (instead of waiting for the background SA activation process to run), specify such an algorithm.- If you want to create a Workflow Process when a service agreement of a given type is added, specify such an algorithm. <p>Click here to see the algorithm types available for this system event.</p>
SA Information	Optional	<p>We use the term "SA information" to describe the basic information that appears throughout the system to describe a service agreement. The data that appears in "SA information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the "SA information" algorithm on installation options or the system default "SA information" if no such algorithm is defined on installation options.</p> <p>Click here to see the algorithm types available for this system event.</p>
SA Renewal	Optional	<p>These algorithms are executed by the Service Agreement Renewal background process whenever an SA is due for renewal or when the user clicks the Renew button (for Non-Billed Budgets). It performs any activities that are necessary to renew an SA and returns the new renewal and expiration dates for the SA.</p> <p>Click here to see the algorithm types available for this system event.</p>
SA Stop	Optional	<p>These algorithms are executed whenever a service agreement's status changes from pending stop to stopped. The following situations necessitate the definition of a SA stop algorithm:</p>

- For [Non-Billed Budgets](#) to distribute any remaining credit balance from the Non-Billed Budget SA to the covered SAs, you must specify such an algorithm.

- For service credit memberships that have a [refundable membership fee](#), an SA Stop algorithm attempts to refund the fee if this is the last SA linked to the membership that is being stopped.

Click [here](#) to see the algorithm types available for this system event.

SA Stop Initiation

Optional

These algorithms are executed whenever a service agreement's status becomes pending stop. The following situations necessitate the definition of a stop initiation algorithm on an SA type:

- As explained under [Finalizing Pending Stops](#), service agreements are normally transitioned from pending stop to stopped by a background process (or manually). For [Non-Billed Budget SAs](#) to transition to stopped automatically (without waiting for the background process), you must specify such an algorithm.

When does a SA become pending stop?

Service agreements typically become pending stop when a user initiates a request to stop service on [Start Stop - Main](#). A [severance process](#) with an Expire SA [severance event](#) causes a service agreement to become pending stop (when the event is executed). Additionally, the [Stop Expired Service Agreements](#) background process starts the process to initiate the stop of an SA when the expiration date is on or before the process date.

Click [here](#) to see the algorithm types available for this system event.

Start Stop Field Work

Optional

These algorithms are executed to create the field activities necessary to start and stop service. Refer to [Starting Service and Field Activities](#) and to [Stopping Service and Field Activities](#) for a description of when algorithms of this type are called. The following situations necessitate the definition of a start stop fieldwork creation algorithm:

- If a service agreement has field activities created to start and stop service at its service points, its SA type must have an appropriate start stop field work creation algorithm.

SA Type - Billable Charge Overrides

The [BCU2 - Create Billable Charge](#) background process is responsible for creating billable charges for each billable charge upload staging record interfaced into the system. This process will override the values of the various switches referenced on a billable charge upload staging line if the respective service agreement's SA type has an override value for the billable charge upload staging line's billable charge line type.

NOTE:

This information is optional. If you don't need to override the values of a [Billable Charge Line Type](#) you don't need to set up this information.

Open **Admin > Customer > SA Type > Search** and navigate to the **BC Upload Override** page to define override values for a given SA Type / Billable Charge Upload Staging Line Type.

Description of Page

Use the **Billable Charge Overrides** collection to define values to be overridden on billable charge lines uploaded from an external system (refer to the description above for the details). The following switches may be overridden for a given **SA Type** and **Billable Charge Line Type**.

- Use the **Show on Bill** switch to define the value to be defaulted into the Show on Bill indicator on billable charge upload lines that reference this line type.
- Use the **Appear in Summary** switch to define the value to be defaulted into the App in Summary indicator on billable charge upload lines that reference this line type.
- Use **Memo Only, No GL** switch to define the value to be defaulted into the Memo Only, No GL indicator on billable charge upload lines that reference this line type.
- Use **Distribution Code** to define the value to be defaulted into the Distribution Code on billable charge upload lines that reference this line type.

SA Type - Contract Option Type

Open **Admin > Customer > SA Type > Search** and navigate to the **Contract Option Type** page to define the contract option types, which are valid for service agreements of a given type.

Description of Page

Where Used

This information is used to validate the contract options linked to the service agreement. Refer to [Service Agreement - Contract Options](#) for more information.

SA Type - NBB Recommendation Rule

Open **Admin > Customer > SA Type > Search** and navigate to the **NBB Rec'n Rule** page to define the recommendation rules that are valid for Non-Billed Budget SAs of this type.

Description of Page

If the SA Type's special role is Non-Billed Budget, you may define the **Recommendation Rules** that are valid on non-billed budget SAs of this type. Check the **Use As Default** box to indicate the default recommendation rule for service agreements of this type.

FASTPATH:

For more information about Non-Billed Budgets, refer to [Defining Non-Billed Budget Options](#).

Where Used

The Non-Billed Budget recommendation rules are used to recommend the payment amount and payment schedule for Non-Billed Budget service agreements. Refer to [Maintaining Non-Billed Budgets](#) for more information.

Setting Up Start Options

Start options save users time and prevent data entry errors because they default many values on a service agreement (e.g., the rate schedule, recurring charge amount, contract riders, contract terms, characteristics, terms and conditions, etc. can all be defaulted onto a service agreement from a start option).

A SA type may have zero or more start options.

- A SA type without start options is usually one that has a very limited number of options. For example, if a SA type has a single valid rate and no customer-specific contract values, you don't need to setup a start option (the SA's default rate can default based on the information defined when you setup the SA type).
- A SA type with multiple start options is one where many different permutations are possible. For example, a SA type that can have multiple rates and each rate can have multiple riders is a good candidate for start options (where each start option will default, for example, a specific rate and set of contract riders).

When the [Start/Stop](#) transaction is used to start service AND the service being started uses a SA type with start options, the user is asked to select one of the start options. The service agreement that's created is populated with fields from the start option.

When the [Order](#) transaction is used to start service, the user selects start options, but only indirectly. It works like this:

- A user selects a "package" of services to start service for a customer.
- A "package" contains one or more start options.
- When a user selects a package, the system creates a service agreement for each start option on the package (and defaults the information on each service agreement from the respective start option).

A start option's default values may change over time (i.e., the information on a start option is effective-dated). The start service logic uses the version of the start option that is effective on the day service starts.

Start options can cause a great deal of information to be populated on a service agreement. There are several ways to change this default information:

- A user may override this information using the [Service Agreement](#) transaction.
- If the service agreement is in the pending start state, you can use the [Start/Stop - Pending SAs](#) page to change the service agreement's SA type and/or start option.
- If the service agreement is in active or pending stop states, a button appears on [Service Agreement - Main](#) called **Apply New Start Option**. When pressed, the user is allowed to define a start option and the date its terms become effective on the service agreement. Refer to [Changing A Start Option](#) for the details of this functionality.

The topics in this section describe how to setup start options.

NOTE:

The merge transaction can save setup time. The [Start Options Merge](#) transaction can be used to construct a start option by copying pieces from other start options.

Start Option Considerations - Rate-Oriented SA Types

To understand the following discussion, you should be familiar with the following concepts:

- SA types that use rates have one or more valid rate schedules. Only these rate schedules may be defined on service agreements of a given type.
- One of a SA type's rate schedules may be designated as the "default" rate. The system assigns the "default" rate to new service agreements when a CSR doesn't choose a start option.
- Start options may be used by customer service reps when a service is started for a customer. A start option causes the customer's new service agreement to be populated with a specific rate and contract terms (e.g., contract riders, contract values). The use of start options is not allowed if the service's SA type does not require a start option. The use of start options is required if the service's SA type requires a start option.

Whether or not a SA Type has start options is dependent on the following factors:

- If a SA Type has only one valid rate and the rate doesn't use customer-specific contract terms (e.g., contract riders, contract values), the SA Type does not need any start options. Why? Because the system default's the SA type's default rate on new service agreement when no start option is used at start time.
- If a SA Type has only one valid rate, but under unusual circumstances, it uses customer-specific contract terms, you'll want an option for every situation (both the standard one and the unusual ones).
- If a SA Type has a single rate with a variety of contract terms (which, by definition, are different for each customer), then you'd want a start option for each permissible combination of contract terms. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).
- If a SA type has multiple valid rates and a variety of contract terms (a combination of the previous two points), you'd need a start option for each permissible combination. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).

Start Option Considerations - SA Types That Use Recurring Charges

To understand the following discussion, you should be familiar with the following concepts:

- Many SA types use the recurring charge algorithms to generate the bill segments. For example, if you let a customer pay for a \$900 heat pump in 3 installments of \$300, you'd have an SA type called CA/MERCH-I and indicate it uses the recurring charge algorithm.
- When a CSR creates an SA type that uses recurring charge algorithms, they can enter the recurring charge amounts on [Start/Stop Service - Start Confirmation](#) window OR they can specify a start option on this window and let the system populate the recurring charge amount. For example, if you let a customer pay for a \$900 heat pump in 3 installments of \$300, you can set up a start option called HP 3PAY with an installment amount of \$300.
- Depending on the type of service being started, you might also need to generate an adjustment when service is started in order to initialize the total debt. For example, when a customer buys a heat pump we'll need an adjustment issued to realize the entire \$900 of revenue.

The following table provides examples of recurring charge SA types with several typical start options:

CIS Division/	Start Option	Adjustment Type	Install Amount	Comments
---------------	--------------	-----------------	----------------	----------

SA Type

CA/CHARITY	DONATE \$5		5	This causes a charitable contribution to be created with an installment amount of \$5.
CA/CHARITY	DONATE \$10		10	This causes a charitable contribution to be created with an installment amount of \$10.
CA/PA-REGU	PAY \$10 PM		10	This causes a payment arrangement to be created with an installment amount of \$10.
CA/PA-REGU	PAY \$20 PM		20	This causes a payment arrangement to be created with an installment amount of \$20.
CA/PA-UNRE	PAY \$10 PM		10	This causes a payment arrangement to be created with an installment amount of \$10.
CA/PA-UNRE	PAY \$20 PM		20	This causes a payment arrangement to be created with an installment amount of \$20.
CA/MERCH-I	HP 3PAY	HEATPUMP	300	This causes a merchandise service agreement to be created with an installment amount of \$300. It also causes an adjustment to be issued to realize the \$900 of revenue.
CA/MERCH-I	BBQ 3PAY	BBQ	250	This causes a merchandise service agreement to be created with an installment amount of \$250. It also causes an adjustment to be issued to realize the \$750 of revenue.
CA/DEP-I	PAY \$40 PM		40	This causes a deposit service agreement to be created with an installment amount of \$40. The CSR would be required to define the

total deposit amount to be billed over the life of the service agreement on the secondary SA window on the Start Account window.

Start Option Considerations - Initial Adjustment SA Types

To understand the following discussion, you should be familiar with the following concepts:

- Some SA types depend on an adjustment to book their initial debt. For example, the CA/MERCH-I SA type requires an initial adjustment to book the payoff amount for the entire cost of the merchandise. Another example would be a loan service agreement (refer to [Booking The Principal Amount Using An Adjustment](#) for the details).
- When a CSR starts an SA type that requires an initial adjustment, they can create the adjustment immediately after starting service OR then can specify a start option when they start service and let the system generate the adjustment. You could let the system create the adjustment to book the \$900 associated with the heat pump as shown in the previous section.

The following table provides examples of SA types that use adjustments with several typical start options:

CIS Division/ SA Type	Start Option	Adjustment Type	Install Amount	Comments
CA/MERCH-I	HP 3PAY	HEATPUMP	300	This causes a merchandise service agreement to be created with an installment amount of \$300. It also causes an adjustment to be issued to realize the \$900 of revenue.
CA/MERCH-I	BBQ 3PAY	BBQ	250	This causes a merchandise service agreement to be created with an installment amount of \$250. It also causes an adjustment to be issued to realize the \$750 of revenue.
CA/CONNECT	CONNECT	CONNECT		This causes an adjustment to be issued to realize the connection charge.

Start Option - Main

Open **Admin** > **Customer** > **SA Type Start Option** > **Add** to define a SA type's start options.

Description of Page

Every start option is uniquely identified by the following fields:

CIS Division & SA Type Enter the Division and SA type to which the start option is linked.

Start Option Enter the unique identifier of the option. Pick something easy to recognize as this will be used by CSRs to pick an option when they start service.

Effective Date Enter the earliest effective date. It should be the same as the earliest effective date of the start option's rate (although it doesn't hurt for it to be earlier). The date defaults to the current date. (The status, below, should be Active.)

The remaining fields further describe a start option.

Enter a **Description** for the start option.

Indicate its **Status**. For new start options, the status should be Active. When it's no longer applicable, change it to Inactive.

Enter the primary **Rate Schedule** that should be defaulted onto service agreements created using this option. Refer to [Start Option Considerations For SA Types That Use Rates](#) for more information.

FASTPATH:

For more information about a service agreement's rates, refer to [Service Agreement - Rate Info](#).

Enter the **Adjustment Type** that should be generated, if any, when service is started using this option. Refer to [Start Option Considerations For SA Types That Use Initial Adjustments](#) for more information.

Enter the **Recurring Charge Amount** that should be defaulted onto service agreements created using this option. This field is only visible when the SA type allows recurring charges. In addition, the prompt for this field is defined on the SA type table on the billing window (e.g., it could appear as Payment Amount, Budget Amount, or Installment Amount). Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for more information.

Enter the **Currency Code** in which monetary amounts are denominated.

NOTE:

The currency code defaults from the [installation record](#).

Enter the **Total Amount to Bill** that should be defaulted onto service agreements created using this option. This is useful to initiate either a loan or a deposit. The prompt for this field is defined on the SA type table on the billing window (e.g., it could be Deposit Amount or Loan Amount).

Use **Number of Periods** to default the number of payment periods of service agreements created using this option. This field is only allowed for SA types with special role of Loan. Refer to [The Terms Of A Loan Are Stored On A Service Agreement](#) for more information.

If your SA Type has a special role of Billing Determinants Required, you may enter the **Cutoff Time** and **Start Day Option** that should be defaulted onto service agreements that are created using this option. For start day option, you may choose **Current Day** or **Previous Day**.

If your SA Type has a special role of Billable Charge, then you can setup the start option to automatically create a billable charge when a service agreement is created using this start option. For example, you might have a start option that automatically creates a "one-time invoice" service agreement along with a "tree trimming" billable charge. To use this feature you should turn on the **Create Billable Charge** switch and specify the **Billable Charge Template** that will be used to create the billable charge. These fields are only allowed for SA types with special role of Billable Charge.

FASTPATH:

Refer to [Setting Up Billable Charge Templates](#) for more information about templates. Refer to [An Easier Way To Create One Time Charges](#) for an example of how you can setup a campaign with packages that use this type of start option.

NOTE:

The duplicate action in the page actions toolbar enables you to copy another start option. Refer to [Duplicate Button](#) in the system wide standards document for more information.

Start Option - Rate Info

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Rate Info** page to define the start option's default values for contract riders and contract values.

Description of Page

The information in the **Contract Riders** collection defines the contract riders to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Bill Factor The bill factor defines the type of rider. You may only reference bill factors designated as being applicable for contract riders.

Number of Days The number of days the rider should be in effect. This value is used by the system to set the stop date on the service agreement's contract rider. If the rider has no expiration, set this field to 0. Default note: this field will be set to 0 if left blank.

FASTPATH:

For more information about a service agreement's contract riders, refer to [Service Agreement - Contract Riders](#).

The information in the **Contract Values** collection defines the contract values to be defaulted onto service agreements created using this start option. The following fields are required for each event:

Bill Factor The bill factor defines the type of value. You may only reference bill factors designated as allowing values in contract terms.

Number of Days The number of days the value should be in effect. This value is used by the system to set the stop date on the service agreement's contract value. If the value has no expiration, set this field to 0.

Value The amount of the contract value.

FASTPATH:

For more information about a service agreement's contract values, refer to [Service Agreement - Contract Values](#).

Start Option - Characteristics & Qty

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Characteristics & Qty** page to define the start option's default values for characteristics and contract quantities.

Description of Page

The information in the **Characteristics** collection defines the characteristics to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Characteristic Type This defines the type of characteristic. Note: you may only define characteristics valid on service agreements.

Characteristic Value This defines the characteristic value that will be defaulted.

FASTPATH:

For more information about a service agreement's characteristics, refer to [Service Agreement - Characteristics](#).

The information in the **Contract Quantity** collection defines the contract quantities to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Contract Quantity Type This defines the type of contract quantity.

Contract Quantity The amount of the contract quantity.

FASTPATH:

For more information about a service agreement's contract quantities, refer to [Service Agreement - Contract Quantity](#).

Start Option - Contract Option

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Contract Option** page to define the start option's contract option default values.

Description of Page

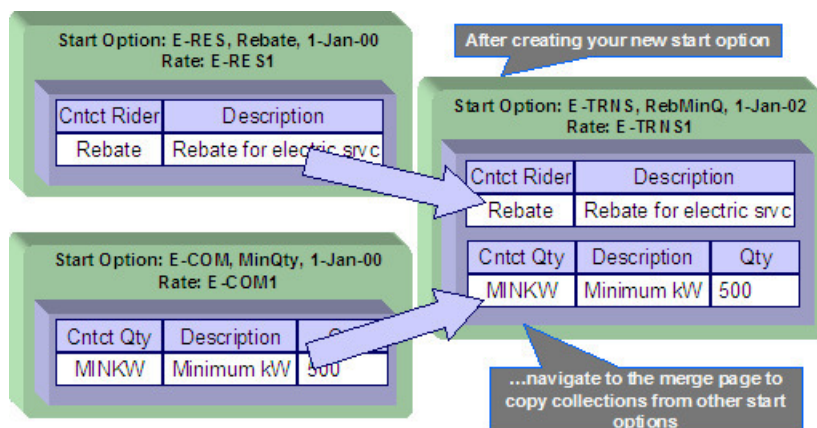

The collection of contract option types will be used to link contract options to a service agreement that will be created with this start option. If the contract option to create for the service agreement will be SA Specific, simply indicate the **Contract Option Type**. This will cause a new contract option to be created with this contract option type and the new contract option will be linked to the new SA at start time. If the contract option to create for the service agreement will be Shared, indicate the contract option type and the **Contract Option ID**. This will cause the specified contract option to be linked to the new SA at start time.

Start Option Merge

Use this page to modify an existing start option by copying information from other start options. This page may be used to copy records from the contract rider, contract value, contract quantity, characteristic, contract option and TOU contract value collections from one or more existing start options to another.

NOTE:

The target start option must exist prior to using this page. If you are creating a new start option, you must first go to the [Start Option](#) page to add the new start option and then navigate to the merge page to copy collection information.

NOTE:

Duplicate versus Merge. The [Start Option](#) page has [Duplication](#) capability. You would duplicate a start option if you want to a) create a new start option AND b) populate it with all the information from an existing start option. You would use the start option merge page if you want to build a start option using pieces of one or more start options.

Start Option Merge - Main

Open **Admin > Customer > SA Type Start Option Merge**.

Description of Page

Select the **Original Start Option**, which is the target for merging the start option collection information.

Select the **Merge From Start Option**, which is your template start option to copy the collections from.

NOTE:

You may only copy information from one Merge From start option at a time. If you wish to copy information from more than one start option, select the first Merge From start option, copy the desired records, Save, then select the next Merge From start option.

The left portion of the page will display any existing records in the collections for the original start option. The right portion of the page will display the existing records in the collections for the Merge From start option.

You may use the **Copy All** button to copy all the records in all the collections from the Merge From start option to the Original start option. If you do not choose to copy all, you may copy records individually as described below.

The left portion of the **Contract Riders** collection initially displays existing contract riders linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor** and **Number of Days** for each contract rider is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Values** collection initially displays existing contract values linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor**, **Number of Days** and **Value** for each contract value is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The topics, which follow, describe how to perform common maintenance tasks:

Removing A Row From A Grid

If you wish to remove a record linked to the Original start option, click the "-" button to the left of the record.

Adding A New Row To A Start Option

You may move any of the records from the Merge From start option to the original start option by selecting the left arrow adjacent to the desired row. Once a record is moved it will disappear from the Merge From information and appear in the Original information with the word Merge in the Merge Type column.

Removing An Uncommitted Row From A Start Option

If you have copied a row across by mistake, you may remove it by clicking on the right arrow adjacent to the appropriate record.

Start Option Merge - Characteristics and Quantities

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Characteristics and Quantities** page to copy rows in the characteristic and contract quantity collections.

Description of Page

The left portion of the **Characteristics** collection initially displays existing characteristics linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Characteristic Type** and **Characteristic Value** for each characteristic are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Quantity** collection initially displays existing contract quantities linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Quantity Type** and **Contract Quantity** for each contract quantity are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

FASTPATH:

Refer to [Start Option Merge - Main](#) for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Contract Option

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Contract Option** page to copy rows in the contract options collection.

Description of Page

The left portion of the **Contract Option** collection initially displays existing contract option information linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Option Type**, **Contract Option ID** and **Description** of the contract option for each contract option row are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

FASTPATH:

Refer to [Start Option Merge - Main](#) for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Terms and Conditions

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Terms and Conditions** page to copy terms and conditions (T&Cs).

Description of Page

The left side of the **Terms and Conditions** grid initially displays the T&Cs linked to the original start option. On the right side, the T&Cs linked to the merge from start option are displayed initially.

FASTPATH:

Refer to [Start Option Merge - Main](#) for a description of how to perform common maintenance tasks for the grids displayed on this page.

Defining SA Relationship Options

We use the term "SA Relationship" to describe functionality that supports the following situations:

- When companies other than your own provide a service to your customers AND you have some type of interaction with these companies. For example, in a deregulated market, customers deal with both distribution and energy supply companies. These companies typically exchange a great deal of information about their joint customers.
- When multiple rates are associated with a service (where each rate corresponds with a sub-category of service). For example, most water companies charge for both water and wastewater service using separate rates for each. While it is possible to set up water and wastewater as separate service agreements, the SA relationship functionality allows you to set up a single "master" service agreement (for the water service) and associate with it a "sub" service agreement (for the wastewater service).
- When a party representing a group of customers negotiates a contract that is applied over and above those of the individual service agreements. For example, the head office of a national chain may negotiate for additional discounts that should be calculated together or individually. The SA relationship functionality may be used to track the covered service agreements and to calculate and transfer discounts to the head office's service agreement. Refer to the special discounts section.

WARNING:

Setting up the SA relationship control tables is as challenging as your organization's business rules. If you don't have requirements similar to those described above, you don't have to set up anything. If you have these types of requirements, your setup process will be taxing as you must design and set up control tables that manage the financial and consumption interactions that take place between you, your customers, and the various service providers.

The topics in this section describe tables that control your SA relationship functionality.

The Big Picture of SA Relationships and Service Providers

You must set up service providers if companies other than your own provide a service to your customers AND you have some type of interaction with these companies. You will have one service provider for each such company. For example, if you are a distribution company in a deregulated market, you will have a service provider for each company that provides any of the following services:

- Energy (commonly referred to as Energy Supply Companies, Energy Service Providers, Retailers, and Suppliers)
- Meter service (commonly referred to as Meter Service Providers and Meter Agents)
- Meter reading (commonly referred to as Meter Data Management Agencies and Meter Reading Service Providers)
- Billing (commonly referred to as Billing Agents)

The topics in this section provide background information about service providers.

Persons and Service Providers

A great deal of information about your service providers is defined using a person. For example, a service provider's name, address, phone numbers, electronic ID's, etc. are all defined on the person object.

In addition, every service provider must have a service provider object created for it. The service provider object contains information about a provider's relationships with the customer and your organization, for example:

- Do you calculate bills for the service provider? If so, do you have their rates or do they interface their charges to you? Refer to [Billing Relationships](#) for more information.
- Do you send the customers' consumption to the service provider? Do they send it to you? Refer to [Consumption Relationships](#) for more information.
- How are financial settlements between your organization and the service provider implemented (do you pay them when you get paid?, do you purchase the receivable for them?, etc.). Refer to [Service Providers Have Service Agreements Too](#) for more information.
- Etc.

FASTPATH:

Refer to [Designing Your SA Relationship Types and Service Providers](#) for more information.

NOTE:

In some situations, you will need to set up a service provider for your own company. Refer to [When Your Company Is A Service Provider](#) for the details.

Service Providers Are Linked To Service Agreements

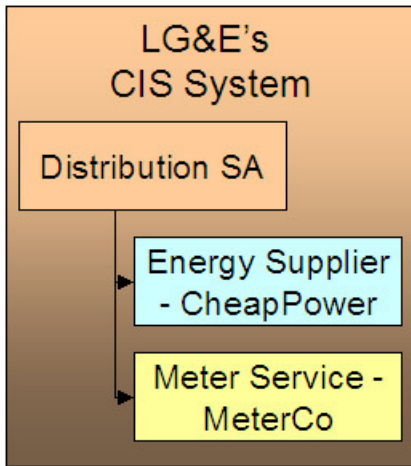

The following diagram illustrates a customer's bill for electric service in a deregulated market. Notice that there are separate sections for energy, distribution and meter service.

NOTE:

Consolidated billing. The following is an example of a bill that consolidates charges from many service providers. Rather than receive a consolidated bill, it is possible for the customer to receive 3 separate bills, one from each service provider (we refer to this as Dual billing).

Customer's Electric Bill	
Energy Supply - Cheap Power	\$12
Distribution - LG&E	\$9
Meter Service - MeterCo	\$2

If we were to look at this customer's service agreement in the distribution company's CIS system, we'd find a service agreement for distribution charges, and linked to it would be information about the meter service and energy service providers:

If we look at this customer's service agreement in the energy supply company's CIS system, we'd find a service agreement for energy charges, and linked to it would be information about the distribution and meter service providers:

And finally, if we look at this customer's service agreement in the meter service company's CIS system, we'd find a service agreement for meter service charges, and linked to it would be information about the distribution and energy providers:

NOTE:

Bottom line. A customer's service providers keep track of the customer and each other in their respective CIS systems. A customer will have a service agreement (or the equivalent) in each service provider's CIS system. A customer's service agreement defines the service providers who supply each type of service.

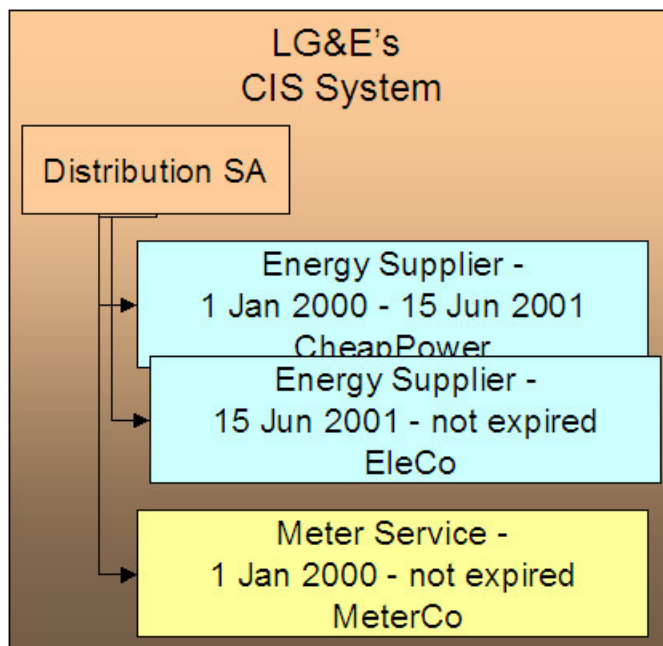

FASTPATH:

Because information about customers and their services needs to be kept up-to-date in many different CIS systems, there is a need for automated communications between service providers. Refer to [Service Providers Have To Communicate About Customers](#) for more information.

Service Providers May Change Over Time

A customer typically has a choice of service providers. Over time, their choice may change. The system keeps track of a customer's service providers throughout time so that it can accurately cancel / rebill historical bills. This means that the service provider relationship is *effective-dated*.

The following diagram illustrates how a distribution company's system keeps track of a customer's service providers (notice the customer changed energy suppliers):

How To Set Up SA Relationships On A Customer's Service Agreement

There are three ways to set up a customer's service providers:

- **Manually.** An operator can manually change a service agreement's SA relationships. The manual method is NOT recommended as changing service providers typically involves many events (e.g., you have to notify the current service provider that they will be dropped).
- **Use Default Service Providers.** The system will default a service provider on a required SA relationship when a service agreement is activated. Refer to [Defaulting Relationship Types And Defaulting Service Providers](#) for more information.

When Your Company Is A Service Provider

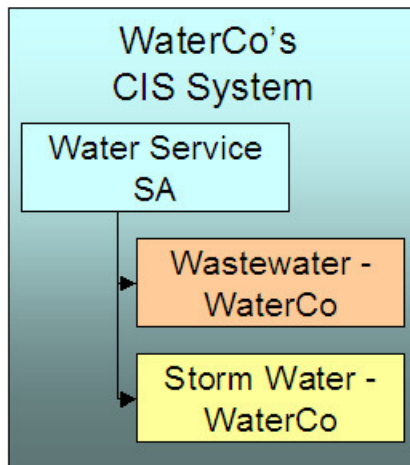

Besides setting up service providers for other companies that provide services to your customer, you may have to set up a service provider for your own company. You have to do this when:

- **Your organization can supply one of the services.** Refer to the illustration in [Service Providers Are Linked To Service Agreements](#). If you are LG&E and you supply energy in addition to distribution, you would need to set up a service provider for your own organization. Why? Because whenever you have a subcategory of service (e.g., energy supply), you must indicate the service provider who provides this service; even when it's you.
- **You decide to break up a service into subcategories** (and have a separate service agreement for each category). For example, a water company may choose to break up service charges into water, wastewater and storm water (they may do this because there are different rates for each category of service). The following is an example of the segregated charges associated with this water company's service charges.

Customer's Water Bill	
Water Service - WaterCo	\$15
Wastewater - WaterCo	\$6
Storm Water - WaterCo	\$5

This water company system may benefit by creating a single service (for water) and indicating there are subcategories of service (for wastewater and storm water). Whenever you have a subcategory of service, you must indicate the service provider who provides this service. And, in this example, the water company would be the sole service provider for each subcategory of service.

Customer's Water Bill	
Water Service - WaterCo	\$15
Wastewater - WaterCo	\$6
Storm Water - WaterCo	\$5

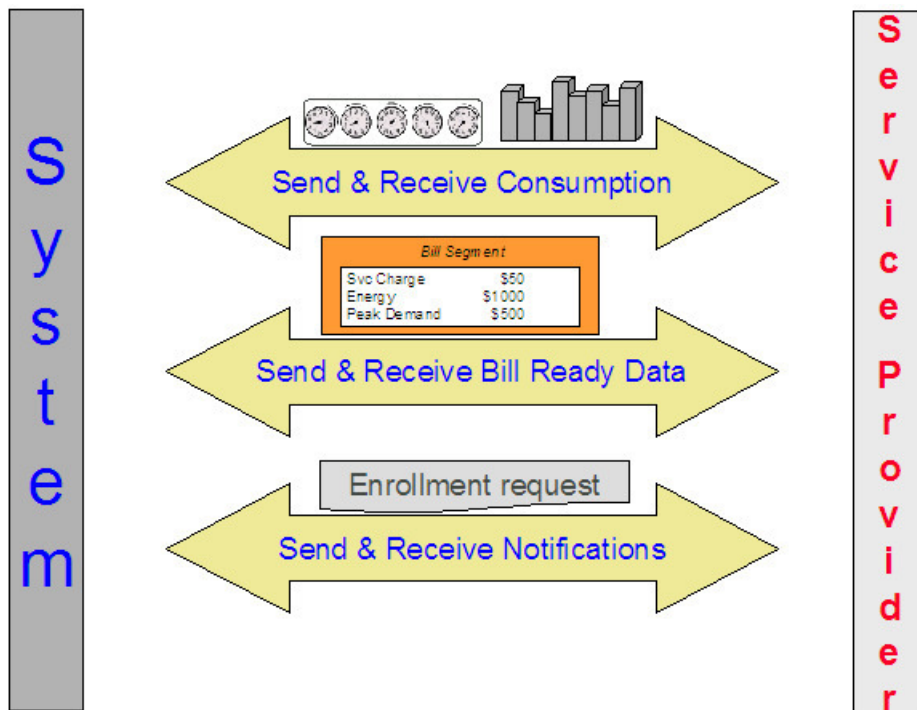

NOTE:

Refer to [We Bill For Them - Rate Ready Bill Segments Are Special](#) for restrictions in respect of using subcategories of service.

Service Providers Have To Communicate About Customers

The providers of service typically have to communicate with each other in respect of the customer's service. The following diagram illustrates the major interfaces of information between your system and your service providers.

Depending on where your organization fits in the service provider hierarchy, you may:

- Bill for other service providers (or they may bill for you). Refer to [Billing Relationships](#) for more information about billing communications.
- Send the customer's consumption to service providers (or they may send it to you). Refer to [Consumption Relationships](#) for more information about consumption communications.
- Apprise service providers of the changes to the customers' service (or they may apprise you). Refer to [How Do You Communicate With Service Providers?](#) for more information about communications between service providers.

Relationships Between Service Providers

Service providers may arrange contractual relationships with other service providers to provide additional services, e.g., an energy service provider may work with a specific meter data management agency to gather and report interval meter read data.

The system does nothing special to enforce or record these inter-relationships. Why? Because most service provider switches are received by notification records. Notification records indicate all the associated service providers. There is no need for the system to maintain the inter-service provider associations.

A Service Agreement Can Have Many Types Of Relationships

As described in the previous sections, a given service can be subdivided into subcategories. Each type of service can have zero, one or more subcategories. We call each subcategory a **SA Relationship Type**. The topics in this section provide information about SA relationship types.

An Example

We'll use the following example of a customer in a municipal utility's CIS system to explain SA Relationship types:

Note the following:

- Electric service has 2 SA relationship types: energy supply and meter service.
- Gas service has 1 SA relationship type: energy supply.
- Water service has 1 SA relationship type: waste water.
- Garbage service has no SA relationship types.

NOTE:

Bottom line. Service providers are related to the customer via "your" service agreement. Each service provider linked to a service agreement is defined in respect of a SA Relationship Type. This relationship is effective-dated because we care about how it changes over time.

Your relationship type is implied. The SA relationship type of "your" service agreement is implied, e.g., if you are a distribution company, "your" service agreement's implied SA relationship type is "distribution".

Valid Relationship Types and Service Providers Are Defined On SA Types

You control which services have SA relationships (and which don't) when you set up your SA types. Each SA type can have zero, one or more SA relationship types. Each relationship type, in turn, can have one or more valid service providers.

FASTPATH:

Refer to [Setting Up SA Relationships For SA Types](#) for the page used to define the service providers and SA relationship types for each SA type.

Defaulting Relationship Types And Defaulting Service Providers

Please be aware of the following:

- A SA relationship type for a given SA type can be marked as being **Required**.
- A service provider for a given SA relationship type / SA type can be marked as being the **Default**.

If, at activation time, the customer's master SA is missing a **Required** SA relationship that has a **Default** service provider, the activation process automatically creates the SA relationship type and links to it the **Default** service provider. If a master service agreement doesn't have all **Required** SA relationships, the service agreement cannot be activated. This is handy when your organization is the default service provider for a relationship type.

FASTPATH:

Refer to [Automatic Creation of Sub SAs](#) for information about how the system will automatically create sub service agreements for the defaulted SA relationship / service provider if your organization provides billing services for the service provider. Refer to [Setting Up SA Relationships For SA Types](#) for the page used to define the service providers and SA relationship types for each SA type.

Required Relationship Types and Billing

When the system attempts to create a bill segment for a service agreement whose SA type has **Required** relationship types, it checks if all such relationships are defined for the service agreement. If not, a bill segment error will be generated.

The reason this restriction exists is to handle the situation when your required relationship types change over time. For example, assume on your first day of production you only need energy suppliers defined on electric service agreements. After several months, gas deregulates. When this happens, you will need to change your control tables to indicate that your gas SA types require an energy supplier. If you don't write a default program to update your existing gas service agreements, billing will complain.

Relationship Types Do Not Impact Start/Stop

Customer service representatives (CSR's) are typically not involved with the customer's choice of service providers. Most organizations hear about a customer's service providers from the service providers or from a central body. This means that the start/stop dialog is not impacted by SA relationships. This also means that CSR's are not impacted by SA relationships (unless something goes wrong). If something goes wrong, the CSR's may need to manually correct SA relationships. Refer to [How To Set Up Service Providers On A Customer's Service Agreement](#) for more information.

Billing Relationships

When you set up a service provider, you must define your organization's billing relationship with the service provider. The following points provide examples of the billing relationships supported in the system,

- If you are an energy supply company, you may provide billing services for the distribution company. This means that your bill contains both your charges and the distribution company's charges. We refer to this as the **We Bill For Them** billing relationship.
- Alternatively, the distribution company may provide billing services for you. This means that the distribution company's bill contains your charges and their charges. We refer to this as the **They Bill For Us** billing relationship.
- Alternatively, you may both send bills to the customer. We refer to this as the **Dual Billing** relationship.
- Alternatively, if you subcategorize your services OR if your company provides one of the services that is provided by your service providers, then the system will create a separate bill segment for the subcategory of service. We refer to this as the **It's Us** billing relationship.

If you provide billing services for another service provider (i.e., you bill for them), there are two ways to determine the service provider's charges:

- You can load the service provider's rates in your system and calculate the charges for the service provider. We call this the **Rate Ready** calculation method.
- You can let the service provider calculate their own charges and interface them to you. We call this the **Bill Ready** calculation method.

If a service provider provides billing services for you (i.e., they bill for you):

- If the service provider has a suitable CIS system, they can load your rates in their system and calculate your charges for you. We call this the **Rate Ready** calculation method.
- You can calculate your charges and interface them to them. We call this the **Bill Ready** calculation method.

If you don't have a billing relationship with a service provider, you still need a service provider record to define such. Why? Because the system needs to know that it doesn't have to worry about a particular service provider in respect of billing. In addition, you may have other interactions with a service provider that have nothing to do with billing, e.g., you may send or receive consumption.

The topics in this section provide a wealth of information about the various billing relationships and the ramifications of each.

Sub Service Agreements

If you provide billing services for another service provider OR if you subcategorize your own charges, there will be a separate service agreement (SA) linked to the customer's account that holds these unique charges. We refer to this new service agreement as a **Sub SA**. We use the term "sub" because this service agreement is subservient to the "master" service agreement. By subservient we mean:

- A sub SA's start and stop dates are the same as the master SA. This statement may seem odd, but it's true – all sub SAs linked to a master service agreement have the same start and stop dates as the master.
- A sub SA's status (i.e., *pending start*, *active*, *pending stop*, *stopped*, etc.) is controlled by its master service agreement. As a rule, the master SA transitions its status first and the sub SA(s) follow.

NOTE: There are situations where the master service agreement transitions its status and the sub service agreement(s) does not. One example of this is when both the master and sub SAs are closed and a payment cancellation occurs that only affects the master SA. In this scenario, the master SA becomes reactivated and the sub SA remains closed. Another example is when a straggling billable charge posts to a sub SA; the master SA is not affected.

- Refer to [The Rate Ready Calculation Method](#) for additional examples of subservience.

NOTE:

You may find it helpful to keep in mind that sub SAs are only used for service providers with a billing relationship of It's Us and We Bill For Them. This is because these are the only relationships that have implicit billing responsibilities.

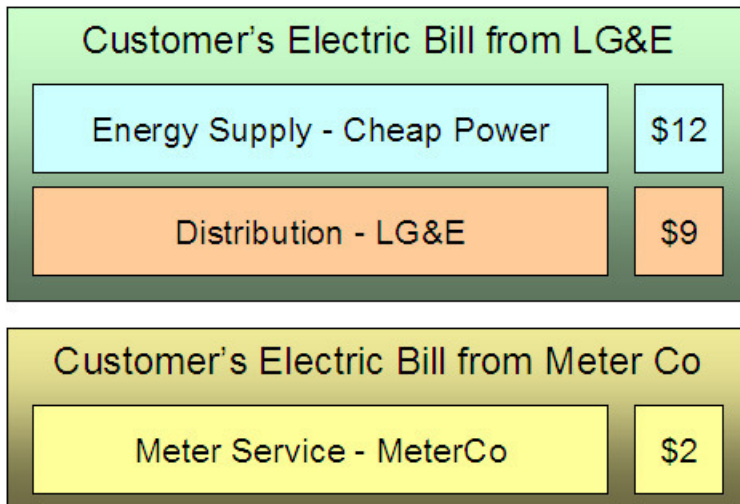

The topics in this section provide additional information about sub SAs.

Only Some Service Providers Have Sub SAs

If you do not provide billing services for a service provider, there will be no sub SAs associated with the service provider's SA relationships. Let's use an example to make the point; assume:

- Service is divided into distribution, energy and meter service charges.
- You are the distribution company and you provide billing services for the energy supply company.
- The meter service company bills the customer independently.

In this situation, the customer will receive two bills: one from you (LG&E), the other from MeterCo. Notice that your bill (LG&E) contains your distribution charges AND CheapPower's energy charges:

If we were to look at the customer information in the three service providers' respective CIS systems, we'd find the following service agreements and SA relationships for the customer:

Notice the following:

- The customer has a service agreement in each supplier's CIS system.
- Because LG&E (the distribution company) bills for CheapPower, all customers who have their energy supplied by CheapPower will have a sub SA in LG&E's system. This sub SA maintains the charges (and receivable balance) associated with CheapPower's energy charges.

- Notice that neither CheapPower's nor MeterCo's CIS systems use sub SAs. This is because neither company bills for other service providers.

NOTE:

Sub SAs are needed if you subcategorize your charges. The above example shows sub SAs being used when a company provides billing service for another company. Sub SAs are also used when you subcategorize your charges - each sub SA contains the rate associated with each subcategory.

Automatic Creation of Sub SAs

The system creates sub SAs for customers choosing service providers where the billing option is It's Us or We Bill For Them. The system creates sub SAs via the following mechanisms:

- The [analyze SA relationships](#) background process (ANLYZSAR) monitors newly activated SA relationships. If the respective service provider is It's Us or We Bill For Them, this process creates the sub SA(s) using the information defined on [SA Type SA Relationship Type - Sub SA Type](#).

NOTE:

The [analyze SA relationships](#) background process also activates and stops sub SAs. Refer to [Sub SA State Transition](#) for the details.

- A button exists on the [SA Relationships](#) page. This button, when pressed, creates sub SAs real-time. This button would only be used if the operator couldn't wait for the background process to run.

The SA type associated with the new sub SAs is defined when you set up each SA Type / SA Relationship Type. Refer to [Setting Up SA Relationships For SA Types](#) for more information.

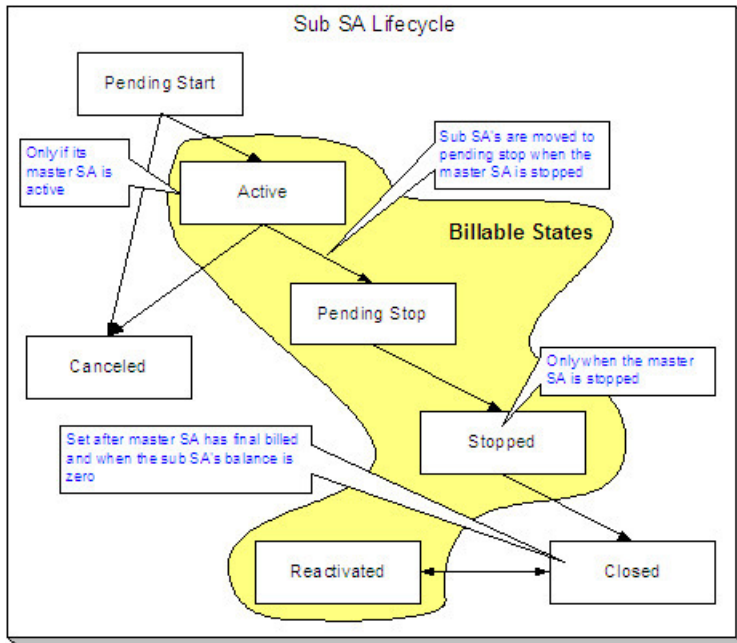

If the SA type uses start options, the start option contains additional values (e.g., rates, contract riders) that are used to populate the newly created sub SAs. Note: start options are typically not used for We Bill For Them - Bill Ready service provider because we don't need to default rates, contract riders and/or contract values on billable charge sub SAs. Refer to [Setting Up SA Relationships For SA Types](#) for more information.

NOTE:

Manually created sub SAs. In very unusual situations, an operator may create a sub SA manually. An operator would do this using the [SA Relationship](#) transaction.

Sub SA State Transition

Sub SAs follow normal SA state transition rules, but have a few additional rules about when the transitions can take place.

The following points highlight the additional state transition rules:

- A sub SA can only become Active if its master SA is Active. Most sub SAs are activated by the [analyze SA relationships](#) background process. However, a user can manually activate a sub SA using the activate button on the [SA maintenance](#) page.
- Sub SAs become Pending Stop when their master becomes Stopped . This typically occurs when the [SA activation background process](#) stops the master SA. However, this can happen real time if a user manually stops a master SA using the stop button on the [SA maintenance](#) page.
- A sub SA can only become Stopped if its master SA is Stopped . Most sub SAs are stopped by the [analyze SA relationships](#) background process. However, a user can manually activate a sub SA using the stop button on the [SA maintenance](#) page.
- A sub SA becomes Closed if its master has been final billed and it has a balance of zero. Most sub SAs are closed when their balance becomes zero after the master SA is final billed. However, a user can manually close a sub SA using the close button on the [SA maintenance](#) page. Note, if additional billable charges are interfaced after the master has been closed, the sub SA will be Reactivated.

We Bill For Them

If you provide billing services for another service provider, then you have a We Bill For Them billing relationship with the service provider. The topics in this section provide information about this type of billing relationship.

Sub SAs Are Used When We Bill For Them

As described under [Sub Service Agreements](#), sub SAs are used for We Bill For Them service providers. The sub SAs hold the service providers charges. It's important to note that the system allows more than one sub SA to be created for a given service provider.

The Rate Ready Calculation Method

If you provide billing services for a service provider (i.e., the service provider has a billing relationship of We Bill For Them), you can load the service provider's rates in your system and calculate the charges for the service provider. We call this the **Rate Ready** calculation method.

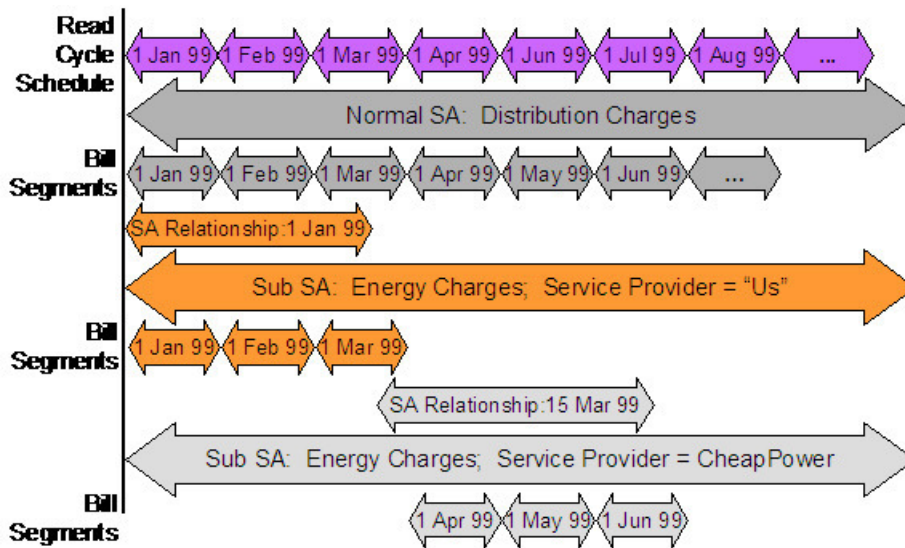

NOTE:

It's Us **can be Rate Ready**. The prior paragraph indicated that the Rate Ready billing option was used for We Bill For Them service providers. If you subcategorize your services and use rates to calculate each subcategory's charges, the service provider(s) set up for your own organization will also be subject to the Rate Ready rules described below.

If a customer uses a We Bill For Them - Rate Ready service provider, the system will create a separate bill segment for the service provider's charges. Keep in mind the following in respect of these types of bill segments:

- The consumption is copied from the "master" service agreement (note: we copy item details and read details after pre-processing calculation groups, if any exist, have been applied). This means that the bill period on the sub SA's bill segment is identical to that on the normal SA. This also means that if the "master" SA is in error, bill segments for the sub SA will not be created.
- The rate defined on the sub SA is applied against this consumption. All pre-processing calculation groups defined on the service provider's rate will be used to manipulate this consumption. If you have pre-processing calculation group on your master SA's rate to apply a line loss or convert a cubic foot to a therm, you don't have to have these pre-processing calculation group on the sub SA's rate (because we copy the consumption from the master to the sub after pre-processing calculation group, if any exist, have been applied).

The following illustration should help:

Be aware of the following:

- This example is from a distribution company's perspective.
- From 1 Jan 99 through 15 Mar 99, the distribution company distributes power AND supplies energy (i.e., the distribution company is the service provider of energy).
- On 15 Mar 99, CheapPower becomes the energy supplier. However, the next bill period ends on 30 Mar 99. This means that CheapPower will only start supplying energy on 1 Apr 99. See the following note for why the effective date of the supplier switch is not the true effective date from billing's perspective.

NOTE:

Service Provider Changes Take Effect On The Next Bill. If the service provider is changed within a customer's billing period, the system assumes that the service provider in effect at the START of the period is effective the entire billing period. This means that a change of service providers will only take effect on the bill whose start date follows the change date.

Please be aware of the following characteristics of Rate Ready bill segments:

- You cannot cancel a Rate Ready bill segment independently from the master bill segment. If you need to cancel / rebill the sub SA's bill segment, you must cancel / rebill the master SA's bill segment.
 - You cannot delete a Rate Ready bill segment independently from the master bill segment. If you need to delete the sub SA's bill segment, you must delete the master SA's bill segment.
 - Similarly, if you cancel / rebill the normal SA's bill segment, all Rate Ready bill segments will be cancelled / rebilled.
-

NOTE:

Bottom line. Creating, freezing, deleting, and canceling a "master" bill segment does the same with all Rate Ready bill segments. You cannot create, freeze, delete or cancel a Rate Ready bill segment independent of its master bill segment.

The Bill Ready Calculation Method

If a customer uses a We Bill For Them - Bill Ready service provider, the service provider calculates their own charges and interfaces them to the system. We then present their charges on our bill; we don't actually calculate anything (sometimes this is referred to as "pass through" billing).

The sub SA linked to a We Bill For Them - Bill Ready must be a billable charge SA. Why? Because billable charge SAs exist to hold bill lines until such time as a bill is created for the customer's account. Refer to [Setting Up Billable Charge Templates](#) for more information.

Please be aware of the following characteristics of Bill Ready bill segments:

- Unlike Rate Ready bill segments, Bill Ready bill segments can span different time periods than the master SA. This is because you cannot predict when a service provider will interface their billable charges to you. In fact, a given bill could contain billable charges that span different periods and these charges could have been interfaced from historic and existing service providers.
- Unlike Rate Ready bill segments, Bill Ready bill segments can be created and deleted independently from the master bill segment.
- Unlike Rate Ready bill segments, Bill Ready bill segments can be cancelled independently from the master bill segment.

[Sending Consumption And Waiting For The Charges](#)

[Uploading Consumption \(Rather Than Uploading Calculated Charges\)](#)

[Calculating Taxes On Uploaded Charges](#)

Sending Consumption And Waiting For The Charges

If your organization supports We Bill For Them - Bill Ready service providers AND you are the source of consumption used by these service provider to calculate their charges, you need to be aware of the following:

- We do NOT recommend sending raw meter reads to service providers. Rather, we recommend sending these service providers the same consumption that you use on your bill segments. Remember, the system maintains a snapshot of billed consumption on bill segments associated with service agreements that are linked to service points.

- But to implement our recommendation (of only interfacing billed consumption to service providers), we need to create a bill segment for the master SA and then wait until the service provider returns the billable charge before sending out the bill. The following points describe how this works:
 - Early in the bill cycle, the system creates a bill segment for the master SA (remember, the system maintains a snapshot of billed consumption on bill segments linked to service points). When the master bill segment is frozen, the system interfaces the snapshot consumption to all service providers associated with the master service agreement who need consumption (this is defined on the service provider). Refer to [We Can Send Billed Consumption To Any Service Provider](#) for more information about interfacing consumption to service providers.
 - The bill associated with the bill segment will not be completed. Why? Because the bill segments associated with the We Bill For Them - Bill Ready service providers will be in Error. This only happens if you use the [Billable Charge](#) bill segment creation algorithm (this algorithm is plugged in on the sub SA's SA type). On the algorithm, make sure to specify a value of Y for the parameter **Wait For The Last Day Of The Bill Cycle**. By doing this, a bill segment in the Error state will exist for the sub SA until the last night of the bill cycle's window.
 - On the last night of the bill cycle window, when the system attempts to create a bill segment for the billable charge SA associated with the We Bill For Them - Bill Ready, it will either find recently interfaced billable charges or it won't. If it finds unbilled, billable charges, a bill segment will be created for the sub SA and the billable charges will be swept onto it. If it doesn't find unbilled billable charges, the bill will be completed (i.e., sent out) without the service provider's charges.

NOTE:

Bottom line. If a customer's account uses We Bill For Them - Bill Ready service providers, the bill will not be completed (i.e., sent out) until the last night of the bill cycle (if you use the appropriate algorithm). Why? Because we wait until the last night of the bill cycle before trying to sweep on recently interfaced billable charges. If no billable charges have been interfaced from the service provider by the last night of the bill cycle, the bill will be sent out without the service provider's charges.

Batch versus Online Bill Creation. If you create a bill online, the system will NOT create an Error bill segment for the We Bill For Them - Bill Ready service provider. Why? Because if you want to create an online bill, either the service provider has interfaced their charges or they haven't. If they have, they should be swept on the bill (via the creation of a bill segment). If they haven't, it shouldn't prevent you from completing the bill.

[Top of the Page](#)

Uploading Consumption (Rather Than Uploading Calculated Charges)

We understand this is confusing, but it is quite possible to set up the system so that the We Bill For Them - Bill Ready service provider passes in CONSUMPTION rather than the calculated bill lines. They would only do this if they are not able to calculate the charges in their system and have therefore provided you with their rates. To do this, you would set up everything as described above. In addition, when you upload the billable charges, you must specify the consumption to be rated in the billable charge's service quantity (SQ) collection.

[Top of the Page](#)

Calculating Taxes On Uploaded Charges

It is possible to set up the system to calculate taxes for billable charges. You would do this if the service providers are passing through the charges and want you to calculate the taxes.

If you want taxes calculated on top of billable charges:

- Create a service quantity (SQ) on the billable charge that contains the total monetary amount that taxes will be calculated on. Note, you would not have to do this if you have a pre-processing calculation group in your rate that calculates the total monetary amount to which taxes should be applied.
- Specify a rate on the billable charge service agreement. This rate will contain calculation rules that calculate taxes. Note, the calculation rules will be simple SQ calculation rules that apply a percentage to the value of the SQ that represents the monetary amount on which taxes should be calculated.

When the system creates the bill segment for the billable charge, it will call the rate and the rate will calculate the taxes and add additional lines (actually, bill calculation headers) to the bill segment.

Pay At Bill Time vs. Pay At Pay Time

If you provide billing services for another service provider (i.e., the service provider has a billing relationship of We Bill For Them), you will owe them money because you will be receiving money from their customers for their service. You have two options in respect of when the system increases the amount you owe the service provider:

- You can tell the system to increase how much you owe the service provider when you freeze the customer's bill segment. Some people refer to this method as "purchasing the receivable from the service provider". We call this the **Pay At Bill Time** method.
- You can tell the system to increase how much you owe the service provider only when you are paid for by the customer. We call this the **Pay At Pay Time** method.

The method used for a service provider is defined on the service provider's record.

FASTPATH:

Refer to [When We Bill For Them, We Owe Them Money](#) for more information.

Paying The Service Provider - Technical Implementation

WARNING:

This section describes, technically, how we increase the amount we owe a We Bill For Them service provider. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with increasing how much we owe a We Bill For Them service provider.

The following points explain the steps:

- When a financial transaction (FT) is frozen, the system executes the FT Freeze algorithms defined on the SA(s) SA type.
- If you've set up the system properly (i.e., you've put the appropriate FT Freeze algorithm on the sub SA's SA type), one of these algorithms will determine if there is a WBFT service provider associated with the sub SA. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that looks at new FT's and determines if a related "payable" adjustment should be created for the We Bill For Them service provider. This batch process uses the service provider's Payment Relationship and Pay Service Provider algorithm to determine when and how to create these "payable" adjustments.

Service Providers Have Service Agreements Too

Most service providers need service agreements as explained in the following topics.

When We Bill For Them, We Owe Them Money

When you bill on behalf of a service provider (i.e., the service provider has a billing relationship of We Bill For Them), you will eventually owe them money (because the customer pays you for the service provider's service). You have two options in respect of when the system increases the amount you owe the service provider:

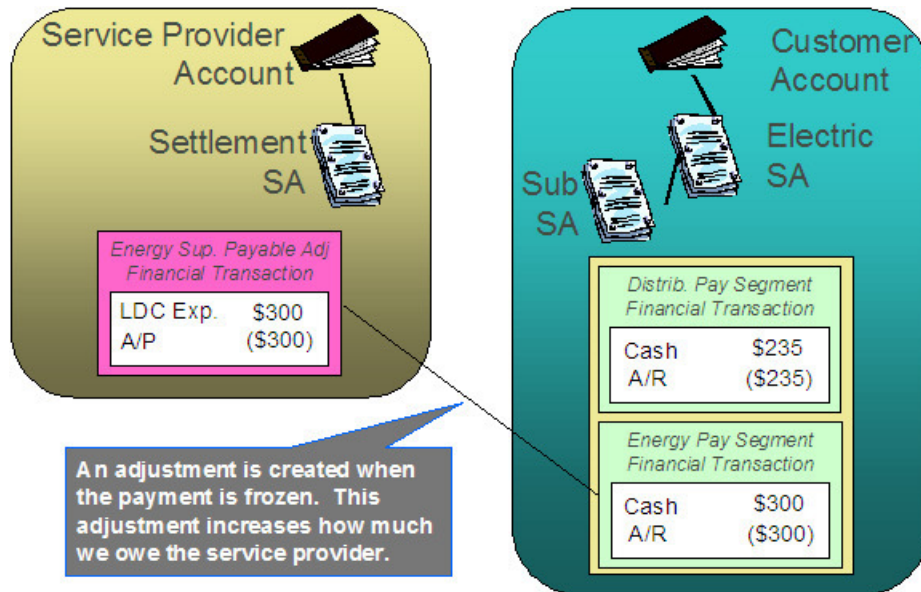

- You can tell the system to increase how much you owe the service provider when you create the customer's bill. Some people refer to this method as "purchasing the receivable from the service provider".
- You can tell the system to increase how much you owe the service provider only when you are paid for by the customer.

The system keeps track of how much you owe a service provider on a service agreement linked to the service provider's account. The system creates adjustments against this service agreement to increase how much you owe them.

If you "purchase the receivable" (i.e., you owe them when you bill the customer), an adjustment is created when the customer is billed. If you owe them only when you are paid by the customer, an adjustment is created when the customer pays. The following example illustrates an adjustment being created when the bill is frozen (illustrating the "purchase the receivable" scenario):

If you only pay the service provider when you are paid, the example would look as follows:

Adjustments and We Bill For Them Service Providers

FASTPATH:

It's important that you are comfortable with the information described under [When We Bill For Them, We Owe Them Money](#) before reading this section.

Adjustments associated with We Bill For Them sub service agreements are tricky. The following points describe how the system "pays" the related service provider when adjustments are issued against the customer's sub service agreement:

- For Pay At Bill Time service providers, most adjustments are treated just like bill segments, i.e., when the adjustment's FT is frozen, a payable adjustment is created for the respective service provider. The reason "most" is underlined in the previous sentence is because A/P adjustments (i.e., adjustments used to interface check requests to your A/P system) are excluded. Why? Because A/P adjustments are used to refund overpayments to the customer. Overpayments are purely between the customer and your company (you never transferred the overpayment to the service provider because it's associated with a Pay At Bill Time service provider).
- For Pay At Pay Time service providers, A/P adjustments are treated just like payment segments, i.e., when the adjustment's FT is frozen, a payable adjustment is created for the respective service provider. All other types of adjustments are ignored. Why? Because A/P adjustments are used to refund overpayments to the customer. Think of it like this - when the customer originally overpaid, you transferred this overpayment to the Pay At Pay Time service provider; therefore, when you refund the overpayment, you get to take the money back from the service provider.

When They Bill For Us, They Owe Us Money

When a service provider bills on behalf of your organization, they will eventually owe you money (because the customer pays them for your service).

The system keeps track of how much a service provider owes you on a service agreement linked to the service provider's account. The question is, How does the system determine how much you are owed when you don't produce a bill? Well, you do produce a bill, it just doesn't get sent to the customer. We understand this is a little confusing, but think about it like this:

- The service provider is presenting your charges on their bill.
- You still have to calculate how much the customer owes your organization otherwise you'll never know how much you are owed by the service provider.

As illustrated below, when a bill is completed, the system determines if there are bill segments and/or adjustments associated with service agreements with a service provider who "bills for us". If it finds these, it transfers the receivable from the customer's service agreement to the service provider's service agreement. If all financial transactions have been transferred to the service provider, no bill is produced for the customer.

NOTE:

Bottom line. We always generate a bill for "us", even though we don't send it to the customer.

They Bill For Us

If a service provider provides billing services for you, then you have a They Bill For Us billing relationship with the service provider. The topics in this section provide information about this type of billing relationship.

The Customer Still Needs A Service Agreement

If a service provider bills for you, you still need a service agreement for the customer. Why? Because:

- As explained under [Service Providers Are Linked To Service Agreements](#), service providers are defined in respect of a customer's service agreement (therefore the customer must have a service agreement).
- As explained under [When They Bill For Us, They Owe Us Money](#), you still have to calculate bills for the customer.

NOTE:

A customer's bill history still exists. Be aware that even when a service provider bills for us, you will still be able to see the customer's billing history. It's just that the customer won't owe you anything because the receivable balance will be transferred to the service provider's account.

They Bill For Us - Bill Ready

At bill completion time, the system determines if there are bill segments and/or adjustments associated with service agreements with a service provider who "bills for us". If it finds these,

- It transfers the receivable from the customer's service agreement to the service provider's service agreement. If all financial transactions have been transferred to the service provider, no bill is produced for the customer.
- Note that payments and A/P adjustments are not transferred. Why? Because payments and A/P adjustments are purely between the customer and your company.
- Each bill segment and adjustment is marked to be interfaced to the service provider (via a separate background process).

They Bill For Us - Rate Ready

The They Bill For Us - Rate Ready option is not a recommended option. Why? Because you really have to compute how much the customer owes as explained above. If you go to the trouble of figuring out how much the customer owes, then it makes sense to interface this to the billing service provider.

The only difference between this option and They Bill For Us - Bill Ready is that the system will not interface the bill segments and adjustments to the billing service provider.

A/R Transfer - Technical Implementation

WARNING:

This section describes, technically, how a customer's A/R balance is transferred to a They Bill For Us service provider. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with the transference of a customer's A/R balance to a They Bill For Us service provider.

The following points explain the steps:

- When a bill is completed, the system executes the bill completion algorithms defined on the bill's master SA(s) SA types.
- If you've set up the system properly (i.e., you've put the appropriate Bill Completion algorithm on the master SA's SA type), one of these algorithms will determine if there is a They Bill For Us service provider associated with each master SA on the bill. If so, it will execute the Transfer A/R algorithm defined on the service provider's record. This algorithm causes a transfer adjustment to be created (transferring the financial transaction's affect on the customer's balance from the customer to the service provider).

NOTE:

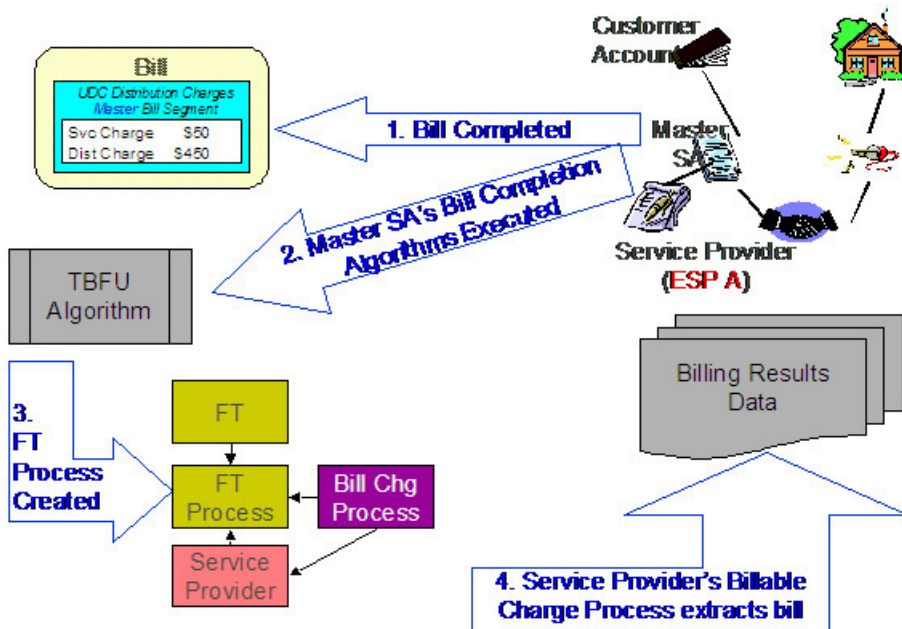

If there are multiple master SAs on a bill, the financial details associated with each respective master SA could be transferred to different service providers (e.g., one service provider could receive the financial details for gas and another for electricity). Refer to [Different Service Providers Can Bill Different Services](#) for more information.

Routing Billable Charges To Service Providers - Technical Implementation

WARNING:

This section describes, technically, how we send billable charges to service providers. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with sending billable charges to service providers.

The following points explain the steps:

- When a bill is completed, the system executes the bill completion algorithms defined on the bill's master SA(s) SA types.
- If you've set up the system properly (i.e., you've put the appropriate Bill Completion algorithm on the master SA's SA type), one of these algorithms will determine if there is a They Bill For Us service provider associated with each master SA on the bill. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that downloads billable charges to the service provider. The ID of the batch process that is referenced on the trigger comes from the Service Provider's Billable Charge Download Process.

NOTE:

If there are multiple master SAs on a bill, the financial details associated with each respective master SA could be routed to different service providers (e.g., one service provider could receive the financial details for gas and another for electricity). Refer to [Different Service Providers Can Bill Different Services](#) for more information.

Bill Routings Are Changed

If all of an account's "master" SAs have a SA relationship with a service provider who bills for us (i.e., the service provider's billing relationship is They Bill For Us), then we have nothing to send to the customer. The system still creates bill routings, but with a couple of differences:

- The Batch Process Id and Run Number are reset.
- The Customer's Name is prefixed with the text from a bill message code 6, 10103. This message code's text is *** Bill not sent.

This way, the operators can easily see that that the bill was not routed and why.

FASTPATH:

Refer to [Different Service Providers Can Bill Different Services](#) for information about how the various services under an account could be billed by different service providers.

Combinations Of Service Provider Billing Methods

Consider the following situation:

In the above example, we are billing for the energy service provider and the meter service provider is billing for us. This means that we will calculate the charges for ourselves, interface charges from CheapPower, and then interface our charges and CheapPower's charges to MeterCo. MeterCo will then produce a bill for the customer that contains our distribution charges, CheapPower's energy charges, and MeterCo's service charges. To help solidify this point, let's look at how this customer would look in MeterCo's CIS system.

There are some restrictions in respect of permissible combinations of service providers that may supply service to a customer as described in the following points:

- If the system encounters a customer with a We Bill For Them (WBFT) - Bill Ready service provider and another service provider that is They Bill For Us (TBFU) - Rate Ready, a billing error will be produced. Why? Because TBFU - Rate Ready means they have everything they need to calculate our bills and therefore we do not interface bill lines to them.

If we don't interface our bill lines to them, then we can't interface the charges that were interfaced from the WBFT - Bill Ready service provider. You may wonder why we don't prohibit WBFT - Rate Ready and TBFU - Rate Ready, because it's conceivable for the TBFU service provider to have our rate and the WBFT service provider's rate.

- If the system encounters a WBFT - Pay At Pay Time service provider and another service provider that is TBFU, a billing error will be produced. Why? Because when the system detects a TBFU service provider, it transfers the receivable from the customer to the service provider (and therefore the customer's account will never be paid).

Different Service Providers Can Bill Different Services

Be aware that the system determines billing relationships at the service agreement level, NOT at the account level. To make the point, check out the following customer in a distribution company's system:

Be aware of the following in respect of the above illustration:

- The distribution company (LG&E) distributes both electricity and gas.
- The customer has a choice of energy service providers for both gas and electricity.
- This customer - John Smith - purchases his electricity from CheapPower and his gas from GasCo.
- LG&E provides billing services for CheapPower.
- GasCo provides billing service for LG&E.

In this situation, LG&E will send bills to the customer that contain both electric distribution and energy charges (but no gas distribution charges). GasCo will also send bills to the customer; these will contain both LG&E's gas distribution charges as well as their own energy charges.

If You Deal With TBFU Service Providers, You Cannot Reopen Bills

FASTPATH:

Refer to [Bill Lifecycle](#) for information about reopening previously completed bills.

If your organization deals with They Bill For Us (TBFU) service providers, a great deal happens when a bill is completed (e.g., the receivable is transferred from the customer to the service provider, we may mark the bill segments and adjustments for routing to the service provider, etc.). These things cannot be undone and therefore the system will not let you reopen bills when these things have occurred.

NOTE:

Technical rule. The specific rule that prevents the reopening of bills is as follows: if a bill contains a service agreement whose SA type has one or more bill completion algorithms, the system will not allow the bill to be reopened. Refer to [SA Type - Algorithms](#) for more information about bill completion algorithms.

Consumption Relationships

When you set up a service provider, you must define your organization's consumption relationship with the service provider - a service provider may send the customers' consumption to you, you may send consumption to them, or you may have no consumption relationship with a given service provider.

The topics in this section provide a wealth of information about the various consumption relationships and the ramifications of each.

Only The Master SA Is Linked To Service Points

The following diagram makes the point that service points cannot be linked to sub SAs (i.e., service agreements that exist to hold charges associated with We Bill For Them service providers). This is because all service points associated with our "master" SA are implicitly linked to all sub SAs.

It's important to understand why the system does not allow sub SAs to reference service points:

- The consumption associated with all service providers should be the same, otherwise the customer will receive inconsistent bills from different service providers.
- The easiest way to ensure consumption is the same for all service providers is to make sure that they all have the same service points (which they must if sub SAs "inherit" their service points from their master).

We Can Send Billed Consumption To Any Service Provider

You can send consumption to any service provider. It doesn't matter what their billing relationship is. Information on the service provider object tells the system if AND how to send consumption to a service provider.

Rather than send raw reads to service providers, we download consumption that has been calculated and snapshot onto the "master" bill segment. We send this billed consumption because:

- It is clean and validated
- Register indexes have been subtracted
- Multiple registers have been summed

NOTE:

We only send consumption after a bill segment is Frozen. If your organization supports We Bill For Them - Bill Ready service providers AND you are the source of consumption used by these service providers to calculate their charges, please refer to [The Bill Ready Calculation Method](#) for an explanation of how the system waits a given amount of time for the recipient of the consumption to interface their charges back to the system before sending the bill to the customer. In other words, the bill sent to the customer should contain the bill segment that triggered the consumption download as well as bill segments containing uploaded billable charges.

Routing Consumption To Service Providers - Technical Implementation

WARNING:

This section describes, technically, how we send consumption to service providers. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with sending consumption to service providers.

The following points explain the steps:

- When a financial transaction (FT) is frozen, the system executes the FT Freeze algorithms defined on the SA(s) SA type.
- If you've set up the system properly (i.e., you've put the appropriate FT Freeze algorithm on the master SA's SA type), one of these algorithms will determine if there are service providers associated with the master SA who need consumption. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that downloads billable consumption to the service provider. If multiple service providers need consumption, multiple rows will be inserted. The ID of the batch process that is referenced on the trigger comes from the Service Provider's Consumption Download Process.

We Can Receive Consumption From Service Providers

We can receive consumption from any source. The system can receive consumption from service providers. Each customer must have:

- A premise
- A service point
- A device with measuring components sufficient to hold the interfaced consumption

NOTE:

You don't have to perfectly model the service points and meters. If you are not the distribution company, you may be worried about how to keep devices and service point information up-to-date. Be aware that you don't have to model the SPs and devices perfectly. Why? Because you just need to set up enough information so that consumption can be received accurately.

MDMAs And Service Cycles

WARNING:

This section uses terminology and concepts described in [The Cyclical Meter Read Process](#).

A Meter Data Management Agency (MDMA) is a service provider who reads meters. In some locales, a meter can be read by a variety of MDMAs, in other locales there is no MDMA as the meter is read by the distribution company. If your organization has MDMAs, then you need to be aware of the following:

- MDMAs must be linked to service agreements as a service provider. Like all service providers, they can change over time.
- When an MDMA is reading a service agreement's meters, the MDMA may override the customer's service cycle (and schedule) with their own cycle. If they do this, the customer's service cycle in the MDMA's system is defined on the service agreement's SA relationship information for the MDMA. Note: whether or not a service provider can override a service cycle is controlled by a switch on the service provider's record. Refer to [Service Provider - Main](#) for more information.
- A service provider's service cycle schedules are maintained using the system's normal service cycle schedule. The ID of the service provider associated with each schedule is defined on the service cycle; in other words, if a service provider reads meters and they can override the customer's service cycle, the service provider's service cycles must be defined in the system. Refer to [Designing Service Cycles, Routes, And Schedules](#) for more information.
- At billing time, the system determines if a service agreement is covered by an MDMA. If so, it uses the service cycle defined on the service agreement's MDMA SA relationship record.
- If your organization ever reads the customers' meters, your regular read cycle should be maintained on your service points. You can think of the service cycle that is defined on a service agreement's MDMA SA relationship record as an override of your service points normal service cycle.
- If the meter read download process detects that a service point is linked to a service agreement with an active MDMA, it still creates a meter read download staging record; however, it marks it as Do Not Need To Read. This means that when a service point is no longer read by an MDMA, the meter read will be downloaded normally.
- Refer to [We Can Receive Consumption From Service Providers](#) for a description of how a service provider interfaces consumption into the system.

Deposits Issues

WARNING:

This section uses terminology and concepts described in [The Big Picture Of Deposits](#).

Deposits should be held using normal deposit service agreements (SAs). You should NOT use the [Sub Service Agreements](#) (sub SA) functionality to hold or bill for deposits because deposit service agreements do not have the same state transition as do master SAs (e.g., you can activate or stop a deposit independent from its master).

However sub SAs can be covered by a deposit. If so, their SA type must reference a deposit class. To make the point, let's examine a few scenarios:

- Assume you have a sub SA for your own charges (this can happen when we use sub SAs to unbundle charges from the Master SA). In this case, it is likely that the sub SA and master SA will be in the same deposit class. This means that a single deposit SA would cover both the master and the sub SA.

- Assume They Bill For Us (Bill or Rate Ready). In this situation, we still have a master SA for our charges and we transfer the charges to the service provider who does the billing. In this case, it is likely that we would be holding the deposit for the service provider, not on the end-use customer. If we are in a situation where 1) we cannot hold a deposit against the service provider, and/or 2) we are not assured of the service provider paying us when the customer doesn't pay them, then we might want to put the master SA in a deposit class and hold a deposit against the customer's account using a normal deposit SA. We would not expect the service provider to bill the customer for the deposit, so we don't need a sub SA. We bill the customer directly for the deposit using our normal deposit SA.
- Assume We Bill For Them (Bill or Rate Ready). In this situation, we could hold a normal deposit SA for the customer's master SA. For sub SAs, we have two scenarios:
 - **We pay at billing time.** Since we purchase the receivable, we would want to increase our normal deposit to cover the Sub SA. To do this, the sub SA's SA type's deposit class should be the same as our master SA's deposit class.
 - **We pay at payment time.** It seems unlikely that we would want to hold a deposit on behalf of a service provider when we don't purchase the receivable. However, it is possible to do so by putting the sub SA into its own deposit class. If you did this, the system will require a separate deposit SA for the service provider's deposit. The system would calculate and refund such deposits using the algorithms defined on the new deposit SA's SA type's deposit class. It's important to be aware that the deposit is not held with respect to the specific service provider. Rather, it is just held in the system as separate deposit that could be used for any service agreement that belongs to its deposit class.

Credit and Collection Issues

WARNING:

This section uses terminology and concepts described in [The Big Picture Of Credit & Collections \(C&C\)](#).

C&C is only tricky if you deal with We Bill For Them service providers. We'll run through the service provider billing relationships to explain why:

- If we have a Dual relationship with a service provider, we don't have their debt, so we only have a responsibility to tell them when we cut a customer (via a Notification). We don't have to worry about collecting their debt.
- If we have a They Bill For Us relationship with a service provider, there is no debt on the customer's SA because it gets transferred to the service provider (and the service provider's SA will fall into arrears if they don't pay us).
- If we have a We Bill For Them or It's Us relationship with a service provider, the customer's debt associated with the service provider's service is maintained on a sub SA (i.e., it is segregated from our debt). This segregation of debt is both a powerful feature and a cause of administrative difficulties. The topics in this section provide more information about this issues.

Debt Class Recommendations

A service agreement's debt class is an important element in determining how a customer's debt is collected. In general, we recommend the following:

- If the service provider has a billing relationship of It's Us, we recommend the sub SAs belong to the same debt class as the "master". Why? Because both SAs' overdue debt should probably be grouped together under a single collection process.
- If you buy the receivable from the service provider (i.e., the service provider has a payment relationship of Pay at Billing Time), we recommend the sub SAs belong to the same debt class as the "master". Why? Because both SAs' overdue debt should probably be grouped together under a single collection process.

- If you don't buy the receivable from the service provider (i.e., the service provider has a payment relationship of Pay at Pay Time), you may want to use a different debt class on the sub SA. Why? Because you may collect the service provider's debt differently.

NOTE:

Bottom line. If both the "master" and the sub SAs fall into arrears, you will have 1 or 2 collection processes, it all depends on the debt class assigned to each SA type.

FASTPATH:

Refer to [Automating Your C&C Activities](#) for information describing how debt class plays a part in this processing.

Severing Service

Sub SAs and severance is tricky. Why?

- Because it's possible for the master SA to be in arrears when the sub SA isn't (for all the standard reasons - directed payments, cancel / rebills, etc.).
- Because it's possible for the sub SA to be on one collection process and the master to be on another (due to different debt classes or different time lines).

Both of these situations could result in severance starting for only one of the service agreements in the master / sub relationship. However, **YOU CAN'T CUT SERVICE FOR ONE WITHOUT CUTTING THE OTHER** because there is only one service point.

Before we describe how to deal with this conundrum, we'd like to remind you that the system starts a unique severance process for each SA (sub or normal) to be severed. It only creates a severance process for those service agreements linked to a collection process when the collection process' Start Severance event is activated. The type of severance process that is created is controlled by each service agreement's SA Type's severance criteria. Please keep in mind the following when designing these severance processes:

- **Only The "Master" Service Agreement Is Linked To Service Points.** This means only master SAs should have a "cut for non payment" severance event. Note: typically, such a severance process will expire the "master SA" several days after the cut event if funds are NOT received.
- As described under [Sub SA State Transition](#), a sub SA becomes Pending Stop (and eventually Stopped) when its "master" is stopped. This means the sub SAs will be finalized when the master is finalized.
- If you start severance on a sub SA when the master isn't being severed, you have a problem because you can't cut the sub SA independent from the master SA.

We'll use an example to illustrate how you should design your severance processes to deal with the above challenge. Assume you have a master and a sub SA where both are being managed under the same collection process. Also assume that the Start Severance event kicks off on 18-Dec-1999. In this situation, we'd recommend the following severance processes to be kicked off.

Master SA Severance Process		
Trigger Dt.	Event Type	Status
18-Dec-99	Set door hanger	Pending
Pending	Cut for non pay	Pending
Pending	Expire SA	Pending

Sub SA Severance Process		
Trigger Dt.	Event Type	Status
3-Jan-00	Create To Do Entry	Pending

Notice that the sub SA's severance process contains a single event that generates a To Do Entry on a date in the future of the Expire SA event on the Master SA. This entry should be something like "sub being severed independent of its master". This event will only be triggered if the master SA is paid off and the sub SA isn't. Why? Because if the master SA's Expire SA event is executed, the Sub SA will be Stopped and stopping a SA cancels outstanding severance processes. If the sub gets paid, the system will cancel the sub's severance process.

Let's change the example and assume that the master starts severance and the sub doesn't. In this situation, the master SA will eventually hit the Expire SA event and the sub SA will also stop. There's no alternative.

And let's change the example again and assume the sub starts severance and the master doesn't. In this situation, the To Do Entry will only be created X days after the start of severance. If you can't stand this date being X days in the future of the creation of the severance process, create an "Severance Criteria Algorithm" that checks if the master is not being severed or collected and generates a different severance process (with a different start date). Refer to [Designing Your Severance Procedures](#) for more information about Severance Criteria Algorithms.

An Object-Oriented Perspective Of Service Providers

WARNING:

Skip this section if you are not technically inclined.

The following object diagram illustrates in a concise format the various types of service providers and the plug in algorithms and processes available for each.

How Do You Communicate With Service Providers?

You communicate with service providers (and they communicate with you) using the following mechanisms:

- You can use traditional interface techniques. For example, if you send consumption to service providers every month (so they can compute their charges), you could use the Consumption Download interface.

- You can use "notifications" to communicate with service providers. Notifications are electronic transactions that service providers exchange to communicate information about a customer. For example, you could use a notification to send a message to an energy supplier when a customer stops service. Note: the term "Direct Access Service Request" (DASR) is synonymous with Notification.

The difference between notifications and traditional interfaces is subtle. Think of notifications as a generic interface that can be used to communicate many different things (e.g., you can use notifications to advise stops, meter exchanges, supplier switches). Traditional interfaces communicate only one thing (and you need one traditional interface for each "thing"). For example, one interface is devoted to downloading consumption, another is responsible for uploading pass through charges, etc.

Off Cycle Switch

If the customer care and billing application integrates with meter data management (mdm) system, it may be set up to generate sub-bill segments for each and every service provider having **We Bill for Them - Rate Ready** or **It's Us** billing relationship, that is effective in the billing period. This requires that the meter data management system can calculate the consumption for each effective SA relationship period.

If the switch is from or to a service provider having **They Bill for Us** billing relationship, separate bills have to be generated manually for each relationship effective in the billing period. This restriction is due to requirement for CCB application to generate a bill for a **They Bill for Us** relationship, so that the customer's charges are calculated and eventually transferred to the service provider. The generated bill for **They Bill for Us** billing relationship is not sent to the customer.

Billing Master Configuration

To enable Off Cycle Switch, navigate to **Admin > General > Master Configuration** and add a new entry for Billing Master Configuration.

Specify the values for **Off Cycle Switch Option**, **Implementation Date** and **Off Cycle Switch Option for Old Bill**. Refer to the embedded help on billing master configuration portal for details.

Rate Schedule

Rate schedules assigned to the sub-SA of service provider, having **We Bill for Them - Rate Ready** or **It's Us** billing relationship, must be configured with an SQ rule (for component-based engine) or a pre-processing calculation rule (for rule-based engine) that will obtain the sub-usage's consumption and load it into the bill segment SQ collection during rate application.

For more information, refer to the base package algorithm types provided for this purpose: [US](#) (component based engine) and [C1-ACRSUBUSG](#) (rule based engine).

Sub-SA Type

When implementing this feature, sub-SA types of service provider having **We Bill for Them - Rate Ready** or **It's Us** billing relationship must be configured as non-bill determinant.

Usage Request

Usage request is sent to the Oracle Utilities Meter Data Management (MDM) system, to obtain the calculated consumption for the billing period - this is used to calculate master bill segment's charges.

In addition, sub-usage request is sent to the mdm system, for each relationship that is effective during the billing period. Calculated consumption on these sub-usage requests is used to calculate sub-bill segment charges.

Sending Consumption to Service Providers

Calculated consumption on these sub-usage requests also serves as the source for consumption download process if consumption is required to be sent to the service provider. A base package algorithm type - [C1-STGCNSMP](#), stages the download by creating an entry in the general process table, capturing the sub-usage id, batch control for consumption download and the batch number.

NOTE: It is implementation responsibility to build the consumption download batch process that will extract the consumption for sub-usage request as required.

Designing Your SA Relationship Types and Service Providers

As explain in [A Service Agreement Can Have Many Types Of Relationships](#), SA relationship types and service providers are only required when you subcategorize your service agreements.

The topics in this section describe how to design your SA relationship types.

Designing SA Relationship Types

The easiest way to design SA relationship types is to start with the matrix of SA types designed in [SA Types And The Financial Design](#). For each SA type in the matrix, determine if either of the following questions is true:

- Can companies other than your own provide some subcategory of the service (and do you have some type of interaction with these companies)? For example, this would be true if you are an energy supply company because a different company is responsible for distributing the power to the customer (and you probably exchange consumption and financial transactions with this company).
- Does your organization use different rates for subcategories of the service? For example, this would be true if you use separate rates for water and wastewater service (even though both are based on the customer's water consumption).

If either of the above is true, you will need a SA relationship type for each subcategory of service.

We'll use an example to help make the point. Using the SA types we designed earlier (see [SA Types And The Financial Design](#)), we'll assume the following:

- We are designing the system for an electric, gas, water, waste water, and cable utility.
- Residential electric customers have a choice of energy supplier.
- Commercial and industrial electric customers can choose an energy supplier and a meter service provider.
- Commercial and industrial gas customers have a choice of energy supplier.

NOTE:

We are not showing most of the SA types that we designed earlier because they do not have subcategories of service.

CIS BU/ SA Type	SA Relationship Type
G/COM	Energy supply
G/IND	Energy supply
E/RES	Energy supply

E/COM	Energy supply
	Meter service
E/IND	Energy supply
	Meter service

NOTE:

Notice that we did not design a SA relationship type for our own distribution service. This is because our relationship type is implied (e.g., if you are a distribution company, you do not have to set up a SA relationship type for distribution service because the customer's "master" service agreement is implicitly associated with distribution service).

Designing Service Providers

After you design your SA relationship types, you need to list every potential service provider for each SA relationship type.

CIS BU/ SA Type	SA Relationship Type	Service Provider
G/COM	Energy supply	AmeriGas
		TransGas
		Green Power
G/IND	Energy supply	AmeriGas
		TransGas
		Green Power
E/RES	Energy supply	Green Power
		Cheap Power
		Us
E/COM	Energy supply	ElectriCorp
		Cheap Power
		TeniCorp
	Meter service	MeterCorp
		Us
E/IND	Energy supply	ElectriCorp
		Cheap Power
		TeniCorp
	Meter service	MeterCorp
		Us

Next, list each unique service provider identified above:

Service Provider
AmeriGas
TransGas

Green Power

Cheap Power

Us

ElectriCorp

TeniCorp

MeterCorp

You will have at least one service provider for each entry in the above list. However, you may have to set up more than one service provider in the system for a given company. The topics below explain how this happens.

Billing Relationship Segmentation

As described under [Billing Relationships](#), a service provider may bill for you, you may bill for them, or you may each send a separate bill to the customer. In the table below, we have shown the assumed billing relationships for each service provider.

Service Provider	Billing Relationship
AmeriGas	We Bill For Them - Bill Ready
TransGas	We Bill For Them - Bill Ready
Green Power	We Bill For Them - Rate Ready
Cheap Power - Res	We Bill For Them - Rate Ready
Cheap Power - Com/Ind	Dual Billing
Us - Billable	It's Us
Us - Non billable	None
ElectriCorp	They Bill For Us - Bill Ready
TeniCorp	We Bill For Them - Bill Ready
MeterCorp	Dual Billing

Notice that we had to introduce additional service providers:

- Cheap Power has two service providers - one for residential customers, the other for commercial/industrial customers. This is necessary because we provide billing service for them for residential customers (We Bill For Them - Rate Ready), but for commercial and industrial customers they bill for themselves (Dual Billing).
- Our own service provider (the service provider known as "Us") has two service providers - one for energy supply because we bill for the energy we supply (It's Us), and another for meter service because we don't create bills for meter service (None).

We Bill For Them - Payment Relationship Segmentation

As described under [Pay At Bill Time vs. Pay At Pay Time](#) when you provide billing service for a service provider you have to define if you pay the service provider when you bill the customer OR only later, when the customer pays you.

In the table below, we have shown the payment relationships for each service provider.

Service Provider	Billing Relationship	Payment Relationship
------------------	----------------------	----------------------

AmeriGas	We Bill For Them - Bill Ready	Pay At Billing Time
TransGas	We Bill For Them - Bill Ready	Pay At Billing Time
Green Power	We Bill For Them - Rate Ready	Pay At Billing Time
Cheap Power - Res	We Bill For Them - Rate Ready	Pay At Billing Time
Cheap Power - Com/Ind	Dual Billing	N/A
Us - Billable	It's Us	N/A
Us - Non billable	None	N/A
ElectriCorp	They Bill For Us - Bill Ready	N/A
TeniCorp - Com	We Bill For Them - Bill Ready	Pay At Billing Time
TeniCorp - Ind	We Bill For Them - Bill Ready	Pay At Pay Time
MeterCorp	Dual Billing	N/A

Notice that we had to introduce an additional service provider for TeniCorp because for commercial customer we purchase the receivable (Pay At Bill Time), but for industrial customers we only pay them when we're paid by the customer (Pay At Pay Time).

Consumption Relationship Segmentation

As described under [Consumption Relationships](#) a service provider may send the customers' consumption to you, you may send consumption to them, or you may have no consumption relationship with a given service provider.

In the table below, we have shown the consumption relationships for each service provider.

Service Provider	Billing Relationship	Payment Relationship	Consumption Relationship
AmeriGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TransGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
Green Power	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Res	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Com/Ind	Dual Billing	N/A	N/A
Us - Billable	It's Us	N/A	N/A
Us - Non billable	None	N/A	N/A
ElectriCorp	They Bill For Us - Bill Ready	N/A	N/A
TeniCorp - Com	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TeniCorp - Ind	We Bill For Them - Bill Ready	Pay At Pay Time	We Send Consumption
MeterCorp	Dual Billing	N/A	N/A

Notice that we didn't have to proliferate service providers due to consumption relationships.

Other Segmentations

The earlier parts of this discussion described the most common factors that cause the creation of service providers. However, many obscure factors could cause the introduction of more service providers. In this section we explain these more obscure factors.

Payment Method

As described under [Pay At Bill Time vs. Pay At Pay Time](#), when you provide billing service for a service provider you have to pay the service provider at some point in time. The algorithm that defines the amount to pay (and how the related adjustment is generated) is defined on the service provider record. If a service provider has different payment algorithms for different customer segments, you must split the service provider accordingly.

Transfer Receivable Method

As described under [When They Bill For Us, They Owe Us Money](#), a service provider will owe you money if they provide billing service for you. The algorithm that defines how to transfer the customer's receivable to the service provider is defined on the service provider record. If a service provider has different transfer A/R algorithms for different customer segments, you must split the service provider accordingly.

Billable Charge Download Process

As described under [They Bill For Us - Bill Ready](#), billable charges are interfaced to service providers who provide billing service for you. The background process that performs the interface of billable charges is defined on the service provider record. If a service provider has different billable charge interfaces for different customer segments, you must split the service provider accordingly.

Consumption Download Process

As described under [We Can Send Billed Consumption To Any Service Provider](#), consumption can be sent to any service provider. The background process that performs the interface of consumption is defined on the service provider record. If a service provider has different consumption interfaces, you must split the service provider accordingly.

Notification Upload Processing

A service provider can send you notifications. Whenever a notification is uploaded, the system creates a workflow process to process each such notification. The type of workflow process that's created is controlled by the service provider's workflow process profile. If a service provider requires a different workflow process for a given type of notification (for whatever reason), you must split the service provider accordingly.

Notification Download Processing

The system will send notifications to service providers when something noteworthy happens and when information is needed from a service provider. The type of notification that is sent to a service provider and the background process that interfaces the notification to the service provider is defined on the service provider's notification download profile. If a service provider requires a different type of notification to be sent or they have different interface protocols for a given type of notification, you must split the service provider accordingly.

Financial Settlement Service Agreement

As described under [Service Providers Have Service Agreements Too](#), service providers have service agreements. These service agreements contain how much you owe the service provider (if you bill for them) and how much they owe you (if they bill for you). If you want to have separate service agreements for financial settlements associated with distinct customer segments, you must split the service provider accordingly.

Geographic Area Segmentation

The following table reflects the new service providers that were added since we started [Designing Service Providers](#).

CIS BU/ SA Type	SA Relationship Type	Service Provider
G/COM	Energy supply	AmeriGas
		TransGas
		Green Power
G/IND	Energy supply	AmeriGas
		TransGas
		Green Power
E/RES	Energy supply	Green Power
		Cheap Power - Res
		Us - Billable
E/COM	Energy supply	ElectriCorp
		Cheap Power - Com/Ind
		TeniCorp - Com
	Meter service	MeterCorp
	Us - Non billable	
E/IND	Energy supply	ElectriCorp
		Cheap Power - Com/Ind
	Meter service	MeterCorp
	Us - Non billable	

Next, determine the postal code ranges in which a service provider is allowed to provide service.

CIS BU/ SA Type	SA Relationship Type	Service Provider	Postal Range
G/COM	Energy supply	AmeriGas	94000 - 95999
		TransGas	94000 - 95999
		Green Power	94000 - 95999
G/IND	Energy supply	AmeriGas	94000 - 95999

		TransGas	94000 - 95999
		Green Power	94000 - 95999
E/RES	Energy supply	Green Power	94000 - 95999
			93000 - 93999
		Cheap Power - Res	94000 - 95999
		Us - Billable	94000 - 95999
E/COM	Energy supply	ElectriCorp	94000 - 95999
		Cheap Power - Com/Ind	94000 - 95999
		TeniCorp - Com	94000 - 95999
	Meter service	MeterCorp	94000 - 95999
		Us - Non billable	94000 - 95999
E/IND	Energy supply	ElectriCorp	94000 - 95999
		Cheap Power - Com/Ind	94000 - 95999
		TeniCorp - Ind	94000 - 95999
	Meter service	MeterCorp	94000 - 95999
		Us - Non billable	94000 - 95999

Next, we need to strip off the SA types because the postal ranges are defined for combinations of service provider and SA relationship type. Notice the problem - we have a service provider - Green Power has different postal ranges for the same SA relationship type. You have two ways to fix this problem, you can split your service provider (have one for the gas and another for the electric), or you can split the SA relationship type (have one for the gas and another for the electric). We've chosen the former in our example.

SA Relationship Type	Service Provider	Postal Range
Energy supply	AmeriGas	94000 - 95999
	TransGas	94000 - 95999
	Green Power - Gas	94000 - 95999
Energy supply	AmeriGas	94000 - 95999
	TransGas	94000 - 95999
	Green Power - Gas	94000 - 95999
Energy supply	Green Power - Electric	94000 - 95999
		93000 - 93999
	Cheap Power - Res	94000 - 95999
	Us - Billable	94000 - 95999
Energy supply	ElectriCorp	94000 - 95999
	Cheap Power - Com/Ind	94000 - 95999
	TeniCorp - Com	94000 - 95999
Meter service	MeterCorp	94000 - 95999
	Us - Non billable	94000 - 95999
Energy supply	ElectriCorp	94000 - 95999
	Cheap Power - Com/Ind	94000 - 95999

	TeniCorp - Ind	94000 - 95999
Meter service	MeterCorp	94000 - 95999
	Us - Non billable	94000 - 95999

In the table below, we have shown the final list of service providers.

Service Provider	Billing Relationship	Payment Relationship	Consumption Relationship
AmeriGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TransGas	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
Green Power - Electric	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Green Power - Gas	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Res	We Bill For Them - Rate Ready	Pay At Billing Time	N/A
Cheap Power - Com/Ind	Dual Billing	N/A	N/A
Us - Billable	It's Us	N/A	N/A
Us - Non billable	None	N/A	N/A
ElectriCorp	They Bill For Us - Bill Ready	N/A	N/A
TeniCorp - Com	We Bill For Them - Bill Ready	Pay At Billing Time	We Send Consumption
TeniCorp - Ind	We Bill For Them - Bill Ready	Pay At Pay Time	We Send Consumption
MeterCorp	Dual Billing	N/A	N/A

Designing Your SA Types And Start Options For Sub SAs

When you were [Designing Service Providers](#), you defined the service providers that were valid for every combination of SA type and SA relationship type. If you provide billing services for another service provider or if you subcategorize your own services, you another task - you have to design the SA types for your sub SAs.

As described earlier, there will be a separate [Sub Service Agreement](#) for every SA relationship for which we calculate a bill segment. Every sub SA must reference an SA type. The following table shows sample SA types (notice that they are only used for We Bill For Them and It's Us service providers).

CIS BU/ SA Type	SA Relationship Type	Service Provider	SA Type(s) for Sub SAs
G/COM	Energy supply	AmeriGas	AG1
		TransGas	TG1
		Green Power - Gas	GP-GC1
G/IND	Energy supply	AmeriGas	AG1
		TransGas	TG1
		Green Power - Gas	GP-GI1
E/RES	Energy supply	Green Power - Electric	GP-ER1
		Cheap Power - Res	CP-ER1
		Us - Billable	US-ER1
E/COM	Energy supply	ElectriCorp	Not applicable - they bill for us

		Cheap Power - Com/Ind	Not applicable - dual billing
		TeniCorp - Com	TC1
	Meter service	MeterCorp	Not applicable - dual billing
		Us - Non billable	Not applicable - no billing
E/IND	Energy supply	ElectriCorp	Not applicable - they bill for us
		Cheap Power - Com/Ind	Not applicable - dual billing
		TeniCorp - Ind	TC1
	Meter service	MeterCorp	Not applicable - dual billing
		Us - Non billable	Not applicable - no billing

The design steps required to set up these SA types are similar to those described under [Designing SA Types For Service Agreements With Service Points](#). The following points provide a few suggestions that will help you design your SA types for sub SAs:

- The business unit should be the same as defined for the master service agreement.
- Service type should be set up as per [Service Segmentation](#).
- Distribution code should be set up as per [Receivable Segmentation](#).
- Obviously, the sub SA switch should be turned on.
- Start options:
 - If the SA type is used for a We Bill For Them - Rate Ready service provider or for yourself, the start options should be Required because rates, contract riders and/or contract values will be populated on the sub SA from a start option. Refer to [Automatic Creation of Sub SAs](#) for more information.
 - If the SA type is used for a We Bill For Them - Bill Ready service provider, the start options should be not allowed because we don't need to default rates, contract riders and/or contract values on billable charge sub SAs.
- The payment distribution and late payment information should be set up as for any SA type. Refer to [Cash Distribution Segmentation](#) and [Late Payment Charge Segmentation](#) for more information.
- If the SA type is used for We Bill For Them - Bill Ready service provider, the special role should be Billable Charge, otherwise it should not be used. Remember, you should not use sub SAs for Cash Deposits.
- Deposit class should be used if the sub SA is covered by a deposit. Refer to [Deposits Issues](#) for more information.
- The one time charge switch should be off.
- Bill segment type:
 - If the SA type is used for a We Bill For Them - Bill Ready service provider, the bill segment type should reference a bill segment creation algorithm that creates bill segments from billable charges (and generates bill segment errors until the last night of the bill cycle). Refer to [The Bill Ready Calculation Method](#) for more information.
 - If the SA type is used for a We Bill For Them - Rate Ready service provider, the bill segment type should reference a get consumption algorithm that gets consumption from the master SA, and a bill segment creation algorithm that applies a rate.
- Specify a characteristic premise is required if the sub SA is associated with premise-oriented service.
- The calendar billing options should not be used.
- The recurring charge information should not be used.
- Sub SAs used for We Bill For Them - Rate Ready service providers should NOT be eligible for budgets and therefore the eligible for budget switch should be off. This admonition is given because budget billing causes current amount due to be out-of-sync with payoff amount due and we don't want this to happen for sub SAs. Why? Because we use the bill segments associated with these sub SAs to determine how much we owe the service provider.

- If the SA type is used for a We Bill For Them - Rate Ready service provider or for your own company, rates need to be set up; otherwise they should not be used.
- Sub SAs never reference service points. Refer to [Only The "Master" Service Agreement Is Linked To Service Points](#) for more information.
- Adjustment types profiles should be set up accordingly.
- Refer to [Credit and Collection Issues](#) for recommendations in respect of the debt class, write off debt class, and severance criteria associated with these SA types.
- Billable charge templates should not be used.
- Completion algorithms cannot be used for sub SAs.
- If the SA type is used for a We Bill For Them service provider, you should link to the SA type the FT freeze algorithm that controls how we pay the service provider. Refer to [Pay At Bill Time vs. Pay At Pay Time](#) for how this algorithm is used.
- The creation of bill segments for the sub SAs occurs after the bill segment for the related master SA is created. If you populate a [billing processing sequence](#) on an SA type for a sub SA, it is used to control the order in which the sub SAs for a given master SA are processed relative to each other.

Refer to [Setting Up SA Types](#) for how to set up these new SA types in the system.

Reference Send Consumption Algorithm On Master SA Types

As explained under [We Can Send Billed Consumption To Any Service Provider](#), when a master SA's bill segment is frozen, the system must check if there are any service providers who need the bill segment's consumption. If so, it sets up the data necessary to interface the master SA's consumption (snapshot on the bill segment) to the service provider(s). The system will only do this if you specify an appropriate FT Freeze Algorithm on the master SA types. Refer to [SA Type - Algorithm](#) (FT Freeze Algorithm) for more information.

Reference TBFU Algorithm On Master SA Types

As explained under [They Bill For Us](#), when a bill is completed, the system needs to check if there are any service providers who bill for us associated with the bills "master" SAs. If so, it sets up the data necessary to interface the master SA's charges to the service provider and to transfer the receivable balance from the customer to the service provider. The system will only do this if you specify an appropriate FT Completion Algorithm on the master SA types. Refer to [SA Type - Algorithm](#) (Bill Completion Algorithm) for more information.

NOTE:

If there are multiple master SAs on a bill, the financial transactions associated with each respective master SA could be routed to different service providers (e.g., one service provider could bill for gas and another could bill for electricity). Refer to [Different Service Providers Can Bill Different Services](#) for more information.

Designing SA Types For Service Provider Financial Settlements

As explained in [Service Providers Have Service Agreements Too](#), We Bill For Them and They Bill For Us service providers require a service agreement. You must create SA types for these types of service agreements. The following points provide a few suggestions that will help you design these financial settlement SA types:

- Service type should probably be a non-service oriented service type.

- Distribution code for We Bill For Them settlement SAs should be a payable account (or treat it as a "contra" receivable. Refer to [Receivable Segmentation](#) for more information.
- The sub SA switch should be turned off.
- Start options are not allowed.
- The payment distribution and late payment information should be set up as for any SA type. Refer to [Cash Distribution Segmentation](#) and [Late Payment Charge Segmentation](#) for more information.
- Special role should not be used.
- Deposit class should be used if the settlement service agreement is covered by a deposit. This would probably only be used for They Bill For Us service providers (because they will owe us money).
- The one time charge switch should be off.
- These service agreements are not billable and therefore none of the billing information should be specified.
- The characteristic premise switch should be off.
- Rates should not be used.
- Service points should not be used.
- Adjustment types profiles should be set up accordingly.
- Debt class, write off debt class, and severance criteria should be set up accordingly.
- Billable charge templates should not be used.
- Completion algorithms should not be used.
- Freeze algorithms should not be used.

Refer to [Setting Up SA Types](#) for how to set up these new SA types in the system.

Setting Up SA Relationship Information

In the previous section, *Designing Your SA Relationship Types and Service Providers*, we presented a case study that illustrated a mythical organization's SA relationship information. In this section we explain how to set up this information.

Setting Up SA Relationship Types

Open **Admin** > **Open Market** > **SA Relationship Type** to define your SA relationship types. Refer to [Designing SA Relationship Types](#) for more information.

Description of Page

Enter an **SA Relationship Type** code and **Description** for every relationship type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_SA_REL_TYPE](#).

Setting Up Service Providers

The topics in this section describe how to set up service providers.

Service Provider - Main

Open **Admin** > **Open Market** > **Service Provider** > **Add** to define core information about a service provider.

Description of Page

Enter a unique **Service Provider** code for the service provider.

End a brief **Description** of the service provider.

If you communicate with this service provider via notification messages or outbound messages, indicate the service provider's **External System**.

If you send notifications to this service provider, select a **Notification DL (download) Profile** that is used to define the configuration of the outgoing messages.

Select the **Person ID** that contains this service provider's phone numbers and demographic information.

If you bill for the service provider or if they bill for you, select the **Service Agreement** that holds how much you owe them or they owe you. Refer to [Service Providers Have Service Agreements Too](#) for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_SPR](#).

Service Provider - Detail

Open **Admin** > **Open Market** > **Service Provider** > **Search** and navigate to the **Detail** page to define additional information about your service providers.

Description of Page

Define the **Billing Relationship** you have with the service provider. Refer to [Billing Relationships](#) for more information.

If you provide billing services for this service provider (i.e., the **Billing Relationship** is We Bill For Them), define the **Payment Relationship**. Refer to [Pay At Bill Time vs. Pay At Pay Time](#) for more information. You may not be paying some service providers as such. Rather, the customer's receivables are simply transferred to the service provider, e.g., when you calculate discounts for special [negotiated terms](#). For these service providers, choose a payment relationship of Pay SP Not Applicable.

Define the **Consumption Relationship** you have with the service provider. Refer to [Consumption Relationships](#) for more information.

If a service provider reads meters and they can override the customer's service cycle, turn on **Overrides ServiceCycle**. Refer to [MDMAs And Service Cycles](#) for more information.

As described under [Pay At Bill Time vs. Pay At Pay Time](#), when you provide billing service for a service provider you have to pay the service provider at some point in time. The **Pay Service Provider Algorithm** defines the amount to pay and how the related adjustment is generated. Refer to [Paying The Service Provider - Technical Implementation](#) for more information about how this algorithm is used. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that increases how much is owed the service provider. Click [here](#) to see the algorithm types available for this plug-in spot.

As described under [When They Bill For Us, They Owe Us Money](#), a service provider will owe you money if they provide billing service for you. The **Transfer A/R Algorithm** defines how to transfer the customer's receivable to the service provider. Refer to [A/R Transfer - Technical Implementation](#) for more information about how this algorithm is used. This

algorithm is also used to transfer receivables when you calculate discounts for special [negotiated terms](#). If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that transfers financial transactions from the customer to the service provider. Click [here](#) to see the algorithm types available for this system event.

As described under [They Bill For Us - Bill Ready](#), billable charges are interfaced to service providers who provide billing service for you. The **Billable Charge Download Process** performs the interface of billable charges to the service provider. Refer to [Routing Billable Charges To Service Providers - Technical Implementation](#) for more information about how this process is used.

As described under [We Can Send Billed Consumption To Any Service Provider](#), consumption can be sent to any service provider. The **Consumption Download Process** performs the interface of consumption to the service provider. Refer to [Routing Consumption To Service Providers - Technical Implementation](#) for more information about how this process is used.

Service Provider - SA Relationship Type

Open **Admin** > **Open Market** > **Service Provider** > **Search** and navigate to the **SA Relationship Type** page to define the types of relationships (e.g., energy supplier, energy distributor, meter data management agency) associated with a service provider and the postal code ranges in which the service provider operates.

Description of Page

Use the **SA Relationship Types** collection to define this service provider's **SA Relationship Types**. Use the collection that appears in the grid to define the **Postal Code** ranges in which this service provider is allowed to operate for each **SA Relationship Type**.

IMPORTANT:

After defining the SA relationship types that can be associated with a service provider, you must then define the SA types on which the service provider / SA relationship type combination can be used. This information is defined using [Setting Up SA Relationships For SA Types](#).

Service Provider - Bill Messages

Open **Admin** > **Open Market** > **Service Provider** > **Search** and navigate to the **Bill Messages** page to define bill messages to appear on bills that contain charges associated with a service provider.

Description of Page

Use the **Bill Messages** collection to define **Bill Message** codes that should appear on bills that contain charges associated with a given service provider. For each message, also specify the **Start Date** and **End Date** when such a message should appear on the bill (leave **End Date** blank if the message should appear indefinitely).

Where Used

The system snaps bill messages on a bill during bill completion. Refer to [The Source Of Bill Messages](#) for more information.

Setting Up SA Types and Start Options For Sub SAs

The SA types and start options described under [Designing Your SA Types And Start Options For Sub SAs](#) must be set up. Refer to [Setting Up SA Types](#) for how to do this.

Setting Up SA Types For Financial Settlements

The SA types described under [Designing SA Types For Service Provider Financial Settlements](#) must be set up. Refer to [Setting Up SA Types](#) for how to do this.

Update Master SA Types With FT Freeze and Bill Completion Algorithms

Refer to [SA Type - Algorithm](#) for more information.

Setting Up SA Relationships For SA Types

SA Type SA Relationship Type - Main

Open **Admin** > **Open Market** > **SA Type SA Rel. Type** > **Add** to define the types of SA relationships and service providers that can be associated with a SA type.

Description of Page

Define the **SA Relationship Type** that can be associated with service agreements of this **SA Type**.

NOTE:

You may only define SA Relationship Types for "master service agreements".

Turn on the **Required** switch if this **SA Relationship Type** must be defined for service agreements of this type. Refer to [Defaulting Relationship Types And Defaulting Service Providers](#) and [Required Relationship Types and Billing](#) for more information.

Indicate if **Gaps in SA Relationships** of this type that are associated with this service agreement type are Allowed or Not Allowed. You should only select Allowed if relationships of this type can be expired without a relationship with another service provider to replace it. Deregulated relationships typically should not have gaps in the relationship. For example, a relationship with an energy service provider should not expire unless a relationship with another energy service provider replaces it. Refer to [negotiated terms](#) for an example of SA relationship types that allow gaps in SA relationships.

Use the collection to define the **Service Providers** who can be associated with this **SA Relationship Type** on service agreements of this **SA Type**.

NOTE:

Only **Service Providers** previously defined as being valid for the **SA Relationship Type** can be specified (refer to [Service Provider - SA Relationship Type](#) for how to link a service provider to a SA relationship type).

Turn on **Default SPR** if the **Service Provider** should be defaulted on newly created SA relationships. Refer to [Defaulting Relationship Types And Defaulting Service Providers](#) for more information.

Use **Status** to control if the **Service Provider's** relationship to the SA Type / SA Relationship type is Active or Inactive. Only Active service providers can be linked to service agreements of this type. The system allows Inactive service providers

in order to support historical service providers who are no longer active and to allow you to set up new service providers in advance of their start date.

Use the drill down button adjacent to a service provider to view the valid Sub SA Types. Alternatively, navigate the Sub SA Type tab and scroll until you find the desired service provider.

Where Used

When a new SA relationship is defined for a service agreement, the system uses this information to make sure the relationship is valid and that the associated service provider is valid.

SA Type SA Relationship Type - Sub SA Type

Open **Admin > Customer > SA Type SA Rel Type > Search** and navigate to the **Sub SA Type** page to define valid sub SA types for service providers associated with a SA type.

If you provide billing services for the service provider (i.e., the service provider's billing relationship is We Bill For Them) or if you subcategorize your own charges (i.e., the service provider is your organization and it has a billing relationship of It's Us) a [Sub Service Agreement](#) will be created for the service provider.

Description of Page

The information in the collection defines the valid **Sub CIS Division** and **Sub SA Types** of these sub service agreements. Those entries marked as **Create Initially** are used by the process that creates sub SAs for new SA relationships. This background process uses this information as follows:

- If the sub SA's SA type doesn't use Start Options (as defined on SA Type - Main), the background process simply creates a sub SA with the given SA type. Note: these types of sub SAs are typically used for service providers who send their charges to you (i.e., they have a billing relationship of We Bill For Them - Bill Ready). This is because Billable Charge service agreements are used for these types of service agreements and billable charge service agreements contain very little information.
- If the sub SA's SA type uses Start Options (as defined on SA Type - Main), the **Start Option** defined in the collection is used to populate the sub SA with default values (e.g., rate, contract rider, etc.). Refer to [Setting Up Start Options](#) for more information.

Where Used

The process that creates sub SAs for new SA relationships uses this information to determine the number and type of sub SAs to create for each SA relationship.

Negotiated Terms

The topics in this section describe the use of SA relationship functionality for applying certain types of negotiated terms. It assumes that you are familiar with SA relationship functionality in general.

NOTE:

Negotiated terms are optional. The functionality described in this section is only relevant if your organization offers this functionality.

Umbrella agreements. If the Contract Management module is not [turned off](#), you may also choose to use umbrella agreements to manage the functionality described here.

Imagine that the head office for a multi-site organization negotiates special terms that cover a number of its sites, each of whom have their own account and service agreement. The negotiated terms typically involve discounts. These discounts may be realized

- Under a single service agreement, separate and distinct from the service agreements that are covered, or
- Individually, for each covered service agreement. In this case, two sub-scenarios exist:
 - The discounts may be reflected on the bill segment of each service agreement, or
 - The discounts may be transferred to another service agreement (the group's service agreement). The discount does NOT appear on the individual bill segment for the service agreements that are covered by the negotiated terms.

SA relationships track and manage complex business relationships between a customer and a service provider. You can define the above relationships using service agreement relationship functionality. This is a special type of SA relationship in which the head office is the service provider.

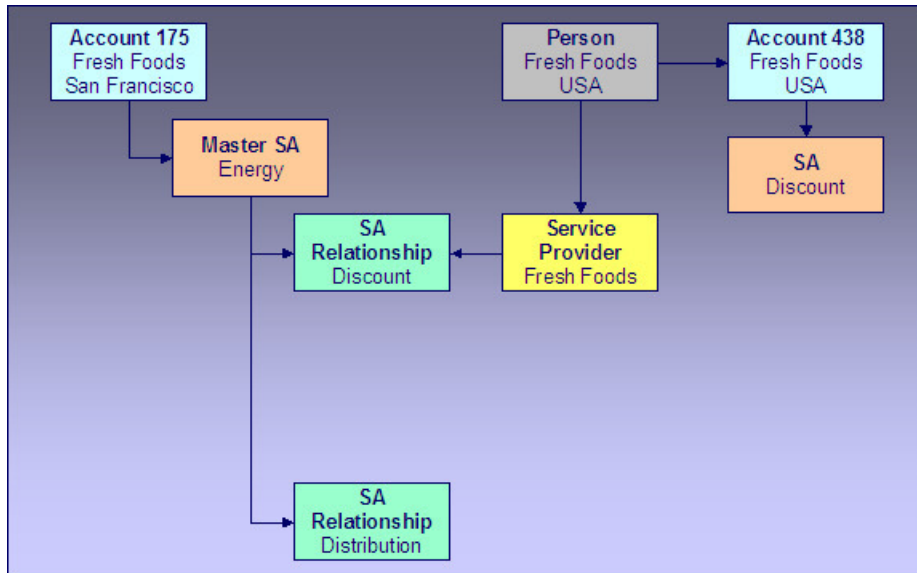

Examples Of Special Discounts

The following topics illustrate examples of how your organization may configure the system to handle this business functionality.

Example Using Aggregated Consumption

A customer, Fresh Foods has 10 stores each with its own account and electric service agreement, i.e., each store is billed separately. Fresh Food's head office decides to negotiate a group discount that applies to one or more of the individual stores.

In the following diagram, one store's account is shown.

Example Using Aggregated Consumption

Note the following:

- An SA relationship is created for the energy SA covered by the negotiated terms.
- The service provider in the relationship is the head office.
- This relationship does not have a sub-SA because no additional billing services are provided for each individual covered service agreement.

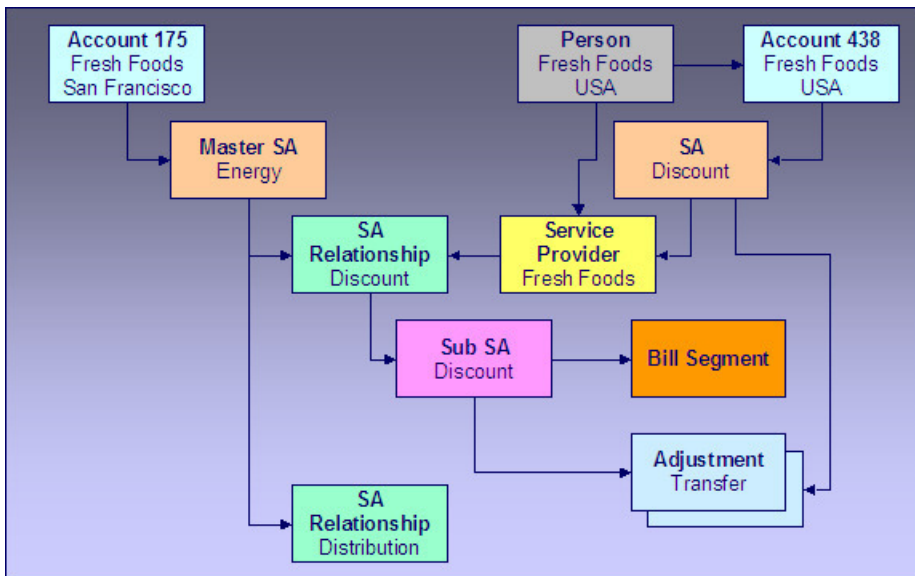

- Discounts are calculated using the head office discount service agreement and affect only this service agreement and therefore only the head office's account.
- The master SA may have other deregulated relationships, such as the distribution relationship shown.

NOTE:

Aggregated consumption algorithm. In this scenario, the service provider's service agreement amalgamates the group's consumption and applies a rate to calculate the discount. This algorithm is not provided - you get to write this algorithm to meet your needs.

Example Using Site-by-site Discount

In this scenario, the discount is calculated on a site-by-site basis.

Example Using Site By Site Discount

Note the following differences between this example and the one where consumption is aggregated:

- Each service agreement participating in the discount has an SA relationship with a sub SA.
- Discounts are calculated on a site-by-site basis by the sub SA for each service agreement covered by the discount agreement.
- The discounts may be transferred to the head office service agreement using transfer adjustments. In this case, you may choose to not show the discount on the individual site's bills.

Setting Up The System To Enable Negotiated Terms

The above topics provided background information about how special negotiated terms could be supported in the system. The following discussion summarizes the various setup tasks alluded to above. These notes highlight the setup required in addition to that detailed in [Setting Up SA Relationships Information](#).

Algorithm

If you use sub SAs to calculate charges / discounts for each covered service agreement individually and you want to transfer the charges / discounts to the service provider's service agreement at bill completion, you will need to set up a bill completion algorithm to do this.

Refer to the algorithm type [BCMP-TR](#) for more information.

SA Relationship Type

You will need an SA relationship type that will be used for each type of negotiated term or discount.

Service Provider

Set up a service provider using the principal party of the negotiated discount. For example, if a head office negotiates a special agreement for its sites, you should set up a new service provider representing the head office.

- **Billing Relationship** will depend on the type of negotiated terms you choose to set up. For terms where debits / credits are calculated for each covered service agreement individually, select We Bill For Them, Rate Ready. We are effectively billing on behalf of the principal party. For terms where the discount is calculated on an amalgamated SA there is no billing relationship because no additional billing services are provided for each covered service agreement.
- Select a **Payment Relationship** of Pay SPR Not Applicable if debits / credits to the sub-SA should not be transferred to the service provider. If you want to transfer charges at bill completion time using a bill completion algorithm, you should also select Pay SPR Not Applicable because you will not be creating adjustments to pay the principal party service at payment time or at billing time.
- Enter a **Transfer A/R Algorithm** to transfer the debit / credit from the sub-SA to the principal party's service agreement. If you do not want to transfer the debit / credit to the principal party's service agreement, you do not need to specify a transfer algorithm.

SA Type SA Relationship Type

Associate the SA relationship type setup for negotiated terms with the SA type(s) of the service agreements that are covered by the terms. The following are suggested values for the SA type SA relationship type:

- **Required.** Relationships of this type should not be required for the SA type because the negotiated terms will only cover selected service agreements with that SA type.
- **Gaps in SA Relationship** are Allowed if service agreements of this type do not have to have an SA relationship of this type with a service provider throughout the effective period of the SA.
- Add the service provider set up above to the list of valid service providers for this SA type and SA relationship type combination.

SA Type

Set up an SA type for the sub SAs that will be used to calculate discounts. This SA type should use the [BCMP-TR](#) bill completion algorithm if you want to transfer the discounts to the head office.

NOTE:

TBFU Deregulated Relationship with WBFT Negotiated Terms Relationship. If you have the unusual situation where a master service agreement has a relationship with a TBFU service provider as well as a negotiated term "relationship" with a WBFT service provider, and you transfer charges / discounts from the discount agreement sub SA to the WBFT service provider, you will not be able to use the algorithms provided to transfer receivables to the service providers. This is because bill completion algorithms associated with the SA type of a master service agreement are executed before any bill completion algorithms associated with the SA types of sub service agreements. Consequently the TBFU XFER algorithm associated with the master service agreement will transfer all receivables from related sub SAs to the TBFU service provider before the BCMP-TR algorithm can transfer the discount agreement receivables. You will need to modify the TBFU XFER bill completion algorithm that transfers receivables from the customer to the TBFU service provider to exclude the discount agreement receivables.

Defining Service Credit Options

Some companies allow their customers to participate in a special rewards program. The term "service credits" is used to describe a program that rewards customers for their business. The topics in this section provide details to help you set up the control tables required to support any service credit program that your company supports.

NOTE:

Penalty Points. The service credits functionality is described in the documentation with the assumption that it is used for accumulating points to reward your customers. However, if your company has a business need to record penalty points for a customer, the service credits functionality may be used for that purpose as well.

The Big Picture Of Service Credits

The topics in this section provide background information about service credit functionality.

Service Credit Membership

Let's look at some examples of special programs that may use service credits functionality:

- Capital credits - When customers receive their utility service from a cooperative, they are considered "members" of the cooperative and may over time receive capital credit allocations from the cooperative based on their service history and the cooperative's profits allocated during that time period.
- Frequent flier miles - Perhaps your company has made an agreement with one or more airlines to allow customers to accumulate frequent flier miles for every x amount spent on service.
- Free pay-per-view movies - Maybe your cable service offers free pay-per-view movies under certain conditions. Using service credits, you can set up your system to accumulate the free pay-per-view movies and use the free movies to offset actual movies viewed by the customer.
- Any other type of loyalty program where the customer earns credits that may later be redeemed in some way.

To participate in a program such as those described above, the customer is linked to a service credit membership. The membership record provides the following functionality:

- It defines the accounts that are linked to the membership.

FASTPATH:

Refer to [Who are the Members?](#) for information about linking persons and accounts to a membership.

- It defines a [membership type](#), which controls certain behavior about the membership.
 - It may define an external ID if the membership is associated with an external program, such as a frequent flier mile program.
 - It may define a [service agreement](#) to use for miscellaneous financial transactions that may get created.
 - It may define characteristics used to capture miscellaneous information about the membership.
 - Over time, service credit events are created for a membership. The events indicate an amount that either adds or subtracts credit units (i.e., points, miles, movies, dollars, etc) for the membership.
-

FASTPATH:

Refer to [The Big Picture of Service Credit Membership](#) for more information about functionality related to a membership.

How Are Service Credits Earned?

Service credits may be monetary rewards for service or they may be non-monetary rewards such as free movies or frequent flier miles. In any case, how the membership earns the points or rewards depends on the business rules for the program you are offering.

A typical scenario is that the service credits are earned for a membership as a result of other services linked to the membership's accounts. For example:

- Perhaps free pay-per-view movies are earned when signing up for cable service. In this case, the pay-per-view movie membership is related to the membership account's cable service agreement. Refer to [Service Credits Earned When Starting Service](#) for more information.
- Perhaps one frequent flier mile is earned for every \$10 spent on electricity. In this case, the frequent flier membership is related to the membership account's electricity service agreements (for example, electricity distribution, electricity retail and lamp service). Refer to [service credits earned through billing](#) for more information.
- For a capital credits membership, capital credit allocations are calculated based on the amount spent by the customer for standard service, for example electricity and/or gas service. In this case, the capital credit membership is related to the membership account's electricity and/or gas service agreements. For capital credits, a background process is used to calculate the allocated amounts. Refer to [Allocating Capital Credit](#) for more information.

It is also possible to earn service credits irrespective of other service for the membership's accounts. (Again, it depends on the business rules for the program you are offering.) For example, perhaps you offer 500 frequent flier miles for signing up for service with your company, regardless of the type of service chosen. In addition, assume that no additional miles are earned for ongoing service. In this example, there is no need to link the membership to any service agreements.

FASTPATH:

Refer to [Service Agreements Contribute to a Membership](#) for more information.

Each earned service credit amount is linked to the membership via a [service credit event](#).

How Are Service Credits Redeemed?

Once service credits have been earned for a membership, how may a customer redeem these credits? The method by which the credits are redeemed depends on the business rules for the program you are offering. Here are some examples of how a service credit may be redeemed:

- For free pay-per-view movies, perhaps your customer's monthly cable bill is credited for any pay-per-view movies until all free movies are used. Refer to [Service Credits Redeemed Through Billing](#) for more information.
- For frequent flier miles, the information about the earned miles is exported to the appropriate airline. The miles are actually redeemed by the customer through the airline, not through your company. Refer to [Interface Membership Information to a Third Party](#) for more information.
- For a capital credit membership, the company periodically (maybe once a year) decides if credits should be redeemed (referred to as "retired") and if so, how much. The company runs a background process to calculate the "retirement" amount. When an amount is retired, the membership balance is reduced by the retirement amount and the amount is transferred to service agreements related to the membership. Refer to [Capital Credit Retirement](#) for more information.

NOTE:

Tracking Membership Balances. If service credits are redeemed via the system, your membership should probably be configured to keep track of a balance. Refer to [Event Amounts May Contribute to a Balance](#) for more information.

Each service credit amount redeemed through the system is linked to the membership via a [service credit event](#).

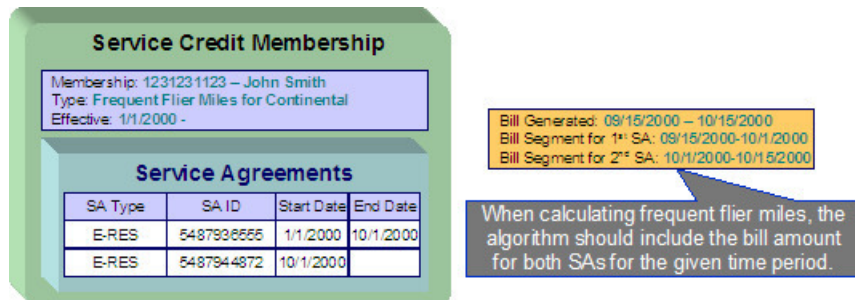

Service Agreements For a Membership

There are three types of service agreements that may be associated with a service credit membership. The following sections describe these types.

SAs Contribute to the Membership

As described in [how are service credits earned](#), many memberships are related to specific service agreements for the membership's accounts. We refer to these service agreements as the SAs that contribute to the membership because often the service credit amounts earned for the membership are based on amounts spent by the customer for these services.

During the lifetime of a membership, service agreements that contribute to a membership may be stopped and other service agreements started. For example, perhaps you have a frequent flier membership that is related to electric service. Imagine that the customer starts out with a certain rate for electric service, but later decides to opt for a different type of rate that requires expiring the old service agreement and creating a new one. How does this affect your frequent flier mile calculation? It depends on how you design the [algorithm](#) that creates the frequent flier events. Essentially, the algorithm must cater for this situation. The following diagram illustrates the scenario.

The service agreements that contribute to a membership are not linked directly to the membership record. This would cause a maintenance burden, requiring links to be updated when service is stopped or started for applicable service agreements.

Rather, this link is indirect. The list of service agreement types is defined for the membership type. The system can determine which service agreements are "linked" to the membership by looking at the SA types for the membership type.

FASTPATH:

Refer to [Determine The Types of Service Agreements That Contribute to the Membership](#) for more information on designing your membership type to include appropriate SA types.

SA Used for Miscellaneous Transactions

For some memberships, you may need to define a special service agreement to use for miscellaneous transactions. For example:

If events created for a membership cause an adjustment to be created to affect the general ledger, rather than allowing the system to arbitrarily pick a service agreement to use for this adjustment, the SA to use should be indicated on the membership. Refer to [An Event May Cause Other Actions to Occur](#) for more information.

Membership Fee SAs

For some memberships, a [membership fee](#) may be applicable. A special service agreement is used to hold the fee. This service agreement is not linked directly to the membership, but is simply a service agreement linked to one of the membership's accounts.

NOTE:

Some fees may be refundable. The refunding of a fee must be handled by an algorithm. Refer to [SAST-RF](#) for information about the algorithm type provided with the base product.

Designing Your Service Credit Options

This section helps you to determine how to design your service credit membership types and service credit event types.

Designing Your Membership Types

This section discusses the options to consider when designing your service credit membership types.

First consider the type of unit that your membership's service credit events represent.

- Is it related to a currency? If so, ensure that your currency is correctly defined on the [currency](#) page.
- Is it a non-currency unit, such as movies, points or miles? If so, you need to define the unit on the [credit unit](#) page.

Next, consider other behavior that your membership may exhibit.

- Should your membership [calculate an overall balance](#) ?
- Will miscellaneous financial transactions be created for you membership over its lifetime? If so you may need to link a [service agreement to your membership](#).
- Should events linked to your membership reference a [fiscal year](#) ?

The table below illustrates three types of memberships: one for capital credits, one for frequent flier miles and one for free pay-per-view movies.

Membership Type	Description	Unit Type / Currency or Credit Unit	Has Balance?	Require SA?	Fiscal Year?
STDCAPCR	Standard capital credit membership	Currency / \$	Yes	Yes	Yes
FFDELTA	Delta frequent flier miles	Credit Unit / Miles	No	No	No
FREEPPV	Free pay-per-view movies	Credit Unit / Movies	Yes	No	No

The following points explain the settings for each membership above:

- The capital credit membership uses a currency of US dollars for its units. Over time, capital credits are allocated and retired. The overall balance of the credits and debits should be calculated and displayed for information purposes. It is common for the allocation and retirement of capital credits to affect the GL, and as a result, a membership SA is required for posting these financial effects. Finally, in a capital credit situation, the allocation is typically related to a specific fiscal year. When calculating and displaying balances, the balance for each fiscal year must also be available. As a result, the fiscal year must be set to required.
- For the frequent flier membership type, a separate membership type must be created for each different airline. This is because a separate membership must exist for each separate airline in order to keep track of the accumulated miles correctly. The membership type does not have a balance because the accumulated miles are interfaced to the airline and the airline keeps track of the balance. In this example, no SA is required because an assumption is being made that the creation of frequent flier miles does not affect the GL. (Accumulating miles is no liability or expense for the company. The miles are simply accumulated on behalf of a third party.) Finally, the frequent flier miles do not need to indicate a fiscal year.
- For the free pay-per-view movies membership, we assume that the credits are redeemed from within the system. For example, perhaps a calculation rule calculation algorithm or pre-processing calculation rule redeems the free pay-per-view movies over time as customers are billed for the movies. As a result, the membership should have a balance. In this example, no SA is required because an assumption is being made that any affect on the GL is posted at the time the free movies are redeemed (i.e., when calculating a bill). (This is just an example. It's possible that you may want to post to the GL when free movies are accumulated to mark a payable for the company.) Finally, free pay-per-view movies do not need to indicate a fiscal year.

More options must be considered for each membership type.

Consider Whether the Membership Should Indicate Subcategories

For some types of memberships, the amount of each service credit event is further grouped by a subcategory. Refer to [Events May Indicate a Subcategory](#) for more information.

Use subcategories if multiple subtypes of credits may be accumulated and redeemed and if balances need to be tracked for each subcategory.

For our sample membership types, only the capital credits type should indicate subcategories.

Membership Type	Description	Subcategories
STDCAPCR	Standard capital credit membership	Distribution Transportation
FFDELTA	Delta frequent flier miles	
FREEPPV	Free pay-per-view movies	

Determine the Types of Service Agreements Linked to the Membership

Memberships typically exist to reward customers for participating in standard service with the company. Refer to [How Are Service Credits Earned?](#) for more information. If memberships of this type are related to standard service for your company, determine the SA types for these service agreements.

NOTE:

Standard Service SA Types. These service agreement types are probably different from the type of service agreement you may link as the membership SA. The membership SA is used for miscellaneous charges like general ledger posting. These SA types are related to electricity service, gas service, etc.

For our three examples, assume that the company provides electric service and cable. The capital credits are related only to electric service, frequent flier miles are accumulated for a combination of services, and free pay-per-view movies are related only to cable service.

Membership Type	Description	SA Types
STDCAPCR	Standard capital credit membership	E-RES (Electric Residential) AL-RES (Area Lighting)
FFDELTA	Delta frequent flier miles	E-RES (Electric Residential) AL-RES (Area Lighting) CABLE -RES (Cable Residential)
FREEPPV	Free pay-per-view movies	CABLE-RES (Cable Residential)

Consider Special Functionality Needed When Adding, Activating or Inactivating a Membership

Should a letter or bill message be generated when a membership is created or activated? Should anything happen when a membership is inactivated? If so, you may need to define one or more algorithms to be plugged in on the membership type.

For our examples, let's say that a bill message is generated when a frequent flier or free pay-per-view membership is created. Let's say that a letter is generated when a capital credits membership is activated. We also assume that when a capital credits membership becomes inactive, any outstanding balance is redeemed. For the frequent flier miles and pay-per-view memberships, we assume nothing special occurs when the membership becomes inactive.

FASTPATH:

Refer to [Lifecycle of a Membership](#) for more information about the various status values for a membership.

Membership Type	Description	Algorithm System Event	Algorithm
STDCAPCR	Standard capital credit membership	Membership Activation	Send Letter
		Membership Inactivation	Redeem Balances
FFDELTA	Delta frequent flier miles	Membership Creation	Generate Bill Message
FREEPPV	Free pay-per-view movies	Membership Creation	Generate Bill Message

NOTE:

Sample Algorithms. The base package does not provide sample algorithms for all the above examples. Refer to [Service Credit Membership Type - Algorithm](#) for more information about the algorithms provided with the system.

Determine Whether The Membership Requires Additional Information

Is there any information about your membership that you need to capture that is not already provided by the base system logic? If the answer is yes, you may need to define characteristics for your membership. Use the [characteristic collection](#) on the membership type to define the types of characteristics allowed for memberships of this type. You may also define default values for you membership's characteristics.

Designing Your Service Credit Event Types

Now that you have designed your membership types, you need to design the types of service credit events that may be created for your membership.

In many cases, a credit event should cause additional functionality to occur. Algorithms are executed when an event is completed and when an event is canceled and are used to perform additional functionality. The following points illustrate possible algorithms that may be needed when a credit event is completed.

- Validate the event as compared to other events. For example, perhaps a new event should never cause the overall membership balance to fall below zero. You could use an algorithm on the service credit event type to check this condition.
- Create an adjustment that posts to the general ledger. Your credit event may not affect the customer's balance when created, but perhaps it should have an effect on the general ledger. For these types of credit events, you may need to create an adjustment to post to the GL.
- Create adjustments to affect the customer's balance. When "redeeming" a credit, you may need to transfer a monetary amount to one or more of the customer's service agreements.
- Create a bill message. Perhaps when a credit is accumulated, you want to inform the customer via a message on the bill indicating the credit amount. A temporary bill message is added to one of the membership's accounts.

NOTE:

One Account Message of the Same Message Type. The temporary bill message collection on the account allows only one bill message of the same bill message type. If it's possible for multiple types of events to be generated for the same account, consider creating a different bill message type for each event type.

- Stamp a batch code and batch run number onto the event. This would be used when your event information needs to be interfaced to an external system.

The following points illustrate possible algorithms that may be needed when a credit event is canceled.

- Validate the event as compared to other events. For example, perhaps canceling an event should never cause the overall membership balance to fall below zero.
- Cancel adjustments that may have been created when the event was completed.

To illustrate examples of when to use some of the algorithms above, we'll design event types for the membership types designed above.

Designing Capital Credit Event Types

The following event types illustrate typical events for a capital credits membership.

SC Event Type	Description	Membership Type	Algorithm System Event	Algorithm
ALLOCATECCR	Capital credit allocation	STDCAPCR	Event Creation	Create Simple Adjustment
			Event Creation	Generate Bill Message
			Event Cancellation	Validate Balance Not < Zero
			Event Cancellation	Cancel Related Adjustments
RETIRECCR	Retire capital credit (apply to customer's balance)	STDCAPCR	Event Creation	Validate Balance Not < Zero
			Event Creation	Create Adjustments to Affect Customer's Balance
			Event Cancellation	Cancel Related Adjustments
FORFEITCCR	Forfeit capital credit (retirement not applied to customer's balance)	STDCAPCR	Event Creation	Validate Balance Not < Zero
			Event Creation	Create Simple Adjustment (affect GL only)
			Event Cancellation	Validate Balance Not < Zero
			Event Cancellation	Cancel Related Adjustments

These event types assume the following:

- When credit events are allocated, the customer is notified via a bill message, the general ledger is affected so a simple GL only adjustment is created. If an event of this type is canceled, any adjustments that were created should be canceled. The event amount should always be positive, so checking that the membership balance does not fall below zero is only checked for event cancellation.
- When capital credits are retired, it's possible that the full membership balance is not applied to the customer's balance. For the portion of the retirement that does affect the customer's balance, you need an algorithm that applies the credits to the customer's service agreements via adjustments. Cancellation of this event should cause any related adjustments to be canceled. It's assumed that the amount of this event is a credit so checking that the membership balance does not fall below zero is only checked for event completion.
- For the portion of the retirement that is not applied to the customer's balance, the event amount should simply affect the GL so a GL only adjustment is created. Cancellation of this event should cause any related adjustments to be canceled. It's assumed that the amount of this event is a credit so checking that the membership balance does not fall below zero is only checked for event completion.

NOTE:

Service credit event types are independent of subcategories. A capital credits membership typically uses subcategories. When events are created for different subcategories, the same service credit event type may be used. As a result, all subcategories use the same event completion and event cancellation algorithms.

Designing Frequent Flier Event Types

The following event types illustrate typical events for a frequent flier membership:

SC Event Type	Description	Membership Type	Algorithm System Event	Algorithm
ADDMILES	Add miles to the membership	FFDELTA	Event Creation	Generate Bill Message
			Event Creation	Populate Batch Information
			Event Cancellation	Event may not be canceled.

This event type assume the following:

- A new event should generate a bill message.
- Information about the event amount should be interfaced to an external system so batch information should be populated when the event is completed.
- Events of this type may not be canceled because the information is interfaced to an external system. Rather, to reverse an event, simply create a new event whose amount is a credit. This credit amount is also interfaced to an external system.

NOTE:

Sample Algorithm. The system does not provide a sample cancellation algorithm that prevents the event from being canceled.

- There is no validation to ensure that the balance does not fall below zero. Recall that this membership was defined as not requiring a balance.

Notice that only one type of event has been defined for this membership. That is because the credits for this membership are not redeemed via this system. Rather they are accumulated on behalf of an external system.

Designing Pay-per-view Event Types

The following event types illustrate typical events for a free pay-per-view movies membership:

SC Event Type	Description	Membership Type	Algorithm System Event	Algorithm
ADDPV	Free pay-per-view movies	FREEPPV	Event Creation	Generate Bill Message
			Event Cancellation	Validate Balance Not < Zero
REDEEMPPV	Redeem pay-per-view movies	FREEPPV	Event Creation	Validate Balance Not < Zero
			Event Creation	Generate Bill Message

These event types assume the following:

- Any type of new event should generate a bill message.
- For adding free movies, it is assumed that the quantity is positive so when the event is cancelled, the algorithm verifies that the balance does not become negative.

- For redeeming free movies, it is assumed that the quantity is negative so when the event is completed, the algorithm verifies that the balance does not become negative.
- These events do not affect the general ledger and they do not directly affect the customer's balance so no adjustment algorithm is needed.

How Are Service Credit Events Created?

Now that you have designed the behavior of your service credit events, an important issue is to determine how these events are created. Consider your business practice for each type of membership.

Let's use our sample memberships to work through different ways that you may create service credits.

Service Credits for Capital Credit Memberships

For a capital credit membership, capital credit allocations are calculated once a year based on billing history and the cost of service. To accomplish this, a background process calculates the amount and creates the service credits. Refer to [allocating capital credits](#) for a sample process provided with the base package.

Credits are redeemed via the retirement process. The company determines when to retire capital credits based on analysis of their financial situation. This retirement process is also handled by a background process. Refer to [capital credit retirement](#) for a process provided with the base package.

For capital credits memberships, special functionality is required when a member dies. The capital credits are considered part of the person's estate and may need to be retired and applied to a beneficiary's account. This process depends on the company's business practice. However, typically, the membership status would change to inactive so that new capital credit allocations are not created for the membership. The system provides a sample inactivation algorithm called [SCMI-RB](#) that transfers part or all of the outstanding credit balance to the member's service agreements. From there, a user can cut a check to the beneficiary.

NOTE:

Some Credits Are Never Retired. For many cooperatives, some types of allocated credits are never retired. Refer to [Partial Retirement](#) for more information.

Service Credits for Frequent Flier Memberships

In our example, frequent flier miles were related to both the electricity and phone service. Let's assume that frequent flier miles are accumulated every \$x spent on electricity and phone service. In this example, a bill completion algorithm creates service credits based on the bill segment amounts for these service agreements. Refer to [Service Credits Earned Through Billing](#) for more information.

As mentioned before, the frequent flier miles are not redeemed using this system, but are interfaced to a third party for redemption.

Service Credits for Free Movies Memberships

NOTE:

Sample Algorithms. No base package algorithm types are provided to support the logic described in this example.

In this scenario, let's suppose that a customer receives three free pay-per-view movies when signing up for new service. To handle this, perhaps an SA creation algorithm creates the membership and the service credits when the service is started. Or perhaps you want to wait until the first bill is generated and a bill completion algorithm is used to generate the first credit. It depends on your business practice.

For redeeming the free pay-per-view movies, it is assumed that the movies are credited during billing after it is determined that the customer has been billed for a movie. The number of movies used for the membership is reduced until all the free movies are used.

FASTPATH:

Refer to [Service Credits Redeemed Through Billing](#) for more information.

Setting Up Service Credit Options

Setting Up Credit Units

Credit unit is used for service credit membership types whose [events](#) record non-monetary units. Open **Admin > Service Credit > Credit Unit** to set up credit units.

Description of Page

The following fields display for each credit unit:

Credit Unit The unique identifier of the credit unit.

Description The description of the unit. This also acts as a label for the unit when displaying information about a service credit event.

Symbol / Label Position Indicates whether or not the label for this credit unit appears as a Prefix or as a Suffix to the service credit event amount.

Decimal Positions Indicates the number of decimal positions used for this credit unit. This information should be used by any algorithm or background process that creates a service credit event to determine how to store the event amount. It is also use to correctly display the service credit amounts.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CR_UNIT](#).

Setting Up SC Membership Inactive Reasons

The service credit membership inactive reason must be specified when the status of a service credit membership changes to inactive. Open **Admin > Service Credit > Service Credit Membership Inactive Reason** to set up service credit inactive reasons.

Description of Page

The following fields display for each inactive reason:

Inactive Reason The unique identifier of the service credit membership inactive reason.

Description The description of the inactive reason.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_SCM_NCTV_RSN](#).

Setting Up Service Credit Membership Types

SC Membership Type - Main

Service credit memberships have a membership type. Open **Admin > Service Credit > Service Credit Membership Type > Add** to define the membership type.

Description of Page

Enter a unique **Service Credit Membership Type** and **Description** for each membership type.

Use the **SA Requirement** flag to indicate whether a [miscellaneous SA](#) must be linked to memberships of this type. The possible values are SA Required and SA Not Allowed .

NOTE:

The value defaults to SA Required.

Use the **Fiscal Year Requirement** flag to indicate whether events linked to memberships of this type should indicate a [fiscal year](#). The possible values are Fiscal Year Required and Fiscal Year Not Allowed.

NOTE:

Default Note. The value defaults to Fiscal Year Not Allowed.

Use the **SCM Event Balance** flag to indicate whether or not a [balance of service credit events](#) linked to memberships of this type should be calculated and displayed. The possible values are Has a Balance and No Balance.

NOTE:

Default Note. The value defaults to Has a Balance.

Use the **SC Membership Type Unit** flag to indicate whether or not the unit for the event amounts for events linked to memberships of this type is Currency or Credit Unit. When the unit is currency, indicate the **Currency Code**. When the unit is credit unit, indicate the **Credit Unit**.

If events linked to memberships of this type must indicate a subcategory, enter a valid **Subcategory Name** and **Description** for each subcategory applicable to this membership.

FASTPATH:

Refer to [Events May Indicate a Subcategory](#) for more information.

Use the **SA Types** grid to indicate the types of [service agreements that contribute to memberships](#) of this type. Indicate the **CIS Division** and **SA Type** for each type of service agreement that is related to a membership of this type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_SCM_TYPE](#).

SC Membership Type - Algorithm

Open **Admin > Service Credit > Service Credit Membership Type > Search** and navigate to the **Algorithm** page to define any algorithms that are associated with a membership type.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description
Membership Creation	Optional	Use this system event for algorithms that are executed when a membership is created. Click here to see the algorithm types available for this system event.
Membership Activation	Optional	Use this system event for algorithms that are executed when a membership becomes active. Click here to see the algorithm types available for this system event. NOTE: Creating Memberships In Active Status. A membership may be created in either pending status or in active status, based on your business practice. For memberships created in active status, the system executes the membership creation algorithms and the membership activation algorithms.
Membership Inactivation	Optional	Use a system event of Membership Inactivation for algorithms that are executed when a membership becomes inactive . Click here to see the algorithm types available for this system event.

SC Membership Type - Characteristics

To define characteristics that can be defined for service credit memberships of a given type, open **Admin > Service Credit > Service Credit Membership Type > Search** and navigate to the **Characteristics** page.

Description of Page

Use the characteristics collection to define characteristics that can be defined for service credit memberships of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on service credit memberships of a given type. Turn on the **Default** switch to default

the **Characteristic Type** when service credit memberships of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Setting Up Service Credit Event Types

Service credit events created for a service credit membership have an event type. Open **Admin > Service Credit Event Type > Add** to set up service credit event types.

Description of Page

Enter a unique **Service Credit Event Type** and **Description** for each event type.

Indicate the **Service Credit Membership Type** to which this event type belongs.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

System Event	Optional / Required	Description
Event Completion	Optional	Use a system event of Event Completion for algorithms that are executed when an event is completed. Refer to An Event May Cause Other Actions to Occur for more information. Click here to see the algorithm types available for this system event.
Event Cancellation	Optional	Use this system event for algorithms that are executed when an event is canceled. Click here to see the algorithm types available for this system event.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_SC_EVT_TYPE](#).

Service Credit Examples

In this section, we provide examples of how to define your control tables to support functionality related to different types of service credit memberships. While your company may not define your environment exactly the same way, this section should help solidify your understanding of how to set up your company's service credit options.

Defining Control Tables for a Refundable Fee

If your membership requires payment of a [fee](#) that is refundable, you must define an SA type to use for the refundable fee.

Adjustment Type for Refundable Fee

This example assumes that the fee is set up similarly to a deposit. The adjustment used to charge the fee would affect the current balance, but not the payoff balance or the general ledger because the fee is not considered a "receivable", rather it is an amount collected and held for the customer.

Create an [adjustment type](#) for levying the fee. Indicate the fee amount and indicate the adjustment FT creation algorithm [ADJT-CA](#), which affects the current balance, but not the payoff balance or the general ledger.

NOTE:

Adjustment Type Profiles. Be sure to add this adjustment type to an appropriate [adjustment type profile](#) and ensure this profile is linked to your SA type.

SA Type for Refundable Fee

Create an SA type to use for the fee. This SA type should be marked as not billable.

Indicate the appropriate adjustment type profile that includes the adjustment type to levy the fee.

Indicate an appropriate payment segment type that references the [PSEG-NM](#) payment segment FT algorithm. This algorithm affects the payoff amount and current amount by the payment amount, which should cause the current amount to become zero and the payoff amount to become a credit for the fee amount when the fee is paid.

Start Option for Refundable Fee

For this SA type, define a start option that causes an adjustment to be levied as part of the start service process.

FASTPATH:

Refer to [Including The Membership Fee](#) on campaigns and packages for more information about levying the fee via the order transaction.

Algorithm for Refunding the Fee

The base product provides an algorithm type [SAST-RF](#) that refunds a fee when [service agreements that contribute to the membership](#) are stopped. You must create an algorithm for this algorithm type and enter the SA type created above as an input parameter.

This SA stop algorithm must be plugged in on all SA types that you defined for the [membership type](#).

Defining Control Tables for a Nonrefundable Fee

If your membership requires payment of a [fee](#) that is not refundable, you can set this up in two ways:

- You can create a special SA type to handle charging the fee. For this SA type, define a start option that causes an adjustment to be levied as part of the start service process. This adjustment contains your fee. You may use this option if the membership is related to multiple types of services and not all services need to be present in order to create the membership.

- You can levy an adjustment on one of the other service agreements that is being started. To do this, you would use a start option to define an adjustment to be levied as part of the start service process. You may use this option if the membership is related to a single service (for example, free pay-per-view movies).

For our example, we will set up the SA for the nonrefundable fee with a separate 'fee' SA type.

Adjustment Type for Nonrefundable Fee

Create an [adjustment type](#) for levying the fee. Indicate the fee amount and indicate the adjustment FT creation algorithm [ADJT-NM](#), which affects the current balance and payoff balance by the adjustment amount, and affects the general ledger.

NOTE:

Adjustment Type Profiles. Be sure to add this adjustment type to an appropriate [adjustment type profile](#) and ensure this profile is linked to your SA type.

SA Type for Nonrefundable Fee

Create an SA type to use for the fee. This SA type should be marked as not billable.

Indicate the appropriate adjustment type profile that includes the adjustment type to levy the fee.

Indicate an appropriate payment segment type that references the [PSEG-NM](#) payment segment FT algorithm. This algorithm affects the payoff amount and current amount by the payment amount, which causes the current amount to become zero and the payoff amount to become a credit for the fee amount when the fee is paid.

Start Option for Nonrefundable Fee

For this SA type, define a start option that causes an adjustment to be levied as part of the start service process.

FASTPATH:

Refer to [Including The Membership Fee](#) on campaigns and packages for more information about levying the fee via the order transaction.

Defining an SA Type for Miscellaneous Transactions

Does your membership require a [service agreement](#) to support miscellaneous transactions? If so, you need to consider the SA type to use for this service agreement. This SA type should be marked as not billable.

If you choose to use the order transaction to set up the membership, this SA type must be defined on the [algorithm that creates the membership](#).

It is possible that you may require a start option for this SA type, for example if you want to define a characteristic for service agreements of this type.

Using Campaigns/Packages to Set Up Membership

If enrollment in a membership is a common occurrence for your customers when starting service, you should consider using the [order](#) page to start service for the customer and to create the membership as well.

NOTE:

This section only makes sense if you are familiar with the [Sales and Marketing](#) chapter.

The recommendation is to use a question/miscellaneous field to ask the customer service representative to indicate the appropriate membership type. Algorithms validate this membership type and use it to create a membership of that type.

This section walks you through how to set up the campaign / package required to support this.

Column Reference for Membership Type

In order to ask the customer service representative to define an appropriate service credit membership type, you must define a column reference for the membership type.

Add a new column reference with the following information:

- Column Reference: SCM-TYPE
- Description: SC Membership Type
- FK Reference: SCM TYPE
- Long Description: Service Credit membership type to use when creating a service credit membership at start time.

NOTE:

Column Reference Algorithms. This column reference indicates a validation algorithm and a posting algorithm. However, we have not defined them yet so for now simply save this information.

Algorithms to Create Membership via Order

The base product provides two algorithm types to support the creation of a membership record via the order page: a validation algorithm type and a posting algorithm type.

Validate Membership Information

This algorithm is a column reference validation algorithm that checks that an input membership type is valid. Refer to [CRVL-ME](#) for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used to identify the membership type. For example:

- Algorithm: VAL MEM TYPE
- Description: Validate SC Membership Type
- Algorithm Type: CRVL-ME
- Parameter1: (Column Reference for Membership Type): SCM-TYPE

Post Membership Information

This algorithm is a column reference posting algorithm that creates a membership using the membership type indicated by the user. Refer to [CRPS-ME](#) for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used to identify the membership type. For example:

- Algorithm: CREATE MEMBRSHIP
- Description: Validate SC Membership Type
- Algorithm Type: CRPS-ME
- Parameter1: (Column Reference for Membership Type): SCM-TYPE

- Parameter2: (Service Credit Membership Status): 10 -Pending or 20 -Active. Refer to [Lifecycle of a Membership](#) for more information.
- Parameters3-5: (Division, SA Type, Start Option): Indicate the information needed to create an SA for miscellaneous transactions.

NOTE:

This algorithm first looks for an existing service agreement of this division / SA type linked to the membership's accounts. If one exists, it uses that SA to link to the membership. If an SA does not exist, it creates one with the input division, SA and (optional) start option.

Update the Column Reference. Now that you have defined the validation and posting algorithms, return to your [column reference for membership type](#) and define the algorithms there.

Although your company may support multiple types of memberships, this column reference and its algorithms have been designed such that only one column reference for membership type would be needed to set up any type of membership. Although the posting algorithm for the membership type column reference indicates an SA type to use for miscellaneous transactions, a service agreement is only created and linked if your membership type indicates that an SA is required. As a result, you may use the same column reference for both memberships that require an SA and those that don't require an SA. However, if you have different membership types that require an SA and each uses a different SA type or a different start option for the membership SA, you need to define more than one posting algorithm and, as a result, more than one column reference.

Define a Campaign for Creating a Membership When Starting Service

Many factors must be considered when [designing your campaigns and packages](#). The possible creation of a membership when using the order page is simply another factor to consider.

If you plan to define a question/miscellaneous field to capture a service credit membership type, the available packages linked to the campaign should be ones that are related to memberships. For example, if your membership is related to electric service, it doesn't make sense to create a membership for a campaign designed to generate a one-time charge.

When defining a question/miscellaneous field, you must indicate its applicability. Consider whether a membership type is required, optional or only applicable for certain packages. This helps ensure that your users capture this information when appropriate.

Including the Membership Fee

You must determine the best way to setup your campaign/package to handle the levying of your membership fee, if applicable. Consider some of the following questions.

- If the membership has a fee, is it a refundable fee or a non-refundable fee?
- Is the fee always applicable for the membership? Or is it waived under certain conditions? For example, maybe the fee is applicable if a customer signs up for a single service, but the fee is waived if the customer signs up for two or more services.

The SCM type column reference and question/miscellaneous field are set up to ask the user what type of membership to create. Because the applicability of the fee may differ for each membership type, you should carefully consider the campaign / package setup to levy the fee correctly.

- If a fee is always applicable for a membership, you may consider creating a membership creation algorithm that creates a fee SA with a start option to levy the fee when the membership is created.

NOTE:

Sample Algorithm. The base product does not provide a membership creation algorithm to do this.

- If the fee is not always applicable for a membership, you must determine when the fee is applicable. The recommendation is to include the fee SA type in the SAs-to-create collection for the appropriate package. For example,
 - If the fee is applicable when the customer signs up for a single service, you should define a package for each single service that includes one SA to create for the single service and the fee SA as another SA to create.
 - If the fee is waived when the customer signs up for two or more services, you should define a package for each combination of the multiple services. These packages do not include the fee SA in the SAs to create.
- If the customer signing up for service is a former customer who has returned, perhaps the fee was paid earlier when the customer originally had service. In this case, maybe your business practice is to waive the fee at this time. To do this, you should set up a question/miscellaneous field for the user to mark that this is a returning customer. Based on the answer to this question, perhaps only packages that do not levy any fee are eligible for selection.

Defining Another Person for Your Account

It is common for a capital credit membership to define more than one person for the account being turned on and linked to a membership. A typical example is a married couple. Both spouses are indicated on the account and financially responsible persons and as a result, both are considered [members](#).

Column reference algorithms have been provided by the base product to enable linking a second person to your account via the [order](#) page.

This section walks you through how to set up the column reference and campaign to support this.

NOTE:

Linking A Second Person to the Account. This logic is not restricted to service credit functionality. Any campaign may be designed to include the ability to link a second person to the account being started.

Column References for Additional Person

In order to ask the customer service representative to link an additional person for the account, you must define several column references to use as questions/miscellaneous fields.

- We should assume that the person may already exist in the database. As a result, a question to record the person ID is needed.
- If the person does not already exist, the user should capture the person's name, an ID type and an ID number. Questions for these three fields are needed. The system uses this information to create a new person.
- Whether we are using an existing person or creating a new one, the person's link to the account must include an account relationship type. A question to record the account relationship type is needed.

Add a new column reference for person ID:

- Column Reference: PERSON-ID
- Description: Person ID
- FK Reference: PER
- Long Description: Person ID of the additional person to link to the order's account.

Add a new column reference for person name:

- Column Reference: PERSON-NAME

- Description: Person Name
- FK Reference: not applicable
- Long Description: Name of a new person to create.

Add a new column reference for identifier type:

- Column Reference: PER-ID-TYPE
- Description: Identifier Type
- FK Reference: ID TYPE
- Long Description: Identifier type for the primary ID of the additional person to link to the order's account.

Add a new column reference for identifier number:

- Column Reference: PER-ID-NUM
- Description: Person ID Number
- FK Reference: not applicable
- Long Description: Identifier number for the primary ID of the additional person to link to the order's account.

Add a new column reference for account relationship type:

- Column Reference: ACCT-REL-TYPE
- Description: Account Relationship Type
- FK Reference: ACCT REL
- Long Description: Relationship type to use for the link between the additional person and the order's account.

NOTE:

Column Reference Algorithms. One of the column references above must indicate a validation algorithm and a posting algorithm. However, we have not defined them yet so for now simply save this information. We recommend using the account relationship type record because that is used for all additional persons.

Algorithms to Link Additional Person via Order

The base product has provided two algorithm types to support the linking of an additional person to the account via the order page: a validation algorithm type and a posting algorithm type.

Validate Addition Person Information

This algorithm is a column reference validation algorithm which checks that either a person id or person name, a valid ID type and ID number are provided and that a valid account relationship type is provided. Refer to [CRVL-PE](#) for more information. You must define an appropriate algorithm for this algorithm type and on that algorithm you must define the column reference used for the five fields required for this validation. For example:

- Algorithm: VAL ADD PER
- Description: Validate Additional Person Info
- Algorithm Type: CRVL-PE
- Parameter1: (Column Reference for Person ID): PERSON-ID
- Parameter2: (Column Reference for Person Name): PERSON-NAME
- Parameter3: (Column Reference for Person ID Type): PER-ID-TYPE
- Parameter4: (Column Reference for Person ID Number): PER-ID-NUM

- Parameter5: (Column Reference for Account Relationship Type): ACCT-REL-TYPE

Post Addition Person

This algorithm is a column reference posting algorithm that may link an existing person to the order's account or create a new person and link that person to the order's account. Refer to [CRPS-PE](#) for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used for the five fields required for this logic. For example:

- Algorithm: LINK ADDNTL PER
- Description: Link additional person to order's account
- Algorithm Type: CRPS-PE
- Parameter1: (Column Reference for Person ID): PERSON-ID
- Parameter2: (Column Reference for Person Name): PERSON-NAME
- Parameter3: (Column Reference for Person ID Type): PER-ID-TYPE
- Parameter4: (Column Reference for Person ID Number): PER-ID-NUM
- Parameter5: (Column Reference for Account Relationship Type): ACCT-REL-TYPE

NOTE:

Update the Column Reference. Now that you have defined the validation and posting algorithms, return to your [column reference for account relationship type](#) and define the algorithms there.

Design a Campaign to Include Linking an Additional Person

Any campaign related to a specific account may include the questions and miscellaneous fields defined here to create/link an additional person to the account.

Simply create entries in the questions and miscellaneous fields collection to prompt the user to ask for the required information. A question should exist for each column reference created above. The following table illustrates a possible setup.

Seq	Description	Prompt on Order	Column Reference	Dependency
10	Account relationship type for additional person.	If you would like to link another person to this account, please enter an account relationship type.	ACCT-REL-TYPE	Must have account
20	Person ID for additional person	If the additional person already exists in the database, enter the person id.	PERSON-ID	Must have account
30	Person name for additional person	If you would like to create a new person, please enter the person name.	PERSON-NAME	Must have account
40	ID type for additional person	Please enter the ID type of the new person.	PER-ID-TYPE	Must have account
50	ID Number for additional person	Please enter the ID number of the additional person.	PER-ID-NUM	Must have account

Service Credits Earned When Starting Service

For some memberships, you may want to add service credits when starting the program. For example, the customer gets three free pay-per-view movies when signing on for cable service. Or a customer receives 500 frequent flier miles for signing up for a combination of gas and electric service.

There are various ways that you can accomplish this. You should work with your implementers to consider the various options to determine the method that best suits your business practice.

- You could use an SA activation algorithm to create a membership and an event for the initial points. Use this method if the points are related to a single type of service agreement and the points are earned automatically when starting service (i.e., without any human decision to be made).
- You could use a membership creation or membership activation algorithm to generate a service credit event automatically. This method assumes that the decision to create the membership has been made and that the free initial points are always earned for this type of membership (i.e., regardless of the type of service created).
- You could use questions and miscellaneous fields for a campaign/package to determine a customer's eligibility for participation in the membership and for the initial free points. A column reference posting algorithm could create the membership and/or the service credit event for the free points based on the answers to the questions.
- Perhaps the initial free points are only earned after the first bill is generated. Use a bill completion algorithm to generate the initial points.

You may think of other plug-in spots that could be used to generate free initial points based on your business needs.

Service Credits Earned Through Billing

For some memberships, you may accumulate points as a result of billed amounts for other services. For example, perhaps your customers earn one frequent flier mile for every \$10 spent on the combined electricity, gas and water bills each month.

To accomplish this, you must design an algorithm to be executed at billing time. There are various plug-in spots executed at billing time that you may use, but the recommended plug-in is a post completion algorithm on the customer class. This plug-in is executed after all bill segments are frozen and most of the completion logic has occurred.

Your algorithm should determine the [service agreements that contribute to the membership](#) and calculate the service credit amount for those service agreements bill segments.

This algorithm should also consider what to do when bill segments that contributed to the event are canceled. The algorithm provide with the base product [CBCM-SC](#) checks to see if any canceled bill segments are referenced on any previous events. If so, it includes the canceled amount on the new event. This may cause the new event to be a negative amount. The assumption is that over time, earned credits will compensate for the negative event amount. For a membership that [interfaces information to a third party](#), it is assumed that the negative event amount is also interfaced.

Service Credits Redeemed Through Billing

For some memberships, your customer may redeem their earned points by receiving a discount on their bill. For example, if your cable customer has earned one free pay-per-view movie, you can give them a credit the next time they get billed for a pay-per-view movie.

The base product has not provided any algorithms to credit a bill based on earned service credits. This section will identify considerations your implementers should follow when designing algorithms to redeem service credits through billing.

The recommendation is to credit the customer's bill by generating an adjustment using a pre-bill completion algorithm. This algorithm's responsibilities are as follows:

- Determine if the appropriate bill segment(s) contain the charges that need to be credited. For example, if the service credit is for a free pay-per-view movie, determine if the customer has been billed for a pay-per-view movie.
- Determine if the customer's current service credit balance for this program. For example, how many free pay-per-view movie credits are left?
- Create an adjustment to credit the appropriate service agreement by the eligible credit amount.
- Update the service credit membership balance by creating a new SC event with a credit for the number of points redeemed. Link the adjustment to the event as a contributed to FT.
- Consider cancel/rebill situations. If a cancel/rebill has occurred, determine if there is a change to the redeemed credits. For example, if the original bill had one pay-per-view movie that was credited and the new bill also has one pay-per-view movie, no change is needed to the service credit balance. If the original bill had more pay-per-view movies than the new bill, perhaps one or more redeemed service credit points should be reinstated. If the original bill had fewer pay-per-view movies than the new bill, perhaps more points should be redeemed.

You may wonder why we don't recommend crediting the customer's bill while generating the bill segment. For example, use pre-processing calculation rule to determine if any points should be redeemed and use a calculation rule to generate a bill calculation line with the credit amount.

The reason for this is that cancel/rebill logic is not straightforward. Algorithms executed during rate application should NOT perform any updates, such as updating the service credit membership balance. The balance should be updated using a bill segment freeze algorithm or a bill completion algorithm.

When a cancellation occurs, the service credit balance should be updated to reinstate the redeemed points. Again, this should occur when the cancellation is frozen or at bill completion time. If you perform a cancel/rebill, the calculation of the rebill segment does not have the up-to-date information about the service credit balance because the reinstatement of the points by the canceled segment has not occurred yet.

Designing Your Rate Options for Capital Credits

The capital credit allocation background process relies on certain data configuration in order to function correctly. This section identifies the required data setup.

FASTPATH:

Refer to [Allocating Capital Credits](#) for more information.

Identifying SQ and Sales Information for Historical Bill Segments

To allocate capital credits, the background process retrieves billing history for each SA that contributes to the membership for the given fiscal year. The process needs to calculate the service quantity (SQ) amount billed and the sales amount billed for the SA in that year.

NOTE:

Sales Amount. The sales amount refers to the monetary amount billed. For a capital credit allocation, this amount would generally exclude taxes and may exclude other line item amounts from the bill.

In order to calculate the amounts correctly, the background process must determine which bill calculation lines for each bill segment contain the SQ and/or sales information. Characteristics on the bill calculation lines identify which bill lines should be used.

The rest of this section uses examples to illustrate how you may configure your rate options to support this.

Define Characteristics for SQ and Sales

Char Type for identifying bill lines that hold **SQ information**

- Char Type: CCA-SQ
- Description: Capital credit allocation usage
- Type of Char: Pre-defined
- Values: Y
- Char Entities: Calculation Rule, Bill Calculation Line

Char Type for identifying bill lines that hold **sales information**

- Char Type: CCA-SALES
- Description: Capital credit allocation sales
- Type of Char: Pre-defined
- Values: Y
- Char Entities: Calculation Rule, Bill Calculation Line

Define Calculation Rules

Identify each rate schedule that may be linked to a service agreement that contributes to a capital credit membership.

For each of these rate schedules, identify the calculation rules whose resulting bill calculation line will contain a billable service quantity that should be included in the SQ calculation for allocating capital credits. For each calculation rule that qualifies, define the CCA-SQ char type (defined above) and a char value of Y.

For each rate schedule, identify the calculation rules whose resulting bill calculation line amount should be included in the sales calculation for allocating capital credits. For each calculation rule that qualifies, define the CCA-SALES char type (defined above) and a char value of Y.

NOTE:

Characteristic Information. The system automatically copies characteristic info from a calculation rule to its resulting bill calculation line if the char type entities include both calculation rule and bill calc line.

Define Batch Control Parameters

The background process to allocate capital credits **CPCRALOC** receives the char type and char value to identify the bill calculation lines that contain the SQ and sales amounts. Once you have your characteristics defined, update your batch control to include these values as default parameter values.

Designing Bill Factors for Credit Allocation

The **capital credit allocation** process uses an allocation factor in its calculation. A typical capital credit membership may define multiple subcategories, meaning that allocation amounts are calculated each year for the multiple subcategories. The calculation is the same for each subcategory, but the allocation factor differs.

The process has been designed to calculate the allocation for a single subcategory. If your organization requires allocations calculated for multiple subcategories, the process must be run for each subcategory. The allocation process receives a bill factor as an input parameter. As a result, a different bill factor should be set up to define the allocation factor for each subcategory.

For each subcategory, the allocation factor may differ further for the type of customer. For example, the allocation for a commercial customer may differ from the allocation factor for a residential customer. The allocation background process expects the bill factor for each subcategory to define a characteristic type of revenue class. The process determines each service agreement's revenue class by looking at the value defined on its SA type.

Following is an example of bill factors set up for a capital credit membership with two subcategories: transportation and generation.

Characteristic Type for Allocation Bill Factor

Char Type: REV-CLASS

Description: Revenue Class

Type of Char: Pre-defined

Values: (define all the valid revenue class values)

Char Entity: Bill Factor

Bill Factor for Transportation

Bill Factor Id: CCAF-TRANS

Description: Transportation Allocation Factor

Char Type: REV-CLASS

Char Source: Characteristic Collection

Char Values: (for each year, the new transportation allocation factor for each revenue class must be defined)

Bill Factor for Generation

Bill Factor Id: CCAF-GEN

Description: Generation Allocation Factor

Char Type: REV-CLASS

Char Source: Characteristic Collection

Char Values: (for each year, the new generation allocation factor for each revenue class must be defined)

NOTE:

The characteristic source is characteristic collection. It is the responsibility of the background process to determine the SA's revenue class and to pass this value into the bill factor routines to retrieve the correct bill factor value.

Estimating Allocation Factors. Often the company needs to estimate the allocation factors for the new fiscal year and may adjust the values several times until the calculated allocation amounts are satisfactory. Refer to [Allocating Capital Credit](#) for more information.

Partial Retirement

In the cooperative business, it is common to never retire certain capital credit allocation amounts. The amounts that do not retire should be assigned their own subcategory.

When executing the retirement background process, the subcategory to retire may be input to the process. If you have certain subcategories that you do not retire, you would simply run the background process for the subcategories that do retire.

Cooperatives typically retire amounts and transfer the amounts to a beneficiary when a member dies. This is known as "estate retirement". Refer to [Service Credits for Capital Credit Memberships](#) for more information. If your business practice designates that certain subcategories of allocated amounts do not get retired, this probably holds true for estate retirement as well. If that is the case, your membership inactivation algorithm should be designed to only retire the appropriate amounts by subcategory.

Interface Membership Information to a Third Party

For some memberships, you may accumulate points for a third party, for example accumulating frequent flier miles for an airline. For these types of memberships, you must interface the event information to the third party.

To interface information to a third party, you may choose one of the following options:

- Design an extract program to interface the information
- Use workflow and notification to interface the information via the XAI tool

Interface Via an Extract Program

The service credit event may indicate a batch code and batch run number. Design a program to extract event information to a third party. This extract program would select service credit events marked with its batch code and the current run number.

Your service credit event must define a completion algorithm that stamps the appropriate batch code and run number. The base product provides an algorithm type to perform this logic. Refer to [SCEC-BT](#) for more information.

Other Considerations For Interfacing Info to a Third Party

Because event information is extracted to a third party, you must consider how to handle adjustments to the event amount. For example, if your event is generated based on the creation of a bill segment, what should happen if that bill segment is cancelled?

You may want to prevent these types of events from getting canceled. Validation like this may be added via a user exit or using an event cancellation algorithm.

NOTE:

Sample Algorithms. The product does not provide any base algorithms to prevent an event from being canceled.

You should allow negative event amounts to be created so that this information may also be sent to the third party's system.

Defining Loan Options

The topics in this section describe how to set up the system to enable loan functionality.

NOTE:

Loans are optional. The system configuration requirements described in this section are only relevant if your organization loans money to customers.

The Terms Of A Loan Are Stored On A Service Agreement

Loans are initiated by creating a loan service agreement for a customer. The loan service agreement (and its SA Type) contains the loan's terms:

- The **loan amount** is held in the service agreement's Total Amount to Bill.
- The **customer's periodic payment amount** is held in the service agreement's Recurring Charge Amount.
- The **number of amortization periods** (e.g., 36 months, 240 months, etc.) is held in the service agreement's Number of Payment Periods.
- If the **interest rate** is the same for all customers with this type of loan service agreement, the interest rate is defined on the service agreement's SA type (using a bill factor). A specific interest rate can be defaulted from a start option contract value. If a specific interest rate applies to the customer, the SA type's interest rate can be overridden by specifying a bill factor value on the customer's service agreement (where the bill factor value contains the specific interest rate for the customer).
- The SA type controls the **periodicity of the bills** (e.g., monthly or bi-weekly).

Because a loan is defined using a service agreement, the typical functionality that is controlled by the service agreement's SA type is supported, including:

- How and when it is billed.
- How payments are booked in the GL (and the payment priority relative to other service agreements).
- How its debt is monitored by credit and collections.
- How late payment charges are calculated.

Loan service agreements are created using [Start/Stop](#) just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above. A start option can be specified to override the SA type's interest bill factor.

NOTE:

Automatic calculation of periodic payment amount / number of periods. The system calculates a loan's periodic payment amount or number of payments (whichever is left blank). You can have the system do this on [Start/Stop Maintenance](#) (using the **Calculate** button that appears on the [start service confirmation window](#)), and on [Loan - Main](#) (by clicking the **Calculate** button). Regardless of where you do this, the calculation is performed by an algorithm on the loan's SA type. Refer to the [LPDA-SI](#) algorithm type for more information about the base package algorithm.

Payoff Balance and Current Balance for Loans

As described under [Current Amount versus Payoff Amount](#), a loan service agreement's current balance and payoff balance differ during the lifetime of the loan. Current balance contains how much the customer owes to remain current (typically their periodic payment amount), and payoff balance contains the amount the customer would have to pay to payoff the loan (typically the principal balance plus any accrued interest charges).

Unlike other SAs, loans have two accounts receivable distribution codes: long term and short term. These two codes allow the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). The current balance for a loan is always the amount of the short-term receivables. The payoff balance for a loan is always the net of the short-term receivables and the long-term receivables.

If the SA has a [special role](#) of Loan, the financial transaction algorithms supplied with the base package transfer the current amount between the long-term receivables and the short-term receivables in the GL. For example, when a bill segment is generated for the loan SA, the amount of the periodic payment is transferred from the long-term receivables to the short-term receivables. Don't worry, the examples in the following sections show exactly what these transactions look like.

An operator can see the how the bills, payments and adjustments have affected the GL, current balance and payoff balance using [SA Financial History](#).

The following sections provide examples of how adjustments, bills and payments are recorded in the GL and the subsequent effect on the current and payoff balances. When reading the examples, remember that the payoff balance is always the net of the short-term receivable and the long-term receivable balances.

Booking The Principal Amount Using An Adjustment

When a loan service agreement is activated (i.e., when its status changes from pending start to active), an adjustment is created to book the principal amount. If the customer takes out a loan of 10,000, the adjustment's financial transaction looks as follows:

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated (and an adjustment is created to book the principal)	Long Term Loan Receivable 10,000 Cash <10,000>	0	10,000	0	10,000

This adjustment is issued if:

- The service agreement's SA type indicates a [special role](#) of Loan.
- The loan service agreement's Total Amount to Bill contains an amount (i.e., the loan amount).
- The loan service agreement was created using a [start option](#) on [Start/Stop Maintenance](#) AND the start option references an [adjustment type](#) and this adjustment type has been set up as follows:
 - The adjustment type's distribution code should reference the GL account to credit (e.g., Cash).
 - The adjustment type's FT algorithm reference $\text{Payoff Amt} = \text{Adj Amt} / \text{Current Amt} = 0$ (booking principal only impacts a customer's payoff balance).

Note that because this financial transaction doesn't have a current amount (the customer doesn't actually owe a current amount yet), there is no need to book anything to the short-term receivables distribution code.

Loan Amortization Schedule Calculation

The amortization schedule is a projection of the amount of principal and interest in each payment over the life of the loan. The amortization schedule may change, for example if the interest rate changes or the customer makes an overpayment (reducing the principal balance).

A loan's amortization schedule is calculated when an operator clicks the **Calculate** button on [Loan - Main](#). Please be aware that when this button is clicked, an algorithm plugged in on the loan [SA type](#) actually calculates the amortization schedule (refer to the algorithm type [LSCH-SI](#) for more information).

Billing For Loans And Interest Calculation

A bill segment is produced for a loan when its service agreement's account is next billed.

Factors on a loan's SA type controls when a bill segment is produced for a loan. Typically SA types for loan service agreements are set up to use anniversary [calendar billing](#). For this configuration:

- You must indicate the type of anniversary billing in the calendar billing option. Currently, we only support the Anniversary Future Billing (meaning that loans are billed in advance just like a classic home loan is). Refer to [Using The Anniversary Method](#) for more information about how this billing method controls the end date of the loan bill segment.
- You must reference an [anniversary billing frequency](#) consistent with the [recurring charge frequency](#) (e.g., monthly, quarterly, etc.).

To set up for a loan that is billed on a monthly basis, you would define the following fields in SA Type - Billing:

- **Use Calendar Billing:** Anniversary Future Billing
- **Anniversary Bill Frequency:** Monthly
- **Total Bill Amount:** Required
- **Recurring Charge:** Required
- **Recurring Charge Frequency:** Monthly
- **Total Amount To Bill Label:** Loan Amount
- **Recurring Chg Amt Label:** Payment Amount

If your type of loan must be billed on an exact date (for example, always on the 15th of the month) or with an exact number of days between each bill (for example, every 14 days), then your loan should be set up to use the calendar billing option of Use Bill Period. In order for your loan bills to be created on specific dates, the system makes the following assumptions:

- Your [bill cycle schedule](#) for the loan's account is defined with the dates that you want the loan to bill and is defined with the window start date equal to the window end date.
- You define a [bill period](#) schedule corresponding to your bill cycle schedule. Each bill period schedule's bill date should match your bill cycle window start date and each bill period schedule's bill segment end date should be set to the loan period end date.
- Considerations for the first bill. If the loan SA Type's Initial Start Date Option indicates that the first day of the service agreement should be billed, then the loan SA's start date should match the window start date of the next bill cycle schedule for the account. If the loan SA Type's Initial Start Date Option indicates that first day of the service agreement should not be included, then the loan SA's start date should be one day prior to the window start date of the next bill cycle schedule for the account.
- Define your [recurring charge frequency](#) to match the frequency of your bill periods.

How the bill segment affects the customer's balance, and how it affects the general ledger are controlled by several algorithms defined on the loan service agreement's [SA type](#) and [bill segment type](#):

- The SA type's loan schedule algorithm controls how the [loan amortization schedule](#) is calculated.
- The SA type's loan interest charge algorithm controls how interest is calculated.
- The bill segment type's create algorithm controls how the bill lines are constructed.
- The bill segment type's financial algorithm controls how the general ledger is affected by the bill.

The second entry in the following table contains an example of the financial transaction produced by the base package algorithms (note, the first financial transaction in the table was described under [Booking The Principal Amount Using An Adjustment](#)).

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 10000 Cash <10000>	0	10,000	0	10,000 long-term: 10,000
First bill segment is produced	Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71>	438.71	41.66	438.71	10,041.66 short-term: 438.71 long-term: 9,602.95

Several important points are illustrated above:

- When a bill segment is produced for a loan service agreement, the following takes place (if you use a bill segment creation algorithm of Create Bill Segment for Loans):
 - The loan SA type's bill segment creation algorithm calls the SA type's loan interest charge algorithm.
 - The base package loan interest charge algorithm calculates simple interest based on: 1) unbilled principal (i.e., the service agreement's payoff balance minus the current balance), 2) the number of billing periods covered by the bill, and 3) the [interest rate](#). Refer to the algorithm type [LINT-SI](#) for more information about the base package interest calculation algorithm.

NOTE:

No interest on interest and no interest on past due amounts. Just like a classic home loan, the base package algorithms do not calculate interest on interest, nor do they calculate interest on past due amounts. If you want to levy a late payment charge, use the SA type's late payment processing. If your organization calculates interest differently, you must develop your own algorithm(s).

- The SA type's bill segment creation algorithm uses the calculated interest to format the bill segment's bill lines. It creates one bill line to show the amount of interest in the payment, and another bill line to show the amount of principal. The principal amount is equal to the service agreement's periodic payment amount minus the amount of calculated interest.
- The financial transaction illustrated above is created if you use a bill segment financial algorithm of Payoff Amt = Interest / Current Amt = Bill Amount on the loan's bill segment type. The following explains how this algorithm works:

- The SA's current balance increases by the amount of the loan's periodic payment amount (i.e., its recurring charge amount). In other words, the amount the customer thinks they owe increases by 438.71.
- The SA's payoff balance increases by the amount of interest. In other words, if the customer wanted to payoff the loan, they'd owe 10,041.66.
- The *Interest* portion of the GL accounting is straightforward (if you're an accountant). It simply takes the amount of interest and debits it to the SA type's receivable distribution code (long-term receivables) and credits it to the distribution code defined on the interest rate's bill factor (typically interest revenue).
- The *Transfer* portion of the GL accounting transfers moneys from long-term receivables (i.e., the unbilled principal) to short term receivables (the billed portion of the debt). The amount transferred is equal to the FT's effect on the service agreement's current balance, allowing the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Remember that the payoff balance is the net of the short-term and long-term receivables.

Paying What Is Owed

When a payment is made for a loan:

- The service agreement's payoff amount is reduced by the payment amount.
- The service agreement's current amount is reduced by the payment amount.

The events that happen when a customer makes a payment against a loan is controlled by the FT algorithm plugged in on the loan service agreement's payment segment type. We'll use an example to help explain how this algorithm works. The 3rd entry in the following table illustrates the financial transaction produced when a payment is made (note, the first two financial transactions were described above).

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan Receivable 10000	0	10,000	0	10,000
	Cash <10000>				long-term: 10,000
First bill segment is produced	Interest:	438.71	41.66	438.71	10,041.66
	Long Term Loan Receivable 41.66				short-term: 438.71
	Interest Revenue <41.66>				long-term: 9,602.95
	Transfer Long Term To Short Term:				
	Short Term Loan Receivable 438.71				
	Long Term Loan Receivable <438.71>				
Payment is made	Affect Cash	-438.71	-438.71	0	9,602.95
	Cash 438.71				short-term: 0
	Long Term Loan Receivable <438.71>				long-term: 9,602.95
	Transfer Long Term To Short Term:				

Long Term Loan
 Receivable 438.71
 Short Term Loan
 Receivable <438.71>

The financial transaction illustrated above is created if you use a payment segment FT creation algorithm of Payoff Amt = Current Amt = Pay Amt on the loan's payment segment type. The following explains how this algorithm works:

- The SA's current balance decreases by the amount of the payment amount. In other words, the customer thinks they owe 0 after the payment. Note refer to [Overpayments](#) for information about how an overpayment affects the SA's balances and the general ledger.
- The SA's payoff balance decreases by the amount of the payment. In other words, if the customer wanted to payoff their loan, they'd owe 9,602.95.
- The *Cash* portion of the GL accounting is straightforward (if you're an accountant). It simply takes the amount of the payment and debits it to the payment segment type's distribution code (typically cash) and credits it to the SA type's receivable distribution code (long-term receivable).
- The *Transfer* portion of the GL accounting effectively reduces short-term receivables by the FT's effect on the customer's current balance. This reduction is handled by an offsetting increase to long-term receivables (to make up for reduction made when the cash was applied). Again, this differentiation between short-term and long-term receivables allows the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term).

Overpayments On Loans

You can determine whether you want to accept loan overpayments. Overpayments reduce the principal amount (the amount owed on the loan), which follows the philosophy adopted by a typical home loan.

When the payment is made, any overpayments are distributed according to the overpayment distribution algorithm defined for the customer class. Any customer classes for which you want to allow loan overpayments should use an overpayment distribution algorithm that keeps the overpayment on the loan SA.

When the payment transaction is frozen, the system checks to see if there is a credit amount on the loan SA's current balance. If a credit exists, the customer has made an overpayment and an adjustment is created to zero out the current balance and transfer the amount of the credit from the SA's short-term receivable to long-term receivable. The adjustment may appear on the customer's next bill to show the additional amount paid against the principal.

The algorithm that controls this adjustment to remove the credit on current balance is plugged in on the loan service agreement's SA type and is applied on the SA Type - Payment Freeze system event.

The third and fourth entries in the following table illustrate an overpayment (note, the first two financial transactions were described above).

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan	0	10,000	0	10,000
	Receivable 10000				
	Cash <10000>				
First bill segment is produced	Interest:	438.71	41.66	438.71	10,041.66
	Long Term Loan				short-term: 438.71
	Receivable 41.66				long-term: 9,602.95
	Interest Revenue <41.66>				

	Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71>				
Payment is made (with an overpayment of 200.00)	Affect Cash Cash 638.71 Long Term Loan Receivable <638.71> Transfer Long Term To Short Term: Long Term Loan Receivable 638.71 Short Term Loan Receivable <638.71>	-638.71	-638.71	-200.00	9,402.95 short-term: <200.00> long-term: 9,602.95
Create adjustment to remove SA's credit.	Transfer Short Term Credit to Long Term: Short Term Loan Receivable 200.00 Long Term Loan Receivable <200.00>	200.00	0	0	9,402.95 short-term: 0 long-term: 9,402.95

In the third financial transaction illustrated above, the billed amount of the payment works essentially the same as that illustrated under [Paying What Is Owed](#). If the Keep Overpayment on Loan SA algorithm is plugged in on the overpayment distribution event on the customer class, the overpayment amount is applied to the loan SA, creating a credit on the SA's current balance. The following explains how this algorithm works:

- If the account has an loan SA and there is an excess credit, the credit is applied to the loan SA (as long as this does not cause the loan SA to have a credit payoff balance).
- If there is not a loan SA to which the credit can be applied, the algorithm checks to see if there is an open excess credit SA for the account.
 - If so, the excess credit amount is applied to the excess credit SA.
 - If not, the algorithm creates an excess credit SA and applies the amount to this SA.

The fourth financial transaction illustrated above is created if the Create Adjustment to Remove SA's Credit algorithm is plugged in on the loan's SA type's payment freeze event. The following explains how this algorithm works:

- If the SA's current balance is less than zero, the algorithm creates a frozen adjustment that removes the credit by transferring the credit from the short-term receivable to the long-term receivable. This adjustment ID is captured on the pay segment so the adjustment can be canceled if the payment is later canceled. Note that the adjustment cancel reason used by the system in this case is specified on the Financial Transaction Options [Feature Configuration](#) using the Adjustment Cancel Reason For Payment Linked To Adjustment option type.
- The SA's current balance increases by the amount of the credit transfer. In other words, the customer thinks they owe 0 after the transfer.
- The SA's payoff balance doesn't change because the payoff balance is always the net of the short-term and long-term receivables. In other words, if the customer wanted to payoff their loan, they'd still owe 9,402.95.

NOTE:

Overpayments and interest. The base package interest calculation algorithm (plugged in on the loan's SA type) does not take into consideration the exact date that the overpayment is made when calculating the interest for the period. It only takes into consideration the outstanding principal amount (payoff balance - current balance) at the time of the interest calculation.

Adjusting Loan Amounts

You would issue ad hoc adjustments if you need to change a loan's payoff and/or current balance outside of the normal billing / payment functions.

An adjustment can:

- Reduce a loan's payoff balance.
- Reduce a loan's current balance (i.e., how much the customer thinks they currently owe).
- Reduce both the loan's payoff and current balance.

For adjustments that affect payoff amount only:

- These adjustments are used to change the principal owed, e.g., if an additional amount is loaned.
- The adjustment's adjustment type should reference the Payoff Amt = Adj / Current Amt = 0 FT algorithm.
- GL lines will be generated to reflect the change to principal.

For adjustments that reduce current amount only:

- These adjustments can be used to change the amount that the customer must pay as part of the next bill.
- The adjustment's adjustment type should reference the Payoff Amt = 0 / Current Amt = Adj Amount (no GL) FT algorithm.
- Typically, GL lines are not generated for FTs that only affect the customer's current balance. However, moneys must be transferred from long to short in the amount of the adjustment (as described above under [Payoff Balance and Current Balance for Loans](#)).

For adjustments that reduce both payoff and current amount:

- These adjustment types can be used to levy additional charges, such as late fees, or to correct interest calculations.
- The adjustment's adjustment type should reference the Payoff Amt = Adj / Current Amt = Adj FT algorithm.
- GL lines are generated to reflect the change to principal. In addition, GL lines must be generated to transfer money from long to short in the amount of the adjustment (as described above under [Payoff Balance and Current Balance for Loans](#)).

NOTE:

Adjustments that affect the principal balance (payoff balance - current balance) affect the term of the loan because interest is based on the principal balance.

Adjustments can cause credit balances to exist. If you credit the loan SA, it is possible for the current balance to become negative. You may need to create additional adjustments that affect the current amount, depending on whether the customer needs to pay this amount as part of the next payment.

Writing Off Loans

Loans are written off using the standard write-off processing.

FASTPATH:

Refer to [The Big Picture Of Write Off Processing](#) for background information.

We illustrate the classic financial transactions that transpire to financially write-off a loan to help illustrate important points (these are the fourth and fifth entries in the following table):

Event	GL Accounting	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
Loan service agreement is activated	Long Term Loan	0	10,000	0	10,000
	Receivable 1000				long-term: 10,000
	Cash <1000>				
First bill segment is produced	Interest:	438.71	41.66	438.71	10,041.66
	Long Term Loan				short-term: 438.71
	Receivable 41.66				long-term: 9,602.95
	Interest Revenue <41.66>				
	Transfer Long Term To Short Term:				
	Short Term Loan Receivable 438.71				
Payment is made (with an overpayment of 200.00)	Long Term Loan Receivable <438.71>				
	Affect Cash	-638.71	-638.71	-200.00	9,402.95
	Cash 638.71				short-term: <200.00>
	Long Term Loan Receivable <638.71>				long-term: 9,602.95
	Transfer Long Term To Short Term:				
	Long Term Loan Receivable 638.71				
Create adjustment to remove SA's credit.	Short Term Loan Receivable <638.71>				
	Transfer Short Term Credit to Long Term:	200.00	0	0	9,402.95
	Short Term Loan Receivable 200.00				short-term: 0
	Long Term Loan Receivable <200.00>				long-term: 9,402.95
Sync up current with payoff balance	Transfer Long Term To Short Term:	9,402.95	0	9,402.95	9,402.95
	Short Term Loan Receivable 9,402.95				short-term: 9,402.95
	Long Term Loan Receivable <9,402.95>				long-term: 0
Transfer balance to a write-off SA	Transfer From Loan SA:	-9,402.95	-9,402.95	0	0

Write Off Xfer
Clearing 9,402.95

Long Term Loan
Receivable
<9,402.95>

Long Term Loan
Receivable 9,402.95

Short Term
Loan Receivable
<9,402.95>

Transfer To Write Off
SA:

Bad Loans Expense
9,402.95

Write Off Xfer
Clearing <9,402.95>

Note, these will
cause a balance of
9,402.55 to exist on
the write-off service
agreement.

The only unusual portion of the last two financial transactions is the impact on short and long term receivables. Please see the examples above under [Billing For Loans And Interest Calculation](#) and [Paying What Is Owed](#) to understand how any impact to a loan's current balance causes this type of financial transfer to occur.

Distribution Codes for Loans

As explained above under [Payoff Balance and Current Balance for Loans](#), loans have two accounts receivable distribution codes: long term and short term. These two codes allow the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Both receivables distribution codes are defined on the loan SA type.

In addition, loans have a distribution code used to book interest revenue. The interest revenue distribution code is defined on the loan's bill factor value for a revenue class (defined on the loan's SA type). For example, on the bill factor you can use one distribution code to book interest revenue from the residential revenue class and another distribution code to book interest revenue from the commercial revenue class. In this example, you create two loan SA types, one for residential revenue and the other for commercial revenue.

Loans may also have a bad loan debt (expense) distribution code that is used when writing off a loan. The bad loan debt distribution code is defined on the loan's write-off service agreement type. Refer to [Defining Credit & Collections Options](#) for more information.

Setting Up The System To Enable Loans

The above topics provided background information about how loans are supported in the system. The following discussion summarizes the various setup tasks alluded to above.

Distribution Code

You must set up the following [distribution codes](#):

- Long term receivables
- Short term receivables
- Interest revenue
- Bad loan debt

Adjustment Types

The following adjustment types are needed:

- Activate a loan. This should reference a distribution code associated with cash or the cash equivalent and an FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt} = 0$.

NOTE:

Creating Checks for Loan Amounts. If you want the system to initiate a check to the customer for the loan amount, the loan activation adjustment type should indicate an **A/P Request Type Code**. Refer to [Controls The Interface To A/P & 1099 Reporting](#) for more information.

- Remove Credit (Overpayment). This adjustment should reference an FT algorithm of $\text{Payoff Amt} = 0 / \text{Current Amt} = \text{Adj Amount}$ (no GL). Even though this algorithm indicates that there is no effect on the GL, there is a special exception built in for loan SAs. The special exception creates GL details to transfer the current balance (short-term receivable) to the long-term receivable. Refer to [Overpayments](#) for more information.

NOTE:

Printing Overpayments on Bills. If you want the overpayment adjustment to appear on customers' bills, turn on **Print by Default** and enter a **Description on Bill** (e.g. "Additional Principal"). For more information, refer to [Controls Information Printed On The Bill](#).

- Adjustment types to perform any of the adjustments described under [Adjusting Loan Amounts](#).

Adjustment Type Profile

Create an adjustment type profile that references the adjustment types used on a loan. Besides the above adjustment types, it should also reference adjustment types to levy late payment charges (if applicable), levy non-sufficient funds charges (if applicable), refund overpayments (if applicable), sync current balance with payoff balance at write-off time, transfer balances to a write-off service agreement, and write-down small balances.

Algorithms

Add the following [algorithms](#):

- Overpayment Distribution. This algorithm is later plugged in on the customer class for the Overpayment Distribution system event. Refer to the algorithm type [OVPI-LO-CSA](#) for more information about the base package algorithm.

- Bill Segment Creation for Loans. This algorithm is later plugged in on the loan's bill segment type. Refer to the algorithm type [BSBS-LO](#) for more information about the base package algorithm.
- Bill Segment Financial Transaction Creation for Loans. This algorithm is later plugged in on the loan's bill segment type. Refer to the algorithm type [BSBF-LO](#) for more information about the base package algorithm.
- Amortization Schedule. This algorithm is later plugged in on the SA type for the Loan Schedule system event. Refer to the algorithm type [LSCH-SI](#) for more information about the base package algorithm.
- Interest Calculation. This algorithm is later plugged in on the SA type for the Loan Interest Charge system event. Refer to the [LINT-SI](#) algorithm type for more information about the base package algorithm.
- Payment Periods/Payment Amount Calculation. This algorithm is later plugged in on the SA type for the Loan Periods and Amount system event. Refer to the algorithm type [LPDA-SI](#) for more information about the base package algorithm.
- Loan SA Payment Freeze. This algorithm has a parameter that must reference the Remove Credit adjustment type defined above. This algorithm is later plugged in on the SA type for the Payment Freeze system event. Refer to the algorithm type [STPZ-RMVCR](#) for more information about the base package algorithm.

Bill Factor

You must set up a [bill factor](#) that defines the interest rate. If you have different interest rates for different types of loans, you can create a separate bill factor for each or you can use start options to override the interest rate.

On the bill factor's [bill factor value](#), make sure to reference the GL distribution code used to book interest revenue for the revenue class specified on the loan's SA type.

Customer Class

Any [customer class](#) on which you want to allow overpayments for a loan must use the overpayment distribution algorithm defined above. The overpayment distribution algorithm keeps the overpayment on the loan SA rather than transferring it to an excess credit SA, allowing a subsequent adjustment to apply the overpayment to the principal balance.

Bill Segment Type

Create a bill segment type that references the bill segment creation algorithm defined above and the FT creation algorithm defined above.

Frequency

Create [frequency](#) codes to correspond to the frequency of your loans. When setting up your SA types, you must indicate a recurring charge frequency and, if you use the Anniversary Billing Option, you must indicate an anniversary frequency.

Bill Period

If you use the Use Bill Period option, set up a bill period with an appropriate schedule of dates for billing your loan.

Bill Cycle Schedule

If you use the Use Bill Period option, the bill cycle schedule for these types of loans should be defined with an appropriate schedule of dates for billing your loan.

Collection, Severance and Write Off Processes

You should set up the appropriate credit and collections information. Refer to [Defining Credit & Collections Options](#) for more information.

SA Type

You must set up a [SA type](#) for your loan service agreements (you may need multiple SA types if you have different business rules for different types of loans). The following points describe the minimal requirements for a loan SA type.

SA Type - Main

Define the following options:

- **Distribution Code** should be a long-term receivable code.
- **Service Type** should reference something like "Miscellaneous Service".
- Specify the **Revenue Class** that, together with the interest bill factor, determines the distribution code used to book the loan interest revenue.
- **Start Option** should be turned on.
- The Payment Segment Type should reference the Normal Payment. The base package payment segment financial algorithm ($\text{Payoff Amt} = \text{Current Amt} = \text{Pay Amt}$) used for Normal Payment pay segment types creates the additional GL details to transfer the credit from long-term receivables to short-term receivables if the SA's special role is Loan.
- Turn on **Late Payment Charge** if applicable.
- Define an appropriate **Adjustment Type (Synch Current)** that will cause current balance to be synchronized with payoff balance (if the loan is [written off](#)).

SA Type - Detail

Define the following options:

- **Special Role** is Loan.
- Specify the **Interest Bill Factor** set up above. You can use start options to override.
- Use **Override Interest Flag** to indicate whether the interest rate defined on the interest bill factor may be overridden at the SA level. If you select Allowed, the interest rate may be overridden by a contract value on a start option or the SA.
- Use the short-term receivable account defined above as the **Loan A/R Distribution Code**. If you do not want the system to differentiate between short-term receivables and long-term receivables, make the loan A/R distribution code the same as the distribution code (above).

SA Type - Billing

FASTPATH:

For an overview of some of these options, be sure to refer to [Billing For Loans And Interest Calculation](#) for more information.

Define the following options:

- The **Bill Segment Type** should reference the value created above.
- **Characteristic Premise Required** should not be checked. (A loan SA is not a premise-based service. SA types that have this box checked are filtered out of the SA type search when the start method is Start a SA, so users will never be able to start a loan SA that requires a characteristic premise.)
- **Use Calendar Billing** must equal Anniversary Future Billing or Use Bill Period.
- **Bill Period** is required for the Use Bill Period option.
- **Anniversary Billing Frequency** is required for the Anniversary Future Billing option and must equal the periodicity of the bills (monthly, weekly, etc.).
- **Total Bill Amount** is required (it holds the principal).
- **Total Amount To Bill Label** should reference something like "Loan Amount".
- **Recurring Charge** is required (it holds the periodic payment amount).
- **Recurring Chg Amt Label** should reference something like "Payment Amount".
- **Recurring Charge Frequency** is required (it defines the periodicity associated with the recurring charge amount) and must be the same as the bill period frequency or the anniversary billing frequency (based on your **Use Calendar Billing** option).

SA Type - Rate

Turn off the **Rate Required** switch as loans do not use rates.

SA Type - SP Type

Turn off the **Service Points Required** switch as loans do not have service points.

SA Type - Adjustment Profile

Adjustment Type Profile should reference the profile set up above.

SA Type - Credit and Collections

The credit and collections information should reference a **Severance Process Template** that simply expires the loan. The **Debt Class** and **Write Off Debt Class** should reference an appropriate value consistent with your credit and collections rules. Refer to [Defining Credit & Collections Options](#) for more information.

SA Type - Algorithms

The Loan Schedule, Loan Interest Charge, Loan Periods, and Amounts and Payment Freeze [algorithms](#) defined above must be set up.

Start Options

Loans require a start option to define the adjustment type that is used to create the adjustment to book the initial principal amount when the loan is activated. Loan start options can also specify default values for loan amount, payment amount, and number of periods.

Create at least one start option for each loan SA type. The following information should be defined:

- **Adjustment Type** should reference the adjustment type defined above to book principal.
- **Recurring Charge Amount** (Payment Amount) should only be defined if you have standard loan payments.
- **Total Amount To Bill** (Loan Amount) should only be defined if you have standard loan amounts.
- **Number of Payment Periods** should be the number of payment periods in the loan (if you have a standard loan period).
- If you want to define a set of standard APRs for a loan SA Type, set up a **Contract Value** on the Rate Info page. The **Bill Factor** should match the interest bill factor specified on the [SA Type](#).

Defining Non-Billed Budget Options

A Non-Billed Budget (NBB) is a payment plan that allows your customers to pay set amounts at specified intervals (e.g. every two weeks). Non-Billed Budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. As the name suggests, bills are not created for the Non-Billed Budget's scheduled payments; customers must remember to make their payments at the scheduled intervals. The topics in this section describe how to design and set up non-billed budgets.

NOTE:

Non-Billed Budgets are optional. The system configuration requirements described in this section are only relevant if your organization offers Non-Billed Budgets.

What Is A Non-Billed Budget?

A Non-Billed Budget is a special type of budget or payment plan that encompasses three major elements:

- A set of scheduled payments
- The business rules used to recommend and potentially renew the payment schedule
- The business rules that govern the financial impact on the current and payoff balances of the SAs covered by the payment schedule

Non-Billed Budgets are managed via a service agreement whose SA type has a special role of Non-Billed Budget. If an SA type has a special role of Non-Billed Budget it must have one or more recommendation rules, and SAs of that type are allowed to have payment schedules.

The Financial Impact Of Non-Billed Budgets

When you set up the Non-Billed Budget SA type, you can indicate whether the Non-Billed Budget is monitored by the [account debt monitor](#) process. The following sections contain examples of financial transactions for Non-Billed Budgets that are monitored by the account debt monitor.

NOTE:

Unmonitored Non-Billed Budgets. SAs that are covered by unmonitored Non-Billed Budgets are subject to different financial treatment than those that are monitored. The [financial transactions relevant for unmonitored Non-Billed Budgets](#) are discussed later.

Current Amount For SAs Covered By A Non-Billed Budget

As described under [Current Amount versus Payoff Amount](#), the values of the current balance and payoff balance are the same for most financial transactions. One exception is for SAs that are covered by a Non-Billed Budget in which case the current balance is always zero and the payoff balance is always the amount the customer really owes.

When a Non-Billed Budget is activated or an SA is added to a Non-Billed Budget, the system creates adjustments for all affected SAs to set the current amount equal to zero. The adjustment type that references the Payoff Amt = 0 / Current Amt = Adj Amount (no GL) algorithm is taken from the SA's SA type.

NOTE:

Non-Billed Budgets and Open Item Accounts. If the Non-Billed Budget is for an open item account, no match event is created for the financial transaction that reduces the current amount to zero. This FT must be manually matched if required.

The following example shows the effect of activating a Non-Billed Budget that covers an electric SA with a current balance of 25. The transactions for the electric SA are illustrated on the right and the transactions for the non-billed budget SA are illustrated on the left.

Event	Effect On	Effect On	Current	Payoff	Effect On	Effect On	Current	Payoff
	Current	Payoff			Current	Payoff		
	Balance	Balance			Balance	Balance		
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				

By setting the current balance for the covered SAs to zero, the SAs are insulated from the regular debt monitoring process. Depending on the Non-Billed Budget [recommendation algorithm](#), the payoff balance can be ignored, divided evenly between the scheduled payments or added to the first scheduled payment.

Activating a Non-Billed Budget has no affect on its own current or payoff balances.

Scheduled And Actual Payments On The Non-Billed Budget

When a scheduled payment is due, an adjustment is created to increase the Non-Billed Budget's current balance by the expected amount. The current balance on the SA can be monitored to ensure that payments are being made on time.

When the payment is made, the Non-Billed Budget's current balance is reduced to zero and the Non-Billed Budget's payoff balance reflects the accumulated credit from the payment. This accumulated credit is transferred to the covered SAs when the next bill for the account is completed.

The following example illustrates scheduled and actual payments for the Non-Billed Budget in the previous example. The amount of the scheduled Non-Billed Budget payments is 10. Note that the first two transactions were described above.

Event	Effect On	Effect On	Current	Payoff	Effect On	Effect On	Current	Payoff
	Current	Payoff			Current	Payoff		
	Balance	Balance	Balance	Balance	Balance	Balance	Balance	Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0
Payment					-10	-10	0	-10

An algorithm (Process NBB Scheduled Payment) plugged in on the Non-Billed Budget SA type creates the appropriate financial transactions when the scheduled payment is due. The algorithm is called by the Non-Billed Budget Scheduled Payment Processing ([NBBPS](#)) background process.

The normal payment processing handles the adjustments created when the payment is made.

NOTE:

Non-Billed Budget Payment Cancellation. If a payment is canceled, the financial transaction is reversed.

Automatic Payments And Non-Billed Budgets. Users may set up a Non-Billed Budget to use [automatic payments](#) by setting up the account's auto pay options. Users may also exclude the Non-Billed Budget from automatic payment if the account is set up for automatic payment. The [NBB Scheduled Payment Automatic Payment Create](#) background process calls the [Auto Pay Creation](#) algorithm to create the auto payment for a Non-Billed Budget.

Overpayments for Non-Billed Budgets

Typically, payments in excess of the Non-Billed Budget's current balance are credited to an overpayment (excess credit) SA. When the next adjustment is created for a scheduled payment, the credit on the overpayment SA is used to relieve the non-billed budget current balance.

NOTE:

Overpayment Distribution Algorithm. The overpayment distribution is a function of the overpayment distribution algorithm plugged in on the account's customer class. We strongly recommend that the Non-Billed Budget SA type be

set up so that overpayment is not allowed. Any excess payments should go to an overpayment SA. For more information about overpayment distribution, refer to [Overpayment Segmentation](#).

In the example below, the customer pays 20 for a scheduled payment instead of 10. The non-billed budget SA is illustrated on the right and the overpayment SA is illustrated on the left. The electric SA is not illustrated in the example below because scheduled payments, payments and overpayments have no effect on covered SAs. The first four transactions were illustrated above.

Event	Effect On	Effect On	Current	Payoff	Effect On	Effect On	Current	Payoff
	Current Balance	Payoff Balance	Balance	Balance	Current Balance	Payoff Balance	Balance	Balance
Non-Billed Budget SA				Overpayment SA				
Starting balance								
Non-Billed Budget is activated								
First scheduled payment is due	10	0	10	0				
Payment	-10	-10	0	-10				
Second scheduled payment is due	10	0	10	-10				
Over-payment	-10	-10	0	-20	-10	-10	-10	-10
Third scheduled payment is due	10	0	10	-20				
Transfer Adjustment	-10	-10	0	-30	10	10	0	0

After the Process NBB Scheduled Payment algorithm creates the next scheduled payment, it looks for a credit amount on the overpayment SA and creates an adjustment to transfer the credit balance (or the amount of the payment if the credit is more than the scheduled payment amount) from the overpayment SA to the non-billed budget SA. The overpayment transfer adjustment type and the overpayment SA type are specified as parameters to the algorithm.

Underpayments For Non-Billed Budgets

An insufficient payment or a canceled payment leaves a current balance on the Non-Billed Budget SA.

In the example below, the customer makes a payment of 7 for the fourth scheduled payment. The example below does not show the overpayment SA (illustrated above). The first eight transactions are discussed above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0
Payment					-10	-10	0	-10
Second scheduled payment is due					10	0	10	-10
Over- payment					-10	-10	0	-20
Third scheduled payment is due					10	0	10	-20
Transfer Adjustment					-10	-10	0	-30
Fourth scheduled payment					10	0	10	-30
Underpayment					-7	-7	3	-37

The Process NBB Scheduled Payment algorithm creates a trigger to ensure that the current balance is monitored by the account debt monitor. Refer to [Credit And Collections And Non-Billed Budgets](#) for more information.

Billing For SAs Covered By The Non-Billed Budget

When the next bill for the account is completed, the credit on the Non-Billed Budget is transferred to the covered SAs. The credit is prorated over the covered SAs according to the relative payoff balances on each SA.

In the example below, the electric SA's bill is 33. The first ten transactions are discussed above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				

Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0
Payment					-10	-10	0	-10
Second scheduled payment is due					10	0	10	-10
Over-payment					-10	-10	0	-20
Third scheduled payment is due					10	0	10	-20
Transfer Adjustment					-10	-10	0	-30
Fourth scheduled payment					10	0	10	-30
Underpayment					-7	-7	3	-37
Bill	0	33	0	58				
Bill completion (transfer adjustment)	0	-37	0	21	0	37	3	0

When a bill segment financial transaction is created, the current amount is set to zero for SAs that are covered by the Non-Billed Budget (if you use a bill segment FT algorithm of $\text{Payoff Amt} = \text{Bill Amt} / \text{Current Amt} = \text{Amt Due}$). Though not evident by the name, the $\text{Payoff Amt} = \text{Bill Amt} / \text{Current Amt} = \text{Amt Due}$ algorithm does set the current amount to zero for monitored Non-Billed Budgets. (For SAs with other roles, the current amount is equal to the amount due or the recurring charge.)

A bill completion algorithm transfers money from the Non-Billed Budget to the covered SAs (if you plug in the NBB Credit Transfer bill completion algorithm on the Non-Billed Budget SA type). The algorithm type supplied with the base package distributes the credit using the method described in [Distributing Non-Billed Budget Credit](#).

NOTE:

Canceled Bill Segments. No new processing occurs when a bill segment is canceled; any credit balance remains on the covered SA.

Distributing Non-Billed Budget Credit

Both the NBB Credit Transfer bill completion algorithm type and the Non-Billed Budget SA stop algorithm type supplied with the base package use the same method of distributing a credit from a Non-Billed Budget SA to the covered SAs. The following points describe how the credit is distributed:

- Covered SAs that are already in credit (due to some other circumstance, such as a cancellation and rebill) are excluded from the distribution.
- The distribution to each covered SA will not exceed its total payoff to ensure that none of the covered SAs have a credit balance.
- The credit is prorated over the covered SAs according to the relative payoff balances on each SA.
- The calculation of the payoff balance is adjusted to exclude the current balance to ensure that the credit is prorated over the debt covered by the budget, not any ad-hoc debt for the SA.

NOTE:

The current balance on covered SAs should always be zero. The only exception occurs if an adjustment has been added that directly affected the SA balance. In this case, the distribution assumes that the balance is outside the non-billed budget and needs to be paid separately.

- Any excess credit remains on the Non-Billed Budget SA until the next distribution takes place or until the [Non-Billed Budget SA is stopped](#).
- The type of adjustments created is determined by the **Adjustment Type (Xfer)** specified on the Non-Billed Budget SA type.

The examples in the table below illustrate the points above.

NBB SA Credit	SA 1 Payoff	SA 1 Current	SA 2 Payoff	SA 2 Current	SA 1 Credit Xfer	SA 2 Credit Xfer
-100.00	-100.00	0.00	-200.00	0.00	0.00	0.00
-100.00	150.00	0.00	-50.00	0.00	-100.00	0.00
-300.00	150.00	0.00	50.00	0.00	-150.00	-50.00
-100.00	150.00	0.00	250.00	0.00	-37.50	-62.50
-100.00	150.00	0.00	250.00	50.00	-42.86	-57.14

The first example above shows that covered SAs with a credit balance are excluded from the distribution. Any excess credit remains on the Non-Billed Budget.

The second example shows that one covered SA has a credit balance, so the entire credit is distributed to the remaining SA.

The third example shows the amount distributed to a covered SA does not exceed its payoff balance. Again, any excess credit remains on the Non-Billed Budget SA.

The fourth example illustrates how the credit is prorated based on the payoff balance. The fifth example illustrates the same prorating but with a current balance on one of the SAs (SA 2). (Remember that the prorating excludes any current balance.)

The prorated amount is calculated by subtracting the current balance from the payoff balance then multiplying the result by the distribution amount and dividing by the total payoff owing of all covered SAs.

Stopping an SA Covered By a Non-Billed Budget

If a service agreement covered by a Non-Billed Budget is stopped, the system must bring the current balance and payoff balance of the covered SA back in synch. The system creates an adjustment using the Synch Current adjustment type from the SA's SA type.

In the example below, the electric SA's payoff balance is 21. The first twelve transactions are discussed above.

Event	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance	Effect On Current Balance	Effect On Payoff Balance	Current Balance	Payoff Balance
	Electric SA				Non-Billed Budget SA			
Starting balance	0	0	25	25				
Non-Billed Budget is activated	-25	0	0	25				
First scheduled payment is due					10	0	10	0
Payment					-10	-10	0	-10
Second scheduled payment is due					10	0	10	-10
Over- payment					-10	-10	0	-20
Third scheduled payment is due					10	0	10	-20
Transfer Adjustment					-10	-10	0	-30
Fourth scheduled payment					10	0	10	-30
Underpayment					-7	-7	3	-37
Bill	0	33	0	58				
Bill completion (transfer adjustment)	0	-37	0	21	0	37	3	0
SA is stopped	21	0	21	21				

NOTE:

In addition to syncing the current and payoff balance, the SA being stopped is removed from the covered SAs collection. When the last covered SA is removed from the collection, the Non-Billed Budget is also [stopped](#).

Financial Transactions For Unmonitored Non-Billed Budgets

Some companies have the concept of non-billed budgets where the payments made by the customer are optional. This functionality is implemented as an unmonitored Non-Billed Budget. Unmonitored Non-Billed Budgets allow a customer to make optional prepayments towards a bill.

As explained previously, unmonitored Non-Billed Budgets receive different financial treatment than monitored Non-Billed Budgets. The financial transaction algorithms use the **Non-Billed Budget Monitor** flag on the Non-Billed Budget's SA type to create the appropriate financial transactions. The following table describes the differences in the financial treatment of monitored and unmonitored Non-Billed Budgets.

System Event	Monitored Non-Billed Budgets	Unmonitored Non-Billed Budgets
When a Non-Billed Budget is activated or an SA is added to a Non-Billed Budget...	The system creates adjustments for all affected SAs to set the current balance equal to zero.	The current balances for covered SAs are not zeroed. The activate SA and Non-Billed Budget maintenance processing do not create any adjustments if the Non-Billed Budget is unmonitored.
When a scheduled payment is due...	An adjustment is created to increase the Non-Billed Budget's current balance by the expected amount.	There is no change to the Non-Billed Budget's current balance; it is always zero. The scheduled payment processing background process does not execute the NBB process scheduled payment algorithm .
When the payment is made...	The Non-Billed Budget's current balance is reduced to zero and the Non-Billed Budget's payoff balance reflects the accumulated credit from the payment.	Typically the payments are distributed to an excess credit (overpayment) SA. Refer to Distributing Payments for Unmonitored Non-Billed Budgets for more information.
When a bill segment financial transaction is created...	The current amount is set to zero for SAs that are covered by the Non-Billed Budget.	The covered SAs' current amounts are equal to their payoff amounts.
At bill completion...	Money from the Non-Billed Budget is transferred to the covered SAs. Customers may receive a bill for information purposes, but they are not required to pay it.	Money from the overpayment SA is transferred to the account's SAs. The customer is still liable to pay the outstanding balance.
When the Non-Billed Budget is stopped or an SA is removed from a Non-Billed Budget...	The system creates adjustments for all affected SAs to synchronize their current balances with their payoff balances, thus removing the zero current balance and replacing it with the actual current balance.	There is no change to the current balances for covered SAs as the balances already reflect the actual current balance.

Unmonitored Non-Billed Budgets also receive different credit and collections treatment. Refer to [Credit and Collections and Unmonitored Non-billed Budgets](#) for more information.

Distributing Payments for Unmonitored Non-Billed Budgets

For Non-Billed Budgets, payments are distributed according to the payment and overpayment algorithms on the customer class. The base package payment distribution algorithm applies a payment first towards any SAs that have overdue or current balances (refer to [Distributing A Payment](#) for more information). Since the unmonitored Non-Billed Budget SA doesn't have a current balance, it is not considered by the payment distribution algorithm. If there aren't any SAs with a current balance, the overpayment distribution algorithm handles the remaining credit. You can elect to:

- Apply the overpayment to an excess credit SA. This is the method that we strongly recommend because all financial transactions are then a function of the normal payment, overpayment and billing processes.

- Apply the overpayment to the highest priority SA that is eligible for overpayment (as specified on the SA type). You can use this method to apply the overpayment to the unmonitored Non-Billed Budget SA. If you use this method, you must also set up the system to [transfer the credit from the unmonitored Non-Billed Budget](#).

NOTE:

Use **An Excess Credit SA**. We strongly recommend that payments for unmonitored Non-Billed Budgets are distributed to an excess credit SA. In this case, the Non-Billed Budget is just a shell to hold the covered SAs and recommend a payment schedule; all financial transactions are a function of the normal payment, overpayment and billing processes.

FASTPATH:

Refer to [Overpayment Segmentation](#) for a detailed discussion of overpayment distribution options.

Transferring Credit from Unmonitored Non-Billed Budgets

If you distribute an overpayment to an unmonitored Non-Billed Budget SA (i.e. the unmonitored non-billed budget maintains a credit balance instead of an overpayment SA), you must plug-in a bill completion algorithm on the SA type to transfer the credit balance to the covered SAs at bill completion time. The bill completion algorithm type ([BCMP-NB](#)) supplied with the base package transfers the credit balance to the covered service agreements when the bill is completed. Additionally, the **Adjustment Type (Xfer)** on unmonitored Non-Billed Budget SA types should reference a FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt} = \text{Adj}$ to ensure that the credit is removed from both the current and payoff balances.

WARNING:

You must create your own SA stop algorithm type for correctly stopping an unmonitored non-billed budget that maintains a credit balance. The SA stop algorithm that is supplied with the base package does NOT transfer remaining credit from the unmonitored Non-Billed Budget SA. (The base package SA stop algorithm transfers the remaining credit using the overpayment distribution algorithm on the customer type, which you have set up to transfer to back to the unmonitored non-billed budget.)

Designing Non-Billed Budgets

The topics in this section describe functionality that you must consider when designing non-billed budgets.

Making SAs Eligible For Non-Billed Budgets

A billable SA may be covered by a Non-Billed Budget when its SA type is flagged as Eligible for Non-Billed Budget.

All SAs that are eligible for non-billed budgets should reference a bill segment type that uses the $\text{Payoff Amt} = \text{Bill Amt} / \text{Current Amt} = \text{Amt Due}$ bill segment FT algorithm. This algorithm sets the SA's current amount to zero if it is covered by a monitored Non-Billed Budget.

A list of the SAs covered by a Non-Billed Budget is maintained with the non-billed budget SA. This list is used at bill completion to determine the financial transactions that should occur.

Designing Recommendation Rules

Users (and the renewal process) ask the system to recommend the scheduled payments for a Non-Billed Budget. In general, this recommendation process must establish:

- The amount to be paid
- The dates on which the payments are due

We envision many different types of recommendation rules. For example:

- Recommend 26 scheduled payments to be made on a fortnightly basis that are due on Tuesdays.
- Recommend monthly payments that are due on the nearest workday after the 10th of the month.
- Recommend scheduled payments where the customer pays their annual charges in 10 out of 12 months where the payments are not due in November and December.
- Recommend bi-monthly payments where the payments are due on the first workday following the 5th and 20th of the month.

Additionally, the recommendation rules must determine how to handle any outstanding payoff balances for covered SAs. The true-up rule provided with the base package [payment schedule algorithm type](#) can ignore the payoff balance, divide the payoff balance evenly between the scheduled payments, or add the payoff balance to the first scheduled payment.

A recommendation rule comprises three elements:

- An algorithm to calculate an average daily amount (the [NBDA-DA](#) algorithm type provided with the base package uses premise billing history)

NOTE:

Calculating an Amount for Non-utility SAs. The algorithm type supplied with the base package only handles service-point oriented SAs. For example, the average daily amount algorithm calculates an average daily amount. For non-utility SAs, you must develop the appropriate algorithm types.

- Two algorithm types are provided with the base package to calculate a schedule of payments. [NBPS-MON](#) calculates a monthly schedule and [NBPS-PS](#) calculates a scheduled based on a specified number of days.
- A collection of default parameter values for the payment schedule algorithm type

A recommendation rule (based on the algorithm types provided with the base package) is illustrated below.

Rule: Weekly		
Avg Daily Amt Alg: Use premise history		
Pay Schedule Alg Type: Number of days		
Parameter	Value	Override
Number of days in period	7	Y
Number of payments	52	N
True-up rule	Spread	N

Weekly Payments Recommendation Rule

NOTE:

Additional Parameters. Not all of the parameters associated with the weekly payment schedule algorithm type are illustrated. Refer to the [NBPS-PS](#) algorithm type for a detail description of the parameters.

The default parameter values for the payment schedule algorithm type may change over time, so the collection contains an effective date. If default values are changed, these changes do not affect Non-Billed Budgets already in effect. Existing Non-Billed Budgets keep the parameter values that were used when the Non-Billed Budget was started.

A user may override the default parameter values for the payment schedule algorithm type to customize the schedule if an override is allowed for a parameter. Additionally, a user may edit the payment schedule details at any time (provided the payment has not yet been processed).

The parameter values used for the recommendation rule are kept with the Non-Billed Budget SA, so that any customized parameter changes can be re-applied to a renewed Non-Billed Budget. For example, the parameter that determines the payment due day may default to the first of the month. To customize the schedule, this value may be changed to the fifth of the month. This amended value is kept with the Non-Billed Budget SA to ensure that the renewed budget follows the same monthly schedule.

NOTE:

Normally parameter values for an algorithm type are kept with the algorithm. Because the parameters may vary for each Non-Billed Budget, the parameter values are kept with the SA in the case of Non-Billed Budgets.

Refer to [Non-billed Budgets Recommendation Rule - Main](#) for information on creating recommendation rules.

Example Recommendation Rules

The following examples may be helpful in designing and implementing your recommendation rules.

NOTE:

Developing Your Own Payment Schedule Algorithms. The base package comes supplied with a [monthly payment schedule algorithm type](#). You can use this algorithm as an example when creating payment schedule algorithm types for your implementation.

Fortnightly Payments Recommendation Rule Example

The following diagram illustrates a recommendation rule where the customers pay every two weeks. The current balance for any covered SAs is added to the first payment.

The screenshot shows a configuration window for a recommendation rule. It includes several sections: 'Rule: Fortnightly', 'Avg Daily Amt Alg: Use premise history', and 'Pay Schedule Alg Type: Number of days'. Below these is a table with three columns: 'Parameter', 'Value', and 'Override'.

Parameter	Value	Override
Number of days in period	14	Y
Number of payments	26	N
True-up rule	Spread	N

Fortnightly Payments Recommendation Rule

Monthly Payments Recommendation Rule Example

The following diagram illustrates a recommendation rule where the customers pay twice monthly on the first of the month. The current balance for any covered SAs is spread out over the scheduled payments.

Rule: Monthly		
Avg Daily Amt Alg: Use premise history		
Pay Schedule Alg Type: Monthly		
Parameter	Value	Override
Day of month	1	Y
Number of payments	12	N
True-up rule	Spread	N

Monthly Payments Recommendation Rule

Ten Out of Twelve Months Recommendation Rule Example

The following diagram illustrates a recommendation rule where the customers pay one a month except for months during a holiday season (November and December). The current balance for any covered SAs is added to the first payment.

Rule: 10 of 12		
Avg Daily Amt Alg: Use premise history		
Pay Schedule Alg Type: X out of Y months		
Parameter	Value	Override
Total number of months	12	N
Months with no payment	11,12	Y
True-up rule	1 st pay	N

Ten Out of Twelve Months Recommendation Rule

Activating Non-Billed Budgets

You can plug in an algorithm (of type [SACR-AT](#)) on the SA Creation system event on the Non-Billed Budget SA type to automatically activate the Non-Billed Budget (i.e. transition it from pending start to active status). If you don't use a SA Creation algorithm to activate the Non-Billed Budget, it is activated the next time the [SA activation background process](#) runs.

When a Non-Billed Budget is activated, you can perform special processing using an algorithm plugged in on the SA Activation system event on the Non-Billed Budget SA type. The special processing can be developed to do anything that you would like, for example you could:

- Create a customer contact that with an appropriate letter template can generate a letter to inform the customer of their payment amount and payment schedule.
- Initiate the creation of a payment coupon book for a customer.

The system comes supplied with a sample algorithm type (called [SAAT-CC](#)) that simply creates a customer contact to indicate that the Non-Billed Budget is activated.

Renewing Non-Billed Budgets

A Non-Billed Budget can be renewed either manually or via a background process. When the Non-Billed Budget SA is created, the expiration date, renewal date and the recommendation rule used to create the initial budget are kept with the SA. A renewal flag on the Non-Billed Budget SA type controls if a renewal is required, optional or not allowed. If renewal is required, a user must specify a renewal date when creating the service agreement. The renewal date is defaulted on to an SA based on the value of the **Days Before Expiration for Renewal** field on the SA type.

An algorithm on the SA type can customize the processing required to renew an SA.

The [SA renewal background process](#):

- Executes the SA renewal algorithm (specified on the SA type) when the renewal date is reached (i.e., it is on or before the process date). The base package comes with an algorithm type ([SARN-NB](#)) that determines the current recommendation rule for a non-billed budget and executes the associated payment schedule algorithm using the Non-Billed Budget SA-specific parameter values to generate a new schedule. It returns new expiration and renewal dates.
- If the renewal algorithm is successful, the renewal and expiration date fields on the SA are updated with the new values.
- If the renewal process is not successful, a To Do list entry (of type [TD-SARN](#)) is created for the account and SA.

The new payment schedule that is returned from the renewal process for a Non-Billed Budget is appended to the current schedule.

A user can manually launch the renewal process for a Non-Billed Budget SA by clicking the **Renew NBB** button on the [Non-Billed Budget maintenance page](#).

Expiring Non-Billed Budgets

Non-Billed Budget service agreements may specify an expiration date. The [SA expiration background process](#) initiates the stop process for all pending start or active SAs where the expiration date is reached (before or on the process date).

Stopping Non-Billed Budgets

When a Non-Billed Budget stop is initiated, either on request or because it has expired and is not being renewed, the Non-Billed Budget is transitioned to pending stop status. You can plug in an algorithm (of type [SAIS-ST](#)) on the SA Stop Initiation system event on the Non-Billed Budget SA type to automatically finalize and stop the SA (i.e. transition it to stopped status). If you don't use a SA Stop Initiation algorithm, the Non-Billed Budget is stopped the next time the [SA activation background process](#) runs.

To finalize a pending stop SA, the system first calls the stop SA algorithm plugged-in on the SA Stop system event on the SA type. The stop SA algorithm type ([SAST-NB](#)) supplied with the base package:

- Distributes any credit on the Non-Billed Budget to the covered SAs (using the method described in [Distributing Non-Billed Budget Credit](#))
- Distributes any excess credit remaining on the non-billed budget using the [overpayment distribution](#) algorithm for the account's customer class and the overpayment transfer adjustment type (specified as a parameter to the algorithm)

- Creates a trigger to cause the account to be reviewed by the account debt monitor
- Creates a customer contact (if the customer contact class and customer contact type parameters are populated)

WARNING:

If you do not plug in an SA stop algorithm that transfers the credit balance from the non-billed budget to its covered SAs (or an excess credit SA), the stopped Non-Billed Budget may have a credit balance. You must then manually distribute this credit.

After the SA stop algorithm is finished, the SA stop processing performs the following steps if the SA type has a special role of Non-Billed Budget:

- If the Non-Billed Budget is monitored, create adjustments to synchronize the current and payoff balance of covered SAs using the **Adj. Type (Synch Current)** adjustment type from the covered SAs' SA types
 - Remove the covered SAs from the Non-Billed Budget
 - Remove all the scheduled payments from the non-billed budget
 - Create an adjustment to synchronize current and payoff on the Non-Billed Budget SA using the **Adj. Type (Synch Current)** adjustment type from the Non-Billed Budget's SA type
-

NOTE:

Synchronizing current and payoff effectively sets the current amount to zero on the Non-Billed Budget SA, as the payoff amount should have been reduced to zero by the distribution and overpayment processing in the algorithm for SA Stop.

FASTPATH:

Refer to [The Lifecycle Of A Service Agreement](#) for more information about how a pending stop SA is stopped and closed.

Automatic Payment and Non-Billed Budgets

If a customer wants to pay their non-billed budget scheduled payments automatically, the account must be set up for automatic payment. In addition, the Non-Billed Budget must indicate that automatic payment is being used.

FASTPATH:

Refer to [How To Set Up Automatic Payment For A Non-Billed Budget](#) for more information.

When this is done, a background process referred to as NBBAPAY creates automatic payments on the scheduled payment date by calling the automatic payment creation algorithm plugged in on the installation record.

NOTE:

You must ensure that your auto pay creation algorithm supports Non-Billed Budget scheduled payments. The [APAY-CREATE](#) algorithm type supplied with the base package supports non-billed budget scheduled payments.

Credit and Collections and Non-Billed Budgets

Unless the Non-Billed Budget is **unmonitored**, the [account debt monitor](#) (ADM) monitors a Non-Billed Budget SA's current amount just as it does for any other SA. The [scheduled payment algorithm](#) creates a trigger to ensure that the account debt monitor reviews the account the next time it runs. The review date on the trigger record is set to the process business date.

A separate [debt class](#) is needed for Non-Billed Budget SA types, thus allowing you to define collection class controls, debt criteria and collection process templates specifically for Non-Billed Budgets. The debt criteria should be set up to trigger a collection process when the arrears amount exceeds \$0.01 for more than n payment periods plus the number of grace days that you want to allow.

The collection process template can perform any of the events in standard collection processes, such as sending letters to customers and creating severance processes. At a minimum, the collection process template should be set up to start a severance process for all service agreements in the debt class. (Since the debt class is specifically for Non-Billed Budgets, the Non-Billed Budget is the only SA that will be subject to a severance process.)

The Non-Billed Budget severance process template should include the following event types:

- Populate a characteristic on the SA to indicate that the SA is broken. The base package comes supplied with a severance event algorithm type ([SVEV-NB](#)) that sets an SA characteristic to indicate that it was "severed".
- [Expire Severance Agreement](#) to move the SA to the pending stop state.

When the system subsequently stops the Non-Billed Budget, the system removes the covered SAs from the Non-Billed Budget and synchronizes their current balances with their payoff balances. Since the SAs have current balances again, they are subject to the account debt monitor, which can start subsequent collection processes for any of the SAs that meet the debt criteria for their debt class.

FASTPATH:

Refer to [Stopping Non-billed Budgets](#) for a complete description of the events that occur when a Non-Billed Budget is stopped.

Customers can catch up on their payments and avoid having their Non-Billed Budget broken as long as their current balance doesn't violate the debt criteria for the Non-Billed Budget's collection process.

Credit and Collections and Unmonitored Non-Billed Budgets

If the **Non-Billed Budget Monitor** flag on the Non-Billed Budget's SA type is set to Unmonitored, the [NBB Scheduled Payment Processing](#) background process does not create a trigger for the account debt monitor. Additionally, the Non-Billed Budget's current amount is always equal to zero, so it never violates any debt collection criteria. We recommend using a debt class that has the **Eligible for Collection** flag turned off, such as the N/A debt class.

For unmonitored Non-Billed Budgets, the current balance is kept on the covered SAs so they are subject to the account debt monitor and any debt criteria for their SA types' debt classes. For more information, refer to [Financial Transactions for Unmonitored Non-Billed Budgets](#).

Non-Billed Budget Status

A Non-Billed Budget SA's status is just like any other SA's status. In addition, you can use a characteristic to keep an explicit status relevant to the Non-Billed Budget:

- A base package severance event algorithm type ([SVEV-NB](#)) creates a characteristic value to indicate if a Non-Billed Budget is "broken" (i.e. stopped as a result of a severance process).
- A base package break Non-Billed Budget algorithm type ([NBBR-BRK](#)) creates a characteristic value to indicate if a Non-Billed Budget is "canceled" (i.e. manually stopped by a user).

An active Non-Billed Budget implicitly has a "kept" status (i.e. all scheduled payments have been made).

Alerts For Non-Billed Budgets

The system provides [alerts](#) to highlight the existence of Non-Billed Budgets. These alerts are important to assist the customer service representatives:

- An alert is displayed if the account has a Non-Billed Budget that is not stopped (e.g., pending start, active or pending stop).
- When a user denies a Non-Billed Budget (for whatever reason), the user should create a [customer contact](#) with a given [customer contact type](#). This type of alert prevents the customer from shopping around. An existing alert algorithm type ([CC BY TYPCL](#)) can highlight these customer contacts.
- For customers who are permanently forbidden from having a Non-Billed Budget, the user should put a permanent [alert on the account](#).
- Use an algorithm to highlight cancelled or severed non-billed budgets with an entry in the alert zone. The algorithm type to do this is not provided. Use [PP BY STATUS](#) and [CCAL-WF](#) as examples of how to create this type of algorithm.

FASTPATH:

For more information about introducing alert conditions on Control Central, refer to [Installation Options - Algorithms](#).

Non-Billed Budget Recommendation Rule

Recommendation rules are used to recommend scheduled payments for Non-Billed Budgets. For information about designing recommendation rules, refer to [Designing Recommendation Rules](#).

To define recommendation rules, navigate to **Admin > Financial > NBB Recommendation Rule > Add**.

Description of Page

Enter an easily recognizable **Recommendation Rule** code and **Description** for each recommendation rule.

Specify the **Average Daily Amount Algorithm** used to calculate the average daily amount for this recommendation rule.

Specify the **Payment Schedule Algorithm Type** used to create the recommended payment scheduled for Non-Billed Budgets that use this recommendation rule. The Payment Schedule Algorithm Type cannot be modified if a Non-Billed Budget SA that is not stopped or cancelled is using this recommendation rule.

Payment Schedule Parameters enables you to define collections of default parameter values for the payment schedule algorithm type that are effective dated. For each collection:

- **Effective Date** defines the date on which the collection of parameter values becomes effective.
- **NBB Rule Parameter Value** specifies the default value of each parameter supplied to the algorithm. Note that the [payment schedule algorithm type](#) controls the number and type of parameters.
- **Override Flag** indicates whether the user can override the default value for the parameter.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_NB_RULE](#).

Setting Up The System To Enable Non-Billed Budgets

The above topics provided background information about how Non-Billed Budgets are supported in the system. The topics in this section describe how to set up the system to enable Non-Billed Budget functionality.

NOTE:

Example Setup. This section describes typical non-billed budget configurations. Your set up and configuration may differ depending on your business needs. This section is provided for guidance only. Read the descriptions of Non-Billed Budget functionality above to understand the implications of the described setup.

NBB Distribution Codes

You must set up a Non-Billed Budget Clearance [distribution code](#) that is used on the Non-Billed Budget SA type to credit non-billed payments.

NBB Adjustment Types

NOTE:

Non-Billed Budget Financial Transaction Algorithms. The Non-Billed Budget adjustment types use the standard FT algorithm types that are provided with the base package. If you have not yet defined algorithms for these types in your system, do so before creating the Non-Billed Budget adjustment types.

The following adjustment types are needed:

- **Add SA To Non-Billed Budget.** This adjustment type should reference an FT algorithm of $\text{Payoff Amt} = 0 / \text{Current Amt} = \text{Adj Amount (no GL)}$. Because the adjustment affects the current balance only, there is no entry in the GL. This adjustment type is referenced on **Adjustment Type (Current=0)** on SA types that are eligible for Non-Billed Budgets. Note that this adjustment type is never used if the SA is added to an unmonitored Non-Billed Budget.
- **Bill Complete for Monitored Non-Billed Budget.** This adjustment type should reference a distribution code used for balance transfer clearing. It should reference a FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt} = 0$. This adjustment type is referenced on **Adjustment Type (Xfer)** on SA types that are monitored Non-Billed Budgets.
- **Synch Balance for Non-Billed Budget.** This adjustment type should be set up for **Sync. Current Amount** and should reference a FT algorithm of $\text{Payoff Amt} = 0 / \text{Current Amt} = \text{Adj Amount (no GL)}$. This adjustment type is referenced on the **Adj. Type (Synch Current)** on Non-Billed Budget SA types. It is used when a Non-Billed Budget SA is stopped to synch the current balance with the payoff balance.
- **Scheduled Payment.** This adjustment type should reference an FT algorithm of $\text{Payoff Amt} = 0 / \text{Current Amt} = \text{Adj Amount (no GL)}$. Because the adjustment affects the current balance only, there is no entry in the GL. This adjustment type is referenced on the Non-Billed Budget process scheduled payment algorithm.
- **Overpayment Transfer.** This adjustment type should reference a transfer distribution code and a FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt} = \text{Adj}$. This adjustment is referenced on the non-billed budget process scheduled payment algorithm and the stop non-billed budget algorithm. Note that if there is already a transfer adjustment type created in your system, you do not need to create a new one.

If you are setting up an unmonitored Non-Billed Budget that maintains a credit balance (as opposed to maintaining the credit balance on an overpayment SA), you need to create an adjustment type for Bill Complete for Unmonitored Non-Billed Budget. (Refer to [Transferring Credit from Unmonitored Non-billed Budgets](#) for more information.) The adjustment type should reference a transfer distribution code and a FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt} = \text{Adj}$. This adjustment type is referenced on **Adjustment Type (Xfer)** on SA types that are unmonitored Non-Billed Budgets.

NBB Adjustment Type Profiles

Create an adjustment type profile for Non-Billed Budgets that references the following adjustment types:

- Bill complete for monitored Non-Billed Budget
- Bill complete for unmonitored Non-Billed Budget (if used)
- Synch balance for Non-Billed Budget
- Scheduled payment
- Overpayment transfer

Create an adjustment type profile for eligible SAs that references the following adjustment types:

- Add SAs to monitored Non-Billed Budgets
- Bill complete for monitored Non-Billed Budget
- Bill complete for unmonitored Non-Billed Budget (if used)

NOTE:

Bill Complete Adjustment Types. Because the bill complete adjustment types transfer amounts between two SAs, they must be in profiles for both Non-Billed Budget and eligible SA types.

Overpayment Transfer Adjustment Type. The overpayment transfer adjustment type created above is used to transfer funds from an excess credit SA to a Non-Billed Budget when the scheduled payment is processed. It is also used to transfer excess funds from a Non-Billed Budget that is being closed to an excess credit SA. The transfer adjustment should therefore be added to an adjustment type profile that is referenced on the excess credit SA type.

NBB Characteristic Types

Create a Non-Billed Budget status characteristic type that specifies Service Agreement as its characteristic entity. The characteristic type should include the following predefined values:

- Non-Billed Budget Canceled
- Non-Billed Budget Severed

NBB Customer Contact Class And Types

Create a Non-Billed Budget customer contact class. The contact class may include the following customer contact types:

- Non-Billed Budget Activate
- Non-Billed Budget Renewal
- Non-Billed Budget Stop

NOTE:

Customer Contact Letters. If you want to send letters to your customers when a contact of any of these types is created, you must create an appropriate [letter template](#) and attach it to the contact type.

NBB Algorithms

You must define the following [algorithms](#):

- On [NBB recommendation rule](#), the Non-Billed Budget Daily Amount Calculation. Refer to the [NBDA-DA](#) algorithm type for more information about the base package algorithm.
- On [SA type](#):
 - Non-Billed Budget Process Scheduled Payment. This algorithm has parameters that must reference the Scheduled Payment and Overpayment Transfer adjustment types defined above. Another parameter references an overpayment SA type (that you may need to create if there is not already one in your system). Refer to the [NBPA-PS](#) algorithm type for more information about the base package algorithm.
 - Non-Billed Budget SA Renewal. Refer to the [SARN-NB](#) algorithm type for more information about the base package algorithm.
 - Break Non-Billed Budget SA. Refer to the [NBBR-BRK](#) algorithm type for more information about the base package algorithm.
 - SA Activation - automatically activate SA (if you want to automatically activated Non-Billed Budgets when they are created). Refer to the [SACR-AT](#) algorithm type for more information about the base package algorithm. Note that this same algorithm may be used on many SA types.
 - SA Activation - create customer contact (if you want the system to create a customer contact when NBB SAs are activated). Refer to the [SAAT-CC](#) algorithm type for more information about the base package algorithm.
 - SA Stop - automatically stop SA (if you want to automatically transition Non-Billed Budgets from pending stop to stop when their stop is initiated). Refer to the [SAIS-ST](#) algorithm type for more information about the base package algorithm. Note that this same algorithm may be used on many SA types.
 - SA Stop - Stop Non-Billed Budget. Refer to the [SAST-NB](#) algorithm type for more information about the base package algorithm.
 - Bill Completion - Non-Billed Budget Credit Transfer. Refer to the [BCMP-NB](#) algorithm type for more information about the base package algorithm.
- On [bill segment type](#), the Bill FT Algorithm (for all SAs that are eligible for NBB). Refer to the [BSBF-BA](#) algorithm type for more information about the base package algorithm. Note this is the standard bill FT algorithm type used for common bill transactions. It supports bill FT for non-billed budgets and other SA types. You only need to create it if it doesn't already exist in your system.
- On [severance event type](#), an algorithm for Non-billed Budget Severance. Refer to the [SVEV-NB](#) algorithm type for more information about the base package algorithm.

NOTE:

Payment Schedule Algorithm Types. For Non-Billed Budget payment schedule algorithm types, you need to define the algorithm types (if you add your own algorithm types). You do not need to define algorithms because the parameter values for the algorithm are defaulted on the recommendation rule and stored with the Non-Billed Budget SA. (Normally the algorithm holds the parameter values.) Refer to the [NBPS-MON](#) algorithm type for more information about the base package payment schedule algorithm.

NBB Debt Class And Collection Process

Set up a separate debt class, collection class control, collection process template and severance process template for Non-Billed Budgets according to the information in [Credit and Collections and Non-Billed Budgets](#).

SA Types for SAs Covered by NBBs

You must modify the SA type for any SAs that you want to allow to be covered by a Non-Billed Budget.

- Verify that the specified **Bill Segment Type** (on the Billing page) references a financial transaction algorithm to set the current amount to zero for monitored Non-Billed Budgets. The FT creation algorithm type **BBSF-BA** (i.e., $\text{Payoff Amt} = \text{Bill Amt} / \text{Current Amt} = \text{Amt Due}$) supplied with the base package sets the current amount to zero for SAs that are covered by monitored non-billed budgets, though this is not evident by the name. (For SAs that are not covered by a Non-Billed Budget, the current amount is equal to the amount due or the recurring charge.) Refer to [Billing For SAs Covered By The Non-Billed Budget](#) for more information.
- Set the **Eligible for Non Billed Budget** flag (on the Billing page) to Eligible for Non-Billed Budget .
- Populate the **Adjustment Type (Current = 0)** (on the Detail page) to indicate the adjustment to be used to zero out the current amount on the covered SAs when the Non-Billed Budget SA is activated. Use the Add SA To Non-Billed Budget [adjustment](#) created above. This adjustment type is only called for SAs that are covered by a monitored Non-Billed Budget.
- Reference an **Adjustment Type Profile** (on the Adjustment Profile page) that includes the Add SA To Non-Billed Budget adjustment type referenced in the **Adjustment Type (Current = 0)** field above.
- If not already specified (for write off), an **Adj. Type (Synch Current)** (on the Main page) is also required. It is used to synchronize (make equal) the current amount with the payoff amount when the SA is removed from (i.e. no longer covered by) a Non-Billed Budget.

NBB Recommendation Rules

Set up any [NBB Recommendation Rules](#) that you want to be available for your Non-Billed Budget SAs. Use any Non-Billed Budget Daily Amount Calculation algorithms defined above. Also use the Non-billed Budget Monthly Payment Schedule ([NBPS-MON](#)) algorithm types and specify the default parameters.

Non-Billed Budget SA Types

You must set up a [SA types](#) for your Non-Billed Budget service agreements. You may need multiple Non-Billed Budget SA types if you have different business rules for different types of Non-Billed Budgets, for example, if you have both monitored and unmonitored Non-Billed Budgets or if you support Non-Billed Budgets with different renewal requirements. The following points provide guidelines for creating a non-billed budget SA type.

SA Type - Main (NBB)

Service Type should reference something like "Miscellaneous Service".

Distribution Code should be the one you set up to book credits for Non-Billed Budgets.

Revenue Class should be set to N/A. (Revenue classes are not applicable because Non-Billed Budgets do not apply a rate and revenue classes are only relevant for SA types that use a rate.)

The **Payment Segment Type** should reference the Normal Payment.

Do Not Overpay should be on. Any excess payments should go to the overpayment SA, not the Non-Billed Budget SA.

Late Payment Charge is not applicable and should not be turned on because Non-Billed Budgets are not billed.

Adj. Type (Synch Current) should reference the Synch Balance for Non-Billed Budget adjustment type created above.

SA Type - Detail (NBB)

- **Special Role** is Non-Billed Budget.
- **Adjustment Type (Xfer)** must be populated to indicate the adjustment to be used for transferring accumulated credit from the Non-Billed Budget SA to the covered SAs. This field is not used for unmonitored Non-Billed Budgets.
- **Renewal** may be optional, not allowed, or required depending on your business processes.
- If Renewal is required, specify the **Days Before Expiration for Renewal**.
- **Non-Billed Budget Monitoring** must indicate whether the Non-Billed Budget is monitored by the account debt monitor.

SA Type - Billing (NBB)

Non-Billed Budget SAs do not get billed, so the **Eligible for Billing** flag should be off.

Additionally, the **Characteristic Premise Required** should not be checked for Non-Billed Budgets.

SA Type - Rate (NBB)

Non-Billed Budget SAs do not use rates, so the **Rate Required** flag should be off.

SA Type - SP Type (NBB)

Non-Billed Budget SAs do not have service points, so the **Service Points Required** flag should be off.

SA Type - Adjustment Profile (NBB)

Adjustment Type Profile should reference the [adjustment type profile](#) for Non-Billed Budgets (set up above).

SA Type - Credit and Collections (NBB)

The credit and collections information should reference a **Severance Process Template** that calls the Non-Billed Budget Severance algorithm created above and expires the Non-Billed Budget SA. The **Debt Class** should reference an appropriate value consistent with your credit and collections rules. Typically, monitored Non-Billed Budgets should be in their own debt class. Unmonitored Non-Billed Budgets should have a **Debt Class** that is not Eligible for Collection.

The **Write Off Debt Class** is not applicable because the Non-Billed Budget contains no debt to be written off. Reference a debt class such as N/A. Refer to [Defining Credit & Collections Options](#) for more information.

SA Type - Algorithms (NBB)

The SA type [algorithms](#) defined above must be set up:

- The Non-Billed Budget Credit Transfer algorithm created above should be specified for the Bill Completion system event (not used on unmonitored Non-Billed Budgets).
- The Break Non-Billed Budget SA algorithm created above should be specified for the Break NBB SA system event.
- The Non-Billed Budget Process Scheduled Payment algorithm created above should be specified for the Process NBB Scheduled Payment system event (not used on unmonitored non-billed budgets).

- The Non-Billed Budget SA Renewal algorithm created above should be specified for the SA Renewal system event.
- If you created the Automatic SA Activation algorithm above, it should be specified for the SA Creation system event.
- The Non-Billed Budget SA Activation algorithm created above should be specified for the SA Activation system event.
- If you created the Automatic SA Stop algorithm above, it should be specified for the SA Stop Initiation system event.
- The Stop Non-Billed Budget algorithm created above should be specified for the SA Stop system event.

SA Type - NBB Recommendation Rule (NBB)

Add the recommendation rules defined above that are valid for SAs of this type. Also, indicate which recommendation rule should be used as the default.

NBB Background Processes

Ensure that the following background processes are scheduled:

- Non-Billed Budget Scheduled Payment Processing ([NBBPS](#))
- Non-Billed Budget Scheduled Payment Automatic Payment Create ([NBBAPAY](#))
- Service Agreement Renewal ([SARENEW](#))
- Stop Expired Service Agreements ([SAEXPIRE](#))

Defining Quotation Options

This section describes tables that must be set up before quotations can be created.

FASTPATH:

For more information, refer to [The Big Picture of Quotations](#).

Setting Up SA Types For Quotes

The topics in this section describe additional setup responsibilities required on SA types that can have proposal service agreements.

NOTE:

Assumption. We have assumed that you've already designed your SA types for the services that you sell. If you haven't done this, refer to [Defining Service Agreement Types](#).

Enabling The Automatic Generation Of Billing Scenarios

Enabling The Generation Of Simulated Bill Segments

As described under [Creating Quotes And Quote Details](#), in order for the system to generate simulated bill segments for a proposal SA, you must plug-in a Proposal SA Bill Segment Generation algorithm on the proposal SA's [SA type](#). Refer to [CBSP-AR](#) for an example algorithm that creates a simulated bill segments for each billing scenario linked to the proposal SA by calling rate application.

Enabling The Creation Of A Real SA When A Quote Detail Is Accepted

As described under [Accepting / Declining Quote Details](#), in order for the system to create a real SA when a proposal SA is accepted, you must plug-in a Proposal SA Acceptance algorithm on the proposal SA's [SA type](#). Refer to [PSAA-PS](#) for an example algorithm that creates a real SA by copying the proposal SA.

NOTE:

Setting Up Quote Route Types

Quote route types control how quotes are [routed](#) to customers and prospects. To define a quote route type, open **Admin > Sales & Marketing > Quote Route Type**.

FASTPATH:

Refer to [Printing Quotes](#) for more information about how quotes are routed to customers and prospects.

Description of Page

Enter a unique **Quote Route Type** and **Description** for every quote route type.

Quote Routing Method controls the type of information that may be defined when the respective **Quote Route Type** is selected on [Account - Person Information](#). The following options are available:

- **Postal**: Use this method if the routing is via the postal service.
- **Fax**: Use this method if the routing is via fax.
- **Email**: Use this method if the routing is via email.

NOTE:

The values for **Quote Routing Method** are customizable using the [Lookup](#) table. This field name is QTE_RTG_METH_FLG .

- The next two fields control how quotes that are routed using this method are [printed](#) (both in batch and online).
 - Use **Batch Control** to define the process that creates the flat file that is passed to your quote printing software. Refer to [Technical Implementation of Printing Quotes In Batch](#) for more information about these processes.
 - Use **Extract Algorithm** to define the plug-in that constructs the "flat file records" that contain the information merged onto quotes routed using this method. Refer to [Printing Quotes](#) for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_QTE_RTE_TYPE](#).

Setting Up Terms and Conditions

As described under [Legal Terms and Conditions May Be Specified On SAs](#), your [SA type start options](#) can reference terms and conditions (T&C's) that should be defaulted onto new service agreements (both real and proposal). Each T&C is identified with a terms and condition code. To define a terms and conditions code, open **Admin > Sales & Marketing > Terms and Conditions > Add**.

NOTE:

T&C print order. The value of the T&C code controls the order in which the T&C appears on the printed quote. This means you should assign these codes in some type of structured format (e.g., 01...) if you would like them to appear in a certain order.

Description of Page

Enter a unique **Terms and Condition** code and **Description**. Use **Text** to describe the exact terms.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CL_TC](#).

Setting Up Decline Reasons

A proposal SA decline reason must be supplied when a proposal SA is declined. Open **Admin > Sales & Marketing > Proposal SA Decline Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Decline Reason** and **Description** for each proposal SA decline reason.

Where Used

Decline reasons are used when a [quote detail is declined](#).

Setting Up Customer Classes For Quotes

An optional plug-in spot exists on [customer class](#) where you can introduce additional logic to be executed when a quote is completed for an account that belongs to this customer class. The base package comes supplied with a sample algorithm that creates a workflow process when a quote is completed (refer to the algorithm [QTEC-WP](#) for more information).

Defining Case Management Options

Case management functionality is a highly configurable tool your organization can use to manage many situations, including (but certainly not limited to) the following:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- an application for new service,
- a contractor's request to extend a line,
- a customer's rejection of a quote,

- a customer's request to change service providers on a future date,
- the processing of a market message in a deregulated environment,
- ... (the list is only limited by your time and imagination)

Obviously the steps involved in the resolution of the above cases are very different. The topics in this section describe how to configure the system to manage your cases as per your organization's desires.

NOTE:

Separate module. The Case Management functionality is associated with a separate module. If the Case Management module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

FASTPATH:

Refer to [Case Management](#) for a description of how end-users use cases.

The Big Picture Of Cases

The topics in this section provide background information about how to configure the system to support your case management requirements.

Case Type Controls Everything

Whenever a user creates a case, they must specify the type of case (e.g., high-bill complaint, literature request, etc.). The case type controls how the case is handled.

Case types hold the business rules that control cases. Since these business rules can sometimes be quite complicated, setting up case types requires planning and foresight. The topics in this section describe the type of business rules that can be configured on your case types.

Person / Account / Premise Applicability

Some types of cases may be person-oriented, others may be premise-oriented, and still others may be account-oriented. For example:

- Cases used to keep track of a literature request would reference the person who requested the literature.
- Cases used to keep track of the inspection of a property would reference the premise being inspected.
- Cases used to keep track of a high-bill complaint would reference the account associated with this bill(s) being disputed.

When you set up a case type, you define if its cases must reference a person, account, and/or premise. Note, any combination of these objects is permitted on a case.

Contact Information Applicability

When a case is created, you may want to keep track of how to contact its originator. For example, you may want to record the originator's email address or phone number. When you set up a case type, you define if contact information is required, optional or not allowed on its cases.

Business Object Association

A case type may reference a Business Object, which serves as a link between cases of that type and the options that are associated with the business object.

Additional Information

Some of your cases may require additional information (in the form of [characteristics](#)). For example, a high-bill complaint may require at least one bill. When you set up a case type, you can define the additional fields that are required. In addition, you can define default values for these fields.

The case functionality also allows you to require characteristics when a case enters a given state. Refer to [Required Fields Before A Case Enters A State](#) for the details.

NOTE:

Requiring supporting documents. Because any [type of characteristic](#) can be referenced on a case, you can require references to supporting documents by requiring a file location characteristic.

Access Rights

You can take advantage of the system's [security](#) to restrict cases of a given type to certain users. For example, you can restrict high-bill complaints to specific user groups.

The following points describe how to implement this type of security:

- Create an [application service](#) for each type of case you need to secure
- Define the access modes Add, Inquire and Change for each application service
- Define the applicable application service on each case type
- Link the appropriate [user groups](#) to each application service
 - For user groups that are allowed to add cases of a given type, define Add as a valid access mode.
 - For user groups that are allowed to view cases of a given type, define Inquire as a valid access mode
 - For user groups that are allowed to change cases of a given type, define Change as a valid access mode

If you restrict access to a case type's cases, you can further restrict which users can work on cases given the status of the case. Refer to [Which Users Can Transition A Case](#) for more information.

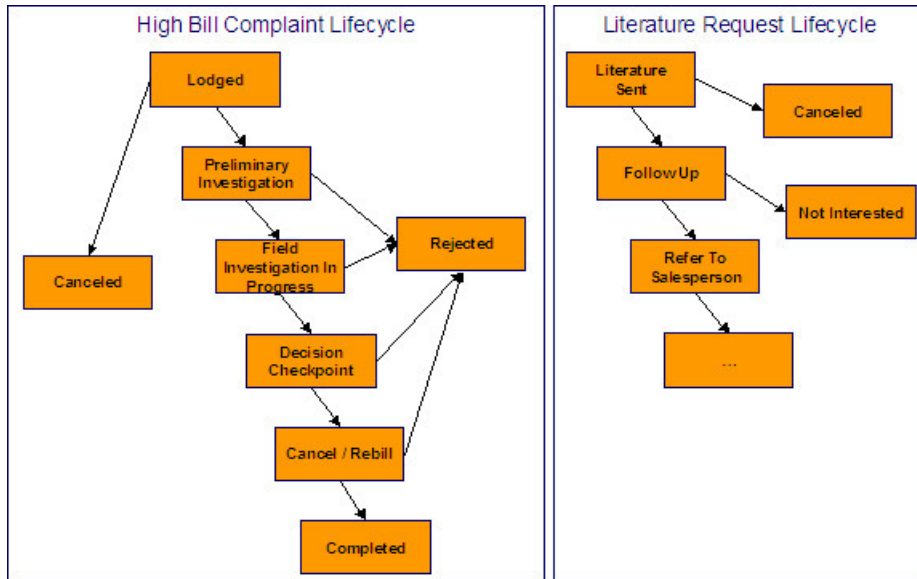

NOTE:

Restricting access to cases is optional. If you don't specify an application service on a case type, all users (who have access to the case transaction) may access its cases.

Lifecycle

Many objects in the system have predefined lifecycles whose rules are governed by the base-package and cannot be changed. For example, a service agreement starts out in the Pending Start state and eventually becomes Closed when it's been final billed (and paid). You can't change the system to allow a service agreement to start its life in the Closed state.

The lifecycle of cases is not governed by the base package. Rather, you define the lifecycle of your cases when you set up their case types. Examine the following diagrams; the one on the left shows the potential lifecycle of a case that manages a high-bill complaint, the one on the right shows the potential lifecycle of a case that manages a customer's literature request.

Potential Lifecycles Of Two Types Of Cases

NOTE:

Just examples. The above lifecycles are just examples. When you set up your case types, you must define the valid states for your case type.

The topics that follow describe important concepts that are illustrated in the above diagrams.

Valid States versus State Transition Rules

The orange boxes in the above diagram show the potential valid states a given case can have. The lines between the boxes indicate the state transition rules. These rules govern the states a case can move to while it's in a given state. For example, the above diagram indicates a high bill complaint that's in the Lodged state can be either Canceled or moved into the Preliminary Investigation state.

When you set up a case type, you define both its valid states and the state transition rules.

Transitory States

You can define a state in a case type as **Transitory** if you do not wish the case to exist in a particular state. For example, let's assume that an algorithm is associated with the Decision Checkpoint state (Enter Processing) that would automatically determine the next state for the case (i.e. Cancel/Rebill or Reject) and also contains logic to transition the case accordingly. In this scenario, you may not ever want the case to exist in the Decision Checkpoint state, so that a user won't ever see a high bill complaint in that state. If the other states were marked as non-transitory, and an error were to occur during the transition from Decision Checkpoint to Cancel/Rebill, the case would roll back any changes to data made in the Cancel/Rebill (Enter Processing) state along with the changes made in the Decision Checkpoint state, and would end up in the Field Investigation In Progress state - the last non-transitory state prior to Decision Checkpoint.

One Initial State and Multiple Final States

When you set up a case type's states, you must pick one as the initial state. The initial state is the state assigned to new cases of a given type. For example, high-bill complaint cases have an initial state of Lodged, whereas literature request cases have an initial state of Literature Sent.

You must also define which statuses are considered to be "final". When a case enters a "final" state, it is complete and no further action is necessary. You might want to think of the "final" states as the potential outcomes of a case. For example, a high-bill complaint has potential outcomes of Completed, Rejected, and Canceled.

The "final" states are used by the system to differentiate between open and closed cases. For example, an alert highlights when the person / account / premise in context has open cases (this alert only exists if you've plugged-in the appropriate installation [alert](#)).

Allowing A Case To Be Reopened

You can set up your state transition rules to allow a case to be reopened (i.e., to be moved from a final state to a non-final state). Neither of the above examples allows this, but it is possible if you configure a case type accordingly.

Make Sure To Have A Canceled State

The system does not allow you to delete a case. Therefore, if you want to support logical deletion, you should have a status of Canceled early in a case type's lifecycle. Doing this allows a user to cancel (i.e., logically delete) a case.

NOTE:

Cancel reason. You might want to consider setting up your case types to require a cancel reason (in the form of a [predefined value characteristic](#)) when a user cancels a case. Refer to [Required Fields Before A Case Enters A State](#) for more information.

Buttons Are Used To Transition A Case From Status To Status

When a case is displayed on [Case - Main](#), a separate button is shown for each state into which the case can be transitioned. For example, a high-bill complaint case that is in the Lodged state would show two buttons: **Start Investigation** and **Cancel**. If the user presses the **Start Investigation** button, the case is transitioned to the Preliminary Investigation state. If the user presses the **Cancel** button, the case is moved to the Canceled state.

You may define the text displayed on the button differently for each state transition. This allows the action description to be varied according to the previous status. For example, the button to transition from New to Active may be labeled **Activate**, but the button to change from Closed to Active may be labeled **Reactivate**.

Refer to [Which Users Can Transition A Case](#) for instructions describing how to restrict users to specific actions.

State Transitions Are Audited

The system maintains an audit trail whenever a case transitions from one state to another. This audit is shown in the case's [log](#).

Reports and Analytics Highlight Productivity

When you set up a case type's lifecycle, keep in mind that several reports and analytics highlight how long it took cases to transition into a state. For example, you can use a report to see how long it took high-bill complaints to be completed (or initially actioned or ...). Refer to the [Reports](#) chapter for the details of case reports.

Status-Specific Business Rules

As described in [Lifecycle](#), when you set up a case type, you define the possible states its cases can pass through. The following topics describe business rules that can be configured for each state.

A Script That Helps A User Work Through A Case

You can define a [Business Process Assistant script](#) that helps a user work a case while it's in a given state. For example, when you set up the Preliminary Investigation state for the high-bill complaint case type, you can define a script. A user can then easily launch this script to help them work through a case in this state.

Please keep the following in mind when you're designing how to integrate BPA scripts with your cases:

- You can have a different script for each state. For example, you could develop a script to help a user work on a case while it's in the Preliminary Investigation state and a different script to help them work in a case while it's in the Decision Checkpoint state.
- Rather than make a user launch a script by pressing a hyperlink on the [case page](#), you can have the system automatically launch the script while the case is in a given state. Refer to [Script Launching Option](#) for more information.
- You can also have the system automatically launch a script when a user selects a To Do entry. Refer to [Launching Scripts When To Do Entries Are Selected](#) for more information.

FASTPATH:

Refer to [Scripts and Cases](#) for more information about how to streamline your case processing with scripts.

Required Fields Before A Case Enters A State

You can define additional fields (i.e., characteristics) that are required before a case can enter a given state. For example,

- You can indicate a high-bill complaint must reference at least one bill before it enters the Preliminary Investigation state.
- You can indicate a case must reference a cancel reason before it enters the Canceled state.

You do this by indicating that [characteristics](#) (that were optional when the case was added) are required when a case enters a given state.

Validation Before A Case Enters A State

You can define validation that executes before a case can enter a given state. For example, you can indicate the case must have been assigned a responsible user before it can enter the Preliminary Investigation state. This validation logic is held in algorithms that are plugged in on the case type and therefore you can define any type of validation.

Additional Processing When Entering A State

You can define additional processing that should happen when a case enters a given state. For example, you can have a [letter](#) created when a high-bill complaint case is Rejected. Similarly, you can have a [To Do entry](#) created when a high bill complaint enters the Preliminary Investigation state. This additional processing is held in algorithms that are plugged in on the case type and therefore you can define any type of additional processing.

You can also incorporate state transitioning logic within routines that are executed when a case enters a state, so that you do not need to rely upon CASETRAN to transition your cases. For example, when the state entry routines of the Preliminary Investigation status for a high-bill complaint are executed, they may be designed to transition the case into either the Rejected or Field Investigation In Progress state without waiting. Note that your Exit Validation and Exit Processing logic, if configured for the case state, will still be executed as part of the state transition. Auto-Transition logic for this state will be ignored during this transition.

Validation Before A Case Exits A State

You can define validation that executes before a case can exit a given state. For example, you might want to check the account's balance is less than a given value before a case can exit a given state. This validation logic is held in algorithms that are plugged in on the case type and therefore you can define any type of validation.

Additional Processing When Exiting A State

You can define additional processing that should happen when a case exits a given state. For example, you can have a [To Do entry](#) automatically completed when a high bill complaint leaves the Decision Checkpoint state. This additional processing is held in algorithms that are plugged in on the case type and therefore you can define any type of additional processing.

Automatic Transition Rules

You can define rules that automatically transition a case into a different state. For example, you can indicate a literature request should be transitioned to the Follow Up state 1 week after the literature is sent. Similarly, you can indicate a high-bill complaint should transition to the Decision Checkpoint state after the fieldwork is complete. These rules are held in algorithms that are plugged in on the case type and therefore you can define any type of automatic transition rules.

Cases in a state with automatic transition rules are monitored by the [CASETRAN](#) background process. Each time this program runs, the respective automatic transition plug-in is called for each such case and it transitions the case if the condition applies.

NOTE:

When to execute CASETRAN. Because your automatic transition rules will be dependent on your business requirements, you need to think carefully about when you run the [CASETRAN](#) background process. For example, if you have automatic transition rules that transition a case to a new state when a related field activity is completed, you would want to schedule this job to run after field activities are uploaded. If you have rules to transition a case after a customer pays a deposit, you'd want to schedule this job to run after payments are uploaded. Bottom line - your business rules will dictate the frequency of execution.

When the user adds a new case or changes the state of a case manually the system attempts to auto-transition the case to subsequent statuses as necessary. If auto-transition rules apply to the new state (and to subsequent ones) they would be

executed right away. In other words, you don't need to wait for the auto-transition background process to be executed. An indication that the case was auto-transitioned online is displayed right below the action buttons section.

NOTE:

Auto-Transition Errors. Online auto-transition is performed recursively committing each successful state transition to the database. It is performed up to 100 times or until an error is encountered during the process. If this happens, auto-transition stops at the last **non-transitory** state into which a successful transition had occurred. Two case log entries will be generated automatically - one containing the message that a transition error has occurred, and a second containing the actual error message. A To Do entry will also be generated automatically upon rollback. The type of this To Do entry will be taken from 1) the Case Transition Exception To Do Type **option** for the **Business Object** associated with the case type, and if this is not populated, 2) the Exception To Do Type indicated on the Case Options Feature Configuration. All of the above error handling is true for both batch and online processing of cases.

NOTE:

Triggering Auto-Transition. If you have a customized process that affects the state of a case and you want the case to be auto-transitioned right away, i.e. not wait for the next scheduled **CASETRAN** background process to execute, you can customize that process to trigger auto-transition for the specific case, or you can put the state transition logic into the routines that execute at state entry time.

Script Launching Option

You can define whether the script associated with a given state is to be automatically launched while the case is in that state. The system supports the following options:

- Launch the script only if no script is currently active.
 - Always launch the script unless this specific script is currently active.
-

WARNING:

With this option, if a script is currently open in the page's BPA script area then it will be automatically closed and the case script will open.

- Do not automatically launch the script.

You do this by plugging-in a Script Launching algorithm for the given state. If no such plug-in is provided the script is not automatically launched.

Which Users Can Transition A Case Into A State

If you have **restricted access** to a case type, you can further restrict which user groups are allowed to transition a case into specific states. For example, you can control which user group can transition a high bill complaint into the Preliminary Investigation state. The following points describe how this is done:

- Define actions on the **application service** defined on the case type. You must define an action for each status that you need to secure.
- Define each status's corresponding action. Note, you only need to link a status to an action if it's secured. Any user with **access** to the case type can perform statuses that aren't linked to actions.
- Define the transition role for each status's valid next status. You can assign valid next statuses to be reachable via system (only), or system and user.

- Define which [user groups](#) have access to the actions (i.e., statuses). In addition, these user groups should have access to the Change action.

Responsible User Applicability

Some of your cases may require a "responsible user". This is the user who has overall responsibility for the case. When you set up a case type, you define if a responsible user is required, optional or not allowed on its cases.

The following points describe how to set up the system if a responsible user is not required when a case is first created, but is later in its lifecycle:

- Indicate that a responsible user is optional on the case type
- Plug-in either an [exit validation](#) or [entry validation](#) algorithm on one of the case type's states to require a responsible user at some point in a case's lifecycle

NOTE:

Address To Do entries to the responsible user. If you use the [base-package algorithm](#) to create a To Do entry when a case enters a given state, you can indicate that the To Do entry should be addressed to the responsible user on the case.

Scripts and Cases

There are three ways [Business Process Assistant scripts](#) can be used to manage cases:

- You can create a BPA script to help users create a case. For example, a script can help a user create a new high-bill complaint.
- Using a script to create a case can save a user a lot of time (and training efforts). This is because the script can automatically populate many fields on the case based on answers to questions.

Refer to [Initiating Scripts](#) for a description of how end-users initiate scripts.

- You can create a script to help users work on a case when it's in a given state. Refer to [A Script That Helps A User Work A Case](#) for more information.
- You can [set up your case types to create To Do entries](#) to notify users when cases exist that require their attention. Users can complete many of these ToDo entries without assistance. However, you can set up the system to automatically launch a script when a user selects a ToDo entry. For example, consider a ToDo entry that highlights a high-bill complaint that requires investigation. You can set up the system to execute a specific script when a user selects this ToDo entry. This script might guide the user through the investigation process (and help them update the case). Refer to [Executing A Script When A To Do Entry Is Selected](#) for more information.

To Do's and Cases

The topics in this section provide background information about how to facilitate case management with [To Do entries](#).

Creating and Completing To Do Entries

You can configure your case types to create and complete [To Do entries](#) when a case enters or exits a state. Let's use the following [lifecycle diagram](#) to illustrate a potential use of To Do's:

Let's assume the following:

- You want a To Do entry created when a literature request case enters the Follow Up state. You want this To Do automatically completed when the case enters either the Refer To Salesperson or Not Interested states. Note, we refer to this as the "first" To Do entry below.
- You want a different To Do entry created when a case enters the Refer To Salesperson state. You do not want the system to automatically complete this entry (the sales person must manually do this). Note, we refer to this as the "second" To Do entry below.

To implement the above, you would set up a case type as follows:

- Plug-in an [entry processing](#) algorithm on the Follow Up status to create the first To Do entry.
- Plug-in an [exit processing](#) algorithm on the Follow Up status to complete the first To Do entry.
- Plug-in an [entry processing](#) algorithm on the Refer To Salesperson status to create the second To Do entry.

While the case type illustrated above had a single To Do entry "active" at any point in time, you can easily configure a case type to have multiple To Do entries active at any point in time. Let's use the following lifecycle diagram to illustrate this point:

Let's assume the following:

- You want a To Do entry created when a high bill complaint is created and you want it completed when the case reaches the Canceled, Rejected or Approved states. This To Do entry could be used by a supervisor to monitor the number of high-bill complaints being worked. Note, we refer to this as the "first" To Do entry below.
- You want a different To Do entry created when the case enters the Preliminary Investigation state and you want this entry automatically completed when the case leaves this state. Note, we refer to this as the "second" To Do entry below.
- You want a different To Do entry created when the case enters the Decision Checkpoint state and you want this entry automatically completed when the case leaves this state. Note, we refer to this as the "third" To Do entry below.

To implement the above, you would set up the case type as follows:

- Plug-in an [entry processing](#) algorithm on the Lodged status to create the first To Do entry. Plug-in an [entry processing](#) algorithm on the Canceled, Rejected and Completed statuses to complete this entry.
- Plug-in an [entry processing](#) algorithm on the Preliminary Investigation status to create the second To Do entry. Plug-in an [exit processing](#) algorithm on the Preliminary Investigation status to complete this entry. We elected to use an exit processing algorithm because we only have to plug it in on one status. If we'd used an entry processing algorithm, we would need to plug it in on the 2 statuses into which a Preliminary Investigation status can transition.
- Plug-in an [entry processing](#) algorithm on the Decision Checkpoint status to create the third To Do entry. Plug-in an [exit processing](#) algorithm on the Decision Checkpoint status to complete this entry.

Launching Scripts When To Do Entries Are Selected

You can set up your case types to create To Do entries to notify users when cases exist that require their attention. Users can complete many of these To Do entries without assistance. However, you can set up the system to automatically launch a script when a user selects a To Do entry. For example, consider a To Do entry that highlights a high-bill complaint that requires investigation. You can set up the system to execute a specific script when a user selects this type of To Do entry. This script might guide the user through the investigation process. Refer to [Executing A Script When A To Do Entry Is Selected](#) for more information.

All To Do Entries Are Visible

When a case is displayed on [Case Maintenance](#), the system summarizes the number of To Do entries associated with the case (if you've [set up your To Do types](#) appropriately).

Examples of Case Types

The topics that follow provide examples of case types related to several business processes. Use the information in this section to form an intuitive understanding of case types. After attaining this understanding, you'll be ready to design your own case types.

High Bill Complaint

Some organizations will set up a case to manage a high-bill complaint. The following diagram illustrates how such a case type might look:

Case Type – High Bill Complaint

Person / Account / Premise Applicability	
Field	Applicability
Person	Required
Account	Required
Premise	Optional

Secured

Yes, all actions

Fields To Be Captured		
Field	Required / Optional	Default Value
Bill ID	Optional	..
Cancel reason	Optional	..
Reject reason	Optional	..

Applicability Rules	
Field	Applicability
Responsible User	Optional
Contact Information	Optional

Note the following about the High Bill Complaint case type:

- Notice that we set up the case type to require a person and an account, but premise is optional. This is because a bill can span multiple premises and knowing the premise isn't so important on cases of this type.
- We need to restrict high-bill complaints to specific user groups. This means we need to [set up a specific application service](#) for this case type (that has a separate "action" for each status).
- Cases of this type have 3 additional fields over their lifetime. Notice the following:

- The **Bill ID** characteristic is set up to be optional. This is because we've assumed that sometimes a high-bill complaint case can be lodged when you can't find the bill in question and you still want to log the case.
- Later in this section, you'll see that we've configured the Preliminary Investigation status to require a **Bill ID** before a case can enter this state.
- Both the **High Bill Complaint Cancel Reason** and **Reject Reason** are optional. Later in this section, you'll see that we've configured the Canceled and Rejected statuses to require these fields, respectively.
- Cases of this type do not need a **Responsible User** when first created. Later in this section, you'll see how we've configured the Preliminary Investigation status to require a **Responsible User** before a case can enter this state.
- Cases of this type do not need **Contact Information**. This was a subjective decision and depends on your organization's philosophy.

The topics that follow describe each of the statuses in a high-bill complaint's [lifecycle](#). We have assumed the following state transition rules:

Lodged High Bill Complaint

The following is an example of the configuration of the Lodged status for high bill complaint cases.

Note the following about this status:

- Lodged is the initial state. The initial state is the state populated on new cases of a given type. Remember that only one status can be defined as the initial state.
- It has a button label even though it's the initial state. The above diagram doesn't allow a user to ever transition a case into this state and therefore there will never be a button with such a label. However, it's a required field just in case you change your business rules.
- We have decided not to use a BPA script to help a user work on a high-bill complaint when it's in this state (this is probably not the best decision as BPA scripts can be quite useful).
- We have associated the Add action with this status. This means that only users with rights to the add action for the application service defined on the case type can add cases of this type.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Canceled and Preliminary Investigation states.
- Notice that the Additional Processing plug-ins create and complete a To Do entry when a case enters and exits this state, respectively.

Preliminary Investigation High Bill Complaint

The following is an example of the configuration of the Preliminary Investigation status for high bill complaint cases.

Note the following about this status:

- Preliminary Investigation is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Start Investigation**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Lodged state as this is the only state that can transition into the Preliminary Investigation state.
- We have decided not to specify a BPA script on this status. Rather, we're going to set up the To Do type used to highlight cases in this state to automatically launch an appropriate BPA script when a user selects the To Do entry.
- We have associated the Start Investigation action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Field Investigation and Rejected states.
- Notice that a **Bill ID** must be specified on the case before it can be moved into this state.
- Notice that the Additional Processing plug-ins do the following:
 - Create and complete a To Do entry when a case enters and exits this state, respectively
 - Require a responsible user before a case can enter this state

Field Investigation High Bill Complaint

The following is an example of the configuration of the Field Investigation In Progress status for high bill complaint cases.

Note the following about this status:

- Field Investigation In Progress is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Send to Field**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Preliminary Investigation state as this is the only state that can transition into the Field Investigation in Progress state.
- We have decided not to specify a BPA script on this status because users don't work cases in this state (see the Additional Processing notes below for why this is the case).
- We have associated the Send to Field action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Decision Checkpoint and Rejected states.
- Notice that the Additional Processing plug-ins do the following:
 - Create a field activity when a case enters this state
 - Cause the case to automatically transition to the Decision Checkpoint state when the field activity is completed

Decision Checkpoint High Bill Complaint

The following is an example of the configuration of the Decision Checkpoint status for high bill complaint cases.

Note the following about this status:

- Decision Checkpoint is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Make Decision**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Field Investigation in Progress state as this is the only state that can transition into the Decision Checkpoint state.
- We have decided not to specify a BPA script on this status. Rather, we're going to set up the To Do type used to highlight cases in this state to automatically launch an appropriate BPA script when a user selects the To Do entry.
- We have associated the Make Decision action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state. Because the system will automatically transition cases into this state when the related field activity is complete, users will probably never press this button (and you may wish to prevent users from pressing this button by restricting security rights to the related action).
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Cancel / Rebill and Rejected states.
- Notice that the Additional Processing plug-ins create and complete a To Do entry when a case enters and exits this state, respectively.

Cancel Rebill High Bill Complaint

The following is an example of the configuration of the Cancel / Rebill status for high bill complaint cases.

Note the following about this status:

- Cancel / Rebill is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Cancel / Rebill**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Decision Checkpoint state as this is the only state that can transition into the Cancel / Rebill state.
- We have referenced a BPA script that can assist a user in the cancel / rebill efforts.
- We have associated the Rebill action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Completed and Rejected states.

Completed High Bill Complaint

The following is an example of the configuration of the Completed status for high bill complaint cases.

Note the following about this status:

- Completed is a final state (meaning that no further action is necessary).
- It has a button label of **Complete**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Cancel / Rebill state as this is the only state that can transition into the Completed state.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Complete action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Completed case to be reopened, you would need to define the state into which a Completed case could be transitioned.
- Notice that the **Net Difference** must be specified on the case before it can be moved into this state. This would be the difference to the customer's balance after the cancel/rebill took place.

Rejected High Bill Complaint

The following is an example of the configuration of the Rejected status for high bill complaint cases.

Note the following about this status:

- Rejected is a final state (meaning that no further action is necessary).
- It has a button label of **Reject**. This is the label on the button that a user presses to move a case into this state. This button will appear on cases that are in the Preliminary Investigation, Field Investigation in Progress, Decision Checkpoint and Cancel / Rebill states.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Reject action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Rejected case to be reopened, you would need to define the state into which a Rejected case could be transitioned.
- Notice that a **Reject Reason** must be specified on the case before it can be moved into this state.

Canceled High Bill Complaint

The following is an example of the configuration of the Canceled status for high bill complaint cases.

Note the following about this status:

- Canceled is a final state (meaning that no further action is necessary).
- It has a button label of **Cancel**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Lodged state as this is the only state that can transition into the Completed state.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Cancel action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Canceled case to be reopened, you would need to define the state into which a Canceled case could be transitioned.
- Notice that a **Cancel Reason** must be specified on the case before it can be moved into this state.

Setting Up Case Management Options

The topics in this section describe how to set up the system to enable case management.

WARNING:

The following topics assume you thoroughly understand the concepts described under [The Big Picture Of Cases](#).

Installation Options

Case Info May Be Formatted By An Algorithm

An algorithm may be plugged in on the [installation record](#) to format the standard case information that appears throughout the system. Refer to [CSIN-DFLT](#) for an example of this algorithm.

This algorithm may be further overridden by a "Case information" plug-in on the [Case Type](#). Refer to [C1-CT-INFO](#) for an example of this algorithm.

Alert Info Is Controlled By An Installation Algorithm

An algorithm that is plugged in on the [installation record](#) is responsible for formatting the alerts that highlight if the person / account / premise in context has open cases. Refer to [CCAL-CASE](#) for an example of this algorithm.

Setting Up Application Services

As described under [Access Rights](#), you can prevent unauthorized users from accessing cases. The following points describe how to implement this type of security:

- Create an [application service](#) for each case type that needs to be secured
- Create an action on the application service for each status you need to secure
- Link the valid [user groups](#) to the application service and define which actions they can perform
- Define the application service on the [case type](#)
- Define the related action for each status on the [case type / status](#)

Setting Up Scripts

As described under [Scripts and Cases](#), BPA scripts can facilitate the creation and working of cases. Refer to the [Defining Script Options](#) for instructions describing how to set up scripts.

Setting Up To Do Types

As described under [To Do's and Cases](#), To Do entries can be used to highlight cases that require user attention.

The following points provide a high-level description of how to create (and complete) To Do entries for a case type:

- Create a To Do type for each different type of To Do entry used during a case's lifecycle
 - On the To Do type, think carefully about the roles whose users can work on the entries
 - Also consider if you would like a BPA script launched when a user selects the entry
- Specify the To Do type on the appropriate [entry processing](#) or [exit processing](#) algorithm
- If you want the system to automatically complete To Do entries, specify the To Do type on the appropriate [entry processing](#) or [exit processing](#) algorithm

Please be aware that the case maintenance transaction highlights the number of open and being worked To Do entries linked to the case being displayed on the page. However, the system can only do this if the To Do entries reference a [foreign-key characteristic](#) whose foreign key references the case table. If you use the [CSEN-TD](#) algorithm to create To Do entries when a case enters a given state, this algorithm will do this for you if:

- You have set up a [foreign-key characteristic type](#) whose [foreign key](#) references the case table
- In addition, the characteristic type must reference a characteristic entity of To Do Entry

Setting Up Characteristic Types

As described under [Additional Information](#), some of your cases may require additional information (in the form of [characteristics](#)). If this is true, you must set up the characteristic types before setting up the case types.

Refer to [Setting Up To Do Types](#) for instructions regarding a characteristic type that must be set up in order for the system to know the To Do entries that are associated with a case.

If you use the [CSEN-CC](#) algorithm to create customer contacts when a case enters a given state, you should set up a [foreign-key characteristic type](#) as follows:

- Its [foreign key](#) must reference the case table
- In addition, the characteristic type must reference a characteristic entity of Customer Contact

Setting Up Case Types

The case type maintenance transaction is used to maintain your case types. The topics in this section describe how to use this transaction.

FASTPATH:

Refer to [The Big Picture Of Cases](#) for more information about how a case type encapsulates the business rules that govern a case.

Case Type - Main

Use this page to define basic information about a case type.

Open the case type page by selecting **Admin > Customer > Case Type > Case Type > Add**.

NOTE:

Recommendation. Before using this transaction, we strongly recommend that you review the [Examples of Case Types](#).

Main Information

Enter a unique **Case Type** code and **Description** for the case type.

Use **Long Description** to provide a more detailed explanation of the purpose of the case type.

If your implementation requires restricting case types by CIS Division, specify a **CIS Division** on the case type.

Person Usage controls the applicability of a person on cases of this type. Select Required if a person must be defined on this type of case. Select Optional if a person can optionally be defined on this type of case. Select Not Allowed if a person is not allowed on this type of case.

Account Usage controls the applicability of an account on cases of this type. Select Required if an account must be defined on this type of case. Select Optional if an account can optionally be defined on this type of case. Select Not Allowed if an account is not allowed on this type of case.

Premise Usage controls the applicability of a premise on cases of this type. Select Required if a premise must be defined on this type of case. Select Optional if a premise can optionally be defined on this type of case. Select Not Allowed if a premise is not allowed on this type of case.

Entity Relationship controls the validation of relationships on cases of this type. *All* ensures that the account belongs to the person and that the account and premise are related. *Person and Account Only* disables the account and premise validation. *Premise and Account Only* disables the person and account validation. *None* disables all validation and allows any values. This setting only impacts the validation of values entered and works in conjunction with the three usage fields described above.

If you need to restrict access to cases of this type to specific user groups, reference the appropriate **Application Service**. Refer to [Setting Up Application Services](#) for the details of how to secure access to your cases.

If you are configuring a case type to handle the processing of data defined via a **Business Object**, associating the case type with a business object serves to link the properties of the business object (e.g. BO options) with cases of that type. Refer to [Business Objects](#) for further information. In addition, refer to [Automatic Transition Rules](#) for information on the role of BO options in case auto-transition errors.

Responsible User Usage controls the applicability of a responsible user on cases of this type. Select Required if a responsible user must be defined on this type of case. Select Optional if a responsible user can optionally be defined on this type of case. Select Not Allowed if a responsible user is not allowed on this type of case. Refer to [Responsible User Applicability](#) for more information.

Contact Information Fields

There are three contact information fields: **Contact Person & Method Usage**, **Contact Instructions Usage**, and **Case Phone Usage**. These fields are used to determine whether or not each type of contact information must be entered on case records with this case type. Select Required if the contact information must be entered, select Optional if the user can choose whether or not to include the contact information on this type of case, or select Not Allowed if the contact information cannot be entered on this type of case.

Algorithms

The **Algorithms** grid contains algorithms that control functions for cases of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Case Information	Optional	<p>We use the term "Case information" to describe the basic information that appears throughout the system to describe a case. The data that appears in "case information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the "Case information" algorithm on installation options or the system default "Case information" if no such algorithm is defined on installation options.</p> <p>Click here to see the algorithm types available for this system event.</p>

Case Type Tree

The tree summarizes the case type's lifecycle. You can use the hyperlinks to transfer you to the **Lifecycle** tab with the corresponding status displayed.

Case Type - Case Characteristics

To define characteristics that can be defined for cases of this type, open **Admin > Customer > Case Type > Search** and navigate to the **Case Characteristics** page.

Description of Page

Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on cases of this type. Turn on the **Default** switch to default the **Characteristic Type** when cases of this type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** box is checked. Refer to [Required Fields Before A Case Enters A State](#) for a description of how you can make option characteristics required at later stages in a case's lifecycle.

Case Type - Lifecycle

Case types that involve multiple users and multiple potential outcomes have complex lifecycles. Before you can design a case type's lifecycle, it's important that you thoroughly understand the concepts described under [Lifecycle](#) and [Status-Specific Business Rules](#). After thoroughly understanding these concepts, we recommend you perform the following design steps:

- Draw a "state transition diagram" as illustrated above under [Lifecycle](#). Keep in mind that if your state transition diagram is complex, your cases will be complex. While some cases warrant complexity, you should always ask yourself if there aren't better ways to achieve the desired results if your first effort results in complexity.
- Determine which characteristics (if any) are required during each stage of a case's lifecycle
- Determine when To Do entries (if any) should be created (and completed) during a case's lifecycle
- Determine additional validation (if any) that should be executed before a case enters and exits each state
- Determine additional processing (if any) that should transpire when a case enters or exits each state
- Determine if scripts are warranted to help users work the cases and, if so, design the scripts for each applicable state

When the above tasks are complete, you will be ready to set up a case type's lifecycle.

Open the Lifecycle page by selecting **Admin > Case Type > Case Type > Search** and navigate to the **Lifecycle** page.

NOTE:

You can navigate to a status by clicking on the respective node in the tree on the Main tab. You can also use the hyperlinks in the Next Statuses grid to display a specific status in the accordion.

Main Information

The **Status** accordion contains an entry for every status in the case type's [lifecycle](#).

Use **Status** to define the unique identifier of the status. This is NOT the status's description, it is simply the unique identifier used by the system.

Use **Description** to define the label that appears on the lifecycle accordion as well as the status displayed on the case.

Use **Script** to reference a BPA script that can assist a user work on a case while it's in this status. Refer to [A Script That Helps A User Work Through A Case](#) for the details.

Use **Access Mode** to define the action associated with this status. This field is disabled if an application service is not specified on the Main page. Refer to [Access Rights](#) for the details of how to use this field to restrict which users can transition a case into this state.

Use **Batch** to specify a batch control that will auto-transition the case. Any case in a status configured with a batch control will be transitioned when the batch job runs (rather than when **CASETRAN** is executed). For this purpose, batch process **C1-CSTRS (Case Scheduled Transition)** is supplied with base package, which will execute all Exit Status logic for the current status, and Enter Status logic for the destination status. You may choose to create a batch process with your own transition logic.

NOTE:

If you wish to defer transitioning a case in a particular status until the batch process on your case type status is executed, you should not populate an Auto-Transition algorithm on that status. Otherwise, CASETRAN will transition the case according to your Auto-Transition logic.

Use **Comment** to describe the status. This is for your internal documentation requirements.

Use **Sequence** to define the relative order of this status in the tree on the Main page.

Use **Status Condition** to define if this status is an Initial, Interim or Final state. Refer to [One Initial State and Multiple Final States](#) for more information about how this field is used.

Use **Transitory State** to indicate whether a case should ever exist in this state. Only Initial or Interim states can have a transitory state value of No.

The **Alert Flag** is used to indicate whether or not an alert should be displayed for customers with cases in the state. (The alert is shown via the base package Installation - Alert algorithm.)

Algorithms

The **Algorithms** grid contains algorithms that control important functions for cases of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Description
Auto Transition	This algorithm is executed to determine if a case that's in this state should be transitioned into another state. Refer to Automatic Transition Rules for the details. Click here to see the algorithm types available for this system event.
Enter Processing	This algorithm holds additional processing that is executed when a case is transitioned into this state. You can also specify state transition logic within Enter Processing routines. Refer to Additional Processing When Entering A State for the details. Click here to see the algorithm types available for this system event.
Enter Validation	This algorithm holds validation logic that executes before a case can enter a given state. Refer to Validation Before A Case Enters A State for the details. Click here to see the algorithm types available for this system event.
Exit Processing	This algorithm holds additional processing that is executed when a case is transitioned out of this state. Refer to Additional Processing When Exiting A State for the details.

Exit Validation	<p>Click here to see the algorithm types available for this system event.</p> <p>This algorithm holds validation logic that executes before a case can be transitioned out of a given state. Refer to Validation Before A Case Exits A State for the details.</p>
Script Launching	<p>Click here to see the algorithm types available for this system event.</p> <p>This algorithm sets the script launching option for the script associated with a given state, if any. Refer to Script Launching Option for the details.</p>
	<p>Click here to see the algorithm types available for this system event.</p>

Next Statuses

Use the **Next Statuses** grid to define the statuses a user can transition a case into while it's in this state. Refer to [Valid States versus State Transition Rules](#) for more information. Please note the following about this grid:

- Use **Action Label** to indicate the verbiage to display on the action button used to transition to this status.
- **Sequence** controls the order of the buttons that appear on [Case - Main](#). Refer to [Buttons Are Used To Transition A Case Into A State](#) for more information.
- **Use as Default** controls which button (if any) is the default button.
- **Transition Condition** may be configured to identify a common transition path for cases of this type in the current state. This transition condition may then be referenced across multiple case types. You'll need to add values to Look Up table field **TR_COND_FLG** that fit the typical transitions for your case types (e.g. Ok, Error, etc.).

By assigning the transition condition value to a given "next status", you can design your Enter State transition or Auto-Transition logic to utilize those flag values *without specifying a status particular to a given case type*. Thus, similar logic may be used across a range of case types to transition a case into, for example, the next Ok state for the case's current status.

- **Transition Role** controls whether only the System or both System and User have the ability to transition a case into a given "next status".
- You can use the status description hyperlink to open the Status accordion to the respective status.
- When you initially set up a case type, none of the statuses will reside on the database and therefore you can't use the search to define a "next status". We recommend working as follows to facilitate the definition of this information:
 - Leave the Next Statuses grid blank when you initially define a case type's statuses
 - After all statuses have been saved on the database, update each status to define its Next Statuses (this way, you can use the search to select the status).

Required Characteristics

Use the **Required Characteristics** grid to define characteristics that are required when a case enters this state. Only Optional characteristics defined on the main page appear in this grid. Refer to [Required Fields Before A Case Enters A State](#) for more information.

Defining Umbrella Agreement Options

Your organization may use umbrella agreement functionality to manage many situations, including (but not limited to) the following:

- Creating a "negotiated contract" with a large customer with many sites.
- Creating a "negotiated contract" with all customers in a common geographic area, for example a specific city or an apartment complex

- Grouping and managing the proposal service agreements created during the quoting process
- Managing the renewal process for special contracts
- Applying override rate terms to one or more service agreements for a given effective period
- more...

NOTE:

Separately module. The umbrella agreement functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

The Big Picture Of Umbrella Agreements

The topics in this section provide background information about how to configure the system to support your umbrella agreement requirements.

Renewable Umbrella Agreements

When defining your umbrella agreement types, you must determine if umbrella agreements of this type are renewable. If so, you must set the renewal flag on the UA type to Renewable and determine the number of days prior to the end date of the umbrella agreement that the renewal process should start.

In addition, you must decide on your renewal procedure and design an appropriate renewal [algorithm](#). You may use one of the sample renewal algorithms provided by the system.

- The sample algorithm [URNW-TD](#) creates a To Do entry. Using this algorithm you can direct the To Do entry to an appropriate role to determine if the umbrella agreement should be renewed. If the umbrella agreement is associated with an account management group, the To Do entry could be assigned to a role defined for that AMG.
- The sample algorithm [URNW-CA](#) creates a [case](#). Using this algorithm you can create an appropriate case to help track the steps required for renewing an umbrella agreement.

If the base algorithms do not provide the logic your organization needs, you may create a new algorithm.

NOTE:

It is the responsibility of the renewal algorithm to change the renewal date as per the business requirements. If renewal requires manual review, the algorithm should reset the date to blank. If the algorithm can determine a new renewal date, the date should be changed to the appropriate value.

Terms Of Service Covered Entities

For each terms of service type you design, consider whether or not a TOS created for this type should reference one or more entities in the system that are "covered" by the terms of service. Following are some examples of covered entities:

- A special contract is created for all the McDonalds franchises in your service area. When creating the terms of service record for the umbrella agreement used for this contract, you want the user to link the person record representing the McDonalds corporate entity as a covered entity for the TOS.
- An umbrella agreement is created for a large customer with several types of services. Perhaps you want to group the services in the contract based on type of service. The service type may be set up as a covered entity.

The covered entities could also be used to denote eligibility. Refer to [Linking To A UA For A Group Of Premises](#) for an example of using the covered entity collection for eligibility.

The covered entities are actually characteristics. You must define the desired characteristic types if they do not already exist. In this case, they would be foreign key characteristic types. The characteristic types that you want to use must reference a characteristic entity of TOS covered entity.

A terms of service record may only reference covered entity types that you designate on the Terms of Service type record. When designing the covered entities that are allowed for TOS records of a given type, you may also configure the Terms of Service type to indicate that one or more covered entity types are required.

Refer to [Terms Of Service Type - Main](#) for more information.

Overriding Rate Terms

If your organization has business rules that require a service agreement's rate terms to be overridden, you can accomplish this using umbrella agreements and terms of service records. There are two levels of overriding that are possible:

- Override rate schedule
- Override other terms on the rate, including contract riders, contract terms and tax exemptions

To override any rate terms, the service agreement must be linked to a terms of service record that references a template service agreement. In addition, you must configure settings in the system to indicate whether or not overriding of terms is allowed.

- The [SA type](#) for the customer's service agreement indicates whether or not the rate schedule may be overridden using the rate source flag.
 - If the rate source value is Check TOS First, then SA, when applying the rate, the system determines if the SA is linked to a TOS effective at the time of the bill with a template SA. If so, the rate schedule on the template SA is used.
 - If the rate source value is Check SA Only, when applying the rate, the always uses the rate schedule on the customer's SA (regardless of whether or not the SA is linked to a TOS effective at the time of the bill with a template SA).
- If any bill factor on one of calculation rule indicates that it is eligible for tax exemptions, contract terms or contract riders, the terms of service usage flag on the bill factor indicates where the system should look for the appropriate value. The flag tells the system to find applicable information either on the TOS's template SA only, on the customer's SA only or it should first check the TOS, then check the customer's SA.

The following table illustrates the different scenarios possible when configuring your bill factors and the resulting behavior. The term "standard behavior" in the tables below indicate that the standard behavior as described in [Defining Bill Factors](#) is followed.

	TOS Usage	Template SA	Customer SA	BF Char Source
Contract Rider Applicability is checked	Check TOS First, then SA	Found	Not checked	If source = SA, the template SA's characteristic collection is checked. If source <> SA, the standard behavior is followed.
		Not Found	Found	If source = SA, the customer SA's characteristic collection is checked. If source <> SA, the standard behavior is followed
		Not Found	Not Found	N/A

Check TOS Only	Found	Not checked	If source = SA, the template SA's characteristic collection is checked. If source <> SA, the standard behavior is followed
	Not Found	Not checked	N/A
Check SA Only	Not checked	Standard behavior	

TOS Usage	Template SA	Customer SA	BF Value Source	BF Char Source	
Value in Contract Term is checked	Check TOS First, then SA	Found	Not checked	Template SA	N/A
		Not Found	Found	Customer SA	N/A
		Not Found	Not Found	Bill Factor Value (based on Char Source)	If source = SA, the template SA's characteristic collection is checked. If source <> SA, the standard behavior is followed
Check TOS Only	Found	Not checked	Template SA	N/A	
	Not Found	Not checked	Bill Factor Value (based on Char Source)	If source = SA, the template SA's characteristic collection is checked. If source <> SA, the standard behavior is followed	
Check SA Only	Not checked	Standard behavior			

TOS Usage	Template SA	Customer SA	BF Value Source	
Tax Exemption is checked	Check TOS First, then SA	Found	Not checked	Template SA
		Not Found	Found	Customer SA
		Not Found	Not Found	No value
Check TOS Only	Found	Not checked	Template SA	
	Not Found	Not checked	No value	
Check SA Only	Not checked	Standard behavior		

Note that [proration](#) logic is followed for the above functionality as expected. For example, imagine that a bill factor with Value in Contract Terms is proratable and the TOS usage value is Check TOS First, then SA. If the template SA has a contract value that is only in effect for the first 10 days of a bill, that value is used for the first 10 days and the remaining days in the bill take the value from the SA (if applicable) or the bill factor value as per the table rules above.

NOTE:

When designing your terms of service type, you must indicate whether a template service agreement is optional, required or not allowed. When the template SA is required, the user setting up the TOS record for this TOS type must

link the correct service agreement as the template SA. If a new template service agreement is required, the new SA must be created first.

Setting Up Umbrella Agreement Options

The topics in this section describe how to set up umbrella agreement options.

Configure SA Types for Umbrella Agreements

For each type of service agreement that may be linked to a terms of service record, you must configure the Rate Source for the [SA type](#) to indicate if the rate should always be taken from the service agreement ([Check SA Only](#)) or if the rate should be taken from the terms of service record for the service agreement, if any ([Check TOS First, then SA](#)).

FASTPATH:

Refer to [Overriding Rate Terms](#) for more information.

NOTE:

The rate source is only visible on SA type if the Contract Management module is not [turned off](#).

Configure Bill Factors for Umbrella Agreements

For each bill factor that has a value in contract term, contract rider applicability or tax exemption applicability, you must indicate where the system should look for a value when a service agreement is linked to a terms of service with a template SA and where this bill factor is referenced by the rate being applied. Using the terms of service usage flag, tell the system to [Check TOS Only](#), [Check SA Only](#) or [Check TOS First, then SA](#).

FASTPATH:

Refer to [Overriding Rate Terms](#) for more information.

NOTE:

The terms of service usage flag is only visible on bill factor if the Contract Management module is not [turned off](#).

Configure A Campaign To Link An SA To A Terms Of Service

The system provides a pair of column reference algorithm types that support linking a new service agreement to an existing terms of service record via an [order](#). The pair includes a validation algorithm type [CRVL-SATOS](#) and a posting algorithm type [CRPS-SATOS](#).

In order to take advantage of this functionality, you must:

- Create an algorithm for each of the above algorithm types. Only one algorithm is needed for each algorithm type because there are no parameters for either one.
- Setup a unique [column reference](#) for the terms of service ID column reference code and plug in the new validation and posting algorithms on the record.

- For campaigns whose orders link a new service agreement to an existing umbrella agreement, make sure to define a [miscellaneous field](#) for the terms of service ID. Note, the miscellaneous field must reference the column reference that you setup above.

Based on your business practice, you may want to further configure your campaign / package for linking a service agreement to an existing terms of service. Refer to [Linking A Service Agreement To A TOS Through Orders](#) for more information.

Setting Up Umbrella Agreement Types

The umbrella agreement type transaction is used to maintain your UA types. The topics in this section describe how to use this transaction.

Umbrella Agreement Type - Main

Open **Admin > Umbrella Agreement > Umbrella Agreement Type > Add** to define basic information about an umbrella agreement type.

Description of Page

Enter a unique **Umbrella Agreement Type** code and **Description** for the UA type.

Use **Renewal** to indicate whether an umbrella agreement of this type is Renewable or Not Renewable. For renewable UA types, indicate the **Renewal Days Before Expiration**. The renewal date for umbrella agreements of this type are calculated based on this number of days before the end date.

Use the characteristics collection to define characteristics that can be defined for umbrella agreements of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on umbrella agreements of a given type. Turn on the **Default** switch to default the **Characteristic Type** when umbrella agreements of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

NOTE:

Characteristic Types. You can only choose characteristic types defined as permissible on an umbrella agreement record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Enter the valid **Terms of Service Types** that may be referenced for umbrella agreements of this type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_UA_TYPE](#).

Umbrella Agreement Type - Algorithms

Open **Admin > Umbrella Agreement > Umbrella Agreement Type > Search** and navigate to the **Algorithms** page.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).

- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

System Event	Description
UA Renewal	<p>Algorithms of this type are executed by the UARENEW background process when an umbrella agreement has reached its renewal date.</p> <p>Only one renewal algorithm is allowed for a given UA type.</p> <p>Click here to see the algorithm types available for this system event.</p>

Setting Up Terms Of Service Types

The terms of service type transaction is used to maintain your Terms of Service types. The topics in this section describe how to use this transaction.

Terms Of Service Type - Main

Open **Admin** > **Umbrella Agreement** > **Terms of Service Type** > **Add** to define basic information about terms of service types.

Description of Page

Enter a unique **Terms of Service Type** code and **Description** for the TOS type.

Use **Template SA Usage** to indicate whether a template SA is Optional, Required or Not Allowed. Refer to [Overriding Rate Terms](#) for more information about using template SAs.

Use the characteristics collection to define characteristics that can be defined for terms of service records of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on terms of service records of a given type. Turn on the **Default** switch to default the **Characteristic Type** when terms of service records of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

NOTE:

Characteristic Types. You can only choose characteristic types defined as permissible on a terms of service record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Use the **Covered Entities** collection to define the types of entities that are "covered" by terms of service records of this type. Refer to [Terms Of Service Covered Entities](#) for more information

NOTE:

Characteristic Types. You can only choose characteristic types defined as permissible for TOS covered entity. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_TOS_TYPE](#).

Terms Of Service Type - UA Types

Open **Admin** > **Umbrella Agreement** > **Terms of Service Type** > **Add** and navigate to the **UA Types** page.

Description of Page

Enter the valid **Umbrella Agreement Types** that may reference this terms of service type.

Setting Up Terms of Service Cancel Reasons

Whenever a terms of service record is canceled, a cancel reason must be specified. Open **Admin** > **Terms of Service Cancel Reason** to specify such cancellation reasons.

Description of Page

Enter an easily recognizable **Terms of Service Cancel Reason** and **Description** for the terms of service cancellation reason.

Umbrella Agreements Configuration Examples

This section provides examples of how you would configure the system to support various business scenarios.

Linking A Service Agreement To A TOS Through Orders

As described in [Configure A Campaign To Link An SA To A Terms Of Service](#), the system has provided a pair of column reference algorithms to enable your users to link a new service agreement to an existing terms of service record (and its umbrella agreement) when starting service via the order transaction.

When designing your campaign and packages to use this option, consider the scenarios where you may use this to determine whether or not you require additional configuration. The following topics describe some possible scenarios.

Linking To A UA For A Given Account

Imagine that you would use this logic when an important customer is starting additional service and has an existing umbrella agreement for other services that the new service should be added to. The user creating the order is probably the account manager for that account and would know the correct terms of service record to link the new service to.

For this scenario, you do not need to provide any "help" to the user to indicate that linking to a TOS is an option or to help select the correct TOS. You simply need to ensure that the campaign that would be used by this account manager to start service for the important customer simply includes a question / miscellaneous field to [link the SA to the terms of service](#).

Linking To A UA For A Group Of Premises

Imagine you have created an umbrella agreement for a group of premises that are not actively managed by a specific user. For example, perhaps there are several apartment complexes that have negotiated a special rate with your company. When new customers sign up for service at a premise that belongs to one of these apartments, the user should be informed that

there is a special contract for this premise. The user may also need help selecting the correct terms of service record. To accomplish this logic, you must define additional algorithms to help your users.

For example, perhaps your standard campaign for residential electric customers includes a package to be used by premises linked to one of these apartment buildings and should only be eligible to one of those premises. You must create an eligibility algorithm for this package. Its logic could be designed based on the following assumptions:

- The qualifying premises are linked to a parent premise
- The parent premise is linked to the appropriate terms of service record in its covered entity collection

The eligibility algorithm checks to see if the order's premise is linked to a parent premise that is referenced on a terms of service record for an umbrella agreement that is currently in effect. It could also be restricted to search for a specific umbrella agreement type or terms of service type if appropriate.

NOTE:

The campaign for this scenario must include a question / miscellaneous field to [link the SA to the terms of service](#). It should be configured with an applicability of only applicable on package. The package that is used to include the SA into the terms of service for the apartment complex would include this question / miscellaneous field.

Once the user chooses this package, user is prompted to provide the correct terms of service record via the question / miscellaneous field. To help the user, you should create a column reference retrieval algorithm to default the correct terms of service record for this premise. It would use the same logic as the eligibility algorithm described above. In other words, it would find the parent premise for this premise and then find the terms of service record covered entity collection includes this parent premise and whose umbrella agreement is currently in effect.

Reports Addendum

This chapter is an addendum to the general [Defining and Designing Reports](#) chapter.

Configuring the System to Invoke Oracle BI Publisher Enterprise Real-Time

In order to invoke Oracle BI Publisher Enterprise from within the system, it must be configured. This topic describes the steps at a high level that are required to configure your system to enable BI Publisher..

Specify Reporting Tool Options

The following information should be defined on Reporting Tool Options table:

- **Reporting Server** is the web server URL where the reporting tool is installed.
- **Reporting Folder** defines the name of the directory on the Oracle BI Publisher server where reports are located. The system's reporting tool algorithm constructs the URL to open Oracle BI Publisher Enterprise based on the information provided on Reporting Options. The same folder name should be used as a report folder in Oracle BI Publisher Enterprise where reports are published.

Reporting Tool Algorithm

The base product provides an installation algorithm plug-in spot called Reporting Tool. This plug-in spot should contain an algorithm that invokes the reporting tool real-time. The corresponding algorithm type, called algorithm reference: [F1-BIPR-INV](#), invokes Oracle BI Publisher Enterprise.

This algorithm relies on information defined in the Reporting Options table: the reporting server and folder names for accessing the reporting tool. The algorithm constructs several strings, for example, the URL of the BI Publisher, information about the report being requested and user info in the format expected by Oracle BI Publisher Enterprise. The Java program returns the correct URL to the browser. The browser then opens a BI Publisher Enterprise window with the appropriate URL.

To use the algorithm reference: [F1-BIPR-INV](#) algorithm type to invoke Oracle BI Publisher Enterprise, perform the following steps:

1. Create an algorithm for this algorithm type.
2. In the installation options, add an entry to the algorithm collection with an algorithm entity of Reporting Tool and indicate the algorithm created in the previous step.

Interface with Oracle BI Publisher Enterprise Batch Scheduler

Presently the base product does not provide support for batch jobs with Oracle BI Publisher. Please use Oracle BI Publisher directly in order to schedule reports to run in batch.

Configuring the System for Batch Bill Print

This section describes the steps for configuring the applications to print bills in batch.

Configure Oracle BI Publisher for Batch Bill Print

1. Configure the Oracle BI Publisher Scheduler to allow report job submission.

NOTE:

Refer to the Oracle Fusion Middleware Administrator's Guide for Oracle Business Intelligence Publisher for more information.

2. Ensure that the CI_BILLPR report artifacts (CI_BILLPR.rtf, CI_BILLPR.xdo, CI_BILLPR.xdm) are deployed to corresponding BI Publisher catalog folder:

Configure Oracle Utilities Customer Care and Billing for Batch Bill Print

1. Go to **Admin > Reporting > Reporting Options** and configure the following values:

- **Reporting Server from Browser** should point to the correct BI Publisher Server URL; for example, `http://<hostname>:port`
 - **Reporting Folder** is the name as the Catalog Folder in BI Publisher where **CI_BILLPR** is located; for example, CCB
 - **Reporting Engine User ID** is the BI Publisher User ID.
 - **Reporting Engine Password** is the BI Publisher Password.
2. Create a custom Bill Route Type Extract Algorithm using the **CI-BLEX-BIP** Algorithm Type. Ensure that the following algorithm soft parameters are set:
 - **Output Directory** is the directory in BI Publisher server where the generated output files will be placed, for example, `/tmp/`
 - **Report Absolute Path** is the path where `CI_BILLPR.xdo` is located in the BI Publisher Catalog, for example, `/CCB/CI_BILLPR/CI_BILLPR.xdo`
 - **Report Format** is the format of the generated output files; for example, `pdf`
 - **Report Code** is the **CI_BILLPR** report code; for example, `CI_BILLPR`
 3. Go to **Admin Menu, B, Bill Route Type** and configure the corresponding Bill Route Type (such as, `POSTAL`) to use the **RTTYPOST** Batch Control and the custom Bill Route Type Extract Algorithm.

Description of Sample Reports

This section provides an overview of each sample report supplied with Oracle Utilities Customer Care and Billing that may be found in the demonstration database. They may be used by your organization as they are or as a starting point for creating a [new report](#).

NOTE:

Account Security. The sample reports provided with the product do NOT incorporate account security. If a user has been given security to view the report, then all the data in the report is available for viewing.

Active Severance Processes - CI_ACSVPR

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Start date to use for reporting severance processes. If not defined, start date is set to 1900-01-01.
End Date	P_TO_DT	End date to use for reporting active severance processes. If not defined to date is set to the current date.

Report Description

This report is used to aid in the monitoring of active severance processes. The report details are used to review how the company is doing as far as the collection of outstanding debt, as well as to monitor the progress of currently active severance processes.

The report selects active severance processes whose creation date is between the input start and end dates.

Bill Print in BI Publisher - CI_BILLPR

Parameters

Parameter	Parameter Code	Description
CC&B user	P_USER_ID	No default value. Required. Returns an error message if user ID is null, empty or does not exist in database.
Batch Switch	P_BATCH_SW	For a single bill print, Batch Switch is 'No' and for multiple bill print, Batch Switch is 'Yes'.
First Bill	P_FROM_BILL_ID	First Bill Id to print for the Bill Range.
Last Bill	P_TO_BILL_ID	Last Bill Id to print for the Bill Range.
Batch Code	P_BATCH_CD	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch code are selected.
Batch Number	P_BATCH_NBR	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch number are selected.
Extract Algorithm	P_EXTRACT_ALG	Passed in by the system the report is submitted in batch. Only bills with a Bill Routing whose bill route type references this extract algorithm are selected.

Report Description

This report is used with BI Publisher to display all the information that appears on the customer's printed bill for the bill ID entered in the input parameters. Refer to the description of the parameters above. The bill is only displayed if the bill is complete.

See below for details of the information extracted for the report. In addition, the sample report layout provided for the base product includes:

- Payment coupon.
- Form for change of address.
- A graph of consumption for current charges.

The following sections highlight the data that is extracted for this report.

that retrieves all the cancel reason codes and descriptions.)

Bill Message Information

One record for every bill message linked to the bill.

Field Name	Format	Source/Value/Description
MSG_PRIORITY_FLG	A12	CI_BILL_SA or CI_FT
INSERT_CD	S15.2	CI_BILL_SA or CI_FT
MSG_ON_BILL	S15.2	CI_BILL_SA or CI_FT

Billed Revenues by Rate - CI_BILREV

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_REV_ACCTY_CHAR	Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts.

Report Description

This is an analysis report for the billed revenues for an accounting period according to the various rates, which were in effect in the system. The information in this report helps to adjust rates in order to achieve better financial results and comply with regulations and market trends.

This report selects all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within input accounting period (parameter 1)
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 2 & 3)

NOTE:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the

benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Case Statistics By Case Type - CI_CSESTS

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Condition (Open, Closed)	P_COND_FLG	If specified, only cases in this condition are included in the report. If left blank, the reports produces statistics for both open and closed cases.

Report Description

This report provides two types of statistics:

1. Open cases whose creation date falls between the input Start Date and End Date (inclusive)
2. Closed cases whose closing date falls between the input Start Date and End Date (inclusive)

The third parameter is only used if you want to restrict the statistics to only open or closed cases. If you leave this parameter blank, both open and closed statistics will be produced.

The following information is provided in graphical format:

- Number of cases by case type
- Percentage of cases by case type

Case Statistics for a Given Status - CI_CSESGS

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used.

If end date is not specified, it is defaulted to the current processing date.

Case Type/Status	P_CASE_STATUS_CD	This is the desired Case Type and Status that will be reported on.
Responsible User	P_CASE_OWNER	If specified, only cases with this responsible user are included in the report.
First Bucket High Limit	P_B1_LIMIT	Cases that took <= this number of days to reach the given status will be grouped together for statistical reporting.
Second Bucket High Limit	P_B2_LIMIT	Cases that took <= this number of days but more than the first bucket high limit to reach the given status will be grouped together for statistics reporting.
Third Bucket High Limit	P_B3_LIMIT	Cases that took <= this number of days but more than the second bucket high limit to reach the given status will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group.

Report Description

This report shows cases of a given case type that transitioned to a given status during a given date range.

Graphs are printed to show the number and percentage of cases grouped by the time it took to reach the status. These statistics are grouped into age buckets whose size is controlled by the last 3 parameters.

Summary statistics are also printed showing the minimum, maximum, average and median times for these cases.

Collection Summary - CI_CLLSUM

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	If from date is not set, the default is one month prior to the current date.
End Date	P_TO_DT	End date of the date range. If not defined by user, it is set to one month after the current date

Report Description

This report provides detailed monthly summary information of all collection activities. The report is typically used by a collection department for resource planning and performance review purposes.

This report selects pending and completed collection events whose event trigger date falls between the input start and end dates.

Customer Contacts by Type - CI_CUSTCN

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Start date to use for reporting customer contacts. If not defined, the start date is set to the current date minus 7 days.
End Date	P_TO_DT	End date to use for reporting customer contacts. If not defined, End Date is set to the current date.
Customer Contact Class / Type	P_CC_TYPE_CD	Specify a Customer Contact Class / Type to restrict the report output to a specific class / type.

Report Description

This report lists all customer contacts in the system created within the input date range. You may optionally restrict the report to customer contacts for a given Customer Contact Class / Type (parameter 3).

NOTE:

Graphs. The information on this report is shown in both textual and graphical formats.

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_CC table on CC_DTTM to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Customers with Life-Support / Sensitive-Load - CI_PMLSSL

Parameters

Parameter	Parameter Code	Description
Service Type	P_SERVICE_TYPE	Service type used to restrict the report to premises with services of this type.

Report Description

This reports displays a detailed list of premises that are coded with Life-Support (LS) or Sensitive-Load (SL) information. It may optionally restrict the output to premises with service points for input service type.

This information is used by a company to make sure that customers at these premises are dealt with appropriately in the case of an outage (planned and unplanned) or service cut due to non-payment.

The report provides detailed information about the premise and the related facility elements providing service to that premise (e.g. substation, feeder and node for electric service).

NOTE:

If ANY person connected to an account has an LS/SL indication in the Person record, then all the premises connected to this account will be treated as LS/SL. This means, for example, that a premise connected to an account that has a 3rd party guarantor with LS/SL is treated as a premise with LS/SL.

GL Accounting Summary - CI_GLACSM

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. The account types for the GL accounts are used for grouping the output to the report.

Report Description

This is a financial audit report used to check the financial details in Oracle Utilities Customer Care and Billing for an accounting period against the GL system. The report summarizes all financial transaction (FT) information for a given accounting period according to the different operating and GL divisions and according to various levels of the account GL information.

NOTE:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Letter Print - BI Publisher Sample Welcome Letters - CI_LTRGN_ENG REPORT

NOTE:

Generating letters in batch is not supported yet.

Parameters

Parameter	Parameter Code	Description
Batch Switch	P_BATCH_SW	For reports accessed online, set the switch to 'No'. Otherwise, it should be set to 'Yes'.
Customer Contact	P_CC_ID	References the customer contact associated with the main customer linked to the account.

Report Description

This sample report template for BI Publisher produces letters that are not associated with any other object (i.e., the template does not have to extract information from another object to merge into a letter). You can use this template as a welcome letter for a new customer.

By default, the English versions of the report templates are provided with the base product. If multilingual report templates are required, your implementation should provide reports for each language. When a letter is generated, the system uses the report template based on the customer's language.

The address and name for the company are extracted from the [installation options](#). The text for the letter is defined in the report layout and not provided by Oracle Utilities Customer Care and Billing. Reports are printed according to the customer's language definition and not based on the user's language definition.

This sample report uses the following text:

Welcome to %1. You have been filed with ID Number %2.

We hope to provide you with our best possible service. If you experience any problems or have any questions, please contact one of our customer service representatives at (800)1234567.

%1 is the company name stored as a message on the [installation options](#).

%2 is Person Id stored on the Customer Contact.

Open Cases By Type - CI_CSEOPN

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date.
End Date	P_TO_DT	See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date.
Case Type	P_CASE_TYPE_CD	If specified, only cases of this type are included in the report.
Responsible User	P_CASE_OWNER	If specified, only cases with this responsible user are included in the report.
First Bucket High Limit	P_B1_LIMIT	Cases that are open for less than or equal to this number of days will be grouped together for statistical reporting.
Second Bucket High Limit	P_B2_LIMIT	Cases that are open less than or equal to this number of days but more than the first bucket high limit will be grouped together for statistics reporting.
Third Bucket High Limit	P_B3_LIMIT	Cases that are open less than or equal to this number of days but more than the second bucket high limit will be grouped together for statistics reporting. Cases that took more than

this number of days are included in another group.

Report Description

This is a report on open cases that were created between a given date range.

The report can be limited to a specific type and/or responsible user.

For each case type, the report shows the following:

- Number of open cases by age bucket (the last 3 parameters control the size (in days) of each bucket)
- Percentage of open cases by age bucket
- Details of the open cases

Payments Balance - CI_PMTBAL

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Report gets all the payments that have been received during a given date range (from and to date parameters). If start date is not defined by the user, it is set to 7 days prior to the current date.
End Date	P_TO_DT	End date of the date range. If not defined by user it is set to the current date

Report Description

This report provides an overall view of all payments created within the input date range. It is typically used for financial control and audit purposes. The report provides summary information about valid payments received and about canceled payment. Data is summarized by the tender source and the type of payment.

Receivables Aging - CI_RCVAGA

Parameters

Parameter	Parameter Code	Description
Cutoff Date	P_CUTOFF_DATE	The date from which the arrears buckets are calculated. If no value is entered, the default is the current date minus 7 days.
First Bucket High Limit	P_B1_LIMIT	High limit of first bucket.
Second Bucket High Limit	P_B2_LIMIT	High limit of second bucket.
Third Bucket High Limit	P_B3_LIMIT	High limit of third bucket.

Report Description

This report lists all accounts and their arrears information as of the input cutoff date using a balance forward accounting method.

Outstanding debt is placed into the buckets provided as input using the age of the debt as of the cutoff date. Credits are applied to the oldest debt first. For each account a separate bucket is used to display new charges. In addition, the total accounts receivable balance is displayed for each account.

NOTE:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ARS_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Tax Payables Analysis - CI_TXPYBL

Parameters

Parameter	Parameter Code	Description
Start Date	P_FROM_DT	Show summary of the tax amounts starting from this date. If not specified, the system will default this value to the current date minus 7 days.
End Date	P_TO_DT	Show summary of the tax amounts up to this date. If not specified, the system will default this value to the current date.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.
Account Type	P_TAX_ACCTY_CHAR	Account Type Char Value for tax related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #3. The parameter value indicated for this parameter should be one that represents tax liability accounts.

Report Description

This report displays a summary of the tax amounts that were levied by the company to customers within the input date range. It also includes the tax exemption information for that period.

This report select all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within the input date range
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 3 & 4)

The report also provides tax exemption information for bill segments whose financial transactions satisfy the above criteria. The tax exemption information is retrieved by looking at the bill calculation lines associated with the FT's bill segment.

NOTE:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

To Do Entries - CI_TDENTR

Parameters

Parameter	Parameter Code	Description
ToDo Entry Status	P_ENTRY_STATUS_FLG	Defines if the To Do entries on the report should be limited to those with a given status value. If this parameter is left blank, the report will show all open and being worked To Do entries.
ToDo Type	P_TD_TYPE_CD	Defines if the To Do entries on the report should be limited to those of a given ToDo type. If this parameter is left blank, the report will show all ToDo type that have at least one open or being worked entry.

Report Description

The report shows open and being worked To Do entries.

You can limit the report to entries in a given status by specifying the desired **To Do Status** (open or being worked). If you don't specify a status, all open and being worked To Do entries will appear on this report.

You can also limit the report to entries of a given To Do Type by specifying the desired To Do Type. If you don't specify a To Do Type, all To Do Types with at least one entry in the open / being worked state will appear on this report.

NOTE:

Graphs. The information on this report is shown in both textual and graphical formats.

Umbrella Agreement Summary - CI_UASUMM

Parameters

At least one parameter is required. If the umbrella agreement is entered, no other parameter value is allowed. The report definition uses the validation algorithm [RPTV-UASUMM](#) to check these conditions.

Parameter	Parameter Code	Description
Umbrella Agreement	P_UA_ID	Specify the Umbrella Agreement to restrict the report to this umbrella agreement (regardless of its status). When this parameter is specified, all other parameters are not allowed.

Account Management Group	P_AMG	Specify a value for this parameter to restrict the report to umbrella agreements related to this Account Management Group.
Umbrella Agreement Characteristic Type	P_CHAR_TYPE	Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type and value (parameter 4).
Umbrella Agreement Characteristic Value	P_CHAR_VALUE	Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type (parameter 3) and value.
Number of Days Before Expiration	P_EXPIRE_IN_X_DAYS	Specify a value for this parameter to restrict the report to completed umbrella agreements whose End Date is on or before the current date less the Number of Days before Expiration.

Report Description

This report provides summary information about one or more [umbrella agreements](#).

If the user does not supply an umbrella agreement ID, but enters one or more of the other parameters, the report only selects umbrella agreements that match the input criteria AND the match the following criteria:

- The status of the umbrella agreement is complete
- The start and end dates of the umbrella agreement include the current date

The report does not include canceled terms of service records or canceled service agreements linked to the above umbrella agreements.

For each umbrella agreement that is included in the report, the output includes information about the umbrella agreement, its collection of terms of service records and for each TOS record, its collection of service agreements.

In addition, the report includes the following graphs:

- Umbrella agreement summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all service agreements linked to the umbrella agreement's terms of service records.
- Terms of service summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all its service agreements

Unbilled Revenues - CI_UBLREV

Parameters

Parameter	Parameter Code	Description
Accounting Period	P_ACCT_PERIOD	Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided.
Account Type Characteristic	P_CHAR_TYPE	Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type.

Account Type

P_REV_ACCTY_CHAR

Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts.

Report Description

This report provides a simplified calculation of estimated unbilled revenue for a given month.

It processes frozen financial transactions associated with bill segments and canceled bill segments whose bill segment end date is within the **Accounting Period** (parameter 1). It determines the billed revenue for the FT and then uses this information to calculate the unbilled revenue.

To determine "revenue", the report summarizes amounts posted to any distribution code with a characteristic entry that matches the input **Account Type Characteristic** type and **Account Type** characteristic value (parameters 2 and 3).

The estimate for the unbilled portion is calculated as (Bill Amount / Number of Days in the Bill Period) * Number of Unbilled Days for the Accounting Period.

For example, consider a bill segment on a monthly-billed cycle for the period of 3/10/03 - 4/9/03, and for \$150 (revenue part of the bill). Assume we are in the April/03 accounting period, which covers 4/1/03 through 4/30/03. This means 21 days are unbilled for April. The unbilled revenue is calculated as $150/31 * 21 = \$101.61$.

The following are some points to note about this report.

- If the report runs for an historical date, it still estimates the unbilled revenue portion based on the above formula even if actual data exists. In other words, it will not try to find actual bills for subsequent months. As a result, this report always shows what would have been the estimated unbilled revenue for a particular month if that month is the most recent one.
- Services can be billed monthly bi-monthly, quarterly or in any desired frequency. This report only performs the revenue recognition estimation using actual bills that were created in the report's accounting period. As a result, it does not estimate unbilled revenue for accounts that were not billed in any portion of the input accounting period.
- Revenue recognition practices are unique and may vary from customer to customer. In a given month we can produce current bills (e.g. for electric service) or future bills (e.g. cable services). In addition in some cases we can have bills that started before the accounting period and ending after it (for example in a cancel-rebill situation). This report will only estimate unbilled revenues for bills with the accounting period equals to the report's accounting period.

NOTE:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_BSEG table on START_DT, END_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Defining Overdue Processing Options

The system periodically monitors how much your customers owe to ensure they haven't violated your collection rules. When a violation is detected, the system initiates the appropriate activities (e.g., letters, disconnect notices, collection agency referrals, and eventually write off). The topics in this section describe how to configure the system to manage your overdue processing requirements.

NOTE:

The overdue processing module has been designed to collect on virtually anything from an unpaid bill to an unmatched financial transaction. You tell the system what you collect on by configuring the various overdue processing control tables. In this release, the base-package is delivered with algorithms that support collecting on overdue bills. If your organization practices balance-forward accounting (i.e., collection is based on overdue service agreement balances), you will not use this functionality. Rather, you will use the functionality described under [Defining Credit and Collections Options](#).

WARNING:

Setting up this module is as challenging as your organization's collection rules. If you have simple rules, the set up process will be straightforward. If your rules are complicated (e.g., they differ based on the type of customer, the age of debt, the type of service, etc.), your setup process will be more challenging.

Case Study - Collecting On Overdue Bills

The following topics introduce a case study that describes how overdue processing can be used to collect on overdue bills. This is just an example as virtually every aspect of overdue processing is configurable. Use this case study to familiarize yourself with the overdue processing core concepts.

Monitoring Overdue Bills

The following diagram illustrates the objects and processes involved with collecting overdue bills.

There are many important concepts illustrated above:

The **Overdue Monitor** checks if your accounts have bills that violate your overdue rules

The **Overdue Monitor** is a background process that periodically reviews your account's financial obligations.

Note well: every account belongs to a collection class. There are two types of collection classes: those whose accounts are monitored by the

[Account Debt Monitor](#), and those that are monitored by the Overdue Monitor. This chapter describes the Overdue Monitor.

Overdue rules define when and how unpaid bills are collected

An account's [collection class overdue rules](#) have algorithms that monitor an account's financial obligations. These algorithms are invoked by the Overdue Monitor when it's [time to review](#) an account's obligations.

These algorithms can contain any type of criteria. However, most are defined using a combination of a threshold age and monetary amount. For example, a classic algorithm would check if a bill has unpaid financial transactions more than 20 days old that exceed \$50.

In the case of bill-oriented collection, the monitoring algorithms look at each of the account's bills to determine if they are paid. Note, a bill is considered paid if its financial transactions (FTs) are linked to a balanced match event. If a monitoring algorithm finds an unpaid bill, it can check if it old enough (and large enough) to be considered a violation.

When you set up a monitoring algorithm, you define the type of overdue process that should be created when an overdue bill is detected. You do this by defining the appropriate "overdue process template".

An overdue process template defines how to handle an overdue bill

An [overdue process template](#) contains one or more [overdue event types](#). These define the number and type of events that are created to prod the customer to pay. For example, you might set up an overdue process template with event types to send a series of letters followed up by a call.

The overdue process template has contains the rules defining [when events are activated](#).

The specific action that's performed by an overdue event is controlled by the Activation algorithm defined on its event type. Refer to [Overdue Event Type - Main](#) for a list of the various Activation algorithms delivered with the base package.

Multiple objects can be associated with a single process

The above diagram shows a single bill linked to an overdue process. It should be noted that an overdue process is capable of referencing multiple bills (or other objects).

Note well: while a single overdue process can reference many overdue objects, all such objects must be of the same type. For example, you cannot commingle bills and service agreements under a single overdue process. The type of object managed by an overdue process is defined on its [overdue process template](#).

If a customer pays the bill, the overdue process is cancelled

If an overdue bill is paid, the [overdue process is canceled](#) real-time. You control if and how an overdue process is cancelled by setting up the appropriate rules on the [overdue process template](#).

The Overdue / Cut Event Manager activates and triggers overdue events

The [Overdue / Cut Event Manager](#) is a background process that activates overdue events on the appropriate date. On this date, the event's Activation algorithm(s) are called.

This Overdue / Cut Event Manager also has the responsibility of recursively activating later events that are dependent on the completion of earlier events.

Events can be activated real-time

[Overdue Process - Main](#) has a button that allows users to activate (and recursively trigger) overdue events online / real-time. This means you don't have to wait for a batch job to activate events.

Overdue events can wait for related activities to complete

As described above, an overdue event's Activation algorithm can create virtually any object. What wasn't explained is that the event can be set up to [wait](#) for the ancillary object to finish before it completes. For example, an event can create a To Do entry and wait for it to complete before the next event is triggered. You can introduce plug-ins to create and wait on virtually any object.

While an overdue event is in the Wait state, the Overdue / Cut Event Manager monitors the state of the related object(s). When the related object completes, the event is transitioned to the Complete state (thus triggering dependent overdue events). Please see [Some Events Wait For Something Before Completing](#) for more information.

Cutting Service Agreements

An overdue process may contain an overdue event that creates a cut process(es). A cut process is used to cut (i.e., stop) a service agreement. The following diagram illustrates the objects and processes involved with cutting a service agreement.

NOTE:

Cut processes aren't required. It's quite conceivable to design an overdue process that doesn't cut service. For example, the overdue process may just contain an event that creates a case and the case manages the collection activities.

An overdue process may contain an overdue event that cuts (i.e., stops) service

If an overdue process's bill remains unpaid, one of the latter overdue events typically creates one or more [cut processes](#). A cut process contains the activities to stop a service agreement (in the hopes that lack of service will inspire the customer to pay). It should be noted that a separate cut process is created for each service agreement.

Cut rules define how to sever service agreements	<p>The system allows you to define rules to control the type of cut process created. For example, you may have a different cut process if the customer has life support equipment, or if it's winter, or ...</p> <p>The cut rules are defined on the service agreement's SA type. This allows different rules for different types of service agreements.</p>
Overdue events can "wait" for related activities to complete	<p>When an overdue event creates cut process(es), it typically enters the Wait state. It enters this state as it is waiting for the cut process(es) to complete before it can itself complete. While in the Wait state, the Overdue / Cut Event Manager monitors the state of the related cut process(es). When the cut process(es) complete, the system transitions the originating overdue event to the Complete state (thus triggering dependent events).</p>
A cut process template defines how to cut a service agreement	<p>Cut processes and events are created using a cut process template. A cut process template defines the actions involved in cutting a given type of service agreement. A cut process template usually contains several cut events. These events are a series of letters and / or disconnection field activities that eventually result in the expiration of a service agreement if payment is not received.</p> <p>An Activation algorithm controls the specific action associated with a cut event and therefore an event can do practically anything. Refer to Cut Event Type - Main for a list of the various Activation algorithms delivered with the base package.</p>
Cut events are also managed by the Overdue / Cut Event Manager	<p>The same background process that manages the activation of overdue events manages cut events. This means you only have to submit one batch job to activate and trigger both overdue and cut events.</p>
Events can be activated real-time	<p>Cut Process - Main has a button that allows users to activate (and recursively trigger) cut events online / real-time. This means you don't have to wait for a batch job to activate events.</p>
Cut events can "wait" just like overdue events	<p>Cut events support the ability to wait for something to complete just like overdue events. For example, if a cut event creates a field activity, it enters the Wait state. While in the Wait state, the Overdue / Cut Event Manager monitors the state of the related field activities. When the field activities complete, the system transitions the originating cut event to the Complete state.</p> <p>And, just like for overdue events, the notion of a cut event creating something and then waiting for it to complete is not limited to field activities. For example, you could have a cut event create a To Do entry and wait for it to complete before the next event is triggered.</p> <p>Please see Some Events Wait For Something Before Completing for more information.</p>
After a service agreement is stopped, it will be final billed	<p>Many cut processes are configured so their last cut event expires the service agreement. What happens at expiration depends on the type of service agreement. However, eventually the service agreement is transitioned into the Stopped state.</p> <p>When the last active service agreement linked to an account is stopped, the system changes the account's bill cycle to bill that evening. If only one of many SAs is stopped, the SA will only be final billed as per the account's original bill cycle schedule.</p>
If a customer doesn't pay their final bill, the final bill will be processed using a different type of overdue process	<p>Final bills only differ from ongoing bills in that the service agreements associated with the bill's FTs are not active. This means that there is</p>

nothing to cut. This means that the type of overdue process used to handle a "final" bill should differ from that used to handle "ongoing" bills.

As described above, overdue rules define how unpaid bills are handled (both ongoing and final). We recommend configuring your overdue rules to use different overdue process templates for final versus ongoing bills.

The last overdue event typically causes the debt to be written off

Ultimately, if the overdue and cut events fail to inspire payment, the debt will be written off. The method used to write-off a bill is controlled by an overdue event Activation algorithm.

How Does The Overdue Monitor Work?

This section describes how the Overdue Monitor background process (C1-ADMOV) uses your overdue rules to collect overdue debt.

This process has an optional input parameter for CIS Division. It can be used if your implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

NOTE:

Recommendation. We recommend that you familiarize yourself with the concepts described in the [case studies](#) before reading this section.

Collecting overdue bills. The examples in the following section frequently refer to how the Overdue Monitor is configured for an organization that collects on unpaid bills. It should be noted that these are just examples as the Overdue Monitor can be used to collect on virtually anything (if you create the appropriate plug-in algorithms).

Different Overdue Rules For Different Customers

The Overdue Monitor uses rules to control how it monitors an account's debt. The system allows you to define different rules for different combinations of collection class, division and currency code. For example,

- You probably have different collection rules for different jurisdictions (i.e., CIS Divisions). For example, if you have customers in different states / provinces, you may have different rules applied to each jurisdiction's debt. The **CIS division on each customer's account** defines the jurisdictional rules applied to the account's debt.
- You probably have different collection rules for different customer segments. For example, bills for large customers might be overdue if they are more than 10 days late, whereas small customers might have 24 days. You differentiate your customers in respect of the overdue via the **collection class on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You will have different criteria for every currency in which you work because the monitoring process always compares a customer's debt against some value and this value must be denominated in the customer's currency. A customer's currency is defined using a **currency code on the account**.

The above means that every combination of CIS division, collection class, and currency code can have different rules. The following matrix is used to illustrate a sample organization's rules (note, we assume a single currency and therefore avoid the third dimension):

Account's Division	Account's Collection Class:	Account's Collection Class:
	Commercial Customer	Residential Customer

North	<p>Highest Priority: If a bill exists with unpaid FT's > \$0 that is older than 45 days, create the commercial 45 days late overdue process.</p> <p>Next Priority: If a bill exists with unpaid FT's > \$100 that is older than 30 days, create the commercial 30 days late overdue process.</p>	<p>Highest Priority: If a bill exists with unpaid FT's > \$0 that is older than 50 days, create the accelerated overdue process for residential customers.</p> <p>Lower Priority: If a bill exists with unpaid FT's > \$25 that is older than 25 days, create the courtesy reminder overdue process for residential customers.</p>
South

Notice that there can be multiple criteria for each cell in the matrix. What differentiates one criteria from another is its priority. The higher priority criteria will be compared first. If the debt violates the criteria, the overdue process is initiated and no further comparisons are performed.

Overdue Rules Are Embodied In Algorithms

Your organization's overdue rules are defined in algorithms plugged in on [Collection Class Overdue Rules](#) (in the Overdue Monitor Rule system event). When the Overdue Monitor analyzes an account, it uses the rules associated with the account's collection class, CIS division and currency code. To analyze an account, it simply invokes these algorithms in sequence order, i.e., the lower the sequence, the higher its priority.

An Overdue Monitor Rule algorithm has two responsibilities:

- it determines if an account violates its overdue rules,
- if so, it creates one or more overdue processes using an [overdue process template](#)

When Is An Account Monitored?

The Overdue Monitor determines if an account violates your overdue rules at least every X days, where X is defined on the [Customer Class - Controls](#) associated with the account's customer class and division (in the field Min Credit Review Freq (Days)).

In addition, the Overdue Monitor examines an account's debt as follows:

- X days after an account's bill due date (X is defined in the field Credit Review Grace Days on [customer class control](#)).
- If a payment is canceled with a cancellation reason that indicates non-sufficient funds.
- If a payment arrangement is broken (assuming you use the base package's break payment arrangement plug-in). Refer to [Breaking A Bill Oriented Payment Arrangement](#) for more information.
- If a pay plan is broken. Refer to [The Pay Plan Monitor](#) for more information.
- If a [match event](#) is added, changed or deleted.
- When a written off bill is [reversed](#).

NOTE:

Additional events. Your implementation can have other events trigger the analysis of an account by the Overdue Monitor. To do this, add logic to insert a row on the CI_ADM_RVW_SCH table when the event occurs. This row simply references the account ID to be reviewed and the desired review date.

Collection Class Defines If And How Accounts Are Monitored

As described above, every account references a collection class. The collection class defines if and how its accounts are monitored. There are three options:

- The accounts are monitored by the [Account Debt Monitor](#)
- The accounts are monitored by the Overdue Monitor (this is described in this chapter).
- The accounts are not monitored for overdue debt.

NOTE:

Migration. If you plan to migrate from the Account Debt Monitor (ADM) method of collection to the Overdue Monitor method, a special Overdue Monitor algorithm ([CI-ACT-CSW](#)) has been supplied that will skip accounts that are eligible for review by the Overdue Monitor if they have an active collection, severance or write-off process. This algorithm should be plugged in the applicable Collection Class Overdue Rules so that it will be invoked first. This allows accounts with active ADM-oriented collection activities to work themselves through the system. When an account no longer has any active ADM-oriented activities, monitoring responsibilities will be assumed by the Overdue Monitor.

The Big Picture Of Overdue Processes

As described above, the Overdue Monitor subjects your accounts to overdue rules. If a rule is violated, an overdue process is created. The topics in this section provide background information about overdue processes.

How Are Overdue Processes Created?

As described [above](#), the system creates an overdue process when an account violates your overdue rules. In addition, a user can manually create an overdue process at their discretion.

The Components Of An Overdue Process

The following topics describe the major components of an overdue process.

Overdue Objects

When an overdue process is created, the system links the overdue object(s) to the process. For example, if an overdue bill is detected, the bill is linked to the overdue process.

When you set up an [overdue process template](#), you define the type of object it collects on by defining the [foreign key characteristic type](#) used to reference the object. For example, when you set up an overdue process template to collect on bills, you define a foreign key characteristic type that references the bill object.

Overdue Events

An overdue process has one or more overdue events. These events are the actions designed to encourage the customer to pay. For example, you might set up overdue events that:

- Send letters (via the creation of a customer contact)
- Create To Do entries
- Impact the account's credit rating
- Create a case (e.g., to seize the customer's assets)
- ... (the list is only limited by your imagination as algorithms are used to perform the event's actions)

You define the number and type of events by configuring [overdue process templates](#). When the system creates an overdue process, it copies the events defined on the specified template.

It's important to note that all overdue events are created when the overdue process is created. A separate background process, the [Overdue / Cut Event Manager](#), is responsible for activating, monitoring, and triggering overdue events. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, start a cut process, refer debt to a collection agency, write-off debt, etc.).

Overdue Log

Every overdue process has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When the process is created, a log entry is created to describe why the process was started.
- When an overdue event is activated, a log entry is created. These entries frequently contain a foreign key to the object that the event created so that users can easily drill down to the object from the log. For example, if an event creates a To Do entry, the To Do entry's foreign key is placed on the log and this allows a user to drill down on the log entry to see the To Do entry.
- When a process is canceled, a log entry is created to describe the circumstances of the cancellation (e.g., manual versus automated).
- Users can manually add log entries (you might want to think of these as "diary" entries) as desired.
- ...

Many of the base-package algorithms involved in overdue processing insert log entries so that a thorough audit trail is maintained. These algorithms have been designed to allow you to control the verbiage in each log entry by defining the desired message number using an algorithm parameter.

The log is viewable on the [Overdue Process - Log](#) page.

NOTE:

More than just an audit trail. The log entries are more than just an audit trail. The system makes use of the log entries to know what it did. For example, when an overdue event needs to monitor the state of the To Do entries that it created, it uses the log to determine the identity of these To Do entries.

Experimenting With Alternative Overdue Process Templates

The system allows you to determine the efficacy of proposed overdue process templates using a small subset of customers before implementing the templates on the entire customer base. We use the term "champion / challenger" to reference this functionality.

We'll use an example to explain. Let's assume your prevailing overdue process template for residential customers starts with a "gentle reminder" letter followed 10 days later by a letter threatening collection agency referral if payment is not received. You may want to experiment with the impact of a change to this template. For example, you may want to change the "gentle reminder" to something more assertive and follow this up 5 days later with an even sterner warning. You can use the "champion / challenger" functionality to perform this experiment.

The following points describe how to implement "champion / challenger" functionality:

- Set up a "challenger" overdue process template for each template that you want to experiment with.
- Insert a new **Champion/Challenger** option on the Overdue Processing [Feature Configuration](#) for every champion template. Each option's value defines:
 - the "champion" overdue process template code
 - the "challenger" overdue process template code
 - the percentage of the time the system should use the "challenger" template
- Keep in mind that you can only experiment with one challenger template per champion template. For example, let's assume you have two prevailing overdue process templates - one for residential customers and another for commercial customers. You can experiment with different challenger templates for the residential and commercial templates. However, you cannot experiment with two different challenger templates for the residential champion template (i.e., a champion template can have 0 or 1 challenger template).

After setting up the above, your implementation's [Overdue Rule Plug-In](#) may include logic to use the challenger template X % of the time rather than the champion template. The sample plug-in provided in the base product, called [C1-CB-CR-RAT](#), includes this logic.

If you are using the Oracle Utilities Analytics product, you can configure analytic zones in innumerable ways to compare the efficacy of the champion versus the challenger. For example,

- You can set up a graph to show the average duration of each type of process.
- You can set up a graph to show the average dollars that were successfully collected.
- You can set up a dimensional scorecard to show how each template performed in different regions (or customer classes or ...).
- Etc (the list is limited by your imagination)

Overdue Process Information Is Overridable

"Overdue process info" is the concatenated string of information that summarizes an overdue process throughout the user interface. The base-package logic constructs this string by concatenating the following information:

- The description of its overdue process template
- Its status
- For active processes, the number of days since it was created. For inactive processes, the number of days since it was inactivated.
- For active processes, the unpaid amount of the objects being collected

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your [overdue process templates](#). This design allows some / all overdue process templates to have an override info string.

Original and Unpaid Amounts

There are two amounts associated with each overdue object linked to an overdue process: its Original Amount and its Unpaid Amount. These amounts are used throughout overdue processing.

You control how these amounts are calculated by defining the appropriate algorithm on your [overdue process templates](#). For example, you can plug in a base-package algorithm ([C1-CUAOA](#)) if you collect on overdue bills and the original amount is the amount of financial transactions linked to the bill, and the unpaid amount is the sum of financial transactions that are not linked to balanced match events.

Overdue Processes Are Highlighted Elsewhere

The topics in this section describe how other parts of the system highlight the existence of overdue and cut processes.

Alert Zone

If you plug-in the appropriate alert algorithm ([C1-OD-PROC](#)) on the Installation record, alert(s) will be shown for active overdue processes in the Alert Zone that appears in the Dashboard and on Control Central - Account Information.

Credit and Collections Zone

The Credit and Collections zone on [Control Central - Account Information](#) shows active overdue and cut processes.

Account Activity History Zone

The Account Activity History Zone on [Control Central - Account Information](#) shows pending and waiting events and inactive processes.

How Are Overdue Processes Cancelled?

A user may cancel an overdue process at their discretion, online / real-time using [Overdue Process - Main](#).

The system will automatically cancel an overdue process when the object(s) associated with the overdue process are sufficiently paid. Exactly when the system checks if an overdue process should be cancelled is dependent on your organization's billing and accounting rules. For example, if you practice [open-item accounting](#), you'd want to analyze an account's active overdue processes whenever a match event is added, changed or deleted (as match events are the only objects that impact if debt is considered paid in an open-item world). The base-package supports this specific example. If you need additional events to check if an overdue process should be canceled (e.g., the creation of a pay plan), a base-package change **MAY** be necessary. Please check with customer support if you have questions.

Two algorithms plugged-in on the [overdue process template](#) handle the cancellation:

- The Cancel Criteria algorithm is responsible for determining if an overdue process should be canceled. Algorithms of this type analyze the outstanding debt on the objects linked to the overdue process and indicate whether a process can be cancelled.

- The Cancel Logic algorithm is responsible for actually canceling the process. The logic involved in cancellation can be quite sophisticated as canceling an overdue process can result in the cancellation of its pending events and cut processes.

NOTE:

Why two algorithms? The reason two algorithms are involved in cancellation is because we want the cancellation logic to be encapsulated in one place so it can be called during both manual and automated cancellation.

Different logic for different templates. Because both the Cancel Criteria and Cancel Logic algorithms are plugged-in on the overdue process's template, you can have different cancellation criteria and logic for different templates.

Overdue Processes Are Created From Templates

As described above, you set up [overdue process templates](#) to define the types of events and when they are executed. When an overdue process is created, its events are created by copying the event types from an overdue process template. The remaining topics in this section provide background information to assist you in setting up your templates.

The Big Picture Of Overdue Events

This section describes the various types of overdue events and their lifecycle.

How Are Overdue Events Created?

Overdue events are created as follows:

- The [Overdue Monitor](#) invokes Overdue Monitor Rules to periodically check your accounts (refer to [Overdue Rules Are Embodied In Algorithms](#) for how this works). An Overdue Monitor Rule creates an overdue process when an account violates your overdue rules. The overdue process has one or more overdue event(s). The number and type of events is controlled by the overdue process template specified on the Overdue Monitor Rule.
- Users can create an overdue process manually on [Overdue Process - Main](#). To do this, they specify an overdue process template. The number and type of overdue events is defaulted from the template.
- An overdue event may be manually added to an existing overdue process by a user on [Overdue Process - Events](#).

NOTE:

Bottom line. Most overdue events are created by the system when it creates an overdue process for delinquent obligations. If you need to create an ad hoc overdue event, you can either create an overdue process whose template contains the desired event OR link the desired event to an existing process.

Overdue Events Can Do Many Things

An overdue event can perform a wide number of activities as the logic is embodied in an algorithm. The following points describe how this works:

- Every overdue event references an [overdue event type](#).
- The overdue event type, in turn, references an Event Activation algorithm.
- The Event Activation algorithm is invoked when the event is [triggered](#).

Overdue Event Information Is Overridable

"Overdue event info" is the concatenated string of information that summarizes an overdue event throughout the system. The base-package logic constructs this string by concatenating the following information:

- The event type's description
- The event's status
- If it's pending:
 - If the event has a trigger date, the number of days until it's triggered plus the verbiage day(s) from today
 - Otherwise, the verbiage dependent on other events
- If it's waiting, the number of days, hours and minutes that it's been waiting
- If it's canceled, the cancel reason code's description
- If it's complete, the number of days, hours and minutes that it's been complete

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your event types. This design allows some / all event types to have an override info string.

Overdue Event Lifecycle

The following diagram shows the possible lifecycle of an overdue event:

Overdue events are initially created in the Pending state. An event can take myriad paths after it's created; it all depends on how you've configured the system. The following topics describe an event's lifecycle:

How and When Events Are Activated

An overdue event contains the date it should be activated; this is referred to as its trigger date. On this date, the Overdue / Cut Event Manager (a background process (C1-ODET)) invokes the Event Activation algorithm plugged-in on the event's event type. The Event Activation algorithm, in turn, will decide on the state in which to leave the overdue event (e.g., it may transition it to the Complete state or the Waiting state).

If a user can't wait for the Overdue / Cut Event Manager real-time, they can click a button on [Overdue Process - Main](#) to activate (and recursively trigger) events online / real-time.

You control how an event's trigger date is populated by configuring the [overdue process template](#). You are given two choices when you link an event type to an overdue process template:

- You can indicate the event should be assigned a trigger date when it is first created. You'd use this approach on the first event and events with no dependencies on earlier events. The following points describe how to configure the overdue process template to do this:
 - Indicate the event type is NOT dependent on other events, and
 - Define the number of days after the process's creation to use when calculating the trigger date.
- You can indicate the event should be assigned a trigger date only after earlier events are Complete. This technique should be used whenever you have an event that is only executed after other events are Complete. The following points describe how to configure the overdue process template to do this:
 - Indicate the event is dependent on other events, and
 - Define the number of days after the completion / cancellation of all dependent event(s) that the trigger date should be set to. The Overdue / Cut Event Manager sets the trigger date on such an event when it detects that all of its dependent events are complete / canceled.

NOTE:

Calendar vs Workdays. When an overdue event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to [Calendar vs. Work Days](#) for more information.

Activating Events Should Add a Log Entry

As described [above](#), an overdue process has a log holding a history of meaningful events in the process's life. Most Event Activation algorithms will add an entry to the process's log.

These log entries are more than just an audit trail as they also reference the objects that are created during activation. For example, if an activation algorithm creates a customer contact, the ID of the customer contact will be referenced on the log (and end-users will be able to drill down on the log entry to see the customer contact).

Holding Events

You can prevent a pending event with a trigger date on / before the current date from activating by plugging-in a Hold Event Activation plug-in on the overdue process template. This might prove useful, for example, if you want to suspend an overdue process while a [case](#) used to investigate the assertion of a customer is outstanding. Then, when the case closes, the overdue process can start up where it left off.

This technique would prove useful, for example, if your users can grant ad hoc suspend periods (e.g., if a customer wants a few extra days to pay before a cutoff). To do this, create a case type that has two states: Open and Close. Make sure to set up the Open state to have an automatic transition algorithm to close the case after X days. Then, all a user has to do is create a case of this type when they want to provide a suspend period. When the suspend period is over and payment isn't received, the case will close and the overdue process will start up where it left off.

Some Events Wait For Something Before They Activate

Consider this scenario - you want an overdue event to create a To Do entry so a user can authorize the next phase of an overdue process. When this event activates, the event's activation algorithm will create a To Do entry, but it will NOT transition the event to complete. Rather, the overdue event will exist in the waiting state. While in the waiting state, the Overdue / Cut Event Manager will monitor the state of the To Do entry. When the To Do entry completes, the original overdue event can transition to the complete state and then latter dependent events can be triggered. The following points describe how to configure the system to support this type of event:

- The event type's Event Activation algorithm should behave as follows:
 - It creates the object on which the overdue event waits.
 - It must link this object to the overdue process by creating a log entry where the prime-key of the related object is referenced (in a foreign-key characteristic). This log entry should also reference the event.
 - It should leave the overdue event in the waiting state.
- The event type must have a Monitor Waiting Event algorithm. This algorithm is invoked each time the [Overdue / Cut Event Manager](#) executes. If the related object has transitioned to a "final" state, the originating overdue event is transitioned to the complete state (and then latter dependent events are triggered).

NOTE:

Bottom line. Two algorithms must be set up on an overdue event type to implement waiting functionality: an Event Activation algorithm that creates the monitored object and a Monitor Waiting Event algorithm to check on the state of the monitored object. The Overdue / Cut Event Manager has the dual responsibility of activating the event and monitoring its related object for completion (and then triggering the dependent events when it completes).

While the above example illustrated how an overdue event could create and then monitor a To Do entry, you can use this functionality to create and monitor any object that has an initial and final state. If the base package does not contain the algorithms you need, simply develop new ones using the base-package algorithms as examples.

How Are Events Canceled

A pending event will be cancelled automatically by the system when the overdue process is canceled. Refer to [How Are Overdue Processes Cancelled](#) for more information.

A user may cancel a pending or waiting event at their discretion.

Regardless of what triggers the cancellation, the Cancel Logic algorithm plugged in on the overdue event type handles the cancellation. This allows you to introduce additional cancellation logic should the need arise. Please note that the base package cancel algorithms insert a [log entry](#) when a user manually cancels an event.

The Big Picture Of Cut Processes

While not required, many overdue processes will contain one or more events that will cut (i.e., stop) service. When such an event activates, it creates a "cut process". A cut process is very similar to an overdue process; the major difference is that a cut process is linked to a specific service agreement (the one being cut), whereas an overdue process is linked to the object(s) in arrears.

The topics in this section provide background information about cut processes.

How Are Cut Processes Created?

The activation of an overdue event can create one or more cut processes.

In addition, a user can manually create a cut process at their discretion using [Cut Process - Main](#).

Overdue Events Wait For The Cut Process To Conclude

Overdue events that create cut processes are perfect examples of events that [wait](#) for the object they create to complete before they, in turn, complete. After the cut process concludes, the originating overdue event will complete thus triggering its dependent events.

Cut Processes Exist Under An Overdue Process

It's important to note that a cut process exists in respect of an overdue process. In other words, you can't create a cut process without referencing a parent overdue process. There are two reasons why:

- A cut process's overdue process defines the objects in arrears. It is these objects that are monitored to determine if the cut process (and overdue process) can be cancelled.
- The [log](#) associated with a cut process's overdue process contains the history of the cut process(es) and their events; there is no log specific to a cut process.

The Components Of A Cut Process

Cut processes are simpler than overdue processes as they simply contain one or more "cut events". These events are the service agreement-specific actions designed to encourage the customer to pay. For example, you might set up cut events that:

- Create [field activities to cut service](#)
- Send letters (via the creation of a customer contact)
- Create To Do entries
- Impact the account's credit rating
- Create a case (e.g., to manage a customer with life support issues)
- ... (the list is only limited by your imagination as algorithms are used to perform the event's actions)

You define the number and type of events by configuring [cut process templates](#). When the system creates a cut process, it copies the events defined on the related template.

It's important to note that all cut events are created when the cut process is created. The Overdue / Cut Event Manager is responsible for activating the cut events at the appropriate time. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, create a field activity, etc.)

Cut processes do not have their own log as their history is maintained on the parent overdue process's [log](#).

Cut Process Information Is Overridable

"Cut process info" is the concatenated string of information that summarizes a cut process throughout the system. The base-package logic constructs this string by concatenating the following information:

- Its cut process template's description
- Its status
- For active processes, the number of days since it was created. For inactive processes, the number of days since it was inactivated.
- For active processes, the unpaid amount of the objects being collected on the cut process's overdue process

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your cut process templates. This design allows some / all cut process templates to have an override info string.

How Are Cut Processes Cancelled?

A user may cancel a cut process at their discretion, online / real-time using [Cut Process - Main](#).

The system will automatically cancel a cut process when the overdue process is cancelled.

Regardless of what triggers the cancellation, the Cancel Cut Process algorithm plugged in on the cut process's [template](#) handles the cancellation.

If a cut process is canceled and the cut process's events created field activities, the cancel logic embodied in the algorithm can be quite sophisticated. Refer to [Field Activities To Cut And Reconnect Service](#) for an example.

Cut Processes and Events Are Created From Templates

When a cut process is created, its cut events are created by copying a cut process template's event types. Cut events follow the same lifecycle and possess the same behavior as [overdue events](#).

Cut Events Are Like Overdue Events

Cut events almost identical to [overdue events](#). The major difference is that cut events exists under a cut process and therefore are oriented towards the cut process's service agreement. The following topics describe other differences between cut events and overdue events.

Field Activities To Cut and Reconnect Service

A cut process that's created for a service agreement whose service can be severed will typically contain a cut event that creates field activity(s) to cut service. The base-package cut event activation algorithm will create field activities for the service points linked to the service agreement being cut. The type of activity is defined on the [field activity type profile](#) defined on each service point's SP type. Please see [C1-CE-CR-FA](#) for the exact details of the base-package algorithm.

If the cut process is canceled after field activity(s) are created and before the cut process completes, different activities can transpire. The specifics of what happens are controlled by a Cancel Logic algorithm plugged in on the [cut process template](#). The following points summarize how a base-package algorithm ([C1-CP-DWFA](#)) works:

- It assembles all Pending, Held and Complete cut for nonpayment field activities (FA) created by the cut process (these are defined in the overdue process's [log](#)).
- Each FA is processed as follows:

- If the FA is Pending or Held and it is not linked to a field order (i.e., it hasn't been dispatched):
 - The FA is cancelled
 - An entry is added to the overdue process log to indicate the cancellation
- If the FA is Pending or Held and it is linked to a field order (i.e., it has been dispatched):
 - A To Do entry is created (the To Do Type is defined on the algorithm)
- If the FA is Complete and the Cut Process's SA is pending start or active (i.e., it hasn't been expired yet):
 - Reconnect field activity(s) are created for every service point that had a cut for non-payment field activity. The type of activity is defined on the [field activity type profile](#) defined on each service point's SP type.

A Cut Event Expires Service Agreements (and May Trigger Final Billing)

The last cut event is typically set up with an activation algorithm that expires the cut process's service agreement. If earlier cut events created "cut for non-payment" field activities, these field activities will be used as the basis for stopping service. Refer to [Finalizing Pending Stops](#) for how the system use the meter reads on these field activities as the "stop reads" on the service agreement. Note, you can see the field activities that are used to "cut" and "stop" service by viewing the Field Activities grid on [Service Agreement - Service Point](#).

NOTE:

Final billing. When the last service agreement linked to an account is expired, the system will schedule the account for billing (outside of its normal bill cycle schedule).

Write Offs Are Implemented Using Overdue Events

The system has been designed to allow overdue events on the original overdue process to write-off the objects being collected. Refer to [Writing Off Bills](#) for a case-study explaining how to do this.

Calendar vs. Work Days

When you set up your overdue and cut process templates, you supply information that controls how each event's trigger date is calculated. You have two options:

- You can say that an event's trigger date can only be populated after earlier, dependent events are complete. For example, the 2nd event (cut service) is triggered 2 days after the 1st event is complete (48 hour warning letter).
- You can say that an event's trigger date is populated when the process is first created. You simply define the number of days after the start of the process when each such event should be triggered. For example, the 2nd event (send cutoff warning) can be triggered 7 days after the start of the process.

In addition to the above, an option defined on the [Feature Configuration for Overdue Processing](#) plays a part in the calculation of an event's trigger date:

- If you set the option to use calendar days, the trigger date of events will be set to the first workday on / after the calculated date. For example, if you indicate that the 2nd event is triggered 7 days after the 1st event, the system will add 7 days to the 1st event's completion date. It then checks if this is a workday (and not a holiday); if so, this is the trigger date of the event; if not, it assigns the trigger date to the next workday.

- If you set the option to use workdays, the trigger date will be calculated by counting workdays. For example, if you indicate that the 2nd event is triggered 7 days after the 1st event, the system will count 7 workdays and set the trigger date accordingly.

NOTE:

Account's division controls the work calendar. The system uses the above information in conjunction with the [work calendar](#) associated with the account's division to determine workdays.

Bill-Oriented Collection - Advanced Topics

The topics in this section provide information on features designed to facilitate the collection of overdue bills.

Miscellaneous Bill-Oriented Collection Topics

The topics in this section provide background information about a variety of bill-oriented collection topics.

Highlights Of The Sample Overdue Monitor Rule Algorithm

A base-package Overdue Monitor Rule algorithm exists to support many different types of overdue rules (see [C1-CB-CR-RAT](#)). Keep in mind that multiple such algorithms can be plugged in on [Collection Class Overdue Rules](#). When the [Overdue Monitor](#) analyzes an account, it calls these algorithms until there are no more to invoke (or until an algorithm tells it that there is nothing more to check). The following points describe its various options:

- **Different rules based on credit ratings.** You can set up algorithms to only be applied to accounts with a credit rating \leq a given value. We anticipate such algorithms will be used in conjunction with other such algorithms to apply different rules based on the customer's credit rating.
- **Different rules based on an account or service agreement characteristic.** You can set up algorithms to only be applied if an account or one of its service agreements has a given characteristic type and value effective within the last X days. For example, you could set up an algorithm that would process an account if it had a broken payment arrangement service agreement within the last 365 days (broken payment arrangement service agreements are marked with a given char type and value). You could set up a different algorithm that treated strategic customers more leniently (given that the definition of "strategic" could be held in an account or service agreement characteristic).
- **Skipping a bill if it has a future postpone date.** You can set up algorithms to ignore an unpaid bill if it has a "postpone date" that's in the future. This date would be defined on the bill using an ad hoc characteristic. The characteristic type is defined as a parameter on the algorithm.
- **Special process for bills with disputed debt.** You can set up an algorithm to create a given type of overdue process if the bill has disputed debt. By "disputed debt", we mean a bill with a financial transaction that's linked to an unbalanced match event that's marked as Disputed.
- **Special process for bills with credit balances.** You can set up an algorithm to create a special overdue process if the bill's total charges are negative (i.e., a credit bill). Such bills should be very unusual as we strongly recommend that credit bills should have their credit balance applied to an overpayment service agreement during bill completion.
- **Different rules when all service agreements are inactive.** You can set up an algorithm that should only be applied if all service agreements are inactive. We anticipate this can be used to differ the type of overdue process as if an account does not have active service agreements; there is nothing to stop to encourage them to pay.
- **Different rules based on age and amount of a bill.** You can set up an algorithm to create different types of overdue processes based on the age and amount of the bills.

NOTE:

You are not limited by the base-package's rules. If your implementation requires options that are not supported by the base-package algorithm, simply develop your own.

Holding A Process's Events

Refer to [Holding Events](#) for a description of how to prevent the activation of an overdue / cut processes events while a given condition is true. The condition is defined in an algorithm so you can set up the system to prevent event activation for practically any condition. For example, you might want to hold event activation while the bill's account has an active case (e.g., a user might set up a case to conduct an ad hoc investigation of billing discrepancies). When the case closes, you'd want the process to start up where it left off.

Bill Info Shows Unpaid and Write-off Amounts

The base-package Bill Information algorithm (plugged in on the [Installation](#) record) is responsible for constructing a bill's summary information that appears throughout the system. This algorithm can be configured to show the unpaid and write-off amounts of each bill.

Writing Off Bills

The topics in this section provide background information on how to write off bills.

After Service Is Cut, Write-Off Oriented Events Can Commence

After the last service agreement has been stopped, overdue events to manage the write-off of the overdue process's bill(s) should be triggered. Please note that a separate overdue process is NOT created to manage write-offs. Rather, events associated with the original overdue process will handle the write-off activities.

Collection Agency Referrals

Before debt is written off, many implementations refer the unpaid bills to a collection agency. The following points describe how to implement this.

- Set up an overdue event type with an activation algorithm that refers an overdue process's bill(s) to a collection agency.
- When such an event is activated, the system creates a [Collection Referral](#) record for a collection agency. The specific agency to which the debt is referred is controlled by the event type's activation algorithm. The sample algorithm simply refers debt to the collection agency with the least amount of referred debt. If you prefer different logic, you must develop your own algorithm.
- A collection agency referral history record is linked to an account. It contains the amount of debt referred to the collection agency. It is the creation of this record that triggers the interface of information to the collection agency. The method used to interface the information to the agency is defined on the collection agency's record. Refer to [Setting Up Collection Agencies](#) for more information.
- If the collection agency is successful in obtaining the funds, a payment will be added. If the payment satisfies the cancel criteria defined on the overdue process template's cancellation plug-in, the overdue process will cancel. When an

overdue process is cancelled, the cancel criteria on the overdue process's template are executed. We strongly recommend plugging in an algorithm that will cancel collection agency referrals when an overdue process is cancelled.

- If the collection agency is not successful in obtaining your funds after a given amount of time, you probably want to cancel the referral and write-off the debt. The cancellation of the referral will happen automatically if you set up your overdue process template to have an event that creates a collection agency cancellation X days after the referral. You can cancel a referral manually by simply creating a new collection agency referral history record (with a type of cancel).
- Collection agencies are notified of the cancellation of a referral by the creation of a new collection agency referral history record (with a type of cancel). This record will be interfaced to the agency in the same manner used to interface a new referral (see above).

NOTE:

Log entry. The base-package overdue event activation algorithms that make and cancel collection agency referrals insert rows in the overdue process's [log](#) to audit these events.

Writing Off Bills Will Create Write-Off Adjustments And Possibly A Match Event

Most overdue process templates will be configured to contain an event that writes-off the unpaid balance of bills.

NOTE:

Processing is redirected to another algorithm. The base-package overdue event activation algorithm that writes off bills simply redirects the call to the Write-Off Bill algorithm plugged in on the account's [Collection Class Overdue Rules](#). The reason for this redirection is because users can manually write-off a bill (using [Bill - Main](#)) and when they do this, we want to invoke the same logic as when an overdue process writes-off a bill.

The base-package Collection Class Overdue Rules - Write-Off Bill algorithm determines the amount that should be written off for each distribution code on each unpaid financial transaction. It then creates a separate adjustment for each service agreement where the lines on the adjustment contain the amount to be written off for each distribution code. If the unpaid financial transactions are not linked to a match event, the write-off adjustments plus the unpaid financial transactions will be linked to a new match event. If the unpaid financial transactions were linked to an unbalanced match event, the write-off adjustments will be added to the existing match event (thus making it balanced).

If partial payments were made against a bill, the amount written off will be prorated in light of the partial payments. For example, if 20% of a bill had been paid, 80% of each distribution code will be written off.

For example, assume the original bill's FT looked as follows (note, if the bill has multiple service agreements this will need to be done for each SA's FT's):

- Debit A/R \$110.00
- Credit Flat Charge Revenue (\$50)
- Credit Usage Revenue (\$50)
- Credit City Tax Payable (\$5)
- Credit State Tax Payable (\$5)

Assume the customer had made a partial payment of \$11 and it was matched to this FT. At write-off time, the system will create an adjustment whose adjustment lines will cause each distribution code to be written off by 90% (100% - \$11 / \$110). For example:

- Debit Flat Charge Revenue (or some W/O Expense) \$45
- Debit Usage Revenue \$45
- Debit City Tax Payable \$4.50
- Debit State Tax Payable \$4.50

- Credit A/R \$99

This adjustment will then be linked to the original match event on which the payment was linked (thus making it Balanced).

NOTE:

Log entry. The base-package overdue event activation algorithm that writes off bills inserts a row into the overdue process's [log](#) for each bill written off.

Small Amount Write-Downs

Many organizations will write-down a bill whose value is small early in an overdue process. The base-package overdue event activation algorithm has parameters to support this requirement (this algorithm allows you to write-off an overdue process's bill(s) if their value is less than a threshold amount).

If your organization writes-down small amounts differently than large amount, simply set up an overdue event type to reference such an activation algorithm and position it in the appropriate place in the overdue process template.

Bill Info Shows Written Off Amounts

The base-package Bill Information algorithm (plugged in on the [Installation](#) record) is responsible for constructing a bill's summary information that appears throughout the system. This algorithm can be configured to show the amount written-off for each bill.

Online Write Off Of Bills Is Performed On Bill-Main

If a bill's account is associated with a [Collection Class Overdue Rule](#) that has a Write Off Bill algorithm, a button appears on [Bill - Main](#) if the bill hasn't been written off. When clicked, the Write Off Bill algorithm is invoked to write-off the bill.

Online Reversal Of Written Off Bills Is Performed On Bill-Main

If a bill's account is associated with a [Collection Class Overdue Rule](#) that has a Write Off Bill algorithm, a button appears on [Bill - Main](#) if the bill has been written off. When clicked, the Write Off Bill algorithm is invoked (in reversal mode). The algorithm cancels the write-off adjustments (thus making the bill payable again). It also schedules the account for review by the [Overdue Monitor](#) the next time it runs.

Write Offs And Overdue Process Cancellation

It should be stressed that writing-off a bill may cause an overdue process to be canceled because the bill's FT will be linked to a balanced match event (note, the specific [cancel criteria](#) are in a plug-in so this is not a hard rule).

The following points highlight interesting aspects of bill write-off and overdue process cancellation:

- If a user writes off a bill [real time](#) and the bill has an Active overdue process, the process's cancel criteria will be invoked. This typically results in the cancellation of the overdue process.
- If an overdue event writes off a bill, the state of the process depends on your cancel criteria and where the overdue event is positioned in the overdue process. For example,

- Imagine an overdue process that has an overdue event that writes off small amounts of debt early in the process. If such a process is applied against bill with a small amount of debt, the process will be canceled (when the event activates).
- Contrast this to an overdue process where the last event writes off the bill. Because there are no other events to activate, the process will complete (i.e., it will not be canceled).

An Alert Can Show Written Off Bills

A base-package Control Central Alert algorithm ([C1-WO-BILL](#)) can be set up to highlight if the account in context has written off bills. This algorithm is plugged in on the [Installation](#) record.

Bill-Oriented Payment Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in **billed** installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

NOTE:

Nomenclature. Some organizations refer to payment arrangements as "current bill plus" agreements because the customer's bills contain charges for both their current debt plus their installment amount. After the customer has paid off their overdue debt, the payment arrangement closes and the customer's bills only contain charges for their current debt.

The topics in this section describe how to set up a payment arrangement and how the system monitors the ongoing arrangements.

Creating Payment Arrangements

When you create a payment arrangement, you are actually creating a service agreement. This service agreement is just like other service agreements in that:

- It holds debt.
- It is periodically billed (thus creating unmatched bill segment financial transactions).
- When a payment is received, the payment segment financial transactions are matched to the bill segment financial transactions.

Debt is transferred to a payment arrangement service agreement (PA SA) from the customer's delinquent bills at the inception of the payment arrangement.

When you transfer debt from the overdue bills to a PA SA, transfer adjustments are created to transfer debt from the delinquent SAs to the PA SA. Match events are created to link the "transfer from" adjustments to the original unpaid financial transactions (FT). When all FT's on a bill are linked to balanced match events, the bill is no longer considered overdue and any active overdue process (and its related cut processes) will be cancelled. Refer to [How Are Overdue Processes Canceled](#) for more information.

NOTE:

Use the Payment Arrangement Transaction. Use the [Payment Arrangement - Bill Oriented](#) to set up bill-oriented payment arrangements. This transaction creates a PA SA, transfers overdue bills to it, and sets up the installment amount. This transaction is also used if you need to break or cancel the payment arrangement.

Installment, Payoff and Current Amounts

WARNING:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

When you set up a payment arrangement service agreement (PA SA), you transfer delinquent debt to the PA SA using transfer adjustments. After moneys are transferred, the system sets the PA SA's current balance to zero. At this point, there will be no overdue bills. If the customer neglects to pay bills containing charges associated with the payment arrangement, an overdue process will ensue.

PA SAs start their life with a non-zero payoff balance (i.e., they have debt when first started). This debt is transferred from the bills whose outstanding debt necessitated the creation of the PA SA.

The installment amount that the customer is billed is determined by the number of installments used to payoff the debt. For example, if the customer owes \$500 and they want to pay this off in 10 installments, you'd set up the installment amount to be \$50. The installment amount is saved on the PA SA's recurring charge amount. If the customer again falls into arrears on their bills, you can transfer additional bills to the PA SA. You can also change the installment amount as needed.

A PA SA's payoff balance typically differs from its current balance. The payoff balance is the amount of debt remaining to be paid off under the terms of the payment arrangement. The current balance is the installment amount that has been billed but not paid. For example, a customer who is paying off \$500 with 10 installments of \$50 would have an initial payoff balance of \$500 and a current balance of \$0. After the first bill, the PA SA would still have a payoff balance of \$500, but its current balance would be \$50. When the customer pays, the PA SA's payoff balance would fall to \$450 and its current balance would return to \$0.

The following table contains a financial example of a customer who sets up a payment arrangement to payoff \$1,000 of debt in \$10 installments.

Event	Normal SA's GL Accounting	PA SA's GL Accounting	Normal SA's Current Balance	Normal SA's Payoff Balance	PA SA's Current Balance	PA SA's Payoff Balance
Prior to creation of payment arrangement	N/A	N/A	1000	1000	N/A	N/A
Transfer debt from normal SA(s) to PA SA	Xfer 1000 A/R <1000>	PA A/R 1000 Xfer <1000>	0	0	1000	1000
Set current balance to zero on PA SA	N/A	N/A	0	0	0	1000
Customer is billed (\$50 for new debt and \$10 of payment arrangement debt)	A/R 50 Revenue <50>	N/A	50	50	10	1000

Customer pays \$60	Cash 50 A/R <50>	Cash 10 PA A/R <10>	0	0	0	990
-----------------------	---------------------	------------------------	---	---	---	-----

When the customer pays off the payment arrangement debt, the system automatically closes the PA SA after it final bills (assuming the PA SA's SA type references a bill segment type that has a bill segment creation algorithm of Recurring Charge With Auto Stop).

Breaking A Bill-Oriented Payment Arrangement

If a customer neglects to pay a bill, an overdue process is created. If the bill contains charges from a payment arrangement, you'll want to "break" the payment arrangement. By "break", we mean cancel the arrangement and reinstate the debt under the originating bills. To do this, you must configure the [cut process template](#) used to cut the PA SA to contain a cut event that breaks the payment arrangement.

NOTE:

Processing is redirected to another algorithm. The base-package cut event activation algorithm that breaks a payment arrangement simply redirects the call to the Bill-Based Payment Arrangement algorithm plugged in on the account's [Collection Class Overdue Rules](#). The reason for this redirection is that users can manually break a payment arrangement (using [Payment Arrangement - Bill Oriented](#)). When they do this, we want to invoke the same logic as when a cut event activation algorithm breaks a payment arrangement.

The base-package Collection Class Overdue Rule - Bill-Based Payment Arrangement algorithm does the following:

- Creates "cancel adjustments" for all unpaid financial transactions associated with the payment arrangement (e.g., billed, but not paid installments).
- Cancels ALL adjustments that were used to transfer the debt to the payment arrangement. When these are cancelled, the original bills will become unpaid (and the debt will be rather old by this point).
- Syncs up current balance with payoff balance on the PA SA.
- Makes the PA SA pending stop and expires it (SA activation will stop the SA when it next runs).
- If there is a credit left on the PA SA (because payments were made against the arrangement), the credit will be distributed amongst the bills that contributed debt to it (the oldest bills are paid off first). This relief will occur via transfer adjustments from the PA SA to the original SAs.
- Note, if there is a debit left (e.g., because LPC were issued or some other type of adjustment was created by an operator), an error is issued as we don't handle new debit on a payment arrangement.
- Inserts a characteristic on the PA SA to indicate that it has been broken (you might want to use this to cause more strict overdue rules to be applied to accounts with broken payment arrangements).
- Marks the account so it will be reviewed by the [Overdue Monitor](#) the next time it runs.

NOTE:

The PA SA must final bill before it closes. It's important to note that the PA SA will only close after the PA SA is final billed. This is OK as it won't have any money left on it.

When the Overdue Monitor next runs, it will analyze the account's reinstated bills. We recommend setting up a Collection Class Overdue Rule - Overdue Monitor Rule algorithm that has more stringent rules if the account has a broken payment arrangement within the last X days. The base-package algorithm ([CI-CB-CR-RAT](#)) supports this type of processing.

NOTE:

Log entry. The base-package overdue event activation algorithm that breaks a payment arrangement SA inserts a row into the overdue process's [log](#).

Online Breaking

A user can click a button on the [Payment Arrangement - Bill Oriented](#) page to break a payment arrangement real time. When clicked, the Collection Class Overdue Rule - Bill-Based Payment Arrangement algorithm is called to break the payment arrangement. This is the same algorithm called when a cut event break a payment arrangement.

Online Canceling

A user can click a button on the [Payment Arrangement - Bill Oriented](#) page to cancel a payment arrangement real time. Cancellation should be used when you want to "logically delete" a PA SA because it shouldn't have been created.

The logic described above for breaking a payment arrangement is executed when a user cancels a payment arrangement; the only difference is that the PA SA is marked with a different characteristic type / value than when it is broken. The "broken" characteristic type / value can be used to apply stricter rules to the account when it's next reviewed by the [Overdue Monitor](#).

Creating Overdue and Cut Procedures

Your overdue procedures define how your organization collects overdue debt. Your cut procedures define how your organization cuts (i.e., stops) service agreements when collection attempts fail. In this section, we describe how to set up the data that controls these procedures.

WARNING:

There are numerous ways to design your overdue and cut procedures. Some designs will result in easy long-term maintenance; others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your overdue and cut procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

Designing Your Overdue Procedures

The design of your overdue procedures is an iterative process. Over time, you will develop skills that will allow you to skip some steps. However, when you're starting out, we recommend you use the following matrix as your guide. When the matrix is complete, you're ready to set up the overdue processing control tables.

Account's Division	Account's Collection Class:	Account's Collection Class:

The topics discussed below will gradually complete this matrix using a simple case study.

FASTPATH:

For more information about how the information in this matrix is used to monitor your customers' debt, refer to [How Does The Overdue Monitor Work](#).

Your Divisions Are Frequently Preordained

An account's division defines the jurisdiction whose rules govern the account. For example, an account's division controls how its payments are distributed, if / how late payment charges are levied, etc. Divisions have typically been designed in advance of designing your overdue rules.

In our example, we assume you have two divisions: North and South.

Account's Division	Account's Collection Class:	Account's Collection Class:
North		
South		

Designing Your Collection Classes

Multiple collection classes are needed when your organization has different overdue rules and / or procedures based on the type of customer. If all customers are treated the same way, you'll have a single collection class (call it Generic). However, if you're like many organizations, you will have multiple collection classes.

For example, for commercial/industrial customers, you probably don't worry until they owe you more than, say, \$100 after 20 days. For residential customers, you probably don't worry until they owe you more than, say, \$5 after 20 days. In this situation, you will have at least two collection classes: one for commercial/industrial customers, the other for residential customers.

In our example, we assume you have two collection classes: Residential and Commercial/Industrial.

Account's Division	Account's Collection Class:	Account's Collection Class:
	Residential	Commercial/Industrial
North		
South		

NOTE:

There are two very different ways to monitor your accounts for overdue debt. This chapter describes the method referred to as Overdue Processing. Refer to [Collection / Severance / Write Off](#) for a description of the other method. We anticipate that most organizations will only use a single method. If your organization opts to use both methods, you will need to set up the corresponding collection classes.

Designing Overdue Monitoring Rules

At this point, we have the rows and columns defined in our matrix. Now it's time to work on the individual cells.

NOTE:

Single currency. We've assumed that your implementation works in a single currency. If this is not true, you will need to add a 3rd dimension that will have a value for each currency code.

Each cell will contain the rules that the [Overdue Monitor](#) uses to determine if an account has overdue debt. These rules will eventually be configured using one or more algorithms on [Collection Class Overdue Rules](#).

Account's Division	Account's Collection Class:	Account's Collection Class:
	Residential	Commercial/Industrial
North		
South		

NOTE:

If the Overdue Monitor encounters an account whose collection class and division does not have overdue rules set up, it will issue an error.

Determining the rules in each cell can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For residential debt (regardless of division) we have the following rules:
 - Highest priority. If a bill exists with unpaid FT's > \$0 that is older than 50 days, create the "accelerated overdue process" for residential customers. We'll talk more about this process later.
 - Medium priority. If the account's has a broken payment arrangement within the last 60 days with an unpaid bill > \$0 that is older than 20 days, create the "broken payment arrangement overdue process".
 - Lower priority. If a bill exists with unpaid FT's > \$25 that is older than 25 days, create the "courtesy reminder overdue process" for residential customers. We'll talk more about this overdue process later.
- For commercial-industrial debt (regardless of division) we have the following rules:
 - Highest priority. If a bill exists with unpaid FT's > \$0 that is older than 45 days, create the "commercial 45 days late overdue process". We'll talk more about this process later.
 - Medium priority. If the account's credit rating is < 550 and has an unpaid bill > \$0 that is older than 20 days, create the "risky commercial customer overdue process".
 - Lower priority. If a bill exists with unpaid FT's > \$100 that is older than 30 days, create the "commercial 30 days late overdue process". We'll talk more about this overdue process later.

Given the above, our matrix will look as follows:

Account's Division	Account's Collection Class:	Account's Collection Class:
	Residential	Commercial/Industrial
North	<p>Highest Priority: If a bill exists with unpaid FT's > \$0 that is older than 50 days, create the accelerated overdue process for residential customers.</p> <p>Medium Priority: If the account has a broken payment arrangement within the last 60 days with an unpaid bill > \$0 that is older than 20 days, create the broken payment arrangement overdue process.</p> <p>Lowest Priority: If a bill exists with unpaid FT's > \$25 that is older than 25 days, create the courtesy reminder overdue process for residential customers.</p>	<p>Highest Priority: If a bill exists with unpaid FT's > \$0 that is older than 45 days, create the commercial 45 days late overdue process.</p> <p>Medium priority. If the account's credit rating is < 550 and has an unpaid bill > \$0 that is older than 20 days, create the risky commercial customer overdue process.</p> <p>Lowest Priority: If a bill exists with unpaid FT's > \$100 that is older than 30 days, create the commercial 30 days late overdue process.</p>

NOTE:

The rules are limited by your imagination (and business requirements). While the base-package Overdue Monitor Rule algorithm ([C1-CB-CR-RAT](#)) supports the above scenarios, we'd like to stress these are just examples. Your implementation can operate using very different rules by either configuring the base-package algorithm (it has many parameters that you can use to tailor your rules) OR by introducing a new algorithm. Refer to [Highlights Of The Sample Overdue Monitor Rule Algorithm](#) for the options delivered with the base-package.

Designing Overdue Process Templates and Event Types

The following table shows a sample overdue process template for one of the rules in the Residential / North cell in the previous section's matrix.

Overdue Process Template	Overdue Event Type	When Triggered
Accelerated overdue process for residential customers	Old debt letter	At inception of process
	Cut active service agreements	10 days after inception
	Reduce customer's credit rating	10 days after inception (i.e., at the same time the cut process is created)
	Write down small debt	0 days after completion of the cut process(es)
	Refer debt to collection agent	0 days after attempting the small write down (this means that either the small write-down or the agency referral will take place as if the write-down is successful, the bill's FTs will be matched to balanced match events and the overdue process will stop)
	Cancel collection agent referral	45 days after referral
	Write-off debt	0 days after collection agent cancellation

You should create a similar table for each of the distinct overdue process templates in your matrix.

At this point, you've designed the distinct overdue process templates. Next, you'll need to design the algorithms that control their overdue processes:

- A template's Calculate Unpaid and Original Amount algorithm calculates the original and unpaid amounts of the objects being collected by a process. These values are used throughout the overdue processing module.
- A template's Cancel Criteria algorithm is executed to determine if a process should be cancelled. Refer to [How Are Overdue Processes Cancelled](#) for the details.
- A template's Cancel Logic algorithm is executed to cancel a process. Refer to [How Are Overdue Processes Cancelled](#) for the details. Please note that the logic embodied in this type of algorithm can be sophisticated because it is responsible for stopping an ongoing process's activities (e.g., this could involve cancelling field activities or cases). Cancellation algorithms are also responsible for inserting [log](#) entry(s).
- A template's Hold Event Activation algorithm is invoked to determine if the [Overdue / Cut Event Manager](#) should [suspend the activation](#) of the process's events.
- A template's Information algorithm is invoked to construct the [override "info string"](#).

Next, extract each unique event type from the above table:

Overdue Event Type	Action
Old debt letter	Create a customer contact
Cut active service agreement(s)	Start a cut process for every active SA with an unpaid FT on the bill
Reduce customer's credit rating	Insert an account credit rating history record
Write down small debt	Create write-down adjustments if unpaid debt is less than \$x
Refer debt to collection agent	Create a collection agency referral
Cancel collection agent referral	Cancel the collection agency referral
Write off unpaid debt	Create adjustments to write-off unpaid debt

At this point, you know the distinct event types. Next, you'll need to design the algorithms that control the lifecycle of each event type:

- The event type's Event Activation algorithm(s) are executed by the [Overdue / Cut Event Manager](#) on its trigger date. The following points describe the logic embodied in such an algorithm:
 - The activity that happens on the trigger date (e.g., creation of a customer contact, To Do, etc.). Refer to [Overdue Events Can Do Many Things](#) for the details.
 - Whether the event is transitioned into the Waiting or Complete state when it's triggered. Refer to [Some Events Can Wait](#) for the details.
 - How the log entry(s) associated with event activation will be constructed. The base-package algorithms allow you to control the verbiage in the log entry by defining the desired message number on the algorithm. This means that you may have to set up new messages. Refer to [Activating Events Should Add A Log Entry](#) for the details.
- The event type's Cancel Logic algorithm(s) are invoked when [an event is cancelled](#). The following points describe the logic embodied in such an algorithm:
 - If the event is allowed to be canceled. This logic may be necessary if some conditions prevent events of this type from canceling. For example, you may want to prevent an event from canceling when there are later dependent events that aren't canceled.
 - Any ancillary actions that take place during cancellation.
 - How the [log entry\(s\)](#) associated with event cancellation will be constructed.
- The event type's Monitor Waiting Event algorithm(s) are invoked to [monitor a waiting event](#). These algorithms are responsible for transitioning a Waiting event to Complete if the object on which it's waiting is complete.
- The event type's Event Information algorithm is invoked to construct the [override "info string"](#).

Once you've designed each event type's algorithms, you're ready to design your cut processes.

Designing Cut Process Templates and Event Types

While not required, many overdue processes will contain an overdue event that cuts (i.e., stops) service (in the hopes that stopping service will inspire the customer to pay). When such an event activates, it creates one or more cut process(es).

The system allows you to control if and how service is cut by setting up Cut Process Rule algorithms on your SA types. This allows different rules for different types of service agreements. In addition, because these rules are embodied in algorithms, a given SA type can have conditional logic that controls the type of cut process created. For example, you may have a different cut process if the customer has life support equipment, or if it's winter, or ...

NOTE:

If a service agreements of a given type should never be cut. If you have certain SA types that should never be cut, do NOT define an algorithm in the SA type's Cut Process Rule .

Determining your Cut Process Rules can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For service agreements associated with metered service, we have the following rules:
 - Highest priority. If the customer has life support requirements, create "cut process in light of life support" process.
 - Lowest priority. Otherwise, create a "metered service" cut process.
- For service agreements associated with charitable contributions, create an "expiration only" cut process.

Once you've determined if / how each SA type is cut, you need to design your cut process templates (you'll need one for each unique method of cutting a service agreement). The following table shows the cut process templates referenced above. Adjacent to each process are its events and an indication of when they are triggered.

Cut Process Template	Event Number	Cut Event Type	Dependent On Event(s)	Trigger Date Set To X Days After Completion Of Dependent Events
Metered service	10	Letter - 48 hour disconnect for non-payment warning	N/A - first event	0
	20	Field activity - disconnect for non-payment	10	2
	30	'Service has been disconnected' letter	20	0
	40	Expire service agreement	20	10
Cut process in light of life support	10	Generate delinquent life support customer To Do entry (seeking approval for the cut)	N/A - first event	0
	20	Letter - 72 hour disconnect for non-payment warning	10	0
	30	Generate impending life support cutoff To Do entry to C&C rep	20	3
	40	Field activity - cut for non-payment	30	0
	50	Service has been disconnected letter	40	0
	60	Expire service agreement	40	10
Expiration only	10	Expire service agreement	N/A - first event	

At this point, you've designed the distinct cut process templates. Next, you'll need to design the algorithms that control the lifecycle of their cut processes:

- A template's Cancel Logic algorithm is executed to cancel a process. In addition to cancelling the event, these algorithms are also responsible for inserting **log** entry(s).
- A template's Information algorithm is invoked to construct the **override "info string"**.

Next, extract each unique event type from the above table:

Cut Event Type	Action
48-hour warning letter	Create a customer contact - 48-hour warning letter (letters are created via customer contacts)
72-hour warning letter	Create a customer contact - 72-hour warning letter
Disconnect for non payment	Create a cut for non-payment field activity
Permission to start a cut process for a life support customer	Create To Do seeking permission to send 72 hour letter
Permission to create a cut field activity for a life support cutoff	Create To Do seeking permission to issue a cut field activity
Service has been disconnected letter	Create a customer contact - service cut letter
Expire service agreement	Expire service agreement

At this point, you know the distinct event types. Next, you'll need to design the algorithms that control the lifecycle of their events:

- The event type's Event Activation algorithm(s) are executed by the [Overdue / Cut Event Manager](#) on its trigger date. The following points describe the logic embodied in such an algorithm:
 - The activity that happens on the trigger date (e.g., creation of a customer contact, To Do, etc.). Refer to [Cut Events Can Do Many Things](#) for the details.
 - Whether the event is transitioned into the Waiting or Complete state when it's triggered. Refer to [Some Events Can Wait](#) for the details.
 - How the log entry(s) associated with event activation will be constructed. The base-package algorithms allow you to control the verbiage in the log entry by defining the desired message number on the algorithm. This means that you may have to set up new messages. Refer to [Activating Events Should Add A Log Entry](#) for the details.
- The event type's Cancel Logic algorithm(s) are invoked when [an event is cancelled](#). The following points describe the logic embodied in such an algorithm:
 - If the event is allowed to be canceled. This logic may be necessary if some conditions prevent events of this type from canceling. For example, you may want to prevent an event from canceling when there are later dependent events that aren't canceled.
 - Any ancillary actions that take place during cancellation.
 - How the [log entry\(s\)](#) associated with event cancellation will be constructed.
- The event type's Monitor Waiting Event algorithm(s) are invoked to [monitor a waiting event](#). These algorithms are responsible for transitioning a Waiting event to Complete if the object on which it's waiting is complete.
- The event type's Event Information algorithm is invoked to construct the [override "info string"](#).

Set Up Tasks

The above topics provided background information about how overdue processing works. The following discussion summarizes the various set up tasks.

Cut Event Types

You will find that most of the time spent setting up your cut event types is spent setting up the objects that are referenced on the cut event type algorithms. For example, if you use the base-package algorithms, you may need to set up the following:

- The various "types" for the objects created by the plug-ins. For example, if a cut event type creates a To Do entry, you must supply the desired To Do type.
- [Foreign key characteristic types](#) that are used to reference the ancillary objects in the [log entries](#) (e.g., if an event creates a customer contact, the log references this customer contact using a FK characteristic type). Note, many of these will exist in the base-package.
- [Messages](#) that are used to define the verbiage in the [log entries](#). For example, if you use the base-package algorithm that creates a customer contact, you must supply the desired message category and number that contains the verbiage that appears in the log when customer contacts are created. Note, messages have been set up for all base-package algorithms (this means you should not have to set up new messages).
- Etc.

The only way to compile the complete list is to design the parameters for each cut event type algorithm. Refer to [Cut Event Type - Main](#) for the supported plug-in spots.

After you've set up the objects referenced on the algorithms, you can then set up the algorithms. Only then can you set up the cut event types.

Cut Process Templates

After your cut event types exist, you can set up your cut process templates. You will find that most of the time spent setting up your cut process templates is spent setting up the objects that are referenced on the cut process template algorithms. Refer to [Cut Process Template - Main](#) for the supported system events.

SA Type - Cut Process Rules

After you've created your cut process templates, you can set up the algorithms that hold your [cut process rules](#). These are plugged-in on [SA Type - Algorithm](#) in the Cut Process Rule system event.

Overdue Event Types

You will find that most of the time spent setting up your overdue event types is spent setting up the objects that are referenced on the overdue event type algorithms. For example, if you use the base-package algorithms, you will set up the following:

- The various "types" for the objects created by the plug-ins. For example,
 - If an overdue event type creates a To Do entry, you must set up the To Do type.
 - If an overdue event type creates a customer contact, you must set up the customer contact type.
 - If an overdue event type writes off debt, you must set up the adjustment types.
 - Etc.
- [Foreign key characteristic types](#) that are used to reference the ancillary objects in the [log entries](#) (e.g., if an event creates a customer contact, the log references this customer contact using a FK characteristic type). Note, many of these will exist in the base-package.
- [Messages](#) that are used to define the verbiage in the [log entries](#). For example, if you use the base-package algorithm that creates a customer contact, you must supply the desired message category and number that contains the verbiage that

appears in the log when customer contacts are created. Note, messages have been set up for all base-package algorithms (this means you should not have to set up new messages).

- Etc.

The only way to compile the complete list is to design the parameters for each overdue event type algorithm. Refer to [Overdue Event Type - Main](#) for the supported plug-in spots.

After you've set up the objects referenced on the algorithms, you can then set up the algorithms. Only then can you set up the overdue event types.

Overdue Process Templates

After your overdue event types exist, you can set up your overdue process templates. You will find that most of the time spent setting up your overdue process templates is spent setting up the objects that are referenced on the overdue process template algorithms. Refer to [Overdue Process Template - Main](#) for the supported system events.

Collection Classes

Set up [collection classes](#) as per your [overdue procedures](#). Make sure to indicate that these collection classes use the Overdue collection method (only accounts linked to collection classes designated as using the Overdue collection method or processed by the Overdue Monitor).

Collection Class Overdue Monitor Rules

After your overdue process templates exist, you can set up your Overdue Monitor Rules. These rules are algorithms plugged in on [Collection Class Overdue Rules](#). You will find most of the time spent setting up these algorithms is spent setting up the objects referenced on the base-package algorithm.

Feature Configuration

You must set up a [Feature Configuration](#) to define parameters that control various overdue processing options.

The following points describe the various **Option Types** that must be defined:

- Trigger Date: Y-Workdays, N-Calendar Days. This option controls how the system computes the trigger dates on overdue and cut events. Enter Y if the system should use workdays. Enter N if the system should use calendar days. Refer to [Calendar vs Work Days](#) for the details.
- Payment Arrangement Type (B/S/A). This option indicates whether your implementation uses the [Balance-Oriented Payment Arrangements](#) (value **S**), [Bill-oriented Payment Arrangements](#) (value **B**) or both (value **A**). The value governs the navigation path for the payment arrangement lines in the [Account History](#) and [Credit & Collection](#) zones.
- Champion Template\$Challenger Template\$Percentage(1-100). You need only set up options of this type if your implementation implements [Champion / Challenger](#) functionality. Options of this type are entered in the format A \$B\$nnn where A is the overdue process template of the champion template, B is the overdue process template of the challenger template, and C is the percent of the time that the system should create the challenger template. The overdue monitor uses this option to override the champion overdue process template X% of the time with the challenger template. You may enter any number of these options (but only one per Champion Template).

Overdue and Cut Event Cancellation Reasons

Overdue events can be cancelled automatically and manually (at the discretion of a user). Regardless of the method of cancellation, a cancellation reason must be supplied. You set up your overdue event cancellation reasons using [Overdue Event Cancellation Reason - Main](#) and [Cut Event Cancellation Reason - Main](#).

Collection Agencies

If you refer debt to collection agents, you must set up your [collection agencies](#).

Alert To Highlight Active Overdue Processes

If you want an alert to appear if the account has active overdue processes, you must configure an appropriate Control Central Alert algorithm ([C1-OD-PROC](#)). This algorithm is plugged in on the [Installation](#) record.

Bill-Oriented Collection - Additional Set Up

The topics in this section provide information on additional set up requirements if you collect on unpaid bills.

One Bill Per Match Event

As mentioned earlier, a bill is considered paid if its financial transactions (FTs) are linked to a balanced match event. To determine a bill's outstanding amount, FTs from different bills cannot be commingled on the same match event (but it's OK for a bill's FTs to be on multiple match events). If you stick by the rule of "just one bill per match event" you will then be able to determine the outstanding balance of a partially paid bill. However, if you mix more than one bill under a match event, a particular bill's balance may become indeterminate.

The following Open-Item algorithm types have been provided by the base package to help enforce this rule:

- The Distribute by Bill Due Date Payment Distribution algorithm ([C1-PYDS-BDU](#)).
- The match by Bill ID Payment Distribution Override algorithm ([C1-PDOV-PYBL](#)).
- The FT cancellation FT Freeze algorithm ([C1-CFTZ-COFT](#)).

If any of your customized plug-ins and processes create match events, it is important that these too enforce this rule. You may want to refer to the base package algorithms as an example of how to do this.

Bill-Based Payment Arrangements

If you set up [payment arrangements for unpaid bills](#), you must configure the Bill-Based Payment Arrangement algorithm and plug it in on your [Collection Class Overdue Rules](#).

It's important to set up the adjustment types used during payment arrangement creation to NOT print on bills. This is because the base-package algorithm will match the adjustments used to transfer debt to the payment arrangement with the adjustment used to reduce the payment arrangement's current amount by the amount of the transfer if all adjustment types are set up to not print.

Bill-Based Write-off

If you [write-off unpaid bills](#), you must set up the following:

- Set up the adjustment type that will be used to write-off an unpaid financial transaction. This adjustment type must be configured as follows:
 - **Adjustment Amount Type** must be Calculated Amount
 - Its distribution code is irrelevant as a separate calculation line will be created for each distribution code on the FT's that is written off and these lines will reference the appropriate distribution code.
 - It must reference an adjustment type char type / value that identifies it as one used to write-off a bill's FTs
 - The following algorithms must be defined on the adjustment type:
- The Generate Adjustment system event must reference an algorithm that has the responsibility of determining how to write-off a FT. This algorithm should be determining the FT's GL details and creating a separate adjustment calculation line for each GL detail. The base package is supplied with a sample algorithm that does this ([C1-ADJG-WO](#)).
- The Adjustment Financial Transaction system event should reference an algorithm that impacts current, payoff and the GL by the amount being written off.
 - The distribution codes referenced on the financial transactions must be set up with a characteristic that holds the distribution code used to write-off the original amounts. For example,
 - Distribution codes used to record tax liabilities will typically reference the same distribution code for write-off (most organizations reverse tax liabilities at write-off time)
 - Distribution codes used to record revenue will typically reference a write-off distribution code used to record a write-off expense.
 - Distribution codes used to record receivables will typically not reference a write-off distribution code because receivables are implicitly written off when revenue and tax liabilities are written off.
 - Set up an adjustment cancellation code used when a users reverses a written-off bill (reversal involves canceling the write off adjustments).
 - Set up a Write Off Bill algorithm and plug it in on your [Collection Class Overdue Rules](#). This algorithm will reference the adjustment type described in the previous point.

Alert To Highlight Written Off Bills

If you want an alert to appear if the account has bills with written-off debt, you must configure an appropriate Control Central Alert algorithm ([C1-WO-BILL](#)). This algorithm is plugged in on the [Installation](#) record.

Open-Item Bill Amount Plug-In

You must set up the algorithm that computes the original, unpaid, and write-off amounts of your open-item bills. This algorithm is called by other algorithms when these amounts are needed. This algorithm is plugged-in on [Installation](#) in the Determine Open Item Bill Amounts spot.

Setting Up Overdue Processing

The topics in this section describe how to set up the control tables to implement your overdue processing.

Setting Up Overdue Event Types

An overdue event type encapsulates the business rules that govern a given type of overdue event. Open **Admin > Credit & Collection > Overdue Event Type > Add** to set up overdue event types.

NOTE:

Recommendation. Before using this transaction, we strongly recommend that you review [The Big Picture Of Overdue Events](#).

Description of Page

Enter a unique **Overdue Event Type** code and **Description** for the overdue event type.

Use **Long Description** to provide a more detailed explanation of the purpose of the overdue event type.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Optional / Required	Description
Cancel Logic	Required	This algorithm is executed to cancel an overdue event. Refer to How Are Events Canceled for the details. Click here to see the algorithm types available for this system event.
Event Activation	Required	This algorithm is executed to activate an overdue event on its trigger date. Refer to Overdue Events Can Do Many Things and How and When Events Are Activated for the details. Click here to see the algorithm types available for this system event.
Event Information	Optional - only used if you want to override an overdue event's info string	This algorithm is executed to construct an overdue event's override info string. Refer to Overdue Event Information Is Overridable for the details. Click here to see the algorithm types available for this system event.
Monitor Waiting Events	Optional - only used if events of this type can enter the Waiting state	This algorithm is invoked by the Overdue / Cut Event Manager for events in the Waiting state. Refer to Some Events Wait For Something Before Completing for the details.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_OD_EVT_TYPE](#).

Setting Up Overdue Process Templates

An overdue process template encapsulates the business rules that govern a given type of overdue process. Open **Admin > Credit & Collection > Overdue Process Template > Add** to set up overdue process templates.

NOTE:

Recommendation. Before using this transaction, we strongly recommend that you review [The Big Picture Of Overdue Processes](#).

Description of Page

Enter a unique **Overdue Process Template** and **Description** for the overdue process template.

Collecting On Object defines the type of object managed by this overdue process. This field actually references a [foreign key characteristic type](#) that references the managed object. For example, if this overdue process template manages overdue bills, you'd reference a foreign key characteristic that references the bill object.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

System Event	Optional / Required	Description
Calculate Unpaid & Original Amount	Required	This algorithm is executed to calculate the unpaid and original amounts of the objects associated with the overdue process. These amounts are shown on the overdue process page and in the base-package overdue info string . Click here to see the algorithm types available for this system event.
Cancel Criteria	Required	This algorithm is executed to determine if an overdue process can be cancelled. Refer to How Are Overdue Processes Cancelled for the details. Click here to see the algorithm types available for this system event.
Cancel Logic	Required	This algorithm is executed to cancel an overdue process. Refer to How Are Overdue Processes Cancelled for the details.

		Click here to see the algorithm types available for this system event.
Hold Event Activation Criteria	Optional - only used if overdue processes of this type can be suspended while some condition is true	This algorithm is executed to determine if the activation of overdue and cut events should be suspended. Refer to Holding Events for the details. Click here to see the algorithm types available for this system event.
Overdue Process Information	Optional - only used if you want to override an overdue process's info string	This algorithm is executed to construct an overdue process's override info string. Refer to Overdue Process Information Is Overridable for the details. Click here to see the algorithm types available for this system event.

The **Event Types** control the number and type of overdue events linked to an overdue process when it is first created. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event type:

- **Event Sequence.** Sequence controls the order in which the overdue event types appear in the scroll.
- **Overdue Event Type.** Specify the type of overdue event to be created.
- **Days After.** If **Dependent on Other Events** is on, events will be triggered this many days after the completion of the dependent events (specified in the grid). Set this value to 0 (zero) if you want the event triggered immediately after the completion of the dependent events. If **Dependent on Other Events** is off, events will be triggered this many days after the creation of the overdue process. Refer to [How and When Events Are Activated](#) for the details.
- If **Dependent on Other Events** is on, define the events that must be completed or cancelled before the event will be triggered.
 - **Sequence** is system-assigned and cannot be specified or changed.
 - **Dependent on Sequence** is the sequence of the dependent event.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_OD_PROC_TMP](#).

Setting Up Cut Event Types

A cut event type encapsulates the business rules that govern a given type of cut event. Open **Admin > Credit & Collection > Cut Event Type > Add** to set up cut event types.

NOTE:

Recommendation. Before using this transaction, we strongly recommend that you review [Cut Events Are Like Overdue Events](#).

Description of Page

Enter a unique **Cut Event Type** code and **Description** for the cut event type.

Use **Long Description** to provide a more detailed explanation of the purpose of the cut event type.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Cancel Logic	Required	This algorithm is executed to cancel a cut event. Refer to How Are Events Canceled for the details. Click here to see the algorithm types available for this system event.
Event Activation	Required	This algorithm is executed to activate a cut event on its trigger date. How and When Events Are Activated for the details. Click here to see the algorithm types available for this system event.
Event Information	Optional - only used if you want to override a cut event's info string	This algorithm is executed to construct a cut event's override info string. Refer to Cut Event Information Is Overridable for the details. Click here to see the algorithm types available for this system event.
Monitor Waiting Events	Optional - only used if events of this type can enter the Waiting state	This algorithm is invoked by the Cut / Cut Event Manager for events in the Waiting state. Refer to Some Events Wait For Something Before Completing for the details. Click here to see the algorithm types available for this system event.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CUT_EVT_TYPE](#).

Setting Up Cut Process Templates

A cut process template encapsulates the business rules that govern a given type of cut process. Open **Admin > Credit & Collection > Cut Process Template > Add** to set up cut process templates.

NOTE:

Recommendation. Before using this transaction, we strongly recommend that you review [The Big Picture Of Cut Processes](#).

Description of Page

Enter a unique **Cut Process Template** and **Description** for the cut process template.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).

- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Cancel Logic	Required	This algorithm is executed to cancel a cut process. Refer to How Are Cut Processes Cancelled for the details. Click here to see the algorithm types available for this system event.
Cut Process Information	Optional - only used if you want to override a cut process's info string	This algorithm is executed to construct a cut process's override info string. Refer to Cut Process Information Is Overridable for the details. Click here to see the algorithm types available for this system event.

The **Event Types** control the number and type of events linked to a cut process when it is first created. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event type:

- Event Sequence.** Sequence controls the order in which the cut event types appear in the scroll.
- Cut Event Type.** Specify the type of cut event to be created.
- Days After.** If **Dependent on Other Events** is on, events will be triggered this many days after the completion of the dependent events (specified in the grid). Set this value to 0 (zero) if you want the event triggered immediately after the completion of the dependent events. If **Dependent on Other Events** is off, events will be triggered this many days after the creation of the cut process. Refer to [How and When Events Are Activated](#) for the details.
- If **Dependent on Other Events** is on, define the events that must be completed or cancelled before the event will be triggered.
 - Sequence** is system-assigned and cannot be specified or changed.
 - Dependent on Sequence** is the sequence of the dependent event.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CL_CUT_PROC_TMP](#).

Setting Up Collection Class Overdue Rules

Collection class overdue rules contain algorithms that impact accounts associated with a given collection class, division and currency code are managed. Open **Admin > Credit & Collection > Collection Class Overdue Rules > Add** to set up collection class overdue rules.

NOTE:

Recommendation. Before using this transaction, we strongly recommend that you review [Different Overdue Rules For Different Customers](#).

Description of Page

Enter the **Collection Class**, **CIS Division** and **Currency Code** to which the rules apply.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

System Event	Optional / Required	Description
Bill-Based Payment Arrangement	Optional - only specified if your implementation uses bill-oriented payment arrangements	This algorithm is executed to handle the creation, breaking and canceling of a Bill-Oriented Payment Arrangements . Click here to see the algorithm types available for this system event.
Overdue Monitor Rule	Required	This algorithm is invoked by the Overdue Monitor to analyze an account's debt. Refer to How Does The Overdue Monitor Work for the details. If you have multiple rules (and therefore multiple algorithms), please take care when assigning the sequence number, as the Overdue Monitor will invoke these rules in sequence order. Click here to see the algorithm types available for this system event.
Write Off Bill	Option - only specified if your implementation writes-off bills	This algorithm is executed to handle the write-off and write-off reversal of a bill. Refer to Writing Off Bills . Click here to see the algorithm types available for this system event.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_OD_RULE_ALG](#).

Setting Up Overdue Event Cancellation Reasons

An overdue event cancel reason must be supplied before an overdue event can be canceled. Open **Admin > Credit & Collection > Overdue Event Cancel Reason** to define overdue event cancellation reasons.

Description of Page

Enter an easily recognizable **Overdue Event Cancel Reason** and **Description** for each cancellation reason.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_OEVT_CAN_RSN](#).

Setting Up Cut Event Cancellation Reasons

A cut event cancel reason must be supplied before a cut event can be canceled. Open **Admin > Credit & Collection > Cut Event Cancel Reason** to define cut event cancellation reasons.

Description of Page

Enter an easily recognizable **Cut Event Cancel Reason** and **Description** for each cancellation reason.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CEVT_CAN_RSN](#).

Defining Prepaid Metering Options

The topics in this section describe how to set up the system to enable prepaid metering functionality.

NOTE:

Prepaid metering is optional. The system configuration requirements described in this section are only relevant if your organization offers prepaid metering service.

The Big Picture of Prepaid Metering

Prepaid metering allows customers to pay for energy before it is actually used.

How Does Prepaid Metering Work?

A traditional electronic prepaid metering system typically operates at three levels:

- Meters that are installed at the customer's home. These meters dispense energy up to the amount that the customer prepaid.
- Vending stations located at the utility's offices or designated payment agencies. These stations/agencies sell prepaid credits to customers.
- Master stations that group vending stations together for administration, reporting and control purposes. Master stations communicate information - e.g. customer information, tariff changes, etc - to the vending stations. The vending stations, in turn, report detailed customer sales and other transaction information to the master station.

A prepaid customer goes to a vendor and purchases credits for his/her meter to dispense energy. The vendor has knowledge of the customer and the rate that the customer is paying. The vendor issues the credits in any of the following forms: a prepaid card, a token (to be inserted into the meter) or a series of numbers (to be keyed into the meter).

Debit Meter vs. Credit Meter

Prepaid meters are commonly referred to as debit meters. Billed meter types are also called credit meters. A meter's state of being 'credit' or 'debit' translates to a specific meter configuration. Having this property set at the meter configuration level enables meters to be switched between 'credit' and 'debit' if needed.

Prepaid credits may be purchased for either new premises or existing premises. In the latter case, the existing premise could initially have a typical 'credit' meter. In this case, fieldwork may be involved in getting the meter switched from 'credit' to 'debit' (prepaid).

Prepaid Metering Transactions Result in Adjustments

There could be numerous types of prepaid transactions. But the most common types are prepaid sales and cancellations.

A sale or cancellation transaction includes a total amount that usually includes tax. In order to post to the general ledger, the prepaid transaction must result in a financial transaction. Moreover, separate GL entries must be created for the breakdown of revenue and tax. In some cases, it may also be necessary to calculate the usage from the revenue amount.

[Calculated Adjustments](#) are used to book revenue from these types of transactions. A base Generate Adjustment algorithm is available to let rate application generate the appropriate GL calculation lines and calculate the corresponding usage, if needed.

Prepaid adjustments do not affect a customer's balance.

Interfacing Prepaid Transactions

An adjustment upload batch process exists for uploading prepaid transactions that result in adjustments. Refer to [Interfacing Adjustments From External Sources](#) for more information.

Prepaid metering options need only be set up if your organization offers prepaid metering service to your customers. Refer to [Defining Prepaid Metering Options](#) for more information.

Prepaid Transactions Can Go Into Suspense

A prepaid transaction goes into suspense if a prepaid SA could not be determined for any of the following reasons:

- The badge number on the transaction is not a valid meter in the system
- The badge number on the transaction is a valid meter in the system, but is:
 - Not linked to a prepaid meter configuration type
 - Not linked to a non-closed, non-canceled prepaid SA

This can be a common occurrence because of the likelihood that transactions get uploaded prior to meter installation/exchange or service agreement information being updated in the system.

When this situation happens, you probably still want to recognize the revenue by posting an adjustment to a suspense SA that you designate. Refer to the base sample Get Prepaid SA Using Badge Number (C1-SABYBADGE) algorithm for an example of how the suspense SA is specified.

A batch process exists for automatically resolving suspense adjustments. Refer to [How Are Suspense Adjustments Resolved](#) for more information.

Setting Up The System To Enable Prepaid Metering

The following sections describe the steps in setting up control information for prepaid metering.

Meter Types

Prepaid meters are set up just like any other meter - i.e. the meter must reference a meter type and the meter's configuration must reference a meter configuration type.

To set up prepaid meter types you must do the following:

- Define the meter configuration types that will be used for recording prepaid usage. Mark each of these configuration types as Prepaid . Define one register with the appropriate UOM (e.g. kWh).
- Define the meter types that will be used for prepaid metering. For each meter type, associate one of the Prepaid meter configuration types that you defined. You can also mark each meter type as Prepaid Capable.

NOTE:

Base logic does not require the meter type to be marked as Prepaid Capable. The Prepaid indicator on the meter configuration type is used to identify prepaid meters.

Characteristic Types

The following characteristic types are needed if you are going to upload prepaid transactions as adjustments and need the system to determine the prepaid SA given a prepaid meter's badge number.

Refer to [Setting Up Characteristic Types](#) for more information.

Prepaid Entity Characteristic Type

Create a characteristic type that identifies whether an SA Type is used for prepaid metering. For example:

- Characteristic Type = `<code>`
- Description = Prepaid Entity
- Char Entities = SA Type
- Subclass = predefined list
- Values = Y, N

Badge Number Characteristic Type

Create a characteristic type for specifying a badge number. For example:

- `<code>`
- Description = Badge Number
- Char Entities = Adjustment, Adjustment Type
- Subclass = Adhoc

Algorithms

The following algorithms need to be set up in order to store prepaid transactions in the system.

Refer to [Setting Up Algorithms](#) for more information.

NOTE:

The following sections describe basic set up needed for uploading 'sale' and 'cancellation' types of prepaid transactions. Your implementation team may have to define additional specific algorithms types for any other prepaid transaction type that you need to upload into or store in the system.

Calculation Rule - Calculation Algorithm

Create an algorithm of type Determine Percent Given Total (C1-PCTGVNTOT) specifying your parameter values for UOM / TOU / SQI.

Create an algorithm of type Back Into Revenue (C1-BACKINREV) specifying your parameter values for UOM / TOU / SQI.

Adjustment Type - Generate Adjustment

Create an algorithm of type Adjustment Generation - Apply Rate (ADJG-RT), specifying your [prepaid rate](#) and parameter values for UOM / TOU / SQI.

Adjustment Type - Determine SA

Create an algorithm of type Get Prepaid SA Using Badge Number (C1-SABYBADGE), specifying your badge number characteristic type, prepaid characteristic type and suspense SA ID (i.e. SA to which the adjustment needs to post when a valid prepaid SA is not found).

Adjustment Type - Resolve Suspense

Create an algorithm of type Cancel Suspense Adjustment (C1-CANSUSADJ) specifying the following:

- [Badge number characteristic type](#)
- [Prepaid entity characteristic type](#)
- [Prepaid adjustment type](#)
- Adjustment cancel reason

If you want this algorithm to create to do entries for adjustments that have been in suspense for too long, specify additional parameter values for number of days and to do type and to do role (optional).

Adjustment Type - Adjustment Information

Specify the SUSPENSE_DESCR parameter on your adjustment information algorithm if you want the information to include an indication of suspense.

Installation - Adjustment Information

Specify the SUSPENSE_DESCR parameter on your adjustment information algorithm if you want the information to include an indication of suspense.

Rate

In order to generate separate calculation lines for the revenue and tax breakdown of the prepaid amount, you need to set up a prepaid rate with components that calculate revenue amount and tax amount given just a total amount.

Create a rate schedule with the following components:

- Tax Calculation Rule
 - Calculation Rule Type = Calculation Algorithm
 - Value Type = Percentage
 - Value Source = Bill Factor
 - Bill Factor = your tax bill factor
 - Calculation Algorithm = the one created for algorithm type C1-PCTGVNTOT. Refer to [Calculation Rule - Calculation Algorithm](#) for information.
 - Distribution Code = *your distribution code for tax liability*
- Revenue Calculation Rule
 - Calculation Rule Type = Calculation Algorithm
 - Derive SQ = checked
 - Value Type = Unit Charge
 - Value Source = Bill Factor
 - Bill Factor = your rate/kWh bill factor
 - UOM/TOD/SQI to use for the resulting calculated usage, for example kWh
 - RC Cross Reference = indicate the sequence for the tax calculation rule (above)
 - Calculation Algorithm = the one created for algorithm type C1-BACKINREV. Refer to [Calculation Rule - Calculation Algorithm](#) for information.
 - Distribution Code = your distribution code for revenue

Adjustment Types

You must define an adjustment type for each type of transaction that you want to store in the system. Refer to [Setting Up Adjustment Types](#) for more information.

For prepaid sales and cancellation transactions, you need to define [calculated adjustment types](#). In addition, plug-in the following algorithms:

- Adjustment FT Creation - GL Only algorithm - so that transaction amounts do not affect the customer's balance. Specify calc lines as the source for adjustment distribution codes.
- [Generate Adjustment](#)
- [Determine SA](#)
- [Resolve Suspense](#), if applicable.
- [Adjustment Information](#), if applicable

Adjustment Type Profiles

Create appropriate [adjustment type profiles](#) for your prepaid service agreements.

Service Agreement Types

You must create a prepaid [SA Type](#) for each unique CIS Division. Each SA Type must be set up as non-billable and requiring a characteristic premise. The SA Types must also indicate that they are used for prepaid by specifying a [prepaid entity characteristic](#) value.

Bill Cycle

Create at least one bill cycle that will be used for prepaid accounts. This bill cycle should not have a schedule defined.

Vendor Information

A vendor could be a vending station, payment agency or master station.

You must create a [person](#) for each of your vendors. Information about the vendor may include names, an address, phone numbers, etc.

Any other miscellaneous information about the vendor can be stored as characteristics on the person.

Hierarchical relationships between vendors can be established through characteristics. For instance, a vending station's person record may contain a foreign key characteristic that points to the master station that the vending station reports to.

Defining Conservation Program Options

Oracle Utilities Customer Care and Billing allows you to define conservation (or energy efficiency) programs and provide rebates to customers.

The Big Picture of Conservation Programs

The purpose of using conservation programs is to provide rebates to customers based on eligibility and verification of newly purchased appliances and hardware that are rated to conserve the demand for energy. To redeem their rebates, customers have to submit a rebate application to the utility with receipts, and the utility has to administer and report on the programs.

Admin and transaction objects are provided in the product to support the definition of conservation programs (admin data) and the subsequent rebate claims (transaction data). Portals and BPA scripts are used to maintain the conservation programs and rebate claims. Adjustments are used to recognize the expense and to process refunds.

The following sections discuss the maintenance objects that support this functionality.

Conservation Program Maintenance Object

A conservation program is an admin maintenance object (MO) used to support the definition of a conservation program. It holds rules that control how the claims for a conservation program are managed. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- A business object option Display Statistics Service Script is provided for business objects of this type. The script plugged into this option retrieves information displayed on the **Conservation Program Statistics Zone**.
- A business object option Display Statistics UI Map is provided for business objects of this type. This is the map used on the **Conservation Program Statistics Zone** to display statistics.
- A separate maintenance object is provided to capture rebate definitions for a conservation program
- Logs are not provided.
- The standard characteristics collection is provided.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CONSV_PROG](#).

FASTPATH:

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin > Database > Maintenance Object > Search** and view the MO C1-CPROG.

Conservation Program Rebate Definition Maintenance Object

A conservation program has rebate definitions that define the rebate amounts and energy savings for different types of products. The superset of such lines is the "rebate matrix". Each row in the matrix defines the rebate and presumed energy savings for a product purchased by the consumer. If your organization wishes to use this maintenance object (MO), you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- The Rebate Definition table can be used to capture information for rebate claim lines such as, appliance type, refund amount, energy savings, and applicable manufacturers and models.
- Logs are not provided for the Rebate Definition.
- A characteristics collection is not provided.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_REBATE_DEFN](#).

FASTPATH:

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin > Database > Maintenance Object > Search** and view the MO C1-RDEF.

Rebate Claim Maintenance Object

When a customer files a claim for a rebate, a rebate claim will be created. The rebate claim maintenance object (MO) is used to support the definition of a claim. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- Depending on the utility's requirements, you can specify single or multiple items on the Rebate Claim. A separate maintenance object is provided to capture rebate claim lines for a rebate claim.
- The standard characteristics collection is provided.
- A log is provided. This can be used to track approval information for the claim, to capture adjustments created as the claim is processed, etc.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_REBATE_CLAIM](#).

FASTPATH:

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin > Database > Maintenance Object > Search** and view the MO C1-RCLAIM.

Rebate Claim Line Maintenance Object

A rebate claim has a rebate claim line for each product eligible for a refund. You use the rebate claim line maintenance object (MO) to create a rebate line. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- SA (service): The SA table is the real service SA. There is a separate SA under which the rebate adjustments are stored.
- Logs are not provided for Rebate Claim Line
- The standard characteristics collection is provided.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_REBATE_LINE](#).

FASTPATH:

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin > Database > Maintenance Object > Search** and view the MO C1-REBLN.

GL Accounting Example

The following table shows the financial transactions that are issued when processing energy conservation rebates. This example shows the financial transactions when a customer files a claim for a dishwasher and insulation.

Notice how the expense adjustments are atomized:

- Separate adjustments are created to expense each item individually.
- A single adjustment is created for the A/P check request.

Event	GL Accounting
Rebate adjustment is created - dishwasher	Rebate Expense 35

	A/P <35>
Rebate adjustment is created - insulation	Rebate Expense 45.45
	A/P <45.45>
A/P check request issued	A/P 80.45
	Cash <80.45>

Setting Up Conservation Programs

Conservation Programs allow administrators to create and maintain conservation programs for which customer can submit rebate claims. To set up a conservation program, open **Admin > Customer > Conservation Program > Add**.

FASTPATH:

For additional information on working with rebate claims, see [Rebate Claims](#).

The topics in this section describe the base-package zones that appear on the Conservation Program portal.

Conservation Program List Zone

The Conservation Program [List zone](#) lists every conservation program. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent conservation program.
- Click the Add link in the zone's title bar to add a new conservation program.

This zone displays the following for each conservation program defined in the system:

- Conservation Program Information (Description, Status, Start Date, End Date)
- The number of Complete Claims
- The total Complete Claims Amount
- The number of Incomplete Claims
- The Statistics Date/Time is the date that the statistics were last calculated

Use the following procedure to create a new conservation program:

- Select **Admin > Customer > Conservation Program > Add** or click **Add** on the title bar of the Conservation Program [List zone](#).
- Enter basic information about the conservation program in the **Main** section, including:
 - Conservation Program code
 - Description
 - Start Date/End Date
 - Statistic Update Frequency (in hours)
- Enter **Financial Information** about the conservation program, including:
 - CIS Division
 - SA Type
 - A/P Adjustment Type

- A/P Taxable Adjustment Type
- Enter **Approval Information** about the conservation program, including:
 - Approval To Do Type
 - Duplicate Claim To Do Role
 - Approval Levels and Threshold Amounts
- Click **Save**. To return to the Conservation Program portal without saving the new program, click **Cancel**.

To view a specific conservation program, click the broadcast icon for the conservation program you wish to view. The remaining zones in the Conservation Program portal open displaying details about the selected conservation program.

Conservation Program Zone

You use the Conservation Program zone to view and maintain individual conservation program. The Conservation Program zone displays the following information about the selected conservation program:

- Basic information about the conservation program, including
 - Conservation Program
 - Description
 - Start Date/End Date
 - Statistic Update Frequency (in hours)
 - Status
- Financial Information about the conservation program, including
 - CIS Division
 - SA Type
 - A/P Adjustment Type
 - A/P Taxable Adjustment Type
- Approval Information about the conservation program, including
 - Approval To Do Type
 - Duplicate Claim To Do Role
 - Approval Levels and Threshold Amounts

Please see the zone's help text for information about this zone's fields.

Conservation Program Status

The Status of a conservation program indicates the current state of the program within the system. Valid statuses include:

- **Pending** indicates the program is pending. This is the initial state of a conservation program when first created.
- **Active** indicates the conservation program is currently active.
- **Inactive** indicates the conservation program is currently inactive.

Conservation Program Actions

You can perform a number of actions on a conservation program, including:

- **Edit:** Used to edit a conservation program
- **Delete:** Used to delete a conservation program
- **Activate:** Used to activate a pending or inactive conservation program
- **Refresh Statistics:** Used to refresh the statistics of an active conservation program
- **Deactivate:** Used to deactivate a pending or active conservation program
- **Pend:** Used to change the status of an active or inactive conservation program to Pending

The actions available are based on the current status of the conservation program. The table below summarizes the actions available at each status.

Status	Valid Action
Pending	Edit, Delete, Activate, Deactivate
Active	Edit, Refresh Statistics, Deactivate, Pend
Inactive	Activate, Pend

Editing Conservation Programs

Use the following procedure to edit an active or pending conservation program:

- Click **Edit**.
- Edit the details of the conservation program as needed.
- Click **Save**.

Deleting Conservation Programs

Use the following procedure to delete a conservation program:

- Click **Pend** to change the status of the conservation program to Pending (if needed).
- Click **Delete**.
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the conservation program, click **Cancel**.

Activating Conservation Programs

To activate an inactive or pending conservation program, click **Activate**.

Deactivating Conservation Programs

To deactivate an active or pending conservation program, click **Deactivate**.

Setting the Status of Conservation Programs to Pending

To set the status of an active or inactive conservation program to Pending, click **Pend**.

Rebate Definition Zone

You use the Rebate Definition zone to add, view, and edit rebate definitions associated with a conservation program. A rebate definition defines the types of rebates allowed for a specific conservation program. The Rebate Definition zone displays the following details for each claim line:

- Rebate Definition
- Status (Active or Inactive)
- Rebate Amount per Unit
- Icons to Edit, Delete, and Activate/Deactivate rebate definitions

Adding Rebate Definitions

Use the following procedure to add a rebate definition:

- Click **Add** in the title bar of the Rebate Definition zone.
- Enter a Description of the rebate definition.
- Select the **Product** for the rebate definition from the dropdown list.
- Select the **Service Type** for the rebate definition from the dropdown list.
- Enter the **Rebate Per Unit Amount** for the rebate definition.
- Enter the **Rebate Unit of Measure** for the rebate definition.
- Select the **Expense Adjustment Type** for the rebate definition from the dropdown list.
- Enter the **Presumed Energy Savings** for the rebate definition.
- Select the **Presumed Energy Savings Unit of Measure** for the rebate definition from the dropdown list.
- Enter the **Manufacturer** and **Model** for each item eligible to be submitted as a rebate claim line.
- To upload manufacturer/model information from a comma-separated-values file, click **CSV File to Upload**.
 - Click **Browse** on the File Upload dialog, and browse to the file to be uploaded.
 - Click **Upload**.
- Click **Save**. To return to the Rebate Definition zone without adding the rebate definition, click **Cancel**.

Editing Rebate Definitions

Use the following procedure to edit a rebate definition:

- Click the edit icon for the rebate definition you wish to delete.
- Edit the details of the claim line as appropriate.

- Click **Save**. To return to the Rebate Definition zone without changing the rebate definition, click **Cancel**.
-

NOTE:

You can edit a rebate definition only when it is Active.

Deleting Rebate Definitions

Use the following procedure to delete a rebate definition:

- Click the delete icon for the rebate definition you wish to delete.
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the rebate definition, click **Cancel**.

Activating Rebate Definitions

To activate an inactive rebate definition, click the **Activate** button for the rebate definition you wish to activate.

NOTE:

You can only activate rebate definition that is currently Inactive.

Deactivating Rebate Definitions

To deactivate an active rebate definition, click the **Deactivate** button for the rebate definition you wish to deactivate.

NOTE:

You can only deactivate rebate definition that is currently Active.

Rebate Claim Statistics Zone

You use the Rebate Claim Statistic zone to view statistics for submitted rebate claims based on the current conservation program. This zone displays the following:

- Conservation Program
- Statistics Date/Time
- Statistics Charts

Statistics Graphs

This zone displays statistics for submitted rebate claims using the following charts:

- **Statistics by Status:** A pie chart that displays the number and percentage of claims for each status.
- **Statistics by Month:** A line chart that displays the number of claims completed each month.
- **Statistics by Product:** A pie chart that displays the total value, percentage, and number of claim lines completed for each product.

- **Statistics by Claim Age:** A line and bar chart that displays the number of new claims per month (line graph) and the number of claims per age grouping (bar graph).

To refresh statistics, click **Refresh Statistics** on the title bar of the Rebate Claim Statistics zone.

Defining Open Market Options

Markets

Understanding Market

The market object is used in deregulated utility markets. Separate instances are created for each individual market that the implementation is operating in – e.g. electricity, gas.

Each deregulated market has market participants that operate within that market. New participants can enter the market and some participants will leave the market. The market object has start and end dates for each of the market participants operating in each market.

This allows each market participant to be associated with each market object. A market participant can be inactive in one market, but still active in another without having to create multiple market participant objects for a single participant.

For implementations operating in deregulated markets, refer to your implementation documentation for further details relating to market objects implemented.

Configuring Market

This portal is used to display and maintain a Market.

Refer to [Understanding Market](#) for more information.

To maintain markets, open **Admin > Open Market > Market**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_MKT](#)

Market Participants

Understanding Market Participants

Market Participants are participants in a deregulated environment. Relationships between market participants are defined in a particular market record. Refer to [Understanding Markets](#) for more information.

Each market participant can be associated to an [external system](#) which is used to define the messages that can be sent to that market participant and how each message is sent.

Configuring Market Participants

This portal is used to display and maintain market participants.

Refer to [Understanding Market Participants](#) for more information.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Participants List:** This zone lists all market participant records. Broadcast a record to display the details of the selected record.
- **Market Participant:** This zone provides information about the selected market participant.
- **Market Participant Characteristics:** This zone lists characteristics defined for the market participant.
- **Market Contracts:** This zone lists market contracts where the market participant is either the Buyer or Seller.
- **Processing Method List:** This zone provides the list of processing methods defined for the market participant.
- **Translation Method List:** This zone provides the list of translation methods defined for the market participant.
- **Inbound BOs Send By Service Provider:** This zone lists inbound business objects that are sent by this market participant. The identification is driven by the business object having a Business Object Option of type "Sent By Service Provider" that references the current market participant.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_SPR](#).

Defining Consumer Contract Options

The topics in this section describe how to set up the system to enable consumer contract functionality.

Understanding Consumer Contracts

Consumer contracts record customer relationships. These relationships can encompass multiple services, multiple sites and multiple accounts. For example a consumer contract can be for a customer's gas and electricity supply at a single site or for a customer's water supply at multiple sites.

A consumer contract can relate to one or more consumer product versions. A consumer product version records values that are common to all consumer contracts related to that consumer product version. A consumer product version also records rules that are applied by customer service requests to set up a new consumer contract or change an existing consumer contract. These rules can for example create service agreements or stop service agreements. Refer to [Understanding Consumer Products](#) for more details. A consumer contract's consumer contract products record the links between the consumer contract and consumer product versions.

Note a consumer contract relates to consumer product versions not to consumer products. The consumer product version linked to a consumer contract is the version of the required consumer produce that is applicable for that consumer contract. This could for example be the consumer product version that is effective for the date the consumer contract was agreed.

Consumer contracts group together service agreements. The relationship between a consumer contract and a service agreement is recorded in the service agreement by linking the service agreement to one of the contract's consumer contract products. A consumer contract can record details that are common for all of the related service agreements.

All consumer contracts have a consumer contract type. A consumer contract type limits which consumer products are valid for a consumer contract of that type. Note the consumer products that are eligible are further limited by the consumer product's eligibility criteria. Refer to [Understanding Consumer Products](#) for more details.

A consumer contract can have milestones where a milestone is a date that is significant to the contract. Milestones can optionally trigger an action. Refer to [Understanding Consumer Contract Milestones](#) for more details.

Understanding Consumer Contract Milestones

Dates that are significant to a consumer contract can be recorded as consumer contract milestones. A consumer contract milestone can optionally trigger an action. For example, a consumer contract milestone could record the date when a fixed-priced period ends and trigger a change to the consumer contract when this date is reached. Another example is a consumer contract milestone that sends a notification to the customer one month prior to the end of the fixed-priced period.

A consumer contract milestone can relate to one or more of the contract's consumer contract products. A contract's consumer contract products record the links between the consumer contract and consumer product versions. In the example above of a consumer contract milestone recording the date when a fixed price period ends, the consumer contract milestone would be related to the consumer contract period whose consumer product version has the fixed priced period.

Each milestone has a consumer contract milestone type. The consumer contract milestone type indicates whether or not a milestone is executable, that is whether or not it triggers an action. For executable milestones, the action to be performed is derived from the consumer contract milestone type.

A consumer contract milestone's executable status can be: Pending, Processed, Not Executable or Canceled. Not Executable indicates that the milestone does not have a related action and Canceled indicates that the milestone is no longer applicable.

The Perform Consumer Contract Milestone Actions (**C1-CCMP**) batch process executes a consumer contract milestone's actions. This batch process selects the consumer contract milestones whose milestone date is today or in the past and whose executable status is Pending. The batch process performs the **Perform Action** algorithms defined on the milestone's Consumer Contract Milestone Type business object. Once a consumer contract milestone's actions have been performed, the batch process changes its executable status to Processed.

NOTE:

This batch process is built using the [Plug-in Driven Background Processes](#) framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. Adjust the batch parameters according to your custom logic, if needed.

The base product provides a **Contract Milestone Type (BO) – Perform Action** algorithm that sends customer notification. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Contract Milestone Type (BO) – Perform Action** algorithm entity in the application.

Understanding Consumer Products

Consumer products record attributes and rules that are used for consumer contracts. A consumer product can for example record attributes for:

- The duration of a fixed-priced period
- The amount of a contractual change, such as an exit fee
- Prices

These attributes can be used when setting up a new consumer contract or changing an existing contract. They could also be used to display details when a product is being selected or to include details in correspondence with customers.

A consumer product's rules are used to set up new consumer contracts and to change existing consumer contracts.

A consumer product's attributes and rules are recorded in the consumer product's version. Refer to [Understanding Consumer Product Versions](#) for more details.

Consumer product eligibility criteria can be used to determine which consumer products that are eligible in particular circumstances. For example a consumer product could be eligible only when autopay is being used. Consumer product eligibility criteria are optional. If a consumer product has eligibility criteria then the consumer product is eligible or not

depending on the criteria. If however a consumer product does not have eligibility criteria then the consumer product is always eligible. The next sections provide more information on this functionality.

Understanding Consumer Product Eligibility Criteria

A consumer product eligibility criteria rule requires the following components:

- Operand to be compared
- Comparison operator
- Comparison value
- Comparison results

The operands to be compared by consumer product eligibility criteria rules are identified using characteristic types. The characteristic types must have a characteristic entity of **Product Engine - Product Criteria**. The value of these characteristics are populated by the Operands algorithms that are defined on the related Consumer Contract Type's business object. The base product provides **Consumer Contract Type (BO) – Operands** algorithm that sets a characteristic value to indicate if the customer is or will be on autopay. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Contract Type (BO) – Operands** algorithm entity in the application.

The comparison operator can be one of the following: <, <=, <>, =, >, >=, Between, In or Is Blank.

The comparison value is recorded in the consumer product eligibility criteria rule.

The comparison results define what action should be taken when the criteria rule is applied. If the comparison is true or false, the result can be that the consumer product is eligible, the consumer product is not eligible or the next eligibility rule should be checked. If there is insufficient data, that is the operand to be compared was not found, the result can be that the consumer product is eligible, the consumer product is not eligible, the next eligibility rule should be checked or an error should be generated.

Understanding Consumer Product Versions

A consumer product version records the product attributes and rules that are applicable for consumer contracts related to the consumer product version.

NOTE: Consumer contracts relate to consumer product versions not to consumer products. The addition of a new consumer product version will not affect existing consumer contracts.

For a consumer contract that is created or changed using a customer service request, the consumer product version is determined using the Determine Version algorithm defined on the Consumer Product business object. The base package provides an algorithm type that determines the effective consumer product version by comparing the version's offer effective date and the date the new contract or contract change was agreed. Alternative custom algorithms could use one or more of the consumer product version's offer effective date, service effective date, offer end date, service end date and consumer product version selection. To see the list of available algorithm(s), search for algorithm types of the **Consumer Product (BO) – Determine Version** algorithm

Consumer products have two kinds of rules: consumer product rules and consumer contract rules. Consumer product rules are used to perform configurable services for a consumer product version. For example, a consumer product rule can determine the fallback product to use when a contract's product is no longer eligible. Consumer contract rules are used to set up new consumer contracts and make changes to existing consumer contracts. For example, a consumer contract rule can be used to create or stop a service agreement.

Consumer product rules relate directly to a consumer product version. Consumer contract rules are organized into groups using consumer product components. The consumer product components can be linked together into a hierarchy. The consumer product version records the consumer product component at the top of the hierarchy.

A consumer product version's attributes are recorded either as consumer product version characteristics or as consumer product component characteristics. Examples of attributes are: the duration of a fixed-price period and the amount of an exit fee.

Consumer product component eligibility criteria determine whether a consumer product component is applicable. The product attributes retrieved or consumer contract rules applied for a consumer product version will vary depending on the consumer product component eligibility criteria rules.

Understanding Consumer Product Rules

Consumer product rules are standard and custom rules that perform actions for a consumer product version. A consumer product rule class defines the type of action that is performed. A consumer product rule class is recorded in the consumer product version for each related consumer product rule. The base product provides the following consumer product rule classes:

- Determine Fallback Product
- Determine If Reapplication Required

A consumer product rule typically includes the following details:

- Basic information about the consumer product rule, including its name, description and detailed description. This is standard information for most consumer product rules.
- Specific parameters used by the consumer product rule.

The base product provides the following consumer product rules:

- **Determine Fallback Product:** A rule that determines the fallback product using a consumer product class recorded in the rule.
- **Determine if Product should be Reapplied:** A rule that determines if reapplication is necessary by deriving the current consumer product component eligibility criteria operands for the consumer product and comparing these with the previous operand values.

Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Product Rule (BO) – Apply Rule** algorithm entity in the application.

Understanding Consumer Product Components

Consumer product components group together product attributes and consumer contract rules.

Consumer product component eligibility criteria rules can be created for a consumer product component. These eligibility rules will determine if a consumer product component's product attributes are applicable and if a consumer product component's consumer contract rules are applied. A consumer product version could, for example, have one consumer product component that is eligible when a customer is on autopay and another consumer product component that is eligible when a customer is not on autopay.

A consumer product component can, optionally, have one or more child consumer product components. This allows consumer product components to be organized into a hierarchy. If a consumer product component is not eligible, any child consumer product components will also not be eligible.

Understanding Consumer Product Component Eligibility Criteria

A consumer product component eligibility criteria rule requires the following components:

- Operand to be compared
- Comparison operator

- Comparison value
- Comparison results

The operands to be compared by consumer product component eligibility criteria rules are identified using characteristic types. The characteristic types must have a characteristic entity of **Product Engine - Product Comp Criteria**. The value of these characteristics are populated by the **Contract Operands** and **Location Operands** algorithms defined on the Consumer Product business object. The base product provides a **Consumer Product (BO) – Contract Operands** algorithm type that sets a characteristic value to indicate if the customer is or will be on autopay. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Product (BO) – Contract Operands** algorithm entity in the application.

The comparison operator can be one of the following: <, <=, <>, =, >, >=, Between, In or Is Blank.

The comparison value is recorded in the consumer product component eligibility criteria rule.

The comparison results define what action should be taken when the criteria rules is applied. If the comparison is true or false, the result can be that the consumer product component should be applied, the consumer product component should not be applied or the next eligibility rule should be checked. If there is insufficient data, that is the operand to be compared was not found, the result can be that the consumer product component should be applied, the consumer product component should not be applied, the next eligibility rule should be checked or an error should be generated.

Understanding Consumer Contract Rules

Consumer contract rules are standard and custom rules that perform actions to set up a new consumer contract or change an existing consumer contract which is related to the consumer product version. A consumer contract rule could for example create a new service agreement.

Consumer contract rules are group together by consumer product components. Consumer product components determine if and when a consumer contract rule will be applied. Refer to [Understanding Consumer Product Components](#) for more details.

Consumer contract rules are applied by a customer service request when a consumer contract is being created or changed. Different consumer product rules can be applied at different stages of the customer service request and for different changes. The consumer product component defines a consumer contract rule usage that determines when a consumer contract rule is applied.

The base product provides the following consumer contract rule usages:

- On Activation – Add: The consumer contract rules are applied during activation set up for the consumer product versions of consumer contract products that have been added.
- On Activation - Remove: The consumer contract rules are applied during activation set up for the consumer product versions of consumer contract products whose end date time has been set.
- On Completion – Add: The consumer contract rules are applied at completion for the consumer product versions of consumer contract products that have been added.
- On Completion – Remove: The consumer contract rules are applied at completion for the consumer product versions of consumer contract products whose end date time has been set.
- Service Location - Add: The consumer contract rules are performed when any action required to add a service point or registration point to a contract, such as field work or a market process, has been performed.
- Service Location – Remove: The consumer contract rules are performed when any action required to remove a service point or registration point from a contract, such as field work or a market process, has been performed.

The base product provides **Consumer Contract Rule (BO) – Apply Rule** algorithms that add a service agreement and that add a consumer contract milestonr. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Contract Rule (BO) – Apply Rule** algorithm entity in the application.

Configuring Consumer Contract Type

This portal is used to display and maintain a Consumer Contract Type.

A Consumer Contract Type defines the Consumer Products that are valid for the type of contract. It also defines the information that is used in determining product eligibility.

Refer to [Understanding Consumer Contracts](#) for more information.

To maintain consumer contract types, open **Admin > Consumer Contract > Consumer Contract Type**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [C1_CONT_TYPE](#)

Configuring Consumer Contract Milestone Type

This portal is used to display and maintain a Consumer Contract Milestone Type.

A Consumer Contract Milestone Type defines milestone dates that can be recorded and whether an action should be performed for the type of milestone.

Refer to [Understanding Consumer Contract Milestones](#) for more information.

To maintain consumer contract milestone types, open **Admin > Consumer Contract > Consumer Contract Milestone Type**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [C1_CONT_MS_TYPE](#)

Configuring Consumer Product

This portal is used to display and maintain a Consumer Product, including the consumer product's versions and eligibility rules.

Refer to [Understanding Consumer Products](#) for more information.

To maintain consumer products, open **Admin > Consumer Contract > Consumer Product**.

This is a standard [All-In-One Portal](#).

Refer to the Consumer Product zone's embedded help text for more information.

This portal also shows zones for Consumer Product Versions and Consumer Product Eligibility.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [C1_PROD](#)

Configuring Consumer Product Version

This portal is used to display and maintain a Consumer Product Version.

Refer to [Understanding Consumer Product Versions](#) for more information.

To maintain consumer product versions, open **Admin > Consumer Contract > Consumer Product Version**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_PROD_VER](#)

Configuring Consumer Product Rule

This portal is used to display and maintain a Consumer Product Rule.

Refer to [Understanding Consumer Product Rules](#) for more information.

To maintain consumer products, open **Admin > Consumer Contract > Consumer Product Rule**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_PROD_RULE](#)

Configuring Consumer Product Component

This portal is used to display and maintain a Consumer Product Component, including child consumer product components, eligibility rules and related consumer product versions.

Refer to [Understanding Consumer Product Components](#) for more information.

To maintain consumer products, open **Admin > Consumer Contract > Consumer Product Component**.

This is a standard [All-In-One Portal](#).

Refer to the Consumer Product Component zone's embedded help text for more information.

This portal also shows zones for Consumer Product Component Eligibility and Related Consumer Product Versions.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_PROD_COMP](#)

Configuring Consumer Contract Rule

This portal is used to display and maintain a Consumer Contract Rule.

Refer to [Understanding Consumer Contract Rules](#) for more information.

To maintain consumer products, open **Admin > Consumer Contract > Consumer Contract Rule**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CONT_RULE](#)

Configuration

This section contains additional configuration topics for .

Configuring Zones

Many zones in Oracle Utilities Customer Care and Billing do not require configuration by your implementation team. For example, the base package is shipped with the Account Financial History zone that appears on the Control Central - Account Information portal. This zone does not require configuration because its zone type has no configurable options (i.e., its behavior is static).

Other zones require configuration before they can be used because their behavior is dynamic. The topics in this section provide tips and techniques on how to configure zones in Oracle Utilities Customer Care and Billing.

FASTPATH:

Refer to [The Big Picture of Portals and Zones](#) in the *Oracle Utilities Application Framework Administration Guide* for a description of portal and zone functionality.

Configuring Timeline Zones

A timeline zone is a zone that may be configured on the account or customer information tabs of Control Central. This type of zone contains one or more "lines" where each line shows when significant events have occurred. For example, you can set up a timeline zone that has two lines: one that shows when payments have been received from a customer, and another that shows when bills have been sent to the customer.

FASTPATH: For a complete description of the numerous features available on a timeline zone, refer to [Timeline Zone](#).

Configuration is required to enable a timeline zone. A timeline zone is made up of one or more algorithms where each algorithm returns "events" for a certain type of record (payment or bill for example). The product delivers several algorithm types for the timeline zone to include "events" for many different transactions in the product. Each algorithm type uses the Account or Person in context to retrieve the related information.

- Refer to [Configuring Timeline Zones](#) in the framework portion of the administration guide for information about the type of detail each event may return. The base provided algorithm types include many parameters to allow the implementation to configure much of this information as desired.
- Click [here](#) to see the algorithm types available for this plug-in spot.

Many of the algorithms support supplying a [BPA script](#) to launch when a user clicks on an event on a timeline. Be sure to review each algorithm type to see what types of events support a BPA script. For each event, determine if your business practice warrants the development of a BPA script.

After configuring the algorithms per your business needs, the following additional steps are needed:

- Set up a [zone](#) that references these algorithms. The zone will reference the **F1-TIMELINE** zone type.
- Link the zone to the appropriate portal(s) (e.g., [Control Central - Account Information](#) or [Control Central - Customer Information](#)).

- Update your users' [portal preferences](#) and [security rights](#) so they can see the zone in the desired location on the portal(s).

You can set up many timeline zones. For example,

- You might want different zones to appear on a portal depending on the type of user. For example, you might want one timeline for billing clerks, and a different one for customer service representatives.
- For aesthetic reasons, you might want multiple simple timeline zones to appear on a given portal rather than one complex timeline zone.
- You might want to set up context specific timeline zones. For example, you might want to have one timeline zone that is premise-oriented and another that is person-oriented.

Configuration Migration Assistant (CMA) Addendum

This section is an addendum to the general [Configuration Migration Assistant](#) section in the *Oracle Utilities Application Framework Administration Guide*. This section assumes that you are familiar with the concepts of Configuration Migration Assistant (CMA).

NOTE: CMA is designed to migrate configuration data only. Since base product data should be updated only through product patching mechanisms, CMA cannot currently be used to migrate master/transactional data that contains system-generated primary keys, such as customer account or billing information.

This addendum describes Configuration Migration Assistant (CMA) functionality that is specific to Oracle Utilities Customer Care and Billing.

The following sections provide information about what is provided in the C1-owned base package:

Base Package Migration Plans

The C1-owned base package provides a large number of migration plans to support migrating configuration and/or administration data from one environment to another.

Use the following procedure to access the base package migration plans:

1. Navigate to **Admin > Implementation Tools > Migration Plan > Search**.
2. Enter “C1” in the **Migration Plan** field.
3. **Click Refresh**.
4. Select a migration plan in the search results list. The details of the selected migration plan are displayed in the Migration Plan portal.

NOTE: The C1-owned base package plans can also be used as a basis for custom migration plans. To create a custom migration plan, select a plan to base the custom migration plan on, click the Duplicate button, and define the custom plan to meet the implementation’s requirements as described in [Defining a Migration Plan](#) in the *Oracle Utilities Application Framework Administration Guide*.

Base Package Migration Request

The C1-owned base package provides two migration request to support migrating configuration and/or administration data from one environment to another.

Use the following procedure to access the base package migration requests:

1. Navigate to **Admin > Implementation Tools > Migration Request > Search**

2. Enter "C1" in the **Migration Request** field.
3. Click **Refresh**.
4. Click the **Copy and Sync Control Data** link in the search results list.

The details of the migration requests are outlined below. Please use the Migration Request portal to view additional details about this migration request.

Base Admin Data Migration Request

- **Migration Request:** C1-AdminBasic
- **Description:** Base Admin Data
- **Detailed Description:** Base Admin Data.
- **Migration Plans:** This migration request includes base package migration plans used by Oracle Utilities Customer Care and Billing.

Copy and Sync Control Data Migration Request

- **Migration Request:** C1-CopyControlTables
- **Description:** Copy and Sync Control Data
- **Detailed Description:** Copy and Sync Control Data.
- **Migration Plans:** This migration request includes base package migration plans used by Oracle Utilities Customer Care and Billing.

For additional information about these migration plans, see [Base Package Migration Plans](#).

NOTE: The C1-owned base package request can also be used as a basis for custom migration requests. To create a custom migration request, select the base package request, click the Duplicate button, and define the request as to meet the implementation's requirements as described in [Defining a Migration Request](#) in the *Oracle Utilities Application Framework Administration Guide*.

Wholesale and Piecemeal Migrations

There are two general types of migrations used with the Configuration Migration Assistant: wholesale migrations and piecemeal migrations.

Wholesale Migrations

Wholesale migrations are used when migrating all the configuration and/or administration data from one environment to another. For example, a wholesale migration might be used when migrating admin data from a development or test environment to a production environment. For more on this type of migration, see [Wholesale Migrations](#) in the *Oracle Utilities Application Framework Administration Guide*.

The following is a high-level overview of the steps involved when executing a wholesale migration.

1. Process the "F1-SchemaAdmin" (FW Foundation) migration request (This request contains migration plans for Field, Lookup, Char Type, Currency Code and FK Ref).
2. Process the "C1-AdminBasic" migration request. This includes copies of framework migration plans (including plans for Business Objects, Algorithms, and Feature Configurations) from the "F1-FrameworkAdmin" migration request, as well as independent base package C1-owned wholesale migration plans which can be run first.
3. Process any of the other delivered framework-based (F1-owned) migration requests as needed (except for the "F1-FrameworkAdmin" migration request which is already incorporated in #2)

4. Process the “C1-CopyControlTables” migration request. This includes base package C1-owned wholesale migration plans with dependency on “C1-AdminBasic” migration request.

Piecemeal Migrations

Piecemeal (or "non-wholesale") migrations are used when migrating a small portion (or piece) of configuration and/or administration data from one environment to another. For example, a piecemeal migration might be used when migrating groups and rules from a development or test environment to a production environment. For more on this type of migration, see [Piecemeal Migrations](#) in the *Oracle Utilities Application Framework Administration Guide*.

The C1-owned base package does not contain piecemeal migration plans for Oracle Utilities Customer Care and Billing.

Processing Notes for Specific Objects

The following limitations apply to certain Oracle Utilities Customer Care and Billing objects when using Configuration Migration Assistant:

- An Issuing Center object references a User. If this user does not exist in the target system, Configuration Migration Assistant cannot apply the requested changes.
- A Case Type object references an Application Service. If this service does not exist in the target system, Configuration Migration Assistant cannot apply the requested changes.
- Collection Agency and Service Provider objects reference a Person. If this person does not exist in the target system, Configuration Migration Assistant cannot apply the requested changes.
- Service Provider and Tender Source objects reference a Service Agreement. If this service agreement does not exist in the target system, Configuration Migration Assistant cannot apply the requested changes.
- If your migrateable object includes log tables, you may add your log entity to the characteristic type F1-MGO. You should also mark the log table as a “Non-Migrateable Table” in the Maintenance Object options.
- Transactions are applied in an unspecified order (and probably in order numerically by a randomly generated ID value). CMA only looks at "hard" constraints when determining what to put into the same transaction. Any "soft" constraints such as characteristics and algorithm parameters that might have FK references to other objects are not processed by CMA. Unless the migration plan ensures that related items go into the same transaction, they will end up in different ones, and must need to apply again and again until eventually all gets applied.

To Do Lists Addendum

This section is an addendum to the general [To Do Lists](#) chapter. This addendum describes the To Do functionality that is specific to Oracle Utilities Customer Care and Billing.

Assigning A To Do Role

As described in [To Do Entries Reference A Role](#), each To Do entry requires a role. To Do entries created in Oracle Utilities Customer Care and Billing may attempt to assign a role based on an account management group or division if it is applicable to the type of data related to the To Do entry.

As described in [The Big Picture of To Do Lists](#), users are informed that something requires their attention by entries that appear in a To Do List. For example, consider what happens when billing can't find a reading (and it's not allowed to estimate):

- The billing process creates a bill segment that is in error (meter read cannot be found).

- This bill segment that's in error, in turn, triggers the creation of a To Do entry.
- The To Do entry is assigned a role. A role is one or more users who can look at / work on the entry.
- When users view a To Do List, they only see entries addressed to roles to which they belong.

You can optionally use account management groups (AMG) to define the respective role to be assigned to To Do entries that are associated with an account and To Do type. For example, you can create an AMG called Credit Risks and assign this to accounts with suspect credit. Then, whenever an account-oriented To Do entry is created for such an account, it will be assigned a role based on the Credit Risks AMG. Refer to [Setting Up Account Management Groups](#) for more information.

By assigning an AMG to an account, you are telling the system to address this account's To Do list entries to the roles defined on the AMG (note, each To Do type can have a different role defined for it on an AMG).

You can optionally use division to define the respective role to be assigned to To Do entries that are associated with an account and To Do type. For example, you may have a division called California Operations and assign this to accounts located in California. Then, whenever an account-oriented To Do entry is created for such an account, it will be assigned a role based on the California Operations division. Refer to [CIS Division Portal](#) for more information.

A To Do Pre-Creation installation options plug-in is provided to determine the appropriate To Do Role for an account based on AMG and division setup. If plugged in, the logic to determine To Do role for an account is performed whenever a To Do entry is created. Refer to [C1-TDCR-DFRL](#) for further details on how this plug-in works.

FASTPATH:

Refer to [To Do Entries Reference A Role](#) for the details of how an initial role is assigned to To Do entries.

System To Do Types

NOTE:

List of available To Do types. The To Do types available with the product may be viewed in the [application viewer](#)'s [To Do type](#) viewer. In addition if your implementation adds To Do types, you may [regenerate](#) the application viewer to see your additions reflected there.

Background Processes Addendum

This chapter is an addendum to the general [Defining Background Processes](#) chapter. This addendum describes the background processes that are provided with .

NOTE: List of system background processes. The list of background processes provided in the base product may be viewed in the [application viewer](#)'s [batch control](#) viewer. In addition if your implementation adds batch control records, you may [regenerate](#) the application viewer to see your additions reflected there.

How To Set Up A New Extract Processes

Several background processes delivered with the system are used to interface information out of the system. The topics in this section describe when and how to introduce an additional extract process.

Setting Up Meter Read Extracts

You will need a meter read extract for every mechanism your company uses to route meter read requests to the software that handles your meter reading requests. For example:

- You will need a meter read extract to interface records to your handheld device software. The MDL process delivered with the system is intended to be used to handle this function. This process will have to be populated to format the output records in keeping with the needs of your meter reading software.
- If you interface some meter read requests to automatic meter reading software, you will need a new meter read extract process.

If you need additional meter read extract processes, set up the following information:

- Add a new [batch control](#) record. Populate the fields as follows:
- **ID.** Assign an easily recognizable unique ID for the meter read extract process.
- **Description.** Enter a description of the meter read extract process.
- **Accumulate All Instances.** Turn this switch on.
- Use [Route Type](#) to define the meter read extract process to be used for each route type.
- It may be necessary to register the process with your scheduler software.

Setting Up Automatic Payment Extracts

You will need an automatic payment extract for every mechanism your company uses to route automatic payment requests to a financial institution / clearing house. For example:

- You will need an automatic payment extract to interface records to the Automated Clearing House (ACH) if you allow customer to pay via credit card or direct debit from a checking account. The **APAYACH** and **C1-APACH** processes delivered with the system are intended to be used to handle this function.

If you need additional automatic payment extract processes, set up the following information:

- Add a new [batch control](#) record. Populate the fields as follows:
- **Batch Process.** Assign an easily recognizable unique ID for the automatic payment extract process.
- **Description.** Enter a description of the automatic payment extract process.
- **Accumulate All Instances.** Turn this switch on.
- Use [Auto Pay Route Type](#) to define the auto pay extract process to be used for each route type.

Choosing Which Records Are Selected

The system is delivered with some background processes that utilize the **Select Records** plug-in spot to select the records to be processed. It is important to note that these background processes do not utilize the Process Records plug-in spot. This logic is hardcoded as these background processes are some of the core system functions such as billing and collections. This functionality provides flexibility in choosing which records are processed, but not how they are processed.

The background processes delivered with the system optionally selects records based on CIS Division. One example is the batch control ([BILLING](#)) and algorithm ([C1-BILL-SR](#)). The background process and select records algorithm work as a pair. The batch control defines the parameter to be used by the select records algorithm. The algorithm defines the thread strategy, key fields, and makes the batch control parameter available to be used in the SQL algorithm parameter. Click [here](#) to see the algorithm types available for the Select Records system event.

Customizing Which Records Are Selected

There are two ways to customize what is provided with the system.

If your organization processes records using the same criteria as the samples delivered in the system, in this case CIS Division, simply create a custom batch control for each CIS Division and specify the corresponding parameter value.

If your organization processes records using different criteria, the following points summarize the steps needed to implement a new background process using plug-ins for the specific functionality:

- Duplicate an existing batch control
- Remove the batch parameter not relevant to your organization and replace with the relevant batch parameter. Note: only the batch parameters associated with selecting records should be removed or updated. Parameters used to process records must remain.
- Duplicate the plug-in script associated with the select records algorithm type. Modify the script to pass the new batch parameter(s) to bind variables and remove those that are no longer batch parameters.
- Duplicate the select records algorithm type and associate with the new script.
- Create an algorithm for the new algorithm type. The SQL parameter value should be copied from the original algorithm type's algorithm parameter value and modified to make use of the newly added bind variables. (**Note:** Do not change the fields selected or their order.)
- Update the batch control to use the new select records algorithm.

The Big Picture of Sample & Submit

Sample and Submit refers to the ability to create Activity Requests. This is functionality that enables an implementer to design an ad-hoc batch process using the configuration tools.

Some examples of such processes are:

- Send a letter to customers that use credit cards for auto pay and the credit card expiration date is within 30 days of the current date.
- Stop auto pay for customers that use credit cards as the form of payment if the credit card has already expired. Notify the customer that their auto pay agreement has been terminated and that they need to call to reinstate.
- Select auto pay accounts that have more than X non-sufficient fund penalties, stop the auto pay agreement and notify the customer.

NOTE:

The terms *activity request* and *sample & submit request* may be used interchangeably.

Activity Request Type Defines Parameters

For each type of process that your implementation wants to implement, you must configure an activity request type to capture the appropriate parameters needed by the activity request.

Preview A Sample Prior To Submitting

To submit a new activity request, a user must select the appropriate activity request type and enter the desired parameter values, as applicable.

After entering the parameters, the following actions are possible

- Click **Preview** to see a sample of records that satisfy the selection criteria for this request. This information is displayed in a separate map. In addition, the map displays the total number of records that will be processed when the request is submitted. From this map you can **Save** to submit the request, go **Back** to adjust the parameters or **Cancel** the request.
- Click **Cancel** to cancel the request.
- Click **Save** to skip the preview step and submit the request.

When an activity request is saved, the job is not immediately submitted for real time processing. The record is save in the status Pending and a monitor process for this record's business object is responsible to transition the record to Complete.

As long as the record is still Pending, it may be edited to adjust the parameters. The preview logic described above may be repeated when editing a record.

The actual work of the activity request, such as generating customer contact records to send letters to a set of customers, is performed when transitioning to Complete (using an enter processing algorithm for the business object).

Credit Card Expiration Notice

The base product supplies a sample process to find customers that use credit cards for auto pay and their credit card expiration date is within *X* days of the current date.

To this functionality the following configuration tasks are needed:

- Define an appropriate [customer contact class](#) and [type](#) to use.
- Define appropriate activity request Cancellation Reasons. Cancellation reasons are defined using a customizable [lookup](#). The lookup field name is C1_AM_CANCEL_RSN_FLG.
- Define an activity request type for the business object C1-NotifyExpiringCreditCardTyp . You may define default parameter values for the number of days for expiration and customer contact class and type.

Exploring Activity Request Data Relationships

Use the following links to open the application viewer where you can explore the physical tables and data relationships behind the activity request functionality:

- Click [C1-ACM-ACTTY](#) to view the activity request type maintenance object's tables.
- Click [C1-ACM-ACTRQ](#) to view the activity request maintenance object's tables.

Defining a New Activity Request

To design a new ad-hoc batch job that users can submit via Sample and Submit, first create a new Activity Request Type business object. The base product BO for the activity type C1-NotifyExpiringCreditCardTyp may be used as a sample.

The business object for the activity request includes the functionality for selecting the records to process, displaying a preview map for the user to review and to perform the actual processing. The base product BO for the activity request C1-NotifyExpiringCreditCardReq may be used as a sample. The following points highlight the important configuration for this business object:

- Special BO options are available for the activity request BOs to support the [Preview Sample](#) functionality.
 - Activity Request Preview Service Script. This script is responsible for retrieving the information displayed when a user asks for a preview of a sample of records.
 - Activity Request Preview Map. This is the map that is invoked to display the preview sample results.

- The enter algorithm plugged into the Complete state is responsible for selecting all the records that satisfy the criteria and processing the records accordingly.

Setting Up Activity Request Types

Activity Request Types define the parameters to capture when submitting an activity request through Sample and Submit. To set up an activity request type, open **Admin > Customer > Activity Request Type > Add**.

The topics in this section describe the base-package zones that appear on the Activity Request Type portal.

Activity Request Type List

The Activity Request Type [List zone](#) lists every activity type. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent activity type.
- Click the Add link in the zone's title bar to add a new activity type.

Activity Request Type

The Activity Request Type zone contains display-only information about an activity request type. This zone appears when an activity request type has been broadcast from the Activity Request Type List zone or if this portal is opened via a drill down from another page. The following functions are available:

- Click the **Edit** button to start a business process that updates the activity request type.
- Click the **Delete** button to start a business process that deletes the activity request type.
- Click the **Duplicate** button to start a business process that duplicates the activity request type.
- State transition buttons are available to transition the activity request type to an appropriate next state.

Please see the zone's help text for information about this zone's fields.

Maintaining Sample & Submit Requests

Use the Sample and Submit transaction to view and maintain pending or historic activity requests. Navigate using **Menu > Tools > Sample & Submit Request > Search**.

Sample & Submit Request Query

Use the [query portal](#) to search for an existing sample & submit request. Once a request is selected, you are brought to the maintenance portal to view and maintain the selected record.

Sample & Submit Request Portal

This portal appears when a sample & submit request has been selected from the Sample & Submit Request Query portal. The topics in this section describe the base-package zones that appear on this portal.

Sample & Submit

The Sample & Submit zone contains display-only information about an activity (sample & submit) request. The following functions are available:

- Click the **Edit** button to modify the parameters. Refer to [Preview A Sample Prior to Submitting](#) for more information.
- If the activity request is in a state that has valid next states, buttons to transition to each appropriate next state are displayed.

Please see the zone's help text for information about this zone's fields.

Sample & Submit Log

This is a standard [log zone](#).

Security Addendum

This chapter is an addendum to the general [Defining Security and User Options](#) chapter. This addendum describes security functionality that is specific to Oracle Utilities Customer Care and Billing.

Implementing Account Security

CAUTION:

This section assumes you understand [The Big Picture of Row Security](#).

When you create an account, you must define which users can access the account's information. For example,

- If you have customers in two geographic territories, you may need to restrict access to accounts based on the office that manages each territory. For example, only users in the northern office may manage accounts in the northern territory.
- If you have industrial and residential customers, you may need to restrict access to these different customer segments based on the skill set of the users. For example, some users are skilled in dealing with industrial customers, while others are skilled in dealing with residential customers.

By granting a user access rights to an account, you are actually granting the user access rights to the account's bills, payment, adjustments, orders, etc.

FASTPATH:

Refer to [If You Do Not Practice Account Security](#) for setup instructions if your organization doesn't practice account security.

NOTE:

Account security may also affect persons and premises. Refer to [Persons Can Also Be Secured](#) for how access to person information is also restricted by account security. Refer to [Premises Can Also Be Secured](#) for how access to premise information is also restricted by account security.

The topics in this section describe how to implement account security.

Persons Can Also Be Secured

It's important to be aware that persons can also be secured as a result of "account security". It works like this:

- If a person is linked to at least one account, users will not be allowed access to the person (or the person's related information) unless they have access to at least one of the person's accounts.
- If a person is not linked to any accounts (a rare situation), any user may access the person.

NOTE:

How are persons linked to accounts? A person is linked to an account when an account is created using the methods described under [How To Add A New Customer From Control Central](#) and [Order User Interface Flow](#). In addition, you may manually link and unlink persons from account using the [Account - Person](#) page.

Premises Can Also Be Secured

It's important to be aware that premises can also be secured as a result of "account security". It works like this:

- If a premise is linked to at least one account, users will not be allowed access to the premise (or the premise's related information) unless they have access to at least one of the premise's accounts.
- If a premise is not linked to an account (a rare situation), then all users may access the premise.

NOTE:

How are premises linked to accounts? A premise is indirectly linked to an account. For the purpose of access restriction, we deem a premise as being linked to an account if at least one of its service points is linked to at least one of the account's service agreements.

Data Becomes Invisible When Access Is Restricted

The following summarizes the impact of a user not having access to an account:

- [Account Security and Control Central](#)
- [Account Security and Searches \(and Maintenance Pages\)](#)
- [Account Security and To Do Lists](#)

Account Security and Control Central

This section summarizes the impact of account security on [Control Central](#):

- Searches are affected as follows:
- An account will only be visible if a user has access to the account's access group.
- Persons that are not linked to accounts will be visible to all users.
- If a person is linked to an account, the person will only be visible if the user has access to at least one of the person's accounts.

- Premises that are not linked to accounts will be visible to all users.
- If a premise is linked to an account, the premise will only be visible if the user has access to at least one of the premise's accounts.
- The alerts that highlight the existence of "multiple relationships" are not impacted by account security. Specifically:
- The alert Person has multiple accounts will appear if the selected person is linked to multiple accounts, even if the user doesn't have access to every account. Note well, the person couldn't have been selected if the user didn't have access rights to at least one account.
- The alert Premise has multiple accounts will appear if the selected premise is linked to multiple account, even if the user doesn't have access to every account. Note well, the premise couldn't have been selected if the user didn't have access rights to at least one account.
- Only accounts to which the user has access will be displayed in the person tree.
- Only accounts to which the user has access will be displayed in the account tree.
- All other pages contain information related to Control Central's current account context. The current account context can never reference an inaccessible account and therefore these pages are not impacted by account security.

NOTE: If your implementation wishes to allow users to search for all accounts through Control Central without validating the user's access rights, this can be configured by setting up the **Search All Account** option type on the Customer Information Options [Feature Configuration](#) . If the user tries to select an account without having the required access, they will not be able to navigate to the Account Information tab on Control Central for the selected account.

Account Security and Searches (and Maintenance Pages)

Searches are the gateway to the information that appears on maintenance pages. In general, account-related information is suppressed when a user doesn't have access rights to the account. This suppression is true for rows that directly reference an account AND for rows that indirectly reference an account. For example:

- A user can only see bills associated with accounts to which they have access rights.
- A user can only see financial transactions associated with service agreements that are, in turn, associated with accounts to which they have access rights.

NOTE:

Person and premise searches are also impacted. Keep in mind that information will be suppress from both person and premise-oriented searches if the person / premise is related to accounts. Refer to [Persons Can Also Be Secured](#) for how access to person information is also restricted by account security. Refer to [Premises Can Also Be Secured](#) for how access to premise information is also restricted by account security.

Account Security and To Do Lists

Account security does NOT impact the information that appears in a user's To Do list. Rather, we have assumed that your To Do roles (and the users assigned to these roles) are consistent with your account security requirements. This can result in anomalies. For example, it's possible for a supervisor to assign a bill segment error to a user who doesn't have access to the bill segment's account. This user will then see the related To Do entry in their Bill Segments In Error To Do list. However, when they drill down on the entry, account security will manifest itself (i.e., the user won't be able to display the bill segment that's in error). This happens because the drill down causes the bill segment search logic to execute. This logic inhibits the selection of bill segments if the user can't access the related account.

To minimize these anomalies, we recommend the following:

- Setup [To Do Roles](#) consistent with your Data Access Roles.

- Setup [Account Management Groups](#) that are consistent with your Access Groups.
- Setup default To Do Roles on your Account Management Groups for each [To Do type](#).

Restricted Transactions

The following table lists all transactions that have some type of account security. The following notation is used to describe the type of account security:

- **Account-oriented.** This notation is used if the respective transaction uses basic account security (i.e., the user must belong to at least one data access role that has access to the account's access group in order to see the information).
- **Person-oriented.** This notation is used if the respective transaction uses person-oriented account security. Refer to [Persons Can Also Be Secured](#) for more information.
- **Premise-oriented.** This notation is used if the respective transaction uses premise-oriented account security. Refer to [Premises Can Also Be Secured](#) for more information.
- None of the above. Some unusual transactions have unusual implementations of account security. These are described below.

Transaction	Type of Account Security
Account	Account-oriented
Account Bill / Payment History	Account-oriented
Account Financial History	Account-oriented
Account Interval Info	Account-oriented
Account Payment History	Account-oriented
Account Person Replicator	Account-oriented
Account SAs for Debt Class	Account-oriented
Adjustment	Account-oriented
Adjustment Calculation Line Characteristics	Account-oriented
Appointment	Premise-oriented
Bill	Account-oriented
Bill Print Group	Person-oriented
Bill Segment	Account-oriented
Billable Charge	Account-oriented
Budget Review	Account-oriented
Case	Account-oriented, Person-oriented and Premise-oriented
Collection Agency Referral	Account-oriented
Collection Process	Account-oriented
Contract Option	Account-oriented
Control Central	Account-oriented, Person-oriented and Premise-oriented
Customer Contact	Person-oriented
Cut Process	Account-oriented
Declaration	Account-oriented
Deposit Review	Account-oriented

Field Activity	Premise-oriented
Field Order	Premise-oriented
Financial Transaction	Account-oriented
Financial Transaction on a Bill	Account-oriented
Financial Transaction on a Payment	Account-oriented
Interval Profile	Account-oriented (for SA-specific profiles)
Landlord Agreement	Account-oriented
Loan	Account-oriented
Match Event	Account-oriented
Multi-Cancel/Rebill	Account-oriented
Non-Billed Budget	Account-oriented
Order	Account-oriented, Person-oriented and Premise-oriented
Overdue Process	Account-oriented
Pay Plan	Account-oriented
Payment	Account-oriented
Payment Arrangement	Account-oriented
Payment Arrangement for Bills	Account-oriented
Payment Event	The user must have access to ALL accounts linked to the payment event.
Payment Event Quick Add	The user must have access to ALL accounts linked to the payment event(s).
Payment Quick Add	Account-oriented
Payment / Tender Search	Account-oriented
Person	Person-oriented
Premise	Premise-oriented
Premise Management	Premise-oriented
Quote	Account-oriented
SA Billing History	Account-oriented
SA Cash Accounting Balance	Account-oriented
SA Financial History	Account-oriented
SA Relationship	Account-oriented
Service Agreement	Account-oriented
Service Credit Event	The user must have access to ALL accounts linked to the service credit membership that has the service credit event.
Service Credit Membership	The user must have access to ALL accounts linked to the service credit membership.
Service Provider SA Relationship	Account-oriented
Severance Process	Account-oriented
Start/Stop	Account-oriented
Statement	The user can see the statement if they have access to at least one account on the statement's statement construct.

Statement Construct	The user can see the statement if they have access to at least one account on the statement construct.
Terms of Service	Account-oriented (User must have access to at least one account linked to the SA collection in the TOS.)
TOU Map	Account-oriented (for SA-specific TOU maps)
Umbrella Agreement	Account-oriented (User must have access to at least one account linked to the SA collection in the UA's TOS.)
Write Off	Account-oriented
Write Off Process	Account-oriented

Account Security Case Studies

The topics in this section contain examples of how to implement account security. Use these examples to form an intuitive understanding of these objects. Once this intuition is obtained, you'll be ready to design the account security objects for your own company.

Securing Accounts Based On Customer Class

Assume the following security requirement exists:

- You have two broad groups of accounts:
 - Residential accounts.
 - Commercial / Industrial accounts.
- Users can be classified as have one of the following access rights:
 - May access all accounts.
 - May only access residential accounts.
 - May only access commercial / industrial accounts.

The following diagram illustrates the access groups and data access roles required to implement these requirements:

Notice the following about the above:

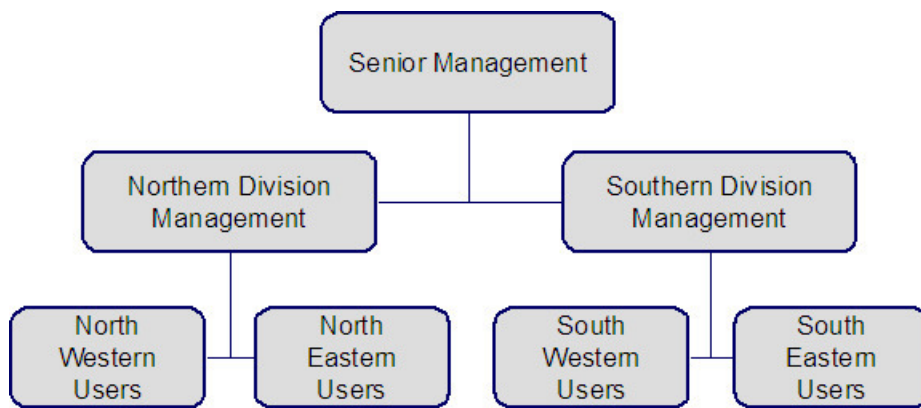

- There are 2 access groups because access to accounts is based on whether the account is considered to be residential or commercial/industrial.
- The Big Customers data access role is only linked to the C&I access group.
- The Small Customers data access role is only linked to the Residential access group.
- The All Customers access role is linked to both the C&I and Residential access groups. Users with this role can therefore access all accounts.

Securing Accounts Based On Region

Assume that accounts are classified as belonging to one of the following regions:

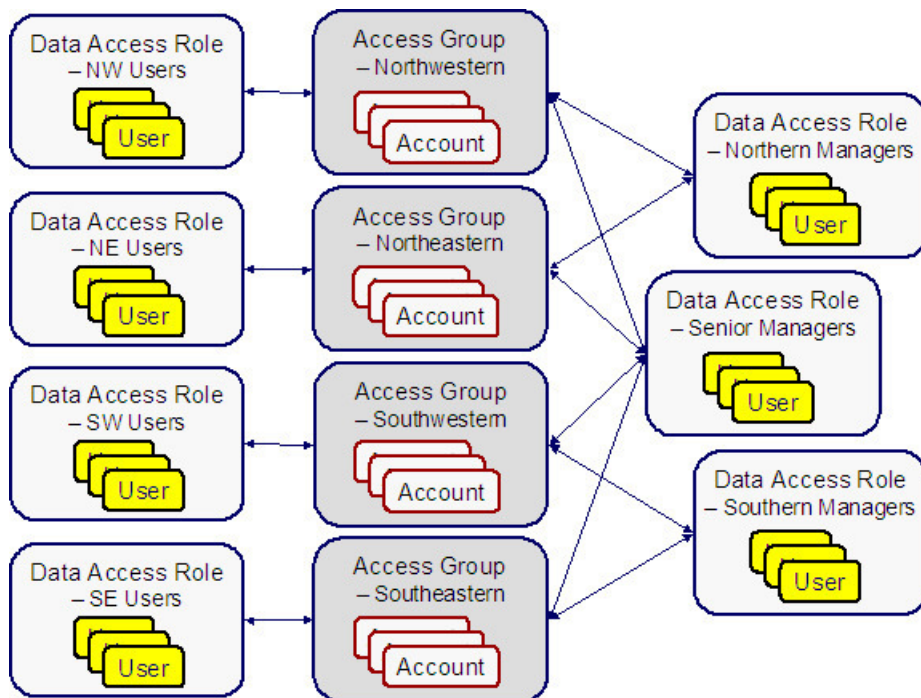

- Northwestern
- Northeastern
- Southwestern
- Southeastern

Assume the following company hierarchy exists:

- Senior Management has access to all customers
- Northern Division Management has access to all customers in the Northwestern and Northeastern divisions.
- Southern Division Management has access to all customers in the Southwestern and Southeastern divisions.
- Northwestern Users have access to all customers in the Northwestern division.
- Northeastern Users have access to all customers in the Northeastern division.
- Southwestern Users have access to all customers in the Southwestern division.
- Southeastern Users have access to all customers in the Southeastern division.

The following diagram illustrates the access groups and data access roles required to implement these requirements:

Notice the following about the above:

- There are 4 access groups because access to accounts is based on the region in which they are located (and there are 4 regions).
- There are 7 data access roles because each component of every layer of the access hierarchy requires a separate data access role.

The Default Access Group

There are two ways an access group can be assigned to an account:

- The base package will default an account's access group based on the user who adds the account. It uses the user's [default access group](#) to do this.
- If you can conceive of a rule to assign an appropriate access group to a newly added account, you can have your programming staff introduce a user exit to the account row program to implement this rule. For example, a user exit could be developed that assigns an access group to an account based on its customer class. The name of the user-exit is AFTER-MOVE-CORR-ADD and the name of the account row program is CIPCACCR.

WARNING:

Regardless of the method used to assign an account's access group, please be aware that the user who adds an account must have access to this access group.

NOTE:

Subsequent changes to an account's access group. A user may change an account's access group to any access group to which they have access.

If You Do Not Practice Account Security

If you do not restrict access to accounts (i.e., all users can access all accounts), you must set up one access group and one data access role and then indicate all users are part of this role. You should also define the access group as the default access group on all of your users (so that new accounts are all labeled with this access group).

Masking Sensitive Data

Refer to [Masking Data](#) for instructions describing how to configure the system to mask sensitive data like a customer's social security number or bank account number. If your implementation intends to mask any of the information that appears in the [Customer Information Zone](#) please navigate to this zone's documentation for special instructions.

Encrypting Sensitive Data

The product provides support for encrypting certain sensitive data, which may be necessary if your implementation wants to meet security standards such as those for credit card transactions, as specified by the Payment Card Industry Security Standards Council.

Please be sure that you are familiar with the information documented in [Database Encryption and Masking](#) before reading further.

The remaining details in this section provide information about the fields in the product that support encryption along with the suggested configuration for the **Encryption** feature configuration entry if your implementation opts to encrypt the data.

External Account ID and Credit Card Number Encryption

If your implementation would like to encrypt credit card IDs, the following entry should be added to the Encryption feature configuration so that the data stored in the External ID column on the Account Automatic Payment table is encrypted:

table='CI_ACCT_APAY', field='EXT_ACCT_ID', encryptedField='ENCR_EXT_ACCT_ID'

NOTE:

- The External Account ID field also exists on other tables such as Auto Pay Clearing Staging table (CI_APAY_CLR_STG) and Payment Event Upload Staging table (CI_PEVT_DTL_ST) . Feature configuration options do not need to be configured for the External Account ID field on these tables as the field on these related tables is encrypted based on the feature configuration specified above for the Account Automatic Payment table (CI_ACCT_APAY).
 - A customer's bank account ID or credit card number may also be stored in a column when an order is completed. A field encryption feature configuration for the Order Field table (CI_ENRL_FLD) does not need to be configured if the customer's bank account ID or credit card number is referenced on this table. The encryption for the field should be handled by a Column Reference - Preprocessing algorithm. The base product provides an Encrypt Account Auto Pay External Account Id Column Reference Value algorithm type for this purpose.
 - A field encryption feature configuration option needs to be configured for each schema field to be encrypted that represents a customer's bank account ID or credit card number. If the value of an encrypted schema field will later be populated on or compared against an encrypted table field, the schema field and the table field must share the same key alias.
-

If your implementation is integrated with a self-service application and one time payment details are captured in Person Self-Service Payment Option (C1_PER_SS_PAYOPT) , the product supports encryption of the Credit Card Number and External Account ID fields on this table. In addition, the product supports a hash representation of this fields for searching purposes. To encrypt Credit Card Number and External Account ID, add the following entries to the Encryption feature configuration:

- **table='C1_PER_SS_OPT', field='CREDIT_CARD_NBR', encryptedField='ENCR_CREDIT_CARD_NBR',hashField='HASH_CREDIT_CARD_NBR'**
- **table='C1_PER_SS_OPT', field='EXT_ACCT_ID', encryptedField='ENCR_EXT_ACCT_ID', hashField='HASH_EXT_ACCT_ID'**

Bank Account Number Encryption

If your implementation would like to encrypt the bank account number stored on the bank account table, the following entry should be added to the Encryption feature configuration:

table='CI_BANK_ACCOUNT', field='ACCOUNT_NBR', encryptedField='ENCR_ACCOUNT_NBR'

MICR ID Encryption

The product provides support for encrypting MICR ID associated with payments. In addition, the product supports capturing a hash representation of this field for searching purposes. This field is captured on three tables and entries should be added to the Encryption feature configuration for each as follows:

- **table='CI_PEVT_DTL_ST', field='MICR_ID', encryptedField='ENCR_MICR_ID', hashField='HASH_MICR_ID'**
- **table='CI_PAY_TNDR_ST', field='MICR_ID', encryptedField='ENCR_MICR_ID', hashField='HASH_MICR_ID'**
- **table='CI_PAY_TNDR', field='MICR_ID', encryptedField='ENCR_MICR_ID', hashField='HASH_MICR_ID'**

NOTE: All configurations must share the same key alias.

Person ID Number Encryption

The product provides support for encrypting an identifier associated with a person. In addition, the product supports capturing a hash representation of this field for searching purposes. Because the ID collection on Person includes an ID type, your implementation may decide to encrypt all IDs captured for the person or may choose to only encrypt IDs of one

or more specific ID types. If you want to encrypt multiple ID types, you must configure a field encryption option type for each ID type. The following shows an example of an encryption feature configuration entry for encrypting an ID with the type “SSN”:

```
table='CI_PER_ID', field='PER_ID_NBR', encryptedField='ENCR_PER_ID_NBR', hashField='HASH_PER_ID_NBR', where='ID_TYPE_CD=SSN'
```

NOTE:

- The Person ID Number also exists on the Order Person ID table (CI_ENRL_PER_ID) table. Feature configuration options do not need to be configured for the Person ID Number field on this table as the field is encrypted based on the feature configuration specified above for the Person Identifier table (CI_PER_ID).
 - The Person ID Number may also be stored in a column when an order is completed. A field encryption feature configuration for the Order Field table (CI_ENRL_FLD) does not need to be configured if the Person ID Number is referenced on this table. The encryption for the field should be handled by a Column Reference - Preprocessing algorithm. The base package provides an Encrypt Column Reference Value algorithm type for this purpose.
 - A field encryption feature configuration option needs to be configured for each schema field to be encrypted that represents a Person ID Number. If the value of an encrypted schema field will later be populated on or compared against an encrypted table field, the schema field and the table field must share the same key alias.
-

Company ID Encryption

The product provides support for encrypting the Company ID that is populated into automatic payment extract files. If your implementation would like to encrypt company IDs on the Auto Pay Route Type table (CI_APAY_RT_TYPE), the following entry should be added to the Encryption feature configuration:

```
table='CI_APAY_RT_TYPE', field='CO_ID', encryptedField='ENCR_CO_ID'
```

In addition, if your implementation allows Company ID overrides by CIS Division, the following entry should be added to the Encryption feature configuration so that the Company ID on the CIS Division Route Type table (C1_CIS_DIV_RTYP) is encrypted.

```
table='C1_CIS_DIV_TRYP', field='OVRD_CO_ID', encryptedField='ENCR_OVRD_CO_ID'
```

Encrypting Legacy Data

If you enable encryption in an existing implementation, you should run the encrypt legacy batch controls to encrypt legacy data that persists in the database:

- F1-ENCRT: Encrypt Legacy Table Field Data
- F1-ENCRS: Encrypt Legacy Schema Field Data
- C1-ECRVL: Encrypt Legacy Order Field Col Ref Value

Before executing the batch processes, you must have a keystore file in the system to hold the keys for encrypting data and define an encryption feature configuration that contains the details for the fields you want to encrypt.

Data Privacy Addendum

This section is an addendum to the general [Data Privacy](#) chapter. This addendum describes Object Erasure functionality that is specific to .

Customer Erasure

A customer's personal information can be erased from the system under certain circumstances - the most common of which is when the information is no longer necessary for the original purposes of which it was collected and processed. This is usually the case when a customer's accounts have been closed for some time and there is no other activity for that customer.

Erasure can be triggered automatically (e.g. as service agreements go into a final state) or manually (e.g. when a customer calls in to request for erasure).

Automatic Trigger Of Customer Erasure

A person's eligibility for erasure can be automatically evaluated when key events occur on that person's accounts. These events include:

- Adding a service agreement
- Closing a service agreement
- Canceling a service agreement
- Reactivating a service agreement
- Accepting a proposal service agreement
- Declining a proposal service agreement
- Reopening a proposal service agreement
- Deleting a proposal service agreement

Monitoring SA Triggers For Customer Erasure

The base product provides an MO Audit algorithm, Monitor SA Manage Erasure Events (C1-SAMNGEREV) that implementations need to plug in on the Service Agreement (SA) MO to enable automatic triggering of erasure.

Note that this algorithm simply creates a General Process record for the Person. This technique allows the system to perform the erasure evaluation (i.e. in the Manage Erasure Schedule algorithm) in batch. This is to minimize the number of times that the Manage Erasure Schedule algorithm is executed for the same Person. For instance, if the customer had one SA closed, another one canceled and another SA created, the erasure evaluation will only be executed once (i.e. when the C1-MNERP batch process runs) even if there were three SA events for that person.

The Manage Erasure Schedule for Person (C1-MNERP) plugin-driven batch process is provided to process the General Process records for managing person erasure. The Process Record algorithm on this batch process invokes the Manage Object Erasure (F1-ManageErasureScheduleDriver) business service. Refer to the C1-MNERP batch control in the application for more details.

Manual Trigger Of Customer Erasure

A customer may call in to request an agent to erase him or her from the system.

The base product provides a Trigger Customer Erasure (C1-TrgCustEr) BPA script that users can configure as a favorite script in their User Preferences.

This script assumes that the user retrieves the Person before running the script – meaning, the Person is already in the current context. The script pulls in the Person ID and renders the information on the map, which also captures Erasure Date, Erasure Reason and Comments as additional inputs.

A Confirm action will invoke the same Manage Erasure Schedule processing that is executed in automatically triggered person erasures. If the customer is eligible for erasure, the Person and its associated Account(s) and Service Agreement(s)

will be scheduled for erasure on the designated Erasure Date. Otherwise, an error will be displayed, indicating ineligibility for erasure.

Refer to the Trigger Customer Erasure (C1-TrgCustEr) BPA script in the application for more details about this script.

The Person MO Controls Customer Erasure

A customer's eligibility for erasure is evaluated at the Person level. This means that only the Person maintenance object will specify a Manage Erasure Schedule algorithm. Eligibility criteria in this algorithm will check the status of the Person's Account(s) and Service Agreement(s) to determine whether or not these objects can be erased. Object Erasure Schedule records are added/updated/discarded, based on the outcome of the eligibility check.

Manage Erasure Schedule Algorithm: Person Erasure Evaluation

The base product supplies a Maintenance Object - Manage Erasure Schedule algorithm – i.e. Person Erasure Evaluation (C1-PEREREVAL) that determines Person Erasure eligibility based on the status of the service agreements (SAs). If all SAs are in some final state - e.g. Closed, Canceled - the Person is deemed eligible for erasure and the corresponding Object Erasure Schedule records are added. Otherwise, the Person is deemed ineligible for erasure. If a person that is already scheduled for erasure happens to have new activity - e.g. started a new SA, reactivated a Closed SA - any existing Object Erasure Schedule records for that Person and its Account(s) and SA(s) will be discarded.

Persons, Accounts And Service Agreements Are Obfuscated

The following sections describe the erasure processing for Person, Account and Service Agreement information.

Purge Versus Obfuscate

Purging involves physical deletion of a record. On the other hand, obfuscation involves updating certain fields in the table that are considered personally identifiable information (PII) – e.g. name, address, etc. The values of these fields are updated to blank or some value that is no longer identifiable to a person – e.g. the random-generated primary key of the Person record.

Base-supplied Person, Account and SA erasure logic performs obfuscation on the root tables of these maintenance objects (MOs). The reasons are:

- Purging could have impacts to external systems
- Purging might cause orphan data or invalid foreign key references within the system

However, base logic does purge most of the data in these MOs' child tables. The exceptions are characteristic tables and some SA child tables that do not contain PII.

Refer to the next sections for details on each object's obfuscation processing.

Person, Account and Service Agreement Erasure BOs

The base product provides the following Object Erasure Business Objects (BOs):

- Person Erasure: C1-ErasureSchedulePerson
- Account Erasure: C1-ErasureScheduleAccoun
- Service Agreement Erasure: C1-ErasureScheduleSA

All are child BOs of the Erasure Root parent BO - F1-ErasureScheduleRoot. These BOs are delivered plugged in on their corresponding maintenance objects.

Refer to the Business Object configuration in the application for more details.

Person, Account and Service Agreement Obfuscation Algorithms

The Person, Account and Service Agreement Erasure business objects include an Enter algorithm (on the Erased state) that is responsible for obfuscating data in the maintenance object's tables. The following sections describe each algorithm.

Person Obfuscation

The Person Erasure (C1-ErasureSchedulePerson) BO is delivered with an enter algorithm on the Erased state - C1-PEROBJERS.

This algorithm performs the following:

- On the Person root table, updates the Address1, City and Postal fields with the PER_ID value.

NOTE: These fields are search fields and are thus indexed.

- Deletes all records in the Person Seasonal Address table
- Deletes all records in the Person Identifier table
- In the Person Name table:
 - The primary name is retained and the name value is replaced with the PER_ID value.

NOTE: Deletion of the primary name makes the Person record and its Account and SA records unsearchable through the user interface - e.g. via Control Central search.

- All other names are deleted
- Deletes all records in the Person Phone table
- Deletes all records in the Person Contact table
- Deletes all records in the Person-to-Person table
- Deletes all records in the Person Self-Service Payment Option table

NOTE: The base algorithm does not obfuscate nor delete any Person Characteristics because this data is implementation-specific. Implementations that store any personally identifiable information (PII) in this table - e.g. in adhoc characteristic values should add their specific obfuscation/delete logic for these characteristics.

Account Obfuscation

The Account Erasure (C1-ErasureScheduleAccount) BO is delivered with an enter algorithm on the Erased state - C1-ACCTOBFS.

This algorithm performs the following:

- In the Account root table:
 - Removes the link to the Mailing Premise Id
 - Clears contents of the Account Data Area
- Deletes all Account Person records except the main Person.

NOTE: Deletion of the 'main' person makes the Account unsearchable through the user interface - e.g. via Control Central search.

- Updates the main Person's Address Source to Person
- Deletes all records in the Person Address Override table
- Deletes all records in the Account Auto Pay table
- Deletes all records in the Account Alerts table
- Deletes all records in the Account Messages table
- Deletes all records in the Account Credit Rating History table
- Deletes all records in the Account Debt Monitor Review Schedule table
- Deletes all records in the Non-Cash Deposit table
- Deletes all records in the Budget Review table
- Deletes all records in the Notification Preferences table and its child tables

NOTE: The base algorithm does not obfuscate nor delete any Account Characteristics because this data is implementation-specific. Implementations that store any personally identifiable information (PII) in this table - e.g. in adhoc characteristic values should add their specific obfuscation/delete logic for these characteristics.

Service Agreement Obfuscation

The Service Agreement Erasure (C1-EraseScheduleSA) BO is delivered with an enter algorithm on the Erased state - C1-SAOBFSCFN.

This algorithm performs the following:

- On the SA root record, removes the link to the Characteristic Premise.
- Deletes all records in the SA/SP table and its child tables: SA/SP Field Activity and SA/SP Characteristics

NOTE: The base algorithm does not obfuscate nor delete any Service Agreement Characteristics because this data is implementation-specific. Implementations that store any personally identifiable information (PII) in this table - e.g. in adhoc characteristic values should add their specific obfuscation/delete logic for these characteristics.

Configuring The System For Customer Erasure

The following are the steps to enable Customer Erasure:

- Plug in the Manage Erasure Schedule - Person Erasure Evaluation algorithm on the Person MO.
- Configure the Erasure Period option on each of the Person, Account and SA MOs.

NOTE: Note: The values for all three MOs should be the same, to ensure the Erasure Dates are the same on the resulting Object Erasure Schedule records.

- Plug in the Monitor SA Manage Erasure Events (C1-SAMNGEREV) Audit algorithm on the SA MO.
- If using the Trigger Customer Erasure (C1-TrgCustEr) script to manually trigger person erasure:
 - Configure values for the Erasure Reason lookup field DP_CUST_ERS_RSN_FLG.
 - Configure the C1-TrgCustEr BPA script as a Favorite Script in User Preferences.

Notifying External Systems About Customer Erasure

When CCB is integrated with a meter data management system (such as Oracle Utilities Meter Data Management) and the Person and SA syncs are used to synchronize Contact and Usage Subscription information with corresponding Person and SA information, the meter data management needs to be notified when such information is already erased in CCB.

The following sync request BO schemas include a Customer Erased switch:

- MDM2 Person Sync Request: C1-MDM2PersonSyncRequest
- MDM2 SA Sync Request: C1-MDM2SASyncRequest

Logic on these BOs sets this switch to true if the related Person/SA has an Object Erasure Schedule record that is in the Erased state.

The meter data management system can use this switch to trigger its own erasure processing for Contact and Usage Subscription information. For an example, refer to the Data Privacy documentation for Oracle Utilities Meter Data Management.

Refer to the Business Object configuration in the application for more details.

Defining Converted COBOL Program Options

The topics in this section describe the transaction that allows you to define the metadata for converted COBOL programs within the current environment's database.

CAUTION: Updating converted COBOL Programs requires technical knowledge of the system. This is an implementation and delivery issue and should not be attempted if you do not have previous experience.

Converted COBOL Program - Main

Use this transaction to define converted COBOL program user exits for your system. Navigate to this page using **Admin > System > Converted COBOL Program > Search**.

Description of Page

The following describes fields that are relevant to defining the user exit code that a converted COBOL Program should use:

Program Component ID represents the internal ID that is given to the converted COBOL program component.

Program Com Name is the physical name of the converted COBOL program component.

Template is the template used to generate the converted COBOL program component.

Location ID (*for development purposes*)

Table (*for development purposes*)

User Exit Program. Specify if you have written user exit code for this converted COBOL program component.

Development Status Flag. Options include Note Generated and Not Regeneratable.

Short Comments provides a short description of the converted COBOL program component.

Long Comments provides more details of the converted COBOL program component.

The **Variable Information** grid (including Variable Name, Occurrence, Variable Sequence, Variable Value, and Variable Alternate Value) is *for development purposes only*.

Advanced Search Options

The product offers an option to perform expanded / fuzzy searching in [Control Central](#) Search by Name and Address. The option is only available if your implementation has appropriately configured your database for fuzzy searching.

Refer to the DBA guide in the installation guide for details on setting up the database to support fuzzy searching. Note that there are some implementations where fuzzy searching will not be possible. For example, it's only available for implementations using the Oracle database. Additionally, not all languages are supported. Refer to the Oracle Database documentation for more information about fuzzy searching.

If your implementation has configured its database to enable fuzzy searching, you must also set up a [Feature Configuration](#) to indicate that feature is supported. Find the Feature Configuration record for the **General System Configuration** feature type. (It may need to be defined if it does not exist). Choose the option type **Enable Expanded Results** and define a value of **Y**.

Integration

CTI-IVR Integration

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with your Computer Telephony Integration/Interactive Voice Response (CTI/IVR) system. The interface provides the following functionality:

- The ability to launch Control Central for a particular account ID or phone number from an external application
- The ability to accept the next call, as dictated by the CTI software,
- The ability to perform an outbound phone call from within Oracle Utilities Customer Care and Billing

This document provides technical information needed by your implementers to fully integrate with your CTI/IVR system.

CTI-IVR Integration Configuration

The integration with your Computer Telephony Integration/Interactive Voice Response (CTI/IVR) system requires the setup of master configuration data that controls the Next Caller and Automated Dialer functions.

To set up the CTI/IVR integration master configuration, navigate using **Admin > General > Master Configuration**. You are brought to an all-in-one portal with options to add/edit the CTI/IVR Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Launching The System From an External Application

The following section describes possible options to launch the system from an external system.

Launching The Application Using a URL

You launch the application using a URL. With this option you can set the system to launch a script upon startup. You can also indicate to the system to automatically load an appropriate page (if this information is not part of the script).

The application includes a simple sample html page that can launch CCB Control Central Search by Phone Number or by Central Search Account Id. The page is called CTISample.HTM and is located in /cm_templates.

FASTPATH:

Refer to [Launching A Script When Starting The System](#) for further information.

Receiving the Next Caller in the Queue

If your CTI-IVR system allows users to request the next caller waiting in a queue, the system provides a mechanism to integrate with this functionality.

A BPA script called **Get Next Caller (C1-GtNxtClrC)** is available that can be used to request the next call waiting in an inbound queue managed by a CTI application.

When the **Get Next Caller** BPA is executed, it launches the **CTI Get Next Caller** and **Launch CTI** processing scripts that are defined in the CTI/IVR Integration master configuration. Your implementation creates the **CTI Get Next Caller** script that retrieves the next account in the queue. The base product supplies a sample **Launch CTI** BPA script that launches Control Central using the **C1-CCByAcct** BPA script and passing in the account that was returned by the **CTI Get Next Caller** script.

Customize Integration to Your Next Caller Function

Your implementation needs to create a **CTI Get Next Caller** processing script that will be responsible for getting the next account in the queue, based on your integrated CTI application. The base-supplied **Launch CTI** processing script can be used to navigate to Control Central with the next caller's account passed in.

In order to integrate the next caller functionality with your CTI-IVR system, perform the following steps:

- Create your custom **CTI Get Next Caller** service script that retrieves the next account from the queue.
- Create a **Launch CTI** BPA script if your business rules require additional logic and/or need to launch a different page in the system..
- Plug in the **CTI Get Next Caller** and **Launch CTI** scripts on the CTI/IVR Integration master configuration.

Initiating an External Call

This section describes the automated dialer functionality provided with the system as well as information about integrating with your own automated dialer.

Overview of Automated Dialer

In order to initiate a call to a customer from within the system, a context menu item **Go To Automated Dialer** is available on the Person context menu. To call a customer displayed in the current context, choose this option from the person context menu and a window appears, showing a list of phone numbers defined for that person.

Select the desired phone number and click **Dial**.

NOTE:

Context Entry Secured. The [navigation key](#) for this window `automatedDialer` refers to an application service to facilitate application security. If your installation does not support an integration with external dialer software, configure the security settings to ensure that users do not have access to the application service for this context entry.

Technical Implementation of Automated Dialer

The popup window is implemented as a BPA script (**C1-LAutoDial**) that calls a configurable **Automated Dialer** BPA script that is responsible for retrieving and displaying person contacts and phone numbers (i.e. if the installation option is set to Use Legacy Person Phone and Email feature configuration option is set to 'Y'). The **C1-AutoDial** sample script provided with the system integrates to any soft phone protocol handler that launches a dialer based on overriding the "tel:" protocol from a browser, for example, Cisco IP Communicator. It launches a UI map to display the person contacts and phone numbers (i.e. if the feature option is set).

Phone Dialer Configuration

If your implementation chooses to use the functionality provided with the system and integrate with a soft-phone dialer, plug in the base-supplied **C1-AutoDial** script in the CTI/IVR Integration master configuration.

Customize Integration to Your Automated Dialer Software

In order to integrate with a different automated dialer software application, your implementers must create your own **Automated Dialer** BPA script, to call your specific dialer.

- Copy the **C1-AutoDial BPA** script and make the appropriate changes to integrate with your automated dialer (e.g. change the protocol from "tel:" to "callto:").
- Plug in your custom Automated Dialer script on the CTI/IVR Integration master configuration.

Customize Automated Dialer User Interface

Your implementation may choose to display a different user interface for the **Go To Automated Dialer** function than the one provided with the system. For example, perhaps there is more information that you would like to display in addition to the person's name and phone numbers. In order to do this, your custom **Automated Dialer** script needs to invoke a custom UI map that you create as follows:

- Copy the base-supplied **C1-AutomatedDialer** UI map and make the necessary changes.
- Invoke your custom UI map from your custom **Automated Dialer** .

Analytics Integration Overview

Analytics Configuration

This section describes functionality provided for integrating with Oracle Utilities Analytics (OUA).

1. – These data load parameters are used to extract, load, and transform data from Oracle Utilities Customer Care and Billing to Oracle Utilities Analytics. These parameters are used to identify and/or filter data when loading them into the data warehouse. Refer to the *Oracle Utilities Customer Care and Billing* section in the *Configuring Oracle Utilities Analytics* chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on each extract parameter.

2. Bucket Configuration List – This is a summary of the bucket configurations that are needed to classify and group extracted data within Oracle Utilities Analytics. The bucket configurations provide the ability to readily report and analyze data by buckets, or groups. Refer to the *Oracle Utilities Customer Care and Billing* section in the *Configuring Oracle Utilities Analytics* chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on each bucket configuration supported by Oracle Utilities Customer Care and Billing.

- **Characteristic Mapping**

Oracle Utilities Customer Care and Billing has identified the objects for which characteristic extraction is supported. This includes mapping the source characteristic entity to the target dimension, and defining which target columns are allowed to be mapped for which target dimension. The following table shows the supported mapping.

Object	Supported Target Dimension	Supported Target Columns
Account Characteristic	Account Dimension	User Defined Fields 6 - 15
Person Characteristic	Person Dimension	User Defined Fields 1 - 6
Premise Characteristic	Premise Dimension	User Defined Fields 6 - 18
Premise Characteristic	Address Dimension	User Defined Fields 7 - 16
Service Agreement Characteristic	Service Agreement Dimension	User Defined Fields 9 - 19

Self-Service Integration

The following sections describe functionality provided for the integration with self-service applications such as Oracle Utilities Customer Self Service (OUCSS).

About Self-Service Tasks

Self-service tasks hold information about self-service operations that customers initiate from an integrated self-service application, such as Oracle Utilities Customer Self-Service (OUCSS).

A few examples of self-service tasks are:

- One time payments
- Account verification
- Start/Stop requests
- Auto pay setup

Refer to the Oracle Utilities Customer Self-Service (OUCSS) documentation for more details on supported self-service operations.

The following sections highlight self-service integration functionality.

Self-Service Task Type Defines Self-Service Task Behavior

Each type of self-service operation has specific processing requirements.

Self-service task type controls how a self-service task is processed. It defines the business object to use when creating the self-service task record. The business object defines the lifecycle of self-service task record.

The self-service task type can also specify common configuration data, such as settings for error handling.

Creating Self-Service Tasks

The customer self-service application invokes inbound web services to create self-service tasks. The system supplies an inbound web service for each supported self-service operation.

Refer to the Oracle Utilities Customer Self-Service (OUCSS) documentation for more details on supplied inbound web services.

Each inbound web service references a service script that processes the specific self-service operation. Refer to the service script system data for processing details.

Setting Up Self-Service Task Configuration

Self-Service Integration Configuration

The integration with a self-service application such as Oracle Utilities Customer Self Service (OUCSS) requires the setup of master configuration data that controls the processing of your self-service operations.

To set up self-service integration master configuration, navigate using **Admin > General > Master Configuration**.

Defining Self-Service Task Types

A self-service task type defines properties that control how a self-service task is processed.

Refer to [About Self-Service Tasks](#) for an overview of service task functionality.

To maintain the types applicable to your product, open **Menu > Self-Service > Self-Service Task Type**.

This is a standard [All-in-One portal](#).

The information captured on the self-service task type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [FI_SVC_TASK_TYPE](#).

Maintaining Self-Service Tasks

This section describes the functionality supported for viewing and maintaining self-service tasks.

Refer to [About Self-Service Tasks](#) for an overview of self-service task functionality.

Navigate using **Menu > Self-Service > Self-Service Task > Search**. You are brought to a query portal with options for searching for self-service tasks.

Once a self-service task record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Self-Service Task** zone provides basic information about a self-service task. Refer to the embedded help for more information.

Configuring Rate Compare Usage Adjustment Profiles

This section describes the steps involved in setting up usage adjustment profiles for use with the Rate Compare feature in Oracle Utilities Customer Self- Service.

1. Create a characteristic type and values for each type of usage adjustment to be made available for rate comparison purposes. For example, if you wanted to allow adjustments for installation of solar panels, use of an energy-efficient appliance, or use of an electric vehicle, you would create three characteristic types (one for each type of adjustment), and values for each option within each type (each type of appliance or electric vehicle supported).
2. Create profile (stand-alone) measuring components that correspond to each characteristic type value.
3. Create profile data for each measuring component. This is interval data that represents the impact of the usage adjustment on a customer's consumption.
4. Create a profile factor for each usage adjustment type.
5. Create factor values for each factor. These values correspond to the characteristic type value, and link characteristic type values to profile measuring components.
6. Create one (or more) [Profile Accumulation](#) usage calculation rules that will apply the usage adjustment profile to the customer's interval consumption when calculating usage for the rate comparison request.
7. Create entries in the CCB Rate Schedule extendable lookup to associate the usage calculation group that contains the "Profile Accumulation" usage calculation rule to a rate schedule.
8. Create entries in the Usage Adjustment Types extendable lookup for each usage adjustment type.
9. Set up the Rate Compare Configuration section of the Self-Service Master Configuration to link usage adjustment factors and usage adjustment types to rate schedules Oracle Utilities Customer Care and Billing (defined in the CCB Rate Schedule extendable lookup).

Characteristic Types

Create a characteristic type and values for each type of usage adjustment you wish to make available to customer self-service users. For example, to create a usage adjustment profile for use of an electric vehicle, you would create an "electric vehicle" characteristic type and define values for each type of electric vehicle users can select.

Example Characteristic Type:

- Characteristic Type: ELEC_VEH
- Description: Electric Vehicles
- Type of Char Value: Predefined Value
- Characteristic Values:

Characteristic Value	Description
LEAF	Nissan Leaf
TESLA	Tesla Model S
VOLT	Chevrolet Volt

Profile Measuring Components

Create profile measuring components for each characteristic type value. These measuring components will be used to store profile data for each type of usage adjustment.

Note: The base package does not include stand-alone measuring component/measuring component type business objects, but the demonstration database contains "Standalone Interval" and "Standalone Interval Measuring Component Type" business objects that can be used to create profile measuring components and types.

Example Profile Measuring Component Type:

- Measuring Component Type: KWH-PROFILE

- Description: KWH Profile
- Measuring Component Business Object: Standalone Interval (demo)
- Measurement Business Object: Measurement
- Service Type: Electric
- Allow Negative Consumption: Allowed
- Consumptive / Subtractive: Consumptive
- Seconds Per Interval: 01:00:00
- Value Identifiers:
- Value Identifier Type: Measurement
- Short-Hand Description: kWh
- UOM: Kilowatt-Hours

Example "Nissan Leaf" Profile Measuring Component:

- Measuring Component Type: KWH Profile
- Number of Digits Left: 5
- Number of Digits Right: 5
- Time Zone: US Pacific Time
- Status: Active
- How To Use: Additive
- External ID: Nissan Leaf

Example "Tesla Model S" Profile Measuring Component:

- Measuring Component Type: KWH Profile
- Number of Digits Left: 5
- Number of Digits Right: 5
- Time Zone: US Pacific Time
- Status: Active
- How To Use: Additive
- External ID: Tesla Model S

Example "Chevrolet Volt" Profile Measuring Component:

- Measuring Component Type: KWH Profile
- Number of Digits Left: 5
- Number of Digits Right: 5
- Time Zone: US Pacific Time
- Status: Active
- How To Use: Additive
- External ID: Chevrolet Volt

Profile Data

Create profile data for each profile measuring component. This data represents the impact of the usage adjustment on a customer's consumption.

Note that this profile data can (and often will) include negative interval values to represent the difference in consumption applicable for the usage adjustment type. For example, if an energy- efficient electric clothes dryer uses an average of 30 kilowatt hours less per month than an average electric clothes dryer, profile data for that appliance might be a "straight line" hourly profile (a profile in which all intervals are of the same value) in which each value equals "0.042" (30 kWh per month divided by an average of 720 hours per month).

Factors / Factor Values

Create a profile factor for each usage adjustment type. This factor should use the "Factor Characteristic Source N/A Algorithm" to derive the appropriate characteristic type value based on the factor value, and should reference the characteristic type created earlier.

Example Electric Vehicle Factor:

- **Factor:** ELECTRIC_VEHICLE
- **Description:** Electric Vehicle
- **Factor Class:** Profile
- **Characteristic Source Algorithm:** Factor Characteristic Source N/A Algorithm
- **Factor Characteristic Type:** Electric Vehicle

Example "Nissan Leaf" Factor Value

- **Factor:** Electric Vehicle
- **Factor Characteristic Type:** Electric Vehicle
- **Factor Characteristic Value:** LEAF
- **Effective Date/Time:** 01-01-2014 12:00:00AM
- **Profile:** Nissan Leaf, KWH Profile

Example "Tesla Model S" Factor Value

- **Factor:** Electric Vehicle
- **Factor Characteristic Type:** Electric Vehicle
- **Factor Characteristic Value:** LEAF
- **Effective Date/Time:** 01-01-2014 12:00:00AM
- **Profile:** Tesla Model S, KWH - 60 Minutes

Example "Chevrolet Volt" Factor Value

- **Factor:** Electric Vehicle
- **Factor Characteristic Type:** Electric Vehicle
- **Factor Characteristic Value:** LEAF
- **Effective Date/Time:** 01-01-2014 12:00:00AM
- **Profile:** Chevrolet Volt / KWH - 60 Minutes

Profile Accumulation Usage Calculation Group and Rule

Create a usage calculation group that contains a "Profile Accumulation" usage calculation rule. This rule will calculate usage by accumulating historical usage with profile data. based on a selected profile factor value.

Note: Profile Accumulation rules should use eligibility criteria to ensure they are only executed when the "Calculation Mode" on the usage transaction is set to "Hypothetical Calculation" (D2HC).

Example: Profile Accumulation Usage Calculation Rule

- **Usage Calculation Group:** Electric Residential Interval KWH
- **Usage Calculation Rule:** KWH_PROFILE_ACCUMULATION
- **Sequence:** 10
- **Description:** KWH Profile Accumulation
- **Category:** Usage Calculation
- **Vector Source Configuration:**
- **Vector Type:** Channels Linked to Usage Subscription
- **Unit of Measure:** Kilowatt-Hours
- **Time of Use:**
- **Service Quantity Identifier:**
- **Target SPI:** 01:00:00
- **Result Processing Configuration:**
- **Apply TOU Map to Derived Vector:** Yes
- **TOU Map:** Summer / Winter, 15 minute interval
- **Result Storage Configuration:**
- **Insert Primary SQ Entry:** Yes
- **Save Derived Vector:** No
- **Service Quantity Identifier:**
- **Extract Interval Data:** No

CC&B Rate Schedule Extendable Lookup

Create an entry in the "CCB Rate Schedule" extendable lookup to associate the usage calculation group that contains the "Profile Accumulation" usage calculation rule to an applicable rate schedule in Oracle Utilities Customer Care and Billing.

Example CCB Rate Schedule extendable lookup:

- **Rate:** E-INT-RES
- **Description:** Electric Residential Interval Rate
- **Default Usage Calculation Group:** Electric Residential Interval KWH (E-INT-RES)

Usage Adjustment Types Extendable Lookup

Create an entry in the "Usage Adjustment Type" extendable lookup for each type of usage adjustment that will be available to customer self-service users. These entries are used in the Rate Compare Configuration section of the Self-Service Master Configuration (see below).

Example Electric Vehicle entry:

- **Usage Adjustment Type:** ELEC_VEHICLE
- **Description:** Purchase of Electric Vehicle
- **Override Description:** Purchase of Electric Vehicle
- **External Reference ID:** Purchase of Electric Vehicle

Self-Service Master Configuration - Rate Compare Configuration

Configure the "Rate Compare Configuration" section of the Self-Service Master Configuration to associate usage adjustment factors and usage adjustment types with an applicable rate schedule in Oracle Utilities Customer Care and Billing (defined in the CCB Rate Schedule extendable lookup).

Example Self-Service Master Configuration:

- **Factor Characteristic Type Indicating No Value Variation:** N/A
- **External Reference Factor Value Characteristic Type:** External Reference ID
- **Minimum Days of Usage Adjustment Data:** 2
- **Rate / Usage Adjustments:**
 - **Rate:** Electric Residential - Interval KWH
 - **Usage Adjustments:**
 - Usage Adjustment Factor: Electric Vehicle
 - Usage Adjustment Type: Purchase of Electric Vehicle

Defining DataConnect Options

DataConnect Data Extracts

Oracle Utilities DataConnect can be used to extract three types of data:

- **Master Data**
(see [Master Data Extracts](#) for more information)
 - Service agreement, account, and person related information
 - Service point related information
 - Install event related information
- **Billing Data**
(see [Billing Data Extracts](#) for more information)
- **Measurement Data**
(see [Consumption Data Extracts](#) for more information)

The data extracted can be correlated in external systems using the service agreement and/or service point data that is included in each type of extract. All data extracts contain a combination of the following data elements that can be used for this correlation:

External systems receiving data extracted from the Oracle Utilities DataConnect facilities can use these IDs to associate billing data and measurement data to extracted master data.

NOTE: There is a version 1 and version 1+ for the DataConnect extracts. In the following pages where a system object such as a batch control or data area is noted the objects are listed as (v1/v1+). When only a single object is noted it applies to both v1 and v1+.

Master Data Extracts

Master data extracts are performed through the use of data synchronization, audit algorithms, business objects, and related batch processes.

Master Data Extracts: Maintenance Object Audit Algorithms

Detecting changes in master data can be identified by audit algorithms on the following maintenance objects:

The Generic Change Data Capture algorithm type (F1-GCHG-CDCP), which is provided in the base package, can be used to create audit algorithms for following maintenance objects:

Master Data Extracts: Business Objects and Algorithms

The maintenance object audit algorithms create data synchronization requests in the following manner:

- If the Generic Change Data Capture (F1-GCHG-CDCP) algorithm type (provided in the base package) is used, the synchronization requests are based on the Sync Request BO maintenance object options.
- Alternatively, if the base package supplied Maintenance Object – Audit algorithm types, which are outlined in the [Master Data Extracts: Maintenance Object Audit Algorithms](#) section are used, the synchronization requests are based on the Sync Request BO defined in the algorithm parameters.

Extraction of service agreements, service points and install events related information is supported by the following data synchronization business objects.

- **SA/Account/Person Sync for DataConnect (C1-ExternalRepoSASync/C1-ExternalRepoPlusCusDataSync):** used to extract service agreement / account / person related information. This business object should be defined as a value for the Sync Request BO option on the Service Agreement maintenance object.
- **SP Sync for DataConnect:** (D1-ExternalRepositorySPSync): used to extract service point information. This business object should be defined as a value for the "Sync Request BO" options on the Service Point maintenance object.
- **Install Event Sync for DataConnect:** (D1-ExternalRepositoryIESync): used to extract install event information. This business object should be defined as a value for the "Sync Request BO" options on the Install Event maintenance object.

These business objects use the following Pre-Processing algorithms to take initial data snapshots, and define the batch control used to extract data and export to a flat file:

- Capture SA-Based Initial Snapshot for DataConnect (C1-CEXTRCSAI/C1-CEXTRCSAD)
- Capture SP Initial Snapshot for DataConnect (D1-SPEINISNP)
- Capture Install Event Initial Snapshot for DataConnect (D1-IEEINISNP)

These algorithms specify the batch control used for the extract process (see below).

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for other pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states verify if a synchronization is needed by capturing the final snapshot of the data and comparing it against the initial snapshot. If changes are detected, the final snapshots of the data are stamped on the synchronization requests for export.

- Capture SA-Based Final Snapshot for DataConnect (C1-CEXTRCSAF/C1-CEXTRPSAF)

- Capture SP Final Snapshot for DataConnect (D1-SPEFNISNP)
- Capture Install Event Final Snapshot for DataConnect (D1-IEEFNISNP)

The Prepare Delimited Extract Data (Ignore Custom Sync Records) Enter algorithm (C1-PRPEXDNCU/C1-PRTBDEXDT) or the Prepare Delimited Extract Data Enter algorithm (D1-PRPEXTDTA) on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the batch control defined by the pre-processing algorithm).

Master Data Extracts: Batch Controls

The master data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch processes are used to create initial synchronization requests:

- **SA-Based Initial Load for DataConnect (C1-SAEIL/C1-CDTIL):** This batch control creates initial synchronization requests for service agreements / accounts / persons.
- **SP Initial Load for DataConnect (D1-SPEIL):** This batch control creates initial synchronization requests for service points.
- **Install Event Initial Load for DataConnect (D1-IEEIL):** This batch control creates initial synchronization requests for install events

The following batch processes are used to create extract files from synchronization requests.

NOTE: These batch processes should be run to create initial load data synchronization requests based on the Sync for DataConnect business objects.

- **SA-Based Extract for DataConnect (C1-SASYX/C1-CUDTX):** This batch control creates extract file(s) for service agreements / accounts / persons related information.
- **SP Extract for DataConnect (D1-SPESR):** This batch control creates extract file(s) that contain service point information.
- **Install Event Extract for DataConnect (D1-IEESR):** This batch control creates extract file(s) that contain install event information.

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the Sync for DataConnect business objects (see above).

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Setting Up and Executing Master Data Extracts

Setting up master data extracts involves the following steps:

1. Add audit algorithms on the Service Agreement, Account, Person, MDM Service Point, Install Event, and Device maintenance objects.
 - a) Add the Generic Change Data Capture algorithm as an audit algorithm on the Service Agreement, MDM Service Point, and Install Event maintenance objects.
 - b) Add the Account Change Data Capture (SA-Based) - Include Reactivated SAs algorithm as an audit algorithm on the Account maintenance object.
 - c) Add the Person Change Data Capture (SA-Based) - Include Reactivated SAs algorithm as an audit algorithm on the Person maintenance object.

- d) Add the Device Change Data Capture (Install Event-Based) algorithm as an audit algorithm on the Device maintenance object.
- 2. Add the DataConnect synchronization request business objects as Sync Request BO options on the Service Agreement, Service Point and Install Event maintenance objects.
- 3. Execute initial load batch processes related to service agreements, service points and install events.
- 4. Once the initial load synchronization has been executed, changes to service agreements, accounts, persons, service points, install events or related devices will trigger the creation of new synchronization requests and resulting extraction files.
- 5. Execute the sync request monitor process.
- 6. Execute the extract batch processes related to service agreements, service points and install events.

Billing Data Extracts

When sending billing related data to an external system, both historical and current data needs to be extracted.

Historical data can be extracted as part of an initial load process, and only needs to be provided during initial setup of the integration. Historical data includes data history for all bill segments for a specified historical period that are:

- Linked to completed bills.
- Not linked to bills but are linked to frozen FTs that are linked to completed bills.

Current data should be extracted on a regular ongoing (or incremental) basis. However, in addition to sending current data, any billing corrections should be extracted as well.

Extraction of billing data is performed through use of data synchronization, post bill completion algorithms, business objects and related batch processes.

Billing Data Extracts: Business Objects and Algorithms

Billing generates synchronization requests when bills complete through a Customer Class – Post Bill Completion algorithm. The Change Data Capture of Billing Data for DataConnect (C1-CAPBILLEX) algorithm type provided in the base package can be used to create a Customer Class – Post Bill Completion algorithm that creates a billing synchronization request record for each of the bill's bill segments if one does not exist in the initial state.

Billing related information extracts are supported by the following data synchronization business object.

- Billing Sync for DataConnect (C1-ExternalRepoBillingSync/C1-ExternalRepoPlusBillingSync). This business object should be defined as an algorithm parameter on the algorithm based on the Change Data Capture of Billing Data for DataConnect (C1-CAPBILLEX) algorithm type.

This business object use the following Pre-Processing algorithm to take an initial data snapshot, and define the batch control used to extract data and export to a flat file. However, since billing data are always synched when it gets completed, no actual initial snapshot is taken. Instead, the parameters used for building the snapshots are taken and stored on the sync request record for later use when building the final snapshot.

- Capture Billing Data Initial Snapshot for DataConnect (C1-EXTRCBLIP)

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states extract a final snapshot of the data if the billing related data is to be extracted and exported.

- Determine if the Billing Sync is Needed (C1-DSCANUSNS/C1-DSCANUSNP) - this is the algorithm that checks if there is a need to export the billing data. It will discard the synchronization request if one of the following is true:

- The synchronization request is for a cancelled bill segment whose original usage has not been previously sent out.
- The synchronization request has been marked for non-synchronization (such as, the bill segments related SA Type is not configured to be extracted on the Billing Data Configuration for DataConnect master configuration record).
- Capture Billing Data Final Snapshot for DataConnect (C1-CAPBILUSN/C1-CAPBILUSP) - this is the algorithm that captures the billing data information and stores it on the synchronization request.

If a single extract file that combines both the billing and master data information is preferred, the following algorithms can be used to capture the master data information of the bill. These algorithms should be plugged in on the Determine if Sync Needed state after the Capture Billing Data Final Snapshot for DataConnect algorithm.

- Capture Billing's SA Final Snapshot for DataConnect (C1-CEXTRCSA) - This is the algorithm that captures the service agreement, account and person information associated with the bill.
- Capture Billing's SP Final Snapshot for DataConnect (C1-CEXTRCSP) - This is the algorithm that captures the service point and premise information associated with the bill.

The Prepare Delimited Extract Data (Process All) Enter algorithm (C1-PRPEXDCUS/C1-PRPTDEXDT) on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the extract batch control defined by the pre-processing algorithm).

Billing Data Extracts: Batch Controls

The billing data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch process is used to create initial synchronization requests:

- Billing Data Initial Load for DataConnect (C1-BLEIL): This batch control creates initial synchronization requests for bills.

This batch processes should be run to create initial load data synchronization requests based on the C1-ExternalRepoBillingSync/C1-ExternalRepoPlusBillingSync business object.

The following batch process is used to create extract files from synchronization requests.

- Billing Data Extract for DataConnect (C1-BSYEX): This batch control creates extract file(s) for billing related information.

This batch control is defined as a value for the Batch Control for Extract algorithm parameter on the Pre-Processing algorithm on the C1-ExternalRepoBillingSync/C1-ExternalRepoPlusBillingSync business object.

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file) for a delimited flat file containing extracted data.

Setting Up and Executing Billing Data Extracts

Setting up billing data extracts involves the following steps:

1. Configure the Billing Data Configuration for the DataConnect master configuration record. This is used to configure the UOM, TOU, and SQI of the SA Type's service quantity and charges that will be extracted. Additionally, you can also configure the UOM, TOU and SQI at the rate level.
2. Add the Change Data Capture of Billing Data for DataConnect (C1-CAPBILLEX) related post bill completion algorithm to the applicable customer classes.
3. Execute initial load batch processes related to billing data.

4. Once the initial load synchronization has been executed, current data should be extracted on a regular ongoing (or incremental) basis. In addition to sending current data, any billing corrections will be extracted as well (data related to bill segments not linked to bills but are linked to frozen FTs that are linked to completed bills).
 5. Execute the sync request monitor process.
 6. Execute the extract batch processes related to billing.
-

Billing Data Configuration for DataConnect Master Configuration

The master configuration business object for Billing Data Configuration for DataConnect defines general configuration details for the DataConnect functionality. This is used to configure the UOM, TOU, and SQI of the SA Type's service quantity and charges that will be extracted. Additionally, you can also configure the UOM, TOU and SQI at the rate level.

Navigate using **Admin > General > Master Configuration**. In the Master Configuration list, scroll to Billing Data Configuration for DataConnect and click the add icon if there is no record yet or the edit icon to modify an existing record.

For more information about specific fields in the master configuration, refer to the embedded help.

Consumption Data Extracts

When sending interval measurement usage data to an external system, both historical and current data needs to be extracted. Historical data can be extracted as part of an initial load process, and only needs to be provided during initial setup of the integration. Historical data should include data history for all active service points for a specified historical period. Current data should be extracted on a regular ongoing (or incremental) basis. However, in addition to sending current data, any historical corrections received by the system should be extracted as well.

Extract Requests

There are several types of consumption extract requests:

- **Initial Load:** Initial load extract requests are created and submitted manually via the Consumption Extract Request portal. Consumption extract requests are based on a specified Consumption Extract Type (see below) and extraction date range. An initial load request must be created and submitted for each consumption extract type defined in the system.
- **Incremental / Ongoing (Current Data):** Incremental / ongoing extract requests can be manually created, but more often will be created via a batch process. The "Create Daily Consumption Extract Requests" batch control scans active consumption extract types and creates a request for each one that has Frequency of "Automated Daily." Ad-hoc incremental requests can be created and submitted manually if needed.
- **Historical Correction:** Historical correction extracts are created via batch process. Algorithms on the Finalized state of the initial measurement and measurement business objects determine if a finalized initial measurement or rederived values are historical corrections. These algorithms create records which are evaluated by a batch process which extracts the measurements for the related initial measurements.

Consumption Extract Type

Consumption Extract Types define the specific parameters used when processing a consumption extract request. Consumption Extract Types control the service point type, type of measurement, and how the measurements are grouped into TOU periods if applicable. Consumption extract types also define the algorithm and batch processes to use when extracting data for different types of requests (initial load, incremental, and historical).

There are two consumption extract type business objects provided with the base package:

- **Consumption Extract Type (D2-ConsumptionExtractType):** This business object retrieves interval data and converts it to a specified Target UOM and Interval Size. This business object does not support TOU mapping.

- **Consumption Extract Type with TOU Mapping (D2-ConsumptionExtractTypeTOU):** This business object retrieves interval data, converts it to a specified Target UOM and Interval Size, and maps it to a specific TOU map prior to extraction.

Historical Versus Current Data

The "Extract Through Date/Time" field on the Consumption Extract Type is used to differentiate between current data (the most recently extracted data) and historical corrections, and is set to the last date on which data was extracted for that extract type. For example, if data is extracted on June 1, 2015, the "Extract Through Date/Time" would be set to "June 1, 2015 12:00AM." If/when data is extracted the next day, "Extract Through Date/Time" would be updated to "June 2, 2015 12:00AM."

When evaluating data for extract:

- Interval data is considered current if its measurement date time is after the "Extract Through Date/Time".
- Interval data is considered a historical correction if its measurement date time is on or before the "Extract Through Date/Time".

Historical data changes to an initial measurement can be detected when it enters the Finalized state. If the initial measurement is determined to be for a historical period by comparing its end date/time against the "Extracted Through Date/Time" on the Consumption Extract Type, a general process record will be written for the initial measurement so that measurements for it can be extracted. In addition, re-derived values on final measurements can also trigger the creation of a general process record for related initial measurements.

The following algorithms are used in this process:

- The "Create General Process Record if IMD is Historical Correction" algorithm is used to determine if a finalized initial measurement data is a historical correction. If it is, the algorithm creates a general process record for the initial measurement. This algorithm is provided in the base package, but not specified on initial measurement business objects by default. This algorithm should be defined as an Enter algorithm on the Finalized state of the initial measurement business objects.
- The "Create General Process Record for Re-derived Values" algorithm creates general process records for initial measurements associated with re-derived values. Processing will proceed as if a historical correction came in through an initial measurement. This algorithm is provided in the base package, but not specified on measurement business object by default. This algorithm should be defined as an Enter algorithm on the Re-derive state of the final measurement business object.

Consumption Extract Requests

Initial load and ongoing consumption extracts are created via Consumption Extract Requests. While extracts of these types can be created via adhoc submission of a batch job, requests are the preferred method for these types of consumption extracts.

The consumption extract request business object lifecycle includes logic that maintains and updates the "Extraction Through Date/Time" field on Consumption Extract Types, which is used to determine if daily requests should be created by the "Create Daily Consumption Extract Requests" batch control, and detect historical corrections.

A single business object is provided in the base package for consumption extract requests:

- **Consumption Request for DataConnect (D2-IntervalDataExtRepository):** This business object contains the information and lifecycle responsible for submitting the extract job, monitoring the run until it's finished, and then updating the Consumption Extract Type's "Extract Through Date/Time" on the Consumption Extract Type. This business object is based on the Request (F1-REQ) maintenance object.

The consumption extract process uses a set of base package algorithms to extract and format the interval data for export. These algorithms are specified in the "Algorithms" section on the Consumption Extract Type as appropriate. These algorithms can be configured to allow for extraction of data for frequently-read scalar measuring components as well as interval measuring components. Frequently-read scalar measuring components are defined as scalar measuring components

whose Read Method is set to "Automatic Read." When extracting measurements for frequently-read scalar measuring components, scalar measurements are converted to interval measurements as part of the extraction process. This conversion uses the profile associated with the measuring component type. If no profile can be found, the interval data uses a flat line profile.

Initial Load / Incremental / Ongoing Requests: the following algorithms are used to extract and format interval data for initial load and incremental / ongoing requests:

- **Extract Initial Load/Ongoing Consumption for DataConnect (D2-IDEXTPRD):** This algorithm retrieves a service point's consumption for a given period and writes the results to a flat file.
- **Extract Initial/Ongoing Consumption and Apply TOU Map for DataConnect (D2-IDEXTPTOU):** This algorithm retrieves a service point's consumption for a given period, applies a TOU Map to the consumption, and writes the results to a flat file

Historical Corrections: the following algorithms are used to extract and format interval data for historical correction requests.

- **Extract Historical Correction Consumption for DataConnect (D2-IDEXTIMD):** This algorithm retrieves historical correction consumption for a service point and writes the results to a flat file.
- **Extract Historical Corrections and Apply TOU Map for DataConnect (D2-IDEXTITOU):** This algorithm retrieves historical correction consumption for a service point, applies a TOU map to the consumption, and writes the results to a flat file.

Consumption Extract Requests - Batch Controls

The consumption extraction process uses a set of base package batch controls to extract and format the interval data for export.

- **Create Daily Consumption Extract Requests (D2-CRERQ):** This batch process scans for active Consumption Extract Types, and for each one that has Frequency of Automated Daily creates a pending request. This process should be scheduled to run daily (or at another regular interval).

The following sample batch controls are provided to extract and format interval data. Unique batch controls of each of these is required for each consumption extract type. You should create custom versions of the above batch controls for each consumption extract type in your implementation. Extract type-specific versions of these batch controls should be specified in the "Batch Control" section on the Consumption Extract Type as appropriate.

- **Initial Load/Ongoing Consumption Extract (D2-IDEPD):** This batch process extracts interval data for a specified period. This batch control uses the "Initial Load/Ongoing Extract Algorithm" defined on the Consumption Extract Type.
- **Historical Corrections Consumption Extract (D2-IDEHC):** This batch process extracts interval data for historical corrections. This batch control uses the "Historical Corrections Extract Algorithm" defined on the Consumption Extract Type.

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Consumption Extract Requests - Setup Steps

Example Setup Steps

Setting up consumption extracts involves the following steps:

1. **Create Consumption Request Types:** you should create a consumption request type for each unique type of request required by your implementation.

2. Create Consumption Extract Types: you should create a consumption extract type for each unique combination of output details (target UOM, target interval size, TOU map/template) and measurement selection criteria.
3. Add the "Create General Process Record if IMD is Historical Correction" historical correction algorithm as an Enter algorithm on the Finalized state of the initial measurement business objects.
4. Add the "Create General Process Record for Re-derived Values" historical correction algorithm as an Enter algorithm on the Finalized state on the measurement business object.
5. Create and submit initial load consumption extract requests for each consumption extract type you created earlier.
6. Set up batch processes for daily extract requests and historical corrections. Batch processing for consumption extracts should include the following:
 1. The **Create Daily Consumption Extract Requests (D2-CRERQ)** batch control should be configured to run on a regular (i.e. daily) schedule to create ongoing consumption extract requests.
 2. The **Request Monitor (Deferred) (F1-SUBRQ)** batch control should be used to monitor for pending requests and transition them to the "Submit Job" state.
 3. **Historical corrections consumption extract batch controls** (based on D2-IDEHC, one for each consumption extract type), should be configured to run on a regular basis to check for and create historical correction extracts.

Extract Flat File Formats

This section outlines the format of output flat files created by master data, billing data, and consumption data extracts.

Data Areas:

- [C1-ExternalRepoSABasedSnapshot](#)
- [D1-ExternalRepositorySPSsnapsht](#)
- [D1-ExternalRepositoryIESnapsht](#)
- [C1-ExternalRepoBillingSnapshot](#)
- [D2-IntervalDataExtRepoSnapshot](#) (used for interval consumption extract)
- [D2-IntervalDataExtRepoTOUSnap](#) (used for interval consumption extract mapped to TOU periods)

Specifics for how the flat files are created are defined on batch controls and algorithms used by the extract process.

- **File Name and Path:** Parameters on batch controls define the file name, path, and other details about the output file.
- **File Size and Contents:** Batch controls for initial load/ongoing consumption requests include a parameter to specify the number of service points to be included in each file.

C1-ExternalRepoSABasedSnapshot

C1-ExternalRepoSABasedSnapshot is used for the service agreement-based master data extracts, and includes the following information:

For DataConnect v1+ please refer to data area C1-CustomerDataSnapshot in the application for the layout/schema.

Business Flags

It is possible that information detected in one product may be useful or even critical to share with another product. The framework provides functionality for receiving information from an external system that acts as a type of flag or alert that may need investigation. This allows any system to store detected business flags in a common way and share that information with one or more other systems. See [Business Flags](#) for more information.

This section provides further information about business flags and their use in the system.

Understanding Business Flags

Refer to [About Business Flags](#) in the *Oracle Utilities Framework Administration User Guide* for detailed information about the components of business flags.

Customer to Meter allows for business flags that typically represent situations, exist at a customer's service point, and are shared across external applications; such as, Oracle DataRaker, Oracle Utilities Mobile Workforce Management / Oracle Field Service Cloud, and Oracle Utilities Operational Device Management. The situations that a business flag can represent range from critical knowledge that requires manual analysis for resolution to purely informational notifications.

Sharing information allows users of each system to quickly understand the status of a service point (or device, or network location in some cases) as it relates to situations or insights that would benefit users of the system. For example, the advanced analytics system (Oracle DataRaker) may identify potential theft situations that should be investigated prior to releasing the next bills from CCB with usage transactions from MDM for the related service point's consumption.

The subsequent sections describe business flag functionality that is specific to the service point business flag, as implemented by this product.

When creating a new MDM device type there are the following options:

Name	Details	Business Object
Service Point Business Flag Type	Provides configuration for business flags associated to a service point. This type offers an ability to hold a business flag for manual analysis.	D1-SPBusinessFlagType
Service Point Monitor Business Flag Type	Provides configuration for business flags that should initiate service issue monitors and convey results of a field activity to the intended subscribers.	D1-SPMonitorBusinessFlagType

Important Business Flag Business Object Options

Below are a list of business object options that are defined on the business flag business object associated to a given business flag type:

- **Valid Action:** identifies a BPA script that can be used to guide the user through an action that can be taken on a business flag. Note: this option should be paired with a business object lifecycle option of "Execution of Valid Actions Permitted" with a value of "true" for any lifecycle status that should support the execution of valid actions.

More detail about these options can be found by visiting a measuring component business object and inspecting the business object options.

Business Flag Available Actions

Allowed actions are implemented as BPA scripts that will guide the user through a particular method of investigating or resolving the business flag. The following actions are supported:

- **Create Field Activity:** This will initiate a field activity associated to the business flag's service point. The type of field activity will be selected by the user.
- **Create Case:** This will initiate a case associated to the business flag's service point. The type of case will be selected by the user.
- **Create Notification:** This will initiate communication with the customer for the business flag's service point. The type of communication will be determined by the notification type selected by the user.
- **Create Service Issue Monitor:** This will initiate a Service Issue Monitor (SIM) process associated to the business flag's service point. The SIM type is identified on the Business Flag Type configuration. If there are already existing SIM records of this type for the service point, the most recent SIM process will be linked to the business flag.

Business Flag Adding Available Actions

To extend the actions that are available to the user for investigating a business flag the following steps can be taken:

1. A new BPA script should be developed that provides the functionality for your particular business use case.
2. That BPA script will be added to the transactional business object for the business flag using the option type "Valid Action".
3. Edit the business flag type to include the newly created action in the "Allowed Actions" section of the business flag type.

Making Allowed Actions Available

Allowed actions are only accessible on those business object statuses that have been configured to support them. To permit access to the available actions on a given status one must add a business object status option for the type "Execution of Valid Actions Permitted" with a value of "Y".

Business Flag Can Prevent Bills from Freezing

Some business flags, particularly those that require investigation, should place a hold on the billing process to prevent potentially incorrect bills from being issued to the customer. When certain types of business flags are present on a service point it indicates that there may be a problem with the reported usage that is underlying the bill and as such it may not be desirable to allow the billing process to complete until the investigation into that usage has been completed. For example, if the business flag indicated potential theft or abnormally high usage it may be preferable to delay issuing the bill until an investigation can be performed and the issue rejected or resolved.

This functionality can be enabled through configuration of the Prevent Bill Segment Freeze Due to Business Flag algorithm.

See algorithm type Prevent Bill Segment Freeze Due to Business Flag ([C1-PRVBSFBF](#)) for more detail.

In MDM, Usage Transactions can also be prevented by configuring the *Valid Business Processes for Hold with Usage Processing* on the Service Point Business Flag Type.

Field Activities Can Determine Business Flag Confidence

When a business flag results in a field activity being issued and a field team is sent to investigate the service point the result of that field activity investigation will determine the confidence of the business flag. This is done through the field remarks left by the field team. The field activity remarks can either be defined as confirming the business flag or rejecting it. By selecting the appropriate field activity remark the field team will conclude the investigation into the business flag and the final confidence will be updated as appropriate.

For those field activity remarks that should either confirm or reject the business flag the Business Flag Confidence Update algorithm type should be provided for the field activity remark - activation plug-in spot.

Refer to algorithm type **Assign Business Flag Final Confidence (D1-ABFFC)** for additional details.

Configuring Business Flags

For information on configuring business flags, see [Setting Up Business Flag Configuration](#) in the Oracle Utilities Application Framework *Administrative User Guide*.

Business Flags Can Require Analysis

For more serious situations a business flag can require manual analysis from a user. These types of business flags will generate a To Do when they are received from the external application. To resolve the To Do a user will investigate the service point based on the type of business flag present. Generally this investigation will result in the business flag being either confirmed or rejected. To reach the conclusion of whether the business flag should be confirmed or denied the user can be provided with a set of available actions that can be performed on the business flag.

See [CI-BFANL](#) for more information.

Configuring Business Flag Integration

Oracle Utilities Meter Data Management includes the following components used when integrating with Oracle DataRaker:

Master Configuration

The following master configurations are used to configure the sync process between MDM and Oracle DataRaker:

Master Configuration	Description
DataRaker Integration Master Configuration	This master configuration is used to enable deep linking into Oracle DataRaker. Multiple URL patterns are supported with an ability to provide substitution variables to satisfy the URL parameters (e.g. "&searchTech="). This also provides a mapping between Oracle Utilities Meter Data Management service types and the Oracle DataRaker point types.

Service Provider Processing Methods

The following processing methods should be associated to the service provider configured for Oracle DataRaker:

Processing Role	Description
-----------------	-------------

Business Flag Confidence Change	This role will identify the appropriate message to send when a business flag confidence has been changed (e.g. from Suspected to Confirmed). When not configured no message will be sent.
Business Flag Discarded Notification	This role will identify the appropriate message to send when a business flag has been discarded. When not configured no message will be sent.
Business Flag Field Work Details	This role will identify the appropriate message to send when a business flag has completed that initiated field work. When not configured no message will be sent.
Business Flag Added Notification	This role will identify the appropriate message to send when a business flag has been created from within Oracle Utilities Meter Data Management. When not configured no message will be sent.

Extendable Lookups

The following extendable lookups should be reviewed for Oracle DataRaker:

Extendable Lookup	Description
Business Flag Standard Name	If Oracle DataRaker will be communicating business flags using a non-standard name provide an entry in the Valid External Name with the non-standard name for each standard name communicated by Oracle DataRaker.

A Field Activity Can Determine Business Flag Confidence

When a business flag results in a field activity being issued and a field team is sent to investigate the service point the result of that field activity investigation will drive the resolution of the business flag. This is done through the field remarks left by the field team. The field activity remarks can either be defined as confirming the business flag or rejecting it. By selecting the appropriate field activity remark the field team will conclude the investigation into the business flag and the final confidence will be updated as appropriate.

For those field activity remarks that should either confirm or reject the business flag the Business Flag Confidence Update algorithm type should be provided for the field activity remark – activation plug-in spot.

Please refer to algorithm type Business Flag Confidence Update ([CI-BSFLGCFUP](#)) for more detail.

Business Flags Can Create Alerts

Some business flags have a high enough importance that they should be highlighted to any user that is viewing data for the service point the business flag is related to. Whether a business flag should create an alert is controlled on the business flag type. Furthermore, the appropriate algorithm must be configured in the “Installation Options – Framework” “Algorithms” page for the “Control Central Alert” system event.

The product delivers the algorithm type “Highlight Open Business Flags”

Please refer to algorithm type *Business Flag Confidence Update* ([CI-BSFLGCFUP](#)) for more detail.

Customer Relationship Management Integration

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with customer relationship management applications such as Oracle Social Relationship Management (SRM).

The following sections describe this functionality.

About Customer Relationship Requests

A customer relationship request is used to process requests that are initiated from an external customer relationship management system.

The following sections highlight customer relationship request functionality.

Social Relationship Management Requests

Oracle Social Relationship Management (SRM) is an example of an external system that can initiate customer relationship requests.

Social network posts cover a vast range of topics, a number of which could be related to the users' concerns with their utility service. For example:

- A Facebook user could post on a community page about a power outage in a specific area.
- A Twitter user might post about specific problems with his/her utility service (*e.g.*, high bill complaints).

Social conversations of this nature can be monitored and managed via Oracle SRM. Oracle SRM's Engage module allows its users to see all social conversations, identify customer-specific issues and route the messages to the appropriate systems/channels.

Requests from social relationship management systems typically include:

- Information about the original posting on the social network/community (*e.g.*, author's identifier, link to the post, etc.).
- Information about the posting within the social relationship management system (*e.g.*, the user that sent the request to the utility, link to the post, etc.).
- Additional details that will help with processing/resolution (*e.g.*, customer/account numbers, address, bill IDs, etc.).

Creating Customer Relationship Requests

Most customer relationship requests will be initiated from an external system.

The base product provides an Add Customer Relationship Request (C1-AddCustRR) inbound web service that can be used in a customer relationship management integration to create customer relationship request records. This inbound web service invokes a processing script that is configured in Customer Relationship Integration master configuration. The base product supplies an example of this processing script. It maps the inbound service's input data into the customer relationship request record. Refer to the C1-CreCustRR service script system data for processing details.

Setting Up Customer Relationship Request Configuration

The following topics highlight the general configuration steps required to use customer relationship request functionality and to integrate with a customer relationship management application such as Oracle Social Relationship Management (SRM).

Customer Relationship Management Integration Configuration

The integration with a customer relationship management application such as Oracle Social Relationship Management (SRM) requires the setup of master configuration data that controls the processing of your customer relationship requests.

To set up customer relationship integration master configuration, navigate using **Admin > General > Master Configuration**. You are brought to an all-in-one portal with options to add/edit the Customer Relationship Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Defining Customer Relationship Request Types

A customer relationship request type defines properties that control how a customer relationship request is processed.

Refer to [About Customer Relationship Requests](#) for an overview of customer relationship request functionality.

To maintain customer relationship request types, open **Admin > Integration > Customer Relationship Request Type > Search**.

This is a standard [All-In-One Portal](#).

The information captured on the customer relationship request type depends on the business objects supported by your implementation. Refer to the embedded help text for more information.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [CI_CUST_REL_REQ_TYPE](#).

Maintaining Customer Relationship Requests

This section describes the functionality supported for viewing and maintaining customer relationship requests.

Refer to [About Customer Relationship Requests](#) for an overview of customer relationship request functionality.

Navigate using **Menu > Integration > Customer Relationship Request > Search**. You are brought to a query portal with options for searching for customer relationship requests.

Once a customer relationship request record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Customer Relationship Request** zone provides basic information about a customer relationship request. Refer to the embedded help for more information.

The **Notes** zone allows users to capture additional notes to the customer relationship request.

RightNow Knowledge Integration

Oracle Utilities Customer Care and Billing provides an integration with Oracle RightNow Knowledge that allows users to view frequently asked questions about business processes/functions that relate to the portal or page that they are currently viewing and/or working on.

The following sections describe this functionality.

Displaying Frequently Asked Questions

The Oracle RightNow Knowledge application can be used to develop content for frequently asked questions about business processes. It also functions within the Oracle Customer Care and Billing application. The RightNow KnowledgeSyndication widget defines the interface for the retrieval of this content.

The Oracle Customer Care and Billing application provides a **Frequently Asked Questions** dashboard zone that uses the RightNow KnowledgeSyndication widget to retrieve content from a RightNow Knowledge base instance. This zone is context-sensitive.

Configuration data controls how information is displayed in the **Frequently Asked Questions** dashboard zone. Refer to [RightNow Knowledge Integration Configuration](#) for more details.

RightNow Knowledge Integration Configuration

The integration with Oracle RightNow Knowledge requires the setup of master configuration data that controls how content from the RightNow Knowledge base is retrieved and presented on the **Frequently Asked Questions** dashboard zone. This configuration includes the following settings:

- The URL of the RightNow Knowledge base instance.
- The list of portals and pages for which the **Frequently Asked Questions** dashboard zone will display.
- Settings for each portal / page:
 - Search terms to pass to the RightNow KnowledgeSyndication widget. The base product supplies a number of common search term types. Implementation-specific search term types can be added.
 - Number of results/answers to display in the **Frequently Asked Questions** dashboard zone.

To set up the RightNow Knowledge Integration master configuration, navigate using **Admin > General > Master Configuration**. You are brought to an all-in-one portal with options to add/edit the RightNow Knowledge Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

External Applications

Understanding External Applications

External Applications Impact Data Import and Export

External Applications are configured to identify how a particular external system communicates data with Oracle Utilities Meter Data Management. This includes:

- The identifier type used to locate devices and measuring components. These are used both on import and export of data.
- The date/time format used in various data imports (i.e. whether or not the date/time format includes time zone information).

Please refer to the embedded help for more information about these fields.

Each external application can be associated to an [external system](#) which is used to define the messages that can be sent to that service provider and how each message is sent.

Configuring External Applications

This portal is used to display and maintain External Applications.

Refer to [Understanding External Applications](#) for more information.

The following zones may appear as part of the portal's **Main** tab page:

- **External Applications List:** This zone lists all External Application records. Broadcast a record to display the details of the selected record.
- **External Application:** This zone provides information about the selected External Application.
- **Processing Method List:** This zone provides the list of processing methods defined for the External Application.
- **Translation Method List:** This zone provides the list of translation methods defined for the External Application.

- **Inbound BOs Sent By Service Provider:** This zone lists inbound Business Objects that are sent by this External Application. The identification is driven by the Business Object having a Business Object Option of type "Sent By Service Provider" that references the current External Application.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_SPR](#).

Configuring Master Data Synchronization

Refer to [Customer To Meter Master Data Synchronization](#) for more information.

Oracle Utilities Operational Device Management

Overview

This section provides an overview of how Oracle Utilities Meter Data Management supports integrations with Oracle Utilities Operational Device Management. In an integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management:

- Oracle Utilities Operational Device Management is typically considered the "system of record" for assets (devices)

Given this breakdown of data between the two systems, any integration between them must account for the passage of data between the two to ensure that each system can accurately perform its business functions. The integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management is based on data synchronization between the two systems.

Configuring Master Data Synchronization

The specific data synchronization flows supported between Oracle Utilities Meter Data Management (MDM) and Oracle Utilities Operational Device Management (ODM) include the following:

- **Asset-Device Synchronization:** As new assets are created or changed in ODM, corresponding devices must be created or changed in MDM
- **Install Events- Asset Location/Disposition:** As devices are installed/removed in MDM, corresponding changes to an asset's Disposition (location and status) must be made in ODM

This synchronization process is supported through a set of business objects, master configurations, batch controls, and pre-configured Inbound Web Services. Refer to the *Oracle Utilities Integration for Device Operations Implementation Guide* for more information about this integration and the data synchronization processes used by this integration.

Master Configuration

The following master configurations are used to configure the sync process between MDM and ODM:

Master Configuration	Name / Description
Master Data Synchronization Configuration	Lists all foreign key references that need resolution. Each one should reference the view that contains the external key / production key cross-reference. For entities that undergo both the initial and the ongoing sync, two views are specified. For entities that undergo the ongoing sync, an external system / ID type mapping is specified to

cater for entities that might be synchronizing from more than one external system.

Seeder Sync Request Master Configuration

Lists the maintenance objects (device, device configuration, etc.) that require synchronization. Each references the synchronization business object that needs to be instantiated when processing a synchronization request for that maintenance object. For maintenance objects that undergo both initial and the ongoing synchronization, two business objects are specified.

ODM Integration Master Configuration

Specifies the external system used to represent Oracle Utilities Operational Management, and the URL for the Oracle Utilities Operational Management application.

Also specifies the outbound message types used to send synchronization requests to Oracle Utilities Operational Management.

Inbound Data Synchronization Business Objects

The integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management uses the following inbound (to Oracle Utilities Meter Data Management) synchronization business objects:

Object Name	Business Object	Description
Device Ongoing Sync Request	D1-OngoingSyncRequestDevice	Used to synchronize devices in Oracle Utilities Meter Data Management based on assets created/updates in Oracle Utilities Operational Device Management.

Outbound Data Synchronization Business Objects

The integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management uses the following outbound (from Oracle Utilities Meter Data Management) synchronization business objects (based on the F1-SYNC REQ maintenance object)

Object Name	Business Object	Description
ODM Sync Request	D1-ODMContactSyncRequest	Used to synchronize contacts in Oracle Utilities Operational Device Management based on contacts created/updated in Oracle Utilities Meter Data Management
ODM Install Event Sync Request	D1-ODMInstallEventSyncRequest	Used to synchronize asset location/disposition in Oracle Utilities Operational Device Management based on install events created/updated in Oracle Utilities Meter Data Management
ODM SP Sync Request	D1-ODMSPSyncRequest	Used to synchronize asset locations in Oracle Utilities Operational Device Management based on service points created/updated in Oracle Utilities Meter Data Management

Oracle DataRaker

This section describes integrations with Oracle DataRaker.

Business Flag Integration

With the business flag integration with Oracle DataRaker:

- Either Oracle Utilities Meter Data Management or Oracle DataRaker can initiate a business flag
- Oracle Utilities Meter Data Management can notify Oracle DataRaker of a change in status of a business flag:
 - if a business flag in error has been discarded
 - if a business flag's confidence has been updated
 - with the results of field work initiated by a business flag

For additional details see [About Business Flags](#) in the Oracle Utilities Application Framework *Administrative User Guide*.

Usage and Event Integration

Oracle Utilities Smart Grid Gateway adapters can be configured to publish initial measurement and device event data for use in Oracle DataRaker or other external systems. Published data is posted to a user-defined directory that Oracle DataRaker can monitor for import.

Initial measurement and device event data is published in the “native” data format (the format of the initial measurement and device event seeder business objects). This format includes normalized unit of measure, condition, and device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: Initial measurement data published via this feature is published prior to VEE processing. In addition, filtering can NOT be applied to initial measurement or device event data published via this feature.

Configuring DataRaker Usage and Event Integration

Oracle Utilities Smart Grid Gateway adapters use OSB and BPEL components when publishing initial measurement and device event data for integration with Oracle DataRaker.

OSB Projects

The following “CM” Oracle Service Bus projects are used to configure the integration between SGG and Oracle DataRaker:

Adapter	OSB Projects
Landis+Gyr	SGG-D3-USAGE-CM (used to publish usage)
	SGG-D3-EVENT-CM (used to publish device events)
NES	SGG-D4-USAGE-CM (used to publish usage)
	SGG-D4-EVENT-CM (used to publish device events)
MV90	SGG-D5-USAGE-CM (used to publish usage)
Sensus	SGG-D6-USAGE-CM (used to publish usage)
	SGG-D6-EVENT-CM (used to publish device events)
Silver Spring Networks	SGG-D7-SSNXML-CM (used to publish usage)

	SGG-D7-CSV-CM (used to publish device events)
Itron OpenWay	SGG-D8-ITRONXML-CM (used to publish usage) SGG-D8-EXCEPTION-CM (used to publish device events)
Adapter Development Kit	SGG-DG-SEEDER-CM (used to publish usage and device events)

The following components provided with these projects are used in publishing measurement data and device events to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This business service is specified in the EnvironmentSettings.xq file (see below).
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Enabling Data Publishing

Publishing initial measurement and device event data is enabled by referencing a publisher business service (DataRakerBusinessService) in the publishServices/service element in the EnvironmentSettings.xq files provided with the OSB projects listed above as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

BPEL Composites

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems.

Configuring Publishing Output

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files.	/spl/sploutput/staging

Parameter	Description	Default Value
	This is used internally and should NOT be changed.	
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Oracle Utilities Network Management System

Outage Care Integration

The following section describes functionality provided for the integration between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.

The Big Picture of Outage Care Integration

Oracle Utilities Customer Care and Billing is the central repository for customer information; for example, name, address, phone number, etc. Oracle Utilities Network Management System is the central repository for outage information; for example, outage calls, affected supply nodes, expected restoration time, etc.

In an integrated environment, each system provides information to the other system so that they can operate together seamlessly.

- The outage system uses the set of current customers to determine and manage outages to minimize their impact.
- The outage system is informed of outages captured in Oracle Utilities Customer Care and Billing.
- Oracle Utilities Customer Care and Billing uses the current status of an outage at a given premise for customer service.

Customer Information Integration

The outage system needs information about current customers to determine and manage outages to minimize their impact. The current customer information in Oracle Utilities Customer Care and Billing must be made available in Oracle Utilities Network Management System. This can be done via data synchronization.

FASTPATH:

Refer to [The Big Picture of Sync Requests](#) for more information about synchronizing data.

Interfacing Outage Calls

The following points describe the integration:

- Oracle Utilities Customer Care and Billing is able to record trouble calls for a particular service point that exists in the system, as well as for an unknown service point, i.e. a fuzzy call. For a fuzzy call, the caller must provide either a street intersection, or a street segment.

- When an outage call is created and sent to the external system, an algorithm on the outage call business object is responsible for creating an outbound message that's sent to the external system. This is a real-time synchronous interface between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.
 - Oracle Utilities Network Management System processes the Calls table and creates Incidents.
-

FASTPATH:

Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage call integration.

Outage Inquiry

Oracle Utilities Customer Care and Billing provides query transactions that can be used to make real-time synchronous calls to NMS and inquire on one of the following:

- Job History for a particular customer, service point, location or call identifier
 - Call History for a particular customer, service point, location or call identifier
 - Planned Outage Jobs for a particular service point
-

FASTPATH:

Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage query integration.

Setting Up The System To Enable Outage Integration

The following section provides an overview of how to enable the integration between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.

External System Setup

An external system must be setup in order integrate Oracle Utilities Network Management System. Once the external system is defined, specify this on the one NMS Integration feature configuration so the system knows which external system to use for outage queries.

Define Outbound Message Types

The following outbound message types are required for the integration:

- An outbound message type is required for each of the outage queries available
 - Job History
 - Call History
 - Planned Outages
- Once the outbound message types are defined, specify this on the one NMS Integration feature configuration so the system knows which outbound message types to use for outage queries.

- In addition, an outage call outbound message type is required for sending outage calls to Oracle Utilities Network Management System. This outbound message type must be referenced on your outage call types.

Define Characteristic Types

The following characteristic types must be defined to facilitate Outage integration:

Outage Group Code Characteristic Type

These characteristics are used to describe the outage problem.

- Create at least one pre-defined characteristic type
- For each characteristic type, define its list of valid values
- Include Service Task Type in the characteristic entity collection

NOTE:

Characteristic Type Prefix. The system attempts to build a dropdown list of your valid outage group codes when maintaining outage group types. To achieve this, all outage group code characteristic types must use the same prefix. This prefix must be defined on the NMS Integration feature configuration.

Integration with Outage Management. The outage codes must be defined in both Oracle Utilities Customer Care and Billing and the outage management system. Refer to your Oracle Utilities Network Management System documentation for information about defining the outage codes there.

Contact Name Characteristic Type

This is used to link the contact name of the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc [characteristic type](#)
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the one NMS Integration feature configuration using the Outage Call Contact Name Characteristic Type feature option

Contact Number Characteristic Type

This is used to link the contact number of the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc [characteristic type](#)
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the one NMS Integration feature configuration using the Outage Call Contact Number Characteristic Type feature option

Call Identifier Characteristic Type

This is used to link the call identifier supplied by the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc [characteristic type](#)
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the one NMS Integration feature configuration using the Outage Call Identifier Characteristic Type feature option

Street Name Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc [characteristic type](#)
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the one NMS Integration feature configuration using the Outage Call Street Name Characteristic Type feature option

Cross Street Name Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc [characteristic type](#)
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the one NMS Integration feature configuration using the Outage Call Cross Street Name Characteristic Type feature option

Block Number Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc [characteristic type](#)
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the one NMS Integration feature configuration using the Outage Call Block Number Characteristic Type feature option

City Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc [characteristic type](#)
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the one NMS Integration feature configuration using the Outage Call City Characteristic Type feature option

State Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc [characteristic type](#)
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the one NMS Integration feature configuration using the Outage Call State Characteristic Type feature option

NMS Integration - Feature Configuration

Create a [feature configuration](#) with the type NMS Integration. Populate entries for all the options.

NOTE:

Only one. The system expects only one NMS Integration feature configuration to be defined.

Configure the options for your interaction with the outage system.

NOTE:

Your implementation may define additional options types. You do this by adding new lookup values to the lookup field NMS_OPT_TYP_FLG.

Option	Description
External System	This defines the external system used on outbound messages created when querying outage information in NMS from the outage management information portal page. Refer to for more information. Only one value is allowed for this option.
Outbound Message Type - Call History	This defines the outbound message type used on outbound messages created when querying outage call history in NMS from the outage management information portal page. Refer to for more information. Only one value is allowed for this option.
Outbound Message Type - Job History	This defines the outbound message type used on outbound messages created when querying outage job history in NMS from the outage management information portal page. Refer to for more information. Only one value is allowed for this option.
Outbound Message Type - Planned Outages	This defines the outbound message type used on outbound messages created when querying planned outages in NMS from the outage management information portal page. Refer to for more information. Only one value is allowed for this option.
Outage Group Code Characteristic Type Prefix	The system uses this prefix to populate the outage group code dropdown list during trouble call processing. Refer to for more information. Only one value is allowed for this option.

Schema Constants - Feature Configuration

Create a [feature configuration](#) with the type Schema Constants. Populate entries for all the options listed below.

NOTE:

Only one. The system expects only one Schema Constants feature configuration to be defined.

Configure the options for your interaction with the outage system.

NOTE:

Your implementation may define additional options types. You do this by adding new lookup values to the lookup field F1CN_OPT_TYP_FLG.

Option	Description
Outage Call Contact Name Characteristic Type	This is used to link the contact name of the caller associated with an outage call as a characteristic on the outage call. Refer to for more information. Only one value is allowed for this option.

Outage Call Contact Number Characteristic Type	<p>This is used to link the contact number of the caller associated with an outage call as a characteristic on the outage call. Refer to for more information.</p> <p>Only one value is allowed for this option.</p>
Outage Call Identifier Characteristic Type	<p>This is used to link the call identifier supplied by the caller associated with an outage call as a characteristic on the outage call. Refer to for more information.</p> <p>Only one value is allowed for this option.</p>
Outage Call Street Name Characteristic Type	<p>This is used to link the street name supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to for more information.</p> <p>Only one value is allowed for this option.</p>
Outage Call Cross Street Name Characteristic Type	<p>This is used to link the cross street name supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to for more information.</p> <p>Only one value is allowed for this option.</p>
Outage Call Block Number Characteristic Type	<p>This is used to link the block number supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to for more information.</p> <p>Only one value is allowed for this option.</p>
Outage Call City Characteristic Type	<p>This is used to link the city supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to for more information.</p> <p>Only one value is allowed for this option.</p>
Outage Call State Characteristic Type	<p>This is used to link the state supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to for more information.</p> <p>Only one value is allowed for this option.</p>

Message Formats

Oracle Utilities Meter Data Management supports three core transactional data imports: Initial Measurement Data, Device Event Data, and Usage Transactions. To see the appropriate format for each of these imports please see the following:

- **Initial Measurement Data:** Please see the IMD Seeder (D1-IMDSeeder) business object for the appropriate format
- **Device Events:** Please see the Device Event Seeder (D1-DeviceEventSeeder) business object for the appropriate format
- **Usage Transactions:** Please see the Usage Transaction Seeder (D2-UsgTranSeeder) business object for the appropriate format*

Data Import - Message Driven Bean Configuration

Overview

This section describes the steps for configuring the Message Driven Bean (MDB) feature of Oracle Utilities Meter Data Management and Oracle Utilities Smart Grid Gateway to listen to inbound JMS messages. This feature is used when importing IMDs and device events from head-end systems or when receiving Usage Transactions from CIS.

JMS Configuration

JMS configuration involves setting up JMS queues which will receive inbound usage readings and device events. The JMS queues need to be created first on the application server where the OSB component is deployed. This server is referred to as remote server in the sections below. In the following section the JMS queue on the remote server is assumed to be created with the name **DestinationQueueWatch-CM**.

Note: The JMS changes described in the following sections are not persistent during patches or upgrades. They will need to be re-created after applying any patches or upgrades to Oracle Utilities Smart Grid Gateway. It is recommended to keep a backup of the `$SPLEBASE/splapp/config.xml` file.

Create a new JMS Module

Log in to the Oracle Utilities Smart Grid Gateway Weblogic console and create a JMS Module with an appropriate name. Specify the following values for this JMS module:

- **Name:** the name of JMS module. For example, JMSModule-CM
- **Target:** the name of the target server where the Oracle Utilities Smart Grid Gateway application is running. This should be specified as myserver.

Create a Foreign JMS Server

Create a Foreign JMS server under the JMS module created in the above step. Specify the following values for this foreign JMS server:

- **Name:** Name of the foreign server. For example, JMSFAServer-CM
- **Target:** This should be specified as myserver
- **JNDI Initial Context Factory:** This should be specified as `weblogic.jndi.WLInitialContextFactory`
- **JNDI Connection URL:** The URL of the server where OSB is deployed. For example: `t3://osbserver:7001`
- **JNDI Properties Credential:** Password for the OSB server user.
- **JNDI Properties:** The `java.naming.security.principal` additional property should be specified and set to the OSB server user. For example, `java.naming.security.principal=weblogic`

Create a Foreign Destination

Create a Foreign destination for each remote queue. Specify the following values for this foreign destination:

- **Name:** Name of foreign destination. For instance, `DestinationQueue-CM`
- **Local JNDI Name:** Local JNDI name for the foreign JMS queue. For example, `ForeignDestinationQueue-CM`
- **Remote JNDI Name:** JNDI name of the queue on the remote server. For example, `DestinationQueueWatch-CM`

Create a Remote Connection Factory

Create a remote connection factory for the foreign JMS server. Specify the following values for this remote connection factory:

- **Name:** Name of remote connection factory. For example, DestinationQueueConnectionFactory-CM
- **Local JNDI Name:** Local JNDI name for the Remote Connection Factory. For example, ForeignDestinationQueueConnectionFactory-CM
- **Remote JNDI Name:** JNDI name of the JMS Connection Factory on the remote server. For example, weblogic.jms.XAConnectionFactory

Message Driven Bean Configuration

Configuration of message driven beans (MDB) involved modifying the **ejb-jar.xml** and **weblogic-*ejb-jar.xml*** configuration files delivered with Oracle Utilities Smart Grid Gateway. It is recommended that instead of modifying these files directly you create "Customer Modification" (CM) versions of these files to make changes to these configuration files. This ensures that your modifications are not overwritten by future application patches.

The following section describes the changes required in the CM files for configuring the MDBs to read from the foreign JMS queues set up in the steps above. This requires creating the following files under \$SPLEBASE/templates:

- cm_ejb-jar.xml.wls.jms_1.include
- cm_ejb-jar.xml.wls.jms_2.include
- cm_weblogic-*ejb-jar.xml*.jms.include.

Note: After making these changes the initialSetup script needs to be run and Oracle Utilities Smart Grid Gateway application needs to be redeployed. However the initialSetup script will overwrite the JMS configuration changes made in the steps above. So it is recommended to keep a backup of the \$SPLEBASE/splapp/config.xml file before running this script.

Changes to cm_ejb-jar.xml.wls.jms_1.include

The following is an example of the cm_ejb-jar.xml.wls.jms_1.include file:

```
<message-driven>
  <description>MDB for DestinationQueue-CM</description>
  <display-name>DestinationQueueWatcher-CM</display-name>

  <ejb-name>DestinationQueueWatch-CM</ejb-name>

  <ejb-class>com.splwg.ejb.mdb.MessageProcessor</ejb-class>
  <messaging-type>javax.jms.MessageListener</messaging-type>
  <transaction-type>Bean</transaction-type>
  <message-destination-type>javax.jms.Queue</message-destination-type>
</message-driven>
```

The values specified in the above file include the following:

- **ejb-name:** This is the name of the MDB.

Changes to cm_ejb-jar.xml.wls.jms_2.include

The following is an example of the cm_ejb-jar.xml.wls.jms_2.include file:

```
<assembly-descriptor>
  <security-role>
  <role-name>cisusers</role-name>
  </security-role>
  <container-transaction>
  <method>

  <ejb-name>DestinationQueueWatch-CM</ejb-name>

  <method-name>onMessage</method-name>
  </method>
```

```
<trans-attribute>NotSupported</trans-attribute>
</container-transaction>
</assembly-descriptor>
```

The values specified in the above file include the following:

- **ejb-name:** This is the name of the MDB

Changes to cm_ejb-jar.xml.wls.jms_2.include

The following is an example of the cm_weblogic-`ejb-jar.xml.jms.include` file:

```
<weblogic-enterprise-bean>
<ejb-name>DestinationQueueWatch-CM</ejb-name>
<message-driven-descriptor>
<pool>
<max-beans-in-free-pool>5</max-beans-in-free-pool>
<initial-beans-in-free-pool>1</initial-beans-in-free-pool>
</pool>
<destination-jndi-name>ForeignDestinationQueue-CM</destination-jndi-name>
<connection-factory-jndi-name>ForeignConnectionFactory-CM</connection-
factory-jndi-name>
</message-driven-descriptor>
</weblogic-enterprise-bean>
```

The values specified in the above file include the following:

- **ejb-name:** This should be the name of the MDB as specified in `ejb-jar.xml`
- **destination-jndi-name:** This should be the JNDI name of the foreign destination as provided in JMS module ' Foreign server ' Foreign destination ' Local JNDI name.
- **connection-factory-jndi-name:** This should be the JNDI name of the connection factory as provided in JMS module ' Foreign server ' Remote Connection Factory ' Local JNDI name.

Notification Queue Configuration

Payload statistics and payload summary records must be submitted sequentially in order for them to be processed correctly. To prevent them from being processed at the same time, you should set the number of notification queue polling threads to 1. Follow these steps to configure the number of notification queue threads:

1. Log in to the WebLogic Server Administration Console.
2. Under Helpful Tools, click **Configure Applications**.
3. Click on **SPLService**.
4. Click on the NotificationQueue link. for the EJB that you want to configure.
5. Go to the Configuration tab.
6. In the Change Center, click **Lock & Edit**.
7. Specify the new value of polling threads in **Max Beans in Free Pool**.
8. Click **Save**.
9. Click **Release Configuration**.
10. Restart the OUAF WebLogic instance.

The Conversion Tool

This section describes the Oracle Utilities Customer Care and Billing conversion tool.

NOTE: The Customer Care and Billing conversion tool described in this section is designed to support specific [master](#) and [transaction](#) entities only. Other entities may be converted using the generic [conversion](#) tool.

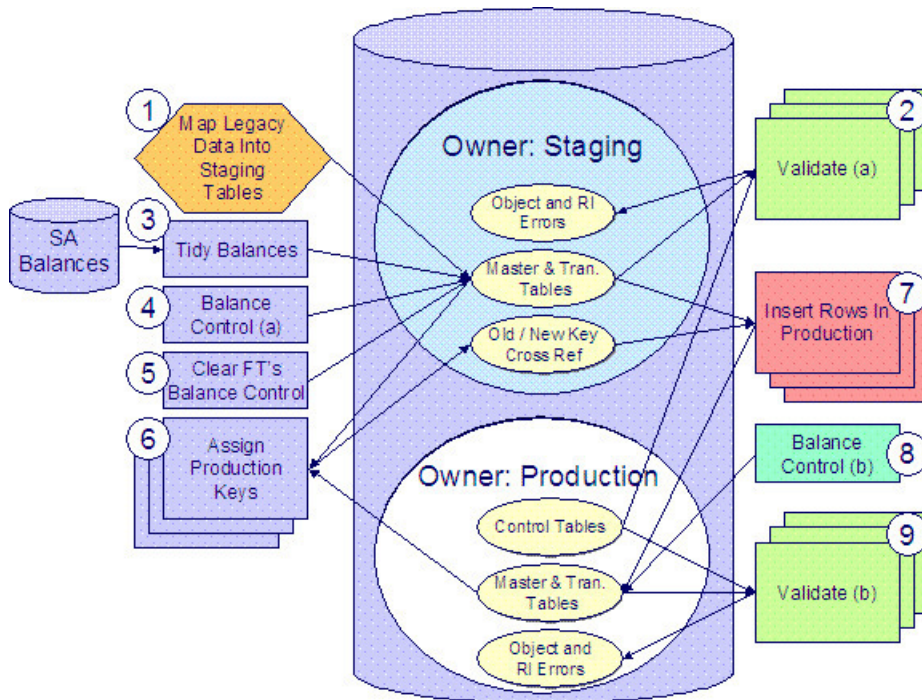

Introduction

When you're ready to convert data from your legacy system into Oracle Utilities Customer Care and Billing, you will have analyzed your CIS processing requirements according to your business and organizational needs and set up the control tables accordingly.

FASTPATH:

Refer to the **Administration Guide** for a complete discussion of the various control tables and the order in which they must be set up.

After the control tables are set up, you are ready to load data into the system from your legacy system. This conversion effort involves several steps as illustrated in the following diagram:

The following points briefly outline each of the above tasks:

- **Map Legacy Data Into Staging.** During this step, your legacy master data (e.g., account, person, premise, meter) and transaction data (e.g., bills, payments, meter reads) is migrated into the system. Notice that you are not migrating this data directly into production. Rather, your rows are loaded into tables that are identical to the production tables; they just have a different owner. Refer to [Appendix B - Multiple Owners In A Single Database](#) for information about table ownership.

WARNING:

The above diagram illustrates how the system is configured to support the conversion effort in the standard installation, i.e., the staging tables are in the same database as the production tables (each with a different owner). However, it is possible for the staging tables to be in a separate database. This option requires additional effort on your part (because you would have to copy the control tables from production into your staging database). Please refer to [Appendix B - Multiple Owners In A Single Database](#) for information about this alternative.

Mapping legacy data into the system is probably the most challenging part of the conversion process because the system is a normalized database (and most legacy applications are not).

- **Validate (a).** During the validation (a) step, the system validates the data you loaded into the staging tables. Two types of validation programs exist:
 - **Object Validation Programs.** Each of the system's master data objects (e.g., person, account, premise, meter, etc.) is validated using the same logic that is used to validate data added by users in your production system.
 - **Referential Integrity Validation Programs.** After you have successfully validated the master data objects, the referential integrity validation programs are executed to validate transaction data and to highlight "orphaned" rows. These programs check the validity of the foreign keys on all rows on all tables.
-

NOTE:

Control tables from production. It's important to notice that the validation programs validate your staging data using the control tables that have been set up in production. Refer to [Appendix B - Multiple Owners In A Single Database](#) for a description of how this works.

- **Tidy Balances.** During this step, the system creates adjustments that cause each SA's current and payoff balances to equal the desired balances. The desired balances are supplied on a flat file prepared by you.
- **Balance Control (a).** During this step, you run the balance control program and then verify that the balances that it generates are consistent with the balances in your legacy system.
- **Clear FT's Balance Control.** In the previous step, the system creates a balance control and links it to the FT's. If the balance control's balances are consistent with the amount of receivables being transferred into the system, you should run the Clear FT's Balance Control program. This program simply resets the Balance Control column on the FT so that the FT's can be included in a balance control (see the last step below) after they have been transferred to production.
- **Assign Production Keys.** During this step, the system allocates random, clustered keys to the rows in the staging database.
- **Insert Rows Into Production.** During this step, the system populates your production tables with rows from the staging. When the rows are inserted, their prime keys are reassigned using the data populated in the previous step.
- **Balance Control (b).** During this step, you run the balance control program against production. You do this to verify the balances in production are consistent with the values of receivables converted from your legacy application.
- **Validate (b).** During this step, you rerun the object validation programs, but this time against production. We recommend rerunning these programs to confirm that the insertion programs have executed successfully. We recommend running these programs in random sample mode (e.g., validate every 1000th object) rather than conducting a full validation in order to save time. However, if you have time, you should run these programs in full validation mode (to validate every object).

Conversion Tool Steps

The following sections provide more details about the steps in the conversion process.

Map Legacy Data Into Staging Tables

This section provides some high level discussion about mapping legacy data to the system's staging tables. Refer to [The Staging Tables](#) for details about the staging tables in the system.

NOTE:

Recommendation. You can use any method you prefer to load Oracle Utilities Customer Care and Billing data from your legacy application. However, we recommend that you investigate your database's mass load utility (as opposed to using insert statements) as the mechanism to load the staging tables. In addition, we strongly recommend that you disable the indexes on these tables before populating these tables and then enable the indexes after populating these tables.

Populating Characteristic Tables. There are many maintenance objects that include a characteristic table used to capture miscellaneous information about the object, e.g. Person, Account, Service Agreement, etc. Most of these tables include an indexed column used when searching by characteristic value called Search Characteristic Value. During conversion and depending on the type of characteristic, this column must be populated as follows:

- Predefined: Populate search characteristic value with the contents of the characteristic value column converted to upper case.
- Ad hoc: Populate search characteristic value with the first 50 bytes of the ad hoc characteristic value column converted to upper case.
- Foreign key: Populate search characteristic value by concatenating the values of each foreign key characteristic value column to a maximum of 50 bytes.

A Note About Keys

The prime keys of the tables in the staging database are either system-assigned random numbers or they aren't. Those tables that don't have system-assigned random numbers have keys that are a concatenation of the parent's prime-key plus one or more additional fields.

Every table whose prime key is a system-assigned random number has a related table that manages its keys; we refer to these secondary tables as "key tables". The following points provide more information about the key tables:

- Key tables are used by programs that allocate new keys. For example, before a new account ID is allocated, the key assignment program checks the account key table to see if it exists.
- Key tables only have two columns:
 - The key of the object.
 - An environment ID. The environment ID identifies the database in which the object resides.
- Key tables are named the same as their primary table with a suffix of "_K". For example:
 - The key table for CI_ACCT is CI_ACCT_K
 - The key table for CI_PREM is CI_PREM_K
- The name of every table's key table is defined under the Generated Keys column in the Table Names sections in [The Staging Tables](#).
- When you populate rows in tables with system-assigned keys, you must also populate a row in the related key table. For example, if you insert a row into CI_ACCT, you must also insert a row into CI_ACCT_K. The environment ID of these rows must be the same as the environment ID on this database's [installation record](#).

- When you populate rows in tables that reference this record as a foreign key, you must use the appropriate key to ensure the proper data relationships. For example, if you insert a row in CI_SA for the above account, the ACCT_ID column must contain the temporary account key.
- When you insert rows into your staging database, the keys do not have to be random, system-assigned numbers. They just have to be unique. A later process, [Allocate Production Keys](#), will allocate random, system-assigned keys prior to production being populated.

Validate Information In The Staging Tables

During the first validation step, the system validates the data you loaded into the staging tables. Two types of validation programs exist:

- **Object Validation Programs.** The object validation programs validate each of the system's master data objects (e.g., person, account, premise, meter, etc.) and a limited number of transaction data objects (e.g., field activity, field order, etc.). Please note that these programs call the same programs that are used to validate data added by users in your production system.
- **Referential Integrity Validation Programs.** After the master data objects have been validated, the referential integrity validation programs are executed to validate transaction data and to highlight "orphaned" rows. These programs simply check the validity of the foreign keys on all rows on all tables.

The contents of this section describe how to execute the validation programs.

Object Validation Programs

Each of the objects described under [Master Data](#) must be validated using the respective object validation program indicated in its Table Names section.

In a limited number of cases object validation is available for [Transaction Data](#) objects, where customers may convert transaction data that is still pending. For example, if you are converting pending field activities, you want to ensure that the data is valid. For these cases you may also be converting historic records. For example, in addition to the pending field activities you are converting completed field activities to keep a historic view. You may not want to perform validation on completed records. As a result the background processes provided for transaction data allow you to limit the validation to records in a give status.

We strongly recommend validating each object in the following steps:

- Execute each object's validation program in random-sample mode to highlight pervasive errors. When you execute a validation in random-sample mode, you are actually telling it to validate every X records (where X is a parameter that you supply to the job). Refer to [Submitting Object Validation Programs](#) for more information about the parameters supplied to these background processes.
- You can view errors highlighted by validation programs using the [Validation Error Summary](#) transaction.
- Correct the errors using SQL. Note, you can use the base package's transactions (e.g., Person Maintenance, Premise Maintenance, etc.) to correct an error if the error isn't so egregious that it prevents the object from being displayed on the browser.
- After all pervasive errors have been corrected; re-execute each object's validation program in all-instances mode to highlight elusive, one-off errors. Refer to [Submitting Object Validation Programs](#) for more information about the parameters supplied to these background processes.

WARNING:

Whenever an object validation program is run, it is necessary to delete all previously recorded errors associated with its tables from the validation error table before it inserts new errors.

After the various object validation programs run cleanly, run the referential integrity validation programs as described in the next section.

NOTE:

Another use for these programs. In addition to validating your objects after conversion or an upgrade, the validation programs are another use. Say for example, you want to experiment with changing the validation of a person and you want to determine the impact of this new validation on your existing persons. You could change the validation and then run the person validation object - it will produce errors for each person that fails the new validation.

Submitting Object Validation Programs

The object validation programs that are described in the [staging tables](#) table names matrices are classic background processes as they can also be run against production data. You submit these processes in the same way you submit any background process in production.

Referential Integrity Validation Programs

It's important to understand that only master data objects (e.g., persons, accounts, meters, premises, etc.) are validated by the object validation programs discussed above. This means that only master data objects will have their foreign keys checked for validity by the object validation programs. You must run the referential integrity programs to validate all other data.

The referential integrity validation programs highlight:

- Orphaned rows because orphan rows, by definition, don't reference an object.
 - Invalid foreign keys on transaction data.
-

NOTE:

Validating Transaction Data. You may wonder why transaction data is not subject to the object validation routines. This is because: a) the production system only needs validation logic for master data because transaction data is not entered by users, and b) most conversions necessitate loading skeletal transaction data because the legacy system typically doesn't contain enough information to create accurate transactions in the system.

Each of the tables described under [Transaction Data](#) must be validated using the respective referential integrity validation program indicated in its Table Names section. We strongly recommend validating each table in the following steps:

- Execute each table's referential integrity validation program. Refer to [Submitting Referential Integrity Validation Programs](#) for more information about the parameters supplied to these background processes.
 - You can view errors highlighted by this process using the [FK Validation Summary](#) transaction.
 - Correct the errors using SQL (you cannot use the application to correct these types of errors).
 - Rerun the referential integrity programs until no errors are produced.
-

WARNING:

Whenever you run a referential integrity validation program, it deletes all errors associated with its table from the referential integrity error table.

In order to highlight orphaned rows in the master data, run the referential integrity validation programs against all tables described under [Master Data](#) using the procedure described above.

When ALL referential integrity programs indicate the staging database is clean, you may now proceed to the next step - [tidy balances](#).

Submitting Referential Integrity Validation Programs

The referential integrity validation programs described under [Master Data](#) and [Transaction Data](#) (in the Table Names matrices) are submitted using a batch driver program, CIPVRNVB, and this program is executed in the staging database. Please note that the referential integrity validation programs may also be run in the production environment on occasion, to determine the integrity of data in the production database.

You should supply the following parameters to this program:

- **Batch code.** The batch code associated with the appropriate table's referential integrity validation program. Refer to each table listed under [Master Data](#) and [Transaction Data](#) (in the Table Names matrices) for each referential integrity batch code / program.
- **Batch thread number.** Thread number is not used and should be left blank.
- **Batch thread count.** Thread count is not used and should be left blank.
- **Batch rerun number.** Rerun number is not used and should be left blank.
- **Batch business date.** Business date is the date supplied to the referential integrity validation programs and the date under which statistics will be logged.
- **Total number of commits.** Total number of commits is not used and should be left blank.
- **Maximum minutes between cursor re-initiation.** Maximum minutes between cursor re-initiation is not used and should be left blank.
- **User ID.** User ID is only used to log statistics for the execution of the batch job.
- **Password.** Password is not used.
- **Language Code.** Language code is used to access language-specific control table values. For example, error messages are presented in this language code.
- **Trace program at start (Y/N), trace program exit (Y/N), trace SQL (Y/N) and output trace (Y/N).** These switches are only used during QA and benchmarking. If trace program start is set to Y, a message is displayed whenever a program is started. If trace program at exist is set to Y, a message is displayed whenever a program is exited. If trace SQL is set to Y, a message is displayed whenever an SQL statement is executed.

Recommendations To Speed Up Validation Programs

The following points describe ways to accelerate the execution of the validation programs:

- Ensure that statistics are recalculated after data has been inserted into the staging tables. For Oracle users, we strongly recommend using the Oracle-provided PL/SQL package to generate statistics rather than the analyze command.
- [Object validation programs](#) should be run multi threaded.
- Execute shorter running validation processes (e.g., less records) first so that the error data can be analyzed while other processes are busy running.
- [Referential integrity validation programs](#) run fairly quickly without much tuning. However, additional benefits are gained by running several programs at the same time.

- Remember that the [object validation programs](#) can be run in "validate every n th row". We recommend running these programs using a largish value for this parameter until the pervasive problems have been rectified.

Tidy Balances

This background process creates adjustments that cause each SA's current and payoff balances to equal its balance in the legacy system (note: the batch control ID of CNV-BAL is used for this process).

NOTE:

Submitting this process. You submit this process in the staging database. Refer to [Tidy Balances](#) for a description of this process and its parameters.

You supply the desired balances to this background process in a flat file in the following format:

Field	Size	Description
SA ID	X10	The unique identifier of the service agreement
Payoff Balance Sign	X1	Positive or Negative value indicates debit or credit balance respectively
Payoff Balance	N15.2	The SA's payoff balance (how much the customer really owes).
Current Balance New Charge Sign	X1	Positive or Negative value indicates debit or credit balance respectively
Current Balance - New Charge	N15.2	The amount of the SA's current balance that is considered a new charge, i.e., it hasn't started aging yet.
Current Balance Amount 1 Sign	X1	Positive or Negative value indicates debit or credit balance respectively
Current Balance - Amount 1	N15.2	The amount of the SA's current balance that is X days old (X is defined in the next field)
Age of Current Balance - Amount 1	N3	The number of days old the prior field is (if you keep your debt in "buckets" as opposed to knowing the exact number of days it has aged, you will have to choose an exact age). Set this value to zero if the value of amount 1 should be considered a "new charge" (i.e., it should only start aging when it is swept onto the next bill produced for the SA's account)
Current Balance Amount 2 Sign	X1	Positive or Negative value indicates debit or credit balance respectively
Current Balance - Amount 2	N15.2	The amount of the SA's current balance that is X days old (X is defined in the next field)
Age of Current Balance - Amount 2	N3	The number of days old the prior field is (if you keep your debt in "buckets" as opposed to knowing the exact number of days it has aged, you will have to choose an exact age)
Current Balance Amount 3 Sign	X1	Positive or Negative value indicates debit or credit balance respectively

Current Balance - Amount 3	N15.2	The amount of the SA's current balance that is X days old (X is defined in the next field)
Age of Current Balance - Amount 3	N3	The number of days old the prior field is (if you keep your debt in "buckets" as opposed to knowing the exact number of days it has aged, you will have to choose an exact age)
Current Balance Amount 4 Sign	X1	Positive or Negative value indicates debit or credit balance respectively
Current Balance - Amount 4	N15.2	The amount of the SA's current balance that is X days old (X is defined in the next field)
Age of Current Balance - Amount 4	N3	The number of days old the prior field is (if you keep your debt in "buckets" as opposed to knowing the exact number of days it has aged, you will have to choose an exact age)
Current Balance Amount 5 Sign	X1	Positive or Negative value indicates debit or credit balance respectively
Current Balance - Amount 5	N15.2	The amount of the SA's current balance that is X days old (X is defined in the next field)
Age of Current Balance - Amount 5	N3	The number of days old the prior field is (if you keep your debt in "buckets" as opposed to knowing the exact number of days it has aged, you will have to choose an exact age)

NOTE:

Submitting this process. You submit this process in the staging database. Refer to [Tidy Balances](#) for a description of this process and its parameters.

Balance Control (a)

During this step, you run the balance control programs and then verify that the balances that it generates are consistent with the balances in your legacy system.

NOTE:

Submitting this process. You submit this process in the staging database. Refer to [The Big Picture of Balance Control](#) for more information about the balance control processes. Refer to [Balance Control](#) for information about the page used to view the balances generated by this process.

Clear FT Balance Control

In the previous step, the system created a balance control and links it to the FT's. If the balance control's balances are consistent with the amount of receivables being transferred into the system, you should run the Clear FT's Balance Control program. This program simply resets the Balance Control column on the FT so that the FT's can be included in a balance control (see the last step below) after they have been transferred to production. Note: the batch control ID of CNV-BCG is used to request this process.

NOTE:

Submitting this process. You submit this process in the staging database. Refer to [Reset Balances](#) for a description of this process and its parameters.

Allocate Production Keys

The topics in this section describe the background processes used to assign production keys to the staging data.

The Big Picture of Key Assignment

It's important to understand that the system does not overwrite the prime-keys on the rows in the staging database, as this is a very expensive IO transaction. Rather, a series of tables exist that hold each row's old key and the new key that will be assigned to it when the row is [transferred into the production database](#). We refer to these tables as the "old key / new key" tables. The old key / new key tables are named the same as their primary table, but rather than being prefixed by "CI", they are prefixed by "CK". For example, the old key / new key table for CI_ACCT is called CK_ACCT.

The insertion programs that transfer the rows into the production database use the new key for the main record of the key along with any other record where this key is a foreign key. Note that the capability of assigning the new key to a foreign key applies to

- "True" foreign keys, i.e. where the key is a column in another table. For example, CI_SA has a column for ACCT_ID.
- FK reference characteristics. These are characteristics that define, through an FK reference, the table and the key that this characteristic represents.

The insertion programs are not able to assign "new keys" to foreign keys defined in an XML structure field (CLOB).

The key assignment programs listed under [Master Data](#) and [Transaction Data](#) (in the table names sections) are responsible for populating the old key / new key tables (i.e., you don't have to populate these tables). Because the population of the rows in these tables is IO intensive, we have supplied detailed instructions that will accelerate the execution time of these programs.

NOTE:

Why are keys reassigned? The conversion process allocates new prime keys to take advantage of the system's parallel processing and data-clustering techniques in the production system (these techniques are dependent on randomly assigned, clustered keys).

Iterative conversions. Rather than perform a "big bang" conversion (one where all customers are populated at once), some implementations have the opportunity to go live on subsets of their customer base. If this describes your implementation, please be aware that the system takes into account the existing prime keys in the production database before it allocates a new key value. This means when you convert the next subset of customers, you can be assured of getting clean keys.

Program Dependencies. The programs used to assign production keys are listed in the Table Names matrices. Most of these programs have no dependencies (i.e., they can be executed in any order you please). The exceptions to this statement are noted in [Program Dependencies](#).

Submitting Key Assignment Programs

The key assignment programs described under [Master Data](#) and [Transaction Data](#) (in the Table Names matrices) are submitted using a batch driver program, CIPVRNKB, and this program is executed in the staging database. You should supply the following parameters to this program:

- **Batch code.** The batch code associated with the appropriate table's key assignment program. Refer to each table listed under [Master Data](#) and [Transaction Data](#) (in the Table Names matrices) for each key assignment batch code / program.
- **Batch thread number.** Thread number is not used and should be left blank.
- **Batch thread count.** Thread count is not used and should be left blank.
- **Batch rerun number.** Rerun number is not used and should be left blank.
- **Batch business date.** Business date is the date supplied to the key assignment programs and the date under which statistics will be logged.
- **Total number of commits.** Total number of commits is not used and should be left blank.
- **Maximum minutes between cursor re-initiation.** Maximum minutes between cursor re-initiation is not used and should be left blank.
- **User ID.** User ID is only used to log statistics for the execution of the batch job.
- **Password.** Password is not used.
- **Language Code.** Language code is used to access language-specific control table values. For example, error messages are presented in this language code.
- **Trace program at start (Y/N), trace program exit (Y/N), trace SQL (Y/N) and output trace (Y/N).** These switches are only used during QA and benchmarking. If trace program start is set to Y, a message is displayed whenever a program is started. If trace program at exist is set to Y, a message is displayed whenever a program is exited. If trace SQL is set to Y, a message is displayed whenever an SQL statement is executed.
- **Mode.** The proper use of this parameter will greatly speed up the key assignment step as described under [Recommendations To Speed Up Key Generation](#). This parameter has three values:
 - If you supply a mode with a value of I (initial key generation), the system allocates new keys to the rows in the staging tables (i.e., it populate the respective old key / new key table).
 - If you supply a mode with a value of D (resolve duplicate keys), the system reassigns keys that are duplicates.
 - If you supply a mode with a value of B (both generate keys and resolve duplicates), the system performs both of the above steps. This is the default value if this parameter is not supplied.
 - Please see [Recommendations To Speed Up Key Generation](#) for how to use this parameter to speed up the execution of these processes.

NOTE:

Parallel Key Generation. No key generation program should be run (either in mode I or B) while another program is being run unless that program is in the same tier (see [Program Dependencies](#) for a description of the tiers).

- **Start Row Number.** This parameter is only used if you are performing conversions where data already exists in the tables in the production database (subsequent conversions). In an Oracle database the key assignment routines create the initial values of keys by manipulation of the Oracle row number, starting from 1. After any conversion run, a subsequent conversion run will start with that row number again at 1, and the possibility of duplicate keys being assigned will be higher. The purpose of this parameter is to increase the value of row number by the given value, and minimize the chance of duplicate key assignment.

Recommendations To Speed Up Key Generation Programs

The following points describe ways to accelerate the execution of the key generation programs.

NOTE:

Naming convention. The convention "CK_<table_name>" is used to denote the old key / new key tables described under [The Big Picture of Key Assignment](#).

- Make the size of your rollback segments large. The exact size is dependent on the number of rows involved in your conversion. Our research has shown that processing 7 million rows generates roughly 3GB of rollback information.
 - Setup the rollback segment(s) to about 10GB with auto extend to a maximum size of 20GB to determine the high water mark
 - A next extent value on the order of 100M should be used.
- Make sure to turn off all small rollback segments (otherwise Oracle will use them rather than the large rollback segments described above).
- After the key assignment programs execute, you can reclaim the space by:
 - Keep a low value for the "minimum extent" parameter for the rollback.
 - Shrink the rollback segments and the underlying data files at the end of the large batch jobs.
- Compute statistics on the CK_<table_name> tables after every 50% increase in table size. Key generation is performed in tiers or steps because of the inheritance dependency between some tables and their keys. Although key generation for the tier currently being processed is performed by means of set-based SQL, computation of statistics between tiers will allow the database to compute the optimum access path to the keys being inherited from the **previous** tier's generation run. For Oracle users, we strongly recommend using the Oracle-provided PL/SQL package to generate statistics rather than the analyze command.
- Optimal use of the **Mode** parameter under [Submitting Key Assignment Programs](#).
 - Before any key assignments, alter both the "old key" CX_ID index and the "new key" CI_ID index on the CK_<table_name> tables to be unusable.
 - Run all [key assignment tiers](#), submitting each job with MODE = "I".
 - Rebuild the CX_ID and CI_ID indexes on the CK_<table_name>. Rebuilding the indexes using both the PARALLEL and NOLOGGING parameters will speed the index creation process in an Oracle DB. Statistics should be computed for these indexes.
 - Run all key assignment tiers that were previously run in MODE = 'I', submitting each job with MODE = "D". This will reassign all duplicate keys.

Insert Production Data

The topics in this section describe the background processes used to populate the production database with the information in the staging database.

The Big Picture Of Insertion Programs

All insertion programs are independent and may run concurrently. Also note, all insertion programs can be run in many parallel threads as described in the next section (in order to speed execution).

Submitting Insertion Programs

The insertion programs described under [Master Data](#) and [Transaction Data](#) (in the Table Names matrices) are submitted using a batch driver program, CIPVRNIB, and this program is executed in the staging database. You should supply the following parameters to this program:

- **Batch code.** The batch code associated with the appropriate table's insertion program. Refer to each table listed under [Master Data](#) and [Transaction Data](#) (in the Table Names matrices) for each insertion batch code / program.
- **Batch thread number.** Thread number contains the relative thread number of the process. For example, if you want to insert accounts into production in 20 parallel threads, each of the 20 execution instances receives its relative thread number (1 through 20). Refer to [Parallel Background Processes](#) for more information.
- **Batch thread count.** Thread count contains the total number of parallel threads that have been scheduled. For example, if the account insertion process has been set up to run in 20 parallel threads, each of the 20 execution instances receives a thread count of 20. Refer to [Parallel Background Processes](#) for more information.
- **Batch rerun number.** Rerun number is not used and should be left blank.
- **Batch business date.** Business date is the date supplied to the insertion programs and the date under which statistics will be logged.
- **Total number of commits.** This is the number of commits IN TOTAL that you want to perform. For example, if you have 1,000,000 accounts and you supply a value of 100; then a commit will be executed for approximately every 10,000 accounts.
- **Maximum minutes between cursor re-initiation.** This should only be populated if you want to override the default value of 15.
- **User ID.** User ID is only used to log statistics for the execution of the batch job.
- **Password.** Password is not used.
- **Language Code.** Language code is used to access language-specific control table values. For example, error messages are presented in this language code.
- **Trace program at start (Y/N), trace program exit (Y/N), trace SQL (Y/N) and output trace (Y/N).** These switches are only used during QA and benchmarking. If trace program start is set to Y, a message is displayed whenever a program is started. If trace program at exist is set to Y, a message is displayed whenever a program is exited. If trace SQL is set to Y, a message is displayed whenever an SQL statement is executed.

Recommendations To Speed Up Insertion Programs

The following points describe ways to accelerate the execution of the insertion programs:

- Before running the first insertion program:
 - Rebuild the index on the prime key on the old key / new key table (i.e., those tables prefixed with "CK").
 - Re-analyze the statistics on the old key / new key table (i.e., those tables prefixed with "CK"). For Oracle users, we strongly recommend using the Oracle-provided PL/SQL package to generate statistics rather than the analyze command.
 - Alter all indexes on the production tables being inserted into to be unusable.
- After the insertion programs have populated production data, rebuild the indexes and compute statistics for these tables. For Oracle users, we strongly recommend using the Oracle-provided PL/SQL package to generate statistics rather than the analyze command.

Run Balance Control Against Production

During this step, you rerun the balance control program, but this time against production. You do this to verify the balances in production are consistent with the values of receivables converted from your legacy application.

NOTE:

Submitting this process. You submit this process in the production database. Refer to [The Big Picture of Balance Control](#) for more information about the balance control processes. Refer to [Balance Control](#) for information about the page used to view the balances generated by this process.

Validate Production

During this step, you rerun the [object validation programs](#), but this time in production. We recommend rerunning these programs to confirm that the insertion programs have executed successfully. We recommend running these programs in random sample mode (e.g., validate every 1000 th object) rather than conducting a full validation in order to save time. However, if you have time, you should run these programs in full validation mode (to validate every object). Please refer to the various "Table Names" sections above for the respective names of the programs to run.

The Validation User Interface

The topics in this section describe the various pages that assist in the conversion effort.

Validation Error Summary

Navigate to **Admin > Conversion > Validation Error Summary** to view validation errors associated with the objects defined in [Master Data](#).

Description of Page

You can use **Table Name** to restrict errors to a specific object. If this field is left blank, all errors on all objects will be displayed.

The grid contains a separate row for each type of error. The following information is displayed:

- **Table Name** is the name of the main table associated with the object.
- **Message Category** and **Message Number** define the type of error. These fields are the unique identifier of the message that describes the error (the verbiage of this message is displayed in the **Message Text** column).
- **Count** contains the number of records with this error. Press the Go To button to see the individual records with the error.

Validation Error Detail

This page is used to view validation errors of a given type associated with one of the objects defined in [Master Data](#). This transaction is not intended to be invoked from the **Admin** menu. Rather, drill into the validation details from [Validation Error Summary](#).

Description of Page

Use **Table Name**, **Message Category**, and **Message Number** to define the object and the type of error you wish to display. The grid contains a separate row for each object with the given type of error. The following information is displayed:

- **Table Name** is the name of the main table associated with the object.

- **Record Identifier** is the unique identifier of the object with the error (e.g., the person ID, the account ID, the premise ID, etc.). Press the Go To button to transfer to the maintenance page associated with the object.
- **Message Category** and **Message Number** define the type of error. These fields are the unique identifier of the message that describes the error (the verbiage of this message is displayed in the **Message Text** column).

FK Validation Summary

Navigate to **Admin > Conversion > FK Validation Summary** to view foreign key validation errors associated with the objects defined in [Master Data](#).

Description of Page

You can use **Table Name** to restrict errors to a specific object. If this field is left blank, all errors on all objects will be displayed.

The grid contains a separate row for each type of error. The following information is displayed:

- **Table Name** is the name of the main table associated with the object.
- **Count** contains the number of records on this table that have this error.
- **Foreign Key Field Names 1 to 6** contain the names of the foreign keys contained on this table that have been found to be in error.
- **Foreign Key Values 1 to 6** contain the values within the foreign key fields that are found to be in error.

FK Validation Detail

This page is used to view foreign key validation errors of a given type associated with one of the objects defined in [Master Data](#). This transaction is not intended to be invoked from the **Admin** menu. Rather, drill into the validation details from [FK Validation Summary](#).

Description of Page

Use **Table Name** to specify the table you wish to view. The names and values of the foreign key fields on the table are displayed. The grid that follows contains the primary key values of this table's records that are in error. The following information is displayed:

- **Table Name** is the name of the main table.
- **FK Fields 1 to 6** are the names of the foreign keys contained in this table. Displayed alongside the key names are the values within these fields. These identify records on other tables to which this table's record is related. For example, the CI_PREM_GEO record identified by its displayed primary keys should be related to a Premise record with the Premise ID shown - it appears in this list only if there is something amiss with this relationship.

The Staging Tables

This section describes the objects into which your legacy data is mapped. For each object, we provide the following:

- A data model.
- An indication of which tables have system-assigned keys.
- The physical table names.
- The name of the batch control to submit to validate the object.

- The name of the program (and related batch control) that validates each table for referential integrity.
- The name of the program (and related batch control) that performs key assignment for each table.
- The name of the program (and related batch control) that inserts the table's rows into production from staging.
- Suggestions to assist in the conversion process.

WARNING:

We recommend you read this document on a browser (or using Word under windows) so you can take advantage of the [Color Coding](#).

NOTE:

Column details do not appear in this document. When you're ready to examine an object's tables, use the hyperlinks in the respective Table Names section to transfer to the [data dictionary](#). The data dictionary will show you the required columns, the foreign keys (and their related tables), the source code of the program that validates the contents of the table, and a host of other information that will assist the conversion process.

WARNING:

In the data models that appear below, you will find a variety of entities that are classified as either a control table or a lookup table. Please refer to [Color Coding](#) for more information about how to recognize such an entity.

A Note About Programs in the Table Names Matrices

For each object described in the master data and transaction data sections, there is a "table names" section that includes a matrix listing the name of each table that is part of the maintenance object. Included in the matrix is information about the programs provided to perform object validation, referential integrity validation, key assignment and insertion. The following are some points about these programs:

- One object validation program exists for the entire set of tables for the maintenance object. The **Object Validation Batch Control** column indicates the batch control used to submit the object validation. Refer to [Submitting Object Validation Programs](#) for more information. Drilling down on the hypertext allows you to see more information about the batch control, including the program associated with it.
- A referential integrity validation program exists for every table whose key includes a parent key of another object. As described in [Submitting Referential Integrity Validation Programs](#), these programs are submitted using a driver supplied by the system where the batch code for the appropriate table is provided. (The driver then executes the program whose name matches the batch code). The **Referential Integrity Validation Batch Control** column indicates the table's batch control / program name.
- One key assignment program exists for the parent table for the maintenance object. As described in [Submitting Key Assignment Programs](#), these programs are submitted using a driver supplied by the system where the batch code for the appropriate table is provided. (The driver then executes the program whose name matches the batch code). The **Key Assignment Batch Control** column indicates the table's batch control / program name.
- An insertion program exists for every table for the maintenance object. As described in [Submitting Insertion Programs](#), these programs are submitted using a driver supplied by the system where the batch code for the appropriate table is provided. (The driver then executes the program whose name matches the batch code). The **Insertion Batch Control** column indicates the table's batch control / program name.

Master Data

This section describes the various "master data" objects (e.g., person, account, meter, etc.) that must be created before you can convert transaction data.

NOTE:

Key Assignment Dictates The Order Of Conversion. The following contents are listed in the order in which the objects should be converted in order to maintain referential integrity.

Person

Each customer must have a person and an account object. This section describes the person object. Refer to [Account](#) for details about the account object.

Person Data Model

The following data model illustrates the person object.

Person Table Names

Data Model Name	Table Name	Generated Keys	Object Validation Batch Control	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Person	CI_PER	Yes CI_PER_K	VAL-PER		CIPVPERK	CIPVPERI
Name	CI_PER_NAME	No. The key is PER_ID plus a sequence number.		CIPVPMNV		CIPVPMNI
Person / Person	CI_PER_PER	No. The key is PER_ID1, PER_ID2, relationship type and start date.		CIPVPPEV		CIPVPPEI
Phone	CI_PER_PHONE	No. The key is PER_ID plus phone type.		CIPVPPHV		CIPVPPHI
Identifier	CI_PER_ID	No. The key is PER_ID plus identifier type.		CIPVPIDV		CIPVPIDI
Characteristic	CI_PER_CHAR	No. The key is PER_ID plus an edate and a char type.		CIPVPRCV		CIPVPRCI
Seasonal Address	CI_PER_ADDR_SEAS	No. The key is PER_ID plus a sequence number.		CIPVPSAV		CIPVPSAI

Person Suggestions

A person must have at least one row on the name table and at least one of the names must be marked as being the primary name.

A person must have at least one row on the identity table and at least one of the identities must be marked as being the primary ID.

The country and state are only necessary if the person has an override mailing address.

Account

Each customer must have a person and an account object. This section describes the account object, refer to [Person](#) for details about the person object.

Account Data Model

The following data model illustrates the account object.

Account Table Names

Data Model Name	Table Name	Generated Keys	Object Validation Batch Control	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Account	CI_ACCT	Yes CI_ACCT_K	VAL-ACCT		CIPVACCK	CIPVACCI
Bill Message	CI_ACCT_MSG	No. The key is account ID plus bill message code.		CIPVMSGV		CIPVMSGI
Autopay Option	CI_ACCT_APAY	Yes CI_ACCT_APAY_K		CIPVAAPV	CIPVAAPK Has dependencies	CIPVAAPI
Characteristic	CI_ACCT_CHAR	No. The key is ACCT_ID plus an edate and a char type.		CIPVACHV		CIPVACHI
Person/Account	CI_ACCT_PER	No. The key is account ID plus person ID.		CIPVACPV		CIPVACPI

Person/Account Address Override	CI_PER_ADDR_OVRD	No. The key is Account ID plus Person ID	CIPVPAOV	CIPVPAOI	
Non Cash Deposit	CI_NCD	No. The key is account ID plus seq number	CIPVNCDV	CIPVNCDI	
Credit Rating Tran	CI_CR_RAT_HIST	Yes CI_CR_RAT_HIST_K	CIPVCRTV	CIPVCRRK Has dependencies	CIPVCRTI
ADM Trigger	CI_ADM_RVW_SCH	No. The key is account ID plus date	CIPVARSV	CIPVARSI	

Account Suggestions

An account must have at least one row on the account / person table and at least one account / person must be marked as being the main customer. Please see column notes for the account / person table for inter-field validation in respect of the various switches (e.g., if main customer switch is on, then the person must also be financially responsible).

We recommend storing an ADM trigger ([CI_ADM_RVW_SCH](#)) for every account where the trigger date is the conversion date. This will cause the account to be reviewed by the [account debt monitor](#) when it next runs. We have supplied a dedicated batch process for this purpose that simply inserts a row in this table with the review date set equal to the current date. This will ensure that all converted accounts are reviewed after they are inserted into production. This program is named CIPVADMB and goes by the batch control ID of CNV-ADM.

If your legacy system has the equivalent of a credit rating or a cash only score, you should create credit rating transactions. The values you create need to be consistent with the beginning and threshold credit rating and cash-only points on the installation record or the account's CIS Division. Refer to the business process guide - customer information - how are credit rating transactions created for more information.

Landlord

Landlord Data Model

The following data model illustrates the landlord object.

Landlord Table Names

Data Model Name	Table Name	Generated Keys	Object Validation Batch Control	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Landlord	CI_LANDLORD	Yes CI_LANDLORD_K	VAL-LL		CIPVLNDK	CIPVLNDI
Revert Option	CI_LL_DETAIL	No. The key is LL_ID plus service type		CIPVLLDV		CIPVLLDI

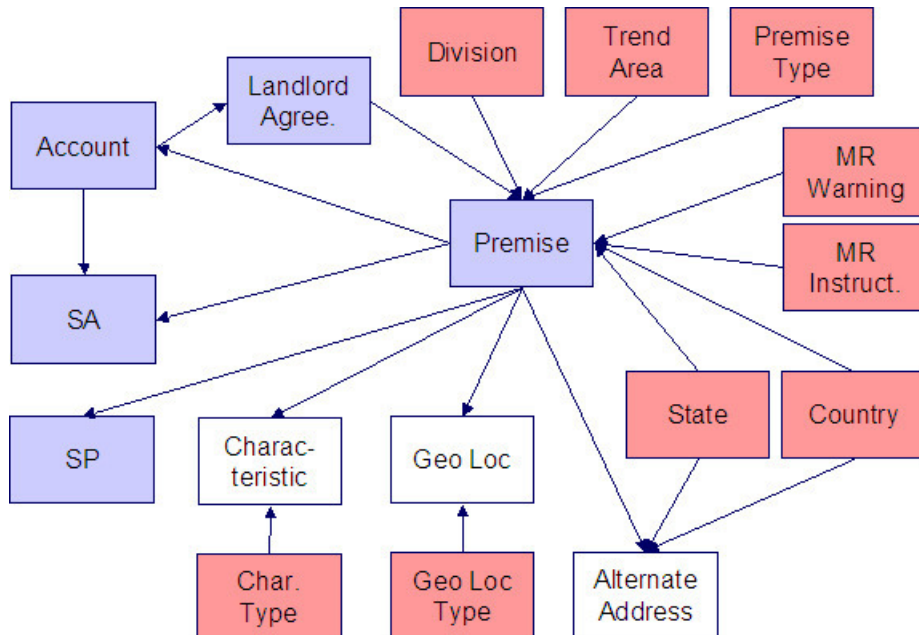

Landlord Suggestions

N/A.

Premise

Premise Data Model

The following data model illustrates the premise object.

Premise Table Names

Data Model Name	Table Name	Generated Keys	Object Validation Batch Control	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Premise	CI_PREM	Yes CI_PREM_K	VAL-PREM		CIPVPRMK Has dependencies	CIPVPRMI
Characteristic	CI_PREM_CHAR	No. The key is PREM_ID plus an edate and a char type.		CIPVPCHV		CIPVPCHI
Geo Loc	CI_PREM_GEO	No. The key is PREM_ID plus geo loc type.		CIPVPGOV		CIPVPGOI
Alternate Address	CI_PRM_ALT_ADDR	Yes CI_PRM_ALT_ADDR_K		CIPVAPAV	CIPVAPAK Has dependencies	CIPVAPAI

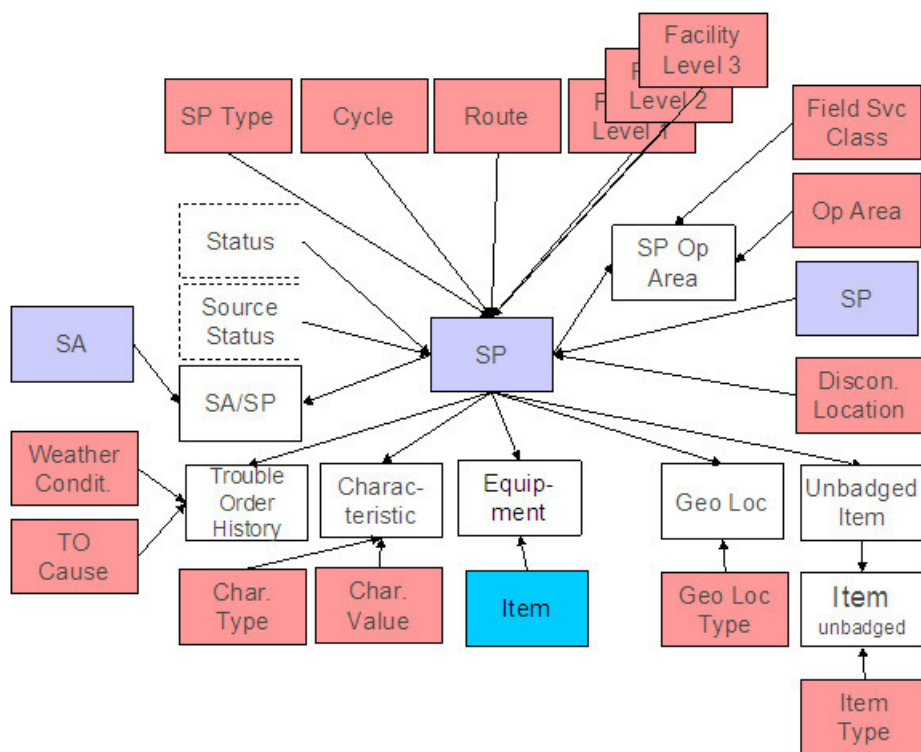

Premise Suggestions

N/A.

Service Point

Service Point Data Model

The following data model illustrates the service point object.

Service Point Table Names

Data Model Name	Table Name	Generated Keys	Object Validation Batch Control	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Service Point	CI_SP	Yes CI_SP_K	VAL-SP		CIPVSPPK	CIPVSPPI
					Has dependencies	
Characteristic	CI_SP_CHAR	No. The key is SP_ID plus an edate and a char type.		CIPVSPCV		CIPVSPCI
Equipment	CI_SP_EQ	No. The key is service point ID plus equipment (service point) ID.		CIPVSEQV		CIPVSEQUI
Geo Loc	CI_SP_GEO	No. The key is service point ID plus geo type.		CIPVSPGV		CIPVSPGI
Unbadged Item	CI_SP_MULT_ITEM	No. The key is SP_ID plus edate.		CIPVSPMV		CIPVSPMI

Item	CI_MULT_ITEM	No. The key is SP_ID, edate and item type.		CIPVSMIV		CIPVSMII
	CI_SP_OP_AREA	No. The key is SP_ID plus field service classification code		CIPVSPOV		CIPVSPOI
SA/SP	CI_SA_SP (note, this table really belongs to the SA object, it is included here for completeness)	Yes CI_SA_SP_K	CIPVSVAB	CIPVSAPV	CIPVSSPK Has dependencies	CIPVSAPI

Service Point Suggestions

N/A.

Service Agreement

Service Agreement Data Model

The following data model illustrates the service agreement object.

Service Agreement Table Names

Data Model Name	Table Name	Generated Keys	Object Validation Batch Control	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Service Agreement	CI_SA	Yes CI_SA_K	VAL-SA		CIPVSVAK Has dependencies	CIPVSAI
Characteristic	CI_SA_CHAR	No. The key is SA_ID plus an edate and a char type.		CIPVSACV		CIPVSACI
Contract Quantity Edate	CI_SA_CONT_QTY	No. The key is service agreement ID plus quantity type plus edate.		CIPVSAQV		CIPVSAQI
Message	CI_SA_MSG	No. The key is service agreement ID plus Bill message code.		CIPVSMGV		CIPVSMGI
Recurring Charge	CI_SA_RCHG_HIST	No. The key is service		CIPVSARV		CIPVSARI

		agreement ID plus edate.				
SA Relationship	CI_SA_REL	Yes CI_SA_REL_K	VAL-SARL	CIPVSRLV	CIPVSRLK Has dependencies	CIPVSRLI
Rate History	CI_SA_RS_HIST	No. The key is service agreement ID plus edate.		CIPVSAHV		CIPVSAHI
SA/SP	CI_SA_SP	Yes CI_SA_SP_K		CIPVSAPV	CIPVSSPK Has dependencies	CIPVSAPI
SA/SP Characteristic	CI_SA_SP_CHAR	No. The key is SA/SP Id plus char type plus effective date.		CIPVSSCV		CIPVSSCI
Tax Exempt	CI_SA_CONTERM - this table is also used for the next 2 entities, the key contains CONTERM_TYPE_FLG that controls the entity	No. This key is service agreement ID plus CONTERM_TYPE_FLG plus BF_CD plus START_DT		CIPVSAOV		CIPVSAOI
Contract Rider	CI_SA_CONTERM - this table is also used for the previous and next entities, the key contains CONTERM_TYPE_FLG that controls the entity	No. This key is service agreement ID plus CONTERM_TYPE_FLG plus BF_CD plus START_DT		CIPVSAOV		CIPVSAOI
Contract Value	CI_SA_CONTERM - this table is also used for the previous 2 entities, the key contains CONTERM_TYPE_FLG that controls the entity	No. This key is service agreement ID plus CONTERM_TYPE_FLG plus BF_CD plus START_DT		CIPVSAOV		CIPVSAOI
SA/Consumer Contract Product	C1_SA_CONT_PROD	No. This key is service agreement ID plus CONT_PROD_ID plus EFF_DT .		CIPVSCTV		CIPVSCTI

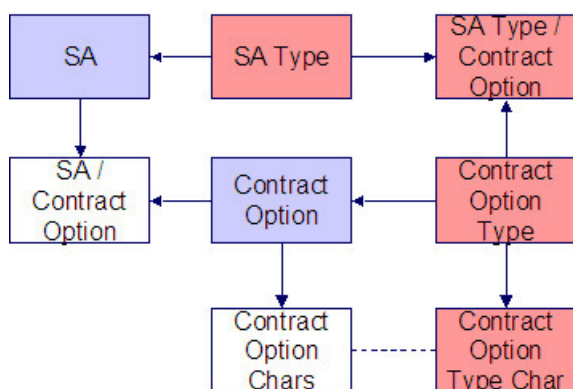

Service Agreement Suggestions

N/A.

Contract Options

Contract Options Data Model

The following data model illustrates the contract options objects.

Contract Options Table Names

Data Model Name	Table Name	Generated Keys	Object Validation Batch Control	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Contract Option	CI_COP	Yes CI_COP_K	VAL-COP		CIPVCOPK	CIPVCOPI
Contract Option Language	CI_COP_L	No. The key is CONT_OPT_ID plus language code		CIPVCOLV		CIPVCOLI
Contract Option Characteristics	CI_COP_CHAR	No. The key is CONT_OPT_ID plus CHAR_TYPE_CD plus EFFDT		CIPVCCFV		CIPVCCAI
SA / Contract Option	CI_SA_COP	Yes CI_SA_COP_K		CIPVSCPV	CIPVSCP	CIPVSCPI

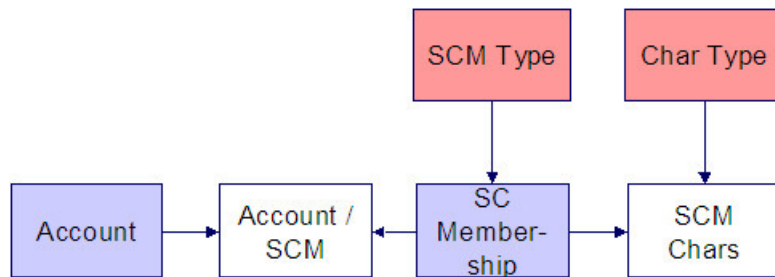

Contract Options Suggestions

N/A.

Service Credit Membership

Service Credit Membership Data Model

The following data model illustrates the Service Credit Membership objects.

Service Credit Membership Table Names

Data Model Name	Table Name	Generated Keys	Object Validation Batch Control	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Service Credit Membership	CI_SCM	Yes CI_SCM_K	VAL-SCM	CIPVSCBV	CIPVSCMK	CIPVSCMI
Service Credit Membership / Account	CI_SCM_ACCT	No. The key is SCM_ID plus ACCT_ID.		CIPVSCAV		CIPVSCAI
Service Credit Membership Characteristics	CI_SCM_CHAR	No. The key is SCM_ID plus CHAR_TYPE_CD plus EFFDT.		CIPVSCCV		CIPVSCCI

Service Credit Membership Suggestions

N/A.

Declaration

Declaration Data Model

The following data model illustrates the Declaration object.

Declaration Table Names

Data Model Name	Table Name	Generated Keys	Object Validation Batch Control	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Declaration	CI_DCL	Yes CI_DCL_K	VAL-DCL		CIPVDCRK	CIPVDCRI

Transaction Data

This section describes the tables in which your transaction data (e.g., bills, payments, meter reads, customer contacts, etc.) resides.

SP / Meter History and On/Off Event

SP / Meter Data Model

The following data model illustrates the service point / meter installation object.

SP / Meter Table Names

Data Model Name	Table Name	Generated Keys	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
SP/Meter History	CI_SP_MTR_HIST	Yes. CI_SP_MTR_HIST_K	CIPVSMHV	CIPVSMHK Has dependencies	CIPVSMHI
On/Off Event	CI_SP_MTR_EVT	No. The key is meter history ID plus sequence number.	CIPVSMEV		CIPVSMEI
Meter Location History	CI_MTR_LOC_HIS	Yes. CI_MTR_LOC_HIS_K	CIPVMLHV	CIPVMLHK	CIPVMLHI

SP / Meter Suggestions

In order to link a meter to a service point, you must

- Link the meter's meter configuration to the service point by inserting a record on the [CI_SP_MTR_HIST](#) table.
- In addition, you must also create a [CI_SP_MTR_EVT](#) record. Note the following about this record:
 - The value of the [SP_MTR_EVT_FLG](#) should be I (for installation).
 - The value of the [MTR_ON_OFF_FLG](#) should be 1 (on).
 - It must reference a read whose read date is the installation date. The reading can be a dummy value unless this customer has not been billed since the install date (i.e., the installation has taken place recently). In this situation, this read must be the true start read for the customer. Note, this read should also be linked to the SA/SP record associated with the SA that's linked to the SP as its start read.

Bill

Bill Data Model

This section contains information about the Bill's data model:

- Bill - Main
- Bill - Read Details
- Bill - FT
- Bill Characteristics
- Bill Messages, Bill Routing, and Bill Review Schedule

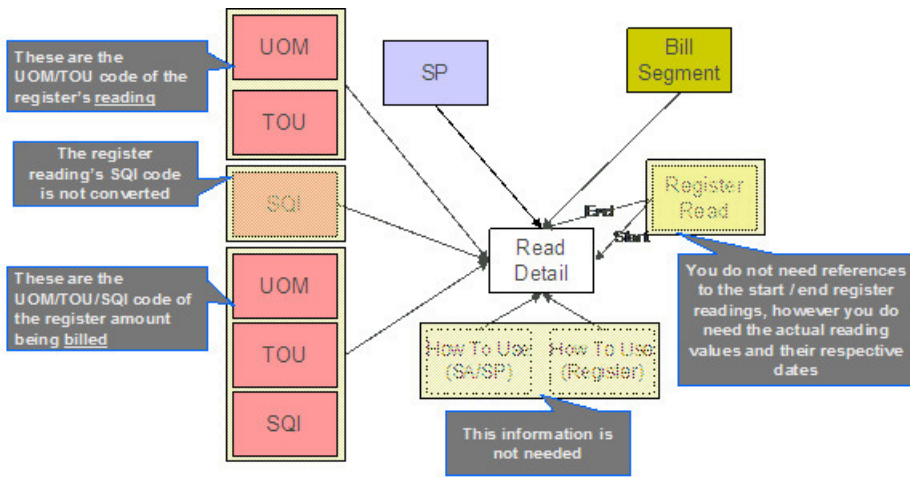

Bill - Main

The following data model illustrates the bill object.

Bill - Read Details

The following data model illustrates the FK references on the read detail entity (a bill segment has one or more read details if the bill segment is associated with metered service).

Bill - FT

The following data model illustrates the FT that must be associated with a bill segment.

Bill Characteristics

The following data model illustrates Bill Characteristics.

Bill Messages, Bill Routing, and Bill Review Schedule

The following data model illustrates Bill Messages, Bill Routing, and Bill Review Schedule.

Bill Table Names

Data Model Name	Table Name	Generated Keys	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Bill	CI_BILL	Yes CI_BILL_K	CIPVLLV	CIPVBILK Has dependencies	CIPVBLLI
SA Balance Snapshot	CI_BILL_SA	No. The key is bill ID plus SA ID.	CIPVBSAV		CIPVBSAI
Bill Segment	CI_BSEG	Yes CI_BSEG_K	CIPVSEGV	CIPVBSGK Has dependencies	CIPVSEGI
Calc Header	CI_BSEG_CALC	No. The key is bill segment ID and a sequence number	CIPVBSKV		CIPVBSCI
Calc Lines	CI_BSEG_CALC_LN	No. The key is bill segment ID, the header sequence number, and a sequence number	CIPVBSLV		CIPVBSLI
Read Detail	CI_BSEG_READ	No. The key is bill segment ID, SP ID and a sequence number	CIPVSRV		CIPVSRRI
Item Detail	CI_BSEG_ITEM	No. The key is bill segment id and a sequence number	CIPVBSIV		CIPVBSII
Service Quantity	CI_BSEG_SQ	No. The key is bill segment ID, uom code, tou code and SQL code	CIPVSQTV		CIPVSQTI
FT (financial transaction)	CI_FT	Yes CI_FT_K	CIPVFTV	CIPVFTXK Has dependencies	CIPVFTFI
FT GL (FT general ledger)	CI_FT_GL	No. The key is FT ID and a GL sequence number	CIPVFTGV		CIPVFTGI

Characteristics	CI_BILL_CHAR	No. The key is bill ID, char type code and a sequence number	CIPVBCHV	CIPVBCHI
Bill Messages	CI_BILL_MSGS	No. The key is bill ID and bill message code.	CIPVBLMV	CIPVBLMI
Bill Routing	CI_BILL_ROUTING	No. The key is bill ID and a sequence number	CIPVBLRV	CIPVBLRI
Bill Review Schedule	CI_BILL_RVW_SCH	No. The key is bill ID, bill review date and batch code.	CIPVBRVV	CIPVBRVI

Bill Suggestions

Most companies have found it impossible to load bill segment item, bill calculation header and lines with sufficient information and therefore these tables are not populated. See the comments in the above ERD's for more information.

Please populate the columns on the FT that's associated with the bill segment as follows:

- CUR_AMT should be set equal to the bill segment amount
- PAY_AMT should be set equal to the bill segment amount
- CRE_DTTM should be set equal to the bill segment end date / time
- FREEZE_SW should be "Y"
- FREEZE_DTTM should be set equal to the bill segment end date / time
- ARS_DT should be set equal to the bill segment end date
- CORRECTION_SW should be "N"
- REDUNDANT_SW should be "N"
- NEW_DEBIT_SW should be "N"
- NOT_IN_ARS_SW should be set to "N"
- SHOW_ON_BILL_SW should be set to "N"
- ACCOUNTING_DT should be set to the current date
- SCHED_DISTRIB_DT should be left blank
- CURRENCY_CD should be the currency on the installation record
- BAL_CTL_GRP_ID should be left blank
- XFERRED_OUT_SW should be set to "Y"
- PARENT_ID should be set to the bill ID
- SIBLING_ID should be set to the bill segment ID
- Do NOT create any GL details for the FT. If GL details are converted, ensure they are populated with the EXACT information SPL CC&B would use to create them. This information is used to create the reversing GL entry when the bill segment is canceled.

Payment

Payment Data Model

The following data model illustrates the payment object.

The following data model illustrates the FT that must be associated with a payment segment.

Payment Table Names

Data Model Name	Table Name	Generated Keys	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Payment	CI_PAY	Yes CI_PAY_K	CIPVPAYV	CIPVPAYK Has dependencies	CIPVPAYI
Payment Event	CI_PAY_EVENT	Yes CI_PAY_EVENT_K		CIPVPYEK Has dependencies	CIPVPYEI
Payment Event Characteristic	CI_PAY_EVT_CHAR	No. The key is PAY_EVENT_ID and a char type.	CIPVBLCV		CIPVBLCI
Payment Tender	CI_PAY_TNDR	Yes CI_PAY_TNDR_K	CIPVTNDV	CIPVTNDK Has dependencies	CIPVTNDI
Payment Segment	CI_PAY_SEG	Yes CI_PAY_SEG_K	CIPVPSGV	CIPVPSGK Has dependencies	CIPVPSGI
FT (financial transaction)	CI_FT	Yes CI_FT_K	CIPVFTFV	CIPVFTXK Has dependencies	CIPVFTFI
FT GL (FT general ledger)	CI_FT_GL	No. The key is FT id and a GL sequence number	CIPVFTGV		CIPVFTGI
Payment Tender Characteristic	CI_PAY_TNDR_CHAR	No. The key is PAY_TENDER_ID, plus a sequence number and a char type	CIPVTNCV		CIPVTNCI
Payment Characteristic	CI_PAY_CHAR	No. The key is PAY_ID, plus a sequence number and a char type	CIPVPYCV		CIPVPYCI

Payment Suggestions

We recommend that you use the system to create a single deposit control and link to it a single tender control using the PRODUCTION tables. The tender control should reference a tender source of "conversion". Use the prime key of the tender control as the foreign key on the tenders that you insert into the STAGING tables. This means you will have an invalid foreign key relationship on CI_PAY_TNDR (it will reference a tender control that doesn't exist).

After converting the payments:

- Re-access the tender control in production and enter the appropriate amounts (per tender type) to balance the tender control.
- Re-access the deposit control in production and enter the appropriate amounts to balance the deposit control.

Please populate the columns on the FT that's associated with the payment segment as follows:

- CUR_AMT should be set equal to the payment segment amount
- PAY_AMT should be set equal to the payment segment amount
- CRE_DTTM should be set equal to the payment segment date / time

- FREEZE_SW should be "Y"
- FREEZE_DTTM should be set equal to the payment segment date / time
- ARS_DT should be set equal to the payment segment date
- CORRECTION_SW should be "N"
- REDUNDANT_SW should be "N"
- NEW_DEBIT_SW should be "N"
- NOT_IN_ARS_SW should be set to "N"
- SHOW_ON_BILL_SW should be set to "N" on all payments other than payments that have been received since the last bill. For recent payments that you want to show on the next bill, this switch must be "Y"
- ACCOUNTING_DT should be set to the current date
- SCHED_DISTRIB_DT should be left blank
- CURRENCY_CD should be the currency on the installation record
- BAL_CTL_GRP_ID should be left blank
- XFERRED_OUT_SW should be set to "Y"
- PARENT_ID should be set to the payment ID
- SIBLING_ID should be set to the payment segment ID
- Do NOT create any GL details for the FT. If GL details are converted, ensure they are populated with the EXACT information SPL CC&B would use to create them. This information is used to create the reversing GL entry when the payment segment is canceled.

Adjustment

Adjustment Data Model

Adjustment Table Names

Data Model Name	Table Name	Generated Keys	Referential Integrity Validation Batch Control	Key Assignment Batch Control	Insertion Batch Control
Adjustment	CI_ADJ	Yes CI_ADJ_K	CIPVADJV	CIPVADJK Has dependencies	CIPVADJI
Adjustment Characteristic	CI_ADJ_CHAR	No. The key is ADJ_ ID and a char type.	CIPVADCV		CIPVADCI
Adjustment A/P Request	CI_ADJ_APREQ	Yes CI_ADJ_ APREQ_K	CIPVAPRV	CIPVAPRK Has dependencies	CIPVAPRI
FT (financial transaction)	CI_FT	Yes CLFT_K	CIPVFTFV	CIPVFTXK Has dependencies	CIPVFTFI

FT GL (FT general ledger)	CI_FT_GL	No. The key is FT ID and a GL sequence number	CIPVFTGV	CIPVFTGI
FT Process	CI_FT_PROC	No. The key is FT id and a sequence number	CIPVFTPV	CIPVFTPI

Adjustment Suggestions

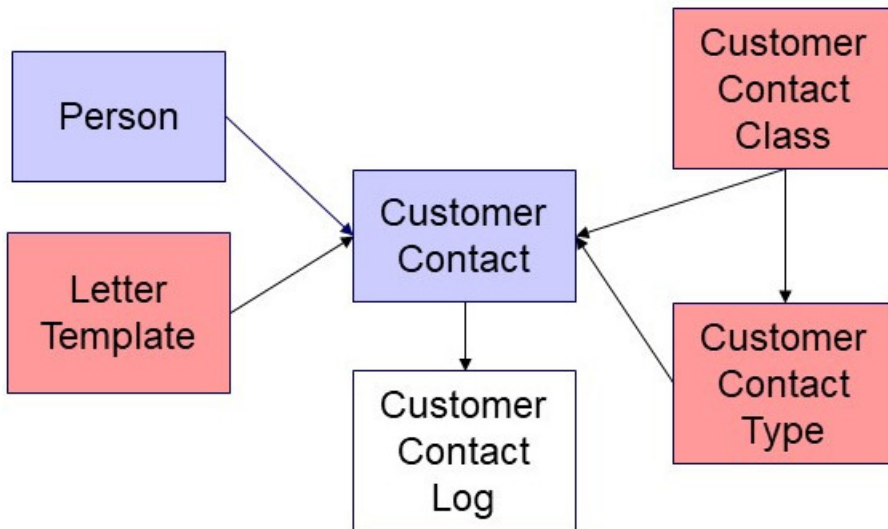

Please populate the columns on the FT that's associated with the adjustment as follows:

- CUR_AMT should be set equal to the adjustment amount
- PAY_AMT should be set equal to the adjustment amount
- CRE_DTTM should be set equal to the adjustment date / time
- FREEZE_SW should be "Y"
- FREEZE_DTTM should be set equal to the adjustment date / time
- ARS_DT should be set equal to the adjustment date
- CORRECTION_SW should be "N"
- REDUNDANT_SW should be "N"
- NEW_DEBIT_SW should be "N"
- NOT_IN_ARS_SW should be set to "N"
- SHOW_ON_BILL_SW should be set to "N" on all adjustments other than adjustments that have been generated since the last bill. For recent adjustments that you want to show on the next bill, this switch must be "Y"
- ACCOUNTING_DT should be set to the current date
- SCHED_DISTRIB_DT should be left blank
- CURRENCY_CD should be the currency on the installation record
- BAL_CTL_GRP_ID should be left blank
- XFERRED_OUT_SW should be set to "Y"
- PARENT_ID should be set to the adjustment's adjustment type
- SIBLING_ID should be set to the adjustment ID
- Do NOT create any GL details for the FT. If GL details are converted, ensure they are populated with the EXACT information SPL CC&B would use to create them. This information is used to create the reversing GL entry when the adjustment is canceled.

Customer Contact

Program Dependencies

The programs used to assign production keys are listed under [Master Data](#) and [Transaction Data](#) (in the Table Names matrices). Most of these programs have no dependencies (i.e., they can be executed in any order you please). The only exceptions to this statement are illustrated in the following diagram.

The tiers in this diagram contain a box for each table whose key assignment program is dependent on the successful execution of other key assignment programs. The numbers that appear in the boxes describe the order in which these programs must be executed.

Please refer to the various "Table Names" sections above for the respective names of the programs to allocate each table's keys.

WARNING:

Prior to running the key generation program for a particular object, it is required that any previously generated keys be cleared from the key allocation tables and the key allocation temporary storage table. It is recommended that the key allocation tables be analyzed between runs to maximize performance.

Appendix A - Entity Relationship Diagramming Standards

Because all data is stored in relational table, you need to be able to read diagrams that illustrate relationships between the various tables. The following entity diagram uses every diagramming notation used in the documentation:

Relationships

The solid line connecting the two entities that is terminated by an arrow represents a relationship between two entities. You read the relationship from the entity without the arrow to the entity with the arrow. For example in the following diagram, the line between Customer Class and Account illustrates that a Customer Class may have many Accounts, but an Account may be part of a single customer class.

Entity

Every box within the [Relationships](#) diagram represents an entity (i.e., a table). An entity may be a physical entity, such as a Person, or a logical construct, such as an Account.

Color Coding

If you can view this document in color, you will notice that each entity is colored. The color indicates the "subsystem" which governs the entity. Know the governing subsystem is important because:

- The system's menu structure is subsystem-oriented (i.e., if you know the subsystem, you will know how to use the menus to navigate to the page used to view and update the entity).

- The system's documentation is subsystem-oriented (i.e., if you know the subsystem, you will know which chapter contains information about the entity).

Some entities are not color-coded (i.e., they are white). These entities do not have a dedicated page, as they are part of a parent entity. For example, the Person / Account entity above is related to the Account object and does not have its own page. You must display the parent entity in order to view such an entity. For example, if you want to look at Person / Account information, you must go to the Account page.

The following table describes the colors utilized in the documentation:

Color	Subsystem
	Customer Information
	Admin (Control) Table. These tables are referenced as foreign keys on master and transaction tables. We do not document the names of these tables in this document as the table names are easily accessible using the Table transaction.
	N/A - the entity is maintained in respect of a higher level entity.
	N/A - the values in these types of entities are defined in a special table referred to as the lookup table. In order to determine the valid values for a column that references a lookup table, use the name of the column as the search value on the Look Up user interface.
	Meter Management
	Meter Reading
	Rates
	Billing
	Financial Transaction
	Payment
	Field Order
	Adjustment

Appendix B - Multiple Owners In A Single Database

In the schematic referenced in the [Introduction](#), you'll notice that there are two table owners in the system database. We refer to the first owner as "staging" and the second owner as "production".

The staging owner is linked to the tables into which you insert your pre-validated data. These tables have an owner ID of CISSTG.

NOTE:

Multiple staging databases. It is possible to have multiple staging databases. In this situation, each one would have a unique owner ID, e.g., CISSTG1, CISSTG2, etc.

The production owner is linked to the tables used by your production system. These tables have an owner ID of CISADM.

When the validation programs run against your staging data, they validate the staging data against the production control tables (and insert errors into the staging error table). This means that the SQL statements that access / update master and transaction data need to use the staging owner (CISSTG). Whereas the SQL statements that access control tables need to use the production owner (CISADM).

But notice that when these same programs run against production (Validate (b)), the SQL statements will never access the staging owner. Rather, they all point at the production owner.

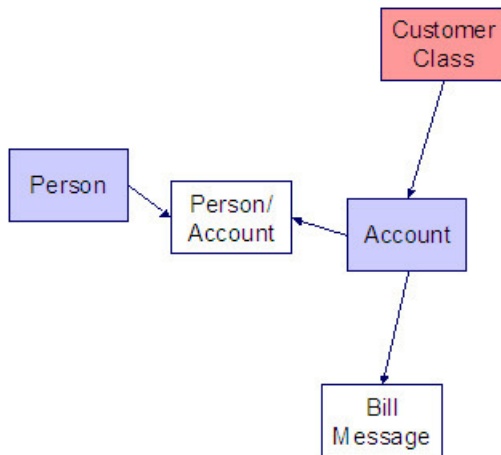

This is accomplished as follows:

- A separate application server must exist for each owner. Each application server points at a specific database user ID.
- The database user ID associated with the staging database uses CISSTG as the owner for the master and transaction tables, but it uses CISADM as the owner of the production control tables.
- The database user ID associated with the production database uses CISADM as the owner for the master, transaction, and control tables.

You may wonder why we went to this trouble. There are several reasons:

- We wanted to reuse the validation logic that exists in the programs that validate your production data. In order to achieve this, these programs must sometimes point at the staging owner, and other times they must point at the production owner (and this must be transparent to the programs otherwise two sets of SQL would be necessary).
- We wanted to let you use the application to look at and correct staging data. This can be accomplished by creating an application server that points at your staging database with the ownership characteristics described above.
- We wanted the validation programs to be able to validate your production data (in addition to your staging data). Why would you want to validate production data if only clean data can be added to production? Consider the following scenarios:
 - After an upgrade, you might want to validate your production data to ensure your pre-existing user-exit logic still works.
 - You may want to conduct an experiment of the ramifications of changing your validation logic. To do this, you could make a temporary change to user exit logic (in production) and then run the validation jobs on a random sample basis.
 - You forget to run a validation program before populating production and you want to see the damage. If you follow the instructions in this document, this should never happen. However, accidents happen. And if they do, at least there's a way to determine the ramifications.

While the redirection of owner ID's is a useful technique for the validation programs, it cannot be used by the key assignment and production insert programs? Why, because these programs have to access the same tables but with different owners. For example, the program that inserts rows into the Person table must select rows from the staging version of the Person table and insert them into the production version of the Person table.

This is accomplished as follows:

- Views exist for each table that exists in both databases. These views have hard-coded the database owner CISADM (production). For example, there is a view called CX_PER that points at person table in production.
- The key assignment and insertion programs use these views whenever then need to access production data.

Appendix C - Known Oddities

Be aware that the following tables reference master data (e.g., persons, accounts). This means that if you look at them using a user ID that defaults ownership to the staging level, you will not be able to see the related master data (because the person / account doesn't exist in the staging owner's tables).

- Collection Agency. References a person.
- Service Provider. References a person and a service agreement.
- 3 rd Party Payor. References an account.
- Tender Source. References a suspense account.

Defining Communication Options

Device Event Types

Understanding Device Event Types

Device Events

Device event types define properties common to specific types of events.

Device event types represent different types of events that can take place relative to a device. Examples of device events include power outages, power restoration, tampering alerts, and other events.

Device event types can be defined by the following attributes:

- **Standard Event Name:** the "standard" name of the event type. Device vendors may have their own specific names for device events. Only a single active device event type may be mapped to a given standard name at any time.
- **Device Event Category:** a category (defined as an Extendable Lookup) used to group device event types.
- **Reporting Category:** a category used to group device event types for reporting purposes.
- **Activity Type:** the activity type for activities created for device events of this type.

Device Event Mapping

The first step to device event type configuration is defining the list of standard event names that will be processed by the system. This is done by populating the Standard Event Name extendable lookup (D1-StdEventNameLookup). More information about this extendable lookup can be found in [About Device Events](#).

With the fully defined list of Standard Event Names each head-end specific event name (which is also called an external event name) that the system will receive from a given head-end should be mapped to a standard event name. This mapping is configured using a device event mapping extendable lookup. Each head-end system should have its own extendable lookup to define event name mapping in order to prevent possible conflicts between mappings. Each of these business objects should be defined as a child of the parent business object Device Event Mapping (D1-DeviceEventMappingLookup).

For example, head-end systems A and B might both use the same event name, such as the code "1", but this event might need to be mapped to "outage" for head-end system A but "tamper" for head-end system B.

The device event mapping extendable lookup business object is configurable. Each Oracle Utilities Smart Grid Gateway adapter includes a device event mapping lookup business object for the supported head-end system.

Lastly, each device event type is associated to a standard name. This means that as each device event that is received will go through the following mapping steps:

1. The head end specific event name is mapped to a standard event name using the head end specific device event mapping extendable lookup
2. The standard event name is mapped to a device event type
3. The device event type is used to select the appropriate device event business object

Device Event - Additional Processing

Certain device event business objects can be used to update master data as a result of device events received into the system. For example, when a utility's field worker arms a meter, the resulting device event can trigger an update to the device's arming status in the Oracle Utilities application. This processing is initiated by the Execute - Additional Processing system event

algorithm during the Additional Processing status of the business object's lifecycle.

The following base package business objects are configured to execute additional processing:

If a standard device event requires additional processing, the algorithms that execute the processing should be specified in the Additional Processing Algorithms list on the Standard Event Name extendable lookup for the event. The base package includes the additional processing algorithm Arm Meter ([D1-ARM-METER](#)).

Only a subset of base package device event business objects are configured to execute additional processing

Description	Business Object Name
Device Event Communication Response	D1-DeviceEventComResp
Standard Device Event	D1-StandardDeviceEvent

If additional processing is required for any business objects not listed above it can easily be added by configuring the algorithm Executer - Additional Processing System Event ([D1-EXTADDPRC](#)) in the Additional Processing status.

Reader Remarks

Reader remark types define properties common to specific types of reader remarks.

Reader remarks are a type of device event used to capture and/or record specific events or circumstances encountered when a meter reader is manually reading scalar meters. Reader remark types represent the different types of remarks that meter readers can record. Examples of reader remark types include evidence of tampering, broken seals, damaged meter, dog on premises, and other notices.

When creating a new device type there are the following options:

Name	Details	Business Object
Reader Remark Type	Provides the configuration for a reader remark type	D1-ReaderRemarkType

Field Activity Remarks

Field activity remark types define properties common to specific types of field activity remarks.

Field activity remarks are a type of device event used to capture and/or record specific events or circumstances encountered when a field worker is performing field work at a service point. Field activity remarks represent can represent situations that are found as well as actions that were taken in the field.

When creating a new device type there are the following options:

Name	Details	Business Object
Device Field Remark Type	Provides the configuration for a field activity remark type	D1-DeviceFieldRemarkType

Configuring Device Event Types

This portal is used to display and maintain a Device Event Type.

Refer to [Understanding Device Event Types](#) for more information.

You can access the portal from the **Admin > Communication > Device Event Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Event Type List:** This zone lists all Device Event Type records. Broadcast a record to display the details of the selected record.
- **Device Event Type:** This zone provides information about the selected Device Event Type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_DVC_EVT_TYPE](#).

Activity Types

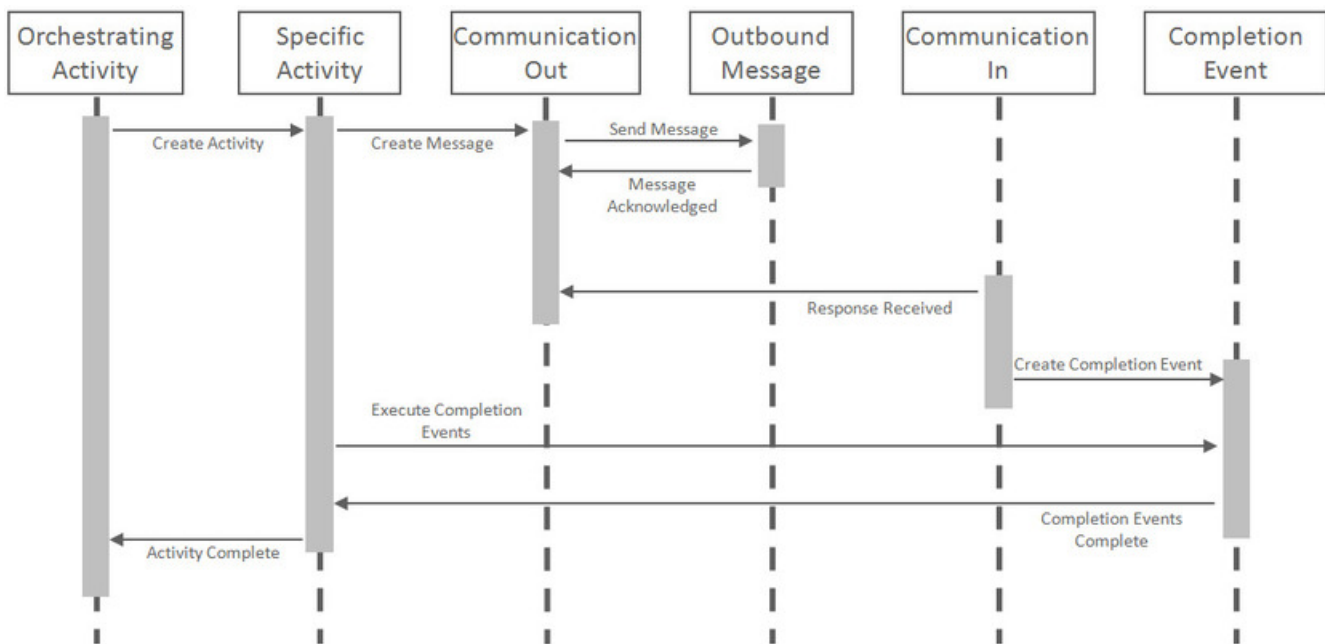

Understanding Activity Types

Activities are records of a communication or event related to a device, measuring component, service point or other entity in the system. Examples of activities include smart meter command request, field activities, meter read downloads (for manually read meters) or the combined event of a "last gasp" and "power up" message sent by devices when they detects they experience an outage.

Each type of activity is assigned to an activity type category, please refer to About Activities for more information about the activity type categories supported by base product.

Activities Orchestrate Communication

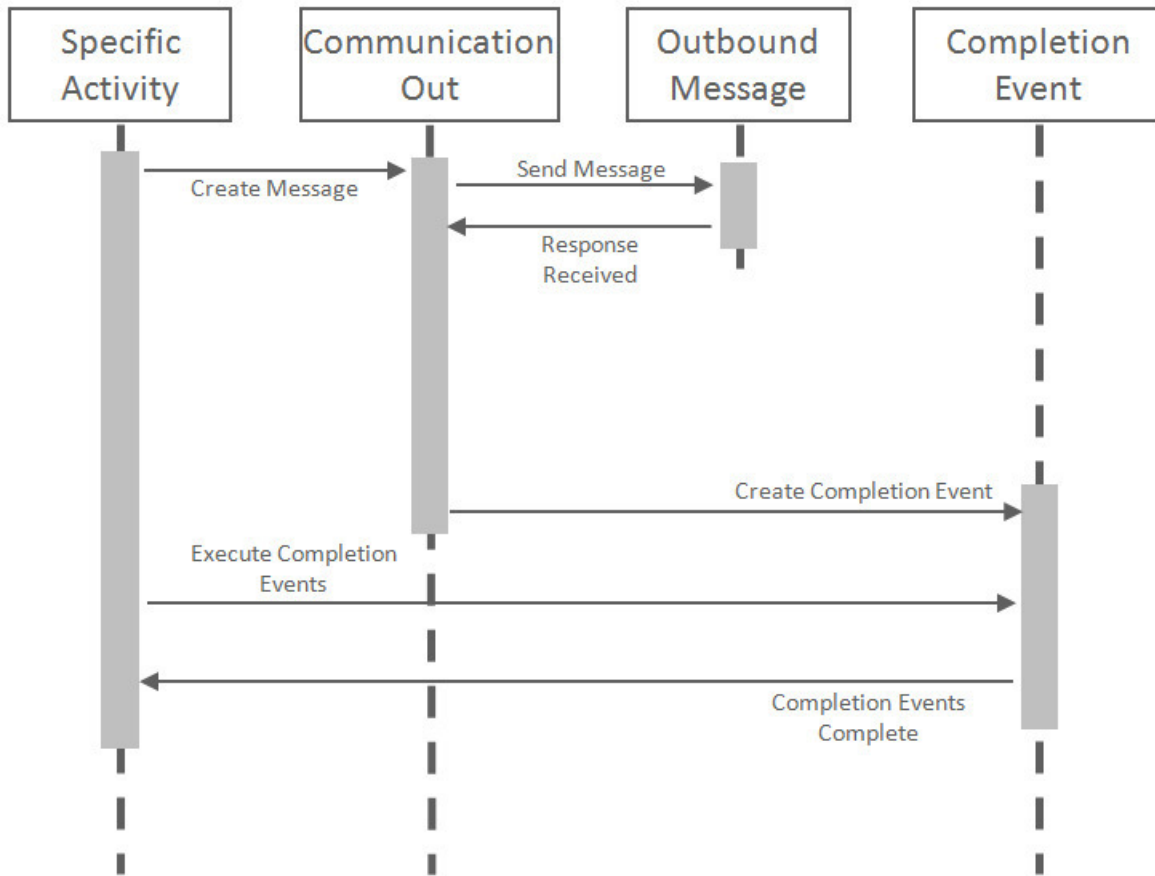

Certain types of activities such as request orchestrators, field activities, and command requests coordinate a large number of child transactions that represent the communication to and from an external application. The below diagram depicts a two way communication with an external system:

Each object in the sequence diagram has a distinct set of duties within the context of the communication:

- **Orchestrating Activity:** controls the overall intent of the communication. For example it may "Start Service" which would include initiating one-to-many specific activities to install the meter and begin the flow of the metered commodity to the service point.
- **Specific Activity:** can be initiated from an orchestrating activity or directly. These activities represent a single task to be carried out such as installing a meter or a remote disconnect smart meter command.
- **Communication Out:** orchestrates the communication to the external application and provides robust handling for any errors that might occur during that communication.
- **Outbound Message:** represents the message payload sent to the external system and the synchronous response.
- **Communication In:** orchestrates the handling of an asynchronous or unsolicited response from an external system.
- **Completion Event:** carries out the results of the communication. For example, in the case of a remote connect it would create the appropriate on off history entry for the device's installation event.

The below diagram involves many of the same objects but instead represents a one-way communication with an external system. All objects maintain the same duties described above with the addition of the communication out handling the synchronous response which contains the result of the message.

Important Activity Type System Events

The activity type supports several business object algorithm system events that relate to calculating the consumption for measuring components of that type:

- **Customer-Device Compatibility:** receives information about the activity being analyzed and returns an indication of whether the customer and device are compatible. This system event is primarily used in service order management. See algorithm type Ensure Device-Usage Calculation Group Compatibility ([D2-ENSDVCCMP](#)) as an example.
- **Override Device / Task:** receives information about the activity such as whether the device is installed at a service point, whether the service point is connected, where it is disconnected (if applicable), and the installation event status override. Based on those inputs it should determine the output device configuration type as well as the field activity business object and field task type. This system event is primarily used in service order management. See algorithm type Evaluate Smart Meter Opt-Out for Device Installation ([D2-EVSMOPDV](#)) as an example.

Configuring Activity Types

This portal is used to display and maintain a Activity Type.

Refer to Understanding Activity Types for more information.

You can access the portal from the **Admin > Communication > Activity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_ACTIVITY_TYPE](#).

Communication Types

Understanding Communication Types

Communication types define properties common to a specific type of communication. This single admin object covers both communication in and communication out types.

Communication types include types of communications between an application and an external system such as a head-end system or the work management system. These are outbound communications such as smart meter command requests or field activities as well as inbound communications such as a message response that indicates the results of a request.

Communication types typically provide configuration around exception handling:

- **To Do Type and Role:** identifies the To Do to be created when an error is encountered
- **Retry Frequency:** defines how often the communication should be retried. As many errors can be due to connectivity the ability to retry provides automatic resolution.
- **Maximum Retries:** provides an upper limit to the number of times a communication can be re-attempted
- Each communication type can have its own unique set of fields, please refer to the embedded help for that communication type for more details on those fields.

Configuring Communication Types

This portal is used to display and maintain a Communication Type.

Refer to [Understanding Communication Types](#) for more information.

You can access the portal from the **Admin > Communication > Communication Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Communication Type List:** This zone works differently than the typical zone that list types in that it displays both those communication types that have been configured as well as those communication types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Communication Type:** This zone provides information about the selected Communication Type

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_COMM_TYPE](#).

Service Task Types

Understanding Service Task Types

Service tasks types define properties common to specific types of service tasks.

Service task types represent types of tasks that can be performed by users of other Oracle Utilities applications, such as Oracle Utilities Customer Self Service or Oracle Utilities Network Management System. Examples of service tasks include self service meter reads, in which users enter their own meter reads via the Customer Self Service application, and service issue monitor types used when determining if service investigation is needed for a service point.

When creating a new record, the following options are available:

Name	Details	Business Object
Service Issue Monitor Type	The service issue monitor type defines the parameters for when a service investigative order should be created. It can also optionally define the completion parameters for that indicate the investigative order was successful in its purpose.	D1-ServiceIssueMonitorType
Self-Service Rate Compare Scenario Request Type	A simple description of a rate compare scenario request type.	D2-RateCompareScenarioRqstType
Self-Service Meter Read Task Type	Provides the default settings for meter reads created through self service.	D2-SSMeterReadTaskType

Configuring Service Task Types

This portal is used to display and maintain a Service Task Type.

Refer to [Understanding Service Task Types](#) for more information.

You can access the portal from the **Admin** > **Customer** > **Service Task Type**

The following zones may appear as part of the portal's **Main** tab page:

- **Service Task Type List:** This zone lists all Service Task Type records. Broadcast a record to display the details of the selected record.
- **Service Task Type:** This zone provides information about the selected Service Task Type.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [F1_SVC_TASK_TYPE](#).

Defining Data Extract Options

Analytics Configuration

This portal provides a bird's eye view of the configuration information for Oracle Utilities Analytics. It provides links and guidelines for the areas that need configuration to successfully run the extract transfer and load processes from Oracle Utilities Analytics.

Refer to the *Oracle Utilities Analytics Administration Guide* for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Bucket Configuration List.** This zone lists bucket configurations to set up.

- **BI-Related Business Objects Information.** This zone lists additional control entities to set up.

The following zones may appear as part of the portal's **OWB-Based ETL** tab page

- **Outbound Sync BOs and Algorithm List.** This zone lists business objects and algorithms involved in the extract process.
- **BI-Oriented Extendable Lookup.** This zone lists extendable lookups to set.
- **External Data Source Indicators List.** This zone lists the external identifiers of the various sources for your analytics data.

Note: Service Point business objects can make use of the following System Events:

- **Service Point Snapshot:** This system event defines the algorithm used to create a snapshot of the Service Point for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - Snapshot."
- **Usage Snapshot:** This system event defines the algorithm used to create a usage snapshot of the Service Point for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - Usage Snapshot."
- **Unreported Usage Analysis Snapshot:** This system event defines the algorithm used to create a snapshot of the Service Point's consumption since the last usage transaction for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - Unreported Usage Analysis Snapshot."
- **SP VEE Exception Snapshot:** This system event defines the algorithm used to create a snapshot of VEE exceptions for the Service Point for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - VEE Exception Snapshot."

Consumption Extract Type

Understanding Consumption Extract Type

The Consumption Extract Type controls which service point's measurements are extracted for Oracle Utilities DataConnect, what type of measurement is extracted, and how the measurements are grouped into TOU periods (if preferred).

The Consumption Extract Type also controls the request type used for creating Consumption Extract Requests of this type, how frequent automated requests are created for incremental extract, the batch jobs that are triggered for extracting data and the algorithms that extract, format, and write the data that is extracted.

Refer to the [Oracle Utilities DataConnect](#) integration section for more details on how this object is specifically put into use.

Configuring Consumption Extract Type

This portal is used to display and maintain a Consumption Extract Type.

Refer to [Understanding Consumption Extract Types](#) for more information.

You can access the portal from the **Admin > Integration > Consumption Extract Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Consumption Extract Type List:** displays all of the Consumption Extract Types so you can choose the one you want to display in more detail
- **Consumption Extract Type:** shows the specific configuration for the selected Consumption Extract Type

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_CONS_EXT_TYPE](#).

Defining Aggregation Options

Standard Aggregation

Configuring an Out-of-the-box Aggregation

Aggregation calculations should be run on an as needed basis. This can include running the following batches:

- Scanning for new aggregation dimension (**D1-ADS**): This process is applicable if the system is configured to use aggregation dimension scanners to detect new aggregation dimensions (such as a service point referencing a new transformer for which an aggregator measuring component doesn't currently exist)
- Performing aggregation calculations (**D2-AGG**): this batch handles the summarization of measurement values in order to create aggregated measurements.

Note that aggregation calculations should precede usage transaction processing if aggregated values serves as input to the calculation of bill determinants.

Refer to the [About Aggregations](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more information on this functionality. Refer to [Understanding Measuring Component Types](#) for information on Measuring Component Types provided for aggregation.

Understanding an Example Out-of-the-box Aggregation

The Oracle Utilities Meter Data Management base package includes an aggregation that aggregates measurement quantities for constituent measuring components based on postal code and service type dimensions. The table below outlines the types of objects used in this aggregation, based on the steps outlined above), and the specific objects for each type.

Dependency Order	Object Type	Base Package Example
1	Aggregator Measuring Component Business Object	D2-Aggregator (Aggregator - Postal and Service Type)
2	Aggregator Measuring Component UI Maps	Display: D2-AggMCDisp (Service Type and Postal Aggregator-Display) Maintenance: D2-AggMCMaint (Service Type and Postal Aggregator-Maintenance)
3	Aggregator Business Object Info Algorithm	D2-AMC-INFO (Service Type and Postal Aggregator - Information)
4	Find Constituent Measuring Components Algorithm	D2-DET-CMC (Find Constituent Measuring Components Based on Service Type and Postal)
5	Measuring Component Type	D2-AggregatorType (Aggregator Type)
6	Query Zone for Consumption Statistics Portal	D2-AGGMCQRY (Aggregator Search)
7	Dimension Scanner Activity Business Object	D2-ActivityAggDimScanner (Aggregator Creator - Postal / Service Type)
8	Dimension Scanner Activity UI Maps	Display: D2-AggDimScannerActDisp (Aggregator DS Activity-Display) Maintenance: D2- AggDimScannerActMaint (Aggregator DS Activity-Maintenance)
9	Dimension Scanner Activity Business Object Info Algorithm	D2-ADS-INFO (Aggregator Dimension Scanner Information)
10	Enter Algorithm for Scan State	D2-CRE-AGGMC (Aggregator MC Creation for Post Code and Service Type)

Refer to the [About Aggregations](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Creating a New Custom Aggregation

This section describes the overall process for creating a new custom Aggregation.

Refer to the [About Aggregations](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Execute the following steps:

1. Create a business object for the aggregator measuring component. This will flatten the dimensional value(s) into searchable characteristics. Whether this business object is a parent or a child of another aggregator business object depends on when periodic aggregation should occur:
 - a. If you want the periodic aggregation to occur when another aggregation occurs, it can be a child business object (meaning that it inherits the lifecycle (and therefore the deferred monitor) of the parent)
 - b. If you want to schedule its periodic aggregation independently from other aggregation business objects, this must NOT be a child business object as it will require its own deferred monitor (and deferred monitors can only be defined on parent business objects)
2. Create UI maps for the aggregator business object as follows:
 - a. One to display the aggregator measuring component (Display)
 - b. One to allow user to change / add a new one (Maintenance)

NOTE: A newer alternative to creating UI Maps would be to use UI Hints directly within the Business Object.

3. Create an info plug-in for the aggregator business object that concatenates together its dimension types and values.
4. Create a "Find Constituent Measuring Components" algorithm and plug it on the aggregator business object. This will be passed the aggregator measuring component and the from and to date/times. It will insert the constituent measuring component IDs and the respective from / to date-time of each onto a temporary table.
5. Create a measuring component type instance and reference the new aggregator measuring component business object (as well as the types of constituent measuring component types that should be aggregated).
6. Create a query zone for Consumption Statistics search to allow users to find the aggregator measuring component.

Optional steps:

1. Create a business object for the dimension scanner activity. This should be a child business object of the base package dimension scanner business object.
2. Create UI maps for the activity business object, as follows:
 - a. One to display the dimension scanner activity (Display).
 - b. One to allow users to change/add a new one (Maintenance).

NOTE: A newer alternative to creating UI Maps would be to use UI Hints directly within the Business Object.

3. Create an info plug-in that will describe what it scans.

4. Create an Enter algorithm on the Scan state that finds distinct combinations of the dimensional values and creates new aggregator measuring components when new ones are detected.

NOTE: You can reuse the base package deferred monitor batch control called **Aggregation Dimension Scanner Monitor (DI-ADS)**.

Dynamic Aggregation

Dynamic Aggregation Configuration Overview

Standard aggregation processing uses specific algorithms configured to work with a specified set of dimensions. For example, the base package Service Type and Postal aggregation uses specific algorithms for dimension scanning and finding constituent measuring components.

In contrast, dynamic aggregation uses dynamic queries for the dimension scanning, find constituents, and aggregation processes. These dynamic queries are based on configuration of administrative data, including:

- **Data Sources** define the source of data to be aggregated, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or other sources of data.
- **Aggregation Measuring Component Types** define the most important properties of aggregation measuring components used to store aggregated data.
- **Aggregation Groups** define the ordering of a series of related aggregations and the schedule of aggregation.
- **Measuring Component Sets** define the dimensions and criteria by which aggregation will be performed.

Aggregation Master Configuration

The Aggregation Master Configuration defines common parameters used with aggregation processing, including:

- Batch Controls used by the dimension scan and aggregation process, for both scheduled and adhoc execution.
- Details for how the system compares interval and billing data for the same set of customers in order to use only one source or other.

Data Sources

Understanding Data Sources

Data Sources define the source of data to be aggregated, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or measuring component sets. Data sources also define configurations used when generating dynamic queries used by aggregation processing.

Data Source Classes

Data sources are defined by classes, each of which is based on a specific business object, and determines the type of configuration used by aggregation processing. More specifically, the data types configured on the data source are used when generating dynamic queries used by aggregation processing.

The table below lists the data source classes and the business object and configuration options for each. Consult the embedded help for more information about the specific configuration options used by each data source class.

Data Source Class	Usage	Business Object	Configuration Options
Measurements from US Service Points	Used when aggregating data from measuring components linked to service points via a usage subscription.	D1-DataSourceMeasurements	Measuring Component Types
Badged Items	Used when aggregating data from badged items.	D1-BadgedItemsDataSource	Item Types
Billed Service Quantities	Used when aggregating data based on billed services quantities.	D1-DataSourceBilledSerQuantity	Usage Subscription Types
Measuring Component Sets	Used when aggregating data from measuring component sets. Data sources of this class are used with composite aggregation.	D1-DataSourceMCSet	Usage Subscription Types
Unbadged Items	Used when aggregating data from unbadged items.	D1-DataSourceUnbadgedItems	Item Types
Measurements from US Direct Links	Used when aggregating data from measuring components directly linked to a usage subscription.	D1-DataSourceMeasurementDirect	Measuring Component Types
Service Point Quantities	Used when aggregating data based on service point quantities.	D1-DataSourceSPQuantities	Service Point Quantity Types
Attribute and Measurement Data Snapshot	Used when aggregating data based on data snapshots	D1-MasterAndMsrmtDataSnapshot	Measurement Data Snapshot Types

Data Source Template SQL

Data sources also provide template structured query language (SQL) used when generating dynamic queries used by aggregation processing. This template SQL is used as the basis for dynamic queries, and is extended by additional SQL generated from the data source configuration as well as configuration defined for measuring component sets, measuring components, and measuring component types that reference the data source. Template SQL is provided via the Data Source SQL (D1-DataSourceSQLLookup) extendable lookup. Values for this extendable lookup are used as the **Option Value** for the following business object options on the data source business object.

- **Dimension Scanner SQL:** The template SQL used when dimension scanning. This SQL is extended by the criteria, dimensions, and individually managed items configured on the measuring component sets being processed.
- **Find Constituents SQL:** The template SQL used when finding constituents. This SQL is extended by attributes defined on the aggregator measuring components being processed.
- **Aggregation SQL:** The template SQL used when performing aggregation. This SQL is extended by the value identifiers defined on the measuring component type of the aggregator measuring components being processed.

Configuring Data Sources

This portal is used to display and maintain data sources.

Refer to [Understanding Data Sources](#) for more information.

You can access the portal by selecting **Admin**, then **Aggregation**, then **Data Source**.

The following zones may appear as part of the portal's **Main** tab page:

- **Data Source List:** This zone lists all data source records. Broadcast a record to display the details of the selected record.
- **Aggregation Data Source:** This zone provides information about the selected data source.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_DATA_SRC](#).

Configuring Data Source Template SQL

Template SQL used when generating dynamic queries used in aggregation processing is defined in the Data Source SQL (D1-DataSourceSQLLookup) extendable lookup. The base package data source business objects reference appropriate base package values from this extendable lookup.

For example, the **Aggregation SQL** option on the Measurements from US Service Points data source business object (D1-DataSourceMeasurements) references the “D1_MSRMT_FROM_US_SP_MCTYPE_SQL” value from the Data Source SQL extendable lookup.

If an implementation requires template SQL that differs from the base package, custom extendable lookup values can be created and referenced on the data source business object.

When creating custom template SQL, start from an existing extendable lookup value. Select the value that most closely matches your requirements and use the **Duplicate** function to create a copy, and edit the SQL as needed.

Use the following procedure to add a custom extendable lookup value to a data source business object.

1. Add a business object option of the appropriate type to the data source business object. For instance, if creating custom SQL for aggregation, add an **Aggregation SQL** option.
2. Enter a **Sequence** higher than the base package option.
3. Specify the custom extendable lookup value in the **Option Value** field.

Dynamic Aggregation Measuring Component Types

Understanding Dynamic Aggregation Measuring Component Types

Like other measuring component types, dynamic aggregation measuring component types define the most important properties of a measuring component. In this case, they define the properties of aggregator measuring components.

Measuring component types used by dynamic aggregation use many of the same attributes as other types of measuring components, but some attributes are used differently. Some attributes used specifically by dynamic aggregation include:

Measuring Component Business Object: This should be an aggregator measuring component business object, such as one of the following:

- Aggregator Interval (D1-AggregatorInterval)
- Aggregator Scalar (D1-AggregatorScalar)
- Aggregator Customer Quantities (D1-AggregatorCustomerQuantity)
- Aggregator Items Measuring Component (D1-AggregatorItems)

Measurement Business Object: Aggregated measurements can be based on either the Measurement (D1-Measurement) business object or the Aggregation Measurement (D1-AggregationMeasurement) business object (based on the Aggregation Measurement maintenance object).

Data Source: The source of the data that will be aggregated and the specific type of data that should be aggregated. Note that the **Service Type** of the data source, as determined by its associated objects (e.g. Measuring Component Type, Device Type, Service Point Type), must match the **Service Type** for this measuring component type.

Value Identifiers: These store the values of UOM, TOU, and SQI that identify the measurements to be aggregated. For each value identifier either the **Value Calculation Method** or **Value Derivation Algorithm** must be defined (not both). These define how measurement values are calculated or derived during aggregation processing.

Refer to [Understanding Measuring Component Types](#) for more information about measuring component types.

Configuring Dynamic Aggregation Measuring Component Types

The **Measuring Component Type** portal is used to display and maintain dynamic aggregation measuring components.

Refer to [Understanding Dynamic Aggregation Measuring Component Types](#) for more information about dynamic aggregation measuring components.

Refer to [Configuring Measuring Component Types](#) for more information about working with measuring component types.

Aggregation Groups

Understanding Aggregation Groups

Aggregation Groups define the ordering of a series of related aggregations based on a set of configured Measuring Component Sets. Aggregation groups define the following attributes for aggregations performed for its Measuring Component Sets:

- The **Time Zone** for aggregated data
- **Aggregation Scheduling** can be based on either a Defined Lag, or a Processing Timetable.
 - **Defined Lag** scheduling uses the following parameters:
 - **Aggregation Cut Off Time:** The end time for aggregation calculations performed for Aggregation Measuring Components for Measuring Component Sets associated with the Aggregation Group. This is used to ensure a consistent end time for aggregation periods. This is especially useful when aggregating other aggregations.
 - **Aggregation Lag:** The number of days between the date on which aggregation calculations are performed and the end date of the aggregation period. This defines the time period between the aggregation calculation date and the aggregation horizon that serves to allow all measurements to arrive. This together with the Aggregation Horizon is used to determine the start and end dates of an aggregation period. For example, with an Aggregation Horizon of 5 and an Aggregation Lag of 2, aggregation calculations performed on January 9 would be for an aggregation period of January 3 through January 7. The next day (January 10), the aggregation period would shift to January 4 through January 8.
 - **Aggregation Horizon:** The number of days in the aggregation period for Aggregation Measuring Components for Measuring Component Sets associated with the Aggregation Group. This reflects the time period during which there's a potential change in measurement data for one or more of the measuring components associated with Aggregation Measuring Components. This together with the Aggregation Lag is used to determine the start and end dates of an aggregation period.
 - **Processing Timetable** scheduling uses a Processing Timetable Type to drive aggregation schedule.

Aggregation groups can be used to perform aggregations for Analytical or Settlement purposes (defined by the Aggregation Category).

Aggregation Group Runs

Aggregation group runs represent individual aggregation executions for an individual aggregation group. Aggregation group runs are used to capture the relevant details for an aggregation and track the status of the execution of the aggregation for each of the Measuring Component Sets for the aggregation group.

Aggregation group runs for a specific aggregation group are listed in the **Aggregation Group Run** zone on the **Aggregation Group** portal. This zone displays the following for each aggregation group run:

- Run Number
- Run Type (Scheduled vs. Ad Hoc)
- Status (Pending, In Progress, Completed, or Error)
- Aggregation Horizon Start
- Aggregation Horizon End
- Details

Details for a specific aggregation group run can be viewed by broadcasting the run in the **Aggregation Group Run** zone. The following is displayed for the selected run in the **Aggregation Group Run Details** zone:

- Sequence
- Measuring Component Set
- Initiation Method
- Batch Run

Configuring Aggregation Groups

This portal is used to display and maintain aggregation groups.

Refer to [Understanding Aggregation Groups](#) for more information.

You can access the portal from **Admin > Aggregation > Aggregation Group**.

The following zones may appear as part of the portal's **Main** tab page:

- **Aggregation Group List:** This zone lists all aggregation group records. Broadcast a record to display the details of the selected record.
- **Aggregation Group:** This zone provides information about a selected aggregation group.
- **Aggregation Measuring Component Sets:** This zone lists measuring component sets associated with the selected aggregation group. Click **Resequence** to change the order of the measuring component sets in the aggregation group. Click **Add** to add a new measuring component set to the aggregation group.
- **Aggregation Group Run:** This zone lists individual aggregation runs performed for the selected aggregation group. Broadcast a record to display the details of the selected record. This zone displays up to 10 records. If there are more than 10 records, use the **Previous** and **Next** buttons to navigate between pages of records. Click **Add** to execute an ad hoc aggregation group run.
- **Aggregation Group Run Details:** This zone displays details for a selected aggregation group run.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [D1_AGG_GROUP](#).

Measuring Component Sets

Understanding Measuring Component Sets

Measuring component sets are used to define the dimensions and criteria by which aggregation will be performed.

A measuring component set's **Measuring Component Type** defines the Measuring Component and Measurement Type to be used in capturing aggregation results, as well as the aggregation functions that will be used on the source transnational data and the Data Source that will identify where that transnational data will be retrieved from.

Measuring component sets are associated with an **Aggregation Group**, which controls when and how aggregation is processed. This includes the sequence in which the aggregation group's measuring component sets are processed, as well as the method by which aggregation processing is initiated for each (this information can be found in the **General Processing** section).

A measuring component set's **Measuring Component Set Class** defines the way in which the measuring component set is used in the aggregation process. Measuring component set classes are based on the measuring component set's business object, and can include:

- **Aggregation Foundation** measuring component sets are used to aggregate transactional data, such as measurements from service points linked via usage subscriptions or billed service quantities.
- **Aggregation Composite** measuring component sets are used to aggregate data from a set of other aggregations (which can be based on either foundation or other composite measuring component sets).
- **Adhoc** measuring component sets are used to aggregate data based on an adhoc, user-defined set of measuring components.

See **Foundation and Composite Aggregation** in [Dynamic Aggregation Processing](#) for more information.

Dimensions, Criteria, and Individually Managed Items

The **Dimensions** and **Criteria** defined for the measuring component set are used by the dimension scanning process to identify individual aggregation measuring components that should be created. Measuring components are also created for each **Individually Managed Item** for which data matches the item's configuration.

- **Dimensions** identify the attributes by which data should be aggregated. Dimensions can include characteristics, identifiers, market participants, and values from specific tables and columns. For example, aggregating data by loss profile code, service point type and service provider would require defining dimensions for a Loss Profile Code characteristic, the Service Point Type column from the Service Point table, and the Service Provider column from the Device table.

NOTE: When configuring measuring component sets for aggregation of data from measurement data snapshots, the **Source Type** and **Source Entity** should be "Attribute Data Snapshot".

- **Criteria** define the ways in which the dimensions are evaluated through a series of inclusions, exclusions, or both. For example, to aggregate data for the "AGG-E-COM" and "AGG-E-RES" service point types, but NOT for devices from the "ELEC" service provider, criteria could be defined to include both of service point type values and exclude the "ELEC" service provider.

NOTE: When configuring measuring component sets for aggregation of data from measurement data snapshots, the **Source Type** and **Source Entity** should be "Attribute Data Snapshot".

- The criteria provided for **Individually Managed Items** is used to identify specific customers that should be aggregated in isolation from all other data that matches the **Dimensions** and **Criteria** defined for the measuring component set.

More specifically, the dimension scanning template SQL (derived from the data source) is extended by the **Dimensions**, **Criteria**, and **Individually Managed Items** configured on the measuring component set being processed.

Consult the embedded help for more information about the specific configuration options used by **Dimensions**, **Criteria**, and **Individually Managed Items**. The Source Type and Source Entity values are defined in the Aggregation Criteria Source Type (D1-CriteriaSourceTypeLookup) extendable lookup. Refer to [Configuring Aggregation Criteria Source Types](#) for more information about this extendable lookup.

The manner in which the criteria provided will be evaluated is defined in formulas configured in the **Criteria Processing** section. Consult the embedded help for more information about defining criteria processing formulas.

Configuring Measuring Component Sets

This portal is used to display and maintain measuring component sets.

Refer to [Understanding Measuring Component Sets](#) for more information.

You can access the portal from **Admin > Aggregation > Measuring Component Set**.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Set:** This zone displays details of a selected measuring component set.
- **Dimensions:** This zone lists the dimensions used to identify the attributes by which the aggregation should be analyzed. Note: Data in this zone is edited by clicking the **Edit** button in the **Measuring Component Zone**.
- **Criteria:** This zone lists the criteria that limits the data to be aggregated through a series of inclusions, exclusions, or both. Note: Data in this zone is edited by clicking the **Edit** button in the **Measuring Component Zone**.
- **Individually Managed Items:** This zone lists the criteria used to identify specific customers that should be aggregated in isolation from all other data that matches the dimensions and criteria defined for the measuring component set. Note: Data in this zone is edited by clicking the **Edit** button in the **Measuring Component Zone**.
- **Measuring Component Set Participants:** This zone displays the measuring components that are in the Measuring Component Set Participant table for the measuring component set. For each measuring component, this zone displays the most recent and last measurement date/times.

Where Used

Follow this link to open the data dictionary where you can view the tables that reference [DI_MEASR_COMP_SET](#).

Configuring Aggregation Criteria Source Types

The options in the **Source Type** and **Source Entity** drop-down lists used when configuring Dimensions, Criteria, and Individually Managed Items are defined in the Aggregation Criteria Source Type (D1-CriteriaSourceTypeLookup) extendable lookup. The measuring component set business objects reference this extendable lookup.

Each of the base package Source Type values (Characteristic, Identifier, Market Participant, and Table) are records in this extendable lookup. The Source Entity values for each of these are defined in the corresponding record.

For example, the “Table” Source Type defines the base package “Table” Source Entity values (Device, Device Event, Measuring Component, Service Point, Usage Subscription, and Usage), along with criteria path details for each (based on data source class).

If an implementation requires Source Type or Source Entity values that differ from the base package, custom extendable lookup values can be created.

When for creating custom values for this extendable lookup, start from an existing extendable lookup value. Select the value that most closely matches your requirements and use the **Duplicate** function to create a copy, and edit as needed.

Configuration Step-by-Step

This section outlines the steps involved when configuring dynamic aggregation.

Create Device and Service Point Administrative Data

Many of the objects used in dynamic aggregation reference other device- and service point-related administration data, such as measuring component types, service point types, usage subscription types, etc. Make sure this data is in place before configuring entities used with dynamic aggregation.

Create Data Sources

Create data sources for each source of data from which data will be aggregated. Note that implementations can have multiple data sources of each class with different data type configuration (Measuring Component Types, Item Types, Usage Subscription Types, etc.). For example, an implementation with 15 measuring component types might want to aggregate data differently based on subsets of measuring component types. In this case, each subset of measuring component types could be defined on a different data source.

If applicable, create custom Template SQL extendable lookup values and add them to Data Source business objects as appropriate.

Create Aggregation Measuring Component Types

Create the aggregation measuring component types that will be used to define the attributes of the measuring components that will be created during aggregation processing.

Aggregation measuring component types reference an appropriate Data Source. Continuing the example above, each subset of measuring component types (each defined on a separate data source) would require a separate aggregation measuring component type.

Create Aggregation Groups

Create the aggregation groups that will be used to control aggregation processing, including aggregation groups for both foundation and composite aggregation processing.

Note: When initially creating aggregation groups, define only the basic data for each (name, category, and optional time zone). Add measuring component sets to aggregation groups when creating the latter in the next step.

Create Measuring Component Sets

Create the measuring component sets that will define the “buckets” by which the aggregated data will be grouped.

Measuring component sets reference aggregation measuring component types and aggregation groups.

Create custom Source Type records (if applicable).

Revise Aggregation Groups (if needed)

After creating measuring component sets, adjust the sequence of each within its aggregation group as appropriate. For example, this would be necessary if measuring component sets are created and added to aggregation groups in an order that differs from their intended sequence.

Extending Dynamic Aggregation

The dynamic aggregation functionality provides extensive flexibility through configuration of data sources, measuring component types, and measuring component sets to handle complex aggregation requirements. However, some implementations may require functionality and configuration options beyond that provided in the base package. For instance, an implementation may need to aggregate data of a source and type not covered by the base package data sources or use different dimensions and criteria or queries for aggregation processing.

In circumstances like these, the dynamic aggregation functionality can be extended through use of the Oracle Utilities Application Framework’s Configuration Tools (see [Configuration Tools](#)) and other options. This section outlines some of the possible approaches to extending this functionality.

Data Source Business Objects: If an implementation requires aggregation of a data type of source beyond those provided with the base package data source business objects, custom business objects can be created to support this requirement. Key considerations when creating custom data source business objects include:

- Configuration options such as “Sourced Measuring Component Types” or “Sourced Usage Subscription Types”
- Values for the “Aggregation SQL”, “Dimension Scanner SQL”, and “Find Constituents SQL” business object options from the Data Source SQL extendable lookup.
- Algorithms for the “Generate SQL For Data Source” system event that leverage the configuration options defined for the data source

Data Source SQL Extendable Lookup Values: If an implementation requires template SQL that differs from the base package, custom values for the Data Source SQL extendable lookup can be created and referenced on the data source business object. When creating custom template SQL, start from an existing extendable lookup value. Select the value that most closely matches the requirements and use the **Duplicate** function to create a copy, and edit the SQL as needed.

Aggregation Measuring Component Type Business Objects: If an implementation requires capturing data for measuring component types not provided in the base package, the base package aggregation measuring component type business objects can be extended as appropriate. Key considerations when creating custom measuring component type business objects include:

- Algorithms for the “Generate SQL For MC Type” system event that leverages the Value Identifiers and other information defined for the measuring component type

Aggregation Measuring Component Business Objects: If an implementation requires capturing data for measuring components not provided in the base package, the base package aggregation measuring component business objects can be extended as appropriate. Key considerations when creating custom measuring component business objects include:

- Algorithms for the “Generate SQL For Aggregator MC” system event that leverages the Value Identifiers and other information defined for the measuring component type
- Algorithms for the “Find Constituents” system event that uses the “Generate SQL for Aggregator MC” algorithm, data source configuration, and other configuration to find constituent data for aggregation
- Algorithms for the business object’s “Active” state, including data aggregation and value derivation

Measuring Component Set Business Objects: If an implementation requires capturing data for measuring component sets not provided in the base package, the base package aggregation measuring component set business objects can be extended as appropriate. Key considerations when creating custom measuring component set business objects include:

- Algorithms for the “Generate SQL For MC Set” system event
- Algorithms for the business object’s lifecycle states, as appropriate

Aggregation Criteria Source Type Extendable Lookup Values: If an implementation requires Source Type or Source Entity values for measuring component sets that differ from the base package, custom extendable lookup values can be created. When creating custom values for this extendable lookup, start from an existing extendable lookup value. Select the value that most closely matches the requirements and use the **Duplicate** function to create a copy, and edit as needed.

Defining Consumption Synchronization Options

Configuring Consumption Synchronization

NOTE: Refer to [Introduction to Consumption Sync](#) for additional functional information about how consumption synchronization works.

Keeping consumption synchronized between two measuring components that meter the same quantity but at different frequencies is a complicated task. As such the configuration for this process is diffuse and requires settings across several key areas of the system to be aligned. This section will help guide you through the process of configuring consumption synchronization.

The consumption synchronization process is really a collection of processes within Oracle Utilities Meter Data Management that all work together to ensure that quantities between related channels remain consistent:

- **Estimation VEE Rules:** several rules align consumption between related channels. These rules allow estimations to be refined based on higher quality measurements from a related channel. These rules are core to the consumption synchronization process. In simple scenarios where a few intervals are missing for an interval measuring component these rules are all that are necessary for synchronization with the related channel (note: it requires that the related channels data for that same time period has already been processed through to final measurements). For more information on these rules please visit the following sections:
 - Interval Adjustment from Scalar
 - Scalar Calculation from Interval
 - Scalar Proration
 - Sum Check
 - Final Measurement Validation

NOTE: Refer to [About IMD Estimations](#) for more information about these rules

- **Periodic Estimation:** both the interval and scalar variations of periodic estimation play an important role in consumption synchronization by ensuring that both channels of data are without gaps. In simple scenarios where one channel is missing data and the other is not periodic estimation is all that is require to produce synchronized consumption. It is important to note that this process itself does not perform estimations but rather it is responsible for creating estimation initial measurements to trigger the estimation VEE rules.
- **Consumption Synchronization Activities:** these activities work to fix alignment issues that occur when data for the related channels are processed out of order or when there are complex outage scenarios. These activities are created when higher quality data is received for one channel and the related channel has measurements that are eligible to be recalculated and adjusted to align the total consumption for the period across the two channels. It is important to note that this process itself does not perform estimations but rather it is responsible for creating estimation initial measurements to trigger the estimation VEE rules.

Device Configuration Type

As a default the system will not generate consumption synch activities for related measuring components. Turning on consumption synchronization activities is done through a few key fields on the device configuration type:

- **Keep Consumption Reference MC in Sync:** defines if the related MCs should be kept in sync. It can be configured to provide a one way synchronization from primary to secondary or a two way synchronization between primary and secondary.
- **Minimum Condition to Sync Primary MC:** when the secondary measuring component can initiate synchronization of the primary this provides an ability to limit those situations to when the incoming data is of a minimum quality.
- **Sum Check VEE Exception Type:** provides further ability to limit initiation of synchronization. When configured the synchronization activities will only be created when the initial measurement being processed encounters a VEE exception of the type configured. More specifically, a sum check VEE exception which will indicate that the two channels are out of synch by a minimum tolerance amount. This can be used to avoid synchronization either when there is no difference between the channels or when there is only a small difference between the channels.

NOTE: Additional detail about these fields can be found in the embedded help for the device configuration type.

Register Auto-Read Measuring Component Type

The configuration available for the register auto-read measuring component type has an indirect impact on the consumption synchronization process. This configuration is primarily intended to allow for a register to re-evaluate previously created estimations when new more accurate readings are received even when no related measuring components exist. Where

this has impact to the consumption synchronization process is that when a new scalar reading is received after a period of estimation it will result in the time period for that new initial measurement being expanded into the past. This is because any estimates prior to this new higher quality initial measurement will be logically removed and the start reading for the initial measurement will in turn be the last non-estimated measurement prior to the initial measurement. This creates an initial measurement that spans the entire period for which estimations exist and as a result when a consumption synchronization activity is generated it will result in that same period of time being re-evaluated on the related measuring component.

This functionality is controlled by a few key fields on the register auto-read measuring component type:

- **Ignore Estimates as IMD Start Reading:** controls whether estimates directly previous to newly received incoming initial measurement should be logically removed when that newly received initial measurement data is non-estimated.
- **Flag Future Estimates as Do Not Use:** controls whether estimates that come directly after newly received incoming initial measurements should be logically removed when that newly received initial measurement data is non-estimated
- **Actuals or Corrections Initial Re-Estimation:** works in tandem with the above two fields. When either scenario results in measurements being logically removed this field, when turned on, will reset the last contiguous measurement date/time for the measuring component making it eligible once more for periodic estimation. With the end result being that those estimated measurements that were removed would recreated as new estimates.

Measuring Components

In order for consumption synchronization to work it must know that two measuring components are related in a way that indicates they are measuring the same consumption. This is achieved by configuring the "Consumption Reference Measuring Component" field on the measuring component.

Not only does this establish the relationship but it also establishes which measuring component is considered to be primary and which is considered to be secondary.

A measuring component is considered to be secondary when it holds the relationship to the Consumption Check Measuring Component (the primary measuring component).

For example, consider the following related measuring components.

- Scalar Measuring Component: ER-SM-007 / 1 / Electric kWh Daily
- Interval Measuring Component: ER-SM-007 / 2 / Electric kWh 60min

If the scalar measuring component is the primary measuring component, it does NOT specify a "Consumption Reference Measuring Component", and the interval measuring component specifies the scalar measuring component as the "Consumption Reference Measuring Component".

If the interval measuring component is the primary measuring component, it does NOT specify a "Consumption Reference Measuring Component", and the scalar measuring component specifies the interval measuring component as the "Consumption Reference Measuring Component".

It is important to note that pending initial measurements for the secondary measuring component are processed by the [D1-IMD](#) batch process after the initial measurements for the primary measuring component. This ensures that the primary measuring component's final measurements will be available to the secondary measuring component's initial measurements VEE process to provide better quality estimations and validations.

Initial Load and Manual Initial Measurement Algorithms

Key to the consumption synchronization process are the algorithms that reside on initial load and manual initial measurements for both scalar and interval measuring components. These algorithms contain logic to identify final measurements on a related channel that are consumption synchronization eligible (typically estimated).

These algorithms allow definition of:

- The consumption synchronization activity created
- The condition range that defines consumption synchronization eligible final measurements

Please refer to the algorithm type descriptions for more information:

Algorithm Type	Description	Where used
D1-UPD-DTMC	Update Latest Measurement Date/Time on MC with Consumption Sync	D1-InitialLoadIMDIInterval D1-ManualIMDIInterval
D1-UDTSCMCRE	Update Latest Measurement Date/Time on Scalar MC with Consumption Sync	D1-InitialLoadIMDScalar D1-ManualIMDScalar

Consumption Synchronization Activities

The consumption synchronization activities are initiated by initial measurements and are responsible for generating the appropriate estimation initial measurements to re-evaluate any consumption synchronization eligible final measurements for the related measuring component being processed.

These activities can be associated to one or more initiating initial measurements and are able to handle a broad combination of time periods which are not required to be contiguous.

If any generated estimation initial measurement does not finalize processing will be halted and details about the failed estimation initial measurement will be provided.

The following table identifies the catalogue of consumption synchronization activities:

Activity Type	Description	Activity Business Object
Related MC Consumption Sync - Scalar	This activity is generated to re-evaluate consumption sync eligible final measurements on scalar measuring components. One estimation initial measurement will be created per measurement needing to be re-evaluated.	D1-RelMCREScalar
Related MC Consumption Sync - Interval	This activity is generated to re-evaluate consumption sync eligible final measurements on interval measuring components. One estimation initial measurement will be created per contiguous set of interval measurements needing to be re-evaluated. Note the generated initial measurements will include non-consumption sync eligible final measurements which will help to feed into the estimation process to provide more accurate results.	D1-RelMCREInterval
Gap Period Consumption Sync	This activity will re-evaluate both measuring components in the relationship for a wider time period than the initiating initial measurement. Specifically the time period will be the total contiguous period of consumption sync eligible final measurements across both channels in the relationship.	D1-GapPeriodConsumpnSync

Each consumption synchronization activity has an algorithm that performs the core logic of the consumption synchronization process.

These algorithms allow definition of:

- The condition range that defines consumption synchronization eligible final measurements

Please refer to the algorithm type descriptions for more information:

Algorithm Type	Description	Where used
D1-RE-SCMC	Scalar MC Consumption Sync	D1-RelMCREScalar
D1-RE-INTVMC	Interval MC Consumption Sync	D1-RelMCREInterval
D1-GAPCSYNC	Gap Period Consumption Sync	D1-GapPeriodConsumpnSync

Periodic Estimation

The algorithm that initiates periodic estimation which is plugged in to the Smart Meter device business object has a key configuration setting related to consumption synchronization:

- **MC Type to Process First:** determines whether interval or scalar measuring components should be estimated first. This should be set to process whichever measuring component type is considered to be primary first.

Please refer to the algorithm type description for more information:

Algorithm Type	Description	Where used
D1-PERESTM	Periodic Estimation	D1-SmartMeter

Related Batch Controls

There are a few batches involved with Consumption Synchronization:

- **Related MC Consumption Sync ([D1-RMCRE](#)):** this processes any pending consumption synchronization activities.
- **Related MC Consumption Sync - Retry Act ([D1-RMCRR](#)):** this retries any consumption synchronization activities that fail to the Issue Detected state.

Defining Dashboard Options

Configuring the MDM Operational Dashboard

This section describes the process for configuring the MDM Operational Dashboard.

Refer to the [Using the MDM Operational Dashboard](#) section of the *Oracle Utilities Meter Solution Business User Guide* for a information on this functionality.

Configuration for the MDM Operational Dashboard is performed by adding or changing a Master Configuration. You can access the portal from the **Admin > General > Master Configuration**.

Once the Master Configuration search screen returns, configure both the **MDM Operational Dashboard Configuration** record. Use the Add button beside the record to configure for the first time. If a record has already been added, then click the Edit button instead. Use the embedded help to guide you through the meaning of each configuration field.

This dashboard also leverages a method of pre-staging data known as Statistics Snapshots. Refer to the *Framework Administrative User Guide* for more information on Statistics Snapshots. For additional information see [About Statistics](#) in the Oracle Utilities Application Framework *Administrative User Guide*.

A method for tracking Performance Targets (also known as Service Level Agreements) is available within the MDM Operational Dashboard as well. To understand how to set up Performance Targets, refer to [About Performance Targets](#) in the Oracle Utilities Application Framework *Administrative User Guide*. The Performance Targets you configure will then be leveraged on the **Batch Performance** and/or **Database** tabs of the MDM Operational Dashboard.

Configuring the Customer Operational Dashboard

This section describes the process for configuring the Customer Operational Dashboard.

Refer to the [Using the Customer Operational Dashboard](#) section of the for more information on this functionality.

Configuration for the Customer Operational Dashboard is performed by adding or changing a Master Configuration. You can access the portal from the **Admin > General > Master Configuration**.

Once the Master Configuration search screen returns, configure the **Customer Operational Dashboard Configuration** record. Use the Add button beside the record to configure for the first time. If a record has already been added, then click the Edit button instead. Use the embedded help to guide you through the meaning of each configuration field.

This dashboard also leverages a method of pre-staging data known as Statistics Snapshots. Refer to [About Statistics](#) in the *Oracle Utilities Application Framework Administrative User Guide* for more information.

A method for tracking Performance Targets (also known as Service Level Agreements) is also available in the Customer Operational Dashboard. To understand how to set up Performance Targets, refer to [About Performance Targets](#) in the *Oracle Utilities Application Framework Administrative User Guide*. The Performance Targets you configure will then be leveraged on the **Batch Performance** page of the Customer Operational Dashboard.

Configuring the Service Order Operational Dashboard

This section describes the process for configuring the Service Order Operational Dashboard.

Refer to the [Using the Service Order Operational Dashboard](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Configuration for the Service Order Operational Dashboard is performed by adding or changing a Master Configuration. You can access the portal from the **Admin > General > Master Configuration**.

Once the Master Configuration search screen returns, locate the **Service Order Management Master Configuration** record. Use the Add button beside the record to configure for the first time. If a record has already been added, then click the Edit button instead. The **Chart Options** section is the primary area for adding configuration that will affect the dashboard. Use the embedded help to guide you through the meaning of each configuration field.

Configuring the Service Order Trends Dashboard

This section describes the process for configuring the Service Order Trends Dashboard.

Refer to the [Using the Service Order Trends Dashboard](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Configuration for the Service Order Trends Dashboard is performed by adding or changing a Master Configuration. You can access the portal from the **Admin > General > Master Configuration**.

Once the Master Configuration search screen returns, locate the **Service Order Management Master Configuration** record. Use the Add button beside the record to configure for the first time. If a record has already been added, then click the Edit button instead. The **Chart Options** section is the primary area for adding configuration that will affect the dashboard. Use the embedded help to guide you through the meaning of each configuration field.

Defining Measurement Reprocessing Options

Configuring Measurement Reprocessing

This section describes the process for configuring Measurement Reprocessing.

Refer to the [About Measurement Reprocessing](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Activity Type Configuration

Configuration for Measurement Reprocessing is performed by adding or changing an Activity Type. You can access the portal from the **Admin > Communication > Activity Type**.

Once the Activity Type search screen returns, locate the following records:

- **Measurement Reprocess Activity - Interval:** this Activity Type handles measurement reprocessing for interval Measuring Components.
- **Measurement Reprocess Activity - Scalar:** this Activity Type handles measurement reprocessing for scalar Measuring Components.

Use the Add button beside the record to configure for the first time. If a record has already been added, then click the Edit button instead. Use the embedded help to guide you through the meaning of each configuration field. By adding these Activity Types you are activating the process within Oracle Utilities Meter Data Management that will monitor changes to either the Measuring Component multiplier changes or Install Event installation constant. If either of these attributes change for a device, then a new Activity will be created that attempts to reprocess the measurements for the affected period.

Related Batch Controls

There are a few batches involved with Measurement Reprocessing:

- **Measurement Reprocessing Monitor (D1-MRAC):** this processes any new Measurement Reprocessing activities that are created.
- **Measurement Reprocessing - Retry Monitor (D1-MRER):** this retries any Measurement Reprocessing activities that fail to the Issue Detected state.

Information Lifecycle Management (ILM)

Understanding Information Lifecycle Management (ILM)

Information Lifecycle Management (ILM) is a separately licensable component of Oracle Utilities that works in tandem with Oracle database feature of the same name.

For further background on the overall ILM process see the [Information Lifecycle Management](#) chapter of the Oracle Utilities Application Framework *Administrative User Guide*.

This section provides an overview of the components used by the Information Lifecycle Management functionality, including:

- ILM-Enabled Maintenance Objects: Single Retention Period
- ILM-Enabled Maintenance Objects: Multiple Retention Periods
- Adjusting Eligibility of Non-Final Transactions
- Archive Eligibility Hierarchy
- Multiple Retention Period Eligibility Crawling Strategies

Refer to the [Information Lifecycle Management](#) chapter of the Oracle Utilities Application Framework *Administrative User Guide* for general information about how ILM works with OUAF applications.

ILM-Enabled Maintenance Objects: Single Retention Periods

The majority of Maintenance Objects support a single retention period. They can either inherit the system wide retention days that are configured on the ILM Configuration master configuration or they can have a retention period specified via the Maintenance Object option ILM Retention Period in Days.

For these objects either the Maintenance Object specific retention period or the system wide retention period will apply to all transactions.

ILM-Enabled Maintenance Objects: Multiple Retention Periods

For several Maintenance Objects the retention period may vary based on the type of transaction. For example, initial measurement data for non-billed units of measure such as voltage might be archived much more rapidly than measurements that feed into the production of billing determinants.

These maintenance objects are differentiated from the single retention period maintenance objects in a few ways:

- The primary table for the entity has an additional column Retention Period (RETENTION_PERIOD) that captures the retention period in days for each transaction. This value is populated based on the ILM Configuration - MDM master configuration.
- There is additional configuration available on the ILM Configuration -MDM master configuration to define multiple retention periods by maintenance object specific criteria
- Initial Measurement Data: retention periods can be specified by type of IMD (Interval vs Scalar), and primary UOM of the measuring component
- Device Events: retention periods can be specified by device event type category
- Activities: retention periods can be specified by activity type category
- There is a special ILM Crawler batch that supports crawling transactions by their specific retention periods
- A combination of each transactions ILM Date and Retention Period are considered when identifying records to evaluate for eligibility. Refer to batch controls ILM Crawler - Device Event ([DI-DECRL](#)), ILM Crawler - IMD ([DI-IMDCL](#)), or ILM Crawler - Activity ([DI-ACTCR](#)) for more details.
- There is an additional maintenance object option ILM Date Partition Months which feeds into the ILM Crawler batch to delay processing until all records on a partition would be eligible. This is explained later in this section under the header Multiple Retention Period Eligibility Crawling Strategies.

Adjusting Eligibility of Non-Final Transactions

As delivered Oracle Utilities maintenance objects allow non-final transactions to be eligible for archive. This is a logical approach when transactional data has a very long retention period (e.g. 3 year old non-final Initial Measurement Data is unlikely to have relevance and in many circumstances shouldn't be finalized).

If non-final transactions should not be eligible for archive this can be controlled at either the Maintenance Object (MO) or Business Object (BO) level:

- **MO - ILM Restrict By Status (Y/N):** Setting this to "Y" opts into the ability to restrict archiving by status, this is required to be set for either of the MO or BO level restrictions to be considered. To enforce the status it requires that either the **ILM Restrict By BO Final Status (Y/N)** or **ILM Final Status Field Value** options be configured as well.
- **MO - ILM Restrict By BO Final Status (Y/N):** Setting this to "Y" indicates the transactions for the MO must be in a final status to be eligible for ILM. A status is considered to be final based on the BO lifecycle configuration. This can be overridden by the BO option **Final Status Required for Archive (Y/N)**. This is only applicable for an MO that is maintained by business objects.

- **BO - Final Status Required for Archive (Y/N):** Setting this to "Y" indicates the transactions for this particular BO must be in a final status. This setting overrides the MO level **ILM Restrict By BO Final Status (Y/N)**.

The following table helps to illustrate how these three settings impact whether a given transaction must be in a final status:

• MO: ILM Restrict By Status	• MO: ILM Restrict By BO Final Status	• BO: Final Status Required for Archive	• Final Status Required for Eligibility?
• N	• Y	• Y	• N
• N	• Y	• N	• N
• N	• N	• Y	• N
• Y	• N	• N	• N
• Y	• Y	• N	• N
• Y	• Y	• Y	• Y
• Y	• N	• Y	• Y
• Y	• Y	• Not Provided	• Y
• Y	• N	• Not Provided	• N

NOTE: There are a few MOs that do not support the BO level setting. To best understand how these fields are interpreted for an MO refer to the detailed description of the algorithm plugged into the ILM Eligibility system event for the MO. For example, the generic ILM Eligibility Based on Status ([F1-ILMELIG](#)) algorithm does not support the BO level override option.

Archive Eligibility Hierarchy

The table below summarizes details of the eligibility algorithms for each maintenance object supported by ILM. Information on this table includes:

- **Cascaded By:** Indicates how archiving for transactions for the maintenance object is initiated. For example, device events can be archived by themselves or as part of a related activity.
- **ILM Date Computation:** Indicates the type(s) of transactions that impact the calculation of the ILM Date for transactions for the maintenance object. "Itself" indicates that the ILM date is not impacted by other transactions.
- **Specific Eligibility Considerations:** Indicates specific considerations used by the eligibility algorithm.
- **Cascaded Transactions:** Indicates other transactions that are archived when transactions for the maintenance object are archived. For example, VEE exceptions are archived with initial measurements.

Maintenance Object	Cascaded By	ILM Date Computation	Specific Eligibility Considerations	Cascaded Transactions
Initial Measurement		Create date	VEE Exceptions must be eligible Associated Related MC Synchronization activity must be complete	VEE Exceptions

VEE Exception	Initial Measurement	Earlier of related Initial Measurement or VEE Exception Create Date	Related Service Issue Monitor must be complete	
Usage Transaction		The latest create date for all related usage transactions	All related usage transactions must be eligible for archiving	Related Usage Transactions
Device Event	Activity	Create date Superseded by paired event create date if earlier (where applicable)	Related paired events must be eligible Related service issue monitor must be complete Related activity must be complete	
Activity	Parent activity	Create date Superseded Device event, child activity, or completion event create date supersede (where applicable)	Cascaded transactions must be eligible Command requests must not be associated to a non-final service issue monitor Command requests must not be associated to an install event on off history entry	Child activities Device events Outbound communications Inbound communications Completion events
Outbound Communication	Activity	Create Date Superseded by initiating activity's create date (where applicable)		Inbound communication
Inbound Communication	Outbound Communication	Create date Superseded by initiating outbound communication create date (where applicable)		Device events

Proactive Archive Eligibility for Transactional Data

Some types of transaction data, including Device Events, Initial Measurement Data, and Usage Transactions can be analyzed for archive eligibility as they are received rather than waiting until their retention period has expired. This means that these records are judged ready to be archived as they are created and do not need to be read, analyzed, and updated during the ILM crawling process. This greatly reduces the number of records to be crawled at the end of the retention period and shortens the window of time required for ILM crawling. This section outlines how the ILM Archive switch (ILM_ARCH_SW) is set to “Y” (Yes) for records of these types as part of their initial processing.

- **Device Events:**

- The ILM Archive switch is set to “Y” for device events that meet the following criteria:
 - No service issue monitors were created for the device event
 - The device event is not a paired device event
- The ILM Archive switch is set to “Y” for device events via the following algorithms:
 - Create Service Issue Monitor from Device Event (D1-DVCEVTSIM)

- Create Service Issue Monitor from Device Event for Paired Event (D1-PRDVEVSIM)
- **Initial Measurement Data:**
 - The ILM Archive switch is set to “Y” by default for initial measurements (this is a different approach than the other record types).
 - The ILM Archive switch is set to “N” for initial measurements that meet the following criteria:
 - A consumption synchronization activity has been created for the initial measurement
 - A service issue monitor initiated from a VEE exception related to the initial measurement
 - The ILM Archive switch is set to “N” for initial measurements that meet the above criteria via the following algorithms:
 - Update Latest Measurement Date/Time on Scalar MC with Consumption Sync (D1-UDTSCMCRE)
 - Update Latest Measurement Date/Time on MC with Consumption Sync (D1-UPD-DTMC)
 - Create Service Issue Monitor from VEE Exception (D2-VEEEXCSIM)
- **Usage Transactions:**
 - The ILM Archive switch is set to “Y” when a usage transaction enters the “Sent” or “Discarded” state (or the “Calculated” or “Discarded” states for a sub-usage transaction) via the following algorithms:
 - Send Usage (D2-SEND-USG)
 - Set ILM Switch to ‘Y’ (D1-SETILMSWY)

Multiple Retention Period Eligibility Crawling Strategies

When multiple retention periods are defined for a maintenance object each record will have its retention period written to the database at the time of record creation. This retention period is then used to identify when the record will be ready for eligibility evaluation (aka crawling).

NOTE: As specified in the Oracle Utilities Meter Data Management Database Administrator's Guide each unique retention period for the maintenance object will be a sub-partition within a given ILM date partition.

The system supports two methodologies for doing so:

- Evaluate Individual Records:
 - This is our default approach
 - This is the standard approach to evaluating ILM retention for all maintenance objects with a single retention period
 - The ILM date for each record will be compared against the current date less the retention period for that type of record. Simply stated, any records older than the retention period will be evaluated for eligibility.
 - In this option we will process a portion of a partition each day and only once we had processed the entire partition would the DBA be able to take an archiving action on the partition
 - This results in many visits to the partition to determine eligibility
 - The image below illustrates how the evaluate individual records method will crawl one day of records on a partition and sub-partition each day until the retention period for the last day of the partition had expired. All records would then be archived together when the last day of the partition was marked as eligible. This results in daily processing of small amounts of records but frequent visits to the partition.

- Evaluate the Entire Partition
- This option will be enabled by configuring the ILM Date Partition Months in the maintenance object options
- In this option all records on a ILM date partition retention period sub-partition will be evaluated at the same time.
- For example, for a monthly partitioning strategy in the month of January we would not evaluate any records in the January partition until January 31st had reached the end of its retention period.
- This means that we would evaluate the 1st through the 31st all at one time
- This option should typically result in a single visit to the partition to determine eligibility
-
- The image below illustrates how the evaluate entire partition method will only crawl records from a given partition and sub-partition when all records on that partition are eligible to be evaluated. Therefore, when the last day of the partition is ready to be evaluated the entire partition will be evaluated. This results in periodic processing with, and in many cases, a single visit to the partition for ILM purposes.

Configuring Information Lifecycle Management (ILM)

For additional information on configuring ILM, see [Enabling ILM for Supported Maintenance Objects](#) in the Oracle Utilities Application Framework *Administrative User Guide*.

The tasks described in the OUAF guide must be applied in conjunction with the task of configuring the Oracle Utilities Meter Data Management specific master configuration.

You can access the portal from the **Admin > General > Master Configuration**.

Once the Master Configuration screen returns, locate the following record:

- **ILM Configuration - MDM:** this enables multiple retention periods to be configured for Initial Measurements, Device Events, and Activities.

Related Eligibility Algorithms

There are a several Oracle Utilities Meter Data Management specific algorithms involved with ILM refer to the detailed description of the algorithm type of each algorithm for more information about the functionality each provides:

1. **ILM Eligibility - Activity (D1-ILMELGACT):** determines eligibility of Activities and cascades child Activities, Communication Out, Communication In, Device Events, and Completion Events.
2. **ILM Eligibility - Communication In (D1-ILMELGCI):** determines eligibility of Communication In.
3. **ILM Eligibility - Communication Out (D1-ILMELGCO):** determines eligibility of Communication Out and cascades Communication In.
4. **ILM Eligibility - IMD (D1-ILMELGIMD):** determines eligibility of Initial Measurement data and cascades VEE Exceptions.
5. **ILM Eligibility - Device Event (D1-ILMELGDE):** determines eligibility of Device Event data and cascades VEE Exceptions.
6. **ILM Eligibility - Usage Transaction (D1-ILMELIGUT):** determines eligibility of Usage Transactions.
7. **ILM Eligibility - Usage Transaction Exception (D1-ILMELGUEX):** determines eligibility of Usage Transaction Exceptions.
8. **ILM Eligibility - VEE Exception (D1-ILMELGVEX):** determines eligibility of VEE Exceptions.

The following provides additional information beyond that provided in the ILM Eligibility - Activity (D1-ILMELGACT) algorithms' detailed descriptions on how specific activity types are handled:

- **Request Orchestration Activities:** Request orchestrations also archive any child activities that were created, and those child activities archive any child activities or data (completion events, device events, etc.).
- **Field Activities / Command Activities:** Field activities and command request activities are archived either as part of a request orchestration or by themselves. When a field activity/command request is archived, it also archives any of the following child transactions:
 - Update/Cancel Orchestrators
 - Communication Out
 - Communication In
 - Completion Event
- **Non-Dispatchable Activities:** Non-Dispatchable activities archived either as part of a request orchestration or by themselves. When a non-dispatchable activity is archived it also archives child completion events.
- **Orchestration Maintenance Activities:** Orchestration Maintenance activities are only archived by themselves if they do not have a related activity. When an orchestration maintenance activity is archived it also archives any of the following child transactions:
 - Communication Out
 - Communication In
- **Device Event Activities:** Presently device event activities are limited to outages which have an initiating and an ending device event. These types of activities cannot be archived until their related device events are either archived or ready to archive. However the device events do not have to wait for the activity to archive so the device events are not updated with the activity's ILM date.

- **Bulk Activities:** Bulk Activities are comprised of the Bulk Header and the Bulk Request/Response, and depending on how the header was created there will be one header to many bulk requests/responses. The Bulk Header will only be eligible for archive if all related Bulk Request activities are also eligible for archiving. All related bulk activities are archived together. Bulk activities also generate one-to-many command request activities. Those individual command activities are archived separately.
- **Payload Statistics Activities:** Payload Statistics activities can either be the Payload Summary record or the Payload Statistic record. Eligibility is based on the Payload Statistics activity, which is only be eligible for archiving if all the related Payload Summary and Payload Error activities are also eligible for archiving. These activities are only archived by themselves if they do not have a related activity. Otherwise both the payload statistics and the payload summary activities are archived at the same time.
- **Extract Request Activities:** These activities are used to request data from the head-end system on a periodic basis. Extract request activities should be in a final state prior to being archived.
- **Other Activities:** Other types of activities can be archived provided they do not require any special logic for handling for archiving purposes, such as checking for related data. These activity types can archive without checking related transactions:
 - Consumption Sync
 - Dimension Scanner
 - Error Activity
 - Measurement Quantity (deprecated)
 - Meter Read Download Activity
 - Suppression
 - Usage Transaction Correction Processor

In the event that your implementation uses custom activity types that require special handling, a custom algorithm should be created and added prior to the base package algorithm to preemptively handle the activity type category.

Related Batch Controls

There are a several Oracle Utilities Meter Data Management specific batch controls involved with ILM:

1. **ILM Crawler - Activity (D1-ACTCR):** identifies and executes eligibility evaluation for Activities. This batch control supports multiple retention periods.
2. **ILM Crawler - Communication In (D1-CICRL):** identifies and executes eligibility evaluation for Communication In.
3. **ILM Crawler - Communication Out (D1-COCRL):** identifies and executes eligibility evaluation for Communication Out.
4. **ILM Crawler - Device Event (D1-DECRL):** identifies and executes eligibility evaluation for Device Events.
5. **ILM Crawler - IMD (D1-IMDCL):** identifies and executes eligibility evaluation for Initial Measurement Data. This batch control supports multiple retention periods.
6. **ILM Crawler - Usage Transaction Exception (D1-UEXCL):** identifies and executes eligibility evaluation for Usage Transaction Exceptions.
7. **ILM Crawler - Usage Transaction (D1-UTCRL):** Identifies and executes eligibility evaluation for Usage Transactions.
8. **ILM Crawler - VEE Exception (D1-VEXCL):** Identifies and executes eligibility evaluation for VEE Exceptions.

For additional details see the [Batch Processes](#) section the Oracle Utilities Application Framework *Administrative User Guide*.

Defining Outage Storm Mode Options

Configuring Outage Storm Mode

This section describes the process for configuring Outage Storm Mode.

NOTE: Refer to the [About Outage Storm Mode](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Master Configuration settings

Once the Master Configuration search screen returns, locate the **MDM Master Configuration**. Use the Add button beside the record to configure for the first time. If a record has already been added, then click the Edit button instead. The **Estimation Eligibility For Widespread Outages** section is the primary section that needs to be configured for Outage Storm Mode to be enabled. Use the embedded help to guide you through the meaning of each configuration field.

Setup Meter Communication Tracking Aggregation

As part of Outage Storm Mode, aggregations are performed to determine the percentage of meter communication that has occurred for an area. The following configuration supports this:

1. Access the portal for Measuring Component Type through **Admin > Device > Measuring Component Type**. Add a new Measuring Component Type using the **Meter Communication Tracking Aggregator Type** (D2-MtrCommTrckngAggregatorType) business object. Follow the embedded help provided for each section. Two areas listed below are crucial to preparing for this specific aggregation:
 - a. When selecting a Measuring Component Business Object for this record, choose the **Meter Communication Tracking Aggregator** Business Object.
 - b. For the Value Identifiers, there are a few metrics that can be defined as listed on the [D2-AGG-MCTM](#) Algorithm Type:
 - a. Read Percentage
 - b. Count of Received Measuring Components
 - c. Count of Total Measuring Components
2. Access the portal for Activity Type through Admin > Communication > Activity Type. Add a new record for the Meter Communication Tracking Dimension Scanner Activity Type.
3. Access the portal for Activity through . Add a new record for the Activity Type you defined in the prior step.

Standard Event Name Configuration

Any Device Event that should close out Estimation Suppression Activities must be configured with the "End Estimation Suppression" algorithm ([D2-EN-ESTSUP](#)) in the Additional Processing Algorithms section. This is often configured for "Power Up" events to indicate that normal power flow has resumed for the meter.

Related Batch Controls

There are a few batches directly involved with Outage Storm Mode:

- **Dimension Scanner (D1-ADS):** monitors the "Meter Communication Tracking Dimension Scanner" business object. New Aggregator Measuring Components will be created for every applicable Service Type, Postal Code, and Head End in the system.

- **Aggregation Monitor (D2-AGG)**: runs to execute the logic for the "Meter Communication Tracking Aggregator" Measuring Component. This logic will aggregate all meters for the defined Service Type, Postal Code, and Head End. Once the read percentage is found for that day then a measurement will be created for the Aggregator Measuring Component.
- **Estimation Suppression Monitor (D1-ESTSU)**: This batch monitors the Estimation Suppression activities for processing. This batch should be scheduled to run regularly so it can clean up Suppression Activities if they have ended.
- **Widespread Outage (D2-WSO)**: This batch queries the Meter Communication Tracking Aggregators to determine if any have experienced a widespread outage. For any actively in outage mode, then the batch will find all related Service Points and execute the logic on the algorithm plugged into the BO system event of "Estimation Suppression". It's recommended that D2-WSO be scheduled shortly after aggregation D2-AGG.

Detailed Examples of Outage Storm Mode

Scenario 1: Meter is marked estimation ineligible then received metered data with outage events

The following configuration settings should be assumed for this example:

Master Config option	Value
Check Widespread Outages	Yes
Read Percentage Days to Examine	7
Percent Drop From Norm - Estimation Ineligible	30.0%
Minimum Device Count For Ineligibility	100
Days Before Becoming Ineligible	0
Fill Missing Data With Zero	No
Days Before Filling Zero	
Maximum Estimation Ineligibility Days	3
Percent Within Norm - Resume Estimation	5.0%

Diagram:

Explanation for diagram:

1. The meter was communicating consistently but then a widespread outage occurs in the same postal code so the meter has an estimation suppression created.
2. Two events are received...a Power Down event and a Power Up event. Also, Regular usage data is received from the meter. The reception of non-estimated data marks the meter as eligible for estimation again.
3. Oracle Utilities Meter Data Management estimates data and takes the two events into account. Intervals marked as outage and filled with zeros are created during the outage period by the D1-SMMTR batch.

Scenario 2: Meter is marked estimation ineligible, is filled with zeros, then receives actual data

The following configuration settings should be assumed for this example:

Master Config option	Value
Check Widespread Outages	Yes
Read Percentage Days to Examine	7
Percent Drop From Norm - Estimation Ineligible	30.0%
Minimum Device Count For Ineligibility	100
Days Before Becoming Ineligible	0
Fill Missing Data With Zero	Yes
Days Before Filling Zero	0
Maximum Estimation Ineligibility Days	3
Percent Within Norm - Resume Estimation	5.0%

Diagram:

Explanation for diagram:

1. The meter loses communication and periodic estimation fills in outage intervals.
2. The meter reestablishes communication and sends in the latest readings and interval data.
3. Oracle Utilities Meter Data Management creates new data that's synchronized to fall in line with the new data from the meter by the Consumption Sync batch. This data replaces the outage measurements as it balances out to the scalar and interval data.

Defining Oracle Utilities Rate Cloud Service Options

Oracle Utilities Rate Cloud Service Admin Data

Oracle Utilities Rate Cloud Service includes access to pages, portals, and zones used to create and maintain various types of administrative configuration data, including:

- Characteristic Types
- Currencies
- Distribution Codes
- Revenue Classes
- Item Device Types
- Frequencies
- Service Types
- Service Quantity Identifiers

- Time of Use codes
- Units of Measure

Refer to the [Defining General Options](#) chapter in the *Administrative User Guide* for detailed information about setting up currencies and characteristic types.

Refer to the [Defining Financial Transaction Options](#) chapter in the *Administrative User Guide* for detailed information about setting up distribution codes and revenue classes.

Refer to the [Defining Device Options](#) chapter in the *Administrative User Guide* for detailed information about setting up device types.

Refer to the [Rates](#) chapter of the *Business User Guide* for detailed information about setting up frequency codes.

Refer to the [Defining Device Measurement Options](#) chapter in the *Administrative User Guide* for detailed information about setting up service types, units of measure, service quantity identifiers, and time of use codes.

Note: Some fields and options used by these types of configuration data are not applicable when using Oracle Utilities Rate Cloud Service when compared to using Oracle Utilities Customer Cloud Service.

Creating Oracle Utilities Rate Cloud Service Users

Oracle Utilities Rate Cloud Service includes a “Rating Services” user group that provides access to the specific pages, portals, and features included with the cloud service.

The “Rating Services” user group should be used as the basis for all new Oracle Utilities Rate Cloud Service users.

Refer to the [Defining Security and User Options](#) chapter in the *Administrative User Guide* for more information about creating new users.

Initiating Calculations from an External System

Oracle Utilities Rate Cloud Service includes an inbound web service that allows rate calculation to be initiated from an external system.

The `clrateCalculation` inbound web service is an inbound REST web service that can be used to request a rate calculation. Some specifics regarding this web service include:

- Master data (such as person, account, service agreement, service point, device, or usage) is not required.
- Service quantities and characteristic types/values must be included with the web service request.
- Calculation results are consistent with online rate calculation using the Rate Check feature.
- Calculation results are returned to the external system that submitted the request.
- Calculation results are not stored in Oracle Utilities Rate Cloud Service.

Refer to the [External Messages](#) chapter in the *Administrative User Guide* for more information about inbound web services.

Use the **Inbound Web Service** portal to view details regarding the `clrateCalculation` inbound web service.

Smart Grid Gateway Adapters

Smart Grid Gateway Adapters and On-Premises Implementations

NOTE: Unless otherwise noted, the contents of this section apply to on-premises implementations of Oracle Utilities Smart Grid Gateway only, and do NOT apply to Oracle Utilities cloud services. See [Smart Grid Gateway Adapters and](#)

[Oracle Utilities Cloud Services](#) for more information about implementing Smart Grid Gateway Adapters with Oracle Utilities cloud services.

Oracle Utilities Smart Grid Gateway (SGG) Adapters support communication with various third-party head-end systems. SGG uses Oracle Service Bus (OSB) and Oracle Business Process Execution Language (BPEL) to facilitate communication with the head-end systems. Most if not all of the functionality shown below is available in each SGG Adapter.

Measurement Data and Device Event Loading: Data parsing and transformation via Oracle Service Bus from head-end system format into the Oracle Utilities Service and Measurement Data Foundation unified format for measurement data and device events.

Measurement Data and Device Event Processing: Configurable mapping for head-end system status codes and device event names to Oracle Utilities Service and Measurement Data Foundation standard values.

Smart Meter Command Processing: Sending/receiving messages to/from third-party applications to initiate smart meter commands from SGG. Most head-end systems support the following types of commands and communications:

- **Device Status Check:** Business objects and BPEL processes to support issuing device status check commands.
- **Meter Commissioning:** Business objects and BPEL processes to support issuing meter commissioning commands (including registration and installation commands).
- **Meter Decommissioning:** Business objects and BPEL processes to support issuing meter decommissioning commands.
- **Meter Retirement:** Business objects and BPEL processes to support issuing meter retire (deregistration) commands.
- **On-Demand Read:** Business objects and BPEL processes to support issuing on-demand read commands.
- **Remote Connect:** Business objects and BPEL processes to support issuing remote connect commands.
- **Remote Disconnect:** Business objects and BPEL processes to support issuing remote disconnect commands.

This information in this guide describes how to configure, extend, and test the SGG Adapter for individual head-end systems. The following head-end systems each have a specific SGG Adapter that can be configured: Itron OpenWay, Landis+Gyr, Networked Energy Services, MV90 for Itron, Sensus RNI, and Silver Spring Networks. Customers also can create their own customized adapter for using Smart Grid Gateway with a specific head-end system. See [Creating a Custom Adapter for Smart Grid Gateway](#) for more information.

Configuring Smart Grid Gateway Adapters

This section describes how to configure Oracle Utilities Smart Grid Gateway Adapters for each supported head-end system. Use the cross-references below to go to the adapter of interest.

[Itron OpenWay](#)

[Landis+Gyr](#)

[Networked Energy Services](#)

[MV90 for Itron](#)

[Sensus RNI](#)

[Silver Spring Networks](#)

NOTE: This section applies to on-premises implementations of Oracle Utilities Smart Grid Gateway only. This section does NOT apply to Oracle Utilities cloud services. See [Smart Grid Gateway Adapters and Oracle Utilities Cloud Services](#) for more information about implementing Smart Grid Gateway Adapters with Oracle Utilities cloud services.

Itron OpenWay

The Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay supports communication with the Itron OpenWay application, including measurement data and device event loading, and command messaging in support of commissioning, connect, disconnect, decommissioning, status check, and on-demand read commands. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Versions	7.0 Itron OpenWay Operations Center SR 4.5
Protocol	Proprietary
Market(s)	Worldwide
Architecture	RF Mesh

Itron OpenWay Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Measurement and device event data must be requested from the Itron OpenWay head-end system via Scheduled Read commands. See [Scheduled Read Commands](#) for more information.

Scheduled Read Commands

NOTE: This section applies to both cloud and on-premises implementations of the Smart Grid Gateway Adapter for Itron OpenWay.

Measurement and device event data must be requested from the Itron OpenWay head-end system via Scheduled Read commands. Schedule read commands are used to request meter reads and/or device events for a group of devices for a specified date and time. Scheduled read commands can be created such that recurring requests based on the same command parameters are sent to the head-end system at regular intervals. For example, a command could be configured to request daily (24 hour) scalar meter readings once per day for a specified group of devices. Another command could be configured to request weekly (168 hours) device events once per week for a group of devices.

Scheduled read commands should be created for all devices from which meter readings and/or device events are to be uploaded via Oracle Utilities Smart Grid Gateway. Separate scheduled read commands can be created for specific groups and for specific types of data. For example, for a given group of scalar devices, you might create separate commands to request scalar usage data and to request device events from the same group (both of which can be based on different recurrence patterns). The specifics concerning request specifics and recurrence patterns should be based on the requirements of the implementation.

Attributes used to define a schedule read command include the following:

- **Status:** the status of the activity

- **Schedule Read Type:** the type of scheduled read
- **Schedule Information:** information about the schedule for the read, including:
 - **One Time Read:** indicates if the request is a one-time request. One-time requests have a defined date/time range during which request and recurrences can take place.
 - **One Time Start Date Time:** specifies the start time for one-time requests (applicable only if **One Time Read** is set to “Yes”)
 - **One Time End Date Time:** specifies the end time for one-time requests (applicable only if **One Time Read** is set to “Yes”)
 - **First Daily Measurement Time:** Indicates starting time for measurements for each day. This field, along with the value from **IMD Length** , will be used to determine when interrogation requests should be made. For example, if the **First Daily Measurement Time** is set to 08:00AM and **IMD Length** is set to 12 hours (12:00:00) then there would be two requests made per day:
 - 8:00AM - 8:00PM
 - 8:00PM - 8:00AM
 - **Interrogation Buffer:** This parameter impacts when interrogation requests are sent. It is entered in the format of hours:minutes:seconds. For example, if set to 1 hour (01:00:00) for our above example, the first request of the day for 8:00AM - 8:00PM would be sent to Itron OpenWay at 7:00PM. The buffer time will decrease if the activity is monitored after 7:00PM, so if the monitor process is executed at 7:30PM the buffer time would only be 30 minutes and if the monitor process were not executed until after 8:00PM there would be no buffer time at all.
 - **IMD Length:** Defines the number of hours, minutes and seconds of data that should be retrieved for each request. It is entered in the format of hours:minutes:seconds. This number must be divisible into 24 since it will determine how many requests will be made per day (i.e. if set to 8 hours (08:00:00) there will be 3 requests per day).
 - **Disable Extended IMD Length Recovery:** By default the schedule read activity will attempt to "catch-up" when interrogation requests have been missed by requesting the entire period from the last interrogation request made. Setting this parameter to "Yes" will turn off this functionality and interrogation requests will only be made in for the exact amount of time defined in the **IMD Length**
 - **Range of Recurrence:** indicates how to define request recurrences. Valid values include “Maximum Recurrence”, “No End Date”, and “Recurrence End Date”
 - **Maximum Recurrence:** The activity will make a set number of requests, once the set number has been reached the activity will expire. When selected, **Maximum Recurrences** must also be provided.
 - **No End Date:** The activity will never expire and will continue to make requests until it is manually transitioned to inactive.
 - **Recurrence End Date:** The activity will continue to make requests until a specified date. When selected, **Recurrence End Date Time** must also be provided.

NOTE: When “No End Data” is selected, the recurrences of the request continue until a user manually changes the status of the command.

 - **Maximum Recurrence:** defines the maximum number of recurrences before the command’s status is changed to “Inactive”.
 - **Recurrence End Date Time:** The date after which no more recurrences are attempted. After this date and time, the command’s status is changed to “Inactive”.
- **Group:** the group of devices used by requests for the command
 - **Group Type:** indicates the type of device group to use for the command. Valid options include Application Group or Configuration Group.
 - **Application Group/Configuration Group Name:** defines the specific group (based on the group type).

NOTE: Groups referenced by Scheduled Read commands and the devices that belong to each are defined in Itron OpenWay head-end system. Each group to be used with these commands must also be defined in either the “Itron — Application Group Lookup” or “Asset Specification” extendable lookup. See the Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay Configuration Guide for more information about these extendable lookups.

- **Default Read Parameters:** specifies details concerning the data to be requested. The read parameters define the exact data that will be requested from the meters. Please consult the Itron OpenWay documentation for the specifics of each parameter.
- **Interrogation Window Hours:** the number of hours used to calculate when to submit requests. For example, to submit requests once per day, this should be set to 24. To submit requests once per week (7 days), this should be set to 168. The current date time (or the Latest Request End Date Time) plus this equals interrogation window end date time.
- **Override Read Parameters:** an alternative set of parameters that can be defined. To leverage this group each parameter must be provided, no parameter is allowed to be left blank. This set of parameters will be used when the request end time is equal to the **First Daily Measurement Time**. For example, a schedule read with a **First Daily Measurement Time** of 12:00AM and an **IMD Length** 12 hours (12:00:00) would make the following requests each day:
 - 12:00AM - 12:00PM
 - 12:00PM - 12:00AMThe **Override Read Parameters** would be used for the 2nd request where the request end time of 12:00AM matches the **First Daily Measurement Time** of 12:00AM. If an extended request is made to "catch up" (i.e. it makes a request that is larger in duration than the configured **IMD Length**), and the request start and request end date time includes the **First Daily Measurement Time** then the **Override Read Parameters** will be used.
- **Outbound Communication Exception Handling Overrides:** parameters used to control retry attempts and expiration for the outbound communication. These parameters take precedence over their outbound communication counterparts
- **Last Read Details:** details concerning the most recent read request sent for the command. This information is used to calculate the time for the next request (based on the **Interrogation Window Hours** parameter).
 - **Latest Request Start Date Time:** the start date and time of the last request
 - **Latest Request End Date Time:** the end date and time of the last request
 - **Recurrence Count:** the number of recurrences of the last request

About Ad Hoc Requests

While scheduled read commands are typically configured to create recurring requests for meter reads and device events, users can also submit ad hoc requests for a specific date and time range based on the parameters of a currently active scheduled read command. This is useful if meter read data or device events are needed before the next request for a command would be submitted based on the command's recurrence settings.

Ad hoc requests are created as separate one-time request commands, with a start and end time based on parameters supplied by the user when initiating the ad hoc request. The group and read parameters for ad hoc requests are the same as those for the command used to send the ad hoc request.

Error Handling

If errors occur when processing scheduled read commands, errors are logged as follows:

- If there is a single error it will create a single log entry
- If there is more than one error, the log entry will perform a count of devices and create a single error message stating the number of devices that were in error.

Initial Measurements

The usage data received from the AMI head-end system as a file in Itron OpenWay XML format is loaded into Oracle Utilities as initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D8-ITRONXML-BASE** contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This project can be upgraded without affecting the customization and environment settings added to SGG-D8-ITRONXML-CM.
2. **SGG-D8-ITRONXML-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-D8-ITRONXML-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
destinationRootElementEvent	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false
filterUsage	Determines if usage should be filtered.	true false
filterRegisterSource	Determines if source register data should be filtered.	true false

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D8-ITRONXML-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **Itron - UOM Code to Standard UOM Mapping** extendable lookup (D8-HeadendUOMLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the `MinimumAge` property in the “InboundProxyService” proxy service for the project. The `MinimumAge` property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (D1RT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Device Events

Itron OpenWay can send real-time events such as meter outage alarms to Oracle Utilities Smart Grid Gateway. These events are referred to as exceptions in the Itron architecture, and are sent to the BPEL ExceptionSubscriberService service by Itron OpenWay without requiring an explicit request from Oracle Utilities Smart Grid Gateway. Exceptions are loaded as device events data and provided to the edge applications.

The required functionality is delivered in the base product as two OSB projects:

1. **SGG-D8-EXCEPTION-BASE** contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This project can be upgraded without affecting the customization and environment settings added to the SGG-D8-EXCEPTION-CM project.
2. **SGG-D8-EXCEPTION-CM** allows the customization and simplifies the future upgrades.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the device event data is populated as raw data.	true
		false
callPreProcessing	Determines if the preprocessing proxy service is called.	true
		false
callPostProcessing	Determines if the postprocessing proxy service is called.	true
		false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true
		false

Publishing Events

The Itron OpenWay adapter can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the `publishServices/service` element in the `EnvironmentSettings.xq` file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D8-EXCEPTION-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the `EnvironmentSettings.xq` file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging

Parameter	Description	Default Value
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **Itron - Device Event Mapping** extendable lookup (D8-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (DIRT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D8-EXCEPTION-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

NOTE: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The Itron OpenWay adapter base package includes the following initial measurement and device event business objects:

Business Object Name	Description
D8-InterrogateByGroup	Itron - Interrogate By Group Performs a Schedule Read for a group of devices (either Application or Configuration) in the Itron OpenWay API.
D8-InterrogateByGroupResult	Itron - Interrogate by Group Result This BO is the inbound asynchronous response to an Interrogate By Group (Schedule Read) outbound communication.
D8-InitialLoadIMDInterval	Itron - Initial Load IMD - Interval Used when loading Itron OpenWay interval measurements into the system for the first time.
D8-InitialLoadIMDScalar	Itron - Initial Load IMD - Scalar Used when loading Itron OpenWay scalar measurements into the system for the first time.
D8-ScheduleRead	Itron - Schedule Read Requests IMD and Event data from the Itron OpenWay Network. This data will later be returned and placed in files to be uploaded.

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Itron OpenWay command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	Itron - Reconnect Meter	Itron - Reconnect Meter Result	Connect Device Completion Event
Remote Disconnect	Itron - Disconnect Meter	Itron - Disconnect Meter Result	Disconnect Device Completion Event
Device Commissioning	Itron - Add Meter Definition		Device Commissioning Completion Event
Device Decommissioning	Itron - Deregister Meter		Device Decommissioning Completion Event
On-Demand Read (Scalar)	Itron - Contingency Read (Scalar)	Itron - Contingency Read Result (Scalar)	Create IMD Completion Event
On-Demand Read (Interval)	Itron - Contingency Read (Interval)	Itron - Contingency Read Result (Interval)	Create IMD Completion Event
Scheduled Read (Scalar)	Itron - Interrogate by Group (Scalar)	Itron - Interrogate by Group Result (Scalar)	Create IMD Completion Event
Scheduled Read (Interval)	Itron - Interrogate by Group (Interval)	Itron - Interrogate by Group Result (Interval)	Create IMD Completion Event

Command	Outbound Communication	Inbound Communication	Completion Event
Device Status Check	Itron - Ping by Endpoints (Status Check)	Itron - Get Ping by Endpoints Result	

Device Communication Base Package Business Objects

The Itron OpenWay Adapter base package includes the following communication business objects:

Business Object Name	Description
D8-AddMeterDefinitions	Itron - Add Meter Definition (Commission)
D8-DeregisterMeter	Itron - Deregister Meter (Decommission)
D8-DetectLoadSideVoltageByMtr	Itron - Detect Load Side Voltage
D8-DetLoadSideVoltageMtrRsIt	Itron - Detect Load Side Voltage Result
D8-DisconnectMeter	Itron - Disconnect Meter (Remote Disconnect)
D8-DisconnectMeterResult	Itron - Disconnect Meter Result
D8-PingByEndpoints	Itron - Ping By Endpoints (Device Status Check)
D8-PingByEndpointsMDResponse	Itron - Multi-Device Ping Response
D8-PingByEndpointsMultiDevice	Itron - Ping By Endpoints Multi-Device
D8-PingByEndpointsResponse	Itron - Ping By Endpoints Response
D8-ReadDisconStateByMtr	Itron - Read Disconnect State
D8-ReadDisconStateMtrRsIt	Itron - Read Disconnect State Result
D8-ReadInterval	Itron - Contingency Read (Interval)
D8-ReadResult	Itron - Contingency Read Result
D8-ReadScalar	Itron - Contingency Read (Scalar)
D8-ReconnectMeter	Itron - Reconnect Meter (Remote Connect)
D8-ReconnectMeterResult	Itron - Reconnect Meter Result

Itron OpenWay Event Data Mapping

The Itron OpenWay event file format maps as follows into the business object, D1-DeviceEventMappingLookup:

Itron OpenWay Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.
Device Identifier	External Device Identifier	
Event Name	External Event Name	
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router
Service Location ID	External Service Location ID	
Communication Module Serial Number	External Communication Module Identifier	
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form):

Itron OpenWay Flat File Field	Device Event Seeder BO Element	Comments
		Alert Information
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgment and response messages are sent and received validating that commands have been transmitted.

Outbound Message Type	Description
D8ITRECO	D8 Itron Remote Connect

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway adapter for Itron OpenWay includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Used for upload of device events. The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event. If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.

Inbound Web Service	Description
D1-DeviceStatusCheck	Device Status Check This service is invoked by the integration layer to instantiate a Device Status Check command.
D1-InitialLoadIMD	Used by OSB to instantiate an IMD The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.
D1-RemoteConnect	Remote Connect This service is invoked by the integration layer to instantiate a Remote Connect command.
D1-RemoteDisconnect	Remote Disconnect This service is invoked by the integration layer to instantiate a Remote Disconnect command.
D8-DetLoadSideVoltageMtrRslt	Itron - Detect Load Side Voltage by Meter Result
D8-DisconnectMeterResult	Itron - Disconnect Meter Result Service
D8-InterrogateByGroupResult	Itron - Interrogate By Group Result XIA
D8-PingByEndpointsMDResponse	Itron - Ping By Endpoints Multi-Device Response XAI Inbound
D8-PingByEndpointsResponse	Itron - Ping By End Response inbound web service
D8-ReadDisconStateMtrRslt	Itron - Read Disconnect State by Meter Result Service
D8-ReadResult	Itron - Contingency Read Result
D8-ReconnectMeterResult	Itron - Reconnect Meter Result Service

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway adapter for Itron OpenWay includes the following message senders:

Message Sender	Description
D8-RemoteCon	D8 Remote Connect

BPEL Processes

These processes are responsible for performing the conversion from Oracle Utilities format to Itron OpenWay format, invoking process callouts and invoking the remote endpoint to trigger the device events. BPEL modules are divided into “Composites,” or collections of business logic.

OnDemandRead Composite Process — The OnDemandRead composite invokes a sequence of web methods that call the head-end system to retrieve meter reading data and send it back to the OUAF layer. In the case of Itron OpenWay, this is accomplished using the ContingencyReadByEndpoints/GetContingencyReadByEndpointsResult services defined in the Data service WSDL.

ConnectDisconnect Composite Process — This composite is responsible for triggering the Connect and Disconnect events on the head-end system. A second, asynchronous reply sends the results back into the OUAF layer when the head-end system signals a change in the status of the device. The Itron OpenWay Adapter uses the ReconnectMeter/

GetReconnectMeterResult web service pair to connect, and the DisconnectMeter/GetDisconnectMeterResult web service pair to disconnect. Each of these services is defined in the Control service WSDL.

CommissionDecommission Composite Process — Commissioning and Decommissioning of devices, sometimes referred to as “Provisioning,” is handled by the CommissionDecommission composite. Commissioning invokes the AddMeterDefinitions web service and Decommissioning uses the DeregisterMeters web service. Both are defined in the Provisioning service.

DeviceStatusCheck Composite — This composite uses the PingByEndpoints and GetPingByEndpointsResult web services to check the health of a device. These Itron OpenWay services are defined in the Control.Diagnostic service.

Common Composite — The Common composite contains three main classes of operations: Proxies, ProcessCallouts, and utility functions. Proxies are usually simple mediators that forward a web service call to a preset endpoint. In this Adapter they have two additional roles. First, they interrogate a composite property and determine whether the supported version of head-end software is 3.70 or 3.90. Some of the proxies will also append the callback URL for the StatusChanged service. Proxies are convenient because they allow head-end URLs and security to be set in a single composite. In this case, they also offer a common location to make these checks. ProcessCallouts are points of customization which allow users to modify data and/or initiate some external business process. Utility functions serve as a central location for business logic needed by multiple composites.

Web Services

The following web services are all defined in the Itron OpenWay head-end system:

- **CommissionDecommissionService**
 - **BPEL Process:** CommissionDecommission
 - **Operation:** AddMeterDefinitions
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/CommissionDecommission/CommissionDecommissionService
- **CommissionDecommissionService**
 - **BPEL Process:** CommissionDecommission
 - **Operation:** DeregisterMeters
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/CommissionDecommission/CommissionDecommissionService
- **ConnectDisconnectService**
 - **BPEL Process:** ConnectDisconnect
 - **Operation:** ReconnectMeter
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/ConnectDisconnect/ConnectDisconnectService
- **ConnectDisconnectService**
 - **BPEL Process:** ConnectDisconnect
 - **Operation:** DisconnectMeter
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/ConnectDisconnect/ConnectDisconnectService
- **DeviceStatusCheckService**
 - **BPEL Process:** DeviceStatusCheck
 - **Operation:** DeviceStatusCheck

- **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/DeviceStatusCheck/DeviceStatusCheckService
- **OnDemandReadService**
 - **BPEL Process:** OnDemandRead
 - **Operation:** ContingencyReadByEndpoints
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/OnDemandRead/OnDemandReadService

Itron OpenWay Web Services

The following table describes Itron OpenWay web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Command	AMI Adapter Business Objects	Itron OpenWay Web Services	Itron OpenWay Operations
Device Commissioning	D8-AddMeterDefinitions	ProvisioningService	AddMeterDefinitions
Device Decommissioning	D8-DeregisterMeter	ProvisioningService	DeregisterMeters
Remote Connect	D8-ReconnectMeter	ControlService	ReconnectMeter
	D8-DetectLoadSideVoltageByMtr	DiagnosticService	DetectLoadSideVoltageByMeter
	D8-ReadDisconStateByMtr		ReadDisconnectStateByMeters
Remote Disconnect	D8-DisconnectMeter	ControlService	DisconnectMeter
Device Status Check	D8-PingByEndpoints	ControlService	PingByEndpoints
			GetPingByEndpointsResult
On-Demand Read	D8-ReadInterval	DataService	ContingencyReadByEndpoints
	D8-ReadScalar		GetContingencyReadByEndpointsResult
	D1-InitialLoadIMD		InterrogateByGroup
	D1-DeviceEventSeeder	GetInterrogateByGroupResult	
		DataSubscriberService (Async Response)	DataArrived
Event Loading	D1-DeviceEventSeeder	ExceptionSubscriberService	ExceptionsArrived

Configuring an Itron OpenWay Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay to communicate with the Itron OpenWay application.

Master Configurations

Master Configurations are sources of global parameter records used by a system implementation. This section describes the master configuration that is specific to Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about other master configurations used by Oracle Utilities Smart Grid Gateway.

Itron Version Master Configuration

This master configuration specifies the version of the Itron head-end system with which the system is communicating. The configuration options are Itron OpenWay 3.70, Itron OpenWay 3.90, and Itron OpenWay 6.10. Only one version can be specified at a time.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the Itron OpenWay application in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder
D1-DeviceStatusCheck	Device Status Check
D1-InitialLoadIMD	Used by OSB to instantiate an IMD
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D8-DetLoadSideVoltageMtrRslt	Itron - Detect Load Side Voltage by Meter Result
D8-DisconnectMeterResult	Disconnect Meter Result Service
D8-InterrogateByGroupResult	Itron - Interrogate By Group Result XIA
D8-PingByEndpointsMDResponse	Itron - Ping By Endpoints Multi-Device Response XAI Inbound
D8-PingByEndpointsResponse	Itron - Ping By Endpoints Response inbound web service
D8-ReadDisconStateMtrRslt	Itron - Read Disconnect State by Meter Result Service
D8-ReadResult	Itron - Contingency Read Result
D8-ReconnectMeterResult	Itron - Reconnect Meter Result Service

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests. An message sender should be configured for each command.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D8-ITRON_IBG	Itron Interrogate By Group
D8-COMM	Itron Commission
D8-DCOMM	Itron Decommission
D8-DLSV	Itron Detect Load Side Voltage
D8-IPBE	Itron Ping By Endpoints
D8-RCONN	Itron Remote Connect
D8-RDCONN	Itron Remote Disconnect
D8-RDSS	Itron Read Disconnect State

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:http://xmlns.oracle.com/ouaf/Itron/<OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Itron/<SERVICE>
- where:
 - <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
 - <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
 - <PASSWORD>: the password used to log into WebLogic Enterprise Manager
 - <EM_SERVER>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
 - <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed
 - <SERVICE>: the service invoked by the message sender (see Service column in the table above)

How to Use Enterprise Manager to Locate the URL for the Message Sender

Follow this procedure to find the correct URL for the command associated with an message sender:

1. Open Enterprise Manager and use the navigation pane to open the dashboard of the service used by the message sender:
2. The top bar of the dashboard contains several buttons and icons. One of these is a “world” icon with a puzzle piece over it. Click this icon to display a list of the WSDLs and endpoint URIs for the service:
3. Click the service’s WSDL URL link to see the WSDL in the browser, or right click and save it to your machine.

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D8-CONREAD	Itron Contingency Read By Endpoints
D8-INTRGRP	Itron Interrogate By Group
D8-COMM	Itron Commission
D8-DCOMM	Itron Decommission
D8-DSC	Itron Device Status Check
D8-DSCMD	Itron Device Status Check Multi Device
D8-DLSV	Itron Detect Load Side Voltage
D8-RCONN	Itron Remote Connect
D8-RDCONN	Itron Remote Disconnect
D8-RDSS	Itron Read Disconnect State

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the Itron OpenWay head end must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - Itron OpenWay:

- **External System:** Itron OpenWay
- **Description:** Itron OpenWay
- **Outbound Message Types:**

Outbound Message Type	Message Sender
D8-INTRGRP	D8-ITRON_IBG
D8-COMM	D8-COMM
D8-DCOMM	D8-DCOMM
D8-DSC	Message sender associated with the Device Status Check Outbound Message Type
D8-DSCMD	Message sender associated with the Device Status Check Multi Device Outbound Message Type
D8-DLSV	D8-DLSV
D8-RCONN	D8-RCONN
D8-RDCONN	D8-RDCONN

Outbound Message Type	Message Sender
D8-RDSS	D8-RDSS

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D8-Request xsl
- **Response XSL:** D8-Response.xsl

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the Itron OpenWay head end must be present in your system. If this are not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - Itron OpenWay:

- **Service Provider:** Itron OpenWay
- **Description:** Itron OpenWay
- **External Reference ID:** Itron OpenWay
- **External System:** Itron OpenWay
- **Our Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **Pre-Commissioning Device ID Type:**
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the Itron OpenWay service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM mapping processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the Itron OpenWay service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D8-AddMeterDefinitions	Commission
Device Decommission	Device Removal	D8-DeregisterMeter	Decommission
Device Status Check	Device Status Check	D8-PingByEndpoints	Device Status Check
Load Check*	Load Check	D8-DetectLoadSideVoltageByMtr	Detect Load Side Voltage by Meter
Multi-Devie Status Check	Multi-Devie Status Check	D8-PingByEndpointsMultiDevice	Read Disconnect State By Meters
On-Demand Read (Scalar)	On-Demand Read (Scalar)	D8-ReadScalar	On Demand Read — Scalar
Remote Connect	Remote Connect	D8-ReconnectMeter	Connect
Remote Disconnect	Remote Disconnect	D8-DisconnectMeter	Disconnect

* The Load Check processing method can be used to ensure that it is safe to connect a meter. The load check processing method is executed during the Connection Ready state of the Remote Connect activity and can be configured to detect the possibility of a load side voltage at the meter, or to check the disconnect meter switch on the meter.

If the Read Disconnect State business object is used as the processing method, you should configure the disconnect switch state values that indicate the state of the switch. These values are defined on the D8-DisconnectSwitchStateLookup extendable lookup, and are then added in the Disconnect Switch State Error Values section of the Itron - Read Disconnect State Result Inbound communication type. See [Itron OpenWay Disconnect Switch State Lookup](#) for more information.

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Itron OpenWay endpoint override DVM (D8–EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Itron OpenWay adapter and the command used with each:

DVM Key	Commands
DataService390	Scheduled Read (Scalar) Scheduled Read (Interval) On-Demand Read (Scalar) On-Demand Read (Interval)
ProvisioningService370	Device Commissioning
ProvisioningService390	Device Decommissioning
ControlService370	Device Status Check (if using v3.70) Remote Connect (if using v3.70) Remote Disconnect (if using v3.70)
ControlService390	Remote Connect (if using v3.90) Remote Disconnect (if using v3.90)
DiagnosticService390	Device Status Check (if using v3.90)
ProcessCallout	User Exit Functions

NOTE:

The numbers in the keys above (370 and 390) designate the version of the Itron OpenWay head-end system.

Only a single version of each key should be defined, based on the version of the Itron OpenWay head-end system

To define an override Endpoint URI for the Itron OpenWay adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is <http://server:port/soa/composer>.

2. Select the D8–EndpointOverrides.dvm in the left panel.

- In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
- In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.

4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:

- **key:** The DVM key for the Endpoint URI you wish to define (see the table above).
- **EndpointURI:** The override Endpoint URI.

6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.

8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Itron OpenWay Extendable Lookups

NOTE: This section applies to both cloud and on-premises implementations of the Smart Grid Gateway Adapter for Itron OpenWay.

This section outlines some of the extendable lookups that must be configured for use with the Itron OpenWay adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Application Group Lookup

The Itron OpenWay head-end system allows users to define addressable groups of meters based on criteria such as a geographic identifier or zip code. These application groups can be represented in Oracle Utilities Smart Grid Gateway by using the Itron OpenWay Application Group Lookup. The groups defined for this lookup are used with Scheduled Read commands. Each value defined for the Itron OpenWay Application Group extendable lookup should include the following:

- **Application Group:** The application group name as defined in the Itron OpenWay head-end system.
- **Description:** A description of the application group.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name:** The event name used by the head-end system
- **Description:** A description of the device event
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Standard Event Name:** The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

Disconnect Switch State Lookup

Some utilities may require verification of the load on a meter to ensure that it is safe to connect the meter. One method of doing this is to check the disconnect switch on the meter to see if it is connected or armed. To use this method, the Itron OpenWay Disconnect Switch State extendable lookup should be configured to list the possible states of the meter disconnect switch. Each value defined for the Itron OpenWay Interval Disconnect Switch State extendable lookup should include the following:

- **Switch State:** The Itron OpenWay disconnect switch state code
- **Description:** A description of the disconnect switch state code.

UOM Code to Standard UOM Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-End Unit of Measure:** The unit of measure code used by the Itron OpenWay application

- **Description:** A description of the unit of measure code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Unit of Measure:** The unit of measure defined in the system.
- **Time of Use:** An optional time of use period, defined in the system, used to further distinguish the unit of measure.
- **Service Quantity Identifier:** An optional service quantity identifier, defined in the system, used to further distinguish the unit of measure.
- **Unit of Measure Magnitude Conversion:**
 - **Magnitude Multiplier:** An optional; multiplier used to convert raw values received from the head-end system to values appropriate for use with the system. For example, if a reading or interval data is received in Wh, a multiplier of “.001” would convert Wh to kWh. If not provided or left blank, no conversion is performed.

Interval Status Code to Condition Mapping

Interval usage received from the Itron OpenWay application can include Itron OpenWay interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Itron OpenWay Interval Status Code to Condition Mapping extendable lookup is used to determine how to map Itron OpenWay interval status codes to standard status codes when receiving usage from the Itron OpenWay application. Each value defined for the Itron OpenWay Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The Itron OpenWay interval status code
- **Description:** A description of the interval status code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.

Other Extendable Lookups

Business Object Name	Description
D8-DvcStatusMappingLookup	Itron - Device Status Lookup
D8-FailureReasonLookup	Itron - Failure Reason Lookup
D8-ItronVersions	Itron - Versions Lookup
D8-JobStatusLookup	Itron - Job Status
D8-ResultLookup	Itron - Result Lookup
D8-RptSelfReadOptionLookup	Itron - Report Self Read Option Lookup

Using the Itron OpenWay Test Harness

Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay includes a test harness that can be configured to simulate a general head-end system for testing the two-way commands. The test harness includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. See [Using Smart Grid Gateway Test Harnesses](#) for more information.

Landis+Gyr

The Oracle Utilities Smart Grid Gateway Adapter for Landis+Gyr supports communication with the Landis+Gyr Gridstream Command Center, including measurement data and device event loading, and command messaging in support of

commissioning, connect, disconnect, decommissioning, and on-demand read. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Version	Gridstream Command Center 7.3
Smart Meter Command Format	MultiSpeak v3.1
Bulk Usage/Event Data Format	California Metering Exchange Protocol (CMEP)
Market(s)	North America, portions of Asia Pacific, Sweden, Australia, New Zealand, and Latin America.
Commodities Supported	Electricity, Gas, Water
Architecture	PLC and RF

Landis+Gyr Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements

The usage data exported from the AMI head-end system as a file in Landis+Gyr format is loaded into Oracle Utilities as initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D3-USAGE-BASE** - contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This can be upgraded without affecting the customization and environment settings added to SGG-D3-USAGE-CM.
2. **SGG-D3-USAGE-CM** allows for customization and simplifies future upgrades.

When importing non-interval usage data, separate initial measurements can be created for difference measurement types. For instance, if the data includes Power Factor or Volt data, separate initial measurements are created for each of these. See [Non-Interval 'Plain' XML to IMD Mapping](#) for more information about specific units of measure that trigger the creation of separate initial measurements.

The runtime configuration settings for the SGG-D3-USAGE-CM project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRawIMD	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false

Element	Description	Valid Values
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
modifyResultXMLInput	Specifies the name of an XQuery document (without the "xq" extension) used to map additional fields from the "plain" XML format to the result XML format sent as initial measurement data. See Mapping Additional Fields for more information.	
dateTimeInUTC	Indicates whether the Landis+Gyr system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device.	true false
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterUsage	Determines if usage should be filtered.	true false

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D3-USAGE-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **Landis+Gyr UOM Code to Standard UOM Mapping** extendable lookup (D3-HeadendUOMLookup) are passed into the system for processing.

NOTE: Filtering of scalar initial measurement data is not supported in the Landis+Gyr adapter.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (D1RT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Device Events

The device event data exported from the head-end system as a file in Landis+Gyr format is loaded into Oracle Utilities as a Device Event. One of your configuration tasks is to customize the device events processing. The required functionality is delivered in the base product as two OSB projects:

1. **SGG-D3-EVENT-BASE** containing components responsible for "actual" processing of incoming data. It can be upgraded in future without affecting the customization and environment settings that done in SGG-D3-EVENT-CM project.
2. **SGG-D3-EVENT-CM** allows the customization and simplifies the future upgrades.

The runtime configuration settings for the SGG-D3-EVENT-CM project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust device event data processing. For example, if you want to load raw data you would specify "true" for the content of the populateRaw element. The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the device event data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
modifyResultXMLInput	Specifies the name of an XQuery document (without the "xq" extension) used to map additional fields from the "plain" XML format to the result XML format sent as device event data. See Mapping Additional Fields for more information.	
dateTimelnUTC	Indicates whether the Landis+Gyr system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device.	true false
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Publishing Events

SGG can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D3-EVENT-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.

- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **Landis+Gyr Device Event Mapping** extendable lookup (D3-DeviceEventMappingLookup) are passed into the system for processing.

Subscribing to Real-Time Device Events

The Landis+Gyr Command Center provides the ability to "subscribe" to device events from within their online interface. This is done by creating a subscriber in Command Center with an associated callback URL as well as a list of events types that subscriber is interested to receive. When an event that is subscribed to occurs it is sent to the callback URL in real time.

Within L+G Events are configured with one of three "alarm" settings. These settings determine how often the events will be sent to subscribers:

1. Alarm: immediately delivered from the meter
2. Advisory: sent based upon a delivery schedule
3. Log Only: sent only upon request (not applicable for our implementation real time event processing)

Command Center will communicate the events using a CIM format that describes the message as a noun/verb combination. The details of the event itself will be contained within a "payload" element of the standard structure. The payload will be formatted using the EndDeviceEvent message structure. This message identifies device events using a CIM 4-part category number. These numbers are four period separated numbers that will describe the type of device and the event. For example: 3.33.1.257 is for "Tamper attempt suspected".

- Segment 1: End Device event domain code (e.g. 3. meter/10. collector/11. router/12. HAN device)
- Segment 2: End Device Event Domain Part Codes (e.g. 1. Access/2. Battery)
- Segment 3: End Device Event Type Codes (e.g. 1. Alarm/2. Alarm Mgt)
- Segment 4: End Device Event Index (e.g. 1. Abort/2. Access Attempt)

Refer to the Landis+Gyr documentation for details about the CIM Category Numbers. CIM Category Numbers must be mapped to standard device event names using the Landis+Gyr Device Event Mapping extendable lookup.

SGG receives these messages through a BPEL composite that saves the incoming request as a file to be picked up by OSB.

The **AMIEventSubscriber** composite is responsible for receiving the event messages based on subscriptions defined in the L+G Command Center. The callback URL configured for the subscription in the Command Center should point to this BPEL composite.

The following OSB projects parse individual device events from the message and perform the validation and mapping of the information to the Device Event Seeder Format.

1. **SGG-D3-CIM-EVENT-BASE** contains components responsible for "actual" processing of incoming data. It can be upgraded in future without affecting the customization and environment settings that done in **SGG-D3-CIM-EVENT-CM** project.
2. **SGG-D3-CIM-EVENT-CM** allows the customization and simplifies the future upgrades.

The runtime configuration settings for the **SGG-D3-CIM-EVENT-CM** project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust device event data processing. For example, if you want to load raw data you would specify "true" for the content of the populateRaw element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the device event data is populated as raw data.	true
		false
callPreProcessing	Determines if the preprocessing proxy service is called.	true
		false
callPostProcessing	Determines if the postprocessing proxy service is called.	true
		false

Element	Description	Valid Values
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Processing statistics are gathered for any real time events that are received (even if there is just one event in the message) in the same manner as device events received via the flat-file interface.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (DIRT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D3-CIM-EVENT-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

NOTE: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The Landis+Gyr adapter base package includes the following initial measurement business objects:

Business Object Name	Description
D3-InitialLoadIMDInterval	Landis+Gyr Initial Load IMD - Interval Used when loading Landis+Gyr interval measurements into the system for the first time.
D3-InitialLoadIMDScalar	Landis+Gyr Initial Load IMD - Scalar

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Landis+Gyr command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect (This command has sub-commands)	Initiate MR by Mtr Num	Reading Changed Notification	Connect Device
	Initiate Connect Disconnect	Connect Disconnect State Changed Notification	Create IMD Completion Event
Remote Disconnect (This command has sub-commands)	Initiate Connect Disconnect	Connect Disconnect State Changed Notification	Disconnect Device
	Initiate MR by Mtr Num	Reading Changed Notification	Create IMD Completion Event
Device Commissioning (Registration)	L+G Add Meter to Inventory		Device Commissioning
Device Commissioning (Installation)	L+G Meter Exchange Notification		Device Commissioning
Device Decommissioning	Meter Remove Notification		Device Decommissioning
Device Deregistration	L+G Meter Retire Notification		Device Deregistration
On-Demand Read (Scalar)	Initiate MR by Mtr Num	Reading Changed Notification	Create IMD Completion Event
On-Demand Read (Scalar) - CIM	CIM Meter On Demand Read (Scalar)	CIM Meter On Demand Read Response	Create IMD Completion Event
On-Demand Read (Interval)	Initiate MR by Mtr Num	Reading Changed Notification	Create IMD Completion Event
On-Demand Read (Interval) - CIM	CIM Meter On Demand Read (Interval)	CIM Meter On Demand Read Response	Create IMD Completion Event
Device Status Check	CIM Ping	CIM Ping Response	
Demand Reset	Schedule Demand Reset (Multispeak)	Schedule Demand Reset Response (Multispeak)	Create IMD Completion Event

Device Registration Commission Commands

Landis+Gyr device commission commands can be used to “register” the device and notify the L+G head-end system that meters have been added to inventory. Device commission commands of this type have the “Registration-Only Mode” flag

set to “Yes”. An Enter algorithm on the “Commission Ready” state evaluates the Registration-Only Mode of the command and if set to “Yes”, the command skips the default “Waiting for Measurement” state and is transitioned to the “Execute Completion Event” state, and an activity log entry is created.

Only the device registration request is sent to the head-end system for device commission commands of this type.

Device registration commands are typically created when new devices are added to inventory in an asset management system such as Oracle Utilities Operational Device Management.

Device Installation Commission Commands

Landis+Gyr device commission commands can be used to notify the L+G head-end system that meters have been installed or exchanged. An Enter algorithm on the “Commission Ready” state evaluates the “Is Installation Check Unnecessary” flag of the command and if set to “False”, the algorithm creates an “L+G Meter Exchange Notification” outbound communication and sends an installation notification to the head-end system.

Device Deregistration Commands

The Landis+Gyr adapter supports the Device Deregistration command (based on the D1-DeviceDeregistration business object). This command sends a communication that deregisters the device in the head-end system, and is most often used when retiring a device. The specific message sent is defined for the Device Deregistration processing role for the L+G head-end system service provider.

Device deegistration commands are typically created when devices are retired in an asset management system such as Oracle Utilities Operational Device Management.

Device Communication Base Package Business Objects

The Landis+Gyr Adapter base package includes the following communication business objects:

Business Object Name	Description
D3-AddMeterToInventoryMultiSp	L+G Add Meter to Inventory (MultiSpeak)
D3-CIMGetLPData	CIM Meter On Demand Read (Interval)
D3-CIMMeterOnDemandRead	CIM Meter On Demand Read (Scalar)
D3-CIMMeterReadingResponse	CIM Meter On Demand Read Response
D3-CIMPing	CIM Ping
D3-CIMPingResponse	CIM Ping Response
D3-ConnectDisconStateChgNtf	Connect Disconnect State Changed Notification
D3-InitiateConnectDisconnect	Initiate Connect Disconnect
D3-InitiateMRByMtrNbr	Initiate Meter Read By Meter (MultiSpeak)
D3-MeterAddNotificationMultiSp	Meter Add Notification (MultiSpeak)
D3-MeterExNotificationMultiSp	L+G Meter Exchange Notification
D3-MeterRetireNotification	L+G Meter Retire Notification
D3-MtrRmvNotifMultiSpeak	Meter Remove Notification (MultiSpeak)
D3-ReadingChgNotification	Reading Changed Notification
D3-ScheduleDemandReset	Schedule Demand Reset (Multispeak)
D3-ScheduleDemandResetResponse	Schedule Demand Reset Response (Multispeak)
D3-ReadingChgNotification	Reading Changed Notification

Landis+Gyr Event Data Mapping

The Landis+Gyr event file format maps as follows into the business object, D1-DeviceEventMappingLookup:

Landis+Gyr Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.
Device Identifier	External Device Identifier	

Landis+Gyr Flat File Field	Device Event Seeder BO Element	Comments
Event Name	External Event Name	
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router
Service Location ID	External Service Location ID	
Communication Module Serial Number	External Communication Module Identifier	
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form): Alert Information
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgment and response messages are sent and received validating that commands have been transmitted. These notifications are based on the following outbound message types.

Outbound Message Type	Description
D3-ADDMTRINV	Add Meter to Inventory
D3-COMMS	Commission Device
D3-CONNECT	Connect Device
D3-DECOMMS	Decommission
D3-DEMRESET	Demand Reset
D3-DERDEV	Deregister Device
D3-DISCONN	Disconnect Device
D3-DVCSTCHK	Device Status Check
D3-INITMRN	Initiate Meter Read by Meter Number
D3-INITMTR	Initiate Meter Read by Meter Number
D3-MTRADDNOT	Meter Add Notification Outbound Message Type

Outbound Message Type	Description
D3-MTREX	Meter Exchange Notification OB MSG
D3-MTRRMV	Meter Remove Notification

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway adapter for Landis+Gyr includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Used for upload of device events. The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event. If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.
D1-InitialLoadIMD	Used for initial measurement upload. The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.
D3-CIMMeterReadingsResponse	CIM Meter On Demand Read Response Retrieve response from CIM On Demand Read command
D3-CIMPingResponse	CIM Ping Response Retrieve response from CIM Device Status Check command
D3-ConDisconStChgNotification	Initiate Connect Disconnect response. Retrieve response from the Initiate Connect Disconnect command.
D3-ReadingChangedNotification	Reading Changed Notification Notification that a Landis+Gyr device reading has changed.
D3-ScheduleDemandResetResponse	Scheduled Demand Reset Response Retrieve response from Demand Reset command

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway adapter for Landis+Gyr includes the following message senders:

Message Sender	Description
D3-Comms	Commission Device
D3-Connect	Connect Device
D3-Decomm	Decommission Device
D3-Decomms	Decommissioning Sender
D3-DemReset	Demand Reset
D3-DerDevice	Deregister Device
D3-Disconnect	Disconnect Device
D3-InitMTR	Initiate Meter Read by Meter Number Outbound Message
D3-MTREMMS	Meter Exchange Notification Message Sender
D3-RTSender	Real Time Sender
D3-RTSnd	Real-time Sender (Landis+Gyr)
D3-SDemReset	SG Demand Reset

BPEL Processes

These processes are responsible for performing the conversion from Oracle Utilities format to MultiSpeak 3.0 format, invoking process callouts and invoking the remote endpoint to trigger the device events.

OnDemandRead Composite Process: Invokes the remote endpoint to trigger the on-demand read event. An asynchronous reply responds to the OUAF layer when the reading arrives.

ConnectDisconnect Composite Process: Invokes the remote endpoint to trigger the connect/disconnect event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

CommissionDecommission Composite Process: Invokes the remote endpoint to trigger the commission or decommission event. After the synchronous call completes, one of the following second business callout services is invoked to determine if the related “received” or “completed” callout should be executed:

- isExecutingCommissionReceivedCallout
- isExecutingCommissionCompletedCallout
- isExecutingDecommissionReceivedCallout
- isExecutingDecommissionCompletedCallout
- isExecutingAddMeterToInventoryReceivedCallout
- isExecutingAddMeterToInventoryCompletedCallout
- isExecutingMeterExchangeNotificationReceivedCallout
- isExecutingMeterExchangeNotificationCompletedCallout

CIMOnDemandRead Composite Process: Invokes the remote endpoint to trigger the CIM on-demand read event. An asynchronous reply responds to the OUAF layer when the reading arrives.

CIMDeviceStatusCheck Composite Process: This process is similar to CIM OndemandRead BPEL process. SGG uses the result of On Demand Read command to identify the status of the meter. If reads are successfully returned, then meter is running healthy otherwise it is considered as meter inactive/dead.

DemandReset Composite Process: Invokes the remote endpoint to trigger the demand reset event. An asynchronous reply responds to the OUAF layer when the reading arrives.

LGProcessCallout Composite: This business callout provides a point at which customers and implementers can incorporate custom business logic and transformations. This composite includes the WSDLs and processing logic for all of the MultiSpeak processes. The default implementation of each method is a direct return of the input.

Web Services

These web services are all defined in the Landis+Gyr head end system. The WSDLs were added to a Meta Data Storage (MDS) layer in OUAF and all references to the WSDL point to this MDS location.

Web Service	Related BPEL Process	Description
MR_CB	OnDemandRead	This web service is defined by the Landis+Gyr head end system's implementation of MR_Server.
	CommissionDecommission	The WSDL defines the interface for requesting a meter reading from the head end system.
	DemandReset	The actual definition can be obtained from L&G or downloaded from multispeak.org. Build 3.0aa is appropriate if obtained from MultiSpeak. Default endpoint must be changed in configuration: http://demo.turtletech.com/Multispeak/webapi/MR_CB.asmx
CD_CB	ConnectDisconnect	This web service is defined by the Landis+Gyr implementation of CB_CD.
		The WSDL defines the interface for requesting a meter's connection or disconnection on the head end system.
		This web service defines the interface for reporting a connection or disconnection by the head end system.
		This web service is only invoked by the head end system; not OUAF. Only the CDStateChangedNotification web method is implemented in the composite. Default endpoint must be changed in configuration: http://demo.turtletech.com/Multispeak/webapi/CD_CB.asmx
CIMService	CIMOnDemandRead	This web service is defined by the L+G head end's implementation of AMIRequest Server.
	CIMDeviceStatusCheck	The WSDL defines the interface for requesting a meter reading from the head end system. The actual definition should be obtained from L&G or downloaded from L&G SDK for CIM 2.0.
LGProcessCallout	OnDemandRead	Imported from LGProcessCallout Composite
	ConnectDisconnect	Default endpoint must be changed in configuration: http://127.0.0.1:8000/soa-infra/services/default/LGProcessCallout/LGProcessCallout
	CommissionDecommission	

Landis+Gyr Command Center Web Services

The following table describes the Land+Gyr Command Center web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Command	AMI Adapter Business Objects	Landis+Gyr Web Services	Landis+Gyr Operations
Device Commissioning	D3-MeterAddNotificationMultiSp	MR	MeterAddNotification
Device Decommissioning	D3-MtrRmvNotifMultiSpeak	MR	MeterRemoveNotification
Remote Connect/ Remote Disconnect	D3-InitiateConnectDisconnect	CD	InitiateConnectDisconnect
On-Demand Read	D3-InitiateMRByMtrNbr	MR	InitiateMeterReadByMeterNumber
On-Demand Read (CIM)	D3-CIMGetLPData D3-CIMMeterOnDemandRead	CIMService	ScheduleDemandRead
Demand Reset	D3-ScheduleDemandReset	MR	CIM

Configuring a Landis+Gyr Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway Adapter for Landis+Gyr to communicate with the Landis+Gyr Command Center software.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the L+G Command Center in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D3-ConDisconStChgNotification	Initiate Connect Disconnect Response
D3-CIMMeterReadingsResponse*	CIM Meter On Demand Read Response
D3-CIMPingResponse	CIM Ping Response
D3-ReadingChangedNotification*	Reading Changed Notification
D3-ScheduleDemandResetResponse	Scheduled Demand Reset Response

*The Landis+Gyr adapter supports both MultiSpeak and CIM On Demand Read commands. You only need to configure the inbound service for the protocol you wish to use.

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D3-Comms	Commission Device
D3-Connect	Connect Device
D3-Decomm	Decommission Device
D3-InitMTR	Initiate Meter Read by Meter Number Outbound Message
D3-RTSender	Real Time Sender
D3-RTSnd	Real-time Sender (Landis+Gyr)
D3_CIMODR	L+G CIM On Demand Read
D3_CIMPING	L+G CIM Ping
D3_SCHDEMRES	L+G Schedule Demand Reset

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tabsysuser00:

- **HTTP Header:** SOAPAction: http://xmlns.oracle.com/ouaf/multispeak_3.0/<OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/D3/<SERVICE>/<SERVICE>

where:

- <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
- <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
- <PASSWORD>: the password used to log into WebLogic Enterprise Manager
- <EM_SERVER_IP>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed

- **<EM_SERVER_PORT>**: the port where the WebLogic Enterprise Manager is installed
- **<SERVICE>**: the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D3-ADDMTRINV	Add Meter to Inventory
D3-COMMS	Commission Device
D3-CONNECT	Connect Device
D3-DECOMMS	Decommission
D3-DEMRESET	Demand Reset
D3-DERDEV	Deregister Device
D3-DISCONN	Disconnect Device
D3-DVCSTSCHK	Device Status Check
D3-INITMRN	Initiate Meter Read by Meter Number
D3-INITMTR	Initiate Meter Read by Meter Number
D3-MTRADDNOT	Meter Add Notification Outbound Message Type
D3-MTREX	Meter Exchange Notification OB MSG
D3-MTRRMV	Meter Remove Notification

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the L+G Command Center must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - Landis+Gyr:

- **External System:** LG
- **Description:** Landis+Gyr
- **Outbound Message Types::**

Outbound Message Type	Description	Message Sender
D3-ADDMTRINV	Add Meter to Inventory	Message sender associated with the Add Meter to Inventory Outbound Message Type
D3-COMMS	Commission Device	Message sender associated with the Commission Device Outbound Message Type

Outbound Message Type	Description	Message Sender
D3-CONNECT	Connect Device	Message sender associated with the Connect Device Outbound Message Type
D3-DECOMMS	Decommission	Message sender associated with the Decommission Device Outbound Message
D3-DEMRESET	Demand Reset	Message sender associated with the Demand Reset Outbound Message Type
D3-DERDEV	Deregister Device	Message sender associated with the Deregister Device Outbound Message Type
D3-DISCONN	Disconnect Device	Message sender associated with the Disconnect Device Outbound Message Type
D3-DVCSTSCHK	Device Status Check	Message sender associated with the Device Status Check Outbound Message Type
D3-INITMRN	Initiate Meter Read by Meter Number	Message sender associated with the Initiate Meter Read By Meter Number Outbound Message Type
D3-INITMTR	Initiate Meter Read by Meter Number	Message sender associated with the Initiate Meter Read By Meter Number Outbound Message Type
D3-MTRADDNOT	Meter Add Notification Outbound Message Type	Message sender associated with the Meter Add Notification Outbound Message Type
D3-MTREX	Meter Exchange Notification OB MSG	Message sender associated with the Meter Exchange Notification Outbound Message Type
D3-MTRRMV	Meter Remove Notification	Message sender associated with the Meter Remove Notification Outbound Message Type

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D3-Request.xml
- **Response XSL:** D3-Response.xml

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the L+G Command Center must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - Landis+Gyr:

- **Service Provider:** LG
- **Description:** Landis+Gyr
- **External Reference ID:** L+G
- **External System:** Landis+Gyr
- **Out Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the L+G service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM mapping processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the L+G service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D3-AddMeterToInventoryMultiSp	Add Meter to Inventory
Device Commission	Device Installation	D3-MeterExNotificationMultiSp	Meter Exchange Notification
Device Decommission	Device Removal	D3-MtrRmvNotifMultiSpeak	Decommission Meter Remove Notification
Device Deregistration	Device Deregistration	D3-MeterRetireNotification	Deregister Device
On-Demand Read (Scalar), Multispeak and CIM	On-Demand Read (Scalar)	MS: D3-InitiateMRByMtrNbr CIM: D3-CIMMeterOnDemandRead	MS: Initiate Meter Read by Meter Number CIM: CIM On Demand Read
On-Demand Read (Interval)	On-Demand Read (Interval)	D3-CIMGetLPData	CIM On Demand Read
Demand Reset	Demand Reset	D3-ScheduleDemandReset	Demand Reset
Device Status Check	Device Status Check	D3-CIMPing	Device Status Check
Remote Connect	Remote Connect	D3-InitiateConnectDisconnect	Connect Device

Command	Processing Role	Default Business Object	Default Outbound Message Type
Remote Disconnect	Remote Disconnect	D3-InitiateConnectDisconnect	Disconnect Device

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Landis+Gyr endpoint override DVM (D3-EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Landis+Gyr adapter and the command used with each:

DVM Key	Commands
CIMService	On-Demand Read (Scalar) - CIM On-Demand Read (Interval) - CIM Device Status Check
CD_CB	Remote Connect Remote Disconnect
Metering	Device Commissioning (Registration)
MR_CB	Device Commissioning Device Decommissioning Device Commissioning (Installation) Device Deregistration On-Demand Read (Scalar) On-Demand Read (Interval)
LGProcessCallout	User Exit Functions

To define an override Endpoint URI for the Landis+Gyr adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is <http://server:port/soa/composer>.

2. Select the D3-EndpointOverrides.dvm in the left panel.

- In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
- In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list). The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.

6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.
8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Landis+Gyr Extendable Lookups

NOTE: This section applies to both cloud and on-premises implementations of the Smart Grid Gateway Adapter for Landis+Gyr.

This section outlines some of the extendable lookups that must be configured for use with the Landis+Gyr adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

CIM Response Status Extendable Lookup

The CIM Response Status extendable lookup is used to map descriptions to response status codes received from the L+G Command Center. Each value defined for the CIM Response Status extendable lookup should include the following:

- **Response Status**: The CIM status code for the response status
- **Description**: A description of the response status
- **Usage Flag**: The status of the lookup value (can be Active or Inactive)

CIM Data Source Extendable Lookup

The CIM Data Source extendable lookup is used to map descriptions to data sources defined in the L+G Command Center. Each value defined for the CIM Data Source extendable lookup should include the following:

- **Data Source**: The CIM code for the data source
- **Description**: A description of the data source
- **Usage Flag**: The status of the lookup value (can be Active or Inactive)

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name**: The event name used by the head-end system
- **Description**: A description of the device event

- **Status:** The status of the lookup value (can be Active or Inactive)
- **Standard Event Name:** The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

UOM Code to Standard UOM Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-end UOM:** The unit of measure code used by the head-end system.
- **Unit of Measure:** The unit of measure defined in the system.
- **Description:** A description of the unit of measure code.

Interval Status Code to Condition Mapping

Interval usage received from the Landis+Gyr Command Center can include interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Landis+Gyr Interval Status Code to Condition Mapping extendable lookup is used for this purpose. Each value defined for the Landis+Gyr Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The interval status code
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.
- **Description:** A description of the interval status code.

Using the Landis+Gyr Test Harness

Oracle Utilities Smart Grid Gateway Adapter for Landis+Gyr (LG) includes a test harness that can be configured to simulate the Landis+Gyr Gridstream Command Center head-end system for testing the two-way commands. The test harness is Multispeak 3.0 standard compliant and includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. See [Using Smart Grid Gateway Test Harnesses](#) for more information.

Landis+Gyr Interval Data Mapping

This section describes how data in Landis+Gyr import files is mapped to the XML document format created by OSB and sent to Oracle Utilities Smart Grid Gateway.

When Landis+Gyr data is processed, it is initially received in a tilda-separated file format, which is converted into a "plan" XML format before being converted into the "result" XML format which is sent to the IMD Seeder and/or Device Event Seeder inbound services.

Non-Interval Usage with Additional Fields

The following is a sample file of non-interval usage that contains additional fields.

```
ID~PremiseID~ESIID~Provisioned~Meter~kWh~DateTime~Peak~PeakDateTime~Dmd~TouA~TouB~TouC~TouD~TouE~Volts~PF~P
EMED01~SL002~~~96968280~34315.000~08042010120000AM~2.66~03122009063000AM~~34315.000~0.000~0.000~0.000~0.000~
EMED01~SL001~~~96968285~33693.000~08042010120000AM~2.62~03122009061500AM~~33693.000~0.000~0.000~0.000~0.000~
```

This data is mapped to the "plain" XML format.

XML 'Plain' XML Format

The "Plain" XML contain elements to hold the extra fields (highlighted in bold).

```
<?xml version="1.0" encoding="utf-8"?>
<xs:schema attributeFormDefault="unqualified" elementFormDefault="qualified"
  targetNamespace=" http://xmlns.oracle.com/LandisGyrUsage"
  xmlns:xs="http://www.w3.org/2001/XMLSchema">

Non-Interval Usage to 'Plain' XML Mapping

The following table shows the mapping between fields in incoming non-interval data and child elements of MeterReads/ MeterRead element in the "Plain" XML format:

L+G Interval Structure Field	"Plain" XML element
ID	RecordType
Premise ID	Premise
ESIID	ESIID
Provisioned	Provisioned
Meter	MeterID
kWh	kWh
Date/Time of initial Read	FirstIntervalDateTime
Peak	Peak
Peak Date/Time	PeakDateTime
Dmd	Dmd
TouA	TouA
TouB	TouB
TouC	TouC
TouD	TouD
TouE	TouE
Volts	Volts
PF	PF
<extraFieldName1>	ExtraFields/ExtraField/FieldName with value of <extraFieldName1> ExtraFields/ExtraField/FieldValue with value in <extraFieldName1>
<extraFieldName2>	ExtraFields/ExtraField/FieldName with value of <extraFieldName2> ExtraFields/ExtraField/FieldValue with value in <extraFieldName2>
<extraFieldName3>	ExtraFields/ExtraField/FieldName with value of <extraFieldName3> ExtraFields/ExtraField/FieldValue with value in <extraFieldName3>
<extraFieldNameN>	ExtraFields/ExtraField/FieldName with value of <extraFieldNameN> ExtraFields/ExtraField/FieldValue with value in <extraFieldNameN>
RawData	A record content from incoming file.

'Plain' XML to IMD Mapping

The following table outlines how data from the "plain" XML format is mapped to the InitialLoadIMD format when the Landis+Gyr record type is set to "MEPMD01" (interval usage).

"Plain" XML element	InitialLoadIMD element	Note
Record Type	N/A	
RecordVersion	N/A	
Premise ID	N/A	
ESIID	N/A	
Provisioned	N/A	
Meter ID	dvclDN	as is
Purpose	N/A	
Commodity	N/A	
Units	externalUOM	as is
CalcConst	mcm	as is
Interval	spi	Transform from DDHHMM to SPI
Count	N/A	
FirstIntervalDateTime	stDt	Convert to OUAF date/time format
Data	msrs	Value -> msrs/mL/q
Status -> msrs/mL/sts/stsL/st		
N/A	imdType	'D1IL
Origin	externalId	the origin attribute in "Plain" XML (incoming file name)
N/A	serviceProviderExternalId	L+G
RawData	rawData	Vendor-specific "raw" data

Non-Interval 'Plain' XML to IMD Mapping

The following table outlines how non-interval data in the "plain" XML format is mapped to the InitialLoadIMD format when the Landis+Gyr record type is set to "EMED01" (non-interval usage).

"Plain" XML Element	InitialLoadIMD element	Notes
RecordType	N/A	
Premise	N/A	
ESIID	N/A	
Provisioned	N/A	
MeterID	dvclDN	as is
kWh	enQty	as is
	uom	KWH
TimeStamp	enDt	Convert to OUAF date/time format This should be mapped to enDt. Relevant only to non-interval data.
Peak	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KW
PeakDateTime	enDt	Convert to OUAF date/time format
Dmd	enQty	as is

"Plain" XML Element	InitialLoadIMD element	Notes
		A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KW and 'Dmd' in " <mcIdN>
TouA	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH and 'kWh Rate A' in " <mcIdN>
TouB	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH and 'kWh Rate B' in " <mcIdN>
TouC	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH and 'kWh Rate C' in " <mcIdN>
TouD	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH and 'kWh Rate D' in " <mcIdN>
TouE	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH and 'kWh Rate E' in " <mcIdN>
Volts	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with Volts
PF	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with PF
N/A	imdType	D1IL
Origin	externalId	the origin element in "Plain" XML (incoming file name)
N/A	serviceProviderExternalId	L+G This is a constant. There is no such field in incoming structure.
RawData	rawData	Vendor-specific "raw" data When the "populateRawIMD" parameters in the EnvironmentSettings.xq file is set to true.

Mapping Additional Fields

Measurement and device event files received from the Landis+Gyr head-end system can include additional fields containing data to be imported into Oracle Utilities Smart Grid Gateway. These additional fields must be mapped to elements within the XML document processed by OSB and sent to Smart Grid Gateway.

This mapping can be performed through use of a custom XQuery document, specified in the EnvironmentSettings.xq file via the "modifyResultXMLInput" parameter.

The following sample XQuery documents illustrate how additional fields can be mapped into the XML format sent to Smart Grid Gateway.

Sample XQuery — Initial Measurements

The following XQuery is an example that shows a transformation that passes in a root element with 3 children (the "result" XML, the "plain" XML, the environment settings) that returns a modified "result" XML. For testing purposes, it changes the original value in the <enQty> "result" element and replaces it with a value from the "plain" XML depending on an environment setting variable. The <serviceProviderExternalId> value was also replaced by a hard-coded value.

```
declare namespace lan = "http://xmlns.oracle.com/LandisGyrUsage";
declare namespace xf = "http://tempuri.org/D3/lgimd";
declare namespace soap = "http://schemas.xmlsoap.org/soap/envelope/";
declare function xf:modifyResultXML($modifyResultXMLInput as element(*)) as element(*){
<InitialLoadIMDList>
```

```

{
  for $InitLoadIMD in $ modifyResultXMLInput/InitialLoadIMDList/InitialLoadIMD
  return
    <InitialLoadIMD>
      <preVEE>
        <dvcIdN>{ data($InitLoadIMD/preVEE/dvcIdN) }</dvcIdN>
        <externalId>{ data($InitLoadIMD/preVEE/externalId)}</externalId>
        <uom>{ data($InitLoadIMD/preVEE/uom)}</uom>
        <mcIdN>{ data($InitLoadIMD/preVEE/mcIdN)}</mcIdN>
        <endT>{ data($InitLoadIMD/preVEE/endT)}</endT>
        {
          if ($modifyResultXMLInput/EnvironmentSettings/test1="true")
          then <enQty>{ data($modifyResultXMLInput/lan:MeterReads/lan:MeterRead/lan:ExtraFields/
lan:ExtraField[lan:FieldName
= 'EF4']/lan:FieldValue) }</enQty>
          else <enQty>{ data($modifyResultXMLInput/lan:MeterReads/lan:MeterRead/lan:ExtraFields/
lan:ExtraField[lan:FieldName= 'EF2']/lan:FieldValue) }</enQty>
          }
        <imdType>{ data($InitLoadIMD/preVEE/imdType) }</imdType>
      </preVEE>
      <serviceProviderExternalId>NewSPId</serviceProviderExternalId>
    </InitialLoadIMD></InitialLoadIMDList>
};
declare variable $modifyResultXMLInput as element(*)external;
xf:modifyResultXML($modifyResultXMLInput)

```

Sample XQuery — Device Events

The following XQuery is an example that shows a transformation that passes in a root element with 3 children (the "result" XML, the "plain" XML, and the environment settings) and returns a modified "result" XML. For testing purposes, it changes the original value in the `<externalCommunicationModuleIdentifier>` "result" element and replaces it with a value from the "plain" XML depending on an environment setting variable. The `<externalServiceLocationId>` value is also replaced by a hard-coded value.

```

declare namespace lan = "http://xmlns.oracle.com/LandisGyrEvent";
declare namespace xf = "http://tempuri.org/D3/event";
declare namespace soap = "http://schemas.xmlsoap.org/soap/envelope/";
declare function xf:modifyResultXML($modifyResultXMLInput as element(*) as element(*){
  <DeviceEventSeeder>
    <externalSenderId>{data($modifyResultXMLInput/DeviceEventSeeder/externalSenderId) }</
externalSenderId>
    <deviceIdentifierNumber>{ data($modifyResultXMLInput/DeviceEventSeeder/
deviceIdentifierNumber) }</deviceIdentifierNumber>
    <externalEventName>{ data($modifyResultXMLInput/DeviceEventSeeder/externalEventName) }</
externalEventName>
    <eventDateTime>{ data($modifyResultXMLInput/DeviceEventSeeder/eventDateTime) }</
eventDateTime>
    <externalSourceIdentifier>{ data($modifyResultXMLInput/DeviceEventSeeder/
externalSourceIdentifier)
}</externalSourceIdentifier>
    <eventInformation>
      <externalEventCategory>{data($modifyResultXMLInput/DeviceEventSeeder/eventInformation/
externalEventCategory)
}</externalEventCategory>
      <externalEventSeverity>{data($modifyResultXMLInput/DeviceEventSeeder/eventInformation/
externalEventSeverity)
}</externalEventSeverity>
      <externalDeviceType>{data($modifyResultXMLInput/DeviceEventSeeder/eventInformation/
externalDeviceType)
}</externalDeviceType>
      <externalServiceLocationId>{1234 }</externalServiceLocationId>
      {
        if ($modifyResultXMLInput/EnvironmentSettings/testA="true")
        then <externalCommunicationModuleIdentifier>{ data($modifyResultXMLInput/lan:DeviceEvents/
lan:DeviceEvent/lan:DeviceType)}</externalCommunicationModuleIdentifier>
        else <externalCommunicationModuleIdentifier>{data($modifyResultXMLInput/lan:DeviceEvents/
lan:DeviceEvent/lan:CategoryId)}</externalCommunicationModuleIdentifier>
        }
      <externalStatusValue>{data($modifyResultXMLInput/DeviceEventSeeder/eventInformation/
externalStatusValue)
}
}

```

```

} </externalStatusValue>
  <externalStatusDateTime>{data($modifyResultXMLInput/DeviceEventSeeder/eventInformation/
externalStatusDateTime)}</externalStatusDateTime>
  </eventInformation>
</DeviceEventSeeder>
};
declare variable $modifyResultXMLInput as element(*) external;
xf:modifyResultXML($modifyResultXMLInput)

```

MV90 for Itron

The Oracle Utilities Smart Grid Gateway MV-90 Adapter for Itron uses Oracle Service Bus (OSB) to facilitate communication between Oracle Utilities Smart Grid Gateway and MV-90. The following functionality is included:

Measurement Data Loading - Data parsing and transformation from MV-90 binary format into the Oracle Utilities Service and Measurement Data Foundation unified format.

Measurement Data Processing - Configurable mapping for MV-90 status codes to Oracle Utilities Service and Measurement Data Foundation standard values, along with configurable device event creation based on MV-90 status codes.

The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Version	SGG supports the .mv9 binary, mainframe data format.
Protocol	Binary file format.
Market(s)	Worldwide, but largely USA.
Architecture	AMR

MV90 Adapter Processing

This section provides details concerning the OSB processing and OUAF objects supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data Loading

The initial measurement data load and subsequent device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway service format. Payloads contain measurements in a head-end specific format OSB then places each service call into a JMS queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel then a service creates initial measurements with data in a common format with head-end-specific processing as needed.

Initial Measurements

The usage data exported from the AMI head-end system as a file in MV-90 format is loaded into Oracle Utilities as Initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D5-USAGE-BASE** contains components responsible for the actual processing of incoming data. It should not be modified during configuration. This project can be upgraded without affecting the customization and environment settings added to the SGG-D5-USAGE-CM project.
2. **SGG-D5-USAGE-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-D5-USAGE-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRawIMD	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterUsage	Determines if usage should be filtered.	true false
usePhysicalChannel	Optional value. Determines whether the physical channel ID is passed to the IMD seeder to create the measuring component identifier number. If this is set to false, the MV90 LOGCHAN field is used.	true false (default)
fieldForDvclidN	Optional value. Specifies which field is used as the value for the device ID.	DC_RECID DC_CUSTID DC_METERID (default)
MV90ScalarChannelSuffix	Optional value. Holds a suffix value to be added to the measuring component identifier number when a scalar IMD is created for register reads. Default value is "_S"	
processMV90ScalarData	Optional value. Determines if register reads are processed.	true false (default)

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D5-USAGE-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Usage

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **MV90 UOM Code to Standard UOM Mapping** extendable lookup (D5-UOMtoStdUOMCodeMapLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (D1RT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Initial Measurement Data Load with Register Reads

In the MV90 format, measurement data can include interval data as well as register reads that can be used to create scalar measurements. For information on configuring the adapter for loading scalar data based on register reads, see [Override Processing Methods for Scalar Initial Measurement Data](#).

Base Package Business Objects

The MV-90 Adapter for Itron base package includes the following initial measurement business objects:

Business Object Name	Description
D5-InitialLoadIMDInterval	MV-90 Initial Load IMD
D5-InitialLoadIMDScalar	MV90 - Initial Load IMD - Scalar

Configuring an MV90 Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway MV-90 Adapter for Itron to receive usage from an MV-90 system.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including incoming usage.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the MV-90 system must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - MV-90:

External System: MV90

Description: MV90 - Mainframe File Format

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the MV-90 system must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about creating service providers.

Service Provider - MV-90:

- **Service Provider:** MV90
- **Description:** Head-End System for MV90
- **External Reference ID:** MV90
- **External System:** MV90 - Mainframe File Format
- **Out Name/ID in Their System:** MV90
- **AMI Device ID Type:** Serial Number
- **AMI Measuring Component ID Type:**

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the MV90 service provider. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Override Processing Methods for Scalar Initial Measurement Data

In the MV-90 format, meter read start and stop values can represent either a calculated read based on the interval data that is included in the MV90 data, or a register read that has been logged using a separate channel. When the values represent a register read the application can create a second file for the scalar initial measurements. The creation of a scalar initial measurement file is triggered by the Register Type flag, DC_REGTYPE, in the MV-90 data and the processMV90ScalarData variable in the EnvironmentSettings.xq file. The following register read values are valid for the DC_REGTYPE field:

Value	Description
V	Visual energy readings
D	Visual demand and energy readings
E	Encoder register readings (energy only).
B	Both encoder and visual energy readings.
C	Calculate stop meter readings from the encoder base reading

In order to configure your adapter to create scalar initial measurements based on register reads, first define new measuring component types and register measuring components. Then use the new measuring component types to specify override processing methods on the Initial Measurement Creation processing method for your service provider.

Measuring Component Types for Scalar Reads: To create initial measurement data for register reads, first create new measuring component types to represent the registers. These will be used to create measuring components for scalar reads.

Example Measuring Component Type

- **Measuring Component Type:** MV90_SCALAR_REG
- **Description:** MV90 Scalar Register
- **Measuring Component Business Object:** Register
- **Measurement Business Object:** Measurement
- **Service Type:** Electric Service
- **Allow Negative Consumption:** Allowed
- **Consumptive/Subtractive:** Subtractive
- **Read Method:** Automatic Read

Other attributes such as Value Identifiers, VEE Groups, and so on, should be defined based on requirements

Register Measuring Components for Scalar Reads: Use the new measuring component types to create measuring components for the scalar measurements created by the register read process. You must create a corresponding register measuring component for each interval channel for which you will receive scalar reads. The channel number for the registers must be based on the channel numbers of the corresponding interval channels, plus the suffix defined in the “MV90ScalarChannelSuffix” environment setting. The default value for this setting is “_S”. These registers must also be added to the device configuration used by the interval channels (in other words, both measuring components - interval and scalar - must be on the same device). The following table shows examples of these values for the measuring components:

Device Type/Serial Number	MV-90 Interval Channel Number	MV-90 Scalar Register Channel Number
MV90 Electric/00001	1	1_S
MV90 Electric/00002	1	1_S
MV90 Electric/00003	1	1_S

Override Processing Methods for MV-90 Service Provider: Add an override processing method to the Initial Measurement Creation processing method for the MV90 service provider for each register measuring component type. The

business object for each override processing method should be “D5-InitialLoadIMDScalar”. The following tables shows examples of the override processing methods:

Measuring Component Type	Business Object
MV90 Scalar Register	D5-InitialLoadIMDScalar
Measuring Component Type 2	D5-InitialLoadIMDScalar
Measuring Component Type n	D5-InitialLoadIMDScalar

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM translation processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map MV90 UOM codes to standard UOM codes when receiving usage from the MV-90 system.

Configuring MV90 Extendable Lookups

NOTE: This section applies to both cloud and on-premises implementations of the Smart Grid Gateway MV90 Adapter for Itron.

This section outlines some of the extendable lookups that must be configured for use with the MV-90 Adapter for Itron. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Interval Status Code to Event Mapping

The MV-90 adapter for does not accept device events from an MV-90 system, but can create device events based on specific interval status codes in an incoming usage reading. The MV-90 Interval Status Code to Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when creating device events based on interval status codes received with usage from the MV-90 system.

Each value defined for the Interval Status Code to Event Mapping extendable lookup should include the following:

- **MV90 Interval Status:** The interval status code used by the MV-90 system
- **Description:** A description of the MV-90 interval status code
- **Event Duration Mode:** The duration type for the event. Can be either “Individual” or “Continuous” (used for events with a duration, such as an outage).
- **Device Event Type:** The Device Event Type for the device event created for this interval status code. For status codes with an Event Duration Mode or “Continuous” this is the start event, or the first of the paired events created for this status code.
- **End Event Type:** The Device Event Type for the “end” device event created for this interval status code. For status codes with an Event Duration Mode or “Continuous” this is the start event, or the last of the paired events created for this status code.

Example: The MV-90 “Low Voltage” status code could be configured to create a “Low Voltage” device event as follows:

- **MV90 Interval Status:** <MV-90 interval status code for low voltage>

- **Description:** Low Voltage detected for meter
- **Event Duration Mode:** Individual
- **Device Event Type:** Low Voltage
- **End Event Type:** N/A

Example: The MV-90 “Power Outage” status code could be configured to create a “Last Gasp” device event, and a “Power Restoration” event as follows:

- **MV90 Interval Status:** <MV-90 interval status code for outage>
- **Description:** Outage
- **Event Duration Mode:** Continuous
- **Device Event Type:** Last Gasp
- **End Event Type:** Power Restoration

UOM Code to Standard UOM Code Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-end UOM:** The unit of measure code used by the head-end system.
- **Unit of Measure:** The unit of measure defined in the system.
- **Description:** A description of the unit of measure code.

Other Extendable Lookups

Business Object Name	Description
D5 - ChanelStatusCodeLookup	MV-90 Channel Status Code Lookup
D5-IntStsCdToCndMapPrLookup	Condition Mapping with Priority

Networked Energy Services

The Oracle Utilities Smart Grid Gateway Adapter for Networked Energy Services (NES) supports two-way communication with the NES server. Communications include measurement data and device event loading, and command messaging in support of commissioning, connect, disconnect, decommissioning, and on-demand read. The adapter uses Oracle Service Bus (OSB) and Oracle Business Process Execution Language Process Manager (BPEL PM) to facilitate communication between Oracle Utilities Smart Grid Gateway and NES. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Version	Networked Energy Services 5.3
Protocol	Proprietary (NES specific)
Market(s)	Worldwide
Architecture	ANSI and IEC, PLC

Networked Energy Services Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements

Usage data is exported from the head-end system as a file in NES format and is loaded into Oracle Utilities as initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D4-USAGE-BASE** contains components responsible for the actual processing of incoming data. This should not be modified during configuration.
2. **SGG-D4-USAGE-CM** allows you to segment your customizations so that future upgrades of base functionality implemented in SGG-D4-USAGE-BASE do not affecting the customization and environment settings.

The runtime configuration settings for the SGG-D4-USAGE-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterUsage	Determines if usage should be filtered.	true false

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the `publishServices/service` element in the `EnvironmentSettings.xq` file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D4-USAGE-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the `EnvironmentSettings.xq` file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging

Parameter	Description	Default Value
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **NES UOMCode Mapping Extendable Lookup** extendable lookup (D4-HeadendUOMLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (D1RT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Device Events

The device event data exported from the head-end system as a file in NES format is loaded into Oracle Utilities as a Device Event. One of your configuration tasks is to customize the device events processing.

The required functionality is delivered in the base product as two OSB projects:

1. **SGG-D4-EVENT-BASE** contains components responsible for the actual processing of incoming data. This should not be modified during configuration.
2. **SGG-D4-EVENT-CM** allows you to segment your customizations so that future upgrades of base functionality implemented in SGG-D4-EVENT-BASE do not affecting the customization and environment settings.

The runtime configuration settings for the SGG-D4-EVENT-CM project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the device event data is populated as raw data.	true
		false
callPreProcessing	Determines if the preprocessing proxy service is called.	true
		false
callPostProcessing	Determines if the postprocessing proxy service is called.	true
		false

Element	Description	Valid Values
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
serviceProviderExternalId	The External ID of the NES service provider.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Publishing Events

The NES adapter can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D4-EVENT-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100

Parameter	Description	Default Value
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the `<filterUsage>` element in the `EnvironmentSettings.xq` file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose `<externalEventName>` matches one of the values defined in the **NES Device Event Mapping** extendable lookup (D4-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (D1RT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D4-EVENT-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.

3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

NOTE: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The NES adapter base package includes the following device, initial measurement, and device event business objects:

Business Object Name	Description
D4-InitialLoadIMDInterval	NES Initial Load IMD Interval
D4-InitialLoadIMDScalar	NES Initial Load MD Scalar
D4-SmartMeter	Smart Meter - NES
D4-EventExtractScheduler	NES Event Extract Scheduler
D4-PayloadExtractScheduler	Payload Extract Scheduler
D4-UsageExtractScheduler	NES Usage Extract Scheduler

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each NES command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	Retrieve Meter Information	Read Load Status Notification	Create IMD
	Read Load Status	Read Billing Data On-Demand Notification	Connect Device
	Read Billing Data On-Demand	Connect Load Notification	
	Connect Load		
Remote Disconnect	Disconnect Load	Disconnect Load Notification	Create IMD
	Read Billing Data On-Demand	Read Billing Data On-Demand Notification	Disconnect Device
Device Commissioning	Add Meter Request	Set ATM Configuration Notification	Device Commissioning
	Set ATM Configuration		
Device Decommissioning	Decommission Meter Request	Decommission Meter Notification	Device Decommissioning
On-Demand Read (Scalar)	Read Billing Data On-Demand	Read Billing Data On-Demand Notification	Create IMD

Command	Outbound Communication	Inbound Communication	Completion Event
On-Demand Read (Interval)	Read Load Profile On Demand	Read Load Profile On-Demand Notification	Create IMD

Commissioning and Decommissioning Communications

Commissioning a previously decommissioned NES device requires a different process than commissioning a new device.

When you commission a device for the first time, a commissioning command is sent to BPEL to create the meter in NES using the DeviceManager.CreateMeter command. If Automatic Topology Management is selected then the DeviceManager.SetATMConfiguration command is also sent.

When you decommission a device, BPEL sends the DeviceManager.Move command to NES for the device. In NES you need to confirm that the device has been moved to a non-DC tree. You then need to manually delete the device from the non-DC tree. To permanently decommission the device you must delete it by using the DeviceManager.Delete command from the NES interface.

To recommission a device that has been previously decommissioned, you need to log into NES and manually move the meter from the non-DC tree to the DC tree that it belonged to previously. This will not be possible if the device has been deleted from within NES.

Device Communication Base Package Business Objects

The NES base package includes the following communication business objects:

Meter Commissioning

Business Object	Description
D4-AddMeterRequest	Add Meter Request
D4-GenericAMIDeviceIdentifier	Generic AMI Device Identifier
D4-RetrieveMeterIdentifier	Retrieve Meter Identifier
D4-RetrieveMeterInfo	Retrieve Meter Information
D4-SetATMConfigNotification	Set ATM Configuration Notification
D4-SetATMConfiguration	Set ATM Configuration

Meter Decommissioning

Business Object	Description
D4-DecommMeterNotification	Decommission Meter Notification
D4-DecommMeterRequest	Decommission Meter Request

On-Demand Read

Business Object	Description
D4-ReadBillingData	Read Billing Data On-Demand
D4-ReadBillingDataNtf	Read Billing Data On-Demand Notification
D4-ReadLoadProfile	Read Load Profile On Demand
D4-ReadLoadProfileNtf	Read Load Profile On-Demand Notification
D4-ReadLoadStatus	Read Load Status

Business Object	Description
D4-ReadLoadStatusNtf	Read Load Status Notification

Remote Connect

Business Object	Description
D4-ConnectLoad	Connect Load
D4-ConnectLoadNtf	Connect Load Notification

Remove Disconnect

Business Object	Description
D4-DisconnectLoad	Disconnect Load
D4-DisconnectLoadNtf	Disconnect Load Notification

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgment and response messages are sent and received validating that commands have been transmitted.

Outbound Message Type	Description
D4-ADDMETREQ	Add Meter Request
D4-CONLOAD	Connect Load
D4-DECMETREQ	Decommission Meter Request
D4-DISCONLD	Disconnect Load
D4-HNLBATEVT	NES - Handle Batch Event
D4-HNLBATUSG	NES - Handle Batch Usage
D4-RDLOADST	Read Load Status
D4-READLP	Read Load Profile
D4-READOUT	Read Billing Data
D4-RETMETID	Retrieve Meter Identifier
D4-RETRIEVE	Retrieve Meter Information
D4-SETATMCFG	Set ATM Configuration

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway Adapter for NES uses the following inbound web services to import usage and device events:

Inbound Web Service	Description
D1-DeviceEventSeeder	Used for upload of device events. The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event. If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.
D1-InitialLoadIMD	Used for initial measurement upload. The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.

The Oracle Utilities Smart Grid Gateway Adapter for NES includes the following inbound web services for receiving communications from the NES:

Inbound Web Service Name	Description
D4-ConnectLoadNotification	Connect Load Notification
D4-DecommMeterNotificationXAI	Meter Decommission Notification
D4-DisconnectLoadNotification	Disconnect Load Notification
D4-ReadBDNotificationXAI	Read Billing Data On-Demand Notification
D4-ReadingATMConfigNotification	Get Response Initiate Read By Meter Number
D4-ReadLoadStatusNotification	Read Load Status Notification
D4-ReadLPNotificationXAI	Read Load Profile On-Demand Notification

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway Adapter for NES includes the following message senders:

Message Sender	Description
D4-ADDMETREQ	Add Meter Request
D4-CONLOAD	Connect Load

Message Sender	Description
D4-DECOMMIS	Device Decommissioning
D4-DISCONLD	Disconnect Load
D4-HNLBATEVT	NES Handle Batch Event
D4-HNLBATUSG	NES Handle Batch Usage
D4-RDLOADST	Read Load status
D4-READBILLD	NES On-Demand Read (Scalar)(2)
D4-READLP	Read Load Profile
D4-RETMETID	Retrieve Meter Identifier
D4-RETRIEVE	Retrieve Meter Information
D4-ReadBill	Read Billing Data
D4-SETATMCFG	Set ATM Configuration

BPEL Processes and Web Services

These processes are responsible for performing the conversion from Oracle Utilities format to NES format, invoking process callouts and invoking the remote endpoint to trigger the device events.

All web services receive XML from an incoming service then transform the call to a format which is recognized by the NES system.

CreateMeter: Receives the incoming XML from the message sender service, transforms it to the NES API parameters node, passes it to the DeviceManager.Create NES API web service method then collects XML from CreateMeter to be returned to Oracle Utilities Smart Grid Gateway.

Messages

CreateMeter RequestMessage: Contains the parameters which are formatted from Oracle Utilities Smart Grid Gateway to match the incoming XML for the NES API DeviceManager.Create method.

CreateMeter ResponseMessage: Contains the Device ID that is used when the DeviceManager.Create method validates the security key and the XML parameters successfully.

Related Processes

Meter Commissioning

ConnectLoadRemoteConnect

Receives the incoming XML from the D4-CONLOAD (Connect Load) message sender in Oracle Utilities Smart Grid Gateway and transforms to NES format.

GrabBatchEvents

Retrieves the un-processed events from the event repository; transforms each batch to replace GUID identifiers with a readable form, and finally prepares a new file for OSB before deleting the batch of events. The scheduled call to this service can contain the preferred dates to query for or can accept the default which is the previous day usage.

Messages

GrabBatchEventsSoapIn

GrabBatchEventsSoapOut

GrabBatchUsage

Retrieves the un-processed usage from the usage repository; transforms each batch to replace GUID identifiers with a readable form, and finally prepares a new file for OSB before deleting the batch of usage. The scheduled call to this service can contain the preferred dates to query for or can accept the default which is the previous day usage.

Messages

GrabBatchUsageSoapIn

GrabBatchUsageSoapOut

Connection

Event Management

Usage Processing

MeterDecommissioning

Receives the incoming XML from the message senderOutbound service and transforms to NES API parameters node to be passed to the DeviceManager.Move NES API web service method. The process then collects the return XML to be returned to Oracle Utilities Smart Grid Gateway.

Messages

MeterDecommissioningRequestMessage: This message is the input for the Move method. The method contains the parameters conveniently formatted from Oracle Utilities Smart Grid Gateway to match the incoming XML for the NES API DeviceManager.Move method.

MeterDecommissioningResponseMessage: This message contains status stating that the DeviceManager.Create method validated the security key and the XML parameters are accepted successfully. If the status is SUCCEEDED, it also contains Tracking ID for the call, Device ID and StatusType ID.

Related Processes

Meter Decommissioning

PerformCommand

This web service facilitates most of the communication between Oracle Utilities Smart Grid Gateway and the NES system. If your implementation requires functionality that was not delivered as part of the base package this web service will play an integral part in managing those customizations.

PerformCommand executes a command which generates the events that advance the Oracle Utilities Smart Grid Gateway lifecycle then returns the output string to the caller. The output might be a tracking ID or information about a device.

Messages

PerformCommandSoapIn: The sXmlParameters input is prepared from within Oracle Utilities Smart Grid Gateway to execute primarily a group of five commands, these are Read Load Status, On-Demand Read, Connect Load, Disconnect Load and Set ATM Configuration.

PerformCommandSoapOut:

The return from PerformCommand is the xml from the DeviceManager.PerformCommand for Read Load Status, On-Demand Read, Connect Load, Disconnect Load and Set ATM Configuration.

ReceivePanoramixEvents

This web service is actually never called by the implementation, but rather it is called by NES and is needed when configuring the NES server.

ReceivePanoramixEvents obtains the APIKey from the NES authentication service, then, with the event definition ID from the parameter list for this service, switches to the branch for the event definition to begin any specific processing. For example, an on-demand read completion event means that the BPEL PM process needs to retrieve the usage using the RESULTID found in the event xml. All events and usage to be passed on to Oracle Utilities Smart Grid Gateway must first be transformed to replace the GUID with a readable form items. This involves using the BPEL PM DVM lookup functionality.

Event Management

PrePerformCommandCallout / PostPerformCommandCallout

These web services are hooks designed to allow customization of messages just prior and just after sending them to the NES server. Your implementation may wish to modify the data for special purposes. This is the one of the only places where modification of BPEL PM code is allowed.

ReceivedPanoramixEventsCallout

This web service is a hook designed to allow customization of messages just prior and just after sending them to the NES server. Your implementation may wish to modify the data for special purposes. This is one of the only places where modification of BPEL PM code is allowed.

ReadBillingDataOnDemand

This web service method, initiate a call to NES system with formatted inbound xml parameter. First it transforms the Parameters received from the calling system in to NES system recognizable format. Then it invokes a call to the NES system's Device Manager Service. When the call is invoked the system receives the return XML from DeviceManager stating the status of the command execution and, if succeeded, the tracking ID of this call.

Messages

ReadBillingDataOnDemandRequestMessage: Contains the input parameter for DeviceManager Perform Command to read billing data OnDemand. It formats parameters from the calling system to match incoming XML for the NES DeviceManager.PerformCommand method.

ReadBillingDataOnDemandResponseMessage: Transforms the response xml from NES system format to Oracle Utilities Smart Grid Gateway format.

Related Processes

On Demand Reads

ReadLoadProfileOnDemand

This web service method, initiate a call to NES system's Device Manager Service with formatted inbound xml parameter. First it transforms the Parameters received from the calling system in to NES system recognizable format. Then it invokes a call to the NES system thru Device Manager Service. After invoking the call, the system receives the response message from DeviceManager stating the status of the command execution and, if succeeded, the tracking ID of this call.

Messages

ReadLoadProfileOnDemandRequestMessage: This message is for interval on demand read request to the NES system. Transforms the incoming XML from Oracle Utilities Smart Grid Gateway to NES recognizable format.

ReadLoadProfileOnDemandResponseMessage: Transforms the response xml for ReadLoadProfileOnDemandRequest from NES system format to Oracle Utilities Smart Grid Gateway format.

Related Processes

On Demand Reads

ReadLoadStatusRemoteConnect

Receives the incoming XML from the D4-RDLOADST (Read Load Status) message sender in Oracle Utilities Smart Grid Gateway and transforms to NES format.

RemoteDisconnect

Receives the incoming XML from the D4-DISCONLD (Disconnect Load) message sender in Oracle Utilities Smart Grid Gateway and transforms to NES format.

RetrieveMeterInfo

Initiates a call to the Request Management Service with formatted inbound xml parameters. First it transforms the Parameters received from the calling system in to NES system recognizable format. Then it invokes a call to the NES system thru Request Management Service and retrieves a response with Meter Information.

Messages

RetrieveMeterInformationRequestMessage: Contains the input parameter for DeviceManager Perform Command to retrieve meter information. It also formats parameters from the calling system to match incoming XML for the NES DeviceManager.PerformCommand method.

RetrieveMeterInformationResponseMessage: Transforms the response xml from NES system format to Oracle Utilities Smart Grid Gateway format.

Related Processes

Remote Disconnect

Remote Connect

RetrieveMeterIdentifier

Receives a call from Oracle Utilities Smart Grid Gateway for RetrieveMeterIdentifier process and invokes the RetrieveByParameter method in the NES system's DeviceManager service.

Converts incoming Oracle Utilities Smart Grid Gateway formatted input to sXmlParameters in NES format then invokes RetrieveMeterIdentifier.

Messages

RetrieveMeterIdentifierRequestMessage: Transforms the xml received from the calling system to match incoming XML for the NES API DeviceManager.RetrieveByParameter method. This method requires the Type of ID and the associated ID as input.

RetrieveMeterIdentifierResponseMessage: When the XML is synchronously returned from the head-end system for the RetrieveByParameter call, the DEVICEID node is only included in the APIPAYLOAD if the status of the call is Succeeded.

Related Processes

Meter Commissioning

SetATMConfiguration

This web service method is specific to set Automated Topology Management (ATM) configuration command which assigns the Meter to the Data Concentrator.

Converts incoming Oracle Utilities Smart Grid Gateway formatted input to sXmlParameters in NES format then invokes the DeviceManager PerformCommand. A connection should establish to begin the NES command processing.

Messages

SetATMConfigurationRequestMessage: This message is the input for the SetATMConfiguration method. The method contains the parameters conveniently formatted from Oracle Utilities Smart Grid Gateway to match the incoming XML for the NES API DeviceManager.PerformCommand method where the COMMANDID is Constants.DeviceCommands.SET_ATM_CONFIGURATION

SetATMConfigurationResponseMessage: when the XML is synchronously returned from the head-end system for the PerformCommand call, the COMMAND node is only included in the APIPAYLOAD if the status of the call is Succeeded.

NES Web Services

The following table describes NES web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Commands	AMI Adapter Business Objects	NES Web Services	NES Operations
Device Commissioning	D4-AddMeterRequest	DeviceManager	Create
	D4-RetrieveMeterIdentifier		RetrieveByParameter
	D4-SetATMConfiguration		PerformCommand: SET_ATM_CONFIGURATION

Smart Grid Gateway Commands	AMI Adapter Business Objects	NES Web Services	NES Operations
Device Decommissioning	D4-DecommMeterRequest	DeviceManager	PerformCommand: MOVE_DEVICE_ADD
Remote Connect	D4-ConnectLoad D4-ReadLoadStatus D4-RetrieveMeterInfo	DeviceManager	Retrieve PerformCommand: CONNECT_LOAD READ_LOAD_STATUS
Remote Disconnect	D4-DisconnectLoad	DeviceManager	PerformCommand: DISCONNECT_LOAD
On-Demand Read	D4-ReadBillingData	DeviceManager	PerformCommand Command ID: READ_BILLING_DATA_ON_ DEMAND (Scalar) READ_LOAD_PROFILE_ON_ DEMAND (Interval)

Configuring a Networked Energy Services Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway NES Adapter to communicate with the NES software.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the NES in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D4-ConnectLoadNotification	Connect Load Notification
D4-DecommMeterNotificationXAI	Meter Decommission Notification
D4-DisconnectLoadNotification	Disconnect Load Notification
D4-ReadBDNotificationXAI	Read Billing Data On-Demand Notification
D4-ReadingATMConfigNotification	Get Response Initiate Meter Read By Meter Number
D4-ReadLoadStatusNotification	Read Load Status Notification
D4-ReadLPNotificationXAI	Read Load Profile On-Demand Notification

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D4-ADDMETREQ	Add Meter Request
D4-CONLOAD	Connect Load
D4-DECOMMIS	Device Decommissioning
D4-DISCONLD	Disconnect Load
D4-HNLBATEVT	NES Handle Batch Event
D4-HNLBATUSG	NES Handle Batch Usage
D4-RDLOADST	Read Load status
D4-READBILLD	NES On-Demand Read (Scalar)(2)
D4-READLP	Read Load Profile
D4-RETMETID	Retrieve Meter Identifier
D4-RETRIEVE	Retrieve Meter Information
D4-ReadBill	Read Billing Data
D4-SETATMCFG	Set ATM Configuration

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDNR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction: http://xmlns.oracle.com/ouaf/echelon/<OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/D4/<SERVICE>/<SERVICE>

where:

- **<OPERATION>**: the operation performed by the message sender (see Operation column in the table above)
- **<USER_ID>**: the user ID used to log into WebLogic Enterprise Manager
- **<PASSWORD>**: the password used to log into WebLogic Enterprise Manager
- **<EM_SERVER>**: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- **<EM_SERVER_PORT>**: the port where the WebLogic Enterprise Manager is installed
- **<SERVICE>**: the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D4-ADDMETREQ	Add Meter Request
D4-CONLOAD	Connect Load
D4-DECMETREQ	Decommission Meter Request
D4-DISCONLD	Disconnect Load
D4-HNLBATEVT	NES - Handle Batch Event
D4-HNLBATUSG	NES - Handle Batch Usage
D4-RDLOADST	Read Load Status
D4-READLP	Read Load Profile
D4-READOUT	Read Billing Data
D4-RETMETID	Retrieve Meter Identifier
D4-RETRIEVE	Retrieve Meter Information
D4-SETATMCFG	Set ATM Configuration

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the NES must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - NES:

- **External System:** NES
- **Description:** NES
- **Outbound Message Types::**

Outbound Message Type	Message Sender
D4-ADDMETREQ	D4-ADDMETREQ
D4-CONLOAD	D4-CONLOAD
D4-DECMETREQ	D4-DECOMMIS
D4-DISCONLD	D4-DISCONLD
D4-HNLBATEVT	D4-HNLBATEVT
D4-HNLBATUSG	D4-HNLBATUSG
D4-RDLOADST	D4-RDLOADST
D4-READLP	D4-READBILLD
D4-READOUT	D4-READLP
D4-RETMETID	D4-RETMETID
D4-RETRIEVE	D4-RETRIEVE
D4-SETATMCFG	D4-SETATMCFG

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D4-Request.xml
- **Response XSL:** D4-Response.xml

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the NES must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - NES

- **Service Provider:** NES
- **Description:** NES
- **External Reference ID:** NES
- **External System:** D4-NES
- **Out Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the NES service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM mapping processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the NES service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1-HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D4-SetATMConfiguration	Set ATM Configuration
Device Decommission	Device Removal	D4-DecommMeterRequest	Decommission Meter Request
On-Demand Read (Scalar)	On-Demand Read (Scalar)	D4-ReadBillingData	Read Billing Data
On-Demand Read (Interval)	On-Demand Read (Interval)	D4-ReadLoadProfile	Read Load Profile
Device Status Check	Device Status Check	D4-ReadLoadStatus	Read Load Status
Remote Connect	Remote Connect	D4-ConnectLoad	Connect Load
Remote Disconnect	Remote Disconnect	D4-DisconnectLoad	Disconnect Load

Other Processing Methods

This section outlines details for other processing methods used by the NES adapter.

Processing Role	Default Business Object	Default Outbound Message Type
NES Add Meter Request	D4-AddMeterRequest	Commission
NES Retrieve Meter Identifier	D4-RetrieveMeterIdentifier	Commission Retrieve Meter Identifier
NES Retrieve Meter Information	D4-RetrieveMeterInfo	Retrieve Meter Info

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The NES endpoint override DVM (D4–EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the NES adapter and the command used with each:

DVM Key	Commands
DeviceManager	Remote Connect Remote Disconnect Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
EventManager	On-Demand Read (Scalar) On-Demand Read (Interval)
GatewayManager	Remote Connect Remote Disconnect Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
SettingManager	Remote Connect Remote Disconnect Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
UserManager	Remote Connect Remote Disconnect Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
ProcessCallout	User Exit Functions

To define an override Endpoint URI for the NES adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is <http://server:port/soa/composer>.

2. Select the D4–EndpointOverrides.dvm in the left panel.

- In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
- In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.
6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.
8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Networked Energy Services Extendable Lookups

NOTE: This section applies to both cloud and on-premises implementations of the Smart Grid Gateway Adapter for Networked Energy Services.

This section outlines some of the extendable lookups that must be configured for use with the NES adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name**: The event name used by the head-end system
- **Description**: A description of the device event
- **Status**: The status of the lookup value (can be Active or Inactive)
- **Standard Event Name**: The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

UOM Code to Standard UOM Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for

this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-end UOM:** The unit of measure code used by the head-end system.
- **Unit of Measure:** The unit of measure defined in the system.
- **Description:** A description of the unit of measure code.

Interval Status Code to Condition Mapping

Interval usage received from the NES can include NES interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The NES Interval Status Code to Condition Mapping extendable lookup is used to determine how to map NES interval status codes to standard status codes when receiving usage from the NES.

Each value defined for the NES Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The NES interval status code
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.
- **Description:** A description of the interval status code.
- **Priority:** The priority of the interval status code, represented as a numeric value where larger numbers correlate to higher priorities.

Other Extendable Lookups

Business Object	Description
D4-EntityTypeLookup	Entity Type
D4-ExtServiceReturnCodeLookup	External Service Return Code
D4-GatewayTypeLookup	Gateway Type
D4-IDTypeLookup	ID Type
D4-InformationReturnCodeLookup	Information Return Code
D4-LoadVoltageStatusTypeLookup	Load Voltage Status Type
D4-TaskPriorityLookup	Task Priority
D4-TimeZoneManagerLookup	Time Zone Manager

Configuring NES Usage and Event Extract Processing

Usage and events received from the NES server must be requested from Oracle Utilities Smart Grid Gateway. Extract requests for usage and events are triggered by a batch process, and sent to the NES via middleware. The NES compiles a batch of usage or events and sends it to BPEL services to create a file to be processed by Oracle Service Bus (OSB) services, it is then loaded as SGG events and/or usage.

This section describes the processing performed by the extract request process, and the configuration steps involved.

Extract Request Processing

This section provides a detailed description of the extract request process.

- The “Usage / Event Extract Scheduler Monitor” batch process (D1-EXTSC) checks for “NES Usage Extract Scheduler” or “NES Event Extract Scheduler” activities that are in the “Active” state, and transitions these to the “Send Request”

state. It also updates the “Latest Request Start Date/Time” and “Latest Request End Date/Time” fields on the activity based on the date and time of the request.

- When the activity enters the “Send Request” state, an Enter algorithm (either “Usage Extract Scheduler Send Request” (D4-USGSNDREQ) or “Event Extract Scheduler Send Request” (D4-EVTSNDREQ)) sends a request via an message sender to the middleware (via the GrabBatchUsage or GrabBatchEvent BPEL services), which in turn send the request to the NES server.
- After the request is sent, the “NES Usage Extract Scheduler” or “NES Event Extract Scheduler” activity to set back to the “Active” state.
- The NES server calls the BPEL services “GrabBatchEvents” and “GrabBatchUsage.” BPEL then routes the incoming events or usage to a file system, which is used by OSB components to process the usage or events.

Extract Request Configuration Steps

This section outlines the objects that must be configured to support batch extracts of usage and events from an NES head-end system. To configure the NES Adapter to support sending extract requests for usage and events, you must do the following:

- Create message senders (one for usage, one for events) to send extract requests.
- Create Outbound Message Types (one for usage, one for events) for extract requests.
- Associate the message senders and Outbound Message Types to the External System used with the head-end system service provider
- Create “NES Usage Extract Scheduler Type” and “NES Event Extract Scheduler Type” activity types.
- Create “NES Usage Extract Scheduler” and “NES Event Extract Scheduler” activities.

The following sections provide details for configuring these object. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders, Outbound Message Types, and External Systems.

Note: Configuration of the OSB and BPEL services used by this process is done when installing and configuring the OSB and BPEL components of the NES Adapter.

Message Sender - NES Handle Batch Event

Create an message sender for event extracts as follows:

Main Tab:

- **Message Sender:** Enter a code for the batch event message sender (D4-HNLBATEVT)
- **Description:** NES Handle Batch Event
- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes messages via HTTP real-time)
- **Active:** True (checked)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:http://xmlns.oracle.com/ouaf/NES/GrabBatchEvents
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/NES/HandleBatchEvent/ BatchEventHandler

where:

- **<USER_ID>**: the user ID used to log into WebLogic Enterprise Manager
- **<PASSWORD>**: the password used to log into WebLogic Enterprise Manager
- **<EM_SERVER>**: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- **<EM_SERVER_PORT>**: the port where the WebLogic Enterprise Manager is installed

Message Sender - NES Handle Batch Usage

Create a message sender for usage extracts as follows:

Main Tab:

- **Message Sender:** Enter a code for the batch usage message sender (D4-HNLBATUSG)
- **Description:** NES Handle Batch Usage
- **Invocation Type:** Real-time
- **Message Class:** RTHHTTPSND (Sender routes messages via HTTP real-time)
- **Active:** True (checked)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:http://xmlns.oracle.com/ouaf/NES/GrabBatchUsage
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/NES/HandleBatchUsage/BatchUsageHandler

where:

- **<USER_ID>**: the user ID used to log into WebLogic Enterprise Manager
- **<PASSWORD>**: the password used to log into WebLogic Enterprise Manager
- **<EM_SERVER>**: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- **<EM_SERVER_PORT>**: the port where the WebLogic Enterprise Manager is installed

Outbound Message Type - NES Handle Batch Event

Create an Outbound Message Type for event extract requests as follows:

- **Outbound Message Type:** Enter a code for the batch event Outbound Message Type (D4-HNLBATEVT)
- **Description:** NES Handle Batch Event
- **Business Object:** D1-OutboundMessage
- **Priority:** - Priority 20 (or lower)

Outbound Message Type - NES Handle Batch Usage

Create an Outbound Message Type for usage extract requests as follows:

- **Outbound Message Type:** Select a code for batch usage Outbound Message Type (D4-HNLBATUSG)
- **Description:** NES Handle Batch Usage

- **Business Object:** D1-OutboundMessage
- **Priority:** Priority 20 (or lower)

External Systems

Add the event and usage extract Outbound Message Types and message senders to the external system used for the NES head-end system as follows:

- **External System:** NES
- **Description:** NES
- **Outbound Message Types:**

Outbound Message Type	Message Sender
D4-HNLBATEVT	D4-HNLBATEVT
D4-HNLBATUSG	D4-HNLBATUSG

Note: The following apply to the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D4-Request xsl
- **Response XSL:** D4-Response.xsl

Activity Type - NES Event Extract Scheduler

Create an Activity Type for event extract requests as follows:

- **Activity Type:** Enter a code for the activity type (NES-EVENT-EXTRACT)
- **Description:** Enter a description for the activity type (NES Event Extract Scheduler Type)
- **Related Transaction BO:** NES Event Extract Scheduler
- **Activity Type Status:** Active
- **Outbound Message Type:** NES Handle Batch Event
- **External System:** The external system used for the NES head-end system
- **Exception Handling:**
 - **To Do Type:** Activity To Do Type
 - **To Do Role:** System Default Role
 - **Retry Frequency:** Select retry frequency in case if Activity reaches an error state (00:03:00)
 - **Maximum Retries:** Select max number of times the activity will be retried - since it reached the error state (1)
 - **Discard Reason:** Select from the dropdown if available.

Activity Type - NES Usage Extract Scheduler

Create an Activity Type for usage extract requests as follows:

- **Activity Type:** Enter a code for the activity type (NES-USAGE-EXTRACT)
- **Description:** Enter a description for the activity type (NES Usage Extract Scheduler Type)
- **Related Transaction BO:** NES Usage Extract Scheduler
- **Activity Type Status:** Active
- **Outbound Message Type:** NES Handle Batch Usage

- **External System:** The external system used for the NES head-end system
- **Exception Handling:**
 - **To Do Type:** Activity To Do Type
 - **To Do Role:** System Default Role
 - **Retry Frequency:** Select retry frequency in case if Activity reaches an error state (00:03:00)
 - **Maximum Retries:** Select max number of times the activity will be retried - since it reached the error state (1)
 - **Discard Reason:** Select from the dropdown if available.

Activity - NES Event Extract Scheduler

Initiate an Activity for event extract requests as follows:

1. Select **Main->Communication->Activity+**
2. Select "NES Event Extract Scheduler Type" from the **Activity Type** drop-down list.
3. Enter the number of hours for each extract request in the **Number of Hours of Data Request** field. The default is 24.
4. *Optional:* Enter start and end dates and times for the first extract request in the **Current Request Start Date/Time** and **Current Request End Date/Time** fields.

Note that these are optional fields. If not populated, the values are populated as follows:

- **Current Request Start Date/Time:** taken from the last request stop date/time (which is populated by the “Event Extract Scheduler Send Request” algorithm (D4-EVTSNDREQ))
- **Current Request End Date/Time:** the Current Request Start Date/Time plus the number of hours in the **Number of Hours of Data Request** field.

Activity - NES Usage Extract Scheduler

Initiate an Activity for usage extract requests as follows:

1. Select **Main->Communication->Activity+**
2. Select "NES Usage Extract Scheduler Type" from the **Activity Type** drop-down list.
3. Enter the number of hours for each extract request in the **Number of Hours of Data Request** field. The default is 24.
4. *Optional:* Enter start and end dates and times for the first extract request in the **Current Request Start Date/Time** and **Current Request End Date/Time** fields.

Note that these are optional fields. If not populated, the values are populated as follows:

- **Current Request Start Date/Time:** taken from the last request stop date/time (which is populated by the “Usage Extract Scheduler Send Request” algorithm (D4-USGSNDREQ))
- **Current Request End Date/Time:** the Current Request Start Date/Time plus the number of hours in the **Number of Hours of Data Request** field.

Executing Extract Requests

To schedule and execute usage and device event extract requests, set up the “Usage / Event Extract Scheduler Monitor” batch process (D1-EXTSC) to run at a frequency appropriate to when you wish to retrieve usage and device events from the NES. For example, to retrieve usage and device events on a daily basis, schedule the “Usage / Event Extract Scheduler Monitor” batch process (D1-EXTSC) to run once every 24 hours.

Sensus

The Oracle Utilities Smart Grid Gateway Adapter for Sensus RNI supports communication with the Sensus Regional Network Interface (RNI), including measurement data and device event loading, and command messaging in support of commissioning, connect, disconnect, decommissioning, status check, and on-demand read. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Version	Sensus RNI 4.4
Protocol	MultiSpeak 3.0 & 4.1. RNI 3.1 and the SGG Sensus RNI adapter support MultiSpeak 4.1
Market(s)	Worldwide
Architecture	Long range radio WAN (mesh)

Sensus Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements

The usage data exported from the AMI head-end system as a file in Sensus RNI format is loaded into Oracle Utilities as Initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D6-USAGE-BASE** contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This can be upgraded without affecting the customization and environment settings added to SGG-D6-USAGE-CM.
2. **SGG-D6-USAGE-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-D6-USAGE-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRawIMD	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	

Element	Description	Valid Values
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
dateTimelnUTC	Indicates whether the Sensus RNI system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device.	true false
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterUsage	Determines if usage should be filtered.	true false
useExternalTOU	Indicates whether or not an externally reference TOU period should be used when processing measurement data.	true false

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D6-USAGE-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads.	DataRakerQueue

Parameter	Description	Default Value
	This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **Sensus UOM Code to Standard UOM Mapping** extendable lookup (D6-HeadendUOMLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (D1RT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Device Events

The device event data exported from the head-end system as a file in Sensus RNI format is loaded into Oracle Utilities as a Device Event. One of your configuration tasks is to customize the device events processing.

The required functionality is delivered in the base product as two OSB projects:

1. **SGG-D6-EVENT-BASE** contains components responsible for “actual” processing of incoming data. It can be upgraded in future without affecting the customization and environment settings that done in SGG-D6-EVENT-CM project.
2. **SGG-D6-EVENT-CM** allows the customization and simplifies the future upgrades.

The runtime configuration settings for the SGG-D6-EVENT-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the event data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
dateTimelnUTC	Indicates whether the Sensus RNI system is sending date/ time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device.	true false
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Publishing Events

The Sensus adapter can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D6-EVENT-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This

format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **Sensus Device Event Mapping** extendable lookup (D6-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (DIRT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D6-EVENT-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

NOTE: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The Sensus RNI adapter base package includes the following device and initial measurement business objects:

Business Object Name	Description
D6-InitialLoadIMDInterval	Sensus Initial Load IMD - Interval Used when loading Sensus interval measurements into the system for the first time.
D6-InitialLoadIMDScalar	Sensus Initial Load IMD - Scalar
D6-SmartMeter	Sensus Smart Meter

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Sensus RNI command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	Sensus – Initiate Connect Disconnect	Sensus – Connect / Disconnect State Change	Connect Device Completion Event
Remote Disconnect	Sensus – Initiate Connect Disconnect	Sensus – Connect / Disconnect State Change	Disconnect Device Completion Event
Device Commissioning	Sensus – Meter Add Notification		Device Commissioning Completion Event
Device Decommissioning	Sensus – Meter Remote Notification		Device Decommissioning Completion Event
On-Demand Read (Scalar)	Sensus – Initiate Meter Read By Meter ID	Sensus – Reading Changed Notification	Create IMD Completion Event
On-Demand Read (Interval)	Interval data not supported		
Device Status Check	Sensus – Initiate Outage Detection	Sensus – Outage Detection Event Notification	

Device Communication Base Package Business Objects

The Sensus RNI Adapter base package includes the following communication business objects:

Business Object Name	Description
D6-ConnectDisconStateChgNtf	Sensus - Connect/Disconnect State Change
D6-InitiateConnectDisconnect	Sensus - Initiate Connect Disconnect
D6-InitiateMeterByMeterId	Sensus - Initiate Meter Read By Meter ID
D6-InitiateOutageDetection	Sensus - Initiate Outage Detection
D6-MeterAddNotification	Sensus - Meter Add Notification
D6-MeterRemoveNotification	Sensus - Meter Remove Notification
D6-OutageDetectEvtNotification	Sensus - Outage Detection Event Notification
D6-ReadingChgNotification	Sensus - Reading Changed Notification
D6-UnsolicitedEvtNotification	Sensus - Unsolicited Event Notification

Sensus Event Data Mapping

The Sensus event file format maps as follows into the business object, D1-DeviceEventMappingLookup:

Sensus Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.
Device Identifier	External Device Identifier	
Event Name	External Event Name	
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router
Service Location ID	External Service Location ID	
Communication Module Serial Number	External Communication Module Identifier	

Sensus Flat File Field	Device Event Seeder BO Element	Comments
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form): Alert Information
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgement and response messages are sent and received validating that commands have been transmitted.

Outbound Message Type	Description
D6-CONDISCON	Sensus Initiate Connect Disconnect
D6-INITMTR	Initiate Meter Read By Meter ID
D6-INTOUTDET	Initiate Outage Detection Request

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway adapter for Sensus RNI includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Used for upload of device events. The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing

Inbound Web Service	Description
	algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event. If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.
D1-InitialLoadIMD	Used for initial measurement upload. The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.
D1-DeviceStatusCheck	Device Status Check This service is invoked by the integration layer to instantiate a Device Status Check command.
D1-InitialLoadIMD	Used by OSB to instantiate an IMD This inbound web service is used by OSB to instantiate an Initial Measurement Data for incoming interval usage in the Sensus format.
D1-RemoteConnect	Remote Connect This service is invoked by the integration layer to instantiate a Remote Connect command.
D1-RemoteDisconnect	Remote Disconnect This service is invoked by the integration layer to instantiate a Remote Disconnect command.
D6-ConDisconStChgNotification	Initiate Connect Disconnect response. Retrieve response from the Initiate Connect Disconnect command.
D6-OutageDetectionEventNotification	Initiate Outage Detection Response Retrieve response from the Initiate Outage Detection Event Notification command.
D6-ReadingChangedNotification	Reading Changed Notification Notification that a Sensus device reading has changed.
D6-UnsolicitedEventNotification	Unsolicited Event Response Retrieve unsolicited notifications when an event triggers an alarm on the meter.

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway adapter for Sensus RNI includes the following message senders:

Message Sender	Description
D6-CONDISCON	Sensus Initiate Connect/Disconnect
D6-INTOUTDET	Initiate Outage Detection Request
D6-InitMID	Initiate Meter Read By Meter ID Outbound Message

BPEL Processes

These processes are responsible for performing the conversion from Oracle Utilities format to MultiSpeak 4.1 format, invoking process callouts and invoking the remote endpoint to trigger the device events.

OnDemandRead Composite Process — Invokes the remote endpoint to trigger the on-demand read event. An asynchronous reply responds to the OUAF layer when the reading arrives.

ConnectDisconnect Composite Process — Invokes the remote endpoint to trigger the connect/disconnect event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

CommissionDecommission Composite Process — Invokes the remote endpoint to trigger the commission or decommission event. After the synchronous call completes, a one of the following second business callout services is invoked to determined if the related “received” or “completed” callout should be executed:

- isExecutingCommissionReceivedCallout
- isExecutingCommissionCompletedCallout
- isExecutingDecommissionReceivedCallout
- isExecutingDecommissionCompletedCallout

DeviceStatusCheck Composite — Invokes the remote endpoint to trigger the initiate outage detection event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

ProcessCallout Composite — This business callout provides a point at which customers and implementers can incorporate custom business logic and transformations. This composite includes the WSDLs and processing logic for all of the MultiSpeak processes. The default implementation of each method is a direct return of the input.

Web Services

These web services are all defined in the Sensus RNI head end system. The WSDLs were added to a Meta Data Storage (MDS) layer in OUAF and all references to the WSDL point to this MDS location. These web services have HTTP security by default. You may need to modify the security as a part of your implementation.

Web Service	Related BPEL Process	Description
CB_ServerService	ConnectDisconnect	<p>This web service defines the return interface, the means by which the status is returned to the calling system.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the CDStateChangeNotification web method is implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Sensus/ConnectDisconnect/CB_ServerService</p>
CB_Server	OnDemandRead	<p>This web service defines the return interface, the means by which the reading is returned to the calling system.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the ReadingChangedNotification web method is implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Sensus/OnDemandRead/CB_Server</p>
OA_ServerService	DeviceStatusCheck	<p>This web service defines the asynchronous return for InitateOutageDetectionEventRequest for solicited responses. It is also used for unsolicited alarms.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the ODEventNotification,</p>

Web Service	Related BPEL Process	Description
		PingURL, and GetMethods web methods are implemented in the composite. The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Sensus/DeviceStatusCheck/OA_ServerService

Sensus RNI Web Services

The following table describes the Sensus RNI web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Command	AMI Adapter Business Objects	Sensus Web Services	Sensus Operations
Device Commissioning	D6-MeterAddNotification	MR	MeterAddNotification
Device Decommissioning	D6-MeterRemoveNotification	MR	MeterRemoveNotification
Remote Connect/ Remote Disconnect	D6-InitiateConnectDisconnect	CD	InitiateConnectDisconnect
	D6-ConnectDisconStateChgNtf	CB	CDStatesChangedNotification (async reply)
Device Status Check	D6-InitiateOutageDetection	OD	InitiateOutageDetectionEventRequest
	D6-OutageDetectEvtNotification	OA	ODEventNotification (async reply)
On-Demand Read	D6-InitiateMeterByMeterId	MR	InitiateMeterReadingsByMeterID
	D6-ReadingChangedNotification	CB	ReadingChangedNotification (async reply)

Configuring a Sensus Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway Adapter for Sensus RNI to communicate with the Sensus RNI.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the Sensus Regional Network Interface (RNI) in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-DeviceEventSeeder	Device Event Seeder
D1-DeviceStatusCheck	Device Status Check
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D6-ConDisconStChgNotification	Initiate Connect Disconnect Response

Inbound Web Service Name	Description
D6-OutageDetectionEventNotification	Initiate Outage Detection Response
D6-ReadingChangedNotification	Reading Changed Notification
D6-UnsolicitedEventNotification	Unsolicited Event Response

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D6-CONDISCON	Sensus Initiate Connect/Disconnect
D6-INTOUTDET	Initiate Outage Detection Request
D6-InitMID	Initiate Meter Read By Meter ID Outbound Message

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:<OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Sensus/<SERVICE>
- where:
 - <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
 - <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
 - <PASSWORD>: the password used to log into WebLogic Enterprise Manager

- **<EM_SERVER_IP>**: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- **<EM_SERVER_PORT>**: the port where the WebLogic Enterprise Manager is installed
- **<SERVICE>**: the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D6-CONDISCON	Sensus Initiate Connect Disconnect
D6-INITMTR	Initiate Meter Read By Meter ID
D6-INTOUTDET	Initiate Outage Detection Request

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the Sensus RNI must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - Sensus:

- **External System:** Sensus
- **Description:** Sensus
- **Outbound Message Types:**

Outbound Message Type	Description	Message Sender
D6-CONDISCON	Sensus Initiate Connect Disconnect	D6-CONDISCON
D6-INITMTR	Initiate Meter Read By Meter ID	D6-InitMID
D6-INTOUTDET	Initiate Outage Detection Request	D6- INTOUTDET

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D6-Request.xml
- **Response XSL:** D6-Response.xml

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment,

outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the Sensus RNI must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about creating service providers.

Service Provider - Sensus:

- **Service Provider:** Sensus
- **Description:** Sensus
- **External Reference ID:** Sensus
- **External System:** Sensus
- **Our Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the Sensus service provider. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM mapping processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the Sensus service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D6-MeterAddNotification	Commission
Device Decommission	Device Removal	D6-MeterRemoveNotification	Decommission
Device Status Check	Device Status Check	D6-InitiateOutageDetection	Initiate Outage Detection Request
On-Demand Read (Scalar)	On-Demand Read (Scalar)	D6-InitiateMeterByMeterId	Initiate Meter Read by Meter ID
Remote Connect	Remote Connect	D6-InitiateConnectDisconnect	Connect Device
Remote Disconnect	Remote Disconnect	D6-InitiateConnectDisconnect	Disconnect Device

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Sensus endpoint override DVM (D6–EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Sensus adapter and the command used with each:

DVM Key	Commands
MR_Server	Device Commissioning Device Decommissioning On-Demand Read (Scalar)
CD_Server	Remote Connect Remote Disconnect
OD_Server	Device Status Check
ProcessCallout	User Exit Functions

To define an override Endpoint URI for the Sensus adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is <http://server:port/soa/composer>.

2. Select the D6–EndpointOverrides.dvm in the left panel.

- In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
- In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.

4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.
6. Click **OK**.

The new DVM value will appear in the list of keys.
7. Click the **Save** icon to save the DVM values.
8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Sensus Extendable Lookups

NOTE: This section applies to both cloud and on-premises implementations of the Smart Grid Gateway Adapter for Sensus.

This section outlines some of the extendable lookups that must be configured for use with the Sensus adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name**: The event name used by the head-end system
- **Description**: A description of the device event
- **Status**: The status of the lookup value (can be Active or Inactive)
- **Standard Event Name**: The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

UOM Code to Standard UOM Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-end UOM**: The unit of measure code used by the head-end system.
- **Unit of Measure**: The unit of measure defined in the system.
- **Description**: A description of the unit of measure code.
- **Status**: The status of the lookup value (can be Active or Inactive)

Interval Status Code to Condition Mapping

Interval usage received from the Sensus RNI can include Sensus interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Sensus Interval Status Code to Condition Mapping extendable lookup is used to determine how to map Sensus interval status codes to standard status codes when receiving usage from the Sensus RNI.

Each value defined for the Sensus Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The Sensus interval status code
- **Description:** A description of the interval status code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.

Other Extendable Lookups

Business Object Name	Description
D6-CDReasonCodeLookup	Sensus Connect/Disconnect Reason Code
D6-LoadActionCodeLookup	Sensus Load Action Code
D6-OutageEventTypeLookup	Sensus Outage Event Type
D6-SensusTimeUnits	Sensus Time Units
D6-ServiceTypeMappingLookup	Sensus Service Type Mapping

Using the Sensus Test Harness

Oracle Utilities Smart Grid Gateway Adapter for Sensus RNI includes a test harness that can be configured to simulate a general head-end system for testing the two-way commands. The test harness includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. See [Using Smart Grid Gateway Test Harnesses](#) for more information.

Silver Spring Networks

The Oracle Utilities Smart Grid Gateway Adapter for Silver Spring Networks supports communication with the Silver Spring Networks UtilityIQ application, including measurement data and device event loading, and command messaging in support of commissioning, connect, disconnect, decommissioning, status check, and on-demand read. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Versions	UtilityIQ Version 4.10
Protocol	Proprietary
Market(s)	Worldwide
Architecture	RF WAN (mesh) based on Access Points

Silver Spring Networks Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements

The usage data exported from the AMI head-end system as a file in Silver Spring Networks XML format is loaded into Oracle Utilities as initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. SGG-D7-SSNXML-BASE contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This project can be upgraded without affecting the customization and environment settings added to SGG-D7-SSNXML-CM.
2. SGG-D7-SSNXML-CM allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-D7-SSNXML-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the initial measurement data is populated as raw data. Valid values are:	true false
callPreProcessing	Determines if the preprocessing proxy service is called. Valid values are:	true false
callPostProcessing	Determines if the postprocessing proxy service is called. Valid values are:	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
destinationRootElementEvent	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false
filterUsage	Determines if usage should be filtered.	true false

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the `publishServices/service` element in the `EnvironmentSettings.xq` file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D7-SSNXML-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the `EnvironmentSettings.xq` file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60

Parameter	Description	Default Value
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **SSN - UOM Code to Standard UOM Mapping** extendable lookup (D7-HeadendUOMLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (D1RT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Device Events

The device event data exported from the head-end system as a file in Silver Spring Networks CSV format is loaded into Oracle Utilities as a device event. One of your configuration tasks is to customize the device events processing.

The required functionality is delivered in the base product as two OSB projects:

1. SGG-D7-CSV-BASE contains components responsible for “actual” processing of incoming data. It can be upgraded in future without affecting the customization and environment settings that done in SGG-D7-CSV-CM project.
2. SGG-D7-CSV-CM allows the customization and simplifies the future upgrades.

The runtime configuration settings for the SGG-D7-CSV-CM project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valie Values
populateRaw	Determines if the device event data is populated as raw data. Valid values are:	true false

Element	Description	Valid Values
callPreProcessing	Determines if the preprocessing proxy service is called. Valid values are:	true false
callPostProcessing	Determines if the postprocessing proxy service is called. Valid values are:	true false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered. Valid values are:	true false

Publishing Events

The Silver Spring Networks adapter can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D7-CSV-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue

Parameter	Description	Default Value
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **SSN - Device Event Mapping** extendable lookup (D7-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (DIRT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D7-CSV-CM project in the Oracle Service Bus Console.

2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

NOTE: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The Silver Spring Networks adapter base package includes the following device and initial measurement business objects:

Business Object Name	Description
D7-InitialLoadIMDInterval	SSN - Initial Load IMD - Interval Used when loading Silver Spring Network (SSN) interval measurements into the system for the first time.
D7-InitialLoadIMDScalar	SSN - Initial Load IMD - Scalar Used when loading Silver Spring Network (SSN) scalar measurements into the system for the first time.
D7-SmartMeter	SSN — Smart Meter

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Silver Spring Networks command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	SSN-Connect or Disconnect	SSN – Connect or Disconnect Response Remote Provisioning Job (Get Status)	Connect Device Completion Event
Remote Disconnect	SSN-Connect or Disconnect	SSN – Connect or Disconnect Response	Disconnect Device Completion Event
Device Commissioning	SSN- Replace Location		Device Commissioning Completion Event
Device Decommissioning	SSN- Replace Device At Location (Decomm)		Device Decommissioning Completion Event

Command	Outbound Communication	Inbound Communication	Completion Event
On-Demand Read (Scalar)	SSN – Add Meter Read Job (Scalar)	SSN – Meter Read Response (Scalar)	Create IMD Completion Event
On-Demand Read (Interval)	SSN – Add Meter Read Job (Interval)	SSN – Meter Read Response (Interval)	Create IMD Completion Event
Device Status Check	SSN – Add Ping job	SSN – Ping Job Response	

Device Communication Base Package Business Objects

The Silver Spring Networks Adapter base package includes the following communication business objects:

Business Object Name	Description
D7-AddMeterReadJobInterval	SSN - Add Meter Read Job (Interval)
D7-AddMeterReadJobScalar	SSN - Add Meter Read Job (Scalar)
D7-AddPingJob	SSN - Add Ping Job
D7-ConnectDisconnect	SSN - Connect or Disconnect
D7-ConnectDisconnectResp	SSN - Connect or Disconnect Response
D7-GetStatus	SSN - Get Status
D7-GetStatusResponse	SSN - Get Status Response
D7-MeterReadResponseInterval	SSN - Meter Read Response (Interval)
D7-MeterReadResponseScalar	SSN - Meter Read Response (Scalar)
D7-PingJobResponse	SSN - Ping Job Response
D7-ReplaceDeviceAtLocForDecomm	SSN - Replace Device At Location (Decomm)
D7-ReplaceLocation	SSN - Replace Location

Silver Spring Networks Event Data Mapping

The Silver Spring event file format maps as follows into the business object, D1-DeviceEventMappingLookup:

Silver Spring Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.
Device Identifier	External Device Identifier	
Event Name	External Event Name	
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router
Service Location ID	External Service Location ID	
Communication Module Serial Number	External Communication Module Identifier	
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form): Alert

Silver Spring Flat File Field	Device Event Seeder BO Element	Comments
		Information
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgment and response messages are sent and received validating that commands have been transmitted.

Outbound Message Type	Description
D7-COMMS	Replace Device At Location
D7-OB MSG TY	Outbound Message Type SSN

Inbound/Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound web services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway adapter for Silver Spring Networks includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Used for upload of device events. The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event. If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.
D1-DeviceStatusCheck	Device Status Check

Inbound Web Service	Description
	This service is invoked by the integration layer to instantiate a Device Status Check command.
D1-InitialLoadIMD	Used by OSB to instantiate an IMD The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.
D1-RemoteConnect	Remote Connect This service is invoked by the integration layer to instantiate a Remote Connect command.
D1-RemoteDisconnect	Remote Disconnect This service is invoked by the integration layer to instantiate a Remote Disconnect command.
D7-ConnectDisconnectResponse	Connect Disconnect Response Retrieves response for Remote provisioning Job Connect or Disconnect commands.
D7-GetStatusResponse	D7-GetStatusResponse Retrieve response from the Get Status command.
D7-MeterReadResponseInterval	SSN - Meter Read Response (Interval)
D7-MeterReadResponseScalar	SSN - Meter Read Response (Scalar)
D7-PingJobResponse	SSN - Ping Response Retrieves response from the Ping Job Response command.

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

BPEL Processes

These processes are responsible for performing the conversion from Oracle Utilities format to Silver Spring Networks format, invoking process callouts and invoking the remote endpoint to trigger the device events.

OnDemandRead Composite Process — Provides access points to edge application and handles data between edge application and head end system. It invokes sequence of web methods to head end system and retrieves meter read and send it back to Edge application.

ConnectDisconnect Composite Process — Performs the conversion from Oracle Utilities format to SSN format, invokes process callouts, and invokes the remote endpoint to trigger the connect event. A second, asynchronous reply will call back into the OUAF layer when the status change is completed at the head-end system. Another asynchronous reply will call back into the OUAF layer to send Meter Read Results.

CommissionDecommission Composite Process — Performs the conversion from Oracle Utilities format to SSN UIQ format, invokes process callouts, and invokes the remote endpoint to trigger the commission or decommission of meter.

DeviceStatusCheck Composite — Performs the conversion from Oracle Utilities format to SSN format, invokes process callouts, and makes a call via a proxy to the head-end system starting the Meter Ping operation. In an ideal scenario, the job status is returned as completed and the results are acquired and sent back to OUAF. If the job takes longer, OUAF will initiate a second request that will poll the head end system for the job status. When the job is completed, the results are returned to OUAF.

Common Composite — Contains two main classes of operations: Proxies and ProcessCallouts. Proxies are simple mediators that forward a web service call to a preset endpoint. No transformations are performed. They are convenient because they allow head end URLs and security to be set in a single composite. ProcessCallouts are points of customization which allow users to modify data and/or initiate some external business process.

BulkRequest Composite — Provides access points to requesting application. It decouples the bulk request into single commands for each meter/device in the request and sends it to edge application for processing.

Web Services

The following web services are all defined in the Silver Spring Networks head-end system:

- **CommissionDecommissionService**
 - **BPEL Process:** CommissionDecommission
 - **Operation:** ReplaceDeviceAtLocation
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/CommissionDecommission/CommissionDecommissionService
- **CommissionDecommissionService**
 - **BPEL Process:** CommissionDecommission
 - **Operation:** ReplaceLocation
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/CommissionDecommission/CommissionDecommissionService
- **ConnectDisconnectService**
 - **BPEL Process:** ConnectDisconnect
 - **Operation:** AddRemoteProvisioningJob
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/ConnectDisconnect/ConnectDisconnectService
- **DeviceStatusCheckService**
 - **BPEL Process:** DeviceStatusCheck
 - **Operation:** AddPingJob
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/DeviceStatusCheck/DeviceStatusCheckService
- **AddMeterReadJobService**
 - **BPEL Process:** AddMeterRead
 - **Operation:** AddMeterReadJob
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/OnDemandRead/AddMeterReadJobService
- **OnDemandReadService**
 - **BPEL Process:** OnDemandRead
 - **Operation:** GetJobStatus
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/OnDemandRead/OnDemandReadService

Silver Spring Networks Utility IQ Web Services

The following table describes the Silver Spring Networks Utility IQ web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Command	AMI Adapter Business Objects	Silver Spring Networks Web Services	Silver Spring Networks Operations
Device Commissioning	D7-ReplaceLocation	Device Manager	findDevice ReplaceLocation
Device Decommissioning	D7-ReplaceDeviceAtLocForDecomm	Device Manager	findDevice ReplaceDeviceAtLocation
Remote Connect/ Remote Disconnect	D7-ConnectDisconnect D7-GetStatus	Device Manager Job Manager DeviceResults	findDevice addRemoteProvisioningJob getJobStatusForDevice getRemoteProvisioningResultsByJobID findJob getJobStatus getMeterReadResultsByJobID
Device Status Check	D7-AddPingJob	Device Manager Job Manager DeviceResults	findDevice addPingJob, getJobStatus getPingResultsByJobID
On-Demand Read	D7-AddMeterReadJobInterval D7-AddMeterReadJobScalar	Device Manager Job Manager DeviceResults	findDevice addMeterReadJob getJobStatus getMeterReadResultsByJobID

Configuring a Silver Spring Networks Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway Adapter for Silver Spring Networks to communicate with the Silver Spring Networks UtilityIQ.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the Silver Spring Networks UtilityIQ application in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder

Inbound Web Service Name	Description
D1-DeviceStatusCheck	Device Status Check
D1-InitialLoadIMD	Used by OSB to instantiate an IMD
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D7-ConnectDisconnectResponse	Connect Disconnect Response
D7-GetStatusResponse	Get Status Response
D7-MeterReadResponseInterval	SSN - Meter Read Response (Interval)
D7-MeterReadResponseScalar	SSN - Meter Read Response (Scalar)
D7-PingJobResponse	SSN - Ping Response

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests. An message sender should be configured for each command.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D7-DECOMM	SSN Replace Device at Location for Decommission
D7-COMM	SSN Replace Location - Commission
D7-ADDJOB	SSN Add Meter Read Job
D7-ADDPING	SSN Add Ping Job
D7-CONNECT	SSN Connect Device
D7-GTSTATUS	SSN Get Status

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSND (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:http://xmlns.oracle.com/ouaf/ssn/<OPERATION>
- **HTTP Login User:** <USER_ID>

- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/<SERVICE>
- where:
- <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
- <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
- <PASSWORD>: the password used to log into WebLogic Enterprise Manager
- <EM_SERVER_IP>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed
- <SERVICE>: the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D7-COMMS	Replace Device At Location
D7-OB MSG TY	Outbound Message Type SSN

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the Silver Spring Networks UtilityIQ must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - Silver Spring Networks:

- **External System:** Silver Spring Networks
- **Description:** Silver Spring Networks
- **Outbound Message Types:**

Outbound Message Type	Description
D7-OB MSG TY	Outbound Message Type SSN

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D7-Request xsl

- **Response XSL:** D7-Response.xml

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the Silver Spring Networks UtilityIQ must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - Silver Spring Networks:

- **Service Provider:** Silver Spring Networks
- **Description:** Silver Spring Networks
- **External Reference ID:** Silver Spring Networks
- **External System:** Silver Spring Networks
- **Our Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **Pre-Commissioning Device ID Type:**
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the Silver Spring Networks service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the Silver Spring Networks service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D7-ReplaceLocation	Commission
Device Decommission	Device Removal	D7-ReplaceDeviceAtLocForDecomm	Decommission
Device Status Check	Device Status Check	D7-AddPingJob	Get Status
On-Demand Read (Scalar)	On-Demand Read (Scalar)	D7-AddMeterReadJobScalar	Read Meter Data
On-Demand Read (Interval)	On-Demand Read (Interval)	D7-AddMeterReadJobInterval	Read Meter Data
Remote Connect	Remote Connect	D7-ConnectDisconnect	Connect Device
Remote Disconnect	Remote Disconnect	D7-ConnectDisconnect	Disconnect Device

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Silver Springs Network endpoint override DVM (D7–EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Silver Springs Network adapter and the command used with each:

DVM Key	Commands
DeviceResults4.4	Remote Connect
DeviceResults4.7	Remote Disconnect
DeviceResults4.10	On-Demand Read (Scalar) On-Demand Read (Interval) Device Status Check
DataAggregation4.4	Not used in this version.
DataAggregation4.7	
DataAggregation4.10	
DeviceManager4.4	Device Commissioning
DeviceManager4.7	Device Decommissioning
DeviceManager4.10	Remote Connect Remote Disconnect On-Demand Read (Scalar) On-Demand Read (Interval) Device Status Check
JobManager4.4	Remote Connect

DVM Key	Commands
JobManager4.7	Remote Disconnect
JobManager4.10	On-Demand Read (Scalar)
	On-Demand Read (Interval)
	Device Status Check
ProcessCallout	User Exit Functions

NOTE:

The numbers in the keys above (4.4, 4.7, and 4.10) designate the version of the Silver Springs Network IQ head-end system.

Only a single version of each key should be defined, based on the version of the Silver Springs Network IQ head-end system

To define an override Endpoint URI for the Silver Springs Network adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is `http://server:port/soa/composer`.

2. Select the `D7-EndpointOverrides.dvm` in the left panel.

- In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
- In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:

- **key:** The DVM key for the Endpoint URI you wish to define (see the table above).
- **EndpointURI:** The override Endpoint URI.

6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.

8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Silver Spring Networks Extendable Lookups

NOTE: This section applies to both cloud and on-premises implementations of the Smart Grid Gateway Adapter for Silver Spring Networks.

This section outlines some of the extendable lookups that must be configured for use with the Silver Spring Networks adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name:** The event name used by the head-end system.
- **Description:** A description of the device event.
- **Status:** The status of the lookup value (can be Active or Inactive).
- **Standard Event Name:** The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

UOM Code to Standard UOM Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-End Unit of Measure:** The unit of measure code used by the head-end system.
- **Description:** A description of the unit of measure code.
- **Status:** The status of the lookup value (can be Active or Inactive).
- **Unit of Measure:** The unit of measure defined in the system.

Interval Status Code to Condition Mapping

Interval usage received from the Silver Spring Networks UtilityIQ can include Silver Spring Networks interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Silver Spring Networks Interval Status Code to Condition Mapping extendable lookup is used to determine how to map Silver Spring Networks interval status codes to standard status codes when receiving usage from the Silver Spring Networks UtilityIQ.

Each value defined for the Silver Spring Networks Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The Silver Spring Networks interval status code
- **Description:** A description of the interval status code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.

Other Extendable Lookups

Business Object Name	Description
D7-ActivationStatusLookup	SSN - Activation Status
D7-ChannelStatusLookup	SSN - Channel Status
D7-DataTimeZoneLookup	SSN - Data Time Zone
D7-DeviceStatusLookup	SSN - Device Status

Business Object Name	Description
D7-ExecutionStatusLookup	SSN - Execution Status
D7-HeadendSQLLookup	SSN - Head-End SQL to Standard SQL
D7-HeadendTOULookup	SSN - Head-End TOU to Standard TOU
D7-IntervalStatusLookup	SSN - Interval Status
D7-MeterConnectionStatusLookup	SSN - Meter Connection Status
D7-MeterReadTypeLookup	SSN - Meter Read Type
D7-OldAdminStateNameLookup	SSN - Old Admin State Name
D7-PriorityLookup	SSN - Priority Status
D7-ProvisioningActionLookup	SSN - Provisioning Action
D7-ProvisioningCommandStatus	SSN - Provisioning Command Status
D7-ProvisioningDataType	SSN - Provisioning Data Type
D7-ReadModeLookup	SSN - Read Mode
D7-RegisterReadSourceLookup	SSN - Register Read Source
D7-RegisterStatusLookup	SSN - Register Status
D7-SSNVersionLookup	SSN - Version
D7-StatusFlagNameLookup	SSN - Status Flag Name

Using the Silver Spring Networks Test Harness

Oracle Utilities Smart Grid Gateway Adapter for Silver Spring Networks (SSN) includes a test harness that can be configured to simulate the Silver Spring Networks UtilityIQ head-end system for testing the two-way commands. The test harness includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. See [Using Smart Grid Gateway Test Harnesses](#) for more information.

Using Smart Grid Gateway Test Harnesses

The Oracle Utilities Smart Grid Gateway Adapter includes test harnesses for each supported head-end system. The test harnesses can be configured to simulate a head-end system for testing one-way or two-way commands. The test harnesses are Multispeak 3.0 standard compliant and include a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. This section describes the general components of the test harnesses.

NOTE: This section applies to on-premises implementations of Oracle Utilities Smart Grid Gateway only. This section does NOT apply to Oracle Utilities cloud services. See [Smart Grid Gateway Adapters and Oracle Utilities Cloud Services](#) for more information about implementing Smart Grid Gateway Adapters with Oracle Utilities cloud services.

Test Harness Design

Each test harness is divided into two main layers: a front end and back end layer. The front end set of services implements the head-end system interfaces, which receive requests corresponding to the specifications shown in the list below. Each of these services calls into the "back end" layer of the test harness, which defines meters and sets their attributes. These meters are stored in a file within the test harness called meterdb.xml.

NOTE: The meterdb.xml file can be modified pre-deployment, but not post-deployment. However, the test harness retains an in-memory "database" of the meters in the file. The in-memory representation can be modified using the utility web services. Note that any changes to the in-memory structure will be lost when the server is restarted or the test harness composite is redeployed.

Locating the WSDL for the Test Harness

Follow these procedures to locate the test harness web service definition language (WSDL):

How to Use Enterprise Manager to Locate the WSDL

1. Open Enterprise Manager and use the navigation pane to open the dashboard of the test harness composite:
2. The top bar of the dashboard contains several buttons and icons. One of these is a “world” icon with a puzzle piece over it. Click this icon to display a list of the WSDLs and endpoint URIs for the composite:

3. Click the UtilService WSDL URL link to see the WSDL in the browser, or right click and save it to your machine

Depending on your requirements, it may be necessary to download the associated schema found in the wsdl:types section. The URL can be pasted into a browser tab and downloaded in the same manner as the WSDL. The main schema has imported schemas that may also be required.

How to Use a Direct URL to locate the WSDL

The WSDL can be accessed without Enterprise Manager by understanding the paths used on the SOA server. In general, they have the following form:

```
http://{server name}:{port number}/soa-infra/services/{partition}/{Composite}/{Web Service}?WSDL
```

For example, the test harness WSDL can be found at the following locations for each SGG adapter.

Itron OpenWay:

```
http://{server name}:{port number}/soa-infra/services/Itron_Test/ItronTestHarness/  
UtilService? WSDL
```

Landis+Gyr:

```
http://{server name}:{port number}/soa-infra/services/LG_Test/LGTestHarness/UtilService?WSDL
```

Sensus RNI:

```
http://{server name}:{port number}/soa-infra/services/Sensus_Test/Sensus/UtilService?WSDL
```

Silver Spring Networks:

```
http://{server name}:{port number}/soa-infra/services/SSN_Test/SSNTestHarness/UtilService?WSDL
```

Web Services

This section describes the web services included in the test harness BPEL composite for each supported head-end system.

General Services

This section describes the general services of the test harness composite.

LoadMeterIndex

This web service loads the data store from the internal file. By default, if the store is already in memory, it will NOT reload. This behavior can be overridden with the forceReload parameter.

Input — LoadMeterIndexInput

Part: payload

Element: LoadMeterIndexRequest

Parameter	Description
forceReload	A switch telling the system whether to reload the meter index from the configuration file. Default is false.

Output — LoadMeterIndexOutput

Part: payload

Element: LoadMeterIndexResult

Parameter	Description
loaded	A boolean value for whether or not the index was reloaded from the configuration file

Fault — [UtilityFault](#) (see [UtilityFault](#) for more details).

ViewAuditTrail

This web service returns the audit log for the entire session.

Input — [ViewAuditTrailInput](#)

Part: payload

Element: [ViewAuditTrailRequest](#)

Output — [ViewAuditTrailOutput](#)

Part: payload

Element: [ViewAuditTrailResult](#)

An Entry consisting of a timestamp and an Operation. Each entry may have an associated meter object showing the latest update.

Fault — See [UtilityFault](#), above.

UtilityFault

Fault with similar mapping to SGG/OUAF faults:

Typically, the `faultCode`, `faultString`, `faultActor`, and `detail/text` elements will be populated.

Locate Meter Services

This section describes the locate meter web services of the test harness composite.

FindMeters

This web service queries the data store for one or more meters. The difference between `GetMeter` and `FindMeters` is `GetMeter` can return at most one meter and it must match the provided ID exactly. `GetMeter` will throw an error if the ID is not found. `FindMeters` can return more than one meter (when using the regex) and will not throw an error when the ID does not match any of the meters in the index.

Input — [FindMetersInput](#)

Part: payload

Element: [FindMetersRequest](#)

Parameter	Description
id	The meter ID for which to search
isRegex	The provided id can be a regex value when this parameter is true. Hint: to search for all meters in the system, use <code>".*"</code> for the ID.

Output — [FindMetersOutput](#)

Part: payload

Element: [FindMetersResult](#)

Zero or more meter objects can be returned from the search

Fault — See [UtilityFault](#). Unlike other methods, FindMeters does not throw an exception if the meter is not found. As such, it can be used to test for the existence of a Meter prior to querying for it.

IsMeterDefined

This web service queries whether a particular meter is defined in the data store.

Input — IsMeterDefinedInput

Part: payload

Element: IsMeterDefinedRequest

Parameter	Description
id	The meter ID for which to search

Output — IsMeterDefinedOutput

Part: payload

Element: IsMeterDefinedResult

Whether or not the provided ID is part of the index.

Fault — See [UtilityFault](#). Thrown when meter id is not found.

GetMeter

This web service returns all the attributes of a single meter from the in-memory data store. The difference between GetMeter and FindMeters is GetMeter can return at most one meter and it must match the provided ID exactly. GetMeter will throw an error if the ID is not found. FindMeters can return more than one meter (when using the regex) and will not throw an error when the ID does not match any of the meters in the index.

Input — GetMeterInput

Part: payload

Element: GetMeterRequest

Parameter	Description
id	The meter ID for which to search

Output — GetMeterOutput

Part: payload

Element: GetMeterResult

The meter object requested by the ID.

Fault — See [UtilityFault](#). Thrown when meter id is not found.

Meter Administration Services

This section describes the meter administration services of the test harness composite.

AddMeters

This web service adds a set of meters to the in-memory data store. This will not permanently add it to the control file.

Input — AddMetersInput

Part: payload

Element: AddMetersRequest

Parameter	Description
id	The identification code for the meter.
macID	A MAC address that must be unique within the system.
utility	An informational string.
serviceType	One of the valid ServiceType values (see schema). "Electric" is the only option at this time.
isCommissioned	Whether or not the meter is in a commissioned state.
loadActionCode	One of the possible LoadActionCode values used in Connect and Disconnect (see schema).
outageEventType	One of the possible OutageEventType values used in Device Status Check (see schema).
executionStatus	One of the possible ExecutionStates (see schema). These values control how the meter will respond to commands.
groupName	The name linking multiple meters together into a set.
jobExecutionStatus	One of the possible Job Execution Status values (see schema). This attribute determines how requested jobs perform.
updateIfExisting	Whether or not to update the meter with the provided values if it already exists in the index.
Comment	An informational string describing the purpose of the meter.
Channels	A listing of unit of measures supported by this meter.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.

Output — AddMetersOutput

Part: payload

Element: AddMetersResult

Whether or not each meter was added to the index.

Fault — See [UtilityFault](#)

RemoveMeter

This web service removes a meter from the in-memory data store. This will not permanently remove it from the control file.

Input — RemoveMeterInput

Part: payload

Element: RemoveMeterRequest

Parameter	Description
id	The ID for the meter to be removed

Output — RemoveMeterOutput

Part: payload

Element: RemoveMeterResult

Whether or not the meter was removed from the index.

Fault — See [UtilityFault](#). Thrown when meter id is not found.

AddMeterChannel

This web service adds a new channel to a single meter.

Input — AddMeterChannelInput

Part: payload

Element: AddMeterChannelRequest

Parameter	Description
id	The identification code for the meter.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.

Output — AddMeterChannelOutput

Part: payload

Element: AddMeterChannelResult

Whether or not the channel was added to the index.

Fault — See [UtilityFault](#). Thrown when meter id is not found.

RemoveMeterChannel

This web service removes a Channel from a meter.

Input — RemoveMeterChannelInput

Part: payload

Element: RemoveMeterChannelRequest

Parameter	Description
id	The ID for the meter to be removed.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.

These three parameters are combined to locate a unique channel

Output — RemoveMeterChannelOutput

Part: payload

Element: RemoveMeterChannelResult

Whether or not the channel was removed from the meter.

Fault — See [UtilityFault](#). Thrown when meter id is not found.

ReadScalarMeter

This web service generates a scalar reading for each channel of a given meter.

Input — ReadScalarMeterInput

Part: payload

Element: ReadScalarMeterRequest

Parameter	Description
id	The ID for the meter to be read

Output — ReadScalarMeterOutput

Part: payload

Element: ReadScalarMeterResult

Zero or more scalar readings for the given meter.

Parameter	Description
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.
value	A random number representing the scalar reading.

Meter Attribute Administration Services

This section describes the meter administration services of the test harness composite.

GetLoadActionCode

This web service queries whether the given meter is connected or disconnected. This method is used by the Connect/Disconnect service. The values for load action code are:

- Connect
- Disconnect

Input — GetLoadActionCodeInput

Part: payload

Element: GetLoadActionCodeRequest

Parameter	Description
id	The ID for the meter for which the load action code status should be retrieved

Output — GetLoadActionCodeOutput

Part: payload

Element: GetLoadActionCodeResult

The connection status of the requested meter.

Fault — See [UtilityFault](#). Thrown when meter id is not found.

SetLoadActionCode

This web service updates the load action code for a given meter. This method is used by the Connect/Disconnect service. The values for load action code are:

- Connect
- Disconnect

Input — SetLoadActionCodeInput

Part: payload

Element: SetLoadActionCodeRequest

Parameter	Description
id	The ID for the meter for which the load action code status should be set.
value	The new value of LoadActionCode to set on the meter.

Output — SetLoadActionCodeOutput

Part: payload

Element: SetLoadActionCodeResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault — See [UtilityFault](#). Thrown when meter id is not found.

IsCommissioned

This web service queries the commissioning status for a given meter. This service is used by the Commission/Decommission process. The commissioning attribute can be true or false.

Input — IsCommissionedInput

Part: payload

Element: IsCommissionedRequest

Parameter	Description
id	The ID for the meter for which the Commissioned status should be retrieved

Output — IsCommissionedOutput

Part: payload

Element: IsCommissionedResult

The value of the Commissioned status attribute for the requested meter.

Fault — See [UtilityFault](#). Thrown when meter id is not found.

SetCommission

This web service updates the commissioning status for a given meter. This service is used by the Commission/Decommission process. The commissioning attribute can be true or false.

Input — SetCommissionedInput

Part: payload

Element: SetCommissionedRequest

Parameter	Description
id	The ID for the meter for which the Commissioned status should be set
value	The new value of Commissioned status to set on the meter

Output — SetCommissionedOutput

Part: payload

Element: SetCommissionedResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault — See [UtilityFault](#). Thrown when meter id is not found.

GetExecutionStatus

This web service queries the status of the property controlling the overall execution of the command. The possible values of execution status are:

- Success - The command should complete successfully
- ResponseTimeout - The asynchronous response will never arrive
- SyncOperationFail - A simulated fault will occur in the during the initial request
- AsyncOperationFailure - A simulated fault will occur in the asynchronous response

Input — GetExecutionStatusInput

Part: payload

Element: GetExecutionStatusRequest

Parameter	Description
id	The ID for the meter for which the ExecutionStatus should be retrieved

Output — GetExecutionStatusOutput

Part: payload

Element: GetExecutionStatusResult

The value of the ExecutionStatus attribute for the requested meter.

Fault — See [UtilityFault](#). Thrown when meter id is not found.

SetExecutionStatus

This web service updates the property controlling the overall completion of the command. The possible values of execution status are:

- Success - The command should complete successfully
- ResponseTimeout - The asynchronous response will never arrive
- SyncOperationFail - A simulated fault will occur in the during the initial request
- AsyncOperationFailure - A simulated fault will occur in the asynchronous response

Input — SetExecutionStatusInput

Part: payload

Element: SetExecutionStatusRequest

Parameter	Description
id	The ID for the meter for which the ExecutionStatus should be set
value	The new value of ExecutionStatus to set on the meter

Output — SetExecutionStatusOutput

Part: payload

Element: SetExecutionStatusResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault — See [UtilityFault](#). Thrown when meter id is not found.

Creating a Custom Adapter for Smart Grid Gateway

Customers can create their own customized adapter for using Smart Grid Gateway with a specific head-end system. This can be done using the Oracle Utilities Smart Grid Gateway Adapter Development Kit. This section describes the Adapter Development Kit and its components.

NOTE: Unless otherwise noted, the contents of this section apply to on-premises implementations of Oracle Utilities Smart Grid Gateway only, and do NOT apply to Oracle Utilities cloud services. See [Smart Grid Gateway Adapters and Oracle Utilities Cloud Services](#) for more information about implementing Smart Grid Gateway Adapters with Oracle Utilities cloud services.

Adapter Development Kit Overview

The Oracle Utilities Smart Grid Gateway (SGG) Adapter Development Kit provides a starting point for customers to create their own customized adapter for using SGG with a specific head-end system. SGG uses Oracle Service Bus (OSB) and Oracle Business Process Execution Language (BPEL) to facilitate communication with other head-end systems. The following functionality can be configured:

Measurement Data and Device Event Loading: Data parsing and transformation via Oracle Service Bus from the smart meter format into the Oracle Utilities Service and Measurement Data Foundation unified format for measurement data and device events.

Measurement Data and Device Event Processing: Configurable mapping for meter status codes and device event names to Oracle Utilities Service and Measurement Data Foundation standard values.

Commissioning Communication: Business objects and BPEL processes to support the Meter Add Notification message.

Connect Communication: Business objects and BPEL processes to support Initiate Connect/Disconnect and Connect/Disconnect State Change Notification messages.

Disconnect Communication: Business objects and BPEL processes to support Initiate Connect/Disconnect and Connect/Disconnect State Change Notification messages.

Decommissioning Communication: Business objects and BPEL processes to support Meter Removal Notification message.

On-Demand Read: Business objects and BPEL processes to support Initiate Meter Read by Meter Number and Reading Changed Notification messages.

Device Status Check: Business objects and Oracle BPEL processes to support the outbound Initiate Outage Detection communication, the inbound Outage Detection Event Notification communication, and the processing of Event Notifications.

What Does the Adapter Development Kit Provide?

The Oracle Utilities Smart Grid Gateway Adapter Development Kit includes the following:

Sample Oracle Service Bus Processes: A file parsing and transformation process framework, delivered as an Oracle Service Bus (OSB) configuration, that can be used as a reference for creating the functionality to import usage readings and device events from a specific head-end system.

Sample Oracle Business Process Execution Language Processes: A set of sample communication processes that support Remote Connect, Remote Disconnect, Commission, Decommission, Device Status Check, and On-Demand Read commands delivered as an Oracle Business Process Execution Language (BPEL) project.

Oracle Utilities Smart Grid Gateway Business Objects: Business objects to support measurement data and device event loading and two-way commands such Commission, Decommission, Remote Connect, Remote Disconnect, and Device Status Check.

Sample Two-Way Communication Test Harness: A head-end system emulator delivered as a BPEL composite.

Demonstration Data: A set of sample data provided in the demonstration database that can be used with the adapter processes as delivered (prior to any customization you might perform as part of your implementation).

Adapter Development Kit Processing

This section provides details concerning the OSB processing, BPEL Processes, and OUAF objects supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and subsequent device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway service format. Payloads contain measurements and meter events in some head-end specific format OSB then places each service call into a JMS queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel then a service creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements and Device Events

The usage and event data exported from the AMI head-end system is loaded into Oracle Utilities as initial measurement and device event data. You can customize processing of this by configuring the following base product OSB projects:

1. **SGG-DG-CSV-BASE** contains components that are not to be changed on customer site. They implement functions specific to the CSV format processing such as validation and transformation.
2. **SGG-DG-CSV-CM** allows for customization and simplifies future upgrades.
3. **SGG-DG-XML-BASE** contains components that are not to be changed on customer site. They implement functions specific to the IMD and event upload format processing such as validation and transformation.
4. **SGG-DG-XML-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-DG-CSV-CM project are stored in the EnvironmentSettings.xq xquery file. You can use this file to adjust initial measurement and device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the SGG-DG-CSV-CM EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementEvent	Holds the name of inbound web service for the device event seeder.	
destinationRootElementIMD	Holds the name of inbound web service for the IMD seeder.	

The runtime configuration settings for the SGG-DG-XML-CM project are stored in the EnvironmentSettings.xq xquery file. You can use this file to adjust initial measurement and device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the SGG-DG-XML-CM EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRawIMD	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElement	Holds the name of inbound web service for the IMD seeder.	

For additional information about the sample OSB implementation included in the Oracle Utilities Smart Grid Gateway Adapter Development Kit, see [Oracle Service Bus Processing](#).

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the SGG-DG-CSV-CM and SGG-DG-XML-CM projects. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Processing Data in the Adapter Development Kit Native Format

Usage and event data exported from the AMI head-end system can be loaded into Oracle Utilities in the “native” initial measurement and device event data formats (the format of the initial measurement and device event seeder business objects). You can customize processing of this by configuring the following base product OSB projects:

1. **SGG-DG-SEEDER-BASE** contains components that are not to be changed on customer site. They implement functions specific to the IMD and event upload format processing such as validation and transformation.
2. **SGG-DG-SEEDER-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-DG-SEEDER-CM project are stored in the EnvironmentSettings.xq xquery file. You can use this file to adjust initial measurement and device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the SGG-DG-SEEDER-CM EnvironmentSettings.xq file:

Element	Description	Valid Values
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
destinationRootElementEvent	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false
filterUsage	Determines if usage should be filtered.	true false

See [The Adapter Development Kit Native Format](#) for more information about the ADK “native” format.

Publishing Initial Measurement Data and Device Events

The Adapter Development Kit can be configured to publish initial measurement data and device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-DG-SEEDER-CM OSB project are used in publishing measurement data and device events to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems.

Initial measurement and device event data is published in the “native” initial measurement data format (the format of the initial measurement and device event seeder business objects). This format includes normalized unit of measure, condition, and device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

NOTE: Initial measurement data published via this feature is published prior to VEE processing. In addition, filtering can NOT be applied to initial measurement or device event data published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The Adapter Development Kit can be configured to filter initial measurement data passed into Oracle Utilities Smart Grid Gateway and Meter Data Management. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **ADK - UOM Code to Standard UOM Mapping** extendable lookup (DG-HeadendUOMLookup) are passed into the system for processing.

Filtering Events

The Adapter Development Kit can be configured to filter device events passed into Oracle Utilities Smart Grid Gateway and Meter Data Management. Filtering data is enabled by setting the <filterEvents> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **ADK - Device Event Mapping** extendable lookup (DG-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (D1RT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D3-CIM-EVENT-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

NOTE: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The adapter development kit base package includes the following device and initial measurement business objects:

Business Object Name	Description
DG-InitialLoadIMDInterval	Generic Initial Load IMD - Interval Used when loading customized adapter interval measurements into the system for the first time.
DG-InitialLoadIMDScalar	Generic Initial Load IMD - Scalar
DG-SmartMeter	ADK — Smart Meter

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, device status check, or an on-demand read. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related head-end system web service. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Adapter Development Kit command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	ADK - Initiate Connect or Disconnect	ADK - Connect/ Disconnect State Change	Connect Device Create IMD
Remote Disconnect	ADK - Initiate Connect Disconnect	ADK - Connect/ Disconnect State Change	Disconnect Device Create IMD
Device Commissioning	ADK - Meter Add Notification		Device Commissioning
Device Decommissioning	ADK - Meter Remove Notification		Device Decommissioning
On-Demand Read (Scalar)	ADK - Initiate Meter Read by Meter ID	ADK - Reading Changed Notification	Create IMD
On-Demand Read (Interval)	ADK - Initiate Meter Read by Meter ID	ADK - Reading Changed Notification	Create IMD
Device Status Check	ADK - Initiate Outage Detection	ADK - Outage Detection Event Notif	

Device Communication Base Package Business Objects

The adapter development kit base package includes the following communication business objects:

Business Object Name	Description
DG-ConnectDisconStateChgNtf	Generic - Connect/Disconnect State Change
DG-InitiateConnectDisconnect	Generic - Initiate Connect Disconnect
DG-InitiateMeterByMeterId	Generic - Initiate Meter Read By Meter ID
DG-InitiateOutageDetection	Generic - Initiate Outage Detection
DG-MeterAddNotification	Generic - Meter Add Notification
DG-MeterRemoveNotification	Generic - Meter Remove Notification
DG-OutageDetectEvtNotification	Generic - Outage Detection Event Notification
DG-ReadingChgNotification	Generic - Reading Changed Notification

Event Data Mapping

The head-end system event file format can map as follows into the business object, D1-DeviceEventMappingLookup:

Head-End System Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.
Device Identifier	External Device Identifier	
Event Name	External Event Name	

Head-End System Flat File Field	Device Event Seeder BO Element	Comments
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router
Service Location ID	External Service Location ID	
Communication Module Serial Number	External Communication Module Identifier	
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form): Alert Information
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The adapter for Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway Adapter Development Kit includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Used for upload of device events. The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event. If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.
D1-InitialLoadIMD	Used for initial measurement upload. The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.
D1-DeviceStatusCheck	Device Status Check This service is invoked by the integration layer to instantiate a Device Status Check command.
D1-InitialLoadIMD	Used by OSB to instantiate an IMD This inbound web service is used by OSB to instantiate an Initial Measurement Data for incoming interval usage in the Generic format.
D1-RemoteConnect	Remote Connect This service is invoked by the integration layer to instantiate a Remote Connect command.
D1-RemoteDisconnect	Remote Disconnect This service is invoked by the integration layer to instantiate a Remote Disconnect command.
DG-ConDisconStChgNotification	Initiate Connect Disconnect response. Retrieves asynchronous response from Initiate Connect Disconnect command.
DG-OutageDetectionEventNotification	Initiate Outage Detection Response Retrieve response from the Initiate Outage Detection Event Notification command.
DG-ReadingChangedNotification	Reading Changed Notification Notification that a device reading has changed.

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway Adapter Development Kit includes the following message senders:

Message Sender	Description
DG-COMM	Generic Adapter Commission
DG-DCOMM	Generic Adapter Decommission
DG-INTOUDET	Generic Adapter — Initiate Outage Detection Request
DG-XAISender	Commission / Decommission Sender

BPEL Processes

These processes are responsible for performing the conversion from Oracle Utilities format to MultiSpeak 4.1 format, invoking process callouts and invoking the remote endpoint to trigger the device events.

OnDemandRead Composite Process: Invokes the remote endpoint to trigger the on-demand read event. An asynchronous reply responds to the OUAF layer when the reading arrives.

ConnectDisconnect Composite Process: Invokes the remote endpoint to trigger the connect/disconnect event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

CommissionDecommission Composite Process: Invokes the remote endpoint to trigger the commission or decommission event. After the synchronous call completes, a one of the following second business callout services is invoked to determined if the related “received” or “completed” callout should be executed:

- isExecutingCommissionReceived-Callout
- isExecutingCommissionCompleted-Callout
- isExecutingDecommissionReceived-Callout
- isExecutingDecommissionCompleted-Callout

DeviceStatusCheck Composite: Invokes the remote endpoint to trigger the initiate outage detection event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

ProcessCallout Composite: This business callout provides a point at which customers and implementers can incorporate custom business logic and transformations. This composite includes the WSDLs and processing logic for all of the MultiSpeak processes. The default implementation of each method is a direct return of the input.

For additional information about the BPEL processes included in the Oracle Utilities Smart Grid Gateway Adapter Development Kit, see [Business Processing Execution Language Processing](#).

Web Services

These web services are all defined in the head-end system. The WSDLs were added to a Meta Data Storage (MDS) layer in OUAF and all references to the WSDL point to this MDS location. These web services have HTTP security by default. You may need to modify the security as a part of your implementation.

Web Service	Related BPEL Process	Description
CB_ServerService	ConnectDisconnect	<p>This web service defines the return interface, the means by which the status is returned to the calling system.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the CDStateChangeNotification web method is implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/</p>

Web Service	Related BPEL Process	Description
		services/Generic Adapter/ConnectDisconnect/CB_ServerService
CB_Server	OnDemandRead	<p>This web service defines the return interface, the means by which the reading is returned to the calling system.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the ReadingChangedNotification web method is implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Generic Adapter/OnDemandRead/CB_Server</p>
OA_ServerService	DeviceStatusCheck	<p>This web service defines the asynchronous return for InitiateOutageDetectionEventRequest for solicited responses.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the ODEventNotification, PingURL, and GetMethods web methods are implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Generic Adapter/DeviceStatusCheck/OA_ServerService</p>

For additional information about the web services included in the Oracle Utilities Smart Grid Gateway Adapter Development Kit, see [Business Processing Execution Language Processing](#).

Oracle Service Bus Processing

This chapter describes how to use Oracle Service Bus (OSB) and the components of the Oracle Utilities Smart Grid Gateway Adapter Development Kit to develop an adapter for importing usage reading and device events.

OSB Overview

The examples in this chapter provide an implementer with the information required to create a customized adapter using the Oracle Utilities Smart Grid Gateway Adapter Development Kit. Customized adapters are required in situations where a productized Smart Grid Gateway adapter is not available for a particular head-end system. The examples below explain how to receive and process inbound meter usage and events. The examples contain two parts: the incoming file parsing functionality implemented in Java, and an easy, configurable and customizable Oracle Service Bus (OSB) configuration, including an implementation of post-parsing functionality.

OSB Prerequisites

Development of an Oracle Utilities Smart Grid Gateway adapter requires a number of technical skills as well as a development environment.

Required Technical Skills

The following technical skills are required for developing an adapter using the development kit:

- Experience in Java programming
- Experience in development using XQuery and XPath
- Experience in XML programming
- Experience in OSB development and administration
- Understanding of Oracle Utilities Service and Measurement Data Foundation (SMDF) architecture

Environment Requirements

Development of the Oracle Utilities Smart Grid Gateway adapter requires an environment configured as follows:

- The Oracle WebLogic server must be installed.
- The OSB must be installed.
- An OSB domain must be created.
- Java Messaging Service (JMS) queues for Initial Measurement Data (IMD) and Notification messages must be created.
- The spl-d1-osb-2.0.1.jar containing the com.splwg.d1.sgg.osb.common Java package must be available. This is a single jar for all vendor-specific adapters.
- The archive sgg-osb-generic-adapter.zip must be available. This file is downloaded as a part of adapter development kit deployment. It contains the FileParser folder with sample source code and the com.splwg.dg.sgg.osb.configuration.jar file with sample OSB projects.

OSB Related Documentation

For more information about using the adapter development kit and Oracle Service Bus, see the following Oracle documents:

- *Oracle Fusion Middleware User's Guide for Technology Adapters*
- *Oracle Fusion Middleware Administrator's Guide for Oracle Service Bus*
- *Oracle Fusion Middleware Developing Applications for Oracle WebLogic Server*
- *Oracle Fusion Middleware User's Guide for Oracle JDeveloper*
- *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide*
- *Oracle Utilities Meter Data Management / Smart Grid Gateway Administrative User Guide*

OSB Processing Terms and Acronyms

This section lists several terms and acronyms used throughout this chapter.

Term	Definition
AMI	Advanced Metering Infrastructure
CSV	Comma-Separated Values
FA	File Adapter. Oracle JCA File Adapter.
FP	File Parser, Java code that parses input file and generates Plain XML
GA	Smart Grid Gateway generic adapter
GFP	Generic File Processor, Java code that is invoked by FA. It communicates with FP
IMD	Initial Measurement Data
IMD XML	The final XML containing the IMD.
JAR	Java Archive
JAXB	Java Architecture for XML Binding
JCA	Java Connector Architecture

Term	Definition
JDeveloper	Freeware Oracle integrated development environment for development of Java-based SOA and Java EE applications
JMS	Java Message Service
MDB	Message Driven Bean
SMDF	Service and Measurement Data Foundation
OSB	Oracle Service Bus
OUAF	Oracle Utilities Application Framework
Plain XML	An intermediate XML containing all of the values from the inbound file. It is necessary because OSB Message Flow can handle only XML.
PPS	Processing Proxy Service, OSB proxy service where the validation and transformation of Plain XML is implemented. It is necessary to catch errors that occurred before Plain XML is transformed to IMD or Device Event seeder structures.
RFD	Rejected File Descriptor, File containing information about a portion of input file that was a cause of error.
RPPS	Result Processing Proxy Service, OSB proxy service where processing of transformation result is implemented. It is necessary to catch errors that occurred after Plain XML is transformed to IMD or Device Event seeder structures.
SGG	Smart Grid Gateway
Weblogic	Oracle J2EE Application Server
WSD	Web Session Directory
XML	eXtensible Markup Language
XPath	Programming language for selecting nodes from an XML document
XQuery	Programming language to query XML.

Oracle Utilities Smart Grid Gateway Adapters

This section contains detailed information on the different components that make up an Oracle Utilities Smart Grid Gateway adapter and the application logic that is needed to implement one.

Adapter Components

The following table lists the adapter components:

Component	Description
JCA File Adapter (FA)	Technology adapter for reading and writing files on the local file system. It is responsible for polling files from incoming folder and passing it to the Generic File Processor.
Generic File Processor (GFP)	Framework component that is implemented in Java. It is responsible for instantiation of the File Parser, getting Plain XML from it, and passing it to OSB message Flow. It also performs payload statistics related functionality such as gathering data and generating notification messages.
File Parser (FP)	<p>Component implemented in Java. It is specific to every different incoming format. It is responsible for parsing the incoming file, breaking the payload into logical parts (debatching), generating Plain XML for every logical part, and returning XML back to invoking GFP.</p> <p>Plain XML could be any logical subset of data that can be mapped to IMD. It is an intermediate format/schema between the raw data and IMD XML. The Plain XML schema must be defined by the file parser developer.</p> <p>Raw data is read in portions from the input file and converted to Plain XML before passing to OSB message flow. The reason for data being read in portions is as follows:</p> <p>Assume that an input file contains readings for 100 Measuring Components. You would want to read the input file in portions for two particular reasons.</p> <ol style="list-style-type: none"> 1. Reading data of exactly one measuring component ensures that it is mapped appropriately to one IMD at a time.

Component	Description
	2. Reading data in portions ensures that the entire file is not loaded into memory, which could cause resource issues.
Inbound Proxy Service	OSB proxy service that contains FA-related configuration settings. It statically routes all messages to Processing proxy Service.
Processing Proxy Service (PPS)	OSB proxy service that validates and transforms Plain XML. This service is necessary for catching errors that occur before Plain XML is transformed to IMD or Device Event seeder structures.
Result Processing Proxy Service (RPPS)	OSB proxy service that processes transformed data. This service is necessary for catching errors that occur after Plain XML is transformed to IMD or Device Event seeder structures.

Processing Life Cycle

This section outlines the life cycle from the initial input file to the initial measurement output. Refer to [OSB Processing Terms and Acronyms](#) for descriptions of the abbreviations and acronyms used in this chapter.

See the [Logic Sequence Diagram](#) for general description of how the components interact.

OSB Processes

1. The JCA File Adapter starts reading the file.
2. FA instantiates and initializes the GFP.
3. FA invokes GFP passing an open stream to the incoming file.
4. GFP sends **D1-PayloadStatistics** notification message to FA.
5. GFP instantiates and initializes (if it is not done yet) the FP that is defined in the Inbound Proxy properties for parsing the file.
6. GFP invokes the FP (See [File Parser Processes](#) below).
7. In case of error in FP it invokes GFP. GFP sends **D1-PayloadErrorNotif** notification message to FA.
8. GFP gets the Plain XML as a return from FP.
9. GFP returns the Plain XML to the FA.
10. The Plain XML is passed via InboundProxyService to Processing Proxy service (PPS). In PPS's message flow, the Plain XML is validated and transformed to IMD XML.
11. PPS passes the IMD to Result Processing Proxy service (RPPS). RPPS publishes the IMD XML to a JMS queue, which is then picked up by Message Driven Bean (MDB).
12. OSB processes 3 through 9 are repeated until FP returns NULL on process 9.
13. GFP sends **D1-PayloadSummary** notification message to FA.

File Parser Processes

1. FP starts reading the input stream
2. FP instantiates a JAXB object of the type of Plain XML. The JAXB related interfaces and implementation classes are generated by using JDeveloper (See *Oracle Fusion Middleware User's Guide for Oracle JDeveloper* or [Generating Java Classes from XML Schemas](#)).
3. FP reads the input stream in segments until it hits a logical end of data with which it could create a Plain XML.
4. FP populates the data that is read into the Plain XML JAXB object.
5. FP marshals the JAXB object into Plain XML and passes back GFP. If the end of file (EOF) is reached FP passes back NULL.

6. File parser processes 2 through 5 are performed for every invocation by GFP.

Java Project

The source code in the example files contains an implementation of functionality to parse an incoming payload in Comma Separated Values (CSV) and XML formats. This implementation can be used as a reference for creating a project that is specific to your head-end system. The descriptions below are mostly related to CSV parsing functionality as it is a more complex and interesting example. The XML related parsing example is provided only to illustrate how XML-based input formats may also be processed.

Logic Sequence Diagram

The sequence diagram below is helpful for understanding the File Parser functionality. The custom class must implement the FileParser and FileParser2 Java interfaces described in the SGG D1 jar to be qualify as a file parser. For more information, see [FileParser Interface](#) and [FileParser2 Interface](#).

When FA finds a file in the input directory, it instantiates and calls GFP which in turn starts an interaction with the FP. The interaction can be categorized into the following three phases:

1. Instantiation and Initialization

- setProcessor()
- setInputStream()
- setStartPosition()

2. Transaction

- getPosition()
- getNextStream()

3. Exception Handling

- getCurrentInputPortion()

Instantiation and Initialization Phase

The GFP is instantiated and receives an Input Stream when a file gets into the input directory. At that point an instance of the FP is instantiated. Certain methods, as specified above, are invoked on the FP to initialize.

Transaction Phase

Once the FP is initialized, GFP uses the FP instance to generate the Plain XML structure. This happens with the invocation of getNextStream() method on the FP.

On every invocation, the FP returns exactly one Plain XML. The FP invocations continues until NULL is returned from the FP. NULL indicates the end of file and an indication that parsing is complete for a specific file. GFP stops invoking getNextStream() for a particular input file when it receives a NULL from the FP.

FP uses the file input stream to read the file in portions. It could read byte-by-byte or line-by-line, but at the end of each getNextStream() method call it would have read only so much that is sufficient to create one Plain XML structure. For example, in an input file, if there is sufficient data for only one Plain XML then the first call to getNextStream() would return a Plain XML and the next one would return NULL. But if there is more than one, getNextStream() calls would continue to return Plain XML structures for every incoming portion until end of file is reached.

Exception Handling Phase

Exception handling inside the FP can be categorized into two phases: **Reactive** and **Recovery**:

Reactive Phase

This phase involves catching an exception and reporting it to the GFP. It is achieved by invoking saveInvalidRow() method on the GFP (this.fileProcessor).

Note that when an exception occurs, no further parsing is done and NULL is passed back from getNextStream().

If one fails to return NULL, errors such as “Simultaneous good and bad result returned by the File Parser” can be found in the Weblogic server log.

When an exception is reported to the GFP, it does three things:

1. Creates an XML payload D1-PayloadErrorNotif and passes it to the OSB message flow. The message is published to the Notification Queue from inside PPS of the BASE OSB project.
2. It increments the “transaction error occurred” variable by invoking the utility method inside the D1 jar. All the errors occurring during the lifetime of a file parsing are captured and are reported through the message D1-PayloadSummary - which is again published to Notification Queue.

3. Finally, it creates a data file in the error directory with the portion of raw data that is read when the error occurred. It also creates a Rejected File Descriptor (RFD) file. The raw input portion is available by utilizing `getCurrentInputPortion()` method, which is discussed below.

As noted in the above image, the `saveInvalidRow()` method takes three input parameters:

1. The position at which the parsing started. It will be written to an RFD file. This is helpful in identifying the location of an error in the input file.
2. The raw data that will be written into error data file. It should be in the same to the incoming file format and it should contain data that is read since current invocation of `getNextStream()` method is started. It will allow correcting troubled data and place “fixed” file into an incoming folder for further re-processing.
3. The error message that is reported in D1-PayloadErrorNotif message. Note, the content of the error message has to be defined by the file parser developer.

Recovery Phase

This phase must not be confused with recovering from a handled exception discussed above. This case is when file parsing gets completely interrupted by power failure or network interruption.

Preparation for recovery: GFP maintains an internal index to the current read position of the file. This is achieved by GFP by invoking `getPosition()` method on the FP before every `getNextStream()` method call.

```
public long getPosition() {
    long retVal = this.fileProcessor.getCurrentInputPosition();
    return retVal;
}
```

Recovery: In case of an interruption and subsequent restore, GFP sets the start position on the File Parser. For instance, if the failure had occurred at byte 415, the start position would be set to 415 so that FP starts to read from that point and not from 0. The value 415 can be referred to as the recovery point.

```
public void setStartPosition(long position) {
    this.startPosition = position;
}
```

When the file parser starts parsing again, two things must occur to ensure that it starts parsing from the recovery point:

1. Store the recovery point to the `startPosition` field.
2. Incorporate skip logic to start the pointer from the recovery point.

Java Implementation

The Java component of the project includes the following classes and packages:

1. **com.splwg.dg.osb.common.FileParserGenGeneric** class is a super class with members that are common for CSV and XML related functionality. It implements the `com.splwg.d1.sgg.osb.common.FileParser` interface (see [FileParser Interface](#)). The implementation of `com.splwg.d1.sgg.osb.common.FileParser2` (see [FileParser2 Interface](#)) has been added to define the IMD & Event Upload Statistics related functionality.
2. **com.splwg.dg.osb.csv.FileParserCSV** class contains the implementation of the parsing functionality for CSV formats. It performs the following logic:
 - Parses the incoming payload.
 - Transforms incoming data to Usage or Event related structures based on incoming data type.
 - Extends those structures with file information and external service provider identifier.
 - Returns one by one that structures as a stream to caller.
3. **com.splwg.dg.osb.plain** package contains JAXB related interfaces and implementation classes corresponding to the Plain XML Schema

4. **com.splwg.dg.osb.xml.FileParserXML** class contains the implementation of parsing functionality for the “IMD and Event Online Upload” XML format (See the *Oracle Utilities Service and Measurement Data Foundation User’s Guide*). It performs the following logic:

- Parses the incoming payload.
- Extracts information about current device.
- Breaks the incoming data to separate initial measurement data structures.
- Extends those structures with device information, file information and external service provider identifier.
- Returns one by one the structures as a stream to caller.

Implementation Details

This section provides an overview of the implementation details. See the comments in the source code for more detailed information.

OSB Configuration

This section outlines the OSB projects provided with the Adapter Development Kit.

OSB Project Summary

The OSB Configuration consists of four projects. These projects can be categorized by either functionality or content:

Functionality by Incoming File Format

CSV format processing:

- SGG-DG-CSV-BASE
- SGG-DG-CSV-CM

XML format processing:

- SGG-DG-SEEDER-BASE
- SGG-DG-SEEDER-CM
- SGG-DG-XML-BASE
- SGG-DG-XML-CM

Content (by purpose of content)

Content containing business logic implementation:

- SGG-DG-CSV-BASE
- SGG-DG-SEEDER-BASE
- SGG-DG-XML-BASE

Content containing configuration settings related to the objects and variables required during the processing of payloads:

- SGG-DG-CSV-CM
- SGG-DG-SEEDER-CM
- SGG-DG-XML-CM

Project Contents

The following table describes the contents of each of these projects:

Project	Description
SGG-DG-CSV-BASE	<p>Contains the components responsible for “actual” processing of data coming in CSV format. It can be upgraded in future releases without affecting the customization and environment settings that are stored in the SGG-DG-CSV-CM project. This project performs the following functions:</p> <ul style="list-style-type: none"> • Processes notification messages that are sent from the GFP. • Calls the customizable local service proxies for pre- and post- processing of passed data • Validates passed data against the XSD schema for Plain XML format • Transforms passed Plain XML into D1-InitialLoadIMD or D1-DeviceEventSeeder formats according to type of incoming data. • Sends result structures to destination JMS queue. • Updates statistic information via calling the messageFlowIncResultIMD or messageFlowIncResultEvent method accordingly. • Handles errors that occur to provide information to the File Processing component. Error handling contains separate handlers for two stages: before and after the Plain XML is transformed to the final XML structure. The separation is necessary to make Java calls to appropriate methods (messageFlowErrorOccurredPlain, messageFlowErrorOccurredIMD or messageFlowErrorOccurredEvent) according to the current processing stage and data type.
SGG-DG-CSV-CM	<p>Contains environment related configuration settings. It allows the customization and simplifies the future upgrades as well (See Configuring the OSB Project for example values).</p>
SGG-DG-XML-BASE	<p>Contains the components responsible for “actual” processing of data coming in XML format. It can be upgraded in future releases without affecting the customization and environment settings that are in SGG-DG-XML-CM project. This project performs the following functions:</p> <ul style="list-style-type: none"> • Processes notification messages that are sent from GFP. • Calls the customizable local service proxies for pre- and post- processing of passed data. • Validates passed data. • Transform passed data. In current tutorial a simple XQuery code is used just to show the functionality available for transformation. • Sends result structures to destination JMS queue in form of acceptable by the D1-DeviceEventSeeder and/or D1-InitialLoadIMD inbound web services. • Updates statistic information via calling messageFlowIncResultIMD method. • Handles errors to provides information to GFP. Error handling contains separate handlers for two stages: before and after the Plain XML is transformed to the final XML structure. The separation is necessary to make a Java calls to appropriate methods (messageFlowErrorOccurred or messageFlowErrorOccurredIMD) according to the current processing stage.
SGG-DG-XML-CM	<p>Contains environment related configuration settings. It allows the customization and simplifies future upgrades as well.</p>
SGG-DG-SEEDER-BASE	<p>Contains the components responsible for processing of data coming in “native” XML format. It can be upgraded in future releases without affecting the customization</p>

Project	Description
	<p>and environment settings that are in SGG-DG-SEEDER-CM project. This project performs the following functions:</p> <ul style="list-style-type: none"> • Processes notification messages that are sent from GFP. • Calls the customizable local service proxies for pre- and post- processing of passed data. • Validates passed data. • Splits payload into individual initial measurements and/or device events. • Sends result structures to destination JMS queue in form of acceptable by the D1-InitialLoadIMD and/or D1-DeviceEventSeeder inbound web services. • Updates statistic information via calling messageFlowIncResultIMD method. • Handles errors to provides information to GFP. Error handling contains separate handlers for two stages: before and after the Plain XML is transformed to the final XML structure. The separation is necessary to make a Java calls to appropriate methods (messageFlowErrorOccurred or messageFlowErrorOccurredIMD) according to the current processing stage.
SGG-DG-SEEDER-CM	Contains environment related configuration settings. It allows the customization and simplifies future upgrades as well.

OSB Project Implementation Details

This section provides an overview of the implementation details. For more detailed information see the comments contained in the source code.

The following diagram shows the major processes and the data flow implemented in the OSB Configuration projects. The implementation description that follows is related to CSV parsing.

Setting Up the Adapter Environment

This section contains detailed information about the setting up of an environment with an example adapter.

Setting Up the Java Project

1. Open the `sgg-osb-generic-adapter.zip` file and extract the `FileParser` folder into a temporary location on your hard disk.
2. Create a Java project in JDeveloper and import source code into it from the folder extracted previously.
3. Add the `spl-d1-osb-2.0.1.jar` file to the project's Libraries and Classpath properties.

4. Deploy the project as a jar file to the destination OSB domain's lib folder.

Note: The WebLogic server should be restarted after jar file is copied to lib folder. For more details, see *Oracle Fusion Middleware Developing Applications for Oracle WebLogic Server*.

Configuring the OSB Project

1. Open the sgg-osb-generic-adapter.zip file and extract the com.splwg.dg.sgg.osb.configuration.jar file into a temporary location on your hard disk.
2. Ensure that OSB is running in the domain that is created for the adapter.
3. Import resources by using the OSB Administration Console via the **System Administration > Import/Export > Import Resources** menu item from the extracted com.splwg.dg.sgg.osb.configuration.jar file. Note that conflicts may occur during import. They will be fixed in the following steps.
4. Check and change the JCA Transport Configuration properties of the SGG-DG-CSV-CM/Proxy Services/InboundProxyService proxy service according to the deployment environment:

Where:

- **Endpoint Properties/SGG_INPUT_PARSER** is a name of class that implements file parsing functionality. See a Java project mentioned early.
 - **Endpoint Properties/SGG_ERROR_FOLDER** is a folder where a rejected transaction from incoming file will be placed in case when the parsing or validation is failed.
 - **Endpoint Properties/SGG_SP_EXT_REF_ID** is a value corresponding to the target Service Provider's external reference id on OUAF side. It is used in the XML structures related to the IMD & Event Upload Stats functionality. Also, this value will be placed into D1-InitialLoadIMD/serviceProviderExternalId and D1-DeviceEventSeeder/externalSenderId elements.
 - **Activation Spec Properties/IncludeFiles** is the naming convention that the Oracle File Adapter uses to poll for inbound files.
 - **Activation Spec Properties/PhysicalArchiveDirectory** is a folder where to archive successfully processed files.
 - **Activation Spec Properties/PhysicalDirectory** is an input folder to be polled.
5. Change the Endpoint URI in the Transport Configuration section of the SGG-DG-CSV-CM/Business Services/DestinationBusinessService business service according to the deployment environment with value containing URI for JMS server and queue where IMD or Device Event structures will be sent (see *Oracle Fusion Middleware Administrator's Guide for Oracle Service Bus* for more detail.):
 6. Change the Endpoint URI in the Transport Configuration section of the SGG-DG-CSV-CM/Business Services/NotificationBusinessService business service according to the deployment environment:
 7. Update the credentials stored in the SGG-DG-CSV-CM/Service Accounts/DestinationServiceAccount service account according to the deployment environment with user ID and password required to access JMS server:
 8. Repeat steps 4-7 for the SGG-DG-XML-CM project

Additional Information

This section contains additional information about the Adapter Development Kit.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the "InboundProxyService" proxy service. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

FileParser Interface

This section provides the source code of the FileParser interface used by the Java class delivered with the Java package described earlier in this section.

```
package com.splwg.dl.sgg.osb.common;
import java.io.IOException;
import java.io.InputStream;
/** <p>
 * FileParser component is responsible for processing the input
 * stream and returning a Plain XML containing all data from
 * incoming transaction in a shape expected by the following
 * Oracle Service Bus message flow.
 * </p>
 */
public interface FileParser {
    /**
     * Returns the next message in Plain XML format
     * or null if there are no more messages
     * @return next message as InputStream
     */
    InputStream getNextStream() throws IOException;
    /**
     * Returns the current position in the currently
     * parsed source input stream
     * @return the position in source input stream after
     * last incoming row was read and parsed
     */
    long getPosition();
    /**
     * Sets source stream
     * @param input the Input Stream that should be parsed
     */
    void setInputStream(InputStream input);
    /**
     * Sets "owner" FileProcessor
     * @param owner the Instance of FileProcessor that will
     * be notified about current processing via call to
     * utility methods (saveInvalidRow and setParseFinishNote)
     */
    void setProcessor(FileProcessor owner);
    /**
     * Sets the position from which the parsing of source
     * stream should be started.
     * It is necessary if last time the processing of
     * current file has been interrupted
     * @param position the starting position
     */
    void setStartPosition(long position);
    /**
     * Returns the byte array that contains a portion of an incoming
     * file that most recently has been read and converted to Plain XML.
     * It should be in the same format as incoming file. The header and
     * tail records, if there are, should be included and updated according
     * to the content
     */
    byte[] getCurrentInputPortion();
    /**
     * Returns type of currently generated transaction - USAGE or EVENT
     */
    FileProcessor.TransactionType getCurrentTransactionType();
    /**
     * Returns the number of successfully generated transactions of given type
     */
    int getTransactionCount(FileProcessor.TransactionType type);
    /**
     * Returns the number of expected transactions in input stream
     * Returns -1 if information not available
     */
    int getTotalExpected();
}
```

FileParser2 Interface

This section provides the source code of the FileParser2 interface used by the Java class delivered with the Java package described earlier in this section. This interface has been added to include a way for the File Processor to retrieve the file creation date which can be stored inside the incoming file.

```
package com.splwg.dl.sgg.osb.common;
import java.util.Date;
public interface FileParser2 extends FileParser {
    /**
     * FileProcessor usage method
     * Returns the File creation date and time stamp stored
     * in the file
     * Returns null if information not available
     */
    Date getCreationDateTime();
}
```

FileProcessor Interface

This section contains a portion of the FileProcessor interface related to the file parsing functionality.

```
package com.splwg.dl.sgg.osb.common;
public interface FileProcessor {
    public enum TransactionType {
        USAGE, EVENT
    }
    /**
     * FileParser usage method
     *
     * @return a string containing the name of currently processed inbound file
     */
    String getOrigin();
    /**
     * FileParser usage method Creates a file in the Error Folder and saves
     * passed row parameter to it
     *
     * @param position
     *         the number representing the position in file where invalid
     *         raw data is started
     * @param row
     *         the byte array containing an invalid raw data in vendor
     *         specific format the same with format of incoming file
     * @param failCause
     *         the string showing the cause of fail It will be used while
     *         logging the fail message.
     */
    void saveInvalidRow(long position, byte[] row, String failCause);
    /**
     * FileParser usage method
     * Returns the current offset in input file
     */
    long getCurrentInputPosition();
}
```

Generating Java Classes from XML Schemas

In JDeveloper you can use JAXB (Java Architecture for XML Binding) to generate Java classes from XML schemas. JAXB is an easy way to incorporate XML data and processing functions in Java applications without having to know XML. You can generate a JAXB 1.0 or 2.0 content model, including the necessary annotations, from an XML schema.

When the JAXB binding compiler is run against an XML schema, JAXB packages, classes, and interfaces are generated. You can then use the generated JAXB packages and the JAXB utility packages in a binding framework to unmarshal, marshal, and validate XML content.

To generate Java classes from XML schemas with JAXB:

1. From the main menu choose **File > New > Business Tier > TopLink/JPA** and select either JAXB 1.0 or 2.0 Content Model from XML Schema to open the compilation dialog.
2. Select the schema file and optionally the JAXB customization file to use and the package to which the generated classes will be added.

The JAXB package and generated classes are added to the Application Resources folder.

Business Processing Execution Language Processing

This section describes the Business Process Execution Language (BPEL) processes included in the Oracle Utilities Smart Grid Gateway Adapter Development Kit that support two-way communication between the adapter and the head-end system. The ideas and general practices described in this section can be applied to any other adapter.

WSDLs, Endpoints, and Messages

WSDLs are Web Service Definition Language files that describe a web service. New services must utilize the WSDLs to determine the structure of requests and responses. For remote services, they contain the locations to access the services. For both remote and local (hosted) services, the files will contain the definitions for each web service including names, arguments, exceptions, and the structure of the input and output messages.

In Oracle Service Oriented Architecture (SOA), WSDLs can be classified as a “service” or as a “reference.” Services are hosted on the SOA server; that is, the implementation of the web service is on the local application server. Referenced services are implemented on a different server. This distinction is also relevant to the composite level. Services are implemented in the current composite. References are located elsewhere, possibly on the same app server, but in a different composite.

An “endpoint” is simply the URL for a web service. Since web services communicate via HTTP, each will have a unique URL. Once a service’s endpoint is known, a message service can be targeted to it.

How to locate WSDLs and Endpoints

There are two ways to locate WSDLs in an installed Adapter: through Enterprise Manager and by using a direct URL. Only “hosted” WSDLs can be located in this way. Referenced (remote) WSDLs must be either located in source code or obtained from the hosted location.

How to Use Enterprise Manager to Locate WSDLs and Endpoints:

1. Open Enterprise Manager and use the navigation pane to open the Dashboard of the desired composite.
2. The top bar of the Dashboard contains several buttons and icons. One of these is an “earth” icon with a puzzle piece over it. Click this icon to display the WSDL and endpoint URIs for the composite.
3. Click the URL link to see the WSDL in the browser, or right click and save it to your machine for use in developing new services.

Depending on the requirements, It may be necessary to download the associated schema or WSDL file(s). Schemas are available within the WSDL’s “types” element. Find associated WSDL URLs within the import element. That URL can be pasted into a browser tab.

The endpoint for the service is also visible in this window. It is this URL that should be added to message sender configuration. For example:

The value HTTP Header/SOA Action is taken from the service’s WSDL. Locate the `wSDL:definitions/wSDL:binding/wSDL:operation/soap:operation` element for the web method being invoked. An attribute called `soapAction` will contain the value for this field. A shortcut to this field is using Enterprise Manager’s Testing framework (locate the Test tab from the dashboard view for the composite). Once the WSDL is parsed, the SOAP Action will appear in a field on the request tab:

The values **HTTP Login User** and **HTTP Login Password** should be set to a valid WebLogic user that has access to the module. The **HTTP Method** should always be set to POST and the HTTP URL 1 should be set to the value of the endpoint above.

How to Use a Direct URL to Locate WSDLs and Endpoints

The WSDLs can be accessed without Enterprise Manager by understanding the paths used on the SOA server. In general, they have the form:

```
http://{server name}:{port number}/soa-infra/services/{partition}/{Composite}/{Web Service}
```

Composite Components

This section outlines several important logical features of the BPEL composites.

Composite Properties

Most composites contain properties within the main file, composite.xml. They are essentially global constants that can be preconfigured with default values and changed at deployment time. They can be accessed post-deployment in Enterprise Manager.

Typically, these properties represent timeouts and boolean properties for activating or deactivating functionality. Other uses might include setting default values of constants such as URLs. They are accessed with the `ora:getPreference()` BPEL function.

They can be changed during development, at deployment time, or after deployment using different techniques for each.

Development Changes

At development time, properties can be created at will within the “component” sections of the composite.xml file. The image below shows an example of the properties found in DeviceStatusCheck:

```
<component name="DeviceStatusCheck">
  <implementation.bpel src="DeviceStatusCheck.bpel"/>
  <property name="bpel.preference.isExecutingInitODRequestReceivedCallout">true</property>
  <property name="bpel.preference.isExecutingInitODEventRequestCompleted">true</property>
  <property name="bpel.preference.isExecutingODEventNotificationArrived">true</property>
  <property name="bpel.preference.timeout.callback.years">0</property>
  <property name="bpel.preference.timeout.callback.months">0</property>
  <property name="bpel.preference.timeout.callback.days">0</property>
  <property name="bpel.preference.timeout.callback.hours">0</property>
  <property name="bpel.preference.timeout.callback.minutes">0</property>
  <property name="bpel.preference.timeout.callback.seconds">45</property>
  <property name="bpel.preference.OD_ServerCallbackEndpoint">http://127.0.0.1:8001/soa-infra/serv
  <property name="bpel.preference.externalSenderID">DSC Sensus</property>
  <property name="partnerLink.OD_ServerProxy.idempotent" type="xs:string"
    many="false">>false</property>
</component>
```

Properties must be prefixed with “bpel.preference.” The BPEL process associated with them (see the `implementation.bpel` element) can use the `ora:getPreference()` method to extract the value. When accessing the values, the “bpel.preference” prefix is dropped.

Pre-Deployment Changes

While the values of properties cannot be changed at runtime, they can be altered using the configuration plan each composite uses for deployment. Most configuration plans will contain multiple property elements within the “component” section. Modifying the value in the replace element and redeploying the composite will change the behavior of the property:

```

<component name="DeviceStatusCheck">
  <property name="bpel.preference.isExecutingInitODRequestReceivedCallout">
    <replace>true</replace>
  </property>
  <property name="bpel.preference.isExecutingInitODEventRequestCompleted">
    <replace>true</replace>
  </property>
  <property name="bpel.preference.isExecutingODEventNotificationArrived">
    <replace>true</replace>
  </property>
  <property name="bpel.preference.timeout.callback.years">
    <replace>0</replace>
  </property>
  <property name="bpel.preference.timeout.callback.months">
    <replace>0</replace>
  </property>
  <property name="bpel.preference.timeout.callback.days">
    <replace>0</replace>
  </property>

```

When the composite is deployed, the properties will contain the values in the “replace” elements.

Post-Deployment Changes

After deployment, changes can still be made to the values of the properties through Enterprise Manager.

1. In the Enterprise Manager navigation window, open WebLogic Domain/{domain name}. Right click on the domain and select **System MBean Browser**.
2. A new navigation pane opens in the window on the right. Select **Application Defined MBeans/oracle.soa.config/Server: {domain name}/SCAComposite/{Composite} [1.0]/SCAComposite.SCAComponent/{Component}** to access the controls for a particular component. A “component” is a single BPEL or Mediator within a larger SOA composite
A list of options will open in the right pane.
3. Select **Properties**.
The Property sheet shows a list of all the properties. Opening one allows editing of the property value.
4. Click **Apply** to save any changes.

Proxies

Proxy web services make no changes to the data going through the system and are just used to centralize endpoint configuration. The message structures are identical to those of the head-end system. Data is passed through without modification. Mediator objects within the Common composite are used to move data from Oracle Utilities Smart Grid Gateway to the head-end system.

Process Callouts

Some services are designated as “Process Callouts.” These services allow integrators direct access to the XML coming to and from the head-end system. They are useful in the event the integrator needs to provide custom enrichment or transformation of the inbound or outbound data. Because process callouts are generally located before and after calls to the head-end system or when data arrives, they can also serve as an “event” trigger if the integrator requires additional processing logic. The services define identical inputs and outputs and are based on head-end schema definitions. To use a callout, the integrator should create a web service implementing one or more of the WSDLs defined in the Common composite. Other composites should then be configured to target the new Callout-type service.

A typical example is for re-rendering the meter identifier being sent to the head-end system. If the standard meter ID should be modified, a process callout service is a candidate for making this change. Note that because the schema is based off the head-end system's definition, deviations from the schema are not allowed.

Configuring and Customizing Adapter BPEL Processes

This section outlines how to configure and customize the Oracle Business Process Execution Language (BPEL) processes provided with the Adapter Development Kit to work with your implementation.

Editing Configuration Files

This section outlines the changes that need to be made in various configuration and build files to enable the application servers used in your implementation to communicate with each other, and to support the specifics of your head-end system. These files are also used in packaging and deploying the processes.

Server Definitions

In order for your adapter to work properly, you must set up the application servers that run the components used by the adapter communicate with each other as follows:

- The Oracle Utilities Smart Grid Gateway application server must be able to send and receive messages to and from the SOA Suite application server.
- The SOA Suite application server must be able to send and receive messages to and from the head-end system application server, and the Oracle Utilities Smart Grid Gateway application server
- The head-end system application server must be able to receive and send messages from and to the SOA Suite application server.

The types of servers and the tokens that need to be replaced for each are listed below. Further below are the specific configuration files that must be modified, as well as the locations in each file that must be modified. Note that a port is listed, but may not be necessary depending on the type of installation. Also note that the SOA Server will have to have the partition name defined that is used.

- **SOA Server:** This is the application server running the SOA Suite components, including Oracle Service Bus (OSB) and Oracle Business Process Execution Language (BPEL). The SOA server is referenced using the following tokens:
 - {SOA_HOST}: the server where the SOA server has been installed
 - {SOA_PORT_NUMBER}: the port used by the SOA server
 - {SOA_PARTITION_DG}: the partition used by the SOA server. There are different partitions for the different adapters used by Oracle Utilities Smart Grid Gateway.
- **XAI (OUAF) Server:** This is the application server running the Oracle Utilities Smart Grid Gateway (including the Oracle Utilities Application Framework, or OUAF) software, including the inbound/outbound message components. This server is referenced using the following tokens:
 - {WEB_WLHOST}: the server where Oracle Utilities Smart Grid Gateway and the message components have been installed
 - {WEB_WLPORT}: the port used by the Oracle Utilities Smart Grid Gateway application
 - {WEB_CONTEXT_ROOT}: the root directory at which the Oracle Utilities Smart Grid Gateway inbound web service
- **AMI Head-end Server:** This is the application server running the head-end system software. The AMI head-end server is referenced using the following tokens:
 - {Headend_MR_Server_DG}: the URL for either the actual head-end system's MR_Server MultiSpeak implementation, or the URL to an emulator test harness being used (if applicable). For example, the Adapter Development Kit includes a soapUI configuration that can be used to emulate a head-end system for testing purposes.

- {Headend_CD_Server_DG}: the URL for either the actual head-end system's CD_Server MultiSpeak implementation, or the URL to an emulator test harness being used (if applicable). For example, the generic adapter includes a soapUI configuration that can be used to emulate a head-end system for testing purposes.
- Headend_OD_Server_DG}: the URL for either the actual head-end system's MR_Server MultiSpeak implementation, or the URL to an emulator test harness being used (if applicable). For example, the generic adapter includes a soapUI configuration that can be used to emulate a head-end system for testing purposes.

In addition, credentials for the WebLogic server must be specified in the build.properties file in the deploy folder:

- {WebLogic_UserID}: the user ID used to connect to the WebLogic server
- {WebLogic_Password}: the password for the {WebLogic_UserID} used to connect to the WebLogic server

Customizing BPEL Processes

This section provides an overview of how the sample BPEL processes provided with the Oracle Utilities Smart Grid Gateway Adapter Development Kit can be customized to meet specific business requirements, such as using custom XSL transformations and adding/editing the steps involved in the process.

Using Custom XSL Files

This process references XSL files to transform the messages from the Oracle Utilities Smart Grid Gateway standard format into the format used by the “generic” head-end system (based on the Multispeak protocol) when sending messages to the head-end system, and from the head-end system format into the Oracle Utilities Smart Grid Gateway standard format when sending messages back to Oracle Utilities Smart Grid Gateway. These XSL file references can be changed to custom XSL files that transform the messages into and from the format used by your head-end system. Refer to Oracle BPEL and Oracle JDeveloper documentation for more information about referencing XSL files within a BPEL process.

Making Changes to the Process

In addition to referencing custom XSL files for transformation, you can also add additional steps to the process to meet the specific business requirements of your implementation, or make other changes to the existing steps. Refer to Oracle BPEL and Oracle JDeveloper documentation for more information about adding and/or changing steps within BPEL process.

Note: Any changes made to this process for a particular AMI vendor and head-end system needs to be modeled based on the head-end system/AMI vendor’s business processes, including configuring the required request/response transactions required for a specific command (such a remote connect).

Commands

This section describes the general structure and flow of each SOA composite in the adapter development kit for the two-way commands. Most follow this basic model:

Common

The Common composite is a repository for files and logic that is used by other composites. For instance, the Proxies and default implementations of Process Callouts are defined in the Common composite.

Composite Properties

None.

Composite WSDLs

Callout Services

Process Callouts are customization points for integrators with identical inputs and outputs based on head-end formats. The Common composite contains default implementations in which incoming data is reflected back in an identical state. Each of the following is a Mediator component and uses an “echo”-type definition.

Process Callouts are usually associated with boolean composite properties which control whether they will be executed. They are activated by default so users can easily inject their customizations, but setting the properties to false can be a performance optimization. When set to false, the associated Process Callout will not be made and execution will continue normally.

Service	Description
OA_CalloutService	Used when the asynchronous reply in DeviceStatusCheck arrives.

Service	Description
MR_CalloutService	Used during Commission/Decommission and OnDemandRead operations.
CB_CalloutService	Used by the asynchronous callback processes of OnDemandRead and Connect/Disconnect.
CD_CalloutService	Used by Connect/Disconnect.
OD_CalloutService	Used in DeviceStatusCheck.

Proxies

Placing all the proxy web services in the Common composite creates a place to conveniently set endpoints. Each is a Mediator component which passes the data to the head-end system without modification

Proxy Web Service	Description
OD_ServerProxy	Used to transmit a DeviceStatusCheck request to the head-end system.
CD_ServerProxy	Used to transmit a Connect/Disconnect request to the head-end system.
MR_ServerProxy	Used to transmit an OnDemandRead request to the head-end system.

Other

AuxiliaryRoutinesService: A container defining helpful, commonly used functions:

- **FindExpTime:** Many MultiSpeak functions contain an expTime element, which is used to deliver the length of time to wait for the command to complete before failing. (The included test harness does not support timeouts.) If the input to the command composite does not contain this timeout, the process will read from its properties the years, months, days, hours, minutes, and seconds to wait for a result. This web service utilizes a Java method to combine these inputs into the proper XML field used in the MultiSpeak API. The properties are also used to control the timeout wait period of asynchronous callbacks within a command's BPEL process.
- **FindTimeout:** When the expTime element and units are supplied as input, it is usually still necessary to compute the timeout used in asynchronous callbacks. This method accepts the MultiSpeak fields and replies in the "P0Y0M0DT0H0M0S" format understood by BPEL.

Commission / Decommission

The CommissionDecommission composite takes care of registering and de-registering a device with the head-end system.

Composite Properties

Property Name	Default Value	Description
isExecutingCommissionReceived-Callout	true	Controls whether the Request Arrived callout executes.
isExecutingCommissionCompleted-Callout	true	Controls whether the Request Completed callout executes.
isExecutingDecommissionReceived-Callout	true	Controls whether the Request Arrived callout executes.
isExecutingDecommissionCompleted-Callout	true	Controls whether the Request Completed callout executes.

Composite WSDLs

Composite	Description
CommissionDecommission Service	Entry point for the CommissionDecommission command. The operations are synchronous, so no additional WSDLs are needed.
MR_ServerCallout	Reference describing the process callout.
MR_ServerProxy	Reference describing the proxy used to invoke the head-end system.

Process Flow

1. SGG/OUAF invokes MeterAddNotification/MeterRemoveNotification operation using CommissionDecommissionService.
2. Test whether MeterAddNotification or MeterRemoveNotification is invoked. In both cases, the following steps are common for both the operations.
3. Composite properties are loaded and local variables are initialized.
4. Both the Header and Body inputs are transformed to MultiSpeak format.
5. If required, execute a process callout in MR_ServerCallout. Assign updated data to head-end request.
6. Invoke MeterAddNotification/MeterRemoveNotification via the MR_ServerProxy to the head-end system.
7. If required, execute a process callout in MR_ServerCallout. Assign updated data to head-end response.
8. Transform Header and Body head-end responses to SGG/OUAF format.
9. Reply to SGG/OUAF with synchronous results.

Connect / Disconnect

The ConnectDisconnect composite is responsible for starting and stopping the recording of usage data for a meter.

Composite Properties

Property Name	Default Value	Description
CB_CDcallbackEndpoint	http://txdev2k3vm5.us.oracle.com:8001/soa-infra/services/DG/ConnectDisconnect/CB_ServerService	The default endpoint to which MultiSpeak should send the asynchronous CB_Server callback.
isExecutingCDReceivedCallout	true	Controls whether the Request Received callout executes.
isExecutingCDCompletedCallout	true	Controls whether the Request Received Completed callout executes.
isExecutingCDStatesChangedArrivedCallout	true	Controls whether the CD States Changed Notification arrival callout executes.
CallbackTimeoutYears	0	The number of years to await a response from the MultiSpeak server. This property only takes effect when the expTime element is

Property Name	Default Value	Description
		not supplied in the input to the service.
CallbackTimeoutMonths	0	The number of months to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutDays	0	The number of days to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutHours	0	The number of hours to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutMinutes	0	The number of minutes to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutSeconds	45	The number of seconds to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.

Composite WSDLs

Composite	Description
ConnectDisconnectService	Entry point for the ConnectDisconnect operation. After a synchronous reply, further updates will be sent to the specified location asynchronously using DG-ConnectDisconnectStateChgNotification.
CB_ServerService	MultiSpeak WSDL hosted to receive asynchronous CDStatesChangedNotification callbacks from the head end system.
CB_ServerCallout	Reference describing the process callout used when the asynchronous callback from the head end system arrives.
CD_ServerCallout	Reference describing the process callout.

Composite	Description
CD_ServerProxy	Reference describing the proxy used to invoke the head end system.
AuxiliaryRoutines	Reference to common helper routines in the Common composite.
DG-ConnectDisconnectStateChgNotification	A reference to an inbound web service capable of processing asynchronous results from a Connect/Disconnect request.

Process Flow

1. SGG/OUAF invokes InitiateConnectDisconnect operation using ConnectDisconnectService.
2. Composite properties are loaded and local variables are initialized.
3. Test whether the input includes a expiration time
 - If Yes: Use AuxiliaryRoutines to compute timeout.
 - If No: Use composite properties and AuxiliaryRoutines to compute expiration time.
4. Both the Header and Body inputs are transformed to MultiSpeak format.
5. If required, execute a process callout in CD_ServerCallout. Assign updated data to head end request.
6. Add a callback URL to the head end request. This is the endpoint the head end will use to send the results.
7. Invoke InitiateConnectDisconnect via the CD_ServerProxy to the head end system.
8. If required, execute a process callout in CD_ServerCallout. Assign updated data to head end response.
9. Transform Header and Body head end responses to SGG/OUAF format.
10. Reply to SGG/OUAF with synchronous results.
11. Check for ErrorObject in the head end response.
12. If error object not found:

Await asynchronous response from head-end system for the period of expiration time calculated during start of this flow:

 - Receive CDStatesChangeNotification from CB_ServiceService.
 - Generate reply with no errors for CDStatesChangeNotification
 - Synchronously reply to the head end.
 - If required, execute a process callout in CB_ServerCallout. Assign updated data to the incoming request.
 - Transform Header and Body of incoming request to OUAF inbound web service format described in DG-ConnectDisconnectStateChgNotification.
 - If request contains responseURL
 - Invoke the inbound web service on given responseURL with the transformed incoming request.
 - Else
 - Invoke the inbound web service on definedURL with the transformed incoming request.

Device Status Check

DeviceStatusCheck is used to determine the health of a meter and to test that the meter can be reached on the network.

Composite Properties

Property Name	Default Value	Description
OD_ServerCallbackEndpoint	http://127.0.0.1:8001/soa-infra/services/DG/DeviceStatusCheck/OA_ServerService	The default endpoint to which MultiSpeak should send the asynchronous OA_Server callback.
isExecutingInitODRequest-ReceivedCallout	true	Controls whether the Request Arrived callout executes.
isExecutingInitODEventRequest-Completed	true	Controls whether the Request Completed callout executes.
isExecutingODEventNotification-Arrived	true	Controls whether the ODEventNotification arrival callout executes.
timeout.callback.years	0	The number of years to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
timeout.callback.months	0	The number of months to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
timeout.callback.days	0	The number of days to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
timeout.callback.hours	0	The number of hours to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
timeout.callback.minutes	0	The number of minutes to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
timeout.callback.seconds	45	The number of seconds to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.

Composite WSDLs

Composite	Description
OD_ServerService	Entry point for DeviceStatusCheck. After a synchronous reply, further updates will be sent to the specified location asynchronously using DG-OutageDetectionEventNotification.
OA_ServerService	MultiSpeak WSDL hosted to received asynchronous ODEventNotification callbacks from the head end system.
OD_ServerProxy	Reference describing the proxy used to invoke the head end system to initiate a Device Status Check.
OA_ServerCallout	Reference describing the process callout used when the asynchronous callback from the head end system arrives.
OD_ServerCallout	Reference describing the process callout used when initiating a Device Status Check.
AuxiliaryRoutines	Reference to common helper routines in the Common composite.
DG-OutageDetectionEventNotificationXAI	A reference to an inbound web service capable of processing asynchronous results from a Device Status Check request.

Process Flow

1. SGG/OUAF Initiates the Outage Detection service using OD_ServerService
2. Composite properties are loaded. Local variables are initialized. These mostly include boolean settings describing the state (such as whether or not the synchronous reply from the head-end system returned)
3. Test whether the input includes a expiration time (expTime element).
 - If Yes: Use AuxiliaryRoutines to compute timeout
 - If No: Use composite properties and AuxiliaryRoutines to compute expiration time
4. Both the Header and Body inputs are transformed to MultiSpeak format. This can be done either through direct mapping or through XSLT. In this instance, XSLT is used to transform the header and the body separately.
5. If the composite property indicates the process callout should occur, execute the “request arrived” process callout in OD_CalloutService. Assign updated data to head end request.
6. Add a callback URL to the head end request. This is the endpoint the head end will use to send the outage detection results. Some head end systems use other approaches, such as pre-configuring the URL for callbacks or allowing polling to find the results. In this case, the URL is configured in a composite property and corresponds to an implementation of the OA_Server WSDL. When the head end system has results, it will deliver them to this URL using the ODEventNotification method.
7. Invoke InitiateOutageDetectionEventRequest via the OD_ServerProxy to the head end system.
8. Split processing to handle simultaneous activities. The Flow activity does this in BPEL and it makes sense here because one process will handle a synchronous response and return it to the caller. The other process will sleep, or “dehydrate,” until the asynchronous ODEventNotification arrives or until the timeout value is reached.
 - Handle synchronous response to SGG/OUAF
 - If the composite property indicates the process callout should occur, execute the “request completed” process callout in OD_CalloutService. Assign updated data to head end response.
 - Transform Header and Body head end responses to SGG/OUAF format.

- Reply to SGG/OUAF with synchronous results.
 - Set boolean variable indicating that the synchronous reply has been returned.
 - Await asynchronous response from head-end system.
 - Receive ODEventNotification from OA_ServerService. If the timeout period elapses, raise an error and stop waiting.
 - Synchronously reply to the head end with no errors
 - If the composite property indicates the process callout should occur, execute the “data arrived” process callout in OA_CalloutService. Assign updated data to the incoming request.
 - Transform Header and Body to inbound web service format described in DG-OutageDetectionEventNotification.
 - Invoke the inbound web service with the new data.
9. Fault Handlers look for any remote Fault returned from the head-end system. The MultiSpeak API does not define named faults, but they are still possible to encounter. For example, a security error or network error could be raised.
- If the synchronous reply has been sent back to the caller, Terminate the flow. This indicates an error has occurred and more research in Enterprise Manager is warranted.
 - If the synchronous reply has not been sent, abort further processing and compose a reply which contains the fault information.

On Demand Read

OnDemandRead interrogates a meter for the usage at the current point in time.

Composite Properties

Property Name	Default Value	Description
CB_ServerCallbackEndpoint	http:// txdev2k3vm5.us.oracle.com:8001/soa- infra/services/DG/OnDemandRead/CB_ Server	The default endpoint to which MultiSpeak should send the asynchronous CB_Server callback
IsExecutingOnDemandReadRequestReceived	true	Controls whether the Request Received callout executes
IsExecutingOnDemandReadRequestReceivedResponse	true	Controls whether the Request Received Completed callout executes
IsExecutingReadingChangedNotification	true	Controls whether the Reading Changed Notification arrival callout executes
CallbackTimeoutYears	0	The number of years to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutMonths	0	The number of months to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutDays	0	The number of days to await a response from the MultiSpeak server. This

Property Name	Default Value	Description
		property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutHours	0	The number of hours to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutMinutes	0	The number of minutes to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutSeconds	45	The number of seconds to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.

Composite WSDLs

Composite	Description
OnDemandReadService	Entry point for the OnDemandRead operation. After a synchronous reply, further updates will be sent to the specified location asynchronously using DG-ReadingChangedNotification.
CB_ServerService	MultiSpeak WSDL hosted to receive asynchronous ReadingChangedNotification callbacks from the head end system.
MR_ServerProxy	Reference describing the proxy used to invoke the head end system to initiate a On Demand Read.
MR_ServerCallout	Reference describing the process callout used when initiating a On Demand Read.
CB_ServerCallout	Reference describing the process callout used when the asynchronous callback from the head end system arrives.
AuxiliaryRoutines	Reference to common helper routines in the Common composite.
DG-ReadingChangedNotificationXAI	A reference to an inbound web service capable of processing asynchronous results from a On Demand Read request.

Process Flow

1. SGG/OUAF invokes InitiateMeterReadingsByMeterID operation using OnDemandReadService.
2. Composite properties are loaded. Local variables are initialized.
3. Test whether the input includes a expiration time
 - If Yes: Use AuxiliaryRoutines to compute timeout
 - If No: Use composite properties and AuxiliaryRoutines to compute expiration time
4. Both the Header and Body inputs are transformed to MultiSpeak format.
5. If required, execute a process callout in MR_ServerCallout. Assign updated data to head end request.

6. Add a callback URL to the head end request. This is the endpoint the head end will use to send the results.
7. Invoke `InitiateMeterReadingsByMeterID` via the `MR_ServerProxy` to the head end system.
8. If required, execute a process callout in `MR_ServerCallout`. Assign updated data to head end response.
9. Transform Header and Body head end responses to SGG/OUAF format
10. Reply to SGG/OUAF with synchronous results
11. Check for `ErrorObject` in the head end response.
12. If error object not found
 - Await asynchronous response from head end for the period of expiration time calculated during start of this flow
 - Receive `ReadingChangedNotification` from `CB_ServiceService`.
 - Generate reply with no errors for `ReadingChangedNotification`.
 - Synchronously reply to the head end.
 - If required, execute a process callout in `CB_ServerCallout`. Assign updated data to the incoming request.
 - Transform Header and Body of incoming request to OUAF inbound web service format described in `DG-ReadingChangedNotificationXAI`.
 - If request contains `responseURL`
 - Invoke the inbound web service on given `responseURL` with the transformed incoming request.
 - Else
 - Invoke the inbound web service on `definedURL` with the transformed incoming request.

Working with Enterprise Manager

Oracle Enterprise Manager (OEM) is useful for troubleshooting and diagnosing issues communicating with the head end system. In particular, security and other communications issues can be discerned.

To locate the instance of a service that is showing a problem, open the **Dashboard** view of the service. Each run instance is time-indexed. The **State** column in the first table contains the most important information for each instance. Completed messages show up with a green check icon. Terminated instances are indicated with a grey stop icon. Instances that are still running are marked as such. Runtime exceptions are in the bottom window.

When you click on the instance ID, a new window opens showing the entire process flow. This view is particularly useful in debugging.

Note the **State** column showing the status of each instance within the flow. SOA processes are made up of several calls to SOA components and web services. The **Instance** column shows a rough ordering of the operations. A typical approach to troubleshooting would find the “lowest” instance of an error or termination. This would be the error that is deepest within the process and is usually the source of the problem. In the above case, the deepest error is in the very first composite for the process. More information can be found by clicking into the link within the **Instance** column.

The level of detail is dependent on the auditing level set on the server. In this case, the error is in the response from the head end system.

OEM also contains a centralized location to control security. On a **Dashboard** screen for a composite, the **Policies** tab shows the OWSM policies attached to the composite. Typically, a log policy is placed on any inbound or outbound communication. Also, all services or references are delivered with attached basic http security policies.

MultiSpeak Implementation

This section lists the subset of MultiSpeak schemas and WSDLs utilized by the Adapter Development Kit.

MultiSpeak Head End System Service Definitions

- CB_Messages.wsdl
- CB_Server.wsdl
- CD_Messages.wsdl
- CD_PortTypes.wsdl
- CD_Server.wsdl
- MR_Messages.wsdl
- MR_PortTypes.wsdl
- MR_Server.wsdl
- OA_Messages.wsdl
- OA_Server.wsdl
- OA_ServerCollisions.wsdl
- OD_Messages.wsdl
- OD_PortTypes.wsdl
- OD_Server.wsdl

MultiSpeak Head End XML Schemas

- cpsm.xsd
- gml.xsd
- xlink.xsd
- mspcommon.xsd
- CB_Server.xsd
- CD_Server.xsd
- MR_Server.xsd
- OA_Server.xsd
- OD_Server.xsd

Configuring an Adapter Development Kit Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway to communicate with the smart meters.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the head-end system in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header

Inbound Web Service Name	Description
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder
D1-DeviceStatusCheck	Device Status Check
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
DG-ConDisconStChgNotification	Initiate Connect Disconnect Response
DG-OutageDetectionEventNotification	Initiate Outage Detection Response
DG-ReadingChangedNotification	Reading Changed Notification

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
DG-COMM	Generic Adapter Commission
DG-DCOMM	Generic Adapter Decommission
DG-INTOUTDET	Initiate Outage Detection Request
DGXAISSender	Used for Meter Decommission

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction: <OPERATION>
- **HTTP Login User:** <USER_ID>

- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Generic/<SERVICE>

where:

- <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
- <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
- <PASSWORD>: the password used to log into WebLogic Enterprise Manager
- <EM_SERVER_IP>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed
- <SERVICE>: the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
DG-COMM	Generic Adapter Commission
DG-DCOMM	Generic Adapter Decommission

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the head-end system must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System — Generic:

- **External System:** Generic
- **Description:** Generic
- **Outbound Message Types:**

Outbound Message Type	Description	Message Sender
DG-COMM	Generic Adapter Commission	DG-COMM
DG-DCOMM	Generic Adapter Decommission	DG-DCOMM

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time

- **Message XSL:** DG-Request.xml
- **Response XSL:** DG-Response.xml

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the head-end system must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - Generic:

- **Service Provider:** Generic
- **Description:** Generic
- **External Reference ID:** Generic
- **External System:** Generic
- **Our Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to the head-end system.

The following types of processing methods must be configured for the head-end system service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from the head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from the head-end system.

UOM Translation

UOM translation processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the head-end system service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	DG-MeterAddNotification	Commission
Device Decommission	Device Removal	DG-MeterRemoveNotification	Decommission
Device Status Check	Device Status Check	DG-InitiateOutageDetection	Get Status
On-Demand Read (Scalar)	On-Demand Read (Scalar)	DG-InitiateMeterByMeterId	Initiate Meter Read by Meter ID
Remote Connect	Remote Connect	DG-InitiateConnectDisconnect	Connect Device
Remote Disconnect	Remote Disconnect	DG-InitiateConnectDisconnect	Disconnect Device

Configuring Endpoint URIs

Part of configuring your adapter is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands.

The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoints URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Adapter Development Kit endpoint override DVM (DG–EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Landis+Gyr adapter and the command used with each:

DVM Key	Commands
MR_Server	Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
CD_Server	Remote Connect Remote Disconnect
OD_Server	Device Status Check

To define an override Endpoint URI for an adapter built from the Adapter Development Kit, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is <http://server:port/soa/composer>.

2. Select the DG–EndpointOverrides.dvm in the left panel.

- In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
- In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.
6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.
8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Adapter Development Kit Extendable Lookups

NOTE: This section applies to both cloud and on-premises implementations of the Smart Grid Gateway Adapter for Itron OpenWay.

This section outlines some of the extendable lookups that must be configured for use with a customized adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system.

Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name**: The event name used by the head-end system.
- **Description**: A description of the device event
- **Status**: The status of the lookup value (can be Active or Inactive)
- **Standard Event Name**: The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

Head-End UOM Code to Standard UOM Mapping

Usage received from the head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The head-end system UOM Code to Standard UOM Mapping extendable lookup is used

to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Each value defined for the head-end system UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-End Unit of Measure:** The unit of measure code used by the head-end system
- **Unit of Measure:** The unit of measure defined in the system.
- **Description:** A description of the unit of measure code.
- **Status:** The status of the lookup value (can be Active or Inactive)

Interval Status Code to Condition Mapping

Interval usage received from the head-end system can include interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Generic Interval Status Code to Condition Mapping extendable lookup is used to determine how to map head-end system interval status codes to standard status codes when receiving usage from the head-end system.

Each value defined for the Generic Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The head-end system interval status code
- **Description:** A description of the interval status code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.

Other Extendable Lookups

Business Object Name	Description
DG-CDReasonCodeLookup	ADK - Connect Disconnect Reason Code
DG-GenericTimeUnits	ADK - Time Units
DG-LoadActionCodeLookup	ADK - Load Action Code
DG-OutageEventTypeLookup	ADK - Outage Event Type
DG-ServiceTypeMappingLookup	ADK - Service Type Mapping

Using the Adapter Development Kit Test Harness

Oracle Utilities Smart Grid Gateway Adapter Development Kit includes a test harness that can be configured to simulate a general head-end system for testing the two-way commands. The test harness includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. This section describes the test harness and its components.

Locating the WSDL for the Test Harness

Follow these procedures to locate the Adapter Development Kit test harness WSDL:

How to Use Enterprise Manager to Locate the WSDL

1. Open Enterprise Manager and use the navigation pane to open the dashboard of the test harness composite:

2. The top bar of the dashboard contains several buttons and icons. One of these is a “world” icon with a puzzle piece over it. Click this icon to display a list of the WSDLs and endpoint URIs for the composite:
3. Click the UtilService WSDL URL link to see the WSDL in the browser, or right click and save it to your machine

Depending on your requirements, it may be necessary to download the associated schema found in the wsdl:types section. The URL can be pasted into a browser tab and downloaded in the same manner as the WSDL. The main schema has imported schemas that may also be required.

How to Use a Direct URL to locate the WSDL

The WSDL can be accessed without Enterprise Manager by understanding the paths used on the SOA server. In general, they have the following form:

```
http://{server name}:{port number}/soa-infra/services/{partition}/{Composite}/{Web Service}?WSDL
```

So by default, the test harness WSDL can be found at

```
http://{server name}:{port number}/soa-infra/services/DG_Test/DGTestHarness/UtilService?WSDL
```

Web Services

This section describes the web services included in the Adapter Development Kit test harness BPEL composite.

General Services

This section describes the general services of the Adapter Development Kit test harness composite.

LoadMeterIndex

This web service loads the data store from the internal file. By default if the store is already in memory, it will *not* reload. This behavior can be overridden with the forceReload parameter.

Input: LoadMeterIndexInput

Part: payload

Element: LoadMeterIndexRequest

Parameter	Description
forceReload	A switch telling the system whether to reload the meter index from the configuration file. Default value is false.

Output: LoadMeterIndexOutput

Part: payload

Element: LoadMeterIndexResult

Parameter	Description
loaded	A boolean value for whether or not the index was reloaded from the configuration file

Fault: UtilityFault (see [UtilityFault](#) for more details).

ViewAuditTrail

This web service returns the audit log for the entire session.

Input: ViewAuditTrailInput

Part: payload

Element: ViewAuditTrailRequest

Parameters: This is an empty request. There are no parameters.

Output: ViewAuditTrailOutput

Part: payload

Element: ViewAuditTrailResult

This element is an entry consisting of a timestamp and an Operation. Each entry may have an associated meter object showing what changed.

Fault: UtilityFault (see [UtilityFault](#) for more details).

UtilityFault

Fault with similar mapping to SGG/OUAF faults:

Typically, the faultCode, faultString, faultActor, and detail/text elements will be populated.

Locate Meter Services

This section describes the locate meter web services of the Adapter Development Kit test harness composite.

FindMeters

This web service queries the data store for one or more meters. The difference between GetMeter and FindMeters is GetMeter can return at most one meter and it must match the provided ID exactly. GetMeter will throw an error if the ID is not found. FindMeters can return more than one meter (when using the regex) and will not throw an error when the ID does not match any of the meters in the index.

Input: FindMetersInput

Part: payload

Element: FindMetersRequest

Parameter	Description
id	The meter ID for which to search
isRegex	The provided id can be a regex value when this parameter is true. Hint: to search for all meters in the system, use ".*" for the ID.

Output: FindMetersOutput

Part: payload

Element: FindMetersResult

Zero or more meter objects can be returned from the search

Fault: See [UtilityFault](#). Unlike other methods, FindMeters does not throw an exception if the meter is not found.

IsMeterDefined

This web service queries whether a particular meter is defined in the data store.

Input: IsMeterDefinedInput

Part: payload

Element: IsMeterDefinedRequest

Parameter	Description
id	The meter ID for which to search

Output: IsMeterDefinedOutput

Part: payload

Element: IsMeterDefinedResult

Whether or not the provided ID is part of the index.

Fault: See [UtilityFault](#). Thrown when meter id is not found.

GetMeter

This web service returns all the attributes of a single meter from the in-memory data store. The difference between GetMeter and FindMeters is GetMeter can return at most one meter and it must match the provided ID exactly. GetMeter will throw an error if the ID is not found. FindMeters can return more than one meter (when using the regex) and will not throw an error when the ID does not match any of the meters in the index.

Input: GetMeterInput

Part: payload

Element: GetMeterRequest

Parameter	Description
id	The meter ID for which to search

Output: GetMeterOutput

Part: payload

Element: GetMeterResult

The meter object requested by the ID.

Fault: See [UtilityFault](#). Thrown when meter id is not found.

Meter Administration Services

This section describes the meter administration services of the Adapter Development Kit test harness composite.

AddMeters

This web service adds a set of meters to the in-memory data store. This will not permanently add it to the control file.

Input: AddMetersInput

Part: payload

Element: AddMetersRequest

Parameter	Description
id	The identification code for the meter.
utility	An informational string.
serviceType	One of the valid ServiceType values (see schema). "Electric" is the only option at this time.
isCommissioned	Whether or not the meter is in a commissioned state.

Parameter	Description
loadActionCode	One of the possible LoadActionCode values used in Connect and Disconnect (see schema).
outageEventType	One of the possible OutageEventType values used in Device Status Check (see schema).
executionStatus	One of the possible ExecutionStates (see schema). These values control how the meter will respond to commands.
updateIfExisting	Whether or not to update the meter with the provided values if it already exists in the index.
Comment	An informational string describing the purpose of the meter.
Channels	A listing of unit of measures supported by this meter.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.

Output: AddMetersOutput

Part: payload

Element: AddMetersResult

Whether or not each meter was added to the index.

Fault: See [UtilityFault](#).

RemoveMeter

This web service removes a meter from the in-memory data store. This will not permanently remove it from the control file.

Input: RemoveMeterInput

Part: payload

Element: RemoveMeterRequest

Parameter	Description
id	The ID for the meter to be removed.

Output: RemoveMeterOutput

Part: payload

Element: RemoveMeterResult

Whether or not the meter was removed from the index.

Fault: See [UtilityFault](#). Thrown when meter id is not found.

AddMeterChannel

This web service adds a new channel to a single meter.

Input: AddMeterChannelInput

Part: payload

Element: AddMeterChannelRequest

Parameter	Description
id	The identification code for the meter.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.

Output: AddMeterChannelOutput**Part:** payload**Element:** AddMeterChannelResult

Whether or not the channel was added to the index.

Fault: See [UtilityFault](#). Thrown when meter id is not found.**RemoveMeterChannel**

This web service removes a Channel from a meter.

Input: RemoveMeterChannelInput**Part:** payload**Element:** RemoveMeterChannelRequest

Parameter	Description
id	The ID for the meter to be removed.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.

These three parameters are combined to locate a unique channel

Output: RemoveMeterChannelOutput**Part:** payload**Element:** RemoveMeterChannelResult

Whether or not the channel was removed from the meter.

Fault: See [UtilityFault](#). Thrown when meter id is not found.**ReadScalarMeter**

This web service generates a scalar reading for each channel of a given meter.

Input: ReadScalarMeterInput**Part:** payload**Element:** ReadScalarMeterRequest

Parameter	Description
id	The ID for the meter to be read.

Output: ReadScalarMeterOutput

Part: payload

Element: ReadScalarMeterResult

Zero or more scalar readings for the given meter.

Parameter	Description
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.
value	A random number representing the scalar reading.

Fault: See [UtilityFault](#). Thrown when meter id is not found.

Meter Attribute Administration Services

This section describes the meter administration services of the Adapter Development Kit test harness composite.

GetOutageEventType

This web service queries the outage event type for a given meter. The OutageEventType is used by DeviceStatusCheck.

Input: GetOutageEventTypeInput

Part: payload

Element: GetOutageEventTypeRequest

Parameter	Description
id	The ID for the meter for which the OutageEventType should be retrieved.

Output: GetOutageEventTypeOutput

Part: payload

Element: GetOutageEventTypeResult

The value of the OutageEventType attribute for the requested meter.

Fault: See [UtilityFault](#). Thrown when meter id is not found.

SetOutageEventType

This web service updates the outage event type for a given meter.

Input: SetOutageEventTypeInput

Part: payload

Element: SetOutageEventTypeRequest

Parameter	Description
id	The ID for the meter for which the OutageEventType should be set.
value	The new value of OutageEventType to set on the meter.

Output: SetOutageEventTypeOutput

Part: payload

Element: SetOutageEventTypeResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault: See [UtilityFault](#). Thrown when meter id is not found.

GetLoadActionCode

This web service queries the load action code for a given meter. This is the Connect/Disconnect behavior.

Input: GetLoadActionCodeInput

Part: payload

Element: GetLoadActionCodeRequest

Parameter	Description
id	The ID for the meter for which the LoadActionCode should be retrieved.

Output: GetLoadActionCodeOutput

Part: payload

Element: GetLoadActionCodeResult

The value of the LoadActionCode attribute for the requested meter.

Fault: See [UtilityFault](#). Thrown when meter id is not found.

SetLoadActionCode

This web service updates the load action code for a given meter.

Input: SetLoadActionCodeInput

Part: payload

Element: SetLoadActionCodeRequest

Parameter	Description
id	The ID for the meter for which the LoadActionCode should be set.
value	The new value of LoadActionCode to set on the meter.

Output: SetLoadActionCodeOutput

Part: payload

Element: SetLoadActionCodeResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault: See [UtilityFault](#). Thrown when meter id is not found.

IsCommissioned

This web service queries the commissioning status for a given meter. This is the Commission/Decommission behavior.

Input: IsCommissionedInput

Part: payload

Element: IsCommissionedRequest

Parameter	Description
id	The ID for the meter for which the Commissioned status should be retrieved.

Output: IsCommissionedOutput

Part: payload

Element: IsCommissionedResult

The value of the Commissioned status attribute for the requested meter.

Fault: See [UtilityFault](#). Thrown when meter id is not found.

SetCommission

This web service updates the commissioning status for a given meter.

Input: SetCommissionedInput

Part: payload

Element: SetCommissionedRequest

Parameter	Description
id	The ID for the meter for which the Commissioned status should be set.
value	The new value of Commissioned status to set on the meter.

Output: SetCommissionedOutput

Part: payload

Element: SetCommissionedResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault: See [UtilityFault](#). Thrown when meter id is not found.

GetExecutionStatus

This web service queries the status of the property controlling the overall execution of the command.

Input: GetExecutionStatusInput

Part: payload

Element: GetExecutionStatusRequest

Parameter	Description
id	The ID for the meter for which the ExecutionStatus should be retrieved.

Output: GetExecutionStatusOutput

Part: payload

Element: GetExecutionStatusResult

The value of the ExecutionStatus attribute for the requested meter.

Fault: See [UtilityFault](#). Thrown when meter id is not found.

SetExecutionStatus

This web service updates the property controlling the overall completion of the command.

Input: SetExecutionStatusInput

Part: payload

Element: SetExecutionStatusRequest

Parameter	Description
id	The ID for the meter for which the ExecutionStatus should be set.
value	The new value of ExecutionStatus to set on the meter.

Output: SetExecutionStatusOutput

Part: payload

Element: SetExecutionStatusResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault: See [UtilityFault](#). Thrown when meter id is not found.

Sample Meters File

The Adapter Development Kit includes an XML file and schema that can be used for configuring one or more meters for use with the test harness. The file, metersdb.xml, is located in the Test/DGTestHarness directory and can be edited with an appropriate XML editor such as XML Spy. This section describes the attributes in the metersdb.xml file.

The meterdb.xml file contains one or more **Meter** elements that have the following attributes:

Meter Attribute	Definition
id	The meter identifier. This value should match the amiDeviceID setting in the Oracle Utilities Application Framework.
utility	This is informational only.
serviceType	This is informational only.
ServiceType	An enumeration that is described in the schema.
isCommissioned	A boolean value that describes whether or not the meter is commissioned or decommissioned. The associated MultiSpeak commands are MeterAddNotification and MeterRemoveNotification.
loadActionCode	This value is for the Connect and Disconnect commands and has enumeration values described in the schema. The value is returned in the CDStatesChangedNotification MultiSpeak command.
outageEventType	This value is used by DeviceStatusCheck and gives the status returned by the ODEventNotification call. Its enumeration values are described in the schema.
executionStatus	This value does not reflect a MultiSpeak command, but is instead intended to give a state of the operation. There are four valid values: Success: When a meter has this status the operation will complete without error. ResponseTimeout: When a meter has this status an asynchronous reply will never arrive (not relevant for Commission/Decommission commands). SyncOperationFailure: When a meter has this status the initial communication to the simulated head-end system will produce an error. AsyncOperationFailure: When a meter has this status, the asynchronous callback from the head-end system will arrive, but will indicate an error (not relevant for Commission/Decommission commands).

A meter can also contain the following elements:

- **Comment:** A field which is for informational use only and is meant to indicate the purpose of the meter.
- **Channels:** Used in reading the meter for On Demand Read commands. A channel contains the following attributes:

Channel Attribute	Definition
uomCode	The units of measure code that should be returned when the meter is read.
uomName	The units of measure name that should be returned when the meter is read.
description	A longer form. When the meter is read, a random number is generated for this value.
decimals	A value to indicate how many places to the right of the decimal that random number should have.

The Adapter Development Kit Native Format

NOTE: This section applies to both cloud and on-premises implementations of the Smart Grid Gateway Adapter for Itron OpenWay.

The Adapter Development Kit supports loading usage and event data exported from the AMI head-end system in the “native” initial measurement and device event data formats (the format of the initial measurement and device event seeder business objects). Processing of the ADK native format is supported by the following OSB projects:

- **SGG-DG-SEEDER-BASE**
- **SGG-DG-SEEDER-CM**

Refer to [Initial Measurements and Device Events](#) and [OSB Project Summary](#) for more information about these OSB projects.

Format Details

The ADK native format is an XML format that contains zero or more initial measurements and/or device events, as follows:

- The collection of initial measurements and/or device events are encapsulated within in an <SGGIMDsEvents> element.
- Each initial measurement or device event is defined in the format of the initial measurement and device event seeder business objects, encapsulated by the following elements:
 - **Initial Measurements:** <D1-InitialLoadIMD>
 - **Device Events:** <D1-DeviceEventSeeder>
- The format can support any number of initial measurements and/or device events.
- Initial measurements can be either scalar or interval measurements.

See [Adapter Development Kit Native Format Example](#) for an example of this format. See [Adapter Development Kit Native Format Schema](#) for the native format XML schema.

Adapter Development Kit Native Format Example

The following is an example of the ADK native format. This example contains 2 initial measurements (1 scalar and 1 interval) and 2 device events (PowerOutage and PowerRestored).

```
<?xml version="1.0" encoding="UTF-8" ?>
<SGGIMDsEvents xmlns="http://oracle.com/SGGIMDsEvents">

Smart Grid Gateway Adapters and Oracle Utilities Cloud Services

This section describes how Oracle Utilities Smart Grid Gateway Adapters are used with Oracle Utilities cloud services such as Oracle Utilities Customer Cloud Service and Oracle Utilities Meter Solution Cloud Service.

Payload Processing

When used with cloud services, Oracle Smart Grid Gateway adapters process usage and device event payloads via batch processing. Files are sent from a head end system to an Oracle Cloud Object Storage location, where they are processed via batch processes.

This process requires set up and configuration of the following:

- **Key Rings and Key Pairs:** Records used to link an Oracle Cloud Object Storage location to records in Oracle Utilities cloud services
- **Object Storage Locations:** One or more Oracle Object Storage buckets where payload files are sent from the head end system for processing
- **File Storage Configuration Extendable Lookup Values:** An extendable lookup value that defines the object storage location and allows it to be referenced by batch processes
- **Head End Systems:** A record that defines how specific types of payload processing are handled, such the business object to use to create initial measurements and device events
- **Adapter Extendable Lookups:** Lookup value that define details used by data mapping and processing
- **SGG Payload Processing Configuration Extendable Lookup Values:** An extendable lookup value that defines payload processing details for a specific head end system

- **Payload Processing Batch Controls:** A batch control used for payload process (based on a template batch control provided with the base package)

See the following sections below for more details about each of these.

Creating Key Rings and Pairs

Connection between the Oracle Utilities cloud service and Oracle Object Storage requires an API signature key. See **API Key Management** in the *Oracle Utilities Cloud Services Object Storage Setup Guide* for more information.

API key rings and key pairs are maintained in the **Key Ring** portal. This portal contains the following zones:

- **Key Ring:** Displays basic information about the key ring
- **Key Pairs:** Displays a list of key pairs for the current key ring

Key rings are defined by the following:

- **Key Ring:** A unique code for the key ring
- **Key Ring Class:** Signature (default)
- **Status:** The current status of the key ring. Note: Key pairs can only be generated for Active key rings. Once a key ring has been deactivated, you can no longer create key pairs for that ring.
- **Description:** A name for the key ring (this will be referenced in the File Location extendable lookup)

Once the key ring is created, you need to generate and activate the key pair. Click **Generate Key** to generate a key pair for the key ring.

Key Pairs are defined by the following:

- **Sequence:** The sequence of the key pair (the order in which the key pair was created)
- **Creation Date/Time:** The date/time when the key pair was created
- **Key Status:** The current status of the key pair. Key pairs are inactive when first created.
- **Public Key:** Click **View** to open a dialog box containing the public key.
- **Action:** Click **Activate** to activate an inactive key pair.

Once the key ring and key pair have been created, the key should be pasted into the **User API Key** in **Oracle Identification and Access Management (IAM)**. See the **User API Keys** section in the **Security and Access Management** section of the **Managing Object Storage** chapter in the *Oracle Cloud Infrastructure Services* documentation. To copy the public key click **View** in the **Actions** column in the **Key Pairs** zone, and select and copy the text in the **View Public Key** dialog box.

The last step is to activate the key. Click **Activate** in the **Actions** column in the **Key Pairs** zone. A dialog box opens displaying the following message: “Warning(s): Activating a key assumes that you have already registered the public key with the appropriate third parties. Press Cancel to abort.” Note: Be sure to copy the public key to **Oracle Identification and Access Management** before activating it. Click **OK** to activate the key. The **Key Status** column will change to “Active”.

Creating Object Storage Locations

You need to create one or more buckets in Oracle Object Storage where payload files will be sent for processing. Refer to the *Oracle Utilities Cloud Services Object Storage Setup Guide* and the *Oracle Cloud Infrastructure* documentation for more information about creating buckets in Oracle Object Storage.

After creating the buckets in Oracle Object Storage, make a note of the following, as this information is needed in later configuration steps:

- Namespace
- User Oracle Cloud ID (User OCID)

- Tenancy Oracle Cloud ID (Tenancy OCID)
- Compartment Oracle Cloud ID (Compartment OCID)

Suggested Buckets for Payload Processing

This section outlined suggested sets of Object Storage buckets for each of the Smart Grid Gateway adapters.

General Guidelines

As a general rule, each adapter should have separate buckets for each of the following:

- Usage payloads
- Usage archive
- Usage errors
- Device Event payloads
- Device Event archive
- Device Event errors

If an adapter uses payloads in more than one format (such as in CSV and XML formats), you should also consider creating separate buckets for each file format type.

NOTE: If possible, archive buckets should be created in an “Archive” storage tier.

Adapter Development Kit

The table below lists suggested Object Storage buckets for the Adapter Development Kit:

Bucket Name	Storage Tier	Smart Grid Gateway Description
adk-csv	Standard	SGG ADK Adapter - CSV input
adk-csv-arch	Archive	SGG ADK Adapter - CSV archive
adk-csv-error	Standard	SGG ADK Adapter - CSV errors
adk-seeder	Standard	SGG ADK Adapter - IMD Seeder input
adk-seeder-arch	Archive	SGG ADK Adapter - IMD Seeder archive
adk-seeder-error	Standard	SGG ADK Adapter - IMD Seeder errors
adk-xml	Standard	SGG ADK Adapter - XML input
adk-xml-arch	Archive	SGG ADK Adapter - XML archive
adk-xml-error	Standard	SGG ADK Adapter - XML errors

Adapter for Itron OpenWay

The table below lists suggested Object Storage buckets for the Adapter for Itron OpenWay:

Bucket Name	Storage Tier	Smart Grid Gateway Description
itronexception	Standard	SGG Itron OW Adapter - event input
itronexception-arch	Archive	SGG Itron OW Adapter - event archive
itronexception-error	Standard	SGG Itron OW Adapter - event errors
itronxml	Standard	SGG Itron OW Adapter - XML input
itronxml-arch	Archive	SGG Itron OW Adapter - XML archive

Bucket Name	Storage Tier	Smart Grid Gateway Description
itronxml-error	Standard	SGG Itron OW Adapter - XML errors

MV90 Adapter for Itron

The table below lists suggested Object Storage buckets for the MV90 Adapter for Itron

Bucket Name	Storage Tier	Smart Grid Gateway Description
mv90-usage	Standard	SGG MV90 Adapter - usage input
mv90-usage-arch	Archive	SGG MV90 Adapter - usage archive
mv90-usage-error	Standard	SGG MV90 Adapter - usage errors

Adapter for Landis+Gyr

The table below lists suggested Object Storage buckets for the Adapter for Landis+Gyr:

Bucket Name	Storage Tier	Smart Grid Gateway Description
lg-cim-event	Standard	SGG Landis+Gyr Adapter - CIM input
lg-cim-event-arch	Archive	SGG Landis+Gyr Adapter - CIM archive
lg-cim-event-error	Standard	SGG Landis+Gyr Adapter - CIM errors
lg-event	Standard	SGG Landis+Gyr Adapter - event input
lg-event-arch	Archive	SGG Landis+Gyr Adapter - events archive
lg-event-error	Standard	SGG Landis+Gyr Adapter - event errors
lg-usage	Standard	SGG Landis+Gyr Adapter - usage input
lg-usage-arch	Archive	SGG Landis+Gyr Adapter - usage archive
lg-usage-error	Standard	SGG Landis+Gyr Adapter - usage errors

Adapter for Sensus

The table below lists suggested Object Storage buckets for the Adapter for Sensus:

Bucket Name	Storage Tier	Smart Grid Gateway Description
sensus-event	Standard	SGG Sensus Adapter - event input
sensus-event-arch	Archive	SGG Sensus Adapter - events archive
sensus-event-error	Standard	SGG Sensus Adapter - event errors
sensus-usage	Standard	SGG Sensus Adapter - usage input
sensus-usage-arch	Archive	SGG Sensus Adapter - usage archive
sensus-usage-error	Standard	SGG Sensus Adapter - usage errors

Adapter for Silver Spring Networks

The table below lists suggested Object Storage buckets for the Adapter for Silver Spring Networks:

Bucket Name	Storage Tier	Smart Grid Gateway Description
ssn-csv	Standard	SGG SSN Adapter - CSV input
ssn-csv-arch	Archive	SGG SSN Adapter - CSV archive
ssn-csv-error	Standard	SGG SSN Adapter - CSV errors
ssn-ssnxml	Standard	SGG SSN Adapter - XML input
ssn-ssnxml-arch	Archive	SGG SSN Adapter - XML archive
ssn-ssnxml-error	Standard	SGG SSN Adapter - XML errors

Creating File Storage Extendable Lookup Values

Once you have object storage buckets created, the next step is to create an extendable lookup value for each. This record will be referenced by the batch controls that will process the payloads.

File storage configuration information is captured in the File Storage Configuration (F1-FileStorage) extendable lookup.

Values for this extendable lookup are defined by the following:

- **Value:** A unique code for the extendable lookup value. This value will be referenced as a batch control parameter value.
- **Description:** A description of the extendable lookup value
- **Status:** The current status of the value. Select “Active”.
- **File Storage Details:** This section defines details for the object storage location, including:
 - **File Adapter:** The type of file adapter for the location. Select “Oracle Cloud Object Storage”.
 - **User:** The user Oracle Cloud ID (ODIC) for the object storage location
 - **Tenancy:** The tenancy Oracle Cloud ID (ODIC) for the object storage location
 - **Compartment:** The compartment Oracle Cloud ID (ODIC) for the object storage location
 - **Namespace:** The namespace for the object storage location
 - **Key Ring:** The Key Ring you created earlier
 - **Region:** The region of the object storage tenancy for the connection (Values for this field are defined in the F1_REGION_FLG lookup).

Refer to **External File Storage** in the *Oracle Utilities Application Framework Administrative User Guide* and the *Oracle Utilities Cloud Services Object Storage Setup Guide* for more information.

Creating Head End Systems

The next step is to create a record for the head end system. This record defines processing methods for the head end system.

Processing Methods for Payload Processing

The following processing methods should be configured to support payload processing:

- **Device Event Mapping:** defines how head end-specific device events are mapped to standard device event names. The Device Event Seeder business object uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.
- **Initial Measurement Creation:** defines the business objects used to create initial measurements. The IMD Seeder business object uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head end system.

- **UOM Translation:** defines how head end-specific unit of measure (UOM) codes are mapped to standard UOM codes.

If usage payload include time of use periods or service quantity identifiers, you should also configure **SQI Translation** and **TOU Translation** processing methods.

See [Head End Systems](#) and [Understanding Processing Methods](#) in the *Administrative User Guide* for more information about creating and configuring a head end system and its processing methods.

Configuring Adapter Extendable Lookups

Smart Grid Gateway adapters use extendable lookups to define data mapping and processing rules specific to each adapter. These include:

- **Device Event Mapping:** used to map head end specific device event codes to standard event names
- **UOM Code to Standard UOM Mapping:** used to map head end specific units of measure (UOM) to standard UOM codes
- **Status Code Mapping:** used to map head end specific interval status codes to standard Condition codes.

Some adapters have additional extendable lookups used to define categories, statuses, and other data.

Creating SGG Payload Processing Extendable Lookup Values

You also have to create an extendable lookup value to define how usage and event payloads will be processed.

Payload processing configuration information is captured in the SGG Payload Processing Configuration (D1-SGGPayloadProcess) extendable lookup.

Values for this extendable lookup are defined by the following:

- **Value:** A unique code for the extendable lookup value. This value will be referenced as a batch control parameter value.
- **Description:** A description of the lookup value
- **Status:** The current status of the value. Set this to “Active”.
- **Processing Details:** This section defines details for payload processing, including
 - **Payload Handler Class Name:** The Java class name for the processing handler to be used. See [Payload Handler Classes and Parameters](#) below for more information.
 - **Head-End System:** The head end system for which the configuration will apply. Select from the drop-down list.
 - **Populate Raw:** A checkbox that indicates if the payload data is populated as raw data.
 - **Payload Processing Result Type:** The type of payload to which the configuration applies. Options include:
 - Device Events
 - Initial Measurements
 - Initial Measurements and Device Events
 - **IMD Seeder BO (Interval):** The seeder business object used to create interval initial measurements. The base package includes the “IMD Seeder” (D1-IMDSeeder) business object for this. Applicable only if the Payload Processing Result Type is “Initial Measurements” or “Initial Measurements and Device Events”.
 - **IMD Seeder BO (Scalar):** The seeder business object used to create scalar initial measurements. The base package includes the “IMD Seeder” (D1-IMDSeeder) business object for this. Applicable only if the Payload Processing Result Type is “Initial Measurements” or “Initial Measurements and Device Events”.
 - **Device Event Seeder BO:** The seeder business object used to create device events. The base package includes the “Device Event Seeder” (D1-DeviceEventSeeder) business object for this. Applicable only if the Payload Processing Result Type is “Device Events” or “Initial Measurements and Device Events”.

- **Filter IMD:** A checkbox that indicates if initial measurements should be filtered. Applicable only if the Payload Processing Result Type is “Initial Measurements” or “Initial Measurements and Device Events”. See **Filtering Payloads** below for more information.
- **Filter Device Events:** A checkbox that indicates if device events should be filtered. Applicable only if the Payload Processing Result Type is “Device Events” or “Initial Measurements and Device Events”. See **Filtering Payloads** below for more information.
- **Dynamic Parameters:** A list of parameter names and values that support additional processing rules, based on the specified Payload Handler Class. See [Payload Handler Classes and Parameters](#) below for specific parameters supported by each adapter.
- **User Exit Interceptors:** Defines custom Groovy Library Scripts to be executed via user exit calls when parsing and transforming incoming usage and device data in custom and non-standard formats. User exit interceptors are defined as follows:

Payload Processing User Exit Type	Groovy Library Script	Groovy Library Method
On Get Parser	Parsing script	getParser
On Get Transformer	Transforming script	getTransformer

See **Adapter Development Kit Custom Payload Processing** and **Payload Processing User Exit Interceptor Scripts** for more information.

NOTE: User Exit Interceptors are applicable only when the **Payload Handler Class Name** is set to `com.splwg.d1.domain.sgg.dg.processing.PayloadHandlerViaUserExits`.

Payload Handler Classes and Parameters

This section provides valid Payload Handler Class Names and associated dynamic parameters for supported head end systems and payload types.

Adapter Development Kit

As delivered, the Adapter Development Kit supports payload processing of usage and event data exported from an AMI head end system in the “native” initial measurement and device event data formats (the format of the initial measurement and device event seeder business objects). See [The Adapter Development Kit Native Format](#) for more information.

Payload Type: ADK CSV

- **Payload Handler Class:** `com.splwg.d1.domain.sgg.dg.processing.CSVPayloadHandler`

Payload Type: ADK XML

- **Payload Handler Class:** `com.splwg.d1.domain.sgg.dg.processing.XMLPayloadHandler`

Payload Type: ADK Seeder

- **Payload Handler Class:** `com.splwg.d1.domain.sgg.dg.processing.SeederPayloadHandler`

Processing Custom and Non-Standard Formats

The Adapter Development Kit can be configured to support payload processing of data from AMI head end systems in custom and non-standard formats. Processing payloads of this type requires a specific **Payload Handler Class** (see below), and creation of Groovy Library Scripts to parse and transform data into the “native” format. See **Adapter Development Kit Custom Payload Processing** and **Payload Processing User Exit Interceptor Scripts** for more information.

- **Payload Handler Class:** `com.splwg.d1.domain.sgg.dg.processing.PayloadHandlerViaUserExits`

Adapter for Itron OpenWay

Payload Type: Itron OpenWay XML

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d8.processing.ItronXMLPayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
intervalValueDecPlaces	Optional value. Specifies the number of digits after the decimal place for the quantity value. If this parameter is missing, the processing logic defaults the number of digits after the decimal place to 6.
filterRegisterSource	Optional value. Determines if source register data should be filtered. Valid values are 'true' and 'false' (default)

Payload Type: Itron OpenWay Exception

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d8.processing.ExceptionPayloadHandler

MV90 Adapter for Itron

Payload Type: MV90

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d5.processing.MV90PayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
usePhysicalChannel	Optional value. Determines whether the physical channel ID is passed to the IMD seeder to create the measuring component identifier number. If this is set to false, the MV90 LOGCHAN field is used.
fieldForDvclidN	Optional value. Specifies which field is used as the value for the device ID. Valid values include: <ul style="list-style-type: none"> • DC_RECID • DC_CUSTID • DC_METERID (default)
MV90ScalarChannelSuffix	Optional value. Holds a suffix value to be added to the measuring component identifier number when a scalarIMD is created for register reads. Default value is "_S"
processMV90ScalarData	Optional value. Determines if register reads are processed. Valid values are 'true' and 'false' (default).
sendStatusAsIs	Optional value. Determines if the status codes will be passed as they came from the head end. If this set to false or not provided, then the default existing behavior when a status code is parsed and status types passed to the IMD seeder in which bits are turned on. Valid values are 'true' and 'false' (default).
MV90DateFormat	Optional value. Holds the date format used to parse provided date-time fields. The code supports the limited list of values for the format. If this parameter is missing or if the value supplied to it does not match the values from this list then the format used will be MDDYYhhmm, the default value. Valid values include: <ul style="list-style-type: none"> • MMDDYYhhmm (default) • MMYDDhhmm • DDMMYYhhmm • DDYYMMhhmm

Dynamic Parameter Name	Description and Valid Values
	<ul style="list-style-type: none"> • YMMDDhhmm • YYDDMMhhmm
MV90IntervalValueDecPlaces	Optional value. Specifies the number of digits after the decimal place for the quantity value. If this parameter is missing, the processing logic defaults the number of digits after the decimal place to 6.
MV90StrtmtrAndStopmtrToDecimal	Optional value. Determines if the MV90 STRTMTR (Start Reading Meter) and STOPMTR (Stop Reading Meter) will be converted to a decimal. The processing logic will treat these fields as decimal use the setting to determine how many decimal points are required.

Adapter for Landis+Gyr

Payload Type: L+G Event

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d3.processing.LGEventPayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
dateTimelnUTC	Indicates whether the Landis+Gyr system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device. Valid values are 'true' and 'false' (default)

Adapter for Sensus

Payload Type: Sensus RNI Usage

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d6.processing.SensusUsagePayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
dateTimelnUTC	Indicates whether the Sensus RNI system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device. Valid values are 'true' and 'false' (default)
useExternalTOU	Indicates whether or not an externally reference TOU period should be used when processing measurement data. Valid values are 'true' and 'false' (default)
sendStatusAsIs	Optional value. Determines if the status codes will be passed as they came from the head end. If this set to false or not provided, then the default existing behavior when a status code is parsed and status types passed to the IMD seeder in which bits are turned on. Valid values are 'true' and 'false' (default)
sendIntervalDateTimes	Optional value. Determines if the "preVEE/msrs/mL/dt" element of the IMD Seeder for interval records exists and contains the last interval instead of calculating based on start date + spi * number of intervals. Valid values are 'true' and 'false' (default)

Payload Type: Sensus RNI Event

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d6.processing.SensusEventPayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
dateTimelnUTC	Indicates whether the Sensus RNI system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device. Valid values are 'true' and 'false' (default)

Adapter for Silver Spring Networks

Payload Type: Silver Spring Networks CSV

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d7.processing.SSNCSVPayloadHandler

Payload Type: Silver Spring Networks XML

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d7.processing.SSNXMLPayloadHandler

Common Parameters

The following parameters can be used by all of the supported head end system adapters.

Dynamic Parameter Name	Description and Valid Values
suppressPayloadStatistics	Optional parameter. Determines if the PayloadStatistics business object will not be created while processing payload. If this set to false or not provided, then the default existing behavior when a PayloadStatistics business object is created at the start of the payload processing. Valid values are 'true' and 'false' (default).
suppressPayloadErrorNotification	Optional parameter. Determines if the PayloadErrorNotification business object will not be created when an error occurs while processing payload. If this set to false or not provided, then the default existing behavior when a PayloadErrorNotification business object is created for every error occurred during the payload processing. If this set to false, the error description will be written into the application log file. Valid values are 'true' and 'false' (default).
suppressPayloadSummary	Optional parameter. Determines if the PayloadSummary business object will not be created while processing payload. If this set to false or not provided, then the default existing behavior when a PayloadSummary business object is created at the end of the payload processing. Valid values are 'true' and 'false' (default).
chunkSize	Optional parameter. Specifies the size in bytes of a portion (chunk) of the payload that will be processed in a single batch "thread". See Background Processing Overview for more information about the batch "thread". This parameter is used when the processing of huge payloads is failing with the "roll back segment too small" error. This parameter is supported only for the following payload formats: <ul style="list-style-type: none">• L+G Usage• L+G Event

Dynamic Parameter Name	Description and Valid Values
------------------------	------------------------------

- MV90
- Sensus RNI Usage
- Sensus RNI Event
- Silver Spring Networks CSV
- ADK CSV

Filtering Payloads

When **Filter IMD** is selected, only measurements whose <externalUOM> matches one of the values defined in the head end system's UOM Code to Standard UOM Mapping extendable lookup are passed into the system for processing.

When **Filter Device Events** is selected, only device events whose <externalEventName> matches one of the values defined in the head end system's Device Event Mapping extendable lookup are passed into the system for processing.

Creating Payload Processing Batch Controls

The last step is to create payload processing monitor batch controls based on the Payload Processing Monitor Template (D1-PLPRM) template. You can create separate batch controls for each head end system or for specific payload types, or any combination of both. For example, you might create a separate batch control for Itron OpenWay usage payloads and device event payloads. Creating specific batch controls allows more control when setting up batch process scheduling for payload processing. For instance, you may want to run usage payload processing every hour, but device payload processing every two hours.

To create a payload processing monitor batch control, search for the "Payload Processing Monitor Template" (D1-PLPRM) batch control, click **Duplicate**, enter a unique code for the duplicate batch control and click **OK**.

This new batch control can be used to process payloads received from head end systems.

Payload Processing Batch Control Parameters

Payload processing batch processing is controlled by the following parameters:

Parameter Name	Description	Detailed Description	Required?
includeFiles	Include Files	The pattern for types of files to pick up during polling. The parameter supports the "glob" syntax for using wildcard characters.	True
fileLocation	File Location	The Object Storage bucket to poll files from. This should be the Value of the File Location Extendable Lookup value for the appropriate bucket (usage or event).	True
processingConfiguration	Processing Configuration	The Value of the SGG Payload Processing Configuration Extendable Lookup value	True
errorLocation	Error Location	The Object Storage bucket where defected portions of payload and related rejection details are stored. This should be the Value of the File Location Extendable Lookup value for the appropriate "error" bucket.	True
postProcessingAction	Post Processing Action	Defines what happens to a file after it has been processed: delete (default), archive or rename. If	False

Parameter Name	Description	Detailed Description	Required?
		"archive" is selected, an archive bucket should be provided.	
archiveLocation	Archive Location	The Object Storage bucket where processed files are moved to. Required if the Post Processing Action is "archive". This should be the Value of the File Location Extendable Lookup value for the appropriate "archive" bucket.	False
processedFileExtension	Processed File Extension	The text to be appended to the file name after the file has been processed. Default is "PROCESSED".	False
maxRaiseSize	Maximum Raise Size	This parameter defines the maximum number of files that the batch program would submit for processing on each polling cycle. Default is No Maximum.	False
DIST-THD-POOL	Thread Pool	Thread pool name to use if the DEFAULT thread pool is not desired.	False

NOTE: Refer to [Creating Object Storage Locations](#) for lists of suggested Object Storage buckets for each adapter.

Adapter Development Kit Custom Payload Processing

This section describes how the Oracle Utilities Smart Grid Gateway Adapter Development Kit can be configured to process custom payload formats, including payloads from non-supported head end systems.

Introduction

As delivered, the Adapter Development Kit supports payload processing of usage and event data exported from an AMI head end system in the "native" initial measurement and device event data formats (the format of the initial measurement and device event seeder business objects).

The Adapter Development Kit can also be configured to support payload processing of data from AMI head end systems in custom and non-standard formats. This involves creation of Groovy Library Scripts to:

- Parse the payload into a "plain XML" format, and
- Transform the plain XML format into the "native" initial measurement and device event data formats

These scripts are executed as User Exit Interceptors configured on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Configuration Extendable Lookup Values](#).

Custom Payload Processing Overview

This section provides an overview of the payload processing logic when converting incoming data into the native format.

Oracle Utilities Meter Data Framework Steps

1. The file upload process program starts reading the file.
2. The upload process creates an instance of the Payload Handler class. This class handles the interaction with the User Exit Interceptor scripts.
3. The upload process invokes the "On Get Parser" User Exit Interceptor. This executes a "parser" Groovy Library Script that returns an instance of a class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadParser` interface.

This “payload parser” is initialized with a stream opened for the incoming file and a business object instance of SGG Payload Processing Configuration extendable lookup.

4. The upload process invokes the “On Get Transformer” User Exit Interceptor. This executes a “transformer” Groovy Library Script that returns an instance of a class that implements `com.splwg.dl.domain.sgg.dg.processing.PayloadTransformer` interface. This “payload transformer” is initialized with a string representing the origin of the payload and business object instance of SGG Payload Processing Configuration extendable lookup.
5. The upload process invokes the payload parser to parse data from the incoming document into the “Plain XML” format. See [Payload Parser Steps](#), below.
6. The upload process invokes the payload transformer, passing the Plain XML data and a Result List parent node.
7. The payload transformer transforms the Plain XML data into a set of Initial Measurements (IMDs) or/and Device Events in the “native” XML format and returns each as child nodes added to the Result List parent node. See [Payload Transformer Steps](#), below.
8. The upload process creates business object instances for all child nodes of the Result List.
9. The process steps (5-9) are repeated until the payload parser returns NULL on step 5 (when there are no further records to process).

Payload Parser Steps

1. The payload parser reads an input stream until it hits the logical end of portion of data (each usage or event record), which could be transformed into Plain XML.
2. The payload parser parses the data and converts into the Plain XML format.
3. The process is performed for each call from the upload process.

Payload Transformer Steps

1. The payload transformer reads the given Plain XML.
2. The payload transformer generates a set of XML nodes representing Initial Measurements (IMDs) or Device Events. Names for nodes are taken from the provided SGG Payload Processing Configuration.
3. The payload transformer adds the generated nodes to the given Result List node.

Payload Processing User Exit Interceptor Scripts

Conversion of data from custom and non-standard formats into the “native” format is performed via a pair of Groovy Library Scripts that are invoked via user exits during payload processing (see [Custom Payload Processing Overview](#)). The two scripts used in this process include a “parser” script, and a “transformer” script.

Parser Script

The “parser” script is responsible for parsing the incoming data and converting it into the Plain XML format. This script should include the `getParser` method that returns an instance of a class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadParser` interface.

To view details of the `PayloadParser` interface in the Application Viewer, select the **Java Docs Viewer**, select the `com.splwg.dl.domain.sgg.dg.processing` Java package, and select `PayloadParser` from the list of interfaces.

The “parser” script should be defined for the “On Get Parser” Payload Processing User Exit Type in the **User Exit Interceptors** section on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.

The base package includes two sample parser scripts that can be used as examples when developing custom parser scripts. See [Sample Implementation](#).

Transformer Script

The “transformer” script is responsible for converting data the Plain XML format into the “native” format. This script should include the `getTransformer` method that returns an instance of a class that implements the `com.splwg.d1.domain.sgg.dg.processing.PayloadTransformer` interface.

To view details of the `PayloadTransformer` interface in the Application Viewer, select the **Java Docs Viewer**, select the `com.splwg.d1.domain.sgg.dg.processing` Java package, and select `PayloadTransformer` from the list of interfaces.

The “transformer” script should be defined for the “On Get Transformer” Payload Processing User Exit Type in the **User Exit Interceptors** section on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.

The base package includes two sample transformer scripts that can be used as examples when developing custom transformer scripts. See [Sample Implementation](#).

Configuration Steps

Configuration of the Adapter Development Kit to support conversion of non-standard formats into the “native” format involves the following steps:

1. Create a “parser script” that converts data from the incoming format into Plain XML format. See [Payload Processing User Exit Interceptor Scripts](#) for more information.
2. Create a “transformer script” that converts data from the Plain XML format to the “native” format. See [Payload Processing User Exit Interceptor Scripts](#) for more information.
3. Create an SGG Payload Processing Configuration extendable lookup value with a **Payload Handler Class Name** of “`com.splwg.d1.domain.sgg.dg.processing.PayloadHandlerViaUserExits`”. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.
4. Specify the parser script for the “On Get Parser” Payload Processing User Exit Type in the **User Exit Interceptors** section on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.
5. Specify the transformer script for the “On Get Transformer” Payload Processing User Exit Type in the **User Exit Interceptors** section on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.
6. Create other objects and data used with payload processing, including:
 - Key Rings and Pairs (See [Creating Key Rings and Pairs](#))
 - Object Storage Locations (See [Creating Object Storage Locations](#))
 - File Storage Extendable Lookup values (See [Creating File Storage Extendable Lookup Values](#))
 - Head End System (See [Creating Head End Systems](#))
 - Payload Processing Batch Controls (See [Creating Payload Processing Batch Controls](#))

Sample Implementation

The Smart Grid Gateway Adapter Development Kit includes sample parser and transformer scripts that demonstrate how custom payload processing works. These sample scripts include samples for processing data in comma separated values (CSV) format and in XML format.

Comma Separated Values Format

This page describes the comma separated values format sample implementation.

Sample File Format

In this sample, data is stored as a comma separated values file.

Note: Values in this example cannot contain a literal comma character. This restriction is added for the simplicity of file parser implementation. The parsing logic can be re-implemented to avoid this restriction. It will not affect the rest of functionality.

The sample CSV file contains the following record types:

Interval Usage: Used for interval usage measurements

Device Events: Used for device events

Trail record: Used to provide the read date/time and number of interval usage and device event records in the file

Interval Usage Format

#	Field Name	Type	Definition
1	Record Type ID	Constant value "U"	Record type identifier
2	Start Date/Time	Time in the Unix Time format.	Meter read's start date/time
3	End Date/Time	Time in the Unix Time format.	Meter read's end date/time
4	Device Id	Arbitrary Text	Device identifier
5	Interval Duration	Numeric Integer	The time interval between readings in seconds (seconds per interval).
6	UOM	Arbitrary Text	Describes the units of the data values
7	Data Entry(s)	Numeric Floating-Point and optional Arbitrary Text separated by ":"	Each record can contain unlimited number of data entry fields. Each data entry is a set of two fields – a reading value and an optional reading status flag. Fields are separated by ":" character. The separator is not present when the reading status flag is not provided.

Device Event Format

#	Field Name	Type	Definition
1	Record Type ID	Constant value "E"	Record type identifier
2	Event Date/Time	Time in the Unix Time format.	The date and time at which the event occurred
3	Device Id	Arbitrary Text	Device identifier

#	Field Name	Type	Definition
4	Event Name	Arbitrary Text	The primary identification name of the event

Trail Record Format

#	Field Name	Type	Definition
1	Record Type ID	Constant value "T"	Record type identifier
2	Creation Date/Time	Time in the Unix Time format.	Meter read's start date/time
3	Total Records	Numeric Integer	Displays number of records in file

Sample File

```
U,1,86400,DEVICE_DG_0,900,KWH,1:S,2.5,-3.99:R,4:B
E,86400,DEVICE_DG_1,Power Outage
U,2,86400,DEVICE_DG_2,900,KWH,1:S,2,3:R,4:B,5,6,7:A
E,86402,DEVICE_DG_3,Tamper attempt suspected
U,3,86400,DEVICE_DG_4,900,KWH,1:S
T,86401,5
```

Sample Scripts

The sample implementation includes the following sample scripts designed for use with the above CSV format:

DG_SmplPrCSV: This sample script includes one method in the Library Interface – `getParser()`. The method returns an instance of the class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadParse` interface. The class contains the following logic:

1. Parses an incoming payload in the CSV Format.
2. Transforms incoming data to Usage or Event related structures based on incoming data type
3. Returns one by one that structures in the Plain XML format

DG_SmplTrCSV: This sample script includes one method in the Library Interface – `getTransformer()`. The method returns an instance of class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadTransformer` interface. The class contains the following logic:

1. Transforms incoming message in the Plain XML format into the “native” format (the IMD Seeder or Device Event Seeder XML nodes).
2. Adds new XML nodes as child nodes to the given Result List.

Use the **Script** portal to view these scripts in more detail.

Parsing

The parser script performs the following data mapping.

Interval Usage to Plain XML Mapping

The following table shows the mapping between fields in incoming interval data and child elements of Payload/Usage element in the Plain XML format:

Interval Usage Field	Plain XML Element
Record Type ID	RecordType

Interval Usage Field	Plain XML Element
Start Date/Time	StartDateTime
End Date/Time	EndDateTime
Device Id	Deviceld
Interval Duration	IntervalDuration
UOM	UOM
Data Entry(s)	Intervals/ Interval/ Value [Status]
Record content from incoming file.	RawData

Device Event to Plain XML Mapping

The following table shows the mapping between fields in incoming interval data and child elements of Payload/Event element in the Plain XML format:

Device Event Field	Plain XML Element
Record Type ID	RecordType
Event Date/Time	DateTime
Device Id	Deviceld
Event Name	Name
Record content from incoming file.	RawData

XML Schema of Plain XML Format

The Plain XML consists of the Interval Usage and Device Event related elements at the same time.

```
<xs:schema attributeFormDefault="unqualified"

    <xs:element name="Name" type="ga:NonEmptyString"/>
  </xs:sequence>
</xs:complexType>
<xs:simpleType name="RecordTypeEventType">
  <xs:restriction base="xs:string">
    <xs:enumeration value="E"/>
  </xs:restriction>
</xs:simpleType>
<xs:simpleType name="NonEmptyString">
  <xs:restriction base="xs:string">
    <xs:minLength value="1"/>
  </xs:restriction>
</xs:simpleType>
</xs:schema>

```

NOTE: Note: A part of incoming file that been used to generate current Plain XML structure will be placed into the Payload/RawData element.

Transformation

The transformer script performs the following mapping.

Plain XML to Seeder XML Mapping

The payload transformer creates the IMD or/and Device Event Seeder XML elements as following:

Usage Mapping: If name of Payload/* node is equal to 'Usage' (interval usage), the script creates an XML element with a name defined in the SGG Payload Processing Configuration field “IMD Seeder BO (Interval)” and the structure according to the following mapping table:

Plain XML Element	IMD Seeder Element	Notes
RecordType	N/A	
DeviceId	dvclIdN	
UOM	externalUOM	
IntervalDuration	spi	
StartDateTime	stDt	Convert to OUAF "dateTime" type
EndDateTime	enDt	Convert to OUAF "dateTime" type
Intervals/		
Interval/		
Value [Status]	msrs	Value

Plain XML Element	IMD Seeder Element	Notes
msrs/mL/q		
Status ->		
msrs/mL/sts/stsL/st		
N/A	imdType	Const value 'D1IL'
	externalId	Value stored in setOrigin method.
	serviceProviderExternalId	Value stored in setConfiguration method.
RawData	rawData	If the SGG Payload Processing Configuration has the Populate RAW checkbox checked.

Device Event Mapping: If name of Payload/* node is equal to 'Event' (device event data) create an XML element with a name defined in the SGG Payload Processing Configuration field “Device Event Seeder BO” and the structure according to the following mapping table:

Plain XML Element	Device Event Seeder Element	Note
RecordType	N/A	
DateTime	eventDateTime	Convert to OUAF "dateTime" type
DeviceId	externalUOM	
Name	externalEventName	
	externalSourceIdentifier	Value stored in setOrigin method.
	externalSenderId	Value stored in setConfiguration method.
RawData	rawEventInformation	If the SGG Payload Processing Configuration has the Populate RAW checkbox checked.

XML Format

This page describes the XML format sample implementation.

Sample File Format

The file format is described in the Online IMD Upload hint on the **Online IMD and Event Upload** screen. (Select **Menu**, select **Communication**, select **Load IMDs/Events (XML)**).

Sample File

```

</initialMeasurementData>
</initialMeasurementDataList>
</device>
</deviceList>

```

Sample Scripts

The sample implementation includes the following sample scripts designed for use with the above XML format:

DG_SmplPrXML: This sample script includes one method in the Library Interface – `getParser()`. The method returns an instance of the class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadParser` interface. The class contains the following logic:

1. Parses an incoming payload in XML format
2. Fetches information about current device
3. Breaks an incoming data into separate initial measurement data structures
4. Extends these structures with device information
5. Returns one by one these structures in the Plain XML format

DG_SmplTrXML: This sample script includes one method in the Library Interface – `getTransformer()`. The method returns an instance of class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadTransformer` interface. The class contains the following logic:

1. Transforms incoming message in the Plain XML format into the IMD Seeder XML nodes.
2. Adds new XML nodes as child nodes to the given Result List

Use the **Script** portal to view these scripts in more detail.

Parsing

The XML parser script maps data from the above XML format into the Plain XML format.

XML Schema of Plain XML Format

```
<xs:schema attributeFormDefault="unqualified"
elementFormDefault="qualified"

    <xs:sequence maxOccurs="unbounded">
      <xs:element name="Interval" type="ga:IntervalType"/>
    </xs:sequence>
  </xs:complexType>
  <xs:complexType name="IntervalType">
    <xs:sequence>
      <xs:element name="Value" type="xs:float"/>
      <xs:element name="Status" type="ga:NonEmptyString" minOccurs="0"/>
    </xs:sequence>
  </xs:complexType>
  <xs:complexType name="EventType">
    <xs:sequence>
      <xs:element name="RecordType" type="ga:RecordTypeEventType"/>
      <xs:element name="DateTime" type="xs:integer"/>
      <xs:element name="DeviceId" type="ga:NonEmptyString"/>
      <xs:element name="Name" type="ga:NonEmptyString"/>
    </xs:sequence>
  </xs:complexType>
  <xs:simpleType name="RecordTypeEventType">
    <xs:restriction base="xs:string">
      <xs:enumeration value="E"/>
    </xs:restriction>
  </xs:simpleType>
  <xs:simpleType name="NonEmptyString">
    <xs:restriction base="xs:string">
      <xs:minLength value="1"/>
    </xs:restriction>
  </xs:simpleType>
</xs:schema>
```

Transformation

The transformer script performs the following mapping.

Plain XML to Seeder XML Mapping

The payload transformer script does the following:

1. Creates an XML element with a name defined in the SGG Payload Processing Configuration field “IMD Seeder BO (Interval)” and copies all elements from the Plain XML as child nodes of new element.
2. Inserts the “externalId” element populated with value stored in `setOrigin` method.
3. Inserts the “serviceProviderExternalId” element populated with value stored in `setConfiguration` method.
4. If the SGG Payload Processing Configuration has the **Populate RAW** checkbox checked, inserts the “rawData” element populated with the textual XML representation of Plain XML element.

Smart Meter Commands

This section provides information about implementing smart meter commands with Oracle Utilities cloud services, including Oracle Utilities Meter Solution Cloud Service.

Device Communication Overview

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The head-end system receives the message, acts on the request, and returns a reply.

See [Communications](#) in the *Business User Guide*, and [About Communications](#) in the *Administrative User Guide* for basic information about command activities and communications.

Cloud Service Command Processing

When implementing Smart Grid Gateway adapters with Oracle Utilities cloud services, command processing works slightly differently than it does in on-premises implementations.

The table below provides a brief description of the communication process, and lists example objects used by the Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay. Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

Step	Process	Example Data
1.	A user initiates a remote connect command for a device. A remote connect activity business object is instantiated for the command.	Activity Business Object: Remote Connect (D1-RemoteConnect)
2.	The remote connect command activity business object creates an outbound communication. The specific type of outbound communication business object created is determined by the head end system (based on the processing role defined in an Enter algorithm of the “Connection Ready” status of the command activity business object’s lifecycle).	Outbound Communication Business Object: Itron - Reconnect Meter (Remote Connect) (D8-ReconnectMeterDR)
3.	The outbound communication creates an outbound message. The specific type of outbound message created is determined by the head end system (based on the processing role defined in an Enter algorithm of the “Awaiting	Outbound Message Type Business Object: Outbound Message for Itron connect command (D8-ItronRemoteConnectOutbndMsg)

Step	Process	Example Data
	Response" status of the outbound communication business object's lifecycle).	
4.	<p>The outbound message is sent to the head end system via an External System, Message Sender, and Outbound Message Type.</p> <p>The head end system sends a synchronous response to acknowledge receipt of the request.</p>	<p>External System: Itron OpenWayHead End System</p> <p>Message Sender: Itron – Remote Connect (D8-Reconnect)</p> <p>Outbound Message Type: Itron – Remote Connect (D8-RemoteConnect)</p>
5.	<p>As the status of the command request is updated, the head end system sends periodic messages.</p> <p>These messages are received by an Inbound Web Service which creates instances of an inbound communication business object.</p> <p>The specific type of inbound communication business object created is determined by the Inbound Web Service.</p>	Inbound Communication Business Object: Itron – StatusChanged (D8-StatusChanged)
6.	<p>When the command request has been completed, it sends a status changed inbound communication with a "Completed" status.</p> <p>This transitions the outbound communication business object to its "Completed" state.</p>	Inbound Communication Business Object: Itron – StatusChanged (D8-StatusChanged)
7.	<p>The remote connect command activity business object creates a "results" outbound communication.</p> <p>The specific type of outbound communication business object created is determined by the head end system (based on the processing role defined in an Enter algorithm of the "Connection Ready" status of the command activity business object's lifecycle).</p>	<p>Outbound Communication Business Object: Itron - Reconnect Meter Results</p> <p>(D8-ReconnectMeterResultDR)</p>
8.	<p>The outbound communication creates an outbound message.</p> <p>The specific type of outbound message created is determined by the head end system (based on the processing role defined in an Enter algorithm of the "Awaiting Response" status of the outbound communication business object's lifecycle).</p>	<p>Outbound Message Type Business Object: Outbound Message for Itron connect result command</p> <p>(D8-ItronRemoteCntRsltOutMsg)</p>
9.	An Enter Algorithm on the "Evaluate Response" status of the outbound message business object's lifecycle evaluates the response.	Enter Algorithm: Evaluate Get Reconnect Results Response (D8-EVGRCMRST)
10.	<p>The "result" outbound communication creates a completion event to update the status of the device to indicate it has been connected.</p> <p>The specific type of completion event business object created is specified in an Enter algorithm on the "Create Completion Event" Status of the outbound communication business object's lifecycle.</p>	<p>Algorithm: Create Connect Completion Event from Result (D8-CRCNCER)</p> <p>Completion Event Business Object: Connect Device (D1-ConnectDevice)</p>
11.	The outbound communication updates the "Connect/ Disconnect Completion Flag" and the original activity business object.	

Step	Process	Example Data
	This update is performed by an Enter algorithm on the "Completed" Status of the outbound communication business object's lifecycle.	

In the case of commands that also request usage readings, such as On Demand Read or Scheduled Read, usage readings are sent separately via DataArrived messages separately to the DataSubscriberService Inbound Web Service, where they can be routed to Object storage for payload processing.

Smart Meter Command Flows

This section provides information about the smart meter command flows used by supported Smart Grid Gateway adapters.

Itron OpenWay Command Flows

The table below lists the communication flows used with each Itron OpenWay command, including:

- **Command:** The specific smart meter command
- **Outbound Communication:** The outbound communication business object created by the command. This sends the command request to the head end system.
 - **Result Outbound Communication** The outbound communication business object used to request the result of a command request
- **Inbound Communication:** The inbound communication created by the response from the head end system.
- **Completion Event:** The completion event(s) triggered by the command, if any. Completion events are used to update data in the system as a result of a smart meter command. For example, if a command changes the status of a device, the completion event is responsible for making that change.

Command	Outbound Communication	Inbound Communication	Completion Event
Device Commissioning	Itron - Add Meter Definition (Commission) (D8-AddMeterDefinitionsDR)		Device Commissioning Completion Event
Device Decommissioning	Itron - Deregister Meter (Decommission) (D8-DeregisterMeterDR)		Device Decommissioning Completion Event
Remote Connect	Itron - Reconnect Meter (Remote Connect) (D8-ReconnectMeterDR)	Itron - StatusChanged (D8-StatusChanged)	Connect Device Completion Event
	Result: Itron - Reconnect Meter Result (D8-ReconnectMeterResultDR)		
Remote Disconnect	Itron - Meter Remote Disconnect (D8-DisconnectMeterDR)	Itron - StatusChanged (D8-StatusChanged)	Disconnect Device Completion Event
	Result: Itron - Disconnect Meter Result (D8-DisconnectMeterResultDR)		
On-Demand Read (Scalar)	Itron - Contingency Read (Scalar) (D8-ReadScalarDR)	Itron - StatusChanged (D8-StatusChanged)	Create IMD Completion Event
	Result: Itron - On Demand Read Result (D8-ReadOnDemandReadResultDR)		
On-Demand Read (Interval)	Itron - Contingency Read (Interval) (D8-ReadIntervalDR)	Itron - StatusChanged (D8-StatusChanged)	Create IMD Completion Event
	Result: Itron - On Demand Read Result (D8-ReadOnDemandReadResultDR)		
Scheduled Read (Scalar)	Itron - Interrogate By Group	Itron - StatusChanged	Create IMD Completion Event

Command	Outbound Communication	Inbound Communication	Completion Event
	(D8-InterrogateByGroupDR)	(D8-StatusChanged)	
	Result: Itron - Interrogate by Group Results (D8- InterrogateByGroupResultDR)		
Scheduled Read (Interval)	Itron - Interrogate By Group (D8-InterrogateByGroupDR)	Itron - StatusChanged (D8-StatusChanged)	Create IMD Completion Event
	Result: Itron - Interrogate by Group Results (D8- InterrogateByGroupResultDR)		
Device Status Check	Itron - Ping By Endpoints (Status Check) (D8-PingByEndpointsDR)	Itron - StatusChanged (D8-StatusChanged)	
	Result: Itron - Ping By Endpoints Result (D8- PingByEndpointsResultDR)		
Multi-Device Status Check	Itron – Ping By Endpoints Multi-Device (D8-PingByEndpointsMultiDvcDR)	Itron – StatusChanged (D8-StatusChanged)	
	Result: Itron – Ping By Endpoints Multi Dvc Result (D8- PingByEndpointsMDRResultDR)		
Load Check	Itron – Detect Load Side Voltage (D8-DetectLoadSideVoltageByMtrDR)	Itron – StatusChanged (D8-StatusChanged)	
	Result: Itron – Detect Load Side Voltage Result (D8- DetLoadSideVoltageMtrRsltDR)		
Read Disconnect State	Itron - Read Disconnect State (D8-ReadDisconStateByMtrDR)	Itron – StatusChanged (D8-StatusChanged)	
	Result: Itron - ReadDisconnectStateByMeter Result (D8-ReadDisconStByMtrResultDR)		

Silver Spring Networks Command Flows

The table below lists the communication flows used with each Silver Spring Networks command, including:

- **Command:** The specific smart meter command
- **Outbound Communication:** The outbound communication business object created by the command. This sends the command request to the head end system.
 - **Get Status Outbound Communication:** The outbound communication business object used to request the status of a command request
 - **Result Outbound Communication:** The outbound communication business object used to request the result of a command request
- **Outbound Messages:** The outbound message business objects for one or more outbound messages created by the outbound communication. These should be configured on the Silver Spring Networks external system.
- **Completion Event:** The completion event(s) triggered by the command, if any. Completion events are used to update data in the system as a result of a smart meter command. For example, if a command changes the status of a device, the completion event is responsible for making that change.

Command	Outbound Communication	Outbound Messages	Completion Event
Device Commissioning	SSN - Replace Location (D7-ReplaceLocationDR)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Replace Location: SSN - Replace Location (Comm) OB Message (D7-ReplaceLocationOBMsg)	Device Commissioning Completion Event

Command	Outbound Communication	Outbound Messages	Completion Event
Device Decommissioning	SSN - Replace Device At Location (Decomm) (D7- ReplDeviceAtLocForDecommDR)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Replace Device at Location: SSN - Replace Device At Loc O/B Message: (D7- ReplaceDeviceAtLocOBMsg)	Device Decommissioning Completion Event
Remote Connect	SSN - Connect or Disconnect (D7- ConnectDisconnectDR)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Connect Disconnect: SSN - Connect Disconnect OB Message (D7-ConnectDisconnectOBMsg)	Connect Device Completion Event
	Get Status: SSN - Get Status (D7-GetStatus)	SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)	
	Result: SSN - Connect Disconnect Results (D7- ConnectDisconnectResultDR)	SSN - GetConnectDisconnectResult OB Message (D7-GetCntDiscntResultOBMsg)	
Remote Disconnect	SSN - Connect or Disconnect (D7- ConnectDisconnectDR)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Connect Disconnect: SSN - Connect Disconnect OB Message (D7-ConnectDisconnectOBMsg)	Disconnect Device Completion Event
	Get Status: SSN - Get Status (D7-GetStatus)	SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)	
	Result: SSN - Connect Disconnect Results (D7- ConnectDisconnectResultDR)	SSN - GetConnectDisconnectResult OB Message (D7-GetCntDiscntResultOBMsg)	
On-Demand Read (Scalar)	SSN - Add Meter Read Job (Scalar) (D7-AddMeterReadJobScalarDR)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Add Meter Read Job Scalar: SSN - Add Meter Read Job Scalar OB Msg Type (D7-AddMeterReadJobScalarOBMsg)	Create IMD Completion Event
	Get Status: SSN - Get Status (D7-GetStatus)	SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)	
	Result: SSN - Meter Read Results (Scalar) (D7-MeterReadResultsScalar)	SSN - GetMeterReadResults(Scalar) By JobId (D7-GetScItrMtrRdRstByJobIdOBMsg)	
On-Demand Read (Interval)	SSN - Add Meter Read Job (Interval) (D7-AddMeterReadJobIntervalDR)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Add Meter Read Job Interval: SSN - AddMeterReadJob Interval OB Msg Type (D7-AddMeterReadJobIntervalOBMsg)	Create IMD Completion Event
	Get Status: SSN - Get Status (D7-GetStatus)	SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)	
	Result: SSN - Meter Read Results (Interval) (D7-MeterReadResultsInterval)	SSN - GetMeterReadResults(Interval) By JobId (D7-GetIntMtrRdRstByJobIdOBMsg)	
Device Status Check	SSN - Add Ping Job (D7-AddPingJobDR)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Add Ping Job: SSN - Add Ping Job OB Message (D7- AddPingJobOBMsg)	

Command	Outbound Communication	Outbound Messages	Completion Event
	Get Status: SSN - Get Status (D7-GetStatus)	SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)	
	Result: SSN - Ping Results (D7-PingResultsDR)	SSN - Get Ping Results O/B Message (D7-GetPingResultsOBMsg)	

Sending Outbound Communications

Sending outbound communications to a head end system involves configuring the following entities:

- **Outbound Message Types:** Define how outbound messages of a specific type are handled. Outbound message types are based on a specific outbound message business object that defines the data structure of the message. See [Defining Outbound Message Types](#) in the *Administrative User Guide* and [Creating Outbound Message Types](#) below for more information.
- **Message Senders:** Define details for sending messages to external systems. See [Message Senders](#) in the *Administrative User Guide* for more information.
- **External System:** Defines a set of outbound message types that can be sent to the head end system. See [External Systems](#) in the *Administrative User Guide* for more information.
- **Head End System:** Defines processing rules for the head end system, such as the specific activities and communications created for smart meter commands. See [Head End Systems](#) and [Processing Methods](#) in the *Administrative User Guide* and [Configuration Processing Methods](#) below for more information.

Creating Outbound Message Types

You must create outbound message types for each command you plan to use in your implementation. The tables below lists the business objects that should be used when creating outbound message types for each Smart Grid Gateway adapter.

Itron OpenWay Outbound Message Types

This table lists the business objects that should be used when creating outbound message types for the Itron OpenWay adapter.

Command	Outbound Message Business Object	“Result” Outbound Message Business Object
Device Commissioning	Outbound Message for Itron Commission (D8-ItronCommissionOutboundMsg)	N/A
Device Decommissioning	Outbound Message for Itron Decommission (D8-ItronDecommissionOutbndMsg)	N/A
Remote Connect	Outbound Message for Itron connect command (D8-ItronRemoteConnectOutbndMsg)	Outbound Message for Itron connect result command (D8-ItronRemoteCntRsltOutMsg)
Remote Disconnect	Outbound Message for Itron disconnect command (D8-ItronRemoteDisconnectOutMsg)	Outbound Message for Itron disconnect result command (D8-ItronRemoteDcntRsltOutMsg)
On-Demand Read (Scalar)	Outbound Message for Itron Contingency Read command (D8-ItronOnDemandReadOutbndMsg)	O/B Msg for Itron Contingency Read Result (D8-ItronOnDemandReadRsltOBMsg)
On-Demand Read (Interval)	Outbound Message for Itron Contingency Read command (D8-ItronOnDemandReadOutbndMsg)	O/B Msg for Itron Contingency Read Result (D8-ItronOnDemandReadRsltOBMsg)
Scheduled Read (Scalar)	Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpOBMsg)	Outbound Message for Itron Schedule Read Result command (D8-ItronInterrogateByGrpRsltOB)

Command	Outbound Message Business Object	“Result” Outbound Message Business Object
Scheduled Read (Interval)	Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpOBMsg)	Outbound Message for Itron Schedule Read Result command (D8-ItronInterrogateByGrpRsltOB)
Device Status Check	Outbound Message for Itron Device status check (D8-ItronDvcStatusChkOutbndMsg)	O/B Msg for Itron DeviceStatusCheck Result (D8-ItronDvcStatusChkRsltOBMsg)
Multi-Device Status Check	Outbound Message for Itron Multi device status check (D8-ItronDvcStChkMtDvcOutbndMsg)	O/B Message for Itron MultiDeviceStatusCheck Result (D8-ItronDvcStChkMtDvcRsltOBMsg)
Load Check	Outbound Message for Itron Detect Load Side Voltage (D8-ItronDetectLoadSideVolOBMsg)	Outbound Message for LoadCheckResult Cmd (D8-ItronDetLSVoltMtrRsltOutMsg)

Silver Spring Networks Outbound Message Types

This table lists the business objects that should be used when creating outbound message types for the Silver Spring Networks adapter.

Command	Outbound Message Business Object	“Result” Outbound Message Business Object
Device Commissioning	SSN - Replace Location (D7-ReplaceLocationDR)	N/A
Device Decommissioning	SSN - Replace Device At Location (Decomm) (D7-ReplDeviceAtLocForDecommDR)	N/A
Remote Connect	SSN - Connect or Disconnect (D7-ConnectDisconnectDR)	SSN - Connect Disconnect Results (D7-ConnectDisconnectResultDR)
Remote Disconnect	SSN - Connect or Disconnect (D7-ConnectDisconnectDR)	SSN - Connect Disconnect Results (D7-ConnectDisconnectResultDR)
On-Demand Read (Scalar)	SSN - Add Meter Read Job Scalar OB Msg Type (D7-AddMeterReadJobScalarOBMsg)	SSN - GetMeterReadResults(Scalar) By JobId (D7-GetSMtrRdRsltJobIdOBMsgTyp)
On-Demand Read (Interval)	SSN - AddMeterReadJob Interval OB Msg Type (D7-AddMtrReadJobIntervalOBMsg)	SSN - GetMeterReadResults(Interval) By JobId (D7-GetIMtrRdRsltJobIdOBMsgTyp)
Device Status Check	SSN - Add Ping Job (D7-AddPingJobDR)	SSN - Ping Results (D7-PingResultsDR)

Creating Message Senders

You must create message senders for each outbound communication that will be sent to the head end system as part of the command communication process.

See [Message Senders](#) in the *Administrative User Guide* for more information about creating message senders.

Creating an External System

You must create an external system that represents the head end system and defines a set of outbound message types that can be sent to the head end system.

External System Outbound Message Types

You must configure an outbound message type on the external system for each type of message you will send to the head end system. An external system's outbound message types are defined by the following:

- **Outbound Message Type:** The outbound message type created for the message (see [Creating Outbound Message Types](#))
- **Processing Method:** The method by which the message will be sent. This should be set to “Real-time” Smart Grid Gateway outbound communications.
- **Message Sender:** The message sender created for the message (see [Creating Message Senders](#))
- **Message XSL / Response XSL:** XSL files used to transform your message and the response to the message into the appropriate format used by the head end system (Message XSL) and Smart Grid Gateway (Response XSL). Each Smart Grid Gateway adapter includes XSL files for each type of outbound communication.

See [External Systems](#) in the *Administrative User Guide* for more information about creating external systems.

Itron OpenWay XSL Files

The table below lists the XSL provided for use with outbound message types based on the outbound message business objects provided with the Itron OpenWay adapter.

Outbound Message Business Object	Message XSL	Response XSL
Outbound Message for Itron Commission (D8-ItronCommissionOutboundMsg)	D8-CommissionRequest.xml	D8-CommissionResponse.xml
Outbound Message for Itron Decommission (D8-ItronDecommissionOutbndMsg)	D8-DecommissionRequest.xml	D8-DecommissionResponse.xml
Outbound Message for Itron connect command (D8-ItronRemoteConnectOutbndMsg)	D8-ReconnectRequest.xml	D8-ReconnectResponse.xml
Outbound Message for Itron connect result command (D8-ItronRemoteCntRsltOutMsg)	D8-GetReconnectRsRequest.xml	D8-GetReconnectRsResponse.xml
Outbound Message for Itron disconnect command (D8-ItronRemoteDisconnectOutMsg)	D8-DisconnectRequest.xml	D8-DisconnectResponse.xml
Outbound Message for Itron disconnect result command (D8-ItronRemoteDcntRsltOutMsg)	D8-GetDisconnectRsRequest.xml	D8-GetDisconnectRsResponse.xml
Outbound Message for Itron Contingency Read command (D8-ItronOnDemandReadOutbndMsg)	D8-ContRdByEndptsRequest.xml	D8-ContRdByEndptsResponse.xml
O/B Msg for Itron Contingency Read Result (D8-ItronOnDemandReadRsltOBMsg)	D8-GetContRdByEndptsRsReq.xml	D8-GetContRdByEndptsRsResp.xml
Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpOBMsg)	D8-InterrogateByGroupReq.xml	D8-InterrogateByGroupResp.xml
Outbound Message for Itron Schedule Read Result command (D8-ItronInterrogateByGrpRsltOB)	D8-GetIntByGroupRsRequest.xml	D8-GetIntByGroupRsResponse.xml
Outbound Message for Itron Device status check	D8-PingByEndpointsRequest.xml	D8-PingByEndpointsResponse.xml

Outbound Message Business Object	Message XSL	Response XSL
(D8-ItronDvcStatusChkOutbndMsg)		
O/B Msg for Itron DeviceStatusCheck Result	D8-GetPingByEndptsRsReq.xml	D8-GetPingByEndptsRsResp.xml
(D8-ItronDvcStatusChkRsltOBMsg)		
Outbound Message for Itron Multi device status check	D8-PingByEndpointsRequest.xml	D8-PingByEndpointsResponse.xml
(D8-ItronDvcStChkMtDvcOutbndMsg)		
O/B Message for Itron MultiDeviceStatusCheck Result	D8-GetPingByEndptsRsReq.xml	D8-GetPingByEndptsRsResp.xml
(D8-ItronDvcStChkMtDvcRsltOBMsg)		
Outbound Message for Itron Detect Load Side Voltage	D8-DetLSVByMeterRequest.xml	D8-DetLSVByMeterResponse.xml
(D8-ItronDetectLoadSideVolOBMsg)		
Outbound Message for LoadCheckResult Cmd	D8-GetDetLSVByMeterRsReq.xml	D8-GetDetLSVByMeterRsResp.xml
(D8-ItronDetLSVoltMtrRsltOutMsg)		
Outbound Message for Itron Read Disconnect State	D8-RdDiscStByMtrsRequest.xml	D8-RdDiscStByMtrsResponse.xml
D8-ItronReadDisconStateOutMsg		
Outbound Message for ReadDisconStateMeter Cmd	D8-GetRdDiscStByMtrsRsReq.xml	D8-GetRdDiscStByMtrsRsResp.xml
D8-ItronRdDiscStByMtrRsltOutMsg		

Silver Spring Networks XSL Files

The table below lists the XSL provided for use with outbound message types based on the outbound message business objects provided with the Silver Spring Networks adapter.

Outbound Message Business Object	Message XSL	Response XSL
SSN - Find Device Outbound Message	D7-FindDeviceRequest.xml	D7-FindDeviceResponse.xml
D7-FindDeviceOutboundMsg		
SSN - Get Job Status Outbound Message	D7-GetJobStatusRequest.xml	D7-GetJobStatusResponse.xml
D7-GetJobStatusOutboundMsgType		
SSN - Replace Location	D7-ReplaceLocationRequest.xml	D7-ReplaceLocationResponse.xml
(D7-ReplaceLocationDR)		
SSN - Replace Device At Location (Decomm)	D7-RepDvcAtLocRequest.xml	D7-RepDvcAtLocResponse.xml
(D7-ReplDeviceAtLocForDecommDR)		
SSN - Connect or Disconnect	D7-AddRemProvJobRequest.xml	D7-AddRemProvJobResponse.xml
(D7-ConnectDisconnectDR)		
SSN - Connect Disconnect Results	D7-GetRemProvRsByJobIDReq.xml	D7-GetRemProvRsByJobIDResp.xml
(D7-ConnectDisconnectResultDR)		
SSN - Add Meter Read Job Scalar OB Msg	D7-AddMtrRdJobScRequest.xml	D7-AddMtrRdJobScResponse.xml
D7-AddMeterReadJobScalarOBMsg		
SSN - GetMeterReadResults(Scalar) By JobId	D7-GetMtrRdRsByJobIDReq.xml	D7-GetMtrRdRsByJobIDResp.xml
D7-GetSclrMtrRdRstByJobIdOBMsg		
SSN - AddMeterReadJob Interval OB Msg	D7-AddMtrRdJobIntRequest.xml	D7-AddMtrRdJobIntResponse.xml

Outbound Message Business Object	Message XSL	Response XSL
D7-GetIntMtrRdRsltByJobIdOBMsg		
SSN - GetMeterReadResults(Interval) By JobId D7-GetMtrRdRsltJobIdOBMsgTyp	D7-GetMtrRdRsByJobIDReq.xsl	D7-GetMtrRdRsByJobIDResp.xsl
SSN - Add Ping Job (D7-AddPingJobDR)	D7-AddPingJobRequest.xsl	D7-AddPingJobResponse.xsl
SSN - Ping Results (D7-PingResultsDR)	D7-GetMtrRdRsByJobIDReq.xsl	D7-GetMtrRdRsByJobIDResp.xsl

Configuring Processing Methods

In order to send smart meter commands to a head end system, appropriate processing methods must be configured on the head end system record. The tables below list the details appropriate to configuring processing methods for each command.

This table includes the following:

- **Command:** The command you wish to configure. When a command is initiated for a device, the system creates a command activity.
- **Processing Role:** The Processing Role appropriate for the command to be configured.
- **Business Object:** The outbound communication business object to be created by the command activity. Note that most commands have separate business objects for the initial command request and the result request.
- **Outbound Message Business Object** The business object that should be used when creating outbound message types for each command. Note that most commands use separate business objects for the initial outbound message type and the result outbound message type.

Itron OpenWay Processing Methods

This table lists the details appropriate to configuring processing methods for each command supported for the Itron OpenWay head end system.

Command	Processing Role	Business Object	Outbound Message Business Object
Device Commissioning	Device Registration	Itron - Add Meter Definition (D8-AddMeterDefinitionsDR)	Outbound Message for Itron Commission D8-ItronCommissionOutboundMsg
Device Decommissioning	Device Deregistration	Itron - Deregister Meter (D8-DeregisterMeterDR)	Outbound Message for Itron Decommission D8-ItronDecommissionOutbndMsg
Remote Connect	Remote Connect	Itron - Reconnect Meter (Remote Connect) D8-ReconnectMeterDR)	Outbound Message for Itron connect command D8-ItronRemoteConnectOutbndMsg
	Get Remote Connect Result	Itron - Reconnect Meter Result (D8-ReconnectMeterResult)	Outbound Message for Itron connect result command (D8-ItronRemoteCntRsltOutMsg)
Remote Disconnect	Remote Disconnect	Itron - Disconnect Meter (D8-DisconnectMeterDR)	Outbound Message for Itron disconnect command D8-ItronRemoteDisconnectOutMsg
	Get Remote Disconnect Result	Itron - Disconnect Meter Result (D8-DisconnectMeterResult)	Outbound Message for Itron disconnect result command (D8-ItronRemoteDcntRsltOutMsg)
On-Demand Read (Scalar)	On-Demand Read (Scalar)	Itron - Contingency Read (Scalar) (D8-ReadScalarDR)	Outbound Message for Itron Contingency Read command D8-ItronOnDemandReadOutbndMsg

Command	Processing Role	Business Object	Outbound Message Business Object
	Get On-Demand Read Result	Itron - On Demand Read Result (D8-ReadOnDemandReadResultDR)	O/B Msg for Itron Contingency Read Result (D8-ItronOnDemandReadRsltOBMsg)
On-Demand Read (Interval)	On-Demand Read (Interval)	Itron - Contingency Read (Interval) (D8-ReadIntervalDR)	Outbound Message for Itron Contingency Read command (D8-ItronOnDemandReadOutbndMsg)
	Get On-Demand Read Result	Itron - On Demand Read Result (D8-ReadOnDemandReadResultDR)	O/B Msg for Itron Contingency Read Result (D8-ItronOnDemandReadRsltOBMsg)
Scheduled Read (Scalar)	Send Schedule Read Request	Itron - Interrogate by Group (Scalar) (D8-InterrogateByGroupDR)	Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpOBMsg)
	Get Schedule Read Result	Itron - Interrogate by Group Results (D8- InterrogateByGroupResultDR)	Outbound Message for Itron Schedule Read Result command (D8-ItronInterrogateByGrpRsltOB)
Scheduled Read (Interval)	Send Schedule Read Request	Itron - Interrogate by Group (Interval) (D8-InterrogateByGroupDR)	Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpOBMsg)
	Get Schedule Read Result	Itron - Interrogate by Group Results (D8- InterrogateByGroupResultDR)	Outbound Message for Itron Schedule Read Result command (D8-ItronInterrogateByGrpRsltOB)
Device Status Check	Device Status Check	Itron - Ping by Endpoints (Status Check) (D8-PingByEndpointsDR)	Outbound Message for Itron Device status check (D8-ItronDvcStatusChkOutbndMsg)
	Get Device Status Check Result	Itron - Ping By Endpoints Result (D8- PingByEndpointsResultDR)	O/B Msg for Itron DeviceStatusCheck Result (D8-ItronDvcStatusChkRsltOBMsg)
Multi-Device Status Check	Multi-Device Status Check	Itron - Ping By Endpoints Multi-Device (D8-PingByEndpointsMultiDvcDR)	Outbound Message for Itron Multi device status check (D8-ItronDvcStChkMtDvcOutbndMsg)
	Get Multi-Device Status Check Result	Itron – Ping By Endpoints Multi Dvc Result (D8- PingByEndpointsMDRResultDR)	O/B Message for Itron MultiDeviceStatusCheck Result (D8-ItronDvcStChkMtDvcRsltOBMsg)
Load Check	Load Check	Itron - Detect Load Side Voltage (D8-DetectLoadSideVoltageByMtrDR)	Outbound Message for Itron Detect Load Side Voltage (D8-ItronDetectLoadSideVolOBMsg)
	Get Load Check Results	Itron – Detect Load Side Voltage Result (D8- DetLoadSideVoltageMtrRsltDR)	Outbound Message for LoadCheckResult Cmd (D8-ItronDetLSVoltMtrRsltOutMsg)

Silver Spring Networks Processing Methods

This table lists the details appropriate to configuring processing methods for each command supported for the Silver Spring Networks head end system.

Command	Processing Role	Business Object	Outbound Message Business Object
Device Commissioning	Device Registration	SSN - Replace Location (D7-ReplaceLocationDR)	SSN - Replace Location (Comm) OB Message (D7-ReplaceLocationOBMsg)
Device Decommissioning	Device Removal	SSN - Replace Device At Location (Decomm) (D7- ReplDeviceAtLocForDecommDR)	SSN - Replace Device At Loc O/B Message: (D7-ReplaceDeviceAtLocOBMsg)
Remote Connect	Remote Connect	SSN - Connect or Disconnect (D7-ConnectDisconnectDR)	SSN - Connect Disconnect OB Message (D7-ConnectDisconnectOBMsg)

Command	Processing Role	Business Object	Outbound Message Business Object
	Get Remote Connect Result	SSN - Connect Disconnect Results (D7-ConnectDisconnectResultDR)	SSN - GetConnectDisconnectResult OB Message (D7-GetCntDiscntResultOBMsg)
Remote Disconnect	Remote Disconnect	SSN - Connect or Disconnect (D7-ConnectDisconnectDR)	SSN - Connect Disconnect OB Message (D7-ConnectDisconnectOBMsg)
	Get Remote Disconnect Result	SSN - Connect Disconnect Results (D7-ConnectDisconnectResultDR)	SSN - GetConnectDisconnectResult OB Message (D7-GetCntDiscntResultOBMsg)
On-Demand Read (Scalar)	On-Demand Read (Scalar)	SSN - Add Meter Read Job (Scalar) (D7-AddMeterReadJobScalarDR)	SSN - Add Meter Read Job Scalar OB Msg Type D7-AddMeterReadJobScalarOBMsg
	Get On-Demand Read Result (Scalar)	SSN - Meter Read Results (Scalar) (D7-MeterReadResultsScalar)	SSN - GetMeterReadResults(Scalar) By JobId (D7-GetSMtrRdRsltJobIdOBMsgTyp)
On-Demand Read (Interval)	On-Demand Read (Interval)	SSN - Add Meter Read Job (Interval) (D7-AddMeterReadJobIntervalDR)	SSN - AddMeterReadJob Interval OB Msg Type (D7-AddMtrReadJobIntervalOBMsg)
	Get On-Demand Read Result (Interval)	SSN - Meter Read Results (Interval) (D7-MeterReadResultsInterval)	SSN - GetMeterReadResults(Interval) By JobId (D7-GetIMtrRdRsltJobIdOBMsgTyp)
Device Status Check	Device Status Check	SSN - Add Ping Job (D7-AddPingJobDR)	SSN - Add Ping Job OB Message (D7-AddPingJobOBMsg)
	Get Device Status Check Result	SSN - Ping Results (D7-PingResultsDR)	SSN - Get Ping Results O/B Message (D7-GetPingResultsOBMsg)

Receiving Inbound Communications

Receiving inbound communications from a head end system involves configuring the following:

- **Inbound Web Services:** These services are used to receive inbound communications from external systems. See [Inbound Web Services](#) in the *Administrative User Guide* for more information.
- **Master Configurations:** Defines configuration settings for individual adapters.

Inbound Web Services

Inbound web services are used to receive inbound communications from external systems. The tables below list the inbound web services provided with each Smart Grid Gateway adapter.

Itron OpenWay Inbound Web Services

The table below lists the inbound web service provided with the Itron OpenWay Adapter.

Name	Description
D8-RequestStatusChangedService	Itron RequestStatusChangedService: Use to receive "status changed" messages from the Itron OpenWay head end system. This service creates instances of the "Itron – StatusChanged" (D8-StatusChanged) inbound communication business object for each message.
D8-DataSubscriberService	Itron DataSubscriberService: Used to receive usage and device event payloads from the Itron OpenWay head end system.

Name	Description
D8-ExceptionSubscriberService	<p>This service invokes the “Itron – DataArrived Request” (D8_DATAARR) service script, which routes the usage or device event payload to Object storage, based on the configuration of the Itron Master Configuration and the File Storage extendable lookup.</p> <p>Itron ExceptionSubscriberService: Used to receive exceptions from the Itron OpenWay head end system.</p> <p>This service invokes the “Itron – ExceptionsArrived Request” (D8_EXCPARR) routes exceptions to Object storage, based on the configuration of the Itron Master Configuration and the File Storage extendable lookup.</p>

Master Configurations

Master configurations define configuration settings for individual adapters. The sections below provide details for the master configuration provided for each Smart Grid Gateway adapter.

Itron OpenWay Master Configuration

The “Itron – Master Config” master configuration defines details used by the Itron OpenWay inbound web services, including the following:

- **Command Status Changed URL Configuration:** Used to define URL configuration for StatusChangedService messages.
 - **Status Changed Service URL Script:** Used to define the service script used to derive the URL for StatusChangedService messages. When determining the URL, the system initially checks if a script has been configured on this field, and if so, that script is used. If this field is blank (which is the default), the Determine Application URL (D1-DetStChSU) script is used to determine the URL.
 - **Default Status Changed Service URL:** The default URL for “Itron RequestStatusChangedService” messages.
 - **Commands:** Command-specific URLs for “Itron RequestStatusChangedService” messages.
- **Arrived Data Save Locations:** Used to define the locations where payloads and exceptions are routed by the DataArrived and ExceptionArrived inbound web services, including:
 - **File Storage:** The location where payloads and exceptions are routed. This should be a File Location Extendable Lookup value.
 - **Bucket/Folder Name:** The specific bucket or folder within the file storage location.
 - **Filename Generation Script:** The service script used to generate file names for payloads and exceptions. The base package include the following scripts that can be used:
 - Default Filename Generator
 - DataArrived Filename Generator

Silver Spring Networks Version Master Configuration

The “SSN – Version Master Config” master configuration specifies the version of the Silver Spring Networks head end system with which the system is communicating:

- **SSN Version:** Used to define the version of the Silver Spring Networks head end system. Options include:
 - SSN Version 4.4
 - SSN Version 4.7
 - SSN Version 4.10

- **SSN - Get Job Status Configuration:** Used to specify the **Retry Limit** and **Wait Duration (in Seconds)** for the Get Job Status requests sent by outbound communications.
