This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software, software documentation, data (as defined in the Federal Acquisition Regulation), or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software," "commercial computer software documentation," or "limited rights data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle®, Java, and MySQL are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Understanding Oracle GoldenGate for Big Data	1-1
Understanding the Java Adapter and Oracle GoldenGate for Big Data	1-1
Oracle GoldenGate VAM Message Capture	1-1
Oracle GoldenGate Java Delivery	1-3
Delivery Configuration Options	1-4
Adapter Integration Options	1-4
Using Oracle GoldenGate Java Adapter Properties	1-6
Monitoring Performance	1-7
What's Supported in Oracle GoldenGate for Big Data?	1-8
Verifying Certification and System Requirements	1-8
Understanding Handler Compatibility	1-8
What are the Additional Support Considerations?	1-9
Dependency Downloader	1-10
Dependency Downloader Setup	1-11
Running the Dependency Downloader Scripts	1-11
Dependency Downloader Scripts	1-13

## 2 Get Started

Getting Started with Oracle GoldenGate (Microservices Architecture) for Big Data	2-1
Working With Deployments	2-1
About Oracle GoldenGate Properties Files	2-2
Parameter Files	2-2
Using the Admin Client	2-2
Controlling Oracle GoldenGate (Microservices Architecture) Processes	2-3

Getting Started with Oracle GoldenGate (Classic) for Big Data	2-3
Verifying Certification, System, and Interoparability Requirements	2-3
What are the Additional Support Considerations?	2-4
About Oracle GoldenGate Properties Files	2-6
Parameter Files	2-6
Setting Up the Java Runtime Environment	2-6
Configuring Java Virtual Machine Memory	2-7
Using GGSCI	2-8
Grouping Transactions	2-8
Controlling Oracle GoldenGate (Classic) Processes	2-8

# 3 Prepare

Preparing for Installation	3-1
Downloading Oracle GoldenGate for Big Data	3-1
Installation Overview	3-2
Contents of the Installation ZIP File	3-2
Using the Generic Build of Oracle GoldenGate	3-3
Considerations for Using a Custom Build for a Big Data Instance of Oracle	
GoldenGate	3-3
Installing to a Non-Generic Instance of Oracle GoldenGate	3-3
Directory Structure	3-4
Setting up Environmental Variables	3-5
Java on Linux/UNIX	3-6
Java on Windows	3-6

# 4 Install

Installing Oracle GoldenGate Microservices for Big Data	4-1
Installing Oracle GoldenGate MA for Big Data Using the UI	4-2
Silent Installation	4-2
Setting Up Secure or Non-Secure Deployments	4-3
How to Add Secure or Non-Secure Deployments	4-3
How to Remove a Deployment	4-9
Installing Oracle GoldenGate Classic for Big Data	4-12
Installation Steps	4-12
Setting Up Oracle GoldenGate for Big Data in a High Availability Environment	4-13
Running Oracle GoldenGate for Big Data from a Single Instance	4-13
Running Oracle GoldenGate for Big Data on a Cluster of Servers	4-13
Shared Storage	4-14

# 5 Upgrade

Upgrading Oracle GoldenGate Microservices for Big Data	5-1
Obtaining the Oracle GoldenGate Distribution	5-1
Scope of Upgrade	5-2
Replicat Upgrade Considerations	5-2
Upgrading Oracle GoldenGate Microservices – GUI Based	5-2
Upgrading Oracle GoldenGate Classic for Big Data	5-3
Upgrading by Overwriting the Existing Installation	5-4
Upgrading by Installing into a New Directory	5-4
Switching Existing Extract Processes to Replicat Processes	5-6

# 6 Configure

Configuring Oracle GoldenGate for Big Data	6-1
Running with Replicat	6-1
Configuring Replicat	6-2
Adding the Replicat Process	6-2
Replicat Grouping	6-2
About Replicat Checkpointing	6-3

## Audience

This guide is intended for system administrators who are configuring and running Oracle GoldenGate for Big Data.

# **Documentation Accessibility**

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup? ctx=acc&id=docacc.

#### Accessible Access to Oracle Support

Oracle customers who have purchased support have access to electronic support through My Oracle Support. For information, visit <a href="http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info">http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info</a> or visit <a href="http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs">http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info</a> or visit <a href="http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs">http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info</a> or visit <a href="http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs">http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs</a> if you are hearing impaired.

# Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
monospace	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Understanding the Java Adapter and Oracle GoldenGate for Big Data

### Understanding the Java Adapter and Oracle GoldenGate for Big Data

The Oracle GoldenGate Java Adapter integrates with Oracle GoldenGate instances.

The Oracle GoldenGate product enables you to:

- Capture transactional changes from a source database.
- Sends and queues these changes as a set of database-independent files called the Oracle GoldenGate trail.
- Optionally alters the source data using mapping parameters and functions.
- Applies the transactions in the trail to a target system database.

Oracle GoldenGate performs this capture and apply in near real-time across heterogeneous databases, platforms, and operating systems.

- Oracle GoldenGate VAM Message Capture
- Oracle GoldenGate Java Delivery
- Delivery Configuration Options
- Adapter Integration Options
- Using Oracle GoldenGate Java Adapter Properties
- Monitoring Performance

#### Oracle GoldenGate VAM Message Capture

Oracle GoldenGate VAM Message Capture only works with the Oracle GoldenGate Extract process. Oracle GoldenGate message capture connects to JMS messaging to parse

messages and send them through a VAM interface to an Oracle GoldenGate Extract process that builds an Oracle GoldenGate trail of message data. This allows JMS messages to be delivered to an Oracle GoldenGate system running for a target database. Java 8 is a required dependency for Oracle GoldenGate VAM Message Capture.

Using Oracle GoldenGate JMS message capture requires the dynamically linked shared VAM library that is attached to the Oracle GoldenGate Extract process.

- Message Capture Configuration Options
- Typical Configuration

#### Message Capture Configuration Options

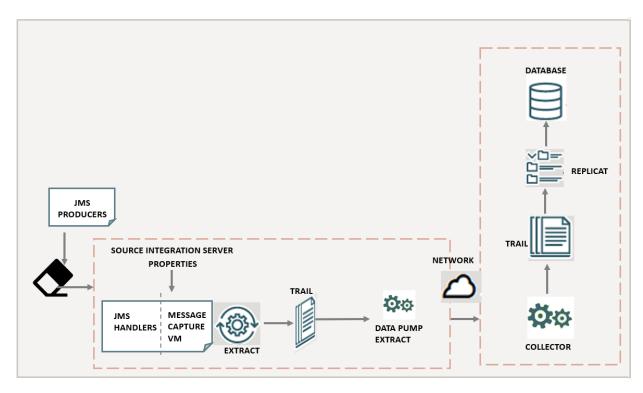

The options for configuring the three parts of message capture are:

- Message connectivity: Values in the property file set connection properties such as the Java classpath for the JMS client, the JMS source destination name, JNDI connection properties, and security information.
- Parsing: Values in the property file set parsing rules for fixed width, comma delimited, or XML messages. This includes settings such as the delimiter to be used, values for the beginning and end of transactions and the date format.
- VAM interface: Parameters that identify the VAM, dll, or so library and a property file are set for the Oracle GoldenGate core Extract process.

#### **Typical Configuration**

The following diagram shows a typical configuration for capturing JMS messages.

#### Figure 1-1 Configuration for JMS Message Capture

In this configuration, JMS messages are picked up by the Oracle GoldenGate for Big Data JMS Handler and transferred using the adapter's message capture VAM to an Extract process. The Extract writes the data to a trail which is sent over the network by a Data Pump Extract to an Oracle GoldenGate target instance. The target Replicat then uses the trail to update the target database.

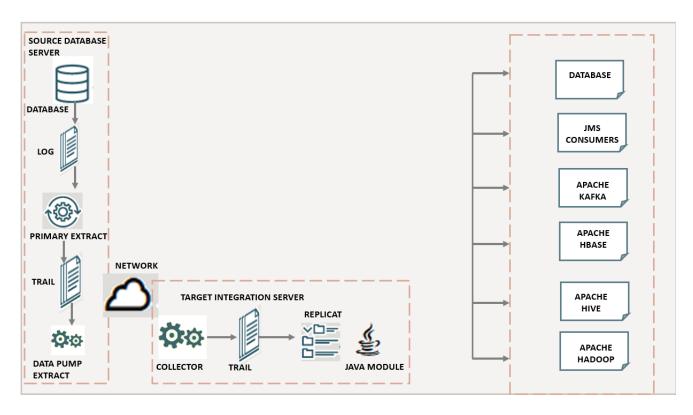

### Oracle GoldenGate Java Delivery

Through the Oracle GoldenGate Java API, transactional data captured by Oracle GoldenGate can be delivered to targets other than a relational database, such as a JMS (Java Message Service), files written to disk, streaming data to a Big Data application, or integration with a custom application Java API. Oracle GoldenGate Java Delivery can work with either an Extract or Replicat process. Using the Oracle GoldenGate Replicat process is considered the best practice. Oracle GoldenGate Java Delivery requires Java 8 as a dependency.

Oracle GoldenGate for Java provides the ability to execute Java code from the Oracle GoldenGate Replicat process. Using Oracle GoldenGate for Java requires the following conditions to be met:

- A dynamically linked or shared library, implemented in C/C++, integrating an extension module of Oracle GoldenGate Replicat process.
- A set of Java libraries (JARs), which comprise the Oracle GoldenGate Java API. This Java framework communicates with the Replicat through the Java Native Interface (JNI).
- Java 8 must be installed and accessible on the machine hosting the Oracle GoldenGate Java Delivery process or processes. Environmental variables must be correctly set to resolve Java and its associated libraries.

#### Figure 1-2 Configuration for Delivering JMS Messages

### **Delivery Configuration Options**

The Java delivery module is loaded by the GoldenGate Replicat process, which is configured using the Replicat parameter file. Upon loading, the Java Delivery module is subsequently configured based on the configuration present in the Adapter Properties file. Application behavior can be customized by:

- Editing the property files; for example to:
  - Set target types, host names, port numbers, output file names, JMS connection settings;
  - Turn on/off debug-level logging, and so on.
  - Identify which message format should be used.
- Records can be custom formatted by:
  - Setting properties for the pre-existing format process (for fixed-length or fielddelimited message formats, XML, JSON, or Avro formats);
  - Customizing message templates, using the Velocity template macro language;
  - (Optional) Writing custom Java code.
- (Optional) Writing custom Java code to provide custom handling of transactions and operations, do filtering, or implementing custom message formats.

There are existing implementations (handlers) for sending messages using JMS and for writing out files to disk. For Big Data targets, there are built in integration handlers to write to supported databases.

There are several predefined message formats for sending the messages (for example, XML or field-delimited); or custom formats can be implemented using templates. Each handler has documentation that describes its configuration properties; for example, a file name can be specified for a file writer, and a JMS queue name can be specified for the JMS handler. Some properties apply to more than one handler; for example, the same message format can be used for JMS and files.

### Adapter Integration Options

There are two major products which are based on the Oracle GoldenGate for Big Data architecture:

- The Oracle GoldenGate Java Adapter is the overall framework. This product allows you to implement custom code to handle Oracle GoldenGate trail records according to their specific requirements. It comes built-in with Oracle GoldenGate File Writer module that can be used for flat file integration purposes.
- Oracle GoldenGate for Big Data. The Oracle GoldenGate for Big Data product contains built-in support to write operation data from Oracle GoldenGate trail records into various Big Data targets (such as, HDFS, HBase, Kafka, Flume, JDBC, Cassandra, and MongoDB). You do not need to write custom code to integrate with Big Data applications. The functionality is separated into handlers that integrate with third party applications and formatters, which transform the data into various formats, such as Avro, JSON, delimited text, and XML. In certain instances, the integration to a third-party tool is proprietary, like the HBase API. In these instances, the formatter exists without an associated handler.

The Oracle GoldenGate Java Adapter and the Oracle GoldenGate for Big Data products have some crossover in functionality so the handler exists without an associated formatter. The following list details the major areas of functionality and in which product or products the functionality is included:

- Read JMS messages and deliver them as an Oracle GoldenGate trail. This feature is included in Oracle GoldenGate for Big Data.
- Read an Oracle GoldenGate trail and deliver transactions to a JMS provider or other messaging system or custom application. This feature is included in Oracle GoldenGate for Big Data products.
- Read an Oracle GoldenGate trail and write transactions to a file that can be used by other applications. This feature is only included in Oracle GoldenGate for Big Data.
- Read an Oracle GoldenGate trail and write transactions to a Big Data targets. The Big Data integration features are only included in Oracle GoldenGate for Big Data product.
- Capturing Transactions to a Trail
- Applying Transactions from a Trail

#### Capturing Transactions to a Trail

Oracle GoldenGate message capture can be used to read messages from a queue and communicate with an Oracle GoldenGate Extract process to generate a trail containing the processed data.

The message capture processing is implemented as a Vendor Access Module (VAM) plug-in to a generic Extract process. A set of properties, rules and external files provide messaging connectivity information and define how messages are parsed and mapped to records in the target Oracle GoldenGate trail.

Currently this adapter supports capturing JMS text messages.

#### Applying Transactions from a Trail

Oracle GoldenGate Java Adapter delivery can be used to apply transactional changes to targets other than a relational database: for example, ETL tools (DataStage, Ab Initio, Informatica), JMS messaging, Big Data Applications, or custom APIs. There are a variety of options for integration with Oracle GoldenGate:

- Flat file integration: predominantly for ETL, proprietary or legacy applications, Oracle GoldenGate File Writer can write micro batches to disk to be consumed by tools that expect batch file input. The data is formatted to the specifications of the target application such as delimiter separated values, length delimited values, or binary. Near real-time feeds to these systems are accomplished by decreasing the time window for batch file rollover to minutes or even seconds.
- Messaging: transactions or operations can be published as messages (for example, in XML) to JMS. The JMS provider is configurable to work with multiple JMS implementation; examples include ActiveMQ, JBoss Messaging, TIBCO, Oracle WebLogic JMS, WebSphere MQ, and others.
- Java API: custom handlers can be written in Java to process the transaction, operation and metadata changes captured by Oracle GoldenGate on the source system. These custom Java handlers can apply these changes to a third-party Java API exposed by the target system.

 Big Data integration: writing transaction data from the source trail files into various Big Data targets can be achieved by means of setting configuration properties. The Oracle GoldenGate for Big Data product contains built in Big Data handlers to write to HDFS, HBase, Kafka, and Flume targets.

All four options have been implemented as extensions to the core Oracle GoldenGate product.

- For Java integration using either JMS or the Java API, use Oracle GoldenGate for Java.
- For Big Data integration, you can configure Oracle GoldenGate Replicat to integrate with the Oracle GoldenGate Big Data module. Writing to Big Data targets in various formats can be configured using a set of properties with no programming required.

### Using Oracle GoldenGate Java Adapter Properties

The Oracle GoldenGate Java Adapters, Big Data Handlers, and formatters are configured through predefined properties. These properties are stored in a separate properties file called the Adapter Properties file. Oracle GoldenGate functionality requires that the Replicat process configuration files must be in the dirprm directory and that configuration files must adhere to the following naming conventions:

Replicat process name.prm

It is considered to be a best practice that the Adapter Properties files are also located in the dirprm directory and that the Adapter Properties files adhere to one of the following naming conventions:

```
Replicat process name.props
```

or

Replicat process name.properties

- Values in Property Files
- Location of Property Files
- Using Comments in the Property File
- Variables in Property Names

#### Values in Property Files

All properties in Oracle GoldenGate for Big Data property files are of the form:

property.name=value

#### Location of Property Files

Sample Oracle GoldenGate for Big Data properties files are installed to the AdapterExamples subdirectory of the installation directory. These files should be copied, renamed, and the contents modified as needed and then moved to the dirprm subdirectory.

You must specify each of these property files through parameters or environmental variables as explained below. These settings allow you to change the name or

location, but it is recommended that you follow the best practice for naming and location.

The following sample files are included:

• ffwriter.properties

This stores the properties for the file writer. It is set with the CUSEREXIT parameter.

• jmsvam.properties

This stores properties for the JMS message capture VAM. This is set with the Extract VAM parameter.

• javaue.properties

This stores properties for the Java application used for message delivery. It is set through the environmental variable:

The name and location of the Adapter properties file is resolved by configuration in the Replicat process properties file.

The following explains how to resolve the name and location of the Adapter Properties file in the Replicat process.

TARGETDB LIBFILE libggjava.so SET property=dirprm/javaue.properties

#### Using Comments in the Property File

Comments can be entered in the properties file with the # prefix at the beginning of the line. For example:

```
# This is a property comment
some.property=value
```

Properties themselves can also be commented. This allows testing configurations without losing previous property settings.

#### Variables in Property Names

Some properties have a variable in the property name. This allows identification of properties that are to be applied only in certain instances.

For example, you can declare more than one file writer using goldengate.flatfilewriter.writers property and then use the name of the file writer to set the properties differently:

1. Declare two file writers named writer and writer2:

goldengate.flatfilewriter.writers=writer,writer2

2. Specify the properties for each of the file writers:

```
writer.mode=dsv
writer.files.onepertable=true
writer2.mode=ldv
writer2.files.onpertable=false
```

### **Monitoring Performance**

For more information about monitoring the performance, see Monitor Performance from the Performance Metrics Service in Using Oracle GoldenGate Microservices Architecture.

# What's Supported in Oracle GoldenGate for Big Data?

- Verifying Certification and System Requirements
   Oracle recommends that you use the certification matrix and system requirements documents with each other to verify that your environment meets the requirements for installation.
- Understanding Handler Compatibility
- What are the Additional Support Considerations?

## Verifying Certification and System Requirements

Oracle recommends that you use the certification matrix and system requirements documents with each other to verify that your environment meets the requirements for installation.

#### 1. Verifying that your environment meets certification requirements:

Make sure that you install your product on a supported hardware and software configuration. See the certification document for your release on the *Oracle Fusion Middleware Supported System Configuration* page.

Oracle has tested and verified the performance of your product on all certified systems and environments. Whenever new certifications are released, they are added to the certification document right away. New certifications can be released at any time. Therefore, the certification documents are kept outside the documentation libraries and are available on Oracle Technology Network.

#### 2. Using the system requirements document to verify certification:

Oracle recommends that you use the *Oracle Fusion Middleware Supported System Configuration* document to verify that the certification requirements are met. For example, if the certification document indicates that your product is certified for installation on 64-Bit Oracle Linux 6.5, use this document to verify that your system meets the required minimum specifications. These include disk space, available memory, specific platform packages and patches, and other operating system-specific requirements. System requirements can change in the future. Therefore, the system requirement documents are kept outside of the documentation libraries and are available on Oracle Technology Network.

#### 3. Verifying interoperability among multiple products:

To learn how to install and run multiple Fusion Middleware products from the same release or mixed releases with each other, see *Oracle Fusion Middleware Supported System Configuration* in *Oracle Fusion Middleware Understanding Interoperability and Compatibility*.

The compatibility of the Oracle GoldenGate for Big Data Handlers with the various data collections, including distributions, database releases, and drivers is included in the certification document.

### Understanding Handler Compatibility

For more information, see the Certification Matrix.

### What are the Additional Support Considerations?

This section describes additional Oracle GoldenGate for Big Data Handlers additional support considerations.

#### **Pluggable Formatters—Support**

The handlers support the Pluggable Formatters as follows:

- The HDFS Handler supports all of the pluggable formatters.
- Pluggable formatters are not applicable to the HBase Handler. Data is streamed to HBase using the proprietary HBase client interface.
- The Kafka Handler supports all of the pluggable formatters.
- The Kafka Connect Handler does *not* support pluggable formatters. You can convert data to JSON or Avro using Kafka Connect data converters.
- The Kinesis Streams Handler supports all of the pluggable formatters described in the Using the Pluggable Formatters topic in the Oracle GoldenGate for Big Data User Guide.
- The Cassandra, MongoDB, and JDBC Handlers do not use a pluggable formatter.

#### Java Delivery Using Extract

Java Delivery using Extract is not supported. Support for Java Delivery is only supported using the Replicat process. Replicat provides better performance, better support for checkpointing, and better control of transaction grouping.

#### MongoDB Handler—Support

- The handler can only replicate unique rows from source table. If a source table has no primary key defined and has duplicate rows, replicating the duplicate rows to the MongoDB target results in a duplicate key error and the Replicat process abends.
- Missed updates and deletes are undetected so are ignored.
- Untested with sharded collections.
- Only supports date and time data types with millisecond precision. These values from a trail with microseconds or nanoseconds precision are truncated to millisecond precision.
- The datetime data type with timezone in the trail is not supported.
- A maximum BSON document size of 16 MB. If the trail record size exceeds this limit, the handler cannot replicate the record.
- No DDL propagation.
- No truncate operation.

#### JDBC Handler—Support

• The JDBC handler uses the generic JDBC API, which means any target database with a JDBC driver implementation should be able to use this handler. There are a myriad of different databases that support the JDBC API and Oracle cannot certify the JDBC Handler for all targets. Oracle has certified the JDBC Handler for the following RDBMS targets:

- Oracle
- MySQL
- Netezza
- Redshift
- Greenplum
- The handler supports Replicat using the REPERROR and HANDLECOLLISIONS parameters, see *Reference for Oracle GoldenGate*.
- The database metadata retrieved through the Redshift JDBC driver has known constraints, see *Release Notes for Oracle GoldenGate for Big Data*.

Redshift target table names in the Replicat parameter file must be in lower case and double quoted. For example:

```
MAP SourceSchema.SourceTable, target "public"."targetable";
```

- DDL operations are ignored by default and are logged with a WARN level.
- Coordinated Replicat is a multithreaded process that applies transactions in parallel instead of serially. Each thread handles all of the filtering, mapping, conversion, SQL construction, and error handling for its assigned workload. A coordinator thread coordinates transactions across threads to account for dependencies. It ensures that DML is applied in a synchronized manner preventing certain DMLs from occurring on the same object at the same time due to row locking, block locking, or table locking issues based on database specific rules. If there are database locking issue, then Coordinated Replicat performance can be extremely slow or pauses.

#### **DDL Event Handling**

Only the TRUNCATE TABLE DDL statement is supported. All other DDL statements, suh as CREATE TABLE, CREATE INDEX, and DROP TABLE are ignored. You can use the TRUNCATE statements one of these ways:

- In a DDL statement, TRUNCATE TABLE, ALTER TABLE TRUNCATE PARTITION, and other DDL TRUNCATE statements. This uses the DDL parameter.
- Standalone TRUNCATE support, which just has TRUNCATE TABLE. This uses the GETTRUNCATES parameter.

# **Dependency Downloader**

Utility scripts are located in the {OGGBD install}/DependencyDownloader directory to download client dependency jars for the various supported Oracle GoldenGate for Big Data integrations.

These scripts use Java and Apache Maven to download the dependency jars from the Maven Central Repository and other publicly available repositories (Hortonworks, Cloudera, Confluent).

#### **Topics:**

- Dependency Downloader Setup
- Running the Dependency Downloader Scripts

Dependency Downloader Scripts

### Dependency Downloader Setup

To complete the Dependency Downloader setup:

1. To verify that Java is installed, execute the following from the command line: java - version.

#### Note:

The Dependency Downloader utility scripts require Java to run. Ensure that Oracle Java is downloaded and is available in the PATH on the machine where the scripts are installed.

- 2. Configure the proxy settings in the following script: {OGGBD install}/ DependencyDownloader/config proxy.sh. Following are the 2 entries in this file:
  - #export PROXY\_SERVER\_HOST=www-proxy-hqdc.us.oracle.com
  - #export PROXY\_SERVER\_PORT=80

To configure the proxy settings:

- a. Uncomment the configuration settings. (remove the # at beginning of the lines).
- b. Change the host name and port number to your correct proxy server settings.

#### Note:

Most companies maintain a private network which in turn has a network firewall to shield it from the public Internet. Additionally, most companies maintain a forwarding proxy server which serves as a gateway between the customer's private network and the public Internet. The Dependency Downloader utilities must access Maven repositories, which are available on the Internet. Therefore, you need to supply configuration for HTTP proxy settings in order to download dependency libraries. Proxy servers are identified by host name and port. If you do not know whether your company employs a proxy server or the settings, then contact your IT or network administrators.

The Dependency Downloader uses Bash scripts in order to invoke Maven and download dependencies. The Bash shell is not supported natively from the Windows Command Prompt. You can run the Dependency Downloader scripts on Windows, but it requires the installation of a Unix emulator. A Unix emulator provides a Unix style command line on Windows and supports various flavors of the Unix shells including Bash. An option for Unix emulators is Cygwin, which is available free of charge. After Cygwin is installed, the setup process is the same. Setup and running of the scripts should be done through the Cygwin64 Terminal. See https://www.cygwin.com/.

### Running the Dependency Downloader Scripts

To run the dependency downloader scripts:

- 1. Use a Unix terminal interface navigate to the following directory: {OGGBD install}/DependencyDownloader.
- 2. Execute the following to run the scripts: ./{the dependency script} {version of the dependencies to download}

For example: ./aws.sh 1.11.893

Dependency libraries get downloaded to the following directory:

{OGGBD install}/DependencyDownloader/dependencies/{the dependency name} {the dependency version}.

For example: {OGGBD install}/DependencyDownloader/dependencies/
aws sdk 1.11.893.

Ensure that the version string exactly matches the version string of the dependency which is being downloaded. If a dependency version doesn't exist in the public Maven repository, then it is not possible to download the dependency and running the script results in an error. Most public Maven repositories support a web-based GUI whereby you can browse the supported versions of various dependencies. The exception is the Confluent Maven repository does not support a web-based GUI. This makes downloading dependencies challenging, because the version string is not independently verifiable through a web interface.

After the dependencies are successfully downloaded, you must configure the gg.classpath variable in the Java Adapter properties file to include the dependencies for the corresponding replicat process.

#### Note:

#### **Best Practices**

- **1.** Whenever possible, use the exact version of the client libraries to the server/application integration to which you are connecting.
- 2. Prior to running the Dependency Downloader scripts, independently verify that the version string exists in the repository through the web GUI.

# Dependency Downloader Scripts

Table 1-1	<b>Relevant Handlers/Capture</b>
-----------	----------------------------------

Client	Script	Description	Relevant Handlers/ Capture	Versions Supported	Depende ncy Link
Amazon Web Services SDK	aws.sh	This script downloads the Amazon Web Services (AWS) SDK, which provides client libraries for connectivity to the AWS cloud.	Kinesis Handler S3 Event Handler	1.11.x and 1.12.x	https:// search.ma ven.org/ artifact/ com.amaz onaws/ aws-java- sdk
Google BigQuery	bigquery.s h	This script downloads the required client libraries for Google BigQuery.	BigQuery Handler	1.x and 2.x	https:// search.ma ven.org/ artifact/ com.googl e.cloud/ google- cloud- bigquery
Cassandra DSE (Datastax Enterprise) Client	cassandra_ dse.sh	This script downloads the Cassandra DSE client. Cassandra DSE is the for-purchase version of Cassandra available from Datastax.	Cassandra Handler	2.0.0 and higher	https:// search.ma ven.org/ artifact/ com.datast ax.dse/ dse-java- driver-core
Apache Cassandra Client	cassandra. sh	This script downloads the Apache Cassandra client.	Cassandra Handler	4.0.0 and higher	https:// search.ma ven.org/ artifact/ com.datast ax.oss/ java- driver-core

Client	Script	Description	Relevant Handlers/ Capture	Versions Supported	Depende ncy Link
Cassandra Capture 3x Client	cassandra_ capture_3x .sh	This script downloads all the client libraries needed for Capture from Cassandra 3.x versions.	Cassandra Capture 3x	3.3.1 (used by default)	https:// mvnreposit ory.com/ artifact/ com.datast ax.cassan dra/ cassandra -driver- core/3.3.1
Cassandra Capture 4x Client	cassandra_ capture_4x .sh	This script downloads all the client libraries needed for Capture from Cassandra 4.x versions.	Cassandra Capture 4x	4.14.1 (used by default)	https:// mvnreposit ory.com/ artifact/ com.datast ax.oss/ java- driver- core/ 4.14.1
Cassandra Capture DSE Client	cassandra_ capture_ds e.sh	This script downloads all the client libraries needed for Capture from DSE Cassandra 6.x versions.	Cassandra Capture DSE	4.14.1 (used by default)	https:// mvnreposit ory.com/ artifact/ com.datast ax.oss/ java- driver- core/ 4.14.1
Elasticsearch REST client	elasticsea rch_rest.s h	This script downloads the Elasticsearc h High Level Rest Client.	Elasticsearch Handler	7.x versions are currently supported	https:// search.ma ven.org/ artifact/ org.elastic search.clie nt/ elasticsear ch-rest- high-level- client
Elasticsearch Java Client	elasticsea rch_java.s h	This script downloads the Elasticsearc h Java Client which is the client use by Oracle GoldenGate for Big Data 21.10.0.00 and later.	Elasticsearch Handler	7.x and 8.x	https:// search.ma ven.org/ artifact/ co.elastic. clients/ elasticsear ch-java

#### Table 1-1 (Cont.) Relevant Handlers/Capture

Client	Script	Description	Relevant Handlers/ Capture	Versions Supported	Depende ncy Link
Elasticsearch Transport Client	elasticsea rch_transp ort.sh	This script downloads the Elasticsearc h Transport Client.	Elasticsearch Handler	6.x and 7.x	https:// search.ma ven.org/ artifact/ org.elastic search.clie nt/ transport
Hadoop Azure Client from Cloudera	hadoop_azu re_clouder a.sh	This script downloads the Hadoop Azure client libraries provided by Cloudera. The Hadoop Azure client libraries cannot be loaded along with the Hadoop client because in Cloudera, the version numbers between the two components do not line up perfectly.	<ul> <li>HDFS Handler</li> <li>HDFS Event Handler</li> <li>ORC Event Handler</li> <li>Parquet Event Handler</li> </ul>	2.x and 3.x	https:// repository. cloudera.c om/ artifactory/ cloudera- repos/org/ apache/ hadoop/ hadoop- azure/
Hadoop Client from Cloudera	hadoop_clo udera.sh	This script downloads the Hadoop client libraries provided by Cloudera.	<ul> <li>HDFS Handler</li> <li>HDFS Event Handler</li> <li>ORC Event Handler</li> <li>Parquet Event Handler</li> </ul>	2.x and 3.x	https:// repository. cloudera.c om/ artifactory/ cloudera- repos/org/ apache/ hadoop/ hadoop- client/
Hadoop Client from Hortonworks	hadoop_hor tonworks.s h		<ul> <li>HDFS Handler</li> <li>HDFS Event Handler</li> <li>ORC Event Handler</li> <li>Parquet Event Handler</li> </ul>	2.x and 3.x	https:// repository. mapr.com/ nexus/ content/ groups/ mapr- public/org/ apache/ hadoop/ hadoop- azure/

Table 1-1 (Cont.) Relevant Handlers/Capt	ure
--	-----

Client	Script	Description	Relevant Handlers/ Capture	Versions Supported	Depende ncy Link
MapR Hadoop Client	hadoop_map r.sh	The Hadoop client libraries provided by MapR.	<ul> <li>HDFS Handler</li> <li>HDFS Event Handler</li> </ul>	2.7.x	https:// repository. mapr.com/ nexus/ content/ groups/ mapr- public/org/ apache/ hadoop/ hadoop- azure/
Apache Hadoop Client Plus Required Libraries for Azure Connectivity		The Hadoop client including the libraries for connectivity to Azure Data Lake.	<ul> <li>HDFS Handler</li> <li>HDFS Event Handler</li> <li>ORC Event Handler</li> <li>Parquet Event Handler</li> </ul>	2.7.x and higher, and 3.x	https:// search.ma ven.org/ artifact/ org.apach e.hadoop/ hadoop- azure
HBase Client Provided by Cloudera	hbase_clou dera.sh	The HBase client libraries provided by Cloudera.	HBase Handler	1.x and 2.x	https:// repository. cloudera.c om/ artifactory/ cloudera- repos/org/ apache/ hbase/ hbase- client/
HBase Client Provided by Hortonworks	hbase_hort onworks.sh		HBase Handler	1.x and 2.x	https:// repository. mapr.com/ nexus/ content/ groups/ mapr- public/org/ apache/ hbase/
Apache HBase Client	hbase.sh	The HBase client.	HBase Handler	1.x and 2.x	https:// search.ma ven.org/ artifact/ org.apach e.hbase/ hbase- client

#### Table 1-1 (Cont.) Relevant Handlers/Capture

Client	Script	Description	Relevant Handlers/ Capture	Versions Supported	Depende ncy Link
Apache Kafka Client plus Kafka Connect Framework and JSON Converter from Cloudera	kafka_clou dera.sh	The Kafka Client plus libraries for the Kafka Connect framework and the Kafka Connect JSON Converter provided by Cloudera.	<ul> <li>Kafka Handler</li> <li>Kafka Connect Handler</li> <li>Kafka Capture</li> </ul>	0.9.x to current	https:// repository. cloudera.c om/ artifactory/ cloudera- repos/org/ apache/ kafka/ kafka- clients/
Apache Kafka Client plus Kafka Connect Framework and JSON Converter from Hortonworks	kafka_hort onworks.sh	The Kafka Client plus libraries for the Kafka Connect framework and the Kafka Connect JSON Converter provided by Hortonworks	<ul> <li>Kafka Handler</li> <li>Kafka Connect Handler</li> <li>Kafka Capture</li> </ul>	0.9.x to current	https:// repository. mapr.com/ nexus/ content/ groups/ mapr- public/org/ apache/ kafka/
Apache Kafka Client plus Kafka Connect Framework and JSON Converter	kafka.sh	The Kafka Client plus libraries for the Kafka Connect framework and the Kafka Connect JSON Converter.	<ul> <li>Kafka Handler</li> <li>Kafka Connect Handler</li> <li>Kafka Capture</li> </ul>	0.9.x to current	https:// search.ma ven.org/ artifact/ org.apach e.kafka/ kafka- clients

#### Table 1-1 (Cont.) Relevant Handlers/Capture

Client	Script	Description	Relevant Handlers/ Capture	Versions Supported	Depende ncy Link
Confluent Kafka Client plus Kafka Connect Framework and JSON and Avro Converters	kafka_conf luent.sh	The Kafka Client plus libraries for the Kafka Connect framework and the Kafka Connect JSON Converter and the Kafka Connect Avro Converter available from Confluent.	<ul> <li>Kafka Handler</li> <li>Kafka Connect Handler</li> <li>Kafka Capture</li> </ul>	Confluent platform 4.1.0 and higher.	The Confluent Maven repository does not provide a web GUI interface.
MapR Kafka Client	kafka_mapr .sh	The MapR Kafka Client libraries.	Kafka Handler	0.x, 1.x, and 2.x	https:// repository. mapr.com/ nexus/ content/ groups/ mapr- public/org/ apache/ kafka/ kafka- clients/
Confluent Kafka Client plus Kafka Connect Framework and Protobuf Converter	kafka_conf luent_prot obuf.sh	The Kafka Client plus libraries for the Kafka Connect framework and the Kafka Connect Protobuf converter available from Confluent.	<ul> <li>Kafka Handler</li> <li>Kafka Connect Handler</li> </ul>	Confluent 5.x and higher	The Confluent Maven repository does not provide a web GUI interface.
MongoDB Client	mongodb.sh	The MongoDB client libraries.	MongoDB capture	4.4.x	https:// search.ma ven.org/ artifact/ org.mongo db/ mongodb- driver- reactivestr eams

Table 1-1	(Cont.) Relevant Handlers/Capture

Client	Script	Description	Relevant Handlers/ Capture	Versions Supported	Depende ncy Link
Oracle NoSQL SDK Client	oracle_nos ql_sdk.sh	The Oracle NoSQL client libraries.	Oracle NoSQL Handler	5.x	https:// search.ma ven.org/ artifact/ com.oracle .nosql.sdk/ nosqldriver
Oracle OCI Client	oracle_oci .sh	The Oracle OCI client libraries.	Oracle OCI Event Handler	1.x and 2.x	https:// search.ma ven.org/ artifact/ com.oracle .oci.sdk/ oci-java- sdk-full
Apache ORC (Optimized Row Columnar) Client	orc.sh	The Apache ORC client libraries. ORC is built on top of the Hadoop client so the ORC Event Handler needs the Hadoop client in order to run. The Hadoop client needs to be downloaded separately.	ORC Event Handler	1.x	https:// search.ma ven.org/ artifact/ org.apach e.orc/orc- core
Apache Parquet Client	parquet.sh		Parquet Event Handler	1.x	https:// search.ma ven.org/ artifact/ org.apach e.parquet/ parquet- hadoop

#### Table 1-1 (Cont.) Relevant Handlers/Capture

Client	Script	Description	Relevant Handlers/ Capture	Versions Supported	Depende ncy Link
Apache Velocity	velocity.s h	The Velocity libraries were removed from the Oracle GoldenGate for Big Data installation starting from the 21.1 release. This script downloads the libraries required for formatting using Velocity.	Velocity Formatter	1.x	https:// search.ma ven.org/ artifact/ org.apach e.velocity/ velocity
Google Cloud Storage Java SDK	gcs.sh	This script downloads the required client libraries for Google Cloud Storage.	GCS Event Handler	1.x and 2.x	https:// search.ma ven.org/ artifact/ com.googl e.cloud/ google- cloud- storage
MongoDB Capture	mongodb_ca pture.sh	This script downloads the required client libraries for MongoDB capture.	MongoDB Capture	4.x	https:// search.ma ven.org/ artifact/ org.mongo db/ mongodb- driver- reactivestr eams
Synapse JDBC Driver	synapse.sh	This script downloads the Synapse JDBC driver. Additionally, the Hadoop client is also required to stage data to Azure Data Lake.	Synapse Stage and Merge	8.4.1	https:// mvnreposit ory.com/ artifact/ com.micro soft.sqlser ver/mssql- jdbc/ 8.4.1.jre8

#### Table 1-1 (Cont.) Relevant Handlers/Capture

Client	Script	Description	Relevant Handlers/ Capture	Versions Supported	Depende ncy Link
Snowflake JDBC Driver	snowflake. sh	This script downloads the Snowflake JDBC driver. Other client libraries are likely required for staging the data to AWS or Azure cloud.	Snowflake Stage and Merge	3.13.7	https:// search.ma ven.org/ artifact/ net.snowfl ake/ snowflake- jdbc/ 3.13.7/jar
Jedis client for Redis	redis.sh	This script downloads Jedis which is a Redis client.	Redis Handler	4.x	https:// search.ma ven.org/ artifact/ redis.client s/jedis

#### Table 1-1 (Cont.) Relevant Handlers/Capture

## 2 Get Started

- Getting Started with Oracle GoldenGate (Microservices Architecture) for Big Data You can use Oracle GoldenGate Microservices Architecture (MA) to configure and manage your data replication using an HTML user interface. The Oracle GoldenGate MA comprises the following components: Service Manager, Administration Server, Distribution Server, Receiver Server, Performance Metrics Server, and Admin Client.
- Getting Started with Oracle GoldenGate (Classic) for Big Data

# Getting Started with Oracle GoldenGate (Microservices Architecture) for Big Data

You can use Oracle GoldenGate Microservices Architecture (MA) to configure and manage your data replication using an HTML user interface. The Oracle GoldenGate MA comprises the following components: Service Manager, Administration Server, Distribution Server, Receiver Server, Performance Metrics Server, and Admin Client.

For more information about the Oracle GoldenGate MA components, see Components of Oracle GoldenGate Microservices Architecture.

This topic lists the various tasks that you need to preform to set up Oracle GoldenGate (MA) for Big Data integrations with Big Data targets.

Working With Deployments

Adding deployments is the first task in the process of setting up a data replication platform. Deployments are managed from the Service Manager.

- About Oracle GoldenGate Properties Files
- Using the Admin Client

Admin Client is a command line utility (similar to the classic GGSCI utility). It uses the REST API published by the Microservices Servers to accomplish control and configuration tasks in an Oracle GoldenGate deployment.

Controlling Oracle GoldenGate (Microservices Architecture) Processes
 The standard way to control Oracle GoldenGate (MA) processes is through the Admin Client.

## Working With Deployments

Adding deployments is the first task in the process of setting up a data replication platform. Deployments are managed from the Service Manager.

For more information about installing and deploying Oracle GoldenGate (MA) for Big Data, see Installing Oracle GoldenGate Microservices for Big Data in the *Installing and Upgrading Oracle GoldenGate for Big Data* guide.

After you log into your Service Manager instance, you can create deployments or edit existing ones. You can work with multiple deployments from a single Service Manager instance. For

more information about working with deployments, see Working with Service Manager in *Step by Step Data Replication Using Oracle GoldenGate Microservices Architecture* guide.

## About Oracle GoldenGate Properties Files

There are two Oracle GoldenGate properties files required to run the Oracle GoldenGate Java Deliver user exit (alternatively called the Oracle GoldenGate Java Adapter). It is the Oracle GoldenGate Java Delivery that hosts Java integrations including the Big Data integrations. A Replicat properties file is required in order to run either process. The required naming convention for the Replicat file name is the *process\_name.prm*. The exit syntax in the Replicat properties file provides the name and location of the Java Adapter properties file. It is the Java Adapter properties file that contains the configuration properties for the Java adapter include GoldenGate for Big Data integrations. The Replicat and Java Adapters properties files are required to run Oracle GoldenGate for Big Data integrations.

Alternatively the Java Adapters properties can be resolved using the default syntax, *process\_name.properties*. It you use the default naming for the Java Adapter properties file then the name of the Java Adapter properties file can be omitted from the Replicat properties file.

Samples of the properties files for Oracle GoldenGate for Big Data integrations can be found in the subdirectories of the following directory:

GoldenGate install dir/AdapterExamples/big-data

Parameter Files

Most of the Oracle GoldenGate functionality is controlled by the parameters specified in parameter files. A parameter file is a plain text file that is read by an associated Oracle GoldenGate process. Oracle GoldenGate uses two types of parameter files: a GLOBALS file and runtime parameter files.

#### **Parameter Files**

Most of the Oracle GoldenGate functionality is controlled by the parameters specified in parameter files. A parameter file is a plain text file that is read by an associated Oracle GoldenGate process. Oracle GoldenGate uses two types of parameter files: a gLOBALS file and runtime parameter files.

For more information about working with Parameter Files, see Using Oracle GoldenGate Parameter Files in the *Administering Oracle GoldenGate* guide.

## Using the Admin Client

Admin Client is a command line utility (similar to the classic GGSCI utility). It uses the REST API published by the Microservices Servers to accomplish control and configuration tasks in an Oracle GoldenGate deployment.

For more information about working with the Admin Client, see Using the Admin Clientin the *Administering Oracle GoldenGate* guide.

## Controlling Oracle GoldenGate (Microservices Architecture) Processes

The standard way to control Oracle GoldenGate (MA) processes is through the Admin Client.

Typically, the first time that Oracle GoldenGate processes are started in a production setting is during the initial synchronization process (also called instantiation process). However, you need to stop and start the processes at various points as needed to perform maintenance, upgrades, troubleshooting, or other tasks. For more information, see Controlling Oracle GoldenGate Processes in the *Administering Oracle GoldenGate* guide.

## Getting Started with Oracle GoldenGate (Classic) for Big Data

This topic lists the various tasks that you need to preform to set up Oracle GoldenGate (Classic) for Big Data integrations with Big Data targets.

- Verifying Certification, System, and Interoparability Requirements
  Oracle recommends that you use the certification matrix and system requirements
  documents with each other to verify that your environment meets the requirements for
  installation.
- What are the Additional Support Considerations?
- About Oracle GoldenGate Properties Files
- Setting Up the Java Runtime Environment
- Configuring Java Virtual Machine Memory
- Using GGSCI Learn how to use the Oracle GoldenGate Classic Architecture GoldenGate Software Command Interface (GGSCI) commands, options, and review examples.
- Grouping Transactions
- Controlling Oracle GoldenGate (Classic) Processes
   The standard way to control Oracle GoldenGate (Classic) processes is through the GGSCI interface.

## Verifying Certification, System, and Interoparability Requirements

Oracle recommends that you use the certification matrix and system requirements documents with each other to verify that your environment meets the requirements for installation.

1. Verifying that your environment meets certification requirements:

Make sure that you install your product on a supported hardware and software configuration. See the certification document for your release on the *Oracle Fusion Middleware Supported System Configuration* page.

Oracle has tested and verified the performance of your product on all certified systems and environments. Whenever new certifications are released, they are added to the certification document right away. New certifications can be released at any time. Therefore, the certification documents are kept outside the documentation libraries and are available on Oracle Technology Network.

2. Using the system requirements document to verify certification:

Oracle recommends that you use the *Oracle Fusion Middleware Supported System Configurations* document to verify that the certification requirements are met. For example, if the certification document indicates that your product is certified for installation on 64-Bit Oracle Linux 6.5, use this document to verify that your system meets the required minimum specifications. These include disk space, available memory, specific platform packages and patches, and other operating system-specific requirements. System requirements can change in the future. Therefore, the system requirement documents are kept outside of the documentation libraries and are available on Oracle Technology Network.

#### 3. Verifying interoperability among multiple products:

To learn how to install and run multiple Fusion Middleware products from the same release or mixed releases with each other, see Oracle Fusion Middleware Interoperability and Compatibility in *Oracle Fusion Middleware Understanding Interoperability and Compatibility*.

## What are the Additional Support Considerations?

This section describes additional Oracle GoldenGate for Big Data Handlers additional support considerations.

#### **Pluggable Formatters—Support**

The handlers support the Pluggable Formatters as follows:

- The HDFS Handler supports all of the pluggable formatters.
- Pluggable formatters are not applicable to the HBase Handler. Data is streamed to HBase using the proprietary HBase client interface.
- The Kafka Handler supports all of the pluggable formatters.
- The Kafka Connect Handler does *not* support pluggable formatters. You can convert data to JSON or Avro using Kafka Connect data converters.
- The Kinesis Streams Handler supports all of the pluggable formatters described in the Using the Pluggable Formatters topic in the *Oracle GoldenGate for Big Data User Guide*.
- The Cassandra, MongoDB, and JDBC Handlers do not use a pluggable formatter.

#### Java Delivery Using Extract

Java Delivery using Extract is not supported. Support for Java Delivery is only supported using the Replicat process. Replicat provides better performance, better support for checkpointing, and better control of transaction grouping.

#### MongoDB Handler—Support

- The handler can only replicate unique rows from source table. If a source table has no primary key defined and has duplicate rows, replicating the duplicate rows to the MongoDB target results in a duplicate key error and the Replicat process abends.
- Missed updates and deletes are undetected so are ignored.
- Untested with sharded collections.

- Only supports date and time data types with millisecond precision. These values from a trail with microseconds or nanoseconds precision are truncated to millisecond precision.
- The datetime data type with timezone in the trail is not supported.
- A maximum BSON document size of 16 MB. If the trail record size exceeds this limit, the handler cannot replicate the record.
- No DDL propagation.
- No truncate operation.

#### JDBC Handler—Support

- The JDBC handler uses the generic JDBC API, which means any target database with a JDBC driver implementation should be able to use this handler. There are a myriad of different databases that support the JDBC API and Oracle cannot certify the JDBC Handler for all targets. Oracle has certified the JDBC Handler for the following RDBMS targets:
  - Oracle
  - MySQL
  - Netezza
  - Redshift
  - Greenplum
- The handler supports Replicat using the REPERROR and HANDLECOLLISIONS parameters, see *Reference for Oracle GoldenGate*.
- The database metadata retrieved through the Redshift JDBC driver has known constraints, see *Release Notes for Oracle GoldenGate for Big Data*.

Redshift target table names in the Replicat parameter file must be in lower case and double quoted. For example:

MAP SourceSchema.SourceTable, target "public"."targetable";

- DDL operations are ignored by default and are logged with a WARN level.
- Coordinated Replicat is a multithreaded process that applies transactions in parallel instead of serially. Each thread handles all of the filtering, mapping, conversion, SQL construction, and error handling for its assigned workload. A coordinator thread coordinates transactions across threads to account for dependencies. It ensures that DML is applied in a synchronized manner preventing certain DMLs from occurring on the same object at the same time due to row locking, block locking, or table locking issues based on database specific rules. If there are database locking issue, then Coordinated Replicat performance can be extremely slow or pauses.

#### **DDL Event Handling**

Only the TRUNCATE TABLE DDL statement is supported. All other DDL statements, suh as CREATE TABLE, CREATE INDEX, and DROP TABLE are ignored. You can use the TRUNCATE statements one of these ways:

• In a DDL statement, TRUNCATE TABLE, ALTER TABLE TRUNCATE PARTITION, and other DDL TRUNCATE statements. This uses the DDL parameter.

• Standalone TRUNCATE support, which just has TRUNCATE TABLE. This uses the GETTRUNCATES parameter.

## About Oracle GoldenGate Properties Files

There are two Oracle GoldenGate properties files required to run the Oracle GoldenGate Java Deliver user exit (alternatively called the Oracle GoldenGate Java Adapter). It is the Oracle GoldenGate Java Delivery that hosts Java integrations including the Big Data integrations. A Replicat properties file is required in order to run either process. The required naming convention for the Replicat file name is the *process\_name.prm*. The exit syntax in the Replicat properties file provides the name and location of the Java Adapter properties file. It is the Java Adapter properties file that contains the configuration properties for the Java adapter include GoldenGate for Big Data integrations. The Replicat and Java Adapters properties files are required to run Oracle GoldenGate for Big Data integrations.

Alternatively the Java Adapters properties can be resolved using the default syntax, *process\_name.properties*. It you use the default naming for the Java Adapter properties file then the name of the Java Adapter properties file can be omitted from the Replicat properties file.

Samples of the properties files for Oracle GoldenGate for Big Data integrations can be found in the subdirectories of the following directory:

GoldenGate install dir/AdapterExamples/big-data

• Parameter Files

Most of the Oracle GoldenGate functionality is controlled by the parameters specified in parameter files. A parameter file is a plain text file that is read by an associated Oracle GoldenGate process. Oracle GoldenGate uses two types of parameter files: a GLOBALS file and runtime parameter files.

#### **Parameter Files**

Most of the Oracle GoldenGate functionality is controlled by the parameters specified in parameter files. A parameter file is a plain text file that is read by an associated Oracle GoldenGate process. Oracle GoldenGate uses two types of parameter files: a GLOBALS file and runtime parameter files.

For more information about working with Parameter Files, see Using Oracle GoldenGate Parameter Files in the *Administering Oracle GoldenGate* guide.

## Setting Up the Java Runtime Environment

The Oracle GoldenGate for Big Data integrations create an instance of the Java virtual machine at runtime. Oracle GoldenGate for Big Data requires that you install Oracle Java 8 Java Runtime Environment (JRE) at a minimum.

Oracle recommends that you set the JAVA\_HOME environment variable to point to Java 8 installation directory. Additionally, the Java Delivery process needs to load the libjvm.so and libjsig.so Java shared libraries. These libraries are installed as part of the JRE. The location of these shared libraries need to be resolved and the appropriate environmental variable set to resolve the dynamic libraries needs to be set so the libraries can be loaded at runtime (that is, LD LIBRARY PATH, PATH, Or LIBPATH).

## Configuring Java Virtual Machine Memory

One of the difficulties of tuning Oracle GoldenGate for Big Data is deciding how much Java virtual machine (JVM) heap memory to allocate for the Replicat process hosting the Java Adapter. The JVM memory must be configured before starting the application. Otherwise, the default Java heap sizing is used. Specifying the JVM heap size correctly sized is important because if you size it to small, the JVM heap can cause runtime issues:

- A Java Out of Memory exception, which causes the Extract or Replicat process to abend.
- Increased frequency of Java garbage collections, which degrades performance. Java garbage collection invocations de-allocate all unreferenced Java objects resulting in reclaiming the heap memory for reuse.

Alternatively, too much heap memory is inefficient. The JVM reserves the maximum heap memory (-Xmx) when the JVM is launched. This reserved memory is generally not available to other applications even if the JVM is not using all of it. You can set the JVM memory with these two parameters:

- -Xmx The maximum JVM heap size. This amount gets reserved.
- -Xms The initial JVM heap size. Also controls the sizing of additional allocations.

The -Xmx and -Xms properties are set in the Java Adapter properties file as follows:

jvm.bootoptions=-Xmx512m -Xms32m

There are no rules or equations for calculating the values of the maximum and initial JVM heap sizes. Java heap usage is variable and depends upon a number of factors many of which are widely variable at runtime. The Oracle GoldenGate Java Adapter log file provides metrics on the Java heap when the status call is invoked. The information appears in the Java Adapter log4j log file similar to:

INFO 2017-12-21 10:02:02,037 [pool-1-thread-1] Memory at Status : Max: 455.00 MB, Total: 58.00 MB, Free: 47.98 MB, Used: 10.02 MB

You can interpret these values as follows:

- Max The value of heap memory reserved (typically the -Xmx setting reduced by approximately 10% due to overhead).
- Total The amount currently allocated (typically a multiple of the -Xms setting reduced by approximately 10% due to overhead).
- Free The heap memory currently allocated, but free to be used to allocate Java objects.
- Used The heap memory currently allocated to Java objects.

You can control the frequency that the status is logged using the gg.report.time=30sec configuration parameter in the Java Adapter properties file.

You should execute test runs of the process with actual data and review the heap usage logging. Then analyze your peak memory usage and then allocate 25% - 30% more memory to accommodate infrequent spikes in memory use and to make the memory allocation and garbage collection processes efficient.

The following items can increase the heap memory required by the Replicat process:

• Operating in tx mod (For example, gg.handler.name.mode=tx.)

- Setting the Replicat property GROUPTRANSOPS to a large value
- Wide tables
- CLOB or BLOB data in the source
- Very large transactions in the source data

## Using GGSCI

Learn how to use the Oracle GoldenGate Classic Architecture GoldenGate Software Command Interface (GGSCI) commands, options, and review examples.

See GGSCI Command Line Interface Commands in *Command Line Interface Reference for Oracle GoldenGate*.

## **Grouping Transactions**

The principal way to improve performance in Oracle GoldenGate for Big Data integrations is using transaction grouping. In transaction grouping, the operations of multiple transactions are grouped together in a single larger transaction. The application of a larger grouped transaction is typically much more efficient than the application of individual smaller transactions. Transaction grouping is possible with the Replicat process discussed in Running with Replicat.

## Controlling Oracle GoldenGate (Classic) Processes

The standard way to control Oracle GoldenGate (Classic) processes is through the GGSCI interface.

Typically, the first time that Oracle GoldenGate processes are started in a production setting is during the initial synchronization process (also called instantiation process). However, you need to stop and start the processes at various points as needed to perform maintenance, upgrades, troubleshooting, or other tasks. For more information, see Controlling Oracle GoldenGate Processes in the *Administering Oracle GoldenGate* guide.

## 3 Prepare

Preparing for Installation

## **Preparing for Installation**

Prepare your Java environment by ensuring that you have the correct version of Java installed, and that the environmental variables have been set up and configured correctly.

- Downloading Oracle GoldenGate for Big Data
- Installation Overview
- Directory Structure
- Setting up Environmental Variables

## Downloading Oracle GoldenGate for Big Data

Oracle GoldenGate (both Classic and Microservices) for Big Data are available for Windows, Linux, and UNIX. To download, first visit the Oracle support site to see if there is a patch available for your operating system and architecture.

#### Note:

If you are not planning to use the generic build included in the installation, ensure that the major release of the Oracle GoldenGate for Big Data build you download matches (or is known to be compatible with) the major release of the Oracle GoldenGate instance that will be used with it.

- 1. Navigate to http://support.oracle.com.
- 2. Sign in with your Oracle ID and password.
- 3. Select the Patches and Upgrades tab.
- 4. On the Search tab, click Product or Family.
- 5. In the **Product** field, type **Oracle GoldenGate for Big Data**.
- 6. From the Release drop-down list, select the release version that you want to download.
- 7. Make sure Platform is displayed as the default in the next field, and then select the platform from the drop-down list.
- 8. Leave the last field blank.
- 9. Click Search.
- **10.** In the **Advanced Patch Search Results** list, select the available builds that satisfy the criteria that you supplied.

11. In the file **Download** dialog box, click the ZIP file to begin the download.

If patches are not available on the support site, go to the Oracle delivery site for the release download.

- 1. Navigate to http://edelivery.oracle.com.
- 2. Sign in with your Oracle ID and password.
- 3. On the Terms and Restrictions page:
  - Accept the **Trial License Agreement** (even if you have a permanent license).
  - Accept the Export Restrictions.
  - Click Continue.
- 4. On the Media Pack Search page:
  - Select the Oracle Fusion Middleware Product Pack.
  - Select the platform on which you will be installing the software.
  - Click Go.
- 5. In the Results list:
  - Select the Oracle GoldenGate Applications Big Data Media Pack that you want.
  - Click Continue.
- 6. On the **Download** page:
  - View the Readme file.
  - Click **Download** for each component that you want. Follow the automatic download process to transfer the zip file to your system.

## Installation Overview

This section provides an overview of the installation contents and the Oracle GoldenGate instances used with the Oracle GoldenGate for Big Data.

- Contents of the Installation ZIP File
- Using the Generic Build of Oracle GoldenGate
- Considerations for Using a Custom Build for a Big Data Instance of Oracle GoldenGate
- Installing to a Non-Generic Instance of Oracle GoldenGate

#### Contents of the Installation ZIP File

The Oracle GoldenGate for Big Data installation ZIP file contains:

- Oracle GoldenGate Java Adapter
- A version of Oracle GoldenGate designed to stream data to Big Data targets. This version is labeled *generic* because it is not specific to any database, but it is platform dependent.

## Using the Generic Build of Oracle GoldenGate

For JMS capture, the Java Adapter must run in the generic build of Oracle GoldenGate. However, the generic build is not required when using the adapter for delivery of trail data to a target; in this case, the Java Adapter can be used with any database version of Oracle GoldenGate.

## Considerations for Using a Custom Build for a Big Data Instance of Oracle GoldenGate

There are both advantages and disadvantages to installing a custom build for a Big Data Oracle GoldenGate instance. Also, there are limitations in the releases of Oracle GoldenGate that are compatible with releases of the Big Data.

#### Advantages

- The non-generic instance allows you to configure Extract to login to the database for metadata. This removes the need to use a source definitions file that must be synchronized your the source database DDL.
- There is no need to manage two separate versions of Oracle GoldenGate when doing database capture and JMS delivery on the same server.

#### Disadvantages

- If you need to patch Oracle GoldenGate core instance, you must also copy the Big Data into the new patched installation of Oracle GoldenGate.
- The Oracle GoldenGate for Big Data are only tested and certified with the generic version of Oracle GoldenGate core. New patches of the core can trigger incompatibilities.

#### Limitations

- The Replicat module to write to Big Data targets is only available in the Generic Oracle GoldenGate distribution.
- The generic build must be used with JMS capture, as this is the only version of Extract that is capable of loading the VAM.
- A DEFGEN utility is not included with the Big Data. To generate source definitions, you will need a version of Oracle GoldenGate that is built specifically for your database type.

### Installing to a Non-Generic Instance of Oracle GoldenGate

If you decide to install the Java user exit to a non-generic instance of Oracle GoldenGate, unzip to a temporary location first and then copy the adapter files to your Oracle GoldenGate installation location.

To install the Java user exit to a non-generic instance of Oracle GoldenGate:

- 1. Navigate to the Oracle GoldenGate installation directory, for example C:/ggs.
- 2. Create a temporary directory, and extract the Java user exit ZIP file into this into sub directory within it, for example ggjava.
- 3. Copy or move the files from the ggjava sub directory and shared libraries into the Oracle GoldenGate installation directory (C:/ggs).

#### Note:

You need not copy the shared library ggjava\_vam because, it only works with the generic build.

## **Directory Structure**

The following table is a sample that includes the subdirectories and files that result from unzipping the installation file and creating the subdirectories. The following conventions have been used:

- Subdirectories are enclosed in square brackets []
- Levels are indicated by a pipe and hyphen |-
- The Internal notation indicates a read-only directory that should not be modified
- Text files (\*.txt) are not included in the list
- Oracle GoldenGate utilities, such as Defgen, Logdump, and Keygen, are not included in the list

Table 3-1	Sample installation directory structure
-----------	---

Directory	Explanation
[gg_install_dir]	Oracle GoldenGate installation directory, such as C:/ggs on Windows or /home/user/ggs on UNIX.
-ggsci	Command line interface used to start, stop, and manage processes.
-mgr	Manager process.
-extract	Extract process that will start the Java application.
-replicat	Replicat process that will start the Java application.
-[UserExitExamples]	Sample C programming language user exit code examples.
-[dirprm]	Subdirectory that holds all the parameter and property files created by the user, for example:
	javaue.prm javaue.properties jmsvam.prm jmsvam.properties ffwriter.prm
-[dirdef]	Subdirectory that holds source definitions files (*.def) defining the metadata of the trail:
	Created by the core utility for the user exit trail data.
-[dirdat]	Subdirectory that holds the trail files produced by the VAM Extract or read by the user exit Extract.

Directory	Explanation
-[dirrpt]	Subdirectory that holds log and report files.
-[dirchk]	Internal Subdirectory that holds checkpoint files.
-[dirpcs]	InternalSubdirectory that holds process status files.
-[dirjar]	Internal Subdirectory that holds Oracle GoldenGate Monitor jar files.
-[ggjava]	Internal Installation directory for Java jars. Read-only; do not modify.
- -ggjava.jar	The main Java application jar that defines the class path and dependencies.
- -[resources]	Subdirectory that contains all ggjava.jar dependencies. Includes subdirectories for:
	[class] - properties and resources
	• [lib] - application jars required by ggjava.jar
-ggjava_vam.dll	The VAM shared library. This is libggjava_vam.so on UNIX.
-ggjava.dll	Used by the Replicat based delivery process. This is libgjava.so on UNIX.
	Other subdirectories and files included in the installation or created later.

 Table 3-1
 (Cont.) Sample installation directory structure

## Setting up Environmental Variables

To configure your Java environment for Oracle GoldenGate for Java:

- The PATH environmental variable should be configured to find your Java Runtime
- The shared (dynamically linked) Java virtual machine (JVM) library must also be found.

On Windows, these environmental variables should be set as system variables; on Linux/ UNIX, they should be set globally or for the user running the Oracle GoldenGate processes. Examples of setting these environmental variables for Windows, UNIX, and Linux are in the following sections.

#### Note:

There may be two versions of the JAVA\_HOME/.../client, and another in JAVA\_HOME/.../server. For improved performance, use the server version, if it is available. On Windows, only the client JVM may be there if only the JRE was installed (and not the JDK).

• Java on Linux/UNIX

• Java on Windows

### Java on Linux/UNIX

Configure the environment to find the JRE in the PATH, and the JVM shared library, using the appropriate environmental variable for your system. For example, on Linux (and Solaris), set LD\_LIBRARY\_PATH to include the directory containing the JVM shared library as follows (for sh/ksh/bash):

Note: On AIX platforms, you set LIBPATH=. On HP-UX IA64, you set SHLIB\_PATH=.

#### Example 3-1 Configuring path for Java on Linux

```
export JAVA_HOME=/opt/jdk1.8
export PATH=$JAVA_HOME/bin:$PATH
export LD LIBRARY PATH=$JAVA HOME/jre/lib/amd64/server:$LD LIBRARY PATH
```

In this example, the directory <code>\$JAVA\_HOME/jre/lib/i386/server</code> should contain the <code>libjvm.so</code> and <code>libjsig.so</code> files. The actual directory containing the JVM library depends on the operating system and if the 64-bit JVM is being used.

Verify the environment settings by opening a command prompt and checking the Java version as in this example:

```
$ java -version
java version "1.8.0_92"
Java(TM) SE Runtime Environment (build 1.8.0 92-b14)
```

#### Java on Windows

After Java is installed, configure the PATH to find the JRE and JVM DLL (jvm.dll):

Example 3-2 Configuring Path for Java on Windows

```
set JAVA_HOME=C:\Program Files\Java\jdk1.8.0
set PATH=%JAVA_HOME%\bin;%PATH%
set PATH=%JAVA_HOME%\jre\bin\server;%PATH%
```

In the example above, the directory <code>%JAVA\_HOME%/jre/bin/server</code> should contain the file jvm.dll.

Verify the environment settings by opening a command prompt and checking the Java version as in this example:

```
C:\> java -version
java version "1.8.0_92" Java(TM) SE Runtime Environment (build 1.8.0_92-b14))
```

## 4 Install

- Installing Oracle GoldenGate Microservices for Big Data The Oracle GoldenGate Microservices Architecture (MA) for Big Data is installed using OUI. You can also use a command line silent installation using OUI.
- Installing Oracle GoldenGate Classic for Big Data
- Setting Up Oracle GoldenGate for Big Data in a High Availability Environment

## Installing Oracle GoldenGate Microservices for Big Data

The Oracle GoldenGate Microservices Architecture (MA) for Big Data is installed using OUI. You can also use a command line silent installation using OUI.

This chapter describes how to install a new instance of Oracle GoldenGate Microservices for Big Data. The Installation is a three-step process:

- Install the Oracle GoldenGate MA.
- Set the necessary environment variables.
- Deploy an Oracle GoldenGate instance using the configuration assistant.

The installer registers the Oracle GoldenGate home directory with the central inventory that is associated with the selected database. The inventory stores information about all Oracle software products installed on a host if the product was installed using OUI.

Disk space is also required for the Oracle GoldenGate Bounded Recovery feature. Bounded Recovery is a component of the general Extract checkpointing facility. It caches long-running open transactions to disk at specific intervals to enable fast recovery upon a restart of Extract. At each bounded recovery interval (controlled by the BRINTERVAL option of the BR parameter) the disk required is as follows: for each transaction with cached data, the disk space required is usually 64k plus the size of the cached data rounded up to 64k. Not every long-running transaction is persisted to disk.

Watch this video for a demo on installing and configuring Install and Configure GoldenGate Microservices 21c.

#### **Topics:**

• Installing Oracle GoldenGate MA for Big Data Using the UI

Interactive installation provides a graphical user interface that prompts for the required installation information. These instructions apply to new installations and upgrades.

- Silent Installation Silent installation from the command line interface can be performed if your system does not have an X-Windows or graphical interface or you want to perform the installation in an automated way. Silent installations ensure that multiple users in your organization use the same installation options when installing Oracle products.
- Setting Up Secure or Non-Secure Deployments You can choose to set up a secure or non-secure deployment.

## Installing Oracle GoldenGate MA for Big Data Using the UI

Interactive installation provides a graphical user interface that prompts for the required installation information. These instructions apply to new installations and upgrades.

To install Oracle GoldenGate for Big Data using the UI:

- Create a temporary staging directory into which you will install Oracle GoldenGate. For example, mkdir /u01/stage/oggsc.
- 2. Extract the installation ZIP file into the temporary staging directory. For example: unzip .ggs Linux x64 BigData 64bit services.zip -d ./temp directory
- From the expanded directory, run the ggs\_Linux\_x64\_BigData\_64bit\_services/ Disk1/runInstaller program on UNIX or Linux to display the Installation Wizard.
- 4. On the **Select Installation Option** page, select the Oracle Database version for your environment, then click **Next**.
- 5. If you are on Windows and running Manager as a service, set the system variable PATH to include jvm.dll, then delete the Manager service and re-add it.
- 6. On the **Specify Installation Details** page, ensure that the following environment variable is set:
  - OGG HOME
- 7. Click Next to display the Summary page.
- 8. Confirm that there is enough space for the installation and that the installation selections are correct.
  - (Optional) Click **Save Response File** to save the installation information to a response file. You can run the installer from the command line with this file as input to duplicate the results of a successful installation on other systems. You can edit this file or create a new one from a template.
  - Click Install to begin the installation or Back to go back and change any input specifications. When upgrading an existing Oracle GoldenGate installation, OUI notifies you that the software location has files or directories. Click Yes to continue.
  - If you created a central inventory directory, then you are prompted to run the INVENTORY\_LOCATION/orainstRoot.sh script. This script must be executed as the root operating system user. This script establishes the inventory data and creates subdirectories for each installed Oracle product (in this case, Oracle GoldenGate).

You are notified when the installation is finished.

9. Click Close to complete the installation.

## Silent Installation

Silent installation from the command line interface can be performed if your system does not have an X-Windows or graphical interface or you want to perform the

installation in an automated way. Silent installations ensure that multiple users in your organization use the same installation options when installing Oracle products.

Silent installations are driven by using a response file. Response files can be saved by selecting the Save Response File option during an interactive Oracle Universal Installer session or by editing the oggcore.rsp template located in the response directory after unzipping the binaries.

The Oracle GoldenGate response file contains a standard set of Oracle configuration parameters in addition to parameters that are specific to Oracle GoldenGate. These parameters correspond to the fields in the interactive session. The response file location is

unzipped\_directory/ggs\_Linux\_x64\_BigData\_64bit\_services/Disk1/response

To perform the installation using a response file, issue the following command:

unzipped\_directory/ggs\_Linux\_x64\_BigData\_64bit\_services.zip/Disk1/runInstaller -silent
-nowait -responseFile absolute\_path\_to\_response\_file

## Setting Up Secure or Non-Secure Deployments

You can choose to set up a secure or non-secure deployment.

A secure deployment involves making RESTful API calls and conveying trail data between the Distribution Server and Receiver Server, over SSL/TLS. You can use your own existing business cerificate from your Certificate Authority (CA) or you might create your own certificates. When first creating the SSL/TLS security certificates, you must ensure that the SSL/TLS security environment variables.

For a non-secure deployment, the RESTful API calls occur over plain-text HTTP and conveyance between Distribution Server and Receiver Server is performed using the wss, ogg, and ws protocols.

This section describes the steps to configure a non-secure deployment and prerequisites and tasks to configure a secure deployment.

- How to Add Secure or Non-Secure Deployments
   Adding deployments is the first task in the process of setting up a data replication
   platform. Deployments are managed from the Service Manager.
- How to Remove a Deployment You can remove a deployment using OGGCA or in silent mode.

### How to Add Secure or Non-Secure Deployments

Adding deployments is the first task in the process of setting up a data replication platform. Deployments are managed from the Service Manager.

After completing the Oracle GoldenGate Microservices installation, you can add initial and subsequent deployments using the Configuration Assistant (OGGCA) wizard.

#### Note:

Oracle recommends that you have a single Service Manager per host, to avoid redundant upgrade and maintenance tasks with Oracle GoldenGate releases.

Use OGGCA to add multiple deployments to a Service Manager. This allows you to upgrade the same Service Manager with new releases or patches. The source and target deployments serve as endpoints for setting up the distribution path for data replication.

 From the OGG\_HOME directory, run the \$OGG\_HOME/bin/oggca.sh program on UNIX or Linux.

The Oracle GoldenGate Configuration Assistant (oggca) is started. Run this program, each time you want to add a deployment.

- 2. In the Select Service Manager Options step:
  - a. Select whether you want to use an existing Service Manager or create a new one. In most configurations, you only have one Service Manager that is responsible for multiple deployments.
  - b. For a new Service Manager, enter or browse to the directory that you want to use for your deployment. Oracle recommends that you create a ServiceManager directory within the deployment sub-directory structure to store the Service Manager files.
  - c. Enter the hostname or IP Address of the server.
  - d. Enter a unique port number that the Service Manager will listen on, or choose the port already in use if selecting an existing Service Manager.
  - e. (Optional) You can register the Service Manager to run as a service so as to avoid manually starting and stopping it.

You can choose to run *one* Service Manager as a service (daemon). If there is an existing Service Manager registered as a service and you select a new Service Manager to register as a service, an alert is displayed indicating that you cannot register the new one as a service. All other Service Managers are started and stopped using scripts installed in the bin directory of the deployment. You cannot register an existing Service Manager as a service.

3. In the Configuration Options step, you can add or remove deployments.

You can only add or remove one deployment for one Service Manager at a time.

#### Note:

Ensure that your Service Manager is up and running prior to launching OGGCA.

- 4. In the Deployment Details step:
  - a. Enter the deployment name using these conventions:
    - Must begin with a letter.

- Can be a standard ASCII alphanumeric string not exceeding 32 characters.
- Cannot include extended ASCII characters.
- Special characters that are allowed include underscore ('\_'), hyphen ('/'), dash ('-'), period ('.'). The name before the / symbol should be "slash" or "forward slash".
- Cannot be "ServiceManager".
- b. Enter or select the Oracle GoldenGate installation directory. If you have set the \$OGG\_HOME environment variable, the directory is automatically populated. Otherwise, the parent directory of the oggca.sh (Linux) or oggca.bat (Windows) script is used.
- c. Click Next.
- 5. On the Select Deployment Directories page:
  - a. Enter or select a deployment directory where you want to store the deployment registry and configuration files. When you enter the deployment directory name, it is created if it doesn't exist. Oracle recommends that you do *not* locate your deployment directory inside your \$OGG\_HOME and that you create a separate directory for easier upgrades. The additional fields are automatically populated based on the specified deployment directory.

#### Note:

The deployment directory name (user deployment directory) needs to be different than the directory name chosen in the first screen (Service Manager deployment directory).

- **b.** You can customize the deployment directories so that they are named and located differently from the default.
- c. Enter or select different directories for the various deployment elements.
- d. Click Next.
- 6. On the Environment Variables page:

Enter the requested values for the environment variables. Double-click in the field to edit it. You can copy and paste values in the environment variable fields. Make sure that you tab or click outside of the field after entering each value, otherwise it's not saved. If you have set any of these environment variables, the directory is automatically populated.

#### OGG\_HOME

The directory where you installed Oracle GoldenGate. This variable is fixed and cannot be changed.

#### Note:

On a Windows platform, ensure that there's no space in the OGG\_HOME directory path otherwise OGGCA will not run.

#### LD\_LIBRARY\_PATH

This variable is used to specify the path to search for libraries on UNIX and Linux. It may have a different name on some operating systems, such as LIBPATH on IBM AIX on POWER Systems (64-Bit), and SHLIB\_PATH on HP-UX. This path points to the Oracle GoldenGate installation directory and the underlying instant client directory by default. It might be extended if USER\_EXITS are in use.

You can add additional environment variables to customize your deployment or remove variables. For instance, you can enter the following variable to default to another international charset:  $ENV_LC_ALL=zh_CN.UTF-8$ 

#### Click Next.

- 7. On the Administrator Account page:
  - a. Enter a user name and password that you want to use to sign in to the Oracle GoldenGate Microservices Service Manager and the other servers. This user is the security user for this deployment. Select the Enable strong password policy in the new deployment checkbox to ensure setting a highly secure password for your user account. The strong password policy has the following requirements:
    - At least one lowercase character [a...z]
    - At least one upposercase character [A...Z]
    - At least one digit [0...9]
    - At least one special character [- ! @ % & \* . #]
    - The length should be between 8 and 30 characters.

If you are using an existing Service Manager, you must enter the same log in credentials that were used when adding the first deployment.

- b. Select the check box that allows you to enable a strong password policy for your new deployment. If you select this option, then the password must adhere to restrictions, otherwise an error occurs, which requires you to specify a stronger password.
- c. Click Next.
- 8. On the Security Options page:
  - a. You can choose whether or not you want to secure your deployment. Oracle recommends that you enable SSL/TLS security. If you do not want to use security for your deployment, deselect the check box.

This operation exposes the option **This non-secure deployment will be used to send trail data to a secure deployment**. Select this check box if the non-secure target deployment is meant to communicate with a secure source deployment.

However, you must enable security if configuring for Oracle GoldenGate sharding support.

- **b.** Also see: About Target-Initiated Paths in Step by Step Data Replication Using Oracle GoldenGate Microservices Architecture Guide.
- c. (Optional) You can specify a client wallet location so that you can send trail data to a secure deployment. This option is useful when Distribution Server from the source deployment is unsecured whereas the Receiver Server on the target deployment is secured. So, the sender may be configured for public

access while the Receiver Server requires authentication and authorization, which is established using PKI before the incoming data is applied. For more information, see Creating a Self Signed Certificate and Creating a Client Certificate Certificate in *Oracle GoldenGate Security Guide*.

d. For your Server, select one of the options, and then provide the required file locations. When using an existing wallet, it must have the appropriate certificates already imported into it. If you choose to use a certificate, enter the corresponding pass phrase.
 When using a self-signed certificate, a new Oracle Wallet is created in the new deployment and these certificates are imported into it. For certificates enter the

deployment and these certificates are imported into it. For certificates, enter the location of the private key file and the pass phrase. The private key files must be in the PKCS#8 format.

- e. For your Client, select one of the options, and then provide the required information as you did for your server.
- f. Click Next.
- 9. (If Security is enabled) On the Advanced Security Settings page, the TLS 1.1 and TLS 1.2 options are available. TLS 1.2 is selected by default.

When you open the Advanced Security Settings for the first time with TLS 1.2, the following cipher suites are listed:

TLS RSA WITH AES 128 CBC SHA256 TLS RSA WITH AES 128 GCM SHA256 TLS RSA WITH AES 256 CBC SHA256 TLS RSA WITH AES 256 GCM SHA384 TLS ECDHE ECDSA WITH AES 128 CBC SHA256 TLS ECDHE ECDSA WITH AES 128 GCM SHA256 TLS ECDHE ECDSA WITH AES 256 CBC SHA384 TLS ECDHE ECDSA WITH AES 256 GCM SHA384 TLS ECDHE RSA WITH AES 128 CBC SHA256 TLS ECDHE RSA WITH AES 128 GCM SHA256 TLS ECDHE RSA WITH AES 256 CBC SHA384 TLS ECDHE RSA WITH AES 256 GCM SHA384 TLS DHE RSA WITH AES 128 CBC SHA256 TLS DHE RSA WITH AES 128 GCM SHA256 TLS DHE RSA WITH AES 256 CBC SHA256 TLS DHE RSA WITH AES 256 GCM SHA384 TLS ECDH ECDSA WITH AES 128 CBC SHA256 TLS ECDH ECDSA WITH AES 128 GCM SHA256 TLS ECDH ECDSA WITH AES 256 CBC SHA384 TLS ECDH ECDSA WITH AES 256 GCM SHA384 TLS ECDH RSA WITH AES 128 CBC SHA256 TLS ECDH RSA WITH AES 128 GCM SHA256 TLS ECDH RSA WITH AES 256 CBC SHA384 TLS ECDH RSA WITH AES 256 GCM SHA384

- a. Use the arrows to add or remove cipher suites.
- b. Use **Up** and **Down** to reorder how the cipher suites are applied
- c. Click Next.

#### Note:

For more information on TCP/IP encryption options with RMTHOST, see RMTHOST in *Reference for Oracle GoldenGate*.

- 10. (If Sharding is enabled) On the **Sharding Options** page:
  - a. Locate and import your Oracle GoldenGate Sharding Certificate. Enter the distinguished name from the certificate that will be used by the database sharding code to identify itself when making REST API calls to the Oracle GoldenGate MA services.
  - b. Enter a unique name for the certificate.
  - c. Click Next.
- **11.** On the **Port Settings** page:
  - a. Enter the Administration Server port number, and then when you leave the field the other port numbers are populated in ascending numbers. Optionally, you can enter unique ports for each of the servers.
  - b. Select Enable Monitoring to use the Performance Metrics Server.
  - c. Click inside the Performance Metrics Server port fields to populate or enter the ports you want to use. Ensure that you choose available ports for TCP.

Select the UDP port for performance monitoring. The option to select the UDP port is displayed only with deployments on Windows and other operating systems that don't support UDS communication with Performance Metric Server. See Supported Operating Systems for UDS.

You can change the TCP port from the Service Manager console after the deployment is done. For more information on PMSRVR, see ENABLEMONITORING.

d. Select the type of datastore that you want the Performance Metrics Server to use, the default Berkeley Database (BDB) data store or Open LDAP Lightning Memory-Mapped Database (LMDB). You can also designate the Performance Monitor as a Critical Service if integrating the Service Manager with XAG.

For BDB information, see Oracle Berkeley DB 12c Release 1. For LMDB information, see http://www.lmdb.tech/doc/.

- e. Select the location of your datastore. BDB and LMDB are in-memory and diskresident databases. The Performance Metrics server uses the datastore to store all performance metrics information.
- f. Click Next.

#### Note:

The oggca utility validates whether or not the port you entered is currently in use or not.

- **12.** On the **Summary** page:
  - a. Review the detailed configuration settings of the deployment before you continue.

b. (Optional) You can save the configuration information to a response file. Oracle recommends that you save the response file. You can run the installer from the command line using this file as an input to duplicate the results of a successful configuration on other systems. You can edit this file or a new one from the provided template.

#### Note:

When saving to a response file, the administrator password is not saved for security reasons. You must edit the response file and enter the password if you want to reuse the response file for use on other systems.

- c. Click Finish to the deployment.
- d. Click Next.
- 13. On the Configure Deployment page:

Displays the progress of the deployment creation and configuration.

a. If the Service Manager is being registered as a service, a pop-up appears that directs you how to run the script to register the service. The Configuration Assistant verifies that these scripts have been run. If you did not run them, you are queried if you want to continue. When you click **Yes**, the configuration completes successfully. When you click **No**, a temporary failed status is set and you click **Retry** to run the scripts.

Click **Ok** after you run the script to continue.

- b. Click Next.
- 14. On the Finish page:

Click **Close** to close the Configuration Assistant.

#### How to Remove a Deployment

You can remove a deployment using OGGCA or in silent mode.

#### **Topics:**

- How to Remove a Deployment: GUI You can remove a deployment using the Oracle GoldenGate Configuration Assistnat wizard.
- How to Remove a Deployment: Silent Mode
   You can remove a deployment silently using the Oracle GoldenGate Configuration
   Assistant (oggca) from the Oracle GoldenGate Home bin directory.

## How to Remove a Deployment: GUI

You can remove a deployment using the Oracle GoldenGate Configuration Assistnat wizard.

#### To remove a deployment:

	Note: When you remove a deployment or uninstall Oracle GoldenGate Microservices, the system does not automatically stop processes. As a result, you may have to stop processes associated with the deployment and you must clean files manually.	
1.	Run the Oracle GoldenGate Configuration Assistant wizard:	
	<pre>\$OGG_HOME/bin</pre>	
2.	Select Existing Service Manager from the Select Service Manager Options screen. Click Next	
3.	Select <b>Remove Existing Oracle GoldenGate Deployment</b> from the Configuration Options screen.	
4.	Select the deployment you need to remove from the <b>Deployment Name</b> list box. Also select the <b>Delete Deployment Files from Disk</b> check box if you want to remove all the deployment files (including configuration files) from the host.	
5.	Enter the Administration account user name and password and click Next.	
6.	See the list of settings that are deleted with the deployment and click Finish.	
То	remove a Service Manager:	
1.	Run Oracle GoldenGate Configuration Assistant wizard:	
	\$OGG_HOME/bin	
2.	Select Existing Service Manager from the Select Service Manager Options screen. Click Next.	
3.	If there are no other deployments to remove, then the option to remove the Service Manager is available in the drop down. Select <b>Remove Service Manager Deployment</b> from the Configuration Options screen.	
4.	Click Finish.	
Files to be Removed Manually After Removing Deployment		
It's mandatory to delete some files manually only in case there's a Service Manager registered but you have to unregister it and register a new one. To remove files manually, you must have root or sudo privileges. The files to be deleted include:		

Operating System	Files to be Removed Manually to Unregister an Existing Service Manager
Linux 6	<ul> <li>/etc/init.d/OracleGoldenGate</li> <li>/etc/rc.d/*OracleGoldenGate</li> <li>/etc/rc*.d/*OracleGoldenGate</li> <li>/etc/oggInst.loc</li> </ul>
Linux 7	/etc/systemd/system/ OracleGoldenGate.service

The following commands are executed to stop the Service Manager:

```
systemctl stop OracleGoldenGate
systemctl disable OracleGoldenGate *
```

#### Note:

If the Service Manager is not registered as a service (with or without the integration with XAG), OGGCA stops the Service Manager deployment, otherwise, a script called unregisterServiceManager is created, and when executed by the user, it runs the systemctl commands and deletes the mentioned files.

#### How to Remove a Deployment: Silent Mode

You can remove a deployment silently using the Oracle GoldenGate Configuration Assistant (oggca) from the Oracle GoldenGate Home bin directory.

By removing a deployment, you can delete various components of the deployment, including, Extracts, Replicats, paths, and configuration files. However, the Service Manager is not deleted.

To remove a deployment silently:

#### Note:

If the Service Manager is registered as a system service, removing a deployment silently will not unregister the service.

- **1.** Ensure that you have a deployment response file. To get the deployment response file, run the OGGCA and the save the response file.
- 2. Update the following lines within the deployment response file:

```
CONFIGURATION_OPTION=REMOVE
ADMINISTRATOR_PASSWORD=********
CREATE_NEW_SERVICEMANAGER=false
DEPLOYMENT_NAME=deployment_name
REMOVE DEPLOYMENT FROM DISK=true
```

In case of multiple deployments, you must specify the deployment name using the DEPLOYMENT\_NAME field. You can use the REMOVE\_DEPLOYMENT\_FROM\_DISK option to remove physical files and folders associated with deployment.

3. Run the OGGCA program from the following location using the -silent and - responseFile options. Providing the exact path to the deployment response is needed.

\$OGG\_HOME/bin/oggca.sh -silent -responseFile
path\_to\_response\_file/response\_file.rsp

Example:

## Installing Oracle GoldenGate Classic for Big Data

This chapter describes how to install a new instance of Oracle GoldenGate for Big Data.

**Topics:** 

Installation Steps

## **Installation Steps**

Perform the following steps to install the Oracle GoldenGate for Big Data:

1. Create an installation directory that has no spaces in its name. Then extract the ZIP file into this new installation directory. For example:

```
Shell> mkdir installation_directory
Shell> cp path/to/installation_zip installation_directory
Shell> cd installation_directory
Shell> unzip installation_zip
```

If you are on Linux or UNIX, run:

Shell> tar -xf installation tar

This downloads the files into several of the subdirectories Directory Structure .

2. Stay on the installation directory and bring up GGSCI to create the remaining subdirectories in the installation location.

Shell> ggsci GGSCI> CREATE SUBDIRS

3. Create a Manager parameter file:

GGSCI> EDIT PARAM MGR

4. Specify a port for the Manager to listen on by using the editor to add a line to the Manager parameter file. For example:

PORT 7801

- 5. If you are on Windows and running Manager as a service, set the system variable PATH to include jvm.dll, then delete the Manager service and re-add it.
- 6. Go to GGSCI, start the Manager, and check to see that it is running:

GGSCI>START MGR GGSCI>INFO MGR

#### Note:

To check for environmental variable problems locating the JVM at runtime:

- Add the parameter GETENV (PATH) for Windows or GETENV (LD\_LIBRARY\_PATH) for UNIX to the Replicat parameter file.
- Start the Replicat process
- Check the output for the report using the GGSCI command: SEND REPLICAT group\_name REPORT

# Setting Up Oracle GoldenGate for Big Data in a High Availability Environment

This topic describes the best practices of achieving high availability of Oracle GoldenGate for Big Data processes.

#### **Topics:**

- Running Oracle GoldenGate for Big Data from a Single Instance
- Running Oracle GoldenGate for Big Data on a Cluster of Servers
- Shared Storage

Most shared storage solutions, including general purpose cluster file systems, can be used to install Oracle GoldenGate or to store the files that Oracle GoldenGate needs to recover.

## Running Oracle GoldenGate for Big Data from a Single Instance

To configure the single server high availability, you need to configure the manager process with AUTOSTART and AUTORESTART parameters. These parameters ensure that the manager process always gets the extract or replicat group to be started back up from an inactive state.

## Running Oracle GoldenGate for Big Data on a Cluster of Servers

Depending on which cluster manager software that is being used, you need to configure it to ensure the following:

- There is **exactly one active node** that is running Oracle GoldenGate for Big Data. It is assumed that the cluster manager can detect that a compute node is down and subsequently spawn another node to be the active.
- Install Oracle GoldenGate for Big Data in shared file system and have that shared file system mounted in the same location for all the nodes participating in the High

Availability (HA) configuration. For more information about installing Oracle GoldenGate for Big Data, see Installing Oracle GoldenGate for Big Data in the *Installing and Upgrading Oracle GoldenGate for Big Data* guide. Most of the state files, including the Input and Output Trail files, Configuration files, and Checkpoint files described in the next point are stored in sub-directories of the Oracle GoldenGate for Big Data install. The Oracle GoldenGate for Big Data installation directory is the same across all managed nodes. This helps the administrator to leverage the exact content of entry point script to bring up Oracle GoldenGate for Big Data as part of its workflow to spawn a new active node. An example of the content of the entry point script is a command to start the Oracle GoldenGate manager process.

- Oracle GoldenGate artifacts are stored in one or more shared file systems or volumes accessible from all nodes. For more information about these files, see Directory Structure in the Installing and Upgrading Oracle GoldenGate for Big Data guide:
  - Input and Output Trail files: Typically these files are located in the gg\_install\_dir/dirdat directory, where gg\_install\_dir is the Oracle GoldenGate installation directory, such as C:/ggs on Windows or /home/user/ggs on UNIX. These files are configurable.
  - Configuration files: The configuration files are located in the gg\_install\_dir/dirprm directory.
  - **Checkpoint files**: These files are stored in an internal subdirectory, such as the *gg\_install\_dir/dirchk* directory.
  - When using File Writer features, for example, File Writer handler, ADW, or Redshift integration, the file writer output files and the state files must be on shared volumes.

For more information about configuring cluster high availability for handlers, see Configuring Cluster High Availability in *Using Oracle GoldenGate for Big Data* guide.

## Shared Storage

Most shared storage solutions, including general purpose cluster file systems, can be used to install Oracle GoldenGate or to store the files that Oracle GoldenGate needs to recover.

The following options are available from Oracle:

- Oracle Cluster File System (OCFS2) –available only on Linux: OCFS2 can also be used for Oracle Database storage, although Oracle recommends the use of Oracle Automatic Storage Management (ASM) starting with Oracle Database 10g. For more information, see http://oss.oracle.com/projects/ocfs2/.
- Oracle Automatic Storage Management (ASM) Cluster File System (ACFS): For more information about the Oracle Database 11g Release 2 ACFS, see Oracle Database Automatic Storage Administrator's Guide as part of the Oracle Database 11g Release 2 documentation set: https://docs.oracle.com/cd/E11882\_01/ server.112/e18951/asmfs\_util001.htm#OSTMG91000.
- Oracle Database File System (DBFS): For more information about DBFS, its restrictions as well as how to configure a DBFS, see Oracle Database Secure File and Large Objects Developer's Guide from the Oracle Database 11g Release 2 documentation set: https://docs.oracle.com/cd/E11882\_01/appdev.112/e18294/ adlob\_fs.htm#BABDHGGJ.

• Oracle ACFS with Oracle Database 11g Release 2

## 5 Upgrade

- Upgrading Oracle GoldenGate Microservices for Big Data For Microservices, the earliest version that can be upgraded from is Oracle GoldenGate 21*c* (21.1.0.0). As a best practice, perform a minimal upgrade first, so that you can troubleshoot more easily in case of any issue. After the environment is upgraded successfully, you can implement the new functionality.
- Upgrading Oracle GoldenGate Classic for Big Data

## Upgrading Oracle GoldenGate Microservices for Big Data

For Microservices, the earliest version that can be upgraded from is Oracle GoldenGate 21*c* (21.1.0.0). As a best practice, perform a minimal upgrade first, so that you can troubleshoot more easily in case of any issue. After the environment is upgraded successfully, you can implement the new functionality.

This chapter describes how to upgrade Oracle GoldenGate Microservices Architecture for Big Data from the previous releases of Oracle GoldenGate Microservices Architecture for BigData to the current release.

The pre-upgrade requirements are as follows:

- Stop all Oracle GoldenGate processes.
- Start Oracle GoldenGate.

#### **Topics:**

- Obtaining the Oracle GoldenGate Distribution
- Scope of Upgrade

Even though you may only upgrade the source or target, rather than both, all processes are involved in upgrade. All processes must be stopped in the correct order for the upgrade, regardless of which component you upgrade, and the trails must be processed until empty.

• Upgrading Oracle GoldenGate Microservices – GUI Based

## Obtaining the Oracle GoldenGate Distribution

To obtain Oracle GoldenGate:

- Go to edelivery.oracle.com. For more information, see My Oracle Support Banner Oracle GoldenGate -- Oracle RDBMS Server Recommended Patches (Doc ID 1557031.1). To access Oracle Technology Network (OTN), go to https://www.oracle.com/integration/ goldengate/
- 2. Find the Oracle GoldenGate 21*c* (21.1.0) release and download the ZIP file onto your system.

For more information about locating and downloading Oracle Fusion Middleware products, see the Oracle® Fusion Middleware Download, Installation, and Configuration Readme Files on OTN.

## Scope of Upgrade

Even though you may only upgrade the source or target, rather than both, all processes are involved in upgrade. All processes must be stopped in the correct order for the upgrade, regardless of which component you upgrade, and the trails must be processed until empty.

Before you start the upgrade, review the information about upgrading Extract and Replicat.

Oracle recommends that you begin your upgrade with the target rather than the source to avoid the necessity of adjusting the trail file format.

#### Replicat Upgrade Considerations

All Replicat installations should be upgraded at the same time. It is critical to ensure that all trails leading to all Replicat groups on all target systems are processed until empty, according to the upgrade instructions.

#### **Replicat Upgrade Considerations**

All Replicat installations should be upgraded at the same time. It is critical to ensure that all trails leading to all Replicat groups on all target systems are processed until empty, according to the upgrade instructions.

Before you start the upgrade, review the information about upgrading Extract and Replicat.

Oracle recommends that you begin your upgrade with the target rather than the source to avoid the necessity of adjusting the trail file format.

## Upgrading Oracle GoldenGate Microservices – GUI Based

To obtain the Oracle GoldenGate installation software and set up the directories for upgrade:

- 1. Download the latest Oracle GoldenGate Microservices 21*c* software from the Oracle Technology Network or eDelivery.
- 2. Upload the Oracle GoldenGate Microservices 21c software to a staging location on the server where a previous release of Oracle GoldenGate Microservices exists.
- 3. Unzip Oracle GoldenGate Microservices 21*c* software in the staging location.

```
$ cd /tmp $ unzip
./fbo_ggs_Linux_x64_services_shiphome.zip
```

- Untar the tar file that gets created after the unzip command: tar -xvf ggs\_Linux\_x64\_Oracle\_64bit.tar
- 5. Move into the unzipped files and execute the runInstaller command.

```
$ cd ./fbo_ggs_Linux_x64_services_shiphome/Disk1
$ ./runInstaller
```

- 6. For Software Location, specify where the new Oracle GoldenGate home is located. This is not the same location as the current Oracle GoldenGate home. Click **Next**.
- 7. Click **Install** to begin installing the new Oracle GoldenGate MA. When the installation is done, click **Close**.

At this point, you should have two Oracle GoldenGate MA home directories: one for your old home (21c) and a new home (21.x.x).

- 8. Verify the current version of Oracle GoldenGate Home through Service Manager.
  - a. Login to the Service Manager:

http://host:servicemanager port

- b. Review the deployment section for your current Oracle GoldenGate home location.
- **9.** Update the Service Manager and the deployments with the location of the new Oracle GoldenGate home.
  - a. Click Service Manager, then Deployment name.
  - **b.** Next to the deployment details, click the pencil icon to display the dialog box to edit the Oracle GoldenGate home.
  - c. Update the Oracle GoldenGate home with the complete path to the new Oracle GoldenGate home. Also update the following, if required:

LD\_LIBRARY\_PATH

- d. Click Apply.
- e. Confirm that the Oracle GoldenGate home has been updated.
- f. Stop all Extracts, Replicats, and Distribution paths.
- g. Use the action button to restart Service Manager or Deployment.

#### Note:

You can confirm that the Oracle GoldenGate home was updated by looking at the process from the operating system for Service Manager. The Service Manager process should be running from the new Oracle GoldenGate home.

 To upgrade the associated deployments, follow the same steps for Service Manager after ensuring that all the Extract and Replicat processes in that deployment have been stopped.

## Upgrading Oracle GoldenGate Classic for Big Data

This chapter describes how to upgrade to Oracle GoldenGate for Big Data 21c (21.1.0.0.0) by downloading the product as described in Downloading Oracle GoldenGate for Big Data, and then choosing the upgrade paths that suits your environment.

After upgrading, you must then convert your Extract processes to Replicat processes.

#### Note:

There is no supported upgrade path from release 12.1.2 to 12.2.0.x.

There is no supported upgrade path from release 12.2.0.1.0 to 12.2.0.1.1.

#### **Topics:**

- Upgrading by Overwriting the Existing Installation
- Upgrading by Installing into a New Directory
- Switching Existing Extract Processes to Replicat Processes

## Upgrading by Overwriting the Existing Installation

The most straightforward upgrade path is to copy the Oracle GoldenGate for Big Data 21c (21.1.0.0.0) files into the existing 12c (19.1.0.0.*x*) installation directory. Overwriting the product files is possible because there is neither structural nor package name changes in the current release. In most cases the 19.1.0.0.*x* handler and formatter configurations are also compatible with the 21.1.0.0.0 release. However, is some cases configuration updates may be required.

- (Source systems) Back up the current Oracle GoldenGate for Big Data installation directory on the source system, and any working directories that you have installed on a shared drive in a cluster (if applicable).
- 2. (Source system) Stop user activity on objects in the Oracle GoldenGate configuration.
- 3. Create a new installation directory for the 21.1.0.0.0 installation with no spaces in its name.
- Extract the ZIP file into this new installation directory, which divides the files into several subdirectories.
- 5. Copy the Oracle GoldenGate for Big Data 21*c* (21.1.0.0*x*) files into the existing 19*c* (19.1.0.0*x*) installation directory.
- 6. Start the Replicat processes and verify that they are running.

```
GGSCI> START MANAGER
GGSCI> START REPLICAT group_name
GGSCI> INFO REPLICAT group_name
GGSCI> VIEW REPORT group_name
```

Certain 19.1.0.0.x JAR files are still present after the overwriting process though the new 21.1.0.0.0 JAR files are used.

## Upgrading by Installing into a New Directory

Use the following steps to install the Oracle GoldenGate for Big Data 19c (19.1.0.0.*x*) files into a new installation directory.

- 1. (Source systems) Back up the current Oracle GoldenGate for Big Data installation directory on the source systems, and any working directories that you have installed on a shared drive in a cluster (if applicable).
- 2. (Source system) Stop user activity on objects in the Oracle GoldenGate configuration.
- 3. Create a new installation directory for the 19.1.0.0 installation with no spaces in its name.
- Extract the ZIP file into this new installation directory, which divides the files into several subdirectories.
- 5. Start GGSCI to create the remaining subdirectories in the installation location.

```
$ ggsci
GGSCI> CREATE SUBDIRS
```

6. Copy all of the dirprm files from your existing installation into the dirprm directory in the new installation location.

#### Note:

All of your configuration files must be in the dirprm directory. If you have property files, Velocity templates, or other configuration files in a location other than dirprm in your old installation, then you must copy them to the dirprm directory in the new installation.

- 7. Copy all of the dirdef files from your existing installation into the dirdef directory in the new installation location.
- 8. If you have data files stored in the 12.3.1.x or 12.2.0.x installation dirdat directory, then copy or move the existing trail files to the dirdat directory of the new installation.
- **9.** If you have additional JAR files or other custom files in your 12.3.1.*x* or 12.2.0.*x* installation, then copy them to the new installation directory.
- Configure the Replicat processes in the new installation directory by starting GGSCI and adding the Replicat and naming the trails.

```
GGSCI> ADD REPLICAT group_name, EXTTRAIL trail_name, ...
GGSCI> ALTER group name EXTSEQNO seqno EXTRBA rba
```

Optionally, you could alter the starting position of Replicat processing as needed.

**11**. Start the Replicat processes and verify that they are running.

```
GGSCI> START MANAGER
GGSCI> START REPLICAT group_name
GGSCI> INFO REPLICAT group_name
GGSCI> VIEW REPORT group_name
```

- Modify the source system to write to the new Oracle GoldenGate for Big Data installation directory:
  - a. (Optional) Upgrade the source database Oracle GoldenGate capture following the upgrade procedure for your database platform.

- **b.** Configure the source database capture to write to the new Oracle GoldenGate for Big Data 12.3.1.*x* installation dirdat directory.
- c. When the old Oracle GoldenGate for Big Data installation has processed all its data, switch over to the process that will send data to the new location.

## Switching Existing Extract Processes to Replicat Processes

In previous releases, you could use an Extract and pump process to write to your Big Data targets. In this release, this solution is deprecated so you must use Replicat.

A typical Extract configuration is similar to:

```
EXTRACT mygroup
SOURCEDEFS path/to/source/def/file
CUSEREXIT libggjava_ue.so CUSEREXIT PASSTHRU INCLUDEUPDATEBEFORES
GETUPDATEBEFORES
TABLE *.*;
```

With Replicat the preceding configuration would be:

```
REPLICAT mygroup
SOURCEDEFS path/to/source/def/file
TARGETDB LIBFILE libggjava.so SET property=/path/to/properties/file
MAP *.* TARGET *.*;
```

The same properties file works in the Replicat configuration so you do not need to change the properties file.

To complete this process, you must add the Replicat group, start the process, and verify that it is running:

```
GGSCI> ADD REPLICAT group_name, EXTTRAIL trail_name, ...
GGSCI> ALTER group_name EXTSEQNO seqno EXTRBA rbaGGSCI> START REPLICAT
group_name
GGSCI> INFO REPLICAT group_name
GGSCI> VIEW REPORT group_name
```

## 6 Configure

- Configuring Oracle GoldenGate for Big Data
- Logging
  - Logging is essential to troubleshooting Oracle GoldenGate for Big Data integrations with Big Data targets.
- Configuring Logging

## Configuring Oracle GoldenGate for Big Data

This topic describes how to configure Oracle GoldenGate for Big Data Handlers.

Running with Replicat

You need to run the Java Adapter with the Oracle GoldenGate Replicat process to begin configuring Oracle GoldenGate for Big Data.

- About Schema Evolution and Metadata Change Events
- About Configuration Property CDATA[] Wrapping
- Using Regular Expression Search and Replace
   You can perform more powerful search and replace operations of both schema data
   (catalog names, schema names, table names, and column names) and column value
   data, which are separately configured. Regular expressions (regex) are characters that
   customize a search string through pattern matching.
- Scaling Oracle GoldenGate for Big Data Delivery
- Configuring Cluster High Availability
  Oracle GoldenGate for Big Data doesn't have built-in high availability functionality. You
  need to use a standard cluster software's high availability capability to provide the high
  availability functionality.
- Using Identities in Oracle GoldenGate Credential Store

The Oracle GoldenGate credential store manages user IDs and their encrypted passwords (together known as credentials) that are used by Oracle GoldenGate processes to interact with the local database. The credential store eliminates the need to specify user names and clear-text passwords in the Oracle GoldenGate parameter files.

## Running with Replicat

You need to run the Java Adapter with the Oracle GoldenGate Replicat process to begin configuring Oracle GoldenGate for Big Data.

This topic explains how to run the Java Adapter with the Oracle GoldenGate Replicat process.

- Configuring Replicat
- Adding the Replicat Process
- Replicat Grouping

- About Replicat Checkpointing
- About Initial Load Support
- About the Unsupported Replicat Features
- How the Mapping Functionality Works

## **Configuring Replicat**

The following is an example of how you can configure a Replicat process properties file for use with the Java Adapter:

```
REPLICAT hdfs
TARGETDB LIBFILE libggjava.so SET property=dirprm/hdfs.properties
--SOURCEDEFS ./dirdef/dbo.def
DDL INCLUDE ALL
GROUPTRANSOPS 1000
MAPEXCLUDE dbo.excludetable
MAP dbo.*, TARGET dbo.*;
```

The following is explanation of these Replicat configuration entries:

REPLICAT hdfs - The name of the Replicat process.

TARGETDB LIBFILE libggjava.so SET property=dirprm/hdfs.properties - Sets the target database as you exit to libggjava.so and sets the Java Adapters property file to dirprm/hdfs.properties.

--SOURCEDEFS ./dirdef/dbo.def - Sets a source database definitions file. It is commented out because Oracle GoldenGate trail files provide metadata in trail.

GROUPTRANSOPS 1000 - Groups 1000 transactions from the source trail files into a single target transaction. This is the default and improves the performance of Big Data integrations.

MAPEXCLUDE dbo.excludetable - Sets the tables to exclude.

MAP dbo.\*, TARGET dbo.\*; - Sets the mapping of input to output tables.

## Adding the Replicat Process

The command to add and start the Replicat process in ggsci is the following:

```
ADD REPLICAT hdfs, EXTTRAIL ./dirdat/gg START hdfs
```

### **Replicat Grouping**

The Replicat process provides the Replicat configuration property, GROUPTRANSOPS, to control transaction grouping. By default, the Replicat process implements transaction grouping of 1000 source transactions into a single target transaction. If you want to turn off transaction grouping then the GROUPTRANSOPS Replicat property should be set to 1.

## About Replicat Checkpointing

In addition to the Replicat checkpoint file ,.cpr, an additional checkpoint file, dirchk/ group.cpj, is created that contains information similar to CHECKPOINTTABLE in Replicat for the database.

## About Initial Load Support

Replicat can already read trail files that come from both the online capture and initial load processes that write to a set of trail files. In addition, Replicat can also be configured to support the delivery of the special run initial load process using RMTTASK specification in the Extract parameter file. For more details about configuring the direct load, see Loading Data with an Oracle GoldenGate Direct Load.

#### Note:

The SOURCEDB or DBLOGIN parameter specifications vary depending on your source database.

## About the Unsupported Replicat Features

The following Replicat features are not supported in this release:

- BATCHSQL
- SQLEXEC
- Stored procedure
- Conflict resolution and detection (CDR)

## How the Mapping Functionality Works

The Oracle GoldenGate Replicat process supports mapping functionality to custom target schemas. You must use the Metadata Provider functionality to define a target schema or schemas, and then use the standard Replicat mapping syntax in the Replicat configuration file to define the mapping. For more information about the Replicat mapping syntax in the Replication configuration file, see Mapping and Manipulating Data.

## About Schema Evolution and Metadata Change Events

The Metadata in trail is a feature that allows seamless runtime handling of metadata change events by Oracle GoldenGate for Big Data, including schema evolution and schema propagation to Big Data target applications. The NO\_OBJECTDEFS is a sub-parameter of the Extract and Replicat EXTTRAIL and RMTTRAIL parameters that lets you suppress the important metadata in trail feature and revert to using a static metadata definition.

The Oracle GoldenGate for Big Data Handlers and Formatters provide functionality to take action when a metadata change event is encountered. The ability to take action in the case of metadata change events depends on the metadata change events being available in the source trail file. Oracle GoldenGate supports metadata in trail and the propagation of DDL data from a source Oracle Database. If the source trail file does not have metadata in trail

and DDL data (metadata change events) then it is not possible for Oracle GoldenGate for Big Data to provide and metadata change event handling.

## About Configuration Property CDATA[] Wrapping

The GoldenGate for Big Data Handlers and Formatters support the configuration of many parameters in the Java properties file, the value of which may be interpreted as white space. The configuration handling of the Java Adapter trims white space from configuration values from the Java configuration file. This behavior of trimming whitespace may be desirable for some configuration values and undesirable for other configuration values. Alternatively, you can wrap white space values inside of special syntax to preserve the whites pace for selected configuration variables. GoldenGate for Big Data borrows the XML syntax of CDATA[] to preserve white space. Values that would be considered to be white space can be wrapped inside of CDATA[].

The following is an example attempting to set a new-line delimiter for the Delimited Text Formatter:

gg.handler.{name}.format.lineDelimiter=\n

This configuration will not be successful. The new-line character is interpreted as white space and will be trimmed from the configuration value. Therefore the gg.handler setting effectively results in the line delimiter being set to an empty string.

In order to preserve the configuration of the new-line character simply wrap the character in the CDATA[] wrapper as follows:

gg.handler.{name}.format.lineDelimiter=CDATA[\n]

Configuring the property with the CDATA[] wrapping preserves the white space and the line delimiter will then be a new-line character.

## Using Regular Expression Search and Replace

You can perform more powerful search and replace operations of both schema data (catalog names, schema names, table names, and column names) and column value data, which are separately configured. Regular expressions (regex) are characters that customize a search string through pattern matching.

You can match a string against a pattern or extract parts of the match. Oracle GoldenGate for Big Data uses the standard Oracle Java regular expressions package, java.util.regex, see Regular Expressions in The Single UNIX Specification, Version 4.

- Using Schema Data Replace
- Using Content Data Replace

## Using Schema Data Replace

You can replace schema data using the gg.schemareplaceregex and gg.schemareplacestring properties. Use gg.schemareplaceregex to set a regular expression, and then use it to search catalog names, schema names, table names, and column names for corresponding matches. Matches are then replaced with the content of the gg.schemareplacestring value. The default value of gg.schemareplacestring is an empty string or "".

For example, some system table names start with a dollar sign like <code>\$mytable</code>. You may want to replicate these tables even though most Big Data targets do not allow dollar signs in table names. To remove the dollar sign, you could configure the following replace strings:

```
gg.schemareplaceregex=[$]
gg.schemareplacestring=
```

The resulting example of searched and replaced table name is mytable. These properties also support CDATA[] wrapping to preserve whitespace in the value of configuration values. So the equivalent of the preceding example using CDATA[] wrapping use is:

```
gg.schemareplaceregex=CDATA[[$]]
gg.schemareplacestring=CDATA[]
```

The schema search and replace functionality supports using multiple search regular expressions and replacements strings using the following configuration syntax:

```
gg.schemareplaceregex=some_regex
gg.schemareplacestring=some_value
gg.schemareplaceregex1=some_regex
gg.schemareplaceregex2=some_regex
gg.schemareplacestring2=some_value
```

## Using Content Data Replace

You can replace content data using the gg.contentreplaceregex and

gg.contentreplacestring properties to search the column values using the configured regular expression and replace matches with the replacement string. For example, this is useful to replace line feed characters in column values. If the delimited text formatter is used then line feeds occurring in the data will be incorrectly interpreted as line delimiters by analytic tools.

You can configure *n* number of content replacement regex search values. The regex search and replacements are done in the order of configuration. Configured values must follow a given order as follows:

```
gg.contentreplaceregex=some_regex
gg.contentreplacestring=some_value
gg.contentreplaceregex1=some_regex
gg.contentreplaceregex2=some_regex
gg.contentreplacestring2=some_value
```

Configuring a subscript of 3 without a subscript of 2 would cause the subscript 3 configuration to be ignored.

#### **NOT\_SUPPORTED:**

Regular express searches and replacements require computer processing and can reduce the performance of the Oracle GoldenGate for Big Data process.

To replace line feeds with a blank character you could use the following property configurations:

```
gg.contentreplaceregex=[\n]
gg.contentreplacestring=CDATA[ ]
```

This changes the column value from:

```
this is me to:
```

Both values support CDATA wrapping. The second value must be wrapped in a CDATA[] wrapper because a single blank space will be interpreted as whitespace and trimmed by the Oracle GoldenGate for Big Data configuration layer. In addition, you can configure multiple search a replace strings. For example, you may also want to trim leading and trailing white space out of column values in addition to trimming line feeds from:

```
^\\s+|\\s+$
```

```
gg.contentreplaceregex1=^\\s+|\\s+$
gg.contentreplacestring1=CDATA[]
```

## Scaling Oracle GoldenGate for Big Data Delivery

Oracle GoldenGate for Big Data supports breaking down the source trail files into either multiple Replicat processes or by using Coordinated Delivery to instantiate multiple Java Adapter instances inside a single Replicat process to improve throughput.. This allows you to scale Oracle GoldenGate for Big Data delivery.

There are some cases where the throughput to Oracle GoldenGate for Big Data integration targets is not sufficient to meet your service level agreements even after you have tuned your Handler for maximum performance. When this occurs, you can configure parallel processing and delivery to your targets using one of the following methods:

 Multiple Replicat processes can be configured to read data from the same source trail files. Each of these Replicat processes are configured to process a subset of the data in the source trail files so that all of the processes collectively process the

source trail files in their entirety. There is no coordination between the separate Replicat processes using this solution.

 Oracle GoldenGate Coordinated Delivery can be used to parallelize processing the data from the source trail files within a single Replicat process. This solution involves breaking the trail files down into logical subsets for which each configured subset is processed by a different delivery thread. For more information about Coordinated Delivery, see https:// blogs.oracle.com/dataintegration/entry/goldengate\_12c\_coordinated\_replicat.

With either method, you can split the data into parallel processing for improved throughput. Oracle recommends breaking the data down in one of the following two ways:

- Splitting Source Data By Source Table –Data is divided into subsections by source table. For example, Replicat process 1 might handle source tables table1 and table2, while Replicat process 2 might handle data for source tables table3 and table2. Data is split for source table and the individual table data is not subdivided.
- Splitting Source Table Data into Sub Streams Data from source tables is split. For example, Replicat process 1 might handle half of the range of data from source table1, while Replicat process 2 might handler the other half of the data from source table1.

Additional limitations:

- Parallel apply is *not* supported.
- The BATCHSQL parameter not supported.

#### Example 6-1 Scaling Support for the Oracle GoldenGate for Big Data Handlers

Handler Name	Splitting Source Data By Source Table	Splitting Source Table Data into Sub Streams
Cassandra	Supported	<ul> <li>Supported when:</li> <li>Required target tables in Cassandra are pre-created.</li> <li>Metadata change events do not occur.</li> </ul>
Elastic Search	Supported	Supported
HBase	Supported when all required HBase namespaces are pre- created in HBase.	<ul> <li>Supported when:</li> <li>All required HBase namespaces are pre-created in HBase.</li> <li>All required HBase target tables are pre-created in HBase. Schema evolution is not an issue because HBase tables have no schema definitions so a source metadata change does not require any schema change in HBase.</li> <li>The source data does not contain any truncate operations.</li> </ul>

Handler Name	Splitting Source Data By Source Table	Splitting Source Table Data into Sub Streams
HDFS	Supported	<ul> <li>Supported with some restrictions.</li> <li>You must select a naming convention for generated HDFS files wherethe file names do not collide. Colliding HDFS file names results in a Replicat abend. When using coordinated apply it is suggested that you configure \$ {groupName} as part of the configuration for the gg.handler.name.fileName MappingTemplate property. The \${groupName} template resolves to the Replicat name concatenated with the Replicat thread number, which provides unique naming per Replicat thread.</li> <li>Schema propagatation to HDFS and Hive integration is not currently supported.</li> </ul>
JDBC	Supported	Supported
Kafka	Supported	Supported for formats that support schema propagation, such as Avro. This is less desirable due to multiple instances feeding the same schema information to the target.
Kafka Connect	Supported	Supported
Kinesis Streams	Supported	Supported
MongoDB	Supported	Supported

Handler Name	Splitting Source Data By Source Table	Splitting Source Table Data into Sub Streams
Java File Writer	Supported	Supported with the following restrictions: You must select a naming convention for generated files where the file names do not collide Colliding file names may results in a Replicat abend and/or polluted data. When using coordinated apply it is suggested that you configure \${groupName} as part of the configuration for the gg.handler.name.fileNameMap pingTemplate property. The \$ {groupName} template resolves to the Replicat name concatenated with the Replicat thread number, which provides unique naming per Replicat thread.

## Configuring Cluster High Availability

Oracle GoldenGate for Big Data doesn't have built-in high availability functionality. You need to use a standard cluster software's high availability capability to provide the high availability functionality.

You can configure a high availability scenario on a cluster so that if the leader instance of Oracle GoldenGate for Big Data on machine fails, another Oracle GoldenGate for Big Data instance could be started on another machine to resume where the failed instance left off.

If you manually configure your instances to share common Oracle GoldenGate for Big Data and Oracle GoldenGate files using a shared disk architecture you can create a fail over situation. For a cluster installation, these files would need to accessible from all machines and accessible in the same location.

The configuration files that must be shared are:

- replicat.prm
- Handler properties file.
- Additional properties files required by the specific adapter. This depends on the target handler in use. For example, Kafka would be a producer properties file.
- Additional schema files you've generated. For example, Avro schema files generated in the dirdef directory.
- File Writer Handler generated files on your local file system at a configured path. Also, the File Writer Handler state file in the dirsta directory.
- Any log4j.properties or logback.properties files in use.

Checkpoint files must be shared for the ability to resume processing:

• Your Replicat checkpoint file (\*.cpr).

• Your adapter checkpoint file (\*.cpj).

## Using Identities in Oracle GoldenGate Credential Store

The Oracle GoldenGate credential store manages user IDs and their encrypted passwords (together known as credentials) that are used by Oracle GoldenGate processes to interact with the local database. The credential store eliminates the need to specify user names and clear-text passwords in the Oracle GoldenGate parameter files.

An optional alias can be used in the parameter file instead of the user ID to map to a userid and password pair in the credential store. The credential store is implemented as an auto login wallet within the Oracle Credential Store Framework (CSF). The use of an LDAP directory is not supported for the Oracle GoldenGate credential store. The auto login wallet supports automated restarts of Oracle GoldenGate processes without requiring human intervention to supply the necessary passwords.

In Oracle GoldenGate for Big Data, you specify the alias and domain in the property file not the actual user ID or password. User credentials are maintained in secure wallet storage.

- Creating a Credential Store
- Adding Users to a Credential Store
- Configuring Properties to Access the Credential Store

## Creating a Credential Store

You can create a credential store for your Big Data environment.

Run the GGSCI ADD CREDENTIALSTORE command to create a file called cwallet.sso in the dircrd/ subdirectory of your Oracle GoldenGate installation directory (the default).

You can the location of the credential store (cwallet.sso file by specifying the desired location with the CREDENTIALSTORELOCATION parameter in the GLOBALS file.

For more information about credential store commands, see *Reference for Oracle GoldenGate*.

#### Note:

Only one credential store can be used for each Oracle GoldenGate instance.

## Adding Users to a Credential Store

After you create a credential store for your Big Data environment, you can added users to the store.

Run the GGSCI ALTER CREDENTIALSTORE ADD USER *userid* PASSWORD *password* [ALIAS *alias*] [DOMAIN *domain*] command to create each user, where:

• *userid* is the user name. Only one instance of a user name can exist in the credential store unless the ALIAS or DOMAIN option is used.

- password is the user's password. The password is echoed (not obfuscated) when this
  option is used. If this option is omitted, the command prompts for the password, which is
  obfuscated as it is typed (recommended because it is more secure).
- *alias* is an alias for the user name. The alias substitutes for the credential in parameters and commands where a login credential is required. If the ALIAS option is omitted, the alias defaults to the user name.

For example:

ALTER CREDENTIALSTORE ADD USER scott PASSWORD tiger ALIAS scsm2 domain ggadapters

For more information about credential store commands, see *Reference for Oracle GoldenGate*.

## Configuring Properties to Access the Credential Store

The Oracle GoldenGate Java Adapter properties file requires specific syntax to resolve user name and password entries in the Credential Store at runtime. For resolving a user name the syntax is the following:

ORACLEWALLETUSERNAME [alias domain name]

For resolving a password the syntax required is the following:

ORACLEWALLETPASSWORD[alias domain name]

The following example illustrate how to configure a Credential Store entry with an alias of myalias and a domain of mydomain.

#### Note:

With HDFS Hive JDBC the user name and password is encrypted.

Oracle Wallet integration only works for configuration properties which contain the string username or password. For example:

gg.handler.hdfs.hiveJdbcUsername=ORACLEWALLETUSERNAME[myalias mydomain]
gg.handler.hdfs.hiveJdbcPassword=ORACLEWALLETPASSWORD[myalias mydomain]

ORACLEWALLETUSERNAME and ORACLEWALLETPASSWORD can be used in the Extract (similar to Replicat) in JMS handler as well. For example:

gg.handler.<name>.user=ORACLEWALLETUSERNAME[JMS\_USR JMS\_PWD]

gg.handler.<name>.password=ORACLEWALLETPASSWORD[JMS\_USR JMS\_PWD]

Consider the user name and password entries as accessible values in the Credential Store. Any configuration property resolved in the Java Adapter layer (not accessed in the C user exit layer) can be resolved from the Credential Store. This allows you more flexibility to be creative in how you protect sensitive configuration entries.

# Logging

Logging is essential to troubleshooting Oracle GoldenGate for Big Data integrations with Big Data targets.

This topic details how Oracle GoldenGate for Big Data integration log and the best practices for logging.

- About Replicat Process Logging
- About Java Layer Logging

## About Replicat Process Logging

Oracle GoldenGate for Big Data integrations leverage the Java Delivery functionality described in the Delivering Java Messages. In this setup, either a Oracle GoldenGate Replicat process loads a user exit shared library. This shared library then loads a Java virtual machine to thereby interface with targets providing a Java interface. So the flow of data is as follows:

Replicat Process -> User Exit-> Java Layer

It is important that all layers log correctly so that users can review the logs to troubleshoot new installations and integrations. Additionally, if you have a problem that requires contacting Oracle Support, the log files are a key piece of information to be provided to Oracle Support so that the problem can be efficiently resolved.

A running Replicat process creates or appends log files into the <code>GoldenGate\_Home/dirrpt</code> directory that adheres to the following naming convention: <code>process\_name.rpt</code>. If a problem is encountered when deploying a new Oracle GoldenGate process, this is likely the first log file to examine for problems. The Java layer is critical for integrations with Big Data applications.

## About Java Layer Logging

The Oracle GoldenGate for Big Data product provides flexibility for logging from the Java layer. The recommended best practice is to use Log4j logging to log from the Java layer. Enabling simple Log4j logging requires the setting of two configuration values in the Java Adapters configuration file.

```
gg.log=log4j
gg.log.level=INFO
```

These gg.log settings will result in a Log4j file to be created in the <code>GoldenGate\_Home/dirrpt</code> directory that adheres to this naming convention, <code>{GROUPNAME}.log</code>. The supported Log4j log levels are in the following list in order of increasing logging granularity.

- OFF
- FATAL
- ERROR
- WARN
- INFO

- DEBUG
- TRACE

Selection of a logging level will include all of the coarser logging levels as well (that is, selection of WARN means that log messages of FATAL, ERROR and WARN will be written to the log file). The Log4j logging can additionally be controlled by separate Log4j properties files. These separate Log4j properties files can be enabled by editing the bootoptions property in the Java Adapter Properties file. These three example Log4j properties files are included with the installation and are included in the classpath:

log4j-default.properties
log4j-debug.properites
log4j-trace.properties

You can modify the bootoptions in any of the files as follows:

```
javawriter.bootoptions=-Xmx512m -Xms64m -Djava.class.path=.:ggjava/ggjava.jar -
Dlog4j.configurationFile=samplelog4j.properties
```

You can use your own customized Log4j properties file to control logging. The customized Log4j properties file must be available in the Java classpath so that it can be located and loaded by the JVM. The contents of a sample custom Log4j properties file is the following:

```
# Root logger option
log4j.rootLogger=INFO, file
# Direct log messages to a log file
log4j.appender.file=org.apache.log4j.RollingFileAppender
log4j.appender.file.File=sample.log
log4j.appender.file.MaxFileSize=1GB
log4j.appender.file.MaxBackupIndex=10
log4j.appender.file.layout=org.apache.log4j.PatternLayout
log4j.appender.file.layout.ConversionPattern=%d{yyyy-MM-dd HH:mm:ss} %-5p %c{1}:%L -
%m%n
There are two important requirements when you use a custom Loq4j properties file.
First, the path to the custom Log4j properties file must be included in the
javawriter.bootoptions property. Logging initializes immediately when the JVM is
initialized while the contents of the qq.classpath property is actually appended to
the classloader after the logging is initialized. Second, the classpath to correctly
load a properties file must be the directory containing the properties file without
wildcards appended.
```

# **Configuring Logging**

- Oracle GoldenGate Java Adapter Default Logging
- Recommended Logging Settings

## Oracle GoldenGate Java Adapter Default Logging

- Default Logging Setup
- Log File Name
- Changing Logging Level

## Default Logging Setup

Logging is enabled by default for the Oracle GoldenGate for BigData. The logging implementation is log4j. By default, logging is enabled at the info level.

### Log File Name

The log output file is created in the standard report directory. The name of the log file includes the replicat group name and has an extension of log.

If the Oracle GoldenGate Replicat process group name is JAVAUE, then the log file name in the report directory is: JAVAUE.log.

## **Changing Logging Level**

To change the recommended  $\log 4j$  logging level, add the configuration shown in the following example to the Java Adapter Properties file:

gg.log.level=error

You can set the gg.log.level to none, error, warn, info, debug, or trace. The default log level is info. Oracle recommends the debug and trace log levels only for troubleshooting as these settings can adversely impact the performance.

## **Recommended Logging Settings**

Oracle recommends that you use log4j logging instead of the JDK default for unified logging for the Java user exit. Using log4j provides unified logging for the Java module when running with the Oracle GoldenGate Replicat process.

Changing to the Recommended Logging Type

## Changing to the Recommended Logging Type

To change the recommended log4j logging implementation, add the configuration shown in the following example to the Java Adapter Properties file.

```
gg.log=log4j
gg.log.level=info
```

The gg.log level can be set to none, error, warn, info, debug, or trace. The default log level is info. The debug and trace log levels are only recommended for troubleshooting as these settings can adversely affect performance.

The result is that a log file for the Java module will be created in the dirrpt directory with the following naming convention:

<process name>\_<log level>log4j.log

Therefore if the Oracle GoldenGate Replicat process is called javaue, and the gg.log.level is set to debug, the resulting log file name is:

javaue\_debug\_log4j.log

# 7 Quickstarts

This article will get help you in quickly getting started with the following tasks in Oracle GoldenGate for Big Data.

- QuickStarts: Prerequisites
- Google Cloud Platform Big Query Stage and Merge Replication
- Google Cloud Storage Replication
- Realtime Replication into Oracle Cloud Infrastructure (OCI) Streaming with GoldenGate for Big Data
- Realtime Parquet Ingestion into AWS S3 Buckets with Oracle GoldenGate for Big Data
- Realtime Data Ingestion into Kafka with Oracle GoldenGate for Big Data
- Realtime Message Streaming to Kafka

## QuickStarts: Prerequisites

- It is assumed that you've installed Oracle GoldenGate for Big Data in your environment or from Oracle Cloud Infrastructure Marketplace. See Installing Oracle GoldenGate MA for Big Data Using the UI.
- It is assumed that you have configured an Oracle GoldenGate extract, which is up and running and the trails are being sent to Oracle GoldenGate for Big Data Deployment. See Add Extracts in Oracle GoldenGate Microservices Documentation.
- Get familiar with Oracle GoldenGate Microservices by watching this video: Introduction to Oracle GoldenGate Microservices.

# Prerequisites: Google Cloud Platform BigQuery Stage and Merge Replicat And Google Cloud Storage Replication

Apart from the prerequisites listed in the above section, the following are the prerequisites specific to Google Cloud Platform Big Query Stage and Merge Replication and Google Cloud Storage Replication Quickstarts.

- Google Cloud Platform (GCP) account set up.
- A Google Cloud Platform (GCP) service account key with relevant permissions. Copy your GCP service account key to a directory on your GoldenGate for Big Data Server.
- A Google Cloud Storage bucket with relevant BigQuery Permissions (Google Cloud Platform BigQuery Stage and Merge Replicat) In case of Google Cloud Storage Replication, a Google Cloud Storage bucket with relevant Bucket Permissions must be set. Ensure that the GCS bucket and the BigQuery dataset exist in the same location/ region.
- Target BigQuery tables can be created before configuring the replicat. If necessary
  permissions are provided, then Oracle GoldenGate for Big Data can auto create the
  target BigQuery tables.

# Google Cloud Platform Big Query Stage and Merge Replication

BigQuery is Google Cloud's fully managed, petabyte-scale, and cost-effective analytics data warehouse that lets you run analytics over vast amounts of data in near real time.

The BigQuery Event handler uses the stage and merge data flow.

The change data is staged in a temporary location in microbatches and eventually merged into to the target table. Google Cloud Storage (GCS) is used as the staging area for change data. GoldenGate for Big Data loads files generated by the File Writer Handler into Google Cloud Storage and runs BigQuery Query jobs to execute MERGE SQL. The SQL operations are performed in batches providing better throughput.

These processes are automatically handled by the Oracle GoldenGate for Big Data Big Query replicat process. See Google BigQuery Stage and Merge

This topic covers a step-by-step process on how to configure and run a replicat targeting GCP Big Query.

- Install Dependency Files
- Create a Replicat in Oracle GoldenGate for Big Data

## Install Dependency Files

Oracle GoldenGate for Big Data uses client libraries in the replication process. You need to download these libraries by using the Dependency Downloader utility available in Oracle GoldenGate for Big Data before setting up the replication process. Dependency downloader is a set of shell scripts that downloads dependency jar files from Maven and other repositories.

To install the required dependency files:

- Go to installation location of Dependency Downloader: GG\_HOME/opt/ DependencyDownloader/.
- 2. Execute gcs.sh and bigquery.sh with the required versions
- 3. Execute gcs.sh and bigquery.sh with the required version.

#### Figure 7-1 Execute gcs.sh and bigquery.sh with the required versions

2 directories are created in GG\_HOME/opt/DependencyDownloader/dependencies. For example, /u01/app/ogg/opt/DependencyDownloader/dependencies/ bigquery\_1.111.10 and /u01/app/ogg/opt/DependencyDownloader/ dependencies/gcs 1.113.9

## Create a Replicat in Oracle GoldenGate for Big Data

To create a replicat in Oracle GoldenGate for Big Data:

1. In the Oracle GoldenGate for Big Data UI, in the **Administration Service** tab, click the + sign to add a replicat.

Figure 7-2 Click + sign to add a replicat

	Services 21.9.0.0.1 for Big Data (ggbd	(219)			0
istration Service Distribution Service	Performance Metrics Service Recei	ver Service

Page 1 of 5 (1 of 8	5 items) K < 1 2 3 4 5 >	к			

2. Select the Replicat Type and click Next.

There are two different Replicat types here: Classic and Coordinated. Classic Replicat is a single threaded process whereas Coordinated Replicat is a multithreaded one that applies transactions in parallel.

Figure 7-3 Select the Replicat Type and click Next.

4. Enter Parameter File details and click Next. In the Parameter File, you can either specify source to target mapping or leave it as-is with a wildcard selection. If Coordinated Replicat is selected as the Replicat Type, then you need to provide an additional parameter: TARGETDB LIBFILE libggjava.so SET property=<ggbd-deployment\_home>/etc/conf/ogg/your\_replicat\_name.properties Oracle GoldenGate for Big Data can be used to replicate into multiple GCP projects with the same replicat. For more information, see BigQuery Dataset and GCP ProjectId Mapping.

Oracle GoldenGate for Big Data maps the table schema name to the BigQuery dataset. The table catalog name is mapped to the GCP projectId.

Figure 7-9 Query Results

#### Note:

- You can run an initial load with Big Query replicat. See INSERTALLRECORDS Support.
- DDL replication is not supported, GGBD can only auto-create target GCP Big Query tables. In case of DDL, replicat will abend.

## **Google Cloud Storage Replication**

Google Cloud Storage (GCS) is a service for storing objects in Google Cloud Platform.

You can use GoldenGate for Big Data to ingest different file formats into GCS. Oracle GoldenGate for Big Data supports the following file formats:

- delimited-text.json
- json
- json row
- json\_op
- avro row
- avro\_op
- avro\_row\_ocf
- avro\_op\_ocf
- parquet

Oracle GoldenGate for Big Data uses a two-step process in GCS replication. First, it creates the files locally in a directory on the server by using the File Writer Handler and then loads these files into GCS.

Ensure that the files are in a closed state to load them to GCS. For more information about how to control the File Writer behaviour, see the File Writer Behaviour blog.

This quick start will load using the default settings.

Install Dependency Files

Create a Replicat in Oracle GoldenGate for Big Data

## Install Dependency Files

Oracle GoldenGate for Big Data uses client libraries in the replication process. You need to download these libraries by using the Dependency Downloader utility available in Oracle GoldenGate for Big Data before setting up the replication process. Dependency downloader is a set of shell scripts that downloads dependency jar files from Maven and other repositories.

To install the required dependency files:

- Go to installation location of Dependency Downloader: GG\_HOME/opt/ DependencyDownloader/.
- 2. Execute gcs.sh and bigquery.sh with the required versions
- 3. Execute gcs.sh and bigquery.sh with the required version.

Figure 7-10 Execute gcs.sh and bigquery.sh with the required versions

A directory is created in GG\_HOME/opt/DependencyDownloader/dependencies. For example, /u01/app/ogg/opt/DependencyDownloader/dependencies/gcs\_1.113.9

## Create a Replicat in Oracle GoldenGate for Big Data

To create a replicat in Oracle GoldenGate for Big Data:

1. In the Oracle GoldenGate for Big Data UI, in the **Administration Service** tab, click the + sign to add a replicat.

Figure 7-11 Click + in the Administration Service tab.

	Services 21.9.0.0.1 for Big Data (ggbd	210)		A 0

					Next >

Figure 7-13 Select the Replicat Type and click Next.

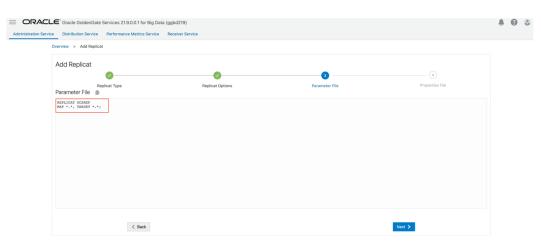

- 3. Enter the basic information, and click Next:
  - a. Process Name: Name of the Replicat
  - **b. Trail Name**: Name of the required trail file. You can use the sample trail file tr which is shipped with Oracle GoldenGate for Big Data.
  - **c.** Trail Subdirectory: Sets the path to trail file. Sample trail file tr is located at OGG HOME/opt/AdapterExamples/trail.
  - d. Target: Google Cloud Storage

Add Replicat				
		2	(3)	
Replicat Type		Replicat Options	Parameter File	Properties File
Basic Information				
	Process Name:	GCSREP		
	Description:			
	Source:	Trail v		
	Trail Name:	tr		
	Trail Subdirectory:	/u01/app/ogg/opt/AdapterExamples/tr		
	Ø Begin:	Position in Trail v		
	Trail Sequence Number	0		
	Trail RBA Offset	0		
	Ø * Target	Google Cloud Storage v		
▶ Encryption Profile			-	

Figure 7-14 Process Name, Trail Name, and Target Names

4. Enter Parameter File details and click Next. In the Parameter File, you can either specify source to target mapping or leave it as-is with a wildcard selection. If Coordinated Replicat is selected as the Replicat Type, then you need to provide an additional parameter: TARGETDB LIBFILE libggjava.so SET property=<ggbd-deployment\_home>/etc/conf/ogg/your\_replicat\_name.properties

#### Figure 7-15 Provide Parameter File details and click Next.

5. In the next screen, update the properties only tagged as TODO. They are as follows:

#### Provide your GCS bucket name:

#TODO: Edit the GCS bucket name
gg.eventhandler.gcs.bucketMappingTemplate=<gcs-bucket-name>

#### Provide path to your GCP service account key:

#TODO: Edit the GCS credentialsFile qg.eventhandler.gcs.credentialsFile=/path/to/gcp/credentialsFile

Provide path to dependency jar files that you downloaded in prerequisites:

#TODO: Edit to include the GCS Java SDK and BQ Java SDK. gg.classpath=/path/to/gcs-deps/\*:/path/to/bq-deps/\*

Without these properties, your replicat will fail. There are also some optional properties that you can modify:

*gg.handler.filewriter.format* controls the format of the output files. By default, it is set **to** *avro\_row\_ocf*. You can change into json, delimitedtext or one of the other Configuring the File Writer Handler.

gg.handler.filewriter.fileRollInterval and
gg.handler.filewriter.inactivityRollInterval controls the file behaviour. A file
should be in a closed state to be loaded into GCS buckets.

*fileRollInterval* starts a timer when file is created and when it is reached, file will be moved to a closed state and moved to GCS bucket. In replicat properties, it is set to 0 which means that it is off. You can set it to **5s**(5 seconds) for this quick start.

*inactivityRollInterval*tracks the inactivity period. Here, inactivity means there are no operations coming from the source system. You can set it to **5s** (5 seconds) for this quick start.

# Realtime Replication into Oracle Cloud Infrastructure (OCI) Streaming with GoldenGate for Big Data

This topic covers a step-by-step process on how to ingest messages into OCI Streaming in real-time with Oracle GoldenGate for Big Data.

- Install Dependency Files
- Create Kafka Producer Properties File
- Create a Replicat in Oracle GoldenGate for Big Data

## **Install Dependency Files**

Oracle GoldenGate for Big Data uses client libraries in the replication process. You need to download these libraries by using the Dependency Downloader utility available in Oracle GoldenGate for Big Data before setting up the replication process. Dependency downloader is a set of shell scripts that downloads dependency jar files from Maven and other repositories.

To install the required dependency files:

- Go to installation location of Dependency Downloader: GG\_HOME/opt/ DependencyDownloader/.
- 2. Execute kafka.sh with the required version.

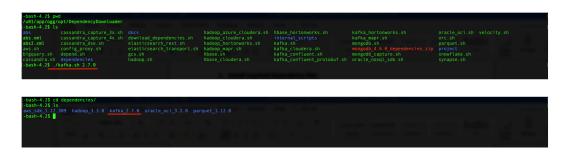

Figure 7-19 Executing kafka.sh with the required versions

A directory is created in GG\_HOME/opt/DependencyDownloader/dependencies. For example, /u01/app/ogg/opt/DependencyDownloader/dependencies/kafka 2.7.0.

## Create Kafka Producer Properties File

Oracle GoldenGate for Big Data must access a Kafka producer configuration file to publish messages to OCI Streaming. The Kafka producer configuration file contains kafka connection settings provided by OCI Streaming. To get OCI Streaming Kafka connection settings, go to Analytics&AI/Streaming/Stream Pools/Stream Pool Details/Kafka Connection Settings. You also need to create an AUTH\_TOKEN.

To create a Kafka producer configuration file:

- In the Oracle GoldenGate for Big Data, go to GGBD\_Deployment\_Home/etc/conf/ ogg.
- 2. Create a Kafka producer config file for OCI Streaming. Sample configuration file:

```
bootstrap.servers=cell-1.streaming.us-phoenix-1.oci.oraclecloud.com:9092
security.protocol=SASL_SSL
sasl.mechanism=PLAIN
value.serializer=org.apache.kafka.common.serialization.ByteArraySerializer
key.serializer=org.apache.kafka.common.serialization.ByteArraySerializer
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
required username="paasdevgg/oracleidentitycloudservice/user.name@oracle.com/
ocidl.streampool.oc1.phx.amaaaaaa3p5c3vqa4hfyl7uv465pay4audmoajughhxlsgj7afc2
an5u3xaq" password="YOUR-AUTH-TOKEN";
```

## Create a Replicat in Oracle GoldenGate for Big Data

To create a replicat in Oracle GoldenGate for Big Data:

1. In the Oracle GoldenGate for Big Data UI, in the **Administration Service** tab, click the **+** sign to add a replicat.

Figure 7-20 Click + in the Administration Service tab.

	ORACLE <sup>®</sup> Oracle GoldenGate Services 21.7.0.0.0 for Big Data (GGBD217)									
Administration Service	Distribution Service	Performance Metrics Service Rece	iver Service

	Critical Events									
	Search In Critical Events	Table Refresh			Page Size: 20	w				
	Code	Date	Severity	Message						
	OGG-08100 Sep 13 2022 11:41:54		0	Oracle GoldenGate Administration Service: Service started.						
	Page 1 of 1 (1 of 1 iter	ns) K < 1 > X								

2. Select the Replicat Type and click Next.

There are two different Replicat types here: Classic and Coordinated. Classic Replicat is a single threaded process whereas Coordinated Replicat is a multithreaded one that applies transactions in parallel.

For KafKa, Oracle recommends Classic replicat as sending messages in multiple threats may result in data consistency problems.

#### Note:

- If target Kafka topic does not exist, then it will be auto created by Oracle GoldenGate for Big Data if you have selected **auto topic create** in OCI streaming Kafka connection settings. See Template Keywords.
- For improving the performance of the OCI Streaming replication, see the blog: How to Improve Kafka Handler Performance in Oracle GoldenGate for Big Data
- Oracle GoldenGate for Big Data supports SSL and kerberos authentication into Kafka. For more information, see Schema Propagation.
- For Kafka connection issues, Oracle Support.

# Realtime Parquet Ingestion into AWS S3 Buckets with Oracle GoldenGate for Big Data

This topic covers a step-by-step process that shows how to ingest parquet files into AWS S3 buckets in real-time with Oracle GoldenGate for Big Data.

- Install Dependency Files
- Create a Replicat in Oracle GoldenGate for Big Data

## Install Dependency Files

Oracle GoldenGate for Big Data uses client libraries in the replication process. You need to download these libraries by using the Dependency Downloader utility available in Oracle GoldenGate for Big Data before setting up the replication process. Dependency downloader is a set of shell scripts that downloads dependency jar files from Maven and other repositories.

Oracle GoldenGate for Big Data uses a 3-step process to ingest parquet into S3 buckets:

- Generating local files from trail files (these local files are not accessible in OCI GoldenGate)
- Converting local files to Parquet format
- Loading files into AWS S3 buckets

For generating local parquet files with Oracle GoldenGate for Big Data, replicat uses File Writer Handler (see Flat Files) and Parquet Event Handler (see Parquet). To load the parquet files into AWS S3, Oracle GoldenGate for Big Data uses S3 Event Handler (see Amazon S3) in conjunction with File Writer and Parquet Event Handler. Oracle GoldenGate for Big Data uses 3 different set of client libraries to create parquet files and loading into AWS S3.

To install the required dependency files:

- Go to installation location of Dependency Downloader: GG\_HOME/opt/ DependencyDownloader/.
- Execute parquet.sh (see Parquet), hadoop.sh (see HDFS Event Handler, and aws.sh with the required versions. A directory is created in GG\_HOME/opt/DependencyDownloader/dependencies. For example,/u01/app/ogg/opt/DependencyDownloader/dependencies/aws\_sdk 1.12.30.

Figure 7-26 Executing parquet.sh, hadoop.sh, and aws.sha with the required versions.

[-bash-4.2\$ pwd /u01/app/ogg/opt/ [-bash-4.2\$ ls aws.sh bigquery.sh cassandra_dse.sh config_proxy.sh dependencies -bash-4.2\$ ./parc	DependencyDownloader docs elasticsearch_rest.sh elasticsearch_transport.sh gcs.sh hadoop_stre_cloudera.sh uet.sh 1.2.2	hadoop_cloudera.sh hadoop_hortonworks.sh hadoop_mapr.sh hbase_sh hbase_cloudera.sh hbase_hortonworks.sh	internal_scripts kafka_Cloudera.sh kafka_Cloudera.sh kafka_confluent_protobuf.sh kafka_confluent_protobuf.sh	kafka_mapr.sh mongodb.sh oracle_nosql_sdk.sh oracle_oci.sh orc.sh parquet.sh	project snowflake.sh synapse.sh velocity.sh

4. Enter Parameter File details and click Next. In the Parameter File, you can either specify source to target mapping or leave it as is with a wildcard selection. If you select Coordinated Replicat as the Replicat Type, then provide the following additional parameter: TARGETDB LIBFILE libggjava.so SET property=<ggbd-deployment\_home>/etc/conf/ogg/your\_replicat\_name.properties

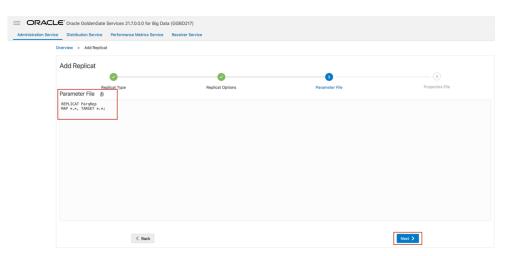

Figure 7-31 Provide Parameter File details and click Next.

 Copy and paste the following property list into the *properties file*, update as needed, and click Create and Run.

#### #The File Writer Handler - no need to change

```
gg.handlerlist=filewriter
gg.handler.filewriter.type=filewriter
gg.handler.filewriter.mode=op
gg.handler.filewriter.pathMappingTemplate=./dirout
gg.handler.filewriter.stateFileDirectory=./dirsta
gg.handler.filewriter.fileRollInterval=7m
gg.handler.filewriter.inactivityRollInterval=30s
gg.handler.filewriter.fileWriteActiveSuffix=.tmp
gg.handler.filewriter.finalizeAction=delete
```

#### ### Avro OCF - no need to change

```
gg.handler.filewriter.format=avro_row_ocf
gg.handler.filewriter.fileNameMappingTemplate=${groupName}_$
{fullyQualifiedTableName}_${currentTimestamp}.avro
gg.handler.filewriter.format.pkUpdateHandling=delete-insert
gg.handler.filewriter.format.iso8601Format=false
gg.handler.filewriter.partitionByTable=true
gg.handler.filewriter.rollOnShutdown=true
```

#### #The Parquet Event Handler - no need to change

```
gg.handler.filewriter.eventHandler=parquet
gg.eventhandler.parquet.type=parquet
gg.eventhandler.parquet.pathMappingTemplate=./dirparquet
gg.eventhandler.parquet.fileNameMappingTemplate=${groupName}_$
{fullyQualifiedTableName}_${currentTimestamp}.parquet
gg.eventhandler.parquet.writeToHDFS=false
gg.eventhandler.parquet.finalizeAction=delete
```

## **#TODO Select S3 Event Handler - no need to change** gg.eventhandler.parquet.eventHandler=s3

#### #TODO Set S3 Event Handler- please update as needed

```
gg.eventhandler.s3.type=s3
gg.eventhandler.s3.region=your-aws-region
gg.eventhandler.s3.bucketMappingTemplate=target s3 bucketname
gg.eventhandler.s3.pathMappingTemplate=ogg/data/${fullyQualifiedTableName}
gg.eventhandler.s3.accessKeyId=XXXXXXXX
```

gg.eventhandler.s3.secretKey=XXXXXXXX

#TODO Set the classpath to the Parquet client libries and the Hadoop client with the path you noted in step1 gg.classpath= jvm.bootoptions=-Xmx512m -Xms32m

6. If replicat starts successfully, then the replicat is in running state. You can go to action/ details/statistics to see the replication statistics.

#### Note:

- If target S3 bucket does not exist, then it will be auto created by Oracle GoldenGate for Big Data. Use Template Keywords to dynamically assign S3 bucket names.
- S3 Event Handler can be configured for the Proxy server. For more information, see Amazon S3.
- You can use different properties to control the behaviour of file writing. You can set file sizes, inactivity periods, and more. For more information, see the blog:Oracle GoldenGate for Big Data File Writer Handler Behavior.
- For Kafka connection issues, see Oracle Support.

# Realtime Data Ingestion into Kafka with Oracle GoldenGate for Big Data

This topic covers a step-by-step process on how to ingest messages into Kafka in realtime with GoldenGate for Big Data.

- Install Dependency Files
- Create Kafka Producer Properties File
- Create a Replicat in Oracle GoldenGate for Big Data

## Install Dependency Files

Oracle GoldenGate for Big Data uses client libraries in the replication process. You need to download these libraries by using the Dependency Downloader utility available in Oracle GoldenGate for Big Data before setting up the replication process. Dependency downloader is a set of shell scripts that downloads dependency jar files from Maven and other repositories.

To install the required dependency files:

- Go to installation location of Dependency Downloader: GG\_HOME/opt/ DependencyDownloader/.
- 2. Execute kafka.sh with the required version.

ashin (2).//afka.sh 2/7.0	parquet.sh project snowflake.sh synapse.sh	<pre>kafka_mapr.sh mongodb.sh mongodb_4.6.0_dependencies.zip mongodb_capture.sh oracle_nosql_sdk.sh</pre>	<pre>ternal_scripts afka_sh afka_sh afka_cloudera.sh afka_confluent.sh afka_confluent_protobuf.sh</pre>	hadoop_cloudera.sh hadoop_hortonworks.sh hadoop_mapr.sh hbase.sh hbase_cloudera.sh	<pre>download_dependencies.sh elasticsearch_rest.sh gcs.sh hadoop.sh</pre>	cassandra_dse.sh config_proxy.sh depend.sh dependencies	
h-4.31 cd dependencies/ h-4.23 1s				1 had spin		d dependencies/	h-4.25 cd

#### Figure 7-34 Executing kafka.sh with the required versions

A directory is created in GG\_HOME/opt/DependencyDownloader/dependencies. For example, /u01/app/ogg/opt/DependencyDownloader/dependencies/kafka 2.7.0.

## Create Kafka Producer Properties File

Oracle GoldenGate for Big Data must access a Kafka producer configuration file to publish messages to Kafka. The Kafka producer configuration file contains Kafka proprietary properties.

To create a Kafka producer configuration file:

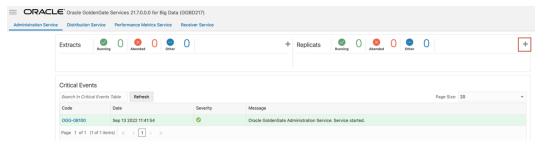

- 1. In the Oracle GoldenGate for Big Data, go to GGBD Deployment Home/etc/conf/ogg.
- 2. Create a Kafka producer config file for OCI Streaming. Sample configuration file:

```
bootstrap.servers=localhost:9092
acks = 1
compression.type = gzip
reconnect.backoff.ms = 1000
value.serializer = org.apache.kafka.common.serialization.ByteArraySerializer
key.serializer = org.apache.kafka.common.serialization.ByteArraySerializer
```

## Create a Replicat in Oracle GoldenGate for Big Data

To create a replicat in Oracle GoldenGate for Big Data:

- In the Oracle GoldenGate for Big Data UI, in the Administration Service tab, click the + sign to add a replicat.
  - Figure 7-35 Click + in the Administration Service tab.

2. Select the Replicat Type and click Next.

There are two different Replicat types here: Classic and Coordinated. Classic Replicat is a single threaded process whereas Coordinated Replicat is a multithreaded one that applies transactions in parallel.

For KafKa, Oracle recommends Classic replicat as sending messages in multiple threats may result in data consistency problems.

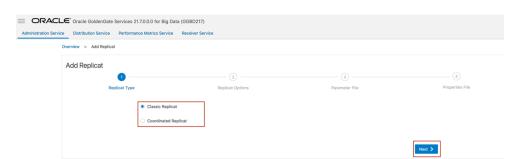

Figure 7-36 Select the Replicat Type and click Next.

- 3. Enter the basic information, and click Next:
  - a. Process Name: Name of the Replicat
  - b. Trail Name: Name of the required trail file
  - c. Target: Kafka

#### Figure 7-37 Process Name, Trail Name, and Target Names

#### Note:

- If target Kafka topic does not exist, then it will be auto created by Oracle GoldenGate for Big Data. See Template Keywords to dynamically assign topic names.
- For improving the performance of Kafka replication, refer the blog: How to Improve Kafka Handler Performance in Oracle GoldenGate for Big Data.
- Oracle GoldenGate for Big Data supports SSL and kerberos authentication into Kafka. For more information, see Schema Propagation.
- For Kafka connection issues, see Oracle Support.

# Realtime Message Streaming to Kafka

This topic covers a step-by-step process that shows how to ingest parquet files into AWS Kinesis in real-time with Oracle GoldenGate for Big Data.

- Install Dependency Files
- Create a Replicat in Oracle GoldenGate for Big Data

# Install Dependency Files

Oracle GoldenGate for Big Data uses client libraries in the replication process. You need to download these libraries by using the Dependency Downloader utility available in Oracle GoldenGate for Big Data before setting up the replication process. Dependency downloader is a set of shell scripts that downloads dependency jar files from Maven and other repositories.

Oracle GoldenGate for Big Data uses AWS Kinesis Java SDK to push data to Amazon Kinesis.

#### Note:

Oracle GoldenGate for Big Data does not ship with the AWS Kinesis Java SDK.

To install the required dependency files:

- Go to installation location of Dependency Downloader: GG\_HOME/opt/ DependencyDownloader/.
- 2. Execute aws.sh with the required version.

igguery.sh elasticsearch_rest.sh hadoop_hortonworks.sh kafka.sh mongodb.sh snowflake.sh bssandra.sh elasticsearch_transport.sh hadoop_mapr.sh kafka_cloudera.sh oracle_nosql_sdk.sh synapse.sh bssandra.dse.sh gcs.sh thabse.sh kafka_confluent.sh oracle_nosql_sdk.sh velocity.sh nfig_provy.sh hadoop_azure_cloudera.sh hbase_loudera.sh kafka_confluent_protout/.sh parquet.sh bash-4_25vams.sh 1.23001	ws.sh igquery.sh	docs elasticsearch rest.sh	hadoop_cloudera.sh	internal_scripts	kafka_mapr.sh mongodb.sh	project snowflake.sh

   Streams Input Limits.

# 8 Replicate Data

Oracle GoldenGate for Big Data supports specific configurations - the handlers (which are compatible with clearly defined software versions) for replicating data.

Handlers in Oracle GoldenGate for Big Data are components that manage the data flow between various sources and targets. They are responsible for reading data from sources such as databases, log files, or message queues, and writing the data to a wide range of target systems. Oracle GoldenGate for Big Data uses Handlers to perform various tasks, such as data ingestion, data transformation, and data integration. Handlers are essential for enabling real-time data movement and data replication across Big Data environments.

This article describes the following Soures and Target Handlers in Oracle GoldenGate for Big Data:

- Source
- Target

# Source

- Amazon MSK
- Apache Cassandra
   The Oracle GoldenGate capture (Extract) for Cassandra is used to get changes from
   Apache Cassandra databases.
- Apache Kafka

The Oracle GoldenGate capture (Extract) for Kafka is used to read messages from a Kafka topic or topics and convert data into logical change records written to GoldenGate trail files. This section explains how to use Oracle GoldenGate capture for Kafka.

- Azure Event Hubs
- Confluent Kafka
- DataStax
- Java Message Service (JMS)
- MongoDB The Oracle GoldenGate capture (Extract) for MongoDB is used to get changes from MongoDB databases.
- OCI Streaming

# Amazon MSK

To capture messages from Amazon MSK and parse into logical change records with Oracle GoldenGate for Big Data, you can use Kafka Extract. For more information, see Apache Kafka as source.

# Apache Cassandra

The Oracle GoldenGate capture (Extract) for Cassandra is used to get changes from Apache Cassandra databases.

This chapter describes how to use the Oracle GoldenGate Capture for Cassandra.

- Overview
- Setting Up Cassandra Change Data Capture
- Deduplication
- Topology Changes
- Data Availability in the CDC Logs
- Using Extract Initial Load
- Using Change Data Capture Extract
- Replicating to RDMBS Targets
- Partition Update or Insert of Static Columns
- Partition Delete
- Security and Authentication
- Cleanup of CDC Commit Log Files You can use the Cassandra CDC commit log purger program to purge the CDC commit log files that are not in use.
- Multiple Extract Support
- CDC Configuration Reference
- Troubleshooting
- Cassandra Capture Client Dependencies What are the dependencies for the Cassandra Capture (Extract) to connect to Apache Cassandra databases?

# Overview

Apache Cassandra is a NoSQL Database Management System designed to store large amounts of data. A Cassandra cluster configuration provides horizontal scaling and replication of data across multiple machines. It can provide high availability and eliminate a single point of failure by replicating data to multiple nodes within a Cassandra cluster. Apache Cassandra is open source and designed to run on low-cost commodity hardware.

Cassandra relaxes the axioms of a traditional relational database management systems (RDBMS) regarding atomicity, consistency, isolation, and durability. When considering implementing Cassandra, it is important to understand its differences from a traditional RDBMS and how those differences affect your specific use case.

Cassandra provides eventual consistency. Under the eventual consistency model, accessing the state of data for a specific row eventually returns the latest state of the data for that row as defined by the most recent change. However, there may be a latency period between the creation and modification of the state of a row and what is returned when the state of that row is queried. The benefit of eventual consistency is

that the latency period is predicted based on your Cassandra configuration and the level of work load that your Cassandra cluster is currently under, see <a href="http://cassandra.apache.org/">http://cassandra.apache.org/</a>.

Review the data type support, see About the Cassandra Data Types.

# Setting Up Cassandra Change Data Capture

#### Prerequisites

- Apache Cassandra cluster must have at least one node up and running.
- Read and write access to CDC commit log files on every live node in the cluster is done through SFTP or NFS. For more information, see Setup SSH Connection to the Cassandra Nodes.
- Every node in the Cassandra cluster must have the cdc\_enabled parameter set to true in the cassandra.yaml configuration file.
- Virtual nodes must be enabled on every Cassandra node by setting the num\_tokens parameter in cassandra.yaml .
- You must download the third party libraries using Dependency downloader scripts. For more information, see Cassandra Capture Client Dependencies.
- New tables can be created with Change Data Capture (CDC) enabled using the WITH CDC=true clause in the CREATE TABLE command. For example:

CREATE TABLE ks\_demo\_rep1.mytable (coll int, col2 text, col3 text, col4 text, PRIMARY KEY (col1)) WITH cdc=true;

You can enable CDC on existing tables as follows:

ALTER TABLE ks\_demo\_rep1.mytable WITH cdc=true;

- Setup SSH Connection to the Cassandra Nodes
   Oracle GoldenGate for BigData transfers Cassandra commit log files from all the
   Cassandra nodes. To allow Oracle GoldenGate to transfer commit log files using secure
   shell protocol (SFTP), generate a known hosts SSH file.
- Data Types
- Cassandra Database Operations
- Set up Credential Store Entry to Detect Source Type

#### Setup SSH Connection to the Cassandra Nodes

Oracle GoldenGate for BigData transfers Cassandra commit log files from all the Cassandra nodes. To allow Oracle GoldenGate to transfer commit log files using secure shell protocol (SFTP), generate a known hosts SSH file.

To generate a known hosts SSH file:

1. Create a text file with all the Cassandra node addresses, one per line. For example:

Generate the known\_hosts file as follows: ssh-keyscan -t rsa -f nodes.txt >> known\_hosts

cat nodes.tx 10.1.1.1 10.1.1.2 10.1.1.3

3. Edit the extract parameter file to include this configuration: TRANLOGOPTIONS SFTP KNOWNHOSTSFILE /path/to/ssh/known hosts.

# Data Types

#### **Supported Cassandra Data Types**

The following are the supported data types:

- ASCII
- BIGINT
- BLOB
- BOOLEAN
- DATE
- DECIMAL
- DOUBLE
- DURATION
- FLOAT
- INET
- INT
- SMALLINT
- TEXT
- TIME
- TIMESTAMP
- TIMEUUID
- TINYINT
- UUID
- VARCHAR
- VARINT

#### **Unsupported Data Types**

The following are the unsupported data types:

- COUNTER
- MAP
- SET
- LIST
- UDT (user defined type)
- TUPLE
- CUSTOM\_TYPE

# Cassandra Database Operations

#### **Supported Operations**

The following are the supported operations:

- INSERT
- UPDATE (Captured as INSERT)
- DELETE

#### **Unsupported Operations**

The TRUNCATE DDL (CREATE, ALTER, and DROP) operation is not supported. Because the Cassandra commit log files do not record any before images for the UPDATE or DELETE operations. The result is that the captured operations can never have a before image. Oracle GoldenGate features that rely on before image records, such as Conflict Detection and Resolution, are not available.

### Set up Credential Store Entry to Detect Source Type

The database type for capture is based on the prefix in the database credential userid. The generic format for useridis as follows: <dbtype>://<db-user>@<comma separated list of server addresses>:<port>

The userid can have multiple server/nodes addresses.

#### **Microservices Build**

More than one node address can be configured in the userid. Example

```
alter credentialstore add user cassandra://db-user@127.0.0.1,127.0.0.2:9042 password db-passwd alias cass
```

#### **Classic Build**

- The userid should contain a single node address.
- If there are more than one node address that needs to be configured for connection, then use the GLOBALS parameter CLUSTERCONTACTPOINTS.
- The connection to the cluster would concatenate the node addresses specified in the userid and CLUSTERCONTACTPOINTS parameter.

#### Example

```
alter credentialstore add user cassandra://db-user@127.0.0.1:9042 password db-passwd alias cass
CLUSTERCONTACTPOINTS 127.0.0.2
```

In this case, the connection will be attempted using 127.0.0.1, 127.0.0.2:9042.

# Deduplication

One of the features of a Cassandra cluster is its high availability. To support high availability, multiple redundant copies of table data are stored on different nodes in the cluster. Oracle GoldenGate for Big Data Cassandra Capture automatically filters out duplicate rows

(**deduplicate**). Deduplication is active by default. Oracle recommends using it if your data is captured and applied to targets where duplicate records are discouraged (for example RDBMS targets).

# **Topology Changes**

Cassandra nodes can change their status (**topology change**) and the cluster can still be alive. Oracle GoldenGate for Big Data Cassandra Capture can detect the node status changes and react to these changes when applicable. The Cassandra capture process can detect the following events happening in the cluster:

- Node shutdown and boot.
- Node decommission and commission.
- New keyspace and table created.

Due to topology changes, if the capture process detects that an active producer node goes down, it tries to recover any missing rows from an available replica node. During this process, there is a possibility of data duplication for some rows. This is a transient data duplication due to the topology change. For more details about reacting to changes in topology, see Troubleshooting.

# Data Availability in the CDC Logs

The Cassandra CDC API can only read data from commit log files in the CDC directory. There is a latency for the data in the active commit log directory to be archived (moved) to the CDC commit log directory.

The input data source for the Cassandra capture process is the CDC commit log directory. There could be delays for the data to be captured mainly due to the commit log files not yet visible to the capture process.

On a production cluster with a lot of activity, this latency is very minimal as the data is archived from the active commit log directory to the CDC commit log directory in the order of microseconds.

# Using Extract Initial Load

Cassandra Extract supports the standard initial load capability to extract source table data to Oracle GoldenGate trail files.

Initial load for Cassandra can be performed to synchronize tables, either as a prerequisite step to replicating changes or as a standalone function.

Direct loading from a source Cassandra table to any target table is not supported.

#### Configuring the Initial Load

Initial load extract parameter file:

```
-- ggsci> alter credentialstore add user cassandra://db-user@127.0.0.1 password
db-passwd alias cass
EXTRACT load
-- When using sdk 3.11 or 3.10 or 3.9
JVMOPTIONS CLASSPATH ggjava/ggjava.jar:/path/to/cassandra-driver-core/3.3.1/
cassandra-driver-core-3.3.1.jar:dirprm:/path/to/apache-cassandra-3.11.0/lib/*:/
path/to/gson/2.3/gson-2.3.jar:/path/to/jsch/0.1.54/jsch-0.1.54.jar
-- When using sdk 3.9
```

```
--JVMOPTIONS CLASSPATH ggjava/ggjava.jar:/path/to/cassandra-driver-core/3.3.1/
cassandra-driver-core-3.3.1.jar:dirprm:/path/to/apache-cassandra-3.9/lib/*:/path/to/
gson/2.3/gson-2.3.jar:/path/to/jsch/0.1.54/jsch-0.1.54.jar
SOURCEDB USERIDALIAS cass
SOURCEISTABLE
EXTFILE ./dirdat/la, megabytes 2048, MAXFILES 999
TABLE keyspace1.table1;
```

#### Note:

Save the file with the name specified in the example (load.prm) into the dirprm directory.

Then you would run these commands in GGSCI:

```
ADD EXTRACT load, SOURCEISTABLE START EXTRACT load
```

### Using Change Data Capture Extract

Review the example .prm files from Oracle GoldenGate for Big Data installation directory under \$HOME/AdapterExamples/big-data/cassandracapture.

1. When adding the Cassandra Extract trail, you need to use EXTTRAIL to create a local trail file.

The Cassandra Extract trail file should not be configured with the RMTTRAIL option.

```
ggsci> ADD EXTRACT groupname, TRANLOG
ggsci> ADD EXTTRAIL trailprefix, EXTRACT groupname
Example:
ggsci> ADD EXTRACT cass, TRANLOG
ggsci> ADD EXTRAIL ./dirdat/z1, EXTRACT cass
```

- 2. To configure the Extract, see the example .prm files in the Oracle GoldenGate for Big Data installation directory in \$HOME/AdapterExamples/big-data/cassandracapture.
- 3. Position the Extract.

ggsci> ADD EXTRACT groupname, TRANLOG, BEGIN NOW ggsci> ADD EXTRACT groupname, TRANLOG, BEGIN 'yyyy-mm-dd hh:mm:ss' ggsci> ALTER EXTRACT groupname, BEGIN 'yyyy-mm-dd hh:mm:ss'

4. Manage the transaction data logging for the tables.

```
ggsci> DBLOGIN SOURCEDB nodeaddress USERID userid PASSWORD password
ggsci> alter credentialstore add user cassandra://db-user@127.0.0.1 password db-
passwd alias cassdblogin useridalias cass
ggsci> ADD TRANDATA keyspace.tablename
ggsci> INFO TRANDATA keyspace.tablename
ggsci> DELETE TRANDATA keyspace.tablename
```

#### Examples:

```
ggsci> dblogin SOURCEDB 127.0.0.1
ggsci> dblogin useridalias cass
ggsci> INFO TRANDATA ks_demo_rep1.mytable
ggsci> INFO TRANDATA ks_demo_rep1.*
ggsci> INFO TRANDATA *.*
```

```
ggsci> INFO TRANDATA ks_demo_rep1."CamelCaseTab"
ggsci> ADD TRANDATA ks_demo_rep1.mytable
ggsci> DELETE TRANDATA ks demo rep1.mytable
```

5. Configure the Extract parameter file:

# Apache Cassandra 4x SDK, compatible with Apache Cassandra 4.0 version Extract parameter file:

```
-- ggsci> alter credentialstore add user cassandra://db-user@127.0.0.1
password db-passwd alias cass
EXTRACT groupname
```

```
JVMOPTIONS CLASSPATH ggjava/ggjava.jar:DependencyDownloader/dependencies/
cassandra_capture_4x/*
JVMOPTIONS BOOTOPTIONS -Dcassandra.config=file://{/path/to/apache-
cassandra-4.x}/config/casandra.yaml -Dcassandra.datacenter={datacenter-name}
```

```
TRANLOGOPTIONS CDCREADERSDKVERSION 4x
TRANLOGOPTIONS CDCLOGDIRTEMPLATE /path/to/data/cdc_raw
SOURCEDB USERIDALIAS cass
EXTTRAIL trailprefix
TABLE source.*;
```

a. Provide the cassandra.yaml file path using JVMOPTIONS BOOTOPTIONS.

```
JVMOPTIONS BOOTOPTIONS -Dcassandra.config=file://{/path/to/apache-
cassandra-4.x}/config/casandra.yaml -Dcassandra.datacenter={datacenter-
name}
```

**b.** Configure cassandra datacenter name under JVMOPTIONS BOOTOPTIONS. If you do not provide a value, then by default, datacenter1 is considered.

# Apache Cassandra 3x SDK, compatible with Apache Cassandra 3.9, 3.10, 3.11

#### Extract parameter file:

```
-- ggsci> alter credentialstore add user cassandra://db-user@127.0.0.1
password db-passwd alias cass
JVMOPTIONS CLASSPATH ggjava/ggjava.jar:DependencyDownloader/dependencies/
cassandra_capture_3x/*
TRANLOGOPTIONS CDCREADERSDKVERSION 3x
TRANLOGOPTIONS CDCLOGDIRTEMPLATE /path/to/data/cdc_raw
SOURCEDB USERIDALIAS cass
EXTTRAIL trailprefix
TABLE source.*;
```

#### DSE Cassandra SDK, compatible with DSE Cassandra 6.x versions Extract parameter file

```
-- ggsci> alter credentialstore add user cassandra://db-user@127.0.0.1
password db-passwd alias cass
    EXTRACT groupname
    JVMOPTIONS CLASSPATH ggjava/ggjava.jar:{/path/to/dse-6.x}/resources/
    cassandra/lib/*:{/path/to/dse-6.x}/lib/*:{/path/to/dse-6.x}/
    resources/dse/lib/*:DependencyDownloader/dependencies/
    cassandra_capture_dse/*
        JVMOPTIONS BOOTOPTIONS -Dcassandra.config=file://{/path/to/dse-6.x}/
    resources/cassandra/conf/casandra.yaml -Dcassandra.datacenter={datacenter-
```

ORACLE

name}
TRANLOGOPTIONS CDCREADERSDKVERSION dse
TRANLOGOPTIONS CDCLOGDIRTEMPLATE /path/to/data/cdc\_raw
SOURCEDB USERIDALIAS cass
EXTTRAIL trailprefix
TABLE source.\*;

a. Provide the cassandra.yaml file path using JVMOPTIONS BOOTOPTIONS:

JVMOPTIONS BOOTOPTIONS -Dcassandra.config=file://{/path/to/dse-6.x}/resources/ cassandra/conf/casandra.yaml -Dcassandra.datacenter={datacenter-name}

**b.** Configure cassandra datacenter name under JVMOPTIONS BOOTOPTIONS. If you do not provide a value, then by default, Cassandra is considered.

#### Note:

For DSE 5.x version, configure the extract with Apache 3x SDK as explained in the Apache 3x section.

Handling Schema Evolution

#### Handling Schema Evolution

#### Syntax

TRANLOGOPTIONS TRACKSCHEMACHANGES

This will enable extract to capture table level DDL changes from the source at runtime.

Enable this to ensure that the table metadata within the trail stays in sync with the source without any downtime.

When TRACKSCHEMACHANGES is disabled, the capture process will ABEND if a DDL change is detected at the source table.

#### Note:

This feature is disabled by default. To enable, update the extract prm file as shown in the syntax above.

# Replicating to RDMBS Targets

You must take additional care when replicating source UPDATE operations from Cassandra trail files to RDMBS targets. Any source UPDATE operation appears as an INSERT record in the Oracle GoldenGate trail file. Replicat may abend when a source UPDATE operation is applied as an INSERT operation on the target database.

#### You have these options:

• OVERRIDEDUPS: If you expect that the source database is to contain mostly INSERT operations and very few UPDATE operations, then OVERRIDEDUPS is the recommended

option. Replicat can recover from duplicate key errors while replicating the small number of the source UPDATE operations. See OVERRIDEDUPS \ NOOVERRIDEDUPS

- UPDATEINSERTS and INSERTMISSINGUPDATES: Use this configuration if the source database is expected to contain mostly UPDATE operations and very few INSERT operations. With this configuration, Replicat has fewer missing row errors to recover, which leads to better throughput. See UPDATEINSERTS | NOUPDATEINSERTS and INSERTMISSINGUPDATES | NOINSERTMISSINGUPDATES.
- No additional configuration is required if the target table can accept duplicate rows or you want to abend Replicat on duplicate rows.

If you configure Replicat to use BATCHSQL, there may be duplicate row or missing row errors in batch mode. Although there is a reduction in the Replicat throughput due to these errors, Replicat automatically recovers from these errors. If the source operations are mostly INSERTS, then BATCHSQL is a good option.

# Partition Update or Insert of Static Columns

When the source Cassandra table has static columns, the static column values can be modified by skipping any clustering key columns that are in the table.

For example:

```
create table ks_demo_rep1.nls_staticcol
(
    teamname text,
    manager text static,
    location text static,
    membername text,
    nationality text,
    position text,
    PRIMARY KEY ((teamname), membername)
)
WITH cdc=true;
insert into ks_demo_rep1.nls_staticcol (teamname, manager, location)
VALUES ('Red Bull', 'Christian Horner', '<unknown>
```

The insert CQL is missing the clustering key membername. Such an operation is a partition insert.

Similarly, you could also update a static column with just the partition keys in the WHERE clause of the CQL that is a partition update operation. Cassandra Extract cannot write a INSERT or UPDATE operation into the trail with missing key columns. It abends on detecting a partition INSERT or UPDATE operation.

# **Partition Delete**

A Cassandra table may have a primary key composed on one or more partition key columns and clustering key columns. When a DELETE operation is performed on a Cassandra table by skipping the clustering key columns from the WHERE clause, it results in a partition delete operation.

#### For example:

```
create table ks_demo_rep1.table1
(
    col1 ascii, col2 bigint, col3 boolean, col4 int,
    PRIMARY KEY((col1, col2), col4)
) with cdc=true;
delete from ks_demo_rep1.table1 where col1 = 'asciival' and col2 =
9876543210; /** skipped clustering key column col4 **/
```

Cassandra Extract cannot write a DELETE operation into the trail with missing key columns and abends on detecting a partition DELETE operation.

### Security and Authentication

- Cassandra Extract can connect to a Cassandra cluster using username and password based authentication and SSL authentication.
- Connection to Kerberos enabled Cassandra clusters is *not* supported in this release.
- Configuring SSL

### Configuring SSL

To enable SSL, add the SSL parameter to your GLOBALS file or Extract parameter file. Additionally, a separate configuration is required for the Java and CPP drivers, see CDC Configuration Reference.

#### SSL configuration for Java driver (GLOBALS file)

```
JVMBOOTOPTIONS -Djavax.net.ssl.trustStore=/path/to/SSL/truststore.file
-Djavax.net.ssl.trustStorePassword=password
-Djavax.net.ssl.keyStore=/path/to/SSL/keystore.file
-Djavax.net.ssl.keyStorePassword=password
```

#### SSL configuration for Java driver (Extract parameter file)

You can also configure the SSL parameters in the Extract parameter file as follows:

```
JVMOPTIONS BOOTOPTIONS -Djavax.net.ssl.trustStore=/path/to/SSL/truststore.file
-Djavax.net.ssl.trustStorePassword=password
-Djavax.net.ssl.keyStore=/path/to/SSL/keystore.file
-Djavax.net.ssl.keyStorePassword=password
```

#### Note:

The Extract parameter file configuration has a higher precedence.

The keystore and truststore certificates can be generated using these instructions:

https://docs.datastax.com/en/cassandra/3.0/cassandra/configuration/secureSSLIntro.html

Using Apache Cassandra 4x SDK / DSE Cassandra SDK

To configure SSL while capturing from Apache Cassandra 4.x versions or DSE Cassandra 6.x versions, do the following:

1. Create the application.conf file with the following properties and override with appropriate values :

```
datastax-java-driver {
 advanced.ssl-engine-factory {
   class = DefaultSslEngineFactory
    # Whether or not to require validation that the hostname of the server
certificate's common
    # name matches the hostname of the server being connected to. If not
set, defaults to true.
   hostname-validation = false
    # The locations and passwords used to access truststore and keystore
contents.
    # These properties are optional. If either truststore-path or keystore-
path are specified,
    # the driver builds an SSLContext from these files. If neither option is
specified, the
    # default SSLContext is used, which is based on system property
configuration.
   truststore-path = {path to truststore file}
    truststore-password = password
   keystore-path = {path to keystore file}
   keystore-password = cassandra
 }
}
```

2. Provide path of the directory containing the application.conf file under JVMCLASSPATH as follows:

```
JVMCLASSPATH
ggjava/ggjava.jar:DependencyDownloader/dependencies/cassandra_capture_4x/*:/
path/to/driver/config
```

#### Note:

This is valid only in case of the GLOBALS file.

You can also configure the SSL parameters in the Extract parameter file as follows:

```
JVMOPTIONS CLASSPATH
ggjava/ggjava.jar:DependencyDownloader/dependencies/cassandra_capture_4x/*:/
path/to/driver/config/
```

For more information, see https://github.com/datastax/java-driver/blob/4.x/core/src/ main/resources/reference.conf.

#### SSL configuration for Cassandra CPP driver

To operate with an SSL configuration, you have to add the following parameter in the Oracle GoldenGate GLOBALS file or Extract parameter file:

CPPDRIVEROPTIONS SSL PEMPUBLICKEYFILE /path/to/PEM/formatted/public/key/file/ cassandra.pem CPPDRIVEROPTIONS SSL PEERCERTVERIFICATIONFLAG 0

This configuration is required to connect to a Cassandra cluster with SSL enabled. Additionally, you need to add these settings to your cassandra.yaml file:

```
client_encryption_options:
    enabled: true
    # If enabled and optional is set to true encrypted and unencrypted connections are
handled.
    optional: false
    keystore: /path/to/keystore
    keystore_password: password
    require_client_auth: false
```

The PEM formatted certificates can be generated using these instructions:

https://docs.datastax.com/en/developer/cpp-driver/2.8/topics/security/ssl/

# Cleanup of CDC Commit Log Files

You can use the Cassandra CDC commit log purger program to purge the CDC commit log files that are not in use.

For more information, see How to Run the Purge Utility.

Cassandra CDC Commit Log Purger

A purge utility for Cassandra Handler to purge the staged CDC commit log files. Cassandra Extract moves the CDC commit log files (located at \$CASSANDRA/data/ cdc\_raw) on each node to a staging directory for processing.

#### Cassandra CDC Commit Log Purger

A purge utility for Cassandra Handler to purge the staged CDC commit log files. Cassandra Extract moves the CDC commit log files (located at \$CASSANDRA/data/cdc\_raw) on each node to a staging directory for processing.

For example, if the cdc\_raw commit log directory is /path/to/cassandra/home/data/ cdc\_raw, the staging directory is /path/to/cassandra/home/data/cdc\_raw/../ cdc\_raw\_staged. The CDC commit log purger purges those files, which are inside cdc raw staged based on following logic.

The Purge program scans the oggdir directory for all the following JSON checkpoint files under dirchk/<EXTGRP>\_casschk.json. The sample JSON file under dirchk looks similar to the following:

```
{
"start_timestamp": -1,
"sequence_id": 34010434,
"updated_datetime": "2018-04-19 23:24:57.164-0700",
"nodes": [
{ "address": "10.247.136.146", "offset": 0, "id": 0 }
,
{ "address": "10.247.136.142", "file": "CommitLog-6-1524110205398.log",
"offset": 33554405, "id": 1524110205398 }
,
{ "address": "10.248.10.24", "file": "CommitLog-6-1524110205399.log",
"offset": 33554406, "id": 1524110205399 }
```

For each node address in JSON checkpoint file, the purge program captures the CDC file name and ID. For each ID obtained from the JSON checkpoint file, the purge program looks into the staged CDC commit log directory and purges the commit log files with the id that are lesser then the id captured in JSON file of checkpoint.

#### Example:

] }

In JSON file, we had ID as 1524110205398.

In CDC Staging directory, we have files as CommitLog-6-1524110205396.log, CommitLog-6-1524110205397.log, and CommitLog-6-1524110205398.log.

The ids derived from CDC staging directory are 1524110205396, 1524110205397 and 1524110205398. The purge utility purges the files in CDC staging directory whose IDs are less than the ID read in JSON file, which is 1524110205398. The files associated with the ID 1524110205396 are 524110205397 are purged.

- How to Run the Purge Utility
- Sample config.properties for Local File System
- Argument cassCommitLogPurgerConfFile
- Argument purgeInterval Setting the optional argument purgeInterval helps in configuring the process to run as a daemon.
- Argument cassUnProcessedFilesPurgeInterval Setting the optional argument cassUnProcessedFilesPurgeInterval helps in purging historical commit logs for all the nodes that do not have a last processed file.

#### How to Run the Purge Utility

- Third Party Libraries Needed to Run this Program
- Command to Run the Program
- Runtime Arguments

Third Party Libraries Needed to Run this Program

```
<dependency>
<groupId>com.jcraft</groupId>
<artifactId>jsch</artifactId>
<version>0.1.54</version>
<scope>provided</scope>
</dependency>
```

#### Command to Run the Program

```
java -Dlog4j.configurationFile=log4j-purge.properties -Dgg.log.level=INFO -cp
<OGG_HOME>/ggjava/resources/lib/*:<OGG_HOME>/thirdparty/cass/jsch-0.1.54.jar
oracle.goldengate.cassandra.commitlogpurger.CassandraCommitLogPurger
--cassCommitLogPurgerConfFile <OGG_HOME>/cassandraPurgeUtil/
commitlogpurger.properties
--purgeInterval 1 --cassUnProcessedFilesPurgeInterval 3
```

Where:

- <OGG HOME>/ggjava/resources/lib/\* is the directory where the purger utility is located.
- <OGG\_HOME>/thirdparty/cass/jsch-0.1.54.jar is the dependent jar to execute the purger program.
- ---cassCommitLogPurgerConfFile, --purgeInterval and -cassUnProcessedFilesPurgeInterval are run time arguments.

#### Sample script to run the commit log purger utility:

```
#!/bin/bash
echo "fileSystemType=remote" > commitlogpurger.properties
echo "chkDir=dirchk" >> commitlogpurger.properties
echo "cdcStagingDir=data/cdc_raw_staged" >> commitlogpurger.properties
echo "userName=username" >> commitlogpurger.properties
echo "password=password" >> commitlogpurger.properties
java -cp ogghome/ggjava/resources/lib/*:ogghome/thirdparty/cass/jsch-0.1.54.jar
oracle.goldengate.cassandra.commitlogpurger.CassandraCommitLogPurger
--cassCommitLogPurgerConfFile commitlogpurger.properties
--purgeInterval 1
--cassUnProcessedFilesPurgeInterval 3
```

#### **Runtime Arguments**

To execute, the utility class CassandraCommitLogPurger requires a mandatory run-time argument cassCommitLogPurgerConfFile.

Available Runtime arguments to CassandraCommitLogPurger class are:

```
[required] --cassCommitLogPurgerConfFile path to config.properties
[optional] --purgeInterval
[optional] --cassUnProcessedFilesPurgeInterval
```

#### Sample config.properties for Local File System

```
fileSystemType=local
chkDir=apache-cassandra-3.11.2/data/chkdir/
cdcStagingDir=apache-cassandra-3.11.2/data/$nodeAddress/commitlog/
```

### Argument cassCommitLogPurgerConfFile

The required cassCommitLogPurgerConfFile argument takes the config file with following mandate fields.

#### Table 8-1 Argument cassCommitLogPurgerConfFile

Parameters	Description
fileSystemType	Default: local Mandatory: Yes
	Legal Values: remote/ local
	<b>Description</b> : In every live node in the cluster, CDC Staged Commit logs can be accessed through SFTP or NFS. If the fileSystemType is
	Remote (SFTP) then we need to supply the Host with Port, username, and password/privateKey (with or without passPhase) to connect and do the operations on remote CDC staging directory.

Parameters	Description
chkDir	Default: None Mandatory: Yes
	Legal Values: checkpoint directory path Description: Location of Cassandra checkpoint directory where _casschk.json file is located (for example, dirchk/ <extgrp>_casschk.json).</extgrp>
cdcStagingDir	Default: None Mandatory: Yes
	Legal Values: staging directory path Description: Location of Cassandra staging directory where CDC commit logs are present. For example, \$CASSANDRA/data/cdc_raw_staged/ CommitLog-6-1524110205396.log).
userName	Default: None Mandatory: No
	<b>Legal Values</b> : Valid SFTP auth username <b>Description</b> : SFTP User name to connect to the server.
password	Default: None Mandatory: No
	Legal Values: Valid SFTP auth password Description: SFTP password to connect to the server.
port	Default: 22 Mandatory: No
	Legal Values: Valid SFTP auth port Description: SFTP port number
privateKey	Default: None Mandatory: No
	Legal Values: valid path to the privateKey file Description: The private key is used to perform the authentication, allowing you to log in without having to specify a password. Providing the privateKey file path allows the purger program to access the nodes with out password.
passPhase	Default: None
	Mandatory: No
	Legal Values: valid password for privateKey Description: The private key is typically password protected. If it is provided, then the passPhase with privateKey and passPhase are required to be passed with the password that helps the purger program to successfully access the nodes.

 Table 8-1
 (Cont.) Argument cassCommitLogPurgerConfFile

Sample config.properties for Local File System

Sample config.properties for Remote File System

#### Sample config.properties for Local File System

```
fileSystemType=local
chkDir=apache-cassandra-3.11.2/data/chkdir/
cdcStagingDir=apache-cassandra-3.11.2/data/$nodeAddress/commitlog/
```

#### Sample config.properties for Remote File System

```
fileSystemType=remote
chkDir=apache-cassandra-3.11.2/data/chkdir/
cdcStagingDir=apache-cassandra-3.11.2/data/$nodeAddress/commitlog/
username=username
password=@@@@@@
port=22
```

#### Argument purgeInterval

Setting the optional argument purgeInterval helps in configuring the process to run as a daemon.

This argument is an integer value representing the time period of clean-up to happen. For example, if purgeInterval is set to 1, then the process runs every day on the time the process started.

#### Argument cassUnProcessedFilesPurgeInterval

Setting the optional argument cassUnProcessedFilesPurgeInterval helps in purging historical commit logs for all the nodes that do not have a last processed file.

If cassUnProcessedFilesPurgeInterval is not set, then the default value is configured to 2 days; the files older than 2 days or as per the configured value days, and the commit log files are purged. The CassandraCommitLogPurger Utility can't purge files that are older than a day. It should be either the default 2 days or more than that. The following is an example of checkpoint file:

```
{
"start_timestamp": -1,
"sequence_id": 34010434,
"updated_datetime": "2018-04-19 23:24:57.164-0700",
"nodes": [
{ "address": "10.247.136.146", "offset": 0, "id": 0 }
,
   ( "address": "10.247.136.142", "file": "CommitLog-6-1524110205398.log", "offset":
33554405, "id": 1524110205398 }
,
   ( "address": "10.248.10.24", "file": "CommitLog-6-1524110205399.log", "offset":
33554406, "id": 1524110205399 }
,
   ( "address": "10.248.10.25", "offset": 0, "id": 0 }
,
   ( "address": "10.248.10.26", "offset": 0, "id": 0 }
]
```

In this example, the Cassandra nodes addresses 10.248.10.25 and 10.248.10.26 do not have a last processed file. The commit log files in those nodes will be purged as per the configured days of cassUnProcessedFilesPurgeInterval argument value.

#### Note:

The last processing file may not be available due to the following reasons:

- A new node was added into the cluster and no commit log files were processed through Cassandra extract yet.
- All the commit log files processed from this node does not contain operation data as per the table wildcard match.
- All the commit log files processed from this node contain operation records that were not written to the trail file due to de-duplication.

# Multiple Extract Support

Multiple Extract groups in a single Oracle GoldenGate for Big Data installation can be configured to connect to the same Cassandra cluster.

To run multiple Extract groups:

- One (and only one) Extract group can be configured to move the commit log files in the cdc\_raw directory on the Cassandra nodes to a staging directory. The movecommitlogstostagingdir parameter is enabled by default and no additional configuration is required for this Extract group.
- 2. All the other Extract groups should be configured with the nomovecommitlogstostagingdir parameter in the Extract parameter (.prm) file.

# **CDC** Configuration Reference

Properties			Default	Explanation
DBOPTIONS ENABLE_CPP_DRI VER_TRACE true	Opti onal	Extract param eter (.prm) file.	false	Use only during initial load process. When set to true, the Cassandra driver logs all the API calls to a driver.log file. This file is created in the Oracle GoldenGate for Big Data installation directory. This is useful for debugging.

The following properties are used with Cassandra change data capture.

Properties	Req uire d/ Opti onal		Default	Explanation
DBOPTIONS FETCHBATCHSIZE number	Opti onal	Extract param eter (.prm) file.	1000 Minimu m is 1 Maximu m is 100000	Use only during initial load process. Specifies the number of rows of data the driver attempts to fetch on each request submitted to the database server. The parameter value should be lower than the database configuration parameter, tombstone_warn_threshold, in the database configuration file, cassandra.yaml. Otherwise the initial load process might fail. Oracle recommends that you set this parameter value to 5000 for initial load Extract optimum performance.
TRANLOGOPTIONS CDCLOGDIRTEMPL ATE path	Req uire d	Extract param eter (.prm) file.	None	The CDC commit log directory path template. The template can optionally have the <i>\$nodeAddress</i> meta field that is resolved to the respective node address.
TRANLOGOPTIONS SFTP options	Opti onal		None	The secure file transfer protocol (SFTP) connection details to pull and transfer the commit log files. You can use one or more of these options: USER user The SFTP user name. PASSWORD password The SFTP password. KNOWNHOSTSFILE file The location of the Secure Shell (SSH)known hosts file. LANDINGDIR dir The SFTP landing directory for the commit log files on the local machine. PRIVATEKEY file The SSH private key file. PASSPHRASE password The SSH private key pass phrase. PORTNUMBER portnumber The SSH port number.

Properties	Req uire d/ Opti onal	Default	Explanation
CLUSTERCONTACT POINTS nodes	d/ Opti onal Opti	 127.0. 0.1	A comma separated list of nodes to be used for a connection to the Cassandra cluster. You should provide at least one node address. The parameter options are: PORT <pre> PORT <port connecting="" database.="" default="" no="" number="" optional="" port="" so="" t<="" td="" the="" to="" use="" when=""></port></pre>

Properties	Req uire d/ Opti onal	Locati on	Default	Explanation
TRANLOGOPTIONS CDCREADERSDKVE RSION version	Opti onal	Extract param eter (.prm) file.	3.11	The SDK Version for the CDC reader capture API.
ABENDONMISSEDR ECORD   NOABENDONMISSE DRECORD	Opti onal	Extract param eter (.prm) file.	true	When set to true and the possibility of a missing record is found, the process stops with the diagnostic information. This is generally detected when a node goes down and the CDC reader doesn't find a replica node with a matching last record from the dead node. You can set this parameter to false to continue processing. A warning message is logged about the scenario.
TRANLOGOPTIONS CLEANUPCDCCOMM ITLOGS	Opti onal	Extract param eter (.prm) file.	false	Purge CDC commit log files post extract processing. When the value is set to false, the CDC commit log files are moved to the staging directory for the commit log files.
JVMOPTIONS [CLASSPATH < <i>classpath&gt;</i>   BOOTOPTIONS < <i>options&gt;</i> ]	Man dato ry	Extract param eter (.prm) file.	None	<ul> <li>CLASSPATH: The classpath for the Java Virtual Machine. You can include an asterisk (*) wildcard to match all JAR files in any directory. Multiple paths should be delimited with a colon (:) character.</li> <li>BOOTOPTIONS: The boot options for the Java Virtual Machine. Multiple options are delimited by a space character.</li> </ul>

Properties	Req uire d/ Opti onal		Default	Explanation
SOURCEDB nodeaddress USERID dbuser PASSWORD dbpassword	Req uire d	Extract param eter (.prm) file.	None	A single Cassandra node address that is used for a connection to the Cassandra cluster and to query the metadata for the captured tables. USER dbuser No default Optional The user name to use when connecting to the database. PASSWORD dbpassword No default Required when USER is used. The user password to use when connecting to the database.
ABENDONUPDATER ECORDWITHMISSI NGKEYS   NOABENDONUPDAT ERECORDWITHMIS SINGKEYS	Opti onal	Extract param eter (.prm) file.	true	If this value is true, anytime an UPDATE operation record with missing key columns is found, the process stops with the diagnostic information. You can set this property to false to continue processing and write this record to the trail file. A warning message is logged about the scenario. This operation is a partition update, see Partition Update or Insert of Static Columns.
ABENDONDELETER ECORDWITHMISSI NGKEYS   NOABENDONDELET ERECORDWITHMIS SINGKEYS	Opti onal	Extract param eter (.prm) file.	true	If this value is true, anytime an DELETE operation record with missing key columns is found, the process stops with the diagnostic information. You can set this property to false to continue processing and write this record to the trail file. A warning message is logged about the scenario. This operation is a partition update, see Partition Delete.
MOVECOMMITLOGS TOSTAGINGDIR   NOMOVECOMMITLO GSTOSTAGINGDIR		Extract param eter (.prm) file.	true	Enabled by default and this instructs the Extract group to move the commit log files in the cdc_raw directory on the Cassandra nodes to a staging directory for the commit log files. Only one Extract group can have movecommitlogstostagingdir enabled, and all the other Extract groups disable this by specifying nomovecommitlogstostagingdir.

Properties	Req uire d/ Opti onal		Default	Explanation
SSL		GLOB ALS or Extract param eter (.prm) file.	false	Use for basic SSL support during connection. Additional JSSE configuration through Java System properties is expected when enabling this. Note: The following SSL properties are in CPPDRIVEROPTION S SSL so this keyword must be added to any other SSL property to work.
CPPDRIVEROPTIO NS SSL PEMPUBLICKEYFI LE cassadra.pem		GLOB ALS or Extract param eter (.prm) file. String that indicat es the absolut e path with fully qualifie d name. This file is must for the SSL connec tion.	the PEMPUB LICKEY FILE property is specifie d, then you	Indicates that it is PEM formatted public key file used to verify the peer's certificate. This property is needed for one-way handshake or basic SSL connection.

Properties	Req uire d/ Opti onal		Default	Explanation
CPPDRIVEROPTIO NS SSL ENABLECLIENTAU TH   DISABLECLIENTA UTH	Opti onal	GLOB ALS or Extract param eter (.prm) file.	false	Enabled indicates a two-way SSL encryption between client and server. It is required to authenticate both the client and the server through PEM formatted certificates. This property also needs the pemclientpublickeyfile and pemclientprivatekeyfile properties to be set. The pemclientprivatekeypasswd property must be configured if the client private key is password protected. Setting this property to false disables client authentication for two- way handshake.
CPPDRIVEROPTIO NS SSL PEMCLIENTPUBLI CKEYFILE public.pem	Opti onal	GLOB ALS or Extract param eter (.prm) file. String that indicat es the absolut e path with fully qualifie d name. This file is must for the SSL connec tion.	the PEMCLI ENTPUB LICKEY FILE property is specifie d, then	Use for a PEM formatted public key file name used to verify the client's certificate. This is must if you are using CPPDRIVEROPTIONS SSL ENABLECLIENTAUTH or for two-way handshake.

Properties	Req uire d/ Opti onal		Default	Explanation
CPPDRIVEROPTIO NS SSL PEMCLIENTPRIVA TEKEYFILE public.pem	Opti onal	GLOB ALS or Extract param eter (.prm) file. String that indicat es the absolut e path with fully qualifie d name. This file is must for the SSL connec tion.	PEMCLI ENTPRI VATEKE YFILE property is specifie d, then	Use for a PEM formatted private key file name used to verify the client's certificate. This is must if you are using CPPDRIVEROPTIONS SSL ENABLECLIENTAUTH or for two-way handshake.
CPPDRIVEROPTIO NS SSL PEMCLIENTPRIVA TEKEYPASSWD privateKeyPass wd	Opti onal	GLOB ALS or Extract param eter (.prm) file. A string	None, unless the PEMCLI ENTPRI VATEKE YPASSW D property is specifie d, then you must specify a value.	Sets the password for the PEM formatted private key file used to verify the client's certificate. This is must if the private key file is protected with the password.
CPPDRIVEROPTIO NS SSL PEERCERTVERIFI CATIONFLAG value	Opti onal	GLOB ALS or Extract param eter (.prm) file. An integer	0	Sets the verification required on the peer's certificate. The range is 0–4: 0–Disable certificate identity verification. 1–Verify the peer certificate 2–Verify the peer identity 3– Not used so it is similar to disable certificate identity verification. 4 –Verify the peer identity by its domain name

Properties	Req uire d/ Opti onal	Locati on	Default	Explanation
CPPDRIVEROPTIO NS SSL ENABLEREVERSED NS	Opti onal	GLOB ALS or Extract param eter (.prm) file.	false	Enables retrieving host name for IP addresses using reverse IP lookup.
TRANLOGOPTIONS TRACKSCHEMACHA NGES	Opti onal	Extract param eter (.prm) file.	By default, the property is disabled	This will enable extract to capture table level DDL changes from the source at runtime. Enable this to ensure that the table metadata within the trail stays in sync with the source without any downtime. When TRACKSCHEMACHANGES is disabled, the capture process will ABEND if a DDL change is detected at the source table.

### Troubleshooting

No data captured by the Cassandra Extract process.

- The Cassandra database has not flushed the data from the active commit log files to the CDC commit log files. The flush is dependent on the load of the Cassandra cluster.
- The Cassandra Extract captures data from the CDC commit log files only.
- Check the CDC property of the source table. The CDC property of the source table should be set to true.
- Data is not captured if the TRANLOGOPTIONS CDCREADERSDKVERSION 3.9 parameter is in use and the JVMCLASSPATH is configured to point to Cassandra 3.10 or 3.11 JAR files.

### Error: OGG-01115 Function getInstance not implemented.

• The following line is missing from the GLOBALS file.

OGGSOURCE CASSANDRA

# Error: Unable to connect to Cassandra cluster, Exception: com.datastax.driver.core.exceptions.NoHostAvailableException

This indicates that the connection to the Cassandra cluster was unsuccessful.

Check the following parameters:

CLUSTERCONTACTPOINTS

### Error: Exception in thread "main" java.lang.NoClassDefFoundError: oracle/goldengate/ capture/cassandra/CassandraCDCProcessManager

Check the JVMOPTIONS CLASSPATH parameter in the GLOBALS file.

Error: oracle.goldengate.util.Util - Unable to invoke method while constructing object. Unable to create object of class "oracle.goldengate.capture.cassandracapture311.SchemaLoader3DOT11" Caused by: java.lang.NoSuchMethodError: org.apache.cassandra.config.DatabaseDescriptor.clientInitialization()V

There is a mismatch in the Cassandra SDK version configuration. The TRANLOGOPTIONS CDCREADERSDKVERSION 3.11 parameter is in use and the JVMCLASSPATH may have the Cassandra 3.9 JAR file path.

## Error: OGG-25171 Trail file '/path/to/trail/gg' is remote. Only local trail allowed for this extract.

A Cassandra Extract should only be configured to write to local trail files. When adding trail files for Cassandra Extract, use the EXTTRAIL option. For example:

ADD EXTTRAIL ./dirdat/z1, EXTRACT cass

#### Errors: OGG-868 error message or OGG-4510 error message

The cause could be any of the following:

- Unknown user or invalid password
- Unknown node address
- Insufficient memory

Another cause could be that the connection to the Cassandra database is broken. The *error message* indicates the database error that has occurred.

#### Error: OGG-251712 Keyspace keyspacename does not exist in the database.

The issue could be due to these conditions:

- During the Extract initial load process, you may have deleted the KEYSPACE *keyspacename* from the Cassandra database.
- The KEYSPACE keyspacename does not exist in the Cassandra database.

### Error: OGG-25175 Unexpected error while fetching row.

This can occur if the connection to the Cassandra database is broken during initial load process.

# Error: "Server-side warning: Read 915936 live rows and 12823104 tombstone cells for query SELECT \* FROM *keyspace.table*(see tombstone\_warn\_threshold)".

When the value of the initial load DBOPTIONS FETCHBATCHSIZE parameter is greater than the Cassandra database configuration parameter, tombstone\_warn\_threshold, this is likely to occur.

Increase the value of tombstone\_warn\_threshold or reduce the DBOPTIONS FETCHBATCHSIZE value to get around this issue.

### Duplicate records in the Cassandra Extract trail.

Internal tests on a multi-node Cassandra cluster have revealed that there is a possibility of duplicate records in the Cassandra CDC commit log files. The duplication in the Cassandra commit log files is more common when there is heavy write parallelism, write errors on nodes, and multiple retry attempts on the Cassandra nodes. In these cases, it is expected that Cassandra trail file will have duplicate records.

### JSchException or SftpException in the Extract Report File

Verify that the SFTP credentials (user, password, and privatekey) are correct. Check that the SFTP user has read and write permissions for the cdc\_raw directory on each of the nodes in the Cassandra cluster.

## ERROR o.g.c.c.CassandraCDCProcessManager - Exception during creation of CDC staging directory [{}]java.nio.file.AccessDeniedException

The Extract process does not have permission to create CDC commit log staging directory. For example, if the cdc\_raw commit log directory is /path/to/cassandra/home/data/ cdc\_raw, then the staging directory would be /path/to/cassandra/home/data/cdc\_raw/../ cdc raw staged.

### Extract report file shows a lot of DEBUG log statements

On production system, you do not need to enable debug logging. To use INFO level logging, make sure that the Extract parameter file include this

JVMBOOTOPTIONS -Dlogback.configurationFile=AdapterExamples/big-data/cassandracapture/ logback.xml

## To enable SSL in Oracle Golden Gate Cassandra Extract you have to enable SSL in the GLOBALS file or in the Extract Parameter file.

If SSL Keyword is missing, then Extract assumes that you wanted to connect without SSL. So if the Cassandra.yaml file has an SSL configuration entry, then the connection fails.

#### SSL is enabled and it is one-way handshake

You must specify the CPPDRIVEROPTIONS SSL PEMPUBLICKEYFILE /scratch/testcassandra/ testssl/ssl/cassandra.pem property.

If this property is missing, then Extract generates this error:.

2018-06-09 01:55:37 ERROR OGG-25180 The PEM formatted public key file used to verify the peer's certificate is missing.

If SSL is enabled, then it is must to set PEMPUBLICKEYFILE in your Oracle GoldenGate GLOBALS file or in Extract parameter file

### SSL is enabled and it is two-way handshake

You must specify these properties for SSL two-way handshake:

```
CPPDRIVEROPTIONS SSL ENABLECLIENTAUTH
CPPDRIVEROPTIONS SSL PEMCLIENTPUBLICKEYFILE /scratch/testcassandra/testssl/ssl/
datastax-cppdriver.pem
CPPDRIVEROPTIONS SSL PEMCLIENTPRIVATEKEYFILE /scratch/testcassandra/testssl/ssl/
```

datastax-cppdriver-private.pem
CPPDRIVEROPTIONS SSL PEMCLIENTPRIVATEKEYPASSWD cassandra

### Additionally, consider the following:

• If ENABLECLIENTAUTH is missing then Extract assumes that it is one-way handshake so it ignores PEMCLIENTPRIVATEKEYFILE and PEMCLIENTPRIVATEKEYFILE. The following error occurs because the cassandra.yaml file should have require client auth set to true.

2018-06-09 02:00:35  $\mbox{ERROR}$  OGG-00868 No hosts available for the control connection.

• If ENABLECLIENTAUTH is used and PEMCLIENTPRIVATEKEYFILE is missing, then this error occurs:

2018-06-09 02:04:46 ERROR OGG-25178 The PEM formatted private key file used to verify the client's certificate is missing. For two way handshake or if ENABLECLIENTAUTH is set, then it is mandatory to set PEMCLIENTPRIVATEKEYFILE in your Oracle GoldenGate GLOBALS file or in Extract parameter file.

• If ENABLECLIENTAUTH is use and PEMCLIENTPUBLICKEYFILE is missing, then this error occurs:

2018-06-09 02:06:20 ERROR OGG-25179 The PEM formatted public key file used to verify the client's certificate is missing. For two way handshake or if ENABLECLIENTAUTH is set, then it is mandatory to set PEMCLIENTPUBLICKEYFILE in your Oracle GoldenGate GLOBALS file or in Extract parameter file.

• If the password is set while generating the client private key file then you must add PEMCLIENTPRIVATEKEYPASSWD to avoid this error:

2018-06-09 02:09:48 ERROR OGG-25177 The SSL certificate: /scratch/ jitiwari/testcassandra/testssl/ssl/datastax-cppdriver-private.pem can not be loaded. Unable to load private key.

 If any of the PEM file is missing from the specified absolute path, then this error occurs:

2018-06-09 02:12:39 ERROR OGG-25176 Can not open the SSL certificate: / scratch/jitiwari/testcassandra/testssl/ssl/cassandra.pem.

#### com.jcraft.jsch.JSchException: UnknownHostKey

If the extract process ABENDs with this issue, then it is likely that some or all the Cassandra node addresses are missing in the SSH known-hosts file. For more information, see Setup SSH Connection to the Cassandra Nodes.

#### **General SSL Errors**

Consider these general errors:

- The SSL connection may fail if you have enabled all SSL required parameters in Extract or GLOBALS file and the SSL is not configured in the cassandra.yaml file.
- The absolute path or the qualified name of the PEM file may not correct. There
  could be access issue on the PEM file stored location.
- The password added during generating the client private key file may not be correct or you may not have enabled it in the Extract parameter or GLOBALS file.

### Cassandra Capture Client Dependencies

What are the dependencies for the Cassandra Capture (Extract) to connect to Apache Cassandra databases?

The following third party libraries are needed to run Cassandra Change Data Capture.

Capturing from Apache Cassandra 3.x versions:

- cassandra-driver-core (com.datastax.cassandra) version 3.3.1
- cassandra-all (org.apache.cassandra) version 3.11.0
- gson (com.google.code.gson) version 2.8.0
- jsch (com.jcraft) version 0.1.54

Capturing from Apache Cassandra 4.x versions:

- java-driver-core (com.datastax.oss) version 4.14.1
- cassandra-all (org.apache.cassandra) version 4.0.5
- gson (com.google.code.gson) version 2.8.0
- jsch (com.jcraft) version 0.1.54

You can use the Dependency Downloader scripts to download the Datastax Java Driver and its associated dependencies. For more information, see Dependency Downloader.

### Apache Kafka

The Oracle GoldenGate capture (Extract) for Kafka is used to read messages from a Kafka topic or topics and convert data into logical change records written to GoldenGate trail files. This section explains how to use Oracle GoldenGate capture for Kafka.

- Overview
- Prerequisites
- General Terms and Functionality of Kafka Capture
- Generic Mutation Builder
- Kafka Connect Mutation Builder
- Example Configuration Files

### Overview

Kafka has gained market traction in recent years and become a leader in the enterprise messaging space. Kafka is a cluster-based messaging system that provides high availability, fail over, data integrity through redundancy, and high performance. Kafka is now the leading application for implementations of the Enterprise Service Bus architecture. Kafka Capture extract process reads messages from Kafka and transforms those messages into logical change records which are written to Oracle GoldenGate trail files. The generated trail files can then be used to propagate the data in the trail file to various RDBMS implementations or other integrations supported by Oracle GoldenGate replicat processes.

### Prerequisites

• Set up Credential Store Entry to Detect Source Type

### Set up Credential Store Entry to Detect Source Type

The database type for capture is based on the prefix in the database credential userid. The generic format for userid is as follows: <dbtype>://<db-user>@<comma separated list of server addresses>:<port>
The userid value for Kafka capture should be any value with the prefix kafka://.

### Example

alter credentialstore add user kafka:// password somepass alias kafka

# Note: You can specify a dummy Password for Kafka while setting up the credentials.

### General Terms and Functionality of Kafka Capture

- Kafka Streams
- Kafka Message Order
- Kafka Message Timestamps
- Kafka Message Coordinates
- Start Extract Modes
- General Configuration Overview
- OGGSOURCE parameter
- The Extract Parameter File
- Kafka Consumer Properties File

### Kafka Streams

As a Kafka consumer, you can read from one or more topics. Additionally, each topic can be divided into one or more partitions. Each discrete topic/partition combination is a Kafka stream. This topic discusses Kafka streams extensively and it is important to clearly define the term here.

The following is an example of five Kafka streams:

- Topic: TEST1 Partition: 0
- Topic: TEST1 Partition: 1
- Topic: TEST2 Partition: 0
- Topic: TEST2 Partition: 1
- Topic: TEST2 Partition: 2

### Kafka Message Order

Messages received from the KafkaConsumer for an individual stream should be in the order as stored in the Kafka commit log. However, Kafka streams move independently from one another and the order in which messages are received from different streams is nondeterministic.

For example, Kafka Capture is consuming messages from two streams:

- Stream 1: Topic TEST1, partition 0
- Stream 2: Topic TEST1, partition 1

Stream 1 in Topic|partition|offset|timestamp format total of 5 messages.

TEST1|0|0|1588888086210 TEST1|0|1|1588888086220 TEST1|0|2|1588888086230 TEST1|0|3|1588888086240 TEST1|0|4|1588888086250

Stream 2 to Topic|partition|offset|timestamp format total of 5 messages.

TEST1|1|0|1588888086215 TEST1|1|1|1588888086225 TEST1|1|2|1588888086235 TEST1|1|3|1588888086245 TEST1|1|4|1588888086255

The Kafka Consumer could deliver the messages in the following order on run 1.

```
TEST1|1|0|1588888086215
TEST1|1|1|588888086225
TEST1|0|0|1588888086210
TEST1|0|2|1588888086200
TEST1|0|2|1588888086230
TEST1|0|3|1588888086240
TEST1|0|4|1588888086250
TEST1|1|2|1588888086255
TEST1|1|3|1588888086255
```

On a secondary run messages could be delivered in the following order.

```
TEST1|0|0|1588888086210
TEST1|0|1|588888086220
TEST1|1|0|1588888086225
TEST1|1|1588888086255
TEST1|0|2|1588888086230
TEST1|0|3|1588888086240
TEST1|0|4|1588888086250
TEST1|1|2|1588888086255
TEST1|1|3|1588888086255
```

### Note:

In the two runs that the messages belonging to the same Kafka stream are delivered in order as they occur in that stream. However, messages from different streams are interlaced in a nondeterministic manner.

### Kafka Message Timestamps

Each Kafka message has a timestamp associated with it. The timestamp on the Kafka message maps to the operation timestamp for the record in the generated trail file. Timestamps on Kafka messages are not guaranteed to be monotonically increasing even in the case where extract is reading from only one stream (single topic and partition). Kafka has no requirement that Kafka message timestamps are monotonically increasing even within a stream. The Kafka Producer provides an API whereby the message timestamp can be explicitly set on messages. This means a Kafka Producer can set the Kafka message timestamp to any value.

When reading from multiple topics and/or a topic with multiple partitions it is almost certain that trail files generated by Kafka capture will not have operation timestamps that are monotonically increasing. Kafka streams move independently from one another and there is no guarantee of delivery order for messages received from different streams. Messages from different streams can interlace in any random order when the Kafka Consumer is reading them from a Kafka cluster.

### Kafka Message Coordinates

Kafka Capture performs message gap checking to ensure message consistency withing the context of a message stream. For every Kafka stream from which Kafka capture is consuming messages, there should be no gap in the Kafka message offset sequence.

If a gap is found in the message offset sequence, then the Kafka capture logs an error and the Kafka Capture extract process will abend.

Message gap checking can be disabled by setting the following in the .prm file.

SETENV (PERFORMMESSAGEGAPCHECK = "false").

### Start Extract Modes

Extract can be configured to start replication from two distinct points.

- Start Earliest
- Start Timestamp

### Start Earliest

Start Kafka Capture from the oldest available message in Kafka.

```
ggsci> ADD EXTRACT kafka, TRANLOG
ggsci> ADD EXTRAIL dirdat/kc, extract kafka
ggsci> START EXTRACT kafka
```

### Start Timestamp

### Start Kafka Capture from the oldest available message in Kafka.

ggsci> ADD EXTRACT kafka, TRANLOG BEGIN 2019-03-27 23:05:05.123456 ggsci> ADD EXTRAIL dirdat/kc, extract kafka ggsci> START EXTRACT kafka

### Or alternatively, start now as now is a point in time.

```
ggsci> ADD EXTRACT kafka, TRANLOG BEGIN NOW
ggsci> ADD EXTRAIL dirdat/kc, extract kafka
ggsci> START EXTRACT kafka
```

### Note:

Note on starting from a point in time. Kafka Capture will start from the first available record in the stream which fits the criteria (time equal to or greater than the configured time). Replicat will continue from that first message regardless of the timestamps of subsequent messages. As previously discussed, there is no guarantee or requirement that Kafka message timestamps are monotonically increasing.

### Alter Extract

### Alter Timestamp

ggsci> STOP EXTRACT kafka ggsci> ALTER EXTRACT kafka BEGIN {Timestamp} ggsci> START EXTRACT kafka

### Alter Now

```
ggsci> STOP EXTRACT kafka
ggsci> ALTER EXTRACT kafka BEGIN NOW
ggsci> START EXTRACT kafka
```

### General Configuration Overview

### **OGGSOURCE** parameter

To enable Kafka extract replication, the GLOBALS parameter file must be configured as follows:

```
OGGSOURCE KAFKA
JVMCLASSPATH ggjava/ggjava.jar:/kafka/client/path/*:dirprm
JVMBOOTOPTIONS -Xmx512m -Dlog4j.configurationFile=log4j-default.properties -
Dgg.log.level=INFO
```

OGGSOURCE KAFKA: The first line indicates that the source of replication is Kafka.

JVMCLASSPATH ggjava/ggjava.jar:/kafka/client/path/\*:dirprm: The second line sets the Java JVM classpath. The Java classpath provides the pathing to load all the required Oracle GoldenGate for Big Data libraries and Kafka client libraries. The Oracle GoldenGate for Big Data library should be first in the list (ggjava.jar). The Kafka client libraries, the Kafka Connect framework, and the Kafka Connect converters are not included with the Oracle

GoldenGate for Big Data installation. These libraries must be obtained independently. Oracle recommends you to use the same version of the Kafka client as the version of the Kafka broker to which you are connecting. The Dependency Downloading tool can be used to download the dependency libraries. Alternately, the pathing can be set to a Kafka installation. For more information about Dependency Downloader, see Dependency Downloader in the *Installing and Upgrading Oracle GoldenGate for Big Data* guide.

JVMBOOTOPTIONS -Xmx512m -Dlog4j.configurationFile=log4j-default.properties -Dgg.log.level=INFO: The third line is the JVM boot options. Use this to configure the maximum Java heap size (-Xmx512m) and the log4j logging parameters to generate the .log file (-Dlog4j.configurationFile=log4j-default.properties -Dgg.log.level=INFO)

### Note:

Starting from Oracle GoldenGate for Big Data release 23.1.0.0.0, this parameter will be deprecated.

### The Extract Parameter File

The extract process configured is configured via a .prm file. The format for the naming of the parameter file is <extract name>.prm. For example, the extract parameter file for the extract process kc would be kc.prm.

```
EXTRACT KC

-- alter credentialstore add user kafka:// password <somepass> alias kafka

SOURCEDB USERIDALIAS kafka

JVMOPTIONS CLASSPATH ggjava/ggjava.jar:/kafka/client/path/*

JVMOPTIONS BOOTOPTIONS -Xmx512m -Dlog4j.configurationFile=log4j-

default.properties -Dgg.log.level=INFO

TRANLOGOPTIONS GETMETADATAFROMVAM

TRANLOGOPTIONS KAFKACONSUMERPROPERTIES kafka_consumer.properties

EXTTRAIL dirdat/kc

TABLE QASOURCE.TOPIC1;
```

EXTRACT KC: The first line sets the name of the extract process.

TRANLOGOPTIONS KAFKACONSUMERPROPERTIES kafka\_consumer.properties: This line sets the name and location of the Kafka Consumer properties file. The Kafka Consumer properties is a file containing the Kafka specific configuration which configures connectivity and security to the Kafka cluster. Documentation on the Kafka Consumer properties can be found in: Kafka Documentation.

EXTTRAIL dirdat/kc: The fourth line sets the location and prefix of the trail files to be generated.

TABLE QASOURCE.TOPIC1;: The fifth line is the extract TABLE statement. There can be one or more TABLE statements. The schema name in the example is QASOURCE. The schema name is an OGG artifact and it is required. It can be set to any legal string. The schema name cannot be wildcarded. Each extact process only supports one schema name. The configured table name maps to the Kafka topic name. The table configuration does support wildcards. Legal Kafka topic names can have the following characters.

• a-z (lowercase a to z)

- A-Z (uppercase A to Z)
- 0-9 (digits 0 to 9)
- . (period)
- \_ (underscore)
- - (hyphen)

If the topic name contains a period, underscore, or hyphen, please include the table name in quotes in the configuration. Topic names are case sensitive so the topic <code>MYTOPIC1</code> and <code>MyTopic1</code> are different Kafka topics.

Examples of legal extract table statements:

```
TABLE TESTSCHEMA.TEST*;
TABLE TESTSCHEMA.MyTopic1;
TABLE TESTSCHEMA."My.Topic1";
```

Examples of illegal configuration - multiple schema names are used:

```
TABLE QASOURCE.TEST*;
TABLE TESTSCHEMA.MYTOPIC1;
```

Example of illegal configuration – Table with special characters not quoted.

TABLE QASOURE.My.Topic1;

Example of illegal configuration – Schema name is a wildcard.

TABLE \*.\*;

Optional .prm configuration.

Kafka Capture performs message gap checking to ensure message continuity. To disable message gap checking set:

```
SETENV (PERFORMMESSAGEGAPCHECK = "false")
```

### Kafka Consumer Properties File

The Kafka Consumer properties file contains the properties to configure the Kafka Consumer including how to connect to the Kafka cluster and security parameters.

### Example:

```
#Kafka Properties
bootstrap.servers=den02box:9092
group.id=mygroupid
key.deserializer=org.apache.kafka.common.serialization.ByteArrayDeserializer
value.deserializer=org.apache.kafka.common.serialization.ByteArrayDeserializer
```

Encrypt Kafka Producer Properties

### Encrypt Kafka Producer Properties

The sensitive properties within the Kafka Producer Configuration File can be encrypted using the Oracle GoldenGate Credential Store. For more information about how to use Credential Store, see Using Identities in Oracle GoldenGate Credential Store.

### For example, the following kafka property:

```
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModul
e required
username="alice" password="alice";
```

### can be replaced with:

```
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModul
e required
username=ORACLEWALLETUSERNAME[alias domain_name]
password=ORACLEWALLETPASSWORD[alias
domain_name];
```

### Generic Mutation Builder

The default mode is to use the Generic Mutation Builder to transform Kafka messages into trail file operations. Kafka messages are comprised of data in any format. Kafka messages can be delimited text, JSON, Avro, XML, text, etc. This makes the mapping of data from a Kafka message into a logical change record challenging. However, Kafka message keys and payload values are at their fundamental form just byte arrays. The Generic Kafka Replication simply propagates the Kafka message key and Kafka message value as byte arrays. Generic Kafka Replication transforms the data into operations of three fields. The three fields are as follows:

- **id**: This is the primary key for the table. It is typed as a string. The value is the coordinates of the message in Kafka in the following format: topic name:partition number:offset. For example, the value for topic TEST, partition 1, and offset 245 would be TEST:1:245.
- **key**: This is the message key field from the source Kafka message. The field is typed as binary. The value of the field is the key from the source Kafka message propagated as bytes.
- payload: This is the message payload or value from the source Kafka message. The field is typed as binary. The value of the field is the payload from the source Kafka message propagated as bytes.

#### Features of the Generic Mutation Builder

- All records are propagated as insert operations.
- Each Kafka message creates an operation in its own transaction.

### Kafka Connect Mutation Builder

The Kafka Connect Mutation Builder parses Kafka Connect messages into logical change records and that are then written to Oracle GoldenGate trail files.

- Functionality and Limitations of the Kafka Connect Mutation Builder
- Primary Key
- Kafka Message Key
- Kafka Connect Supported Types
- How to Enable the Kafka Connect Mutation Builder

Functionality and Limitations of the Kafka Connect Mutation Builder

- All records are propagated as insert operations.
- Each Kafka message creates an operation in its own transaction.
- The Kafka message key must be a Kafka Connect primitive type or logical type.
- The Kafka message value must be either a primitive type/logical type or a record containing only primitive types, logical types, and container types. A record cannot contain another record as nested records are not currently supported.
- Kafka Connect array data types are mapped into binary fields. The content of the binary field will be the source array converted into a serialized JSON array.
- Kafka Connect map data types are mapped into binary fields. The contents of the binary field will be the source map converted into a serialized JSON.
- The source Kafka messages must be Kafka Connect messages.
- Kafka Connect Protobuf messages are not currently supported. (The current Kafka Capture functionality only supports primitive or logical types for the Kafka message key. The Kafka Connect Protobuf Converter does not support stand only primitives or logical types.)

- Each source topic must contain messages which conform to the same schema. Interlacing messages in the same Kafka topic which conform to different Kafka Connect schema is not currently supported.
- Schema changes are not currently supported.

### Primary Key

A primary key field is created in the output as a column named gg\_id. The value of this field is the concatentated topic name, partition, and offset delimited by the : character. For example: TOPIC1:0:1001.

### Kafka Message Key

The message key is mapped into a called named gg key.

### Kafka Connect Supported Types

### Supported Primitive Types

- String
- 8 bit Integer
- 16 bit Integer
- 32 bit Integer
- 64 bit Integer
- Boolean
- 32 bit Float
- 64 bit Float
- Bytes (binary)

### **Supported Logical Types**

- Decimal
- Timestamp
- Date
- Time

### **Supported Container Types**

- Array Only arrays of primitive or logical types are supported. Data is mapped as
  a binary field the value of which is a JSON array document containing the contents
  of the source array.
- List Only lists of primitive or logical types are supported. Data is mapped as a binary field the value of which is a JSON document containing the contents of the source list.

### How to Enable the Kafka Connect Mutation Builder

The Kafka Connect Mutation Builder is enabled by configuration of the Kafka Connect key and value converters in the Kafka Producer properties file.

For the Kafka Connect JSON Converter

key.converter=org.apache.kafka.connect.json.JsonConverter value.converter=org.apache.kafka.connect.json.JsonConverter

### For the Kafka Connect Avro Converter

```
key.converter=io.confluent.connect.avro.AvroConverter
value.converter=io.confluent.connect.avro.AvroConverter
key.converter.schema.registry.url=http://localhost:8081
value.converter.schema.registry.url=http://localhost:8081
```

The Kafka Capture functionality reads the Kafka producer properties file. If the Kafka Connect converters are configured, then the Kafka Connect mutation builder is invoked.

### **Example Configuration Files**

- Example kc.prm file
- Example Kafka Consumer Properties File

### Example kc.prm file

```
EXTRACT KC

OGGSOURCE KAFKA

JVMOOPTIONS CLASSPATH ggjava/ggjava.jar:/path/to/kafka/libs/*

TRANLOGOPTIONS GETMETADATAFROMVAM

--Uncomment the following line to disable Kafka message gap checking.

--SETENV (PERFORMMESSAGEGAPCHECK = "false")

TRANLOGOPTIONS KAFKACONSUMERPROPERTIES kafka_consumer.properties

EXTTRAIL dirdat/kc

TABLE TEST.KC;
```

### Example Kafka Consumer Properties File

```
#Kafka Properties
bootstrap.servers=localhost:9092
group.id=someuniquevalue
key.deserializer=org.apache.kafka.common.serialization.ByteArrayDeserializer
value.deserializer=org.apache.kafka.common.serialization.ByteArrayDeserializer
#JSON Converter Settings
#Uncomment to use the Kafka Connect Mutation Builder with JSON Kafka Connect
```

```
Messages
#key.converter=org.apache.kafka.connect.json.JsonConverter
#value.converter=org.apache.kafka.connect.json.JsonConverter
#Avro Converter Settings
#Uncomment to use the Kafka Connect Mutation Builder with Avro Kafka Connect Messages
#key.converter=io.confluent.connect.avro.AvroConverter
#value.converter=io.confluent.connect.avro.AvroConverter
#key.converter.schema.registry.url=http://localhost:8081
#value.converter.schema.registry.url=http://localhost:8081
```

### Azure Event Hubs

To capture messages from Azure Event Hubs and parse into logical change records with Oracle GoldenGate for Big Data, you can use Kafka Extract. For more information, see Apache Kafka as source.

### Confluent Kafka

To capture Kafka Connect messages from Confluent Kafka and parse into logical change records with Oracle GoldenGate for Big Data, you can use Kafka Connect Mutation Builder. For more information, see Kafka Connect Mutation Builder.

### DataStax

Datastax Enterprise is a NoSQL database built on Apache Cassandra. For more information, see Apache Cassandra for configuring change data capture from Datastax Enterprise.

### Java Message Service (JMS)

This article explains using the Oracle GoldenGate for Big Data to capture Java Message Service (JMS) messages to be written to an Oracle GoldenGate trail.

- Prerequisites
- Configuring Message Capture

### Prerequisites

• Set up Credential Store Entry to Detect Source Type

Set up Credential Store Entry to Detect Source Type

### JMS Capture

Similar to Kafka, for the sake of detecting the source type, user can create a credential store entry with the prefix: jms://.

### Example

alter credentialstore add user jms:// password <anypassword> alias jms

If the extract parameter file does not specify SOURCEDB parameter with USERIDALIAS option, then the source type will be assumed to be JMS, and a warning message will be logged to indicate this.

### Configuring Message Capture

This chapter explains how to configure the VAM Extract to capture JMS messages.

- Configuring the VAM Extract
- Connecting and Retrieving the Messages

### Configuring the VAM Extract

JMS Capture only works with the Oracle GoldenGate Extract process. To run the Java message capture application you need the following:

- Oracle GoldenGate for Java Adapter
- Extract process
- Extract parameter file configured for message capture
- Description of the incoming data format, such as a source definitions file.
- Java 8 installed on the host machine
- Adding the Extract
- Configuring the Extract Parameters
- Configuring Message Capture

### Adding the Extract

To add the message capture VAM to the Oracle GoldenGate installation, add an Extract and the trail that it will create using GGSCI commands:

```
ADD EXTRACT jmsvam, VAM
ADD EXTTRAIL dirdat/id, EXTRACT jmsvam, MEGABYTES 100
```

The process name (jmsvam) can be replaced with any process name that is no more than 8 characters. The trail identifier (id) can be any two characters.

### Note:

Commands to position the Extract, such as **BEGIN** or **EXTRBA**, are not supported for message capture. The Extract will always resume by reading messages from the end of the message queue.

### Configuring the Extract Parameters

The Extract parameter file contains the parameters needed to define and invoke the VAM. Sample Extract parameters for communicating with the VAM are shown in the table.

#### Parameter

### Description

EXTRACT jmsvam

The name of the Extract process.

Parameter	Description
VAM ggjava_vam.dll, PARAMS dirprm/jmsvam.properties	Specifies the name of the VAM library and the location of the properties file. The VAM properties should be in the dirprm directory of the Oracle GoldenGate installation location.
TRANLOGOPTIONS VAMCOMPATIBILITY 1	Specifies the original (1) implementation of the VAM is to be used.
TRANLOGOPTIONS GETMETADATAFROMVAM	Specifies that metadata will be sent by the VAM.
EXTTRAIL dirdat/id	Specifies the identifier of the target trail Extract creates.

### Configuring Message Capture

Message capture is configured by the properties in the VAM properties file (Adapter Properties file. This file is identified by the PARAMS option of the Extract VAM parameter and used to determine logging characteristics, parser mappings and JMS connection settings.

### Connecting and Retrieving the Messages

To process JMS messages you must configure the connection to the JMS interface, retrieve and parse the messages in a transaction, write each message to a trail, commit the transaction, and remove its messages from the queue.

- Connecting to JMS
- Retrieving Messages
- Completing the Transaction

### Connecting to JMS

Connectivity to JMS is through a generic JMS interface. Properties can be set to configure the following characteristics of the connection:

- Java classpath for the JMS client
- Name of the JMS queue or topic source destination
- Java Naming and Directory Interface (JNDI) connection properties
  - Connection properties for Initial Context
  - Connection factory name
  - Destination name
- Security information
  - JNDI authentication credentials
  - JMS user name and password

The Extract process that is configured to work with the VAM (such as the jmsvam in the example) will connect to the message system. when it starts up.

### Note:

The Extract may be included in the Manger's AUTORESTART list so it will automatically be restarted if there are connection problems during processing.

Currently the Oracle GoldenGate for Java message capture adapter supports only JMS text messages.

### **Retrieving Messages**

The connection processing performs the following steps when asked for the next message:

- Start a local JMS transaction if one is not already started.
- Read a message from the message queue.
- If the read fails because no message exists, return an end-of-file message.
- Otherwise return the contents of the message.

### Completing the Transaction

Once all of the messages that make up a transaction have been successfully retrieved, parsed, and written to the Oracle GoldenGate trail, the local JMS transaction is committed and the messages removed from the queue or topic. If there is an error the local transaction is rolled back leaving the messages in the JMS queue.

### MongoDB

The Oracle GoldenGate capture (Extract) for MongoDB is used to get changes from MongoDB databases.

This chapter describes how to use the Oracle GoldenGate Capture for MongoDB.

- Overview
- Prerequisites to Setting up MongoDB
- MongoDB Database Operations
- Using Extract Initial Load
- Using Change Data Capture Extract
- Positioning the Extract
- Security and Authentication
- Mongo DB Configuration Reference
- Columns in Trail File
- Update Operation Behavior
- Oplog Size Recommendations
- Troubleshooting

# MongoDB Capture Client Dependencies What are the dependencies for the MongoDB Capture to connect to MongoDB databases?

### Overview

MongoDB is a document-oriented NoSQL database used for high volume data storage and which provides high performance and scalability along with data modelling and data management of huge sets of data in an enterprise application. MongoDB provides:

- High availability through built-in replication and failover
- Horizontal scalability with native sharding
- End-to-end security and many more

### Prerequisites to Setting up MongoDB

• MongoDB cluster or a MongoDB node must have a **replica set**. The minimum recommended configuration for a replica set is a three member replica set with three data-bearing members: one primary and two secondary members.

Create mongod instance with the replica set as follows:

```
bin/mongod --bind_ip localhost --port 27017 --replSet rs0 --dbpath ../
data/d1/
bin/mongod --bind_ip localhost --port 27018 --replSet rs0 --dbpath ../
data/d2/
bin/mongod --bind_ip localhost --port 27019 --replSet rs0 --dbpath ../
data/d3/
```

bin/mongod --host localhost --port 27017

### Adding a replica set:

```
rs.initiate( {
    __id : "rs0",
    members: [
        { __id: 0, host: "localhost:27017" },
        { __id: 1, host: "localhost:27018" },
        { __id: 2, host: "localhost:27019" }
]
})
```

### Replica Set Oplog

MongoDB capture uses oplog to read the CDC records. The operations log (oplog) is a capped collection that keeps a rolling record of all operations that modify the data stored in your databases.

The MongoDB only removes an oplog entry in the following cases: the oplog has reached the maximum configured size, and the oplog entry is older than the configured number of hours based on the host system clock.

You can control the retention of oplog entries using: oplogMinRetentionHours and replSetResizeOplog.

For more information about oplog, see Oplog Size Recommendations.

- You must download and provide the third party libraries listed in MongoDB Capture Client Dependencies: Reactive Streams Java Driver 4.4.1.
- Set up Credential Store Entry to Detect Source Type

### Set up Credential Store Entry to Detect Source Type

The database type for capture is based on the prefix in the database credential userid. The generic format for userid is as follows: <dbtype>://<db-user>@<comma separated list of server addresses>:<port>. The userid value for MongoDB is any valid MongoDB clientURI without the password.

### **MongoDB Capture**

### Example:

```
alter credentialstore add user "mongodb+srv://user@127.0.0.1:27017" password db-passwd alias mongo
```

### Note:

Ensure that the userid value is in double quotes.

#### **MongoDB** Atlas

#### Example:

```
alter credentialstore add user "mongodb+srv://user@127.0.0.1:27017" password db-passwd alias mongo
```

### MongoDB Database Operations

#### **Supported Operations**

- INSERT
- UPDATE
- DELETE

#### **Unsupported Operations**

The following MongoDB source DDL operations are not supported:

- CREATE collection
- RENAME collection
- DROP collection

On detecting these unsupported operations, extract can be configured to either ABEND or skip these operations and continue processing the next operation.

### Using Extract Initial Load

MongoDB Extract supports the standard initial load capability to extract source table data to Oracle GoldenGate trail files.

Initial load for MongoDB can be performed to synchronize tables, either as a prerequisite step to replicating changes or as a standalone function.

#### **Configuring the Initial Load**

Initial Load Parameter file:

```
-- ggsci> alter credentialstore add user mongodb://db-user@localhost:27017/
admin password db-passwd alias mongo
```

```
EXTRACT LOAD
JVMOPTIONS CLASSPATH ggjava/ggjava.jar:/path/to/mongo-capture/libs/*
SOURCEISTABLE
SOURCEDB USERIDALIAS mongo
TABLE database.collection;
```

Run these commands in AdminClient to add extract for initial load:

```
adminclient> ADD EXTRACT load, SOURCEISTABLE adminclient> START EXTRACT load
```

### Using Change Data Capture Extract

Review the example .prm files from Oracle GoldenGate for Big Data installation directory here: AdapterExamples/big-data/mongodbcapture.

When adding the MongoDB Extract trail, you need to use EXTTRAIL to create a local trail file.

The MongoDB Extract trail file should not be configured with the RMTTRAIL option.

adminclient> ADD EXTRACT groupname, TRANLOG adminclient> ADD EXTTRAIL trailprefix, EXTRACT groupname

#### Example:

adminclient> ADD EXTRACT mongo, TRANLOG adminclient> ADD EXTTRAIL ./dirdat/z1, EXTRACT mongo

### Positioning the Extract

MongoDB extract process allows us to position from EARLIEST, TIMESTAMP, EOF and LSN.

**EARLIEST**: Positions to the start of the Oplog for a given collection.

Syntax:

ADD EXTRACT groupname, TRANLOG, EARLIEST

**TIMESTAMP:** Positions to a given time stamp. Token BEGIN can use either NOW to start from present time or with a given timestamp.

BEGIN {NOW | yyyy-mm-dd[ hh:mi:[ss[.ccccc]]]}

### Syntax

ADD EXTRACT groupname, TRANLOG, BEGIN NOW ADD EXTRACT groupname, TRANLOG, BEGIN 'yyyy-mm-dd hh:mm:ss'

#### EOF: Positions to end of oplog.

### Syntax

ADD EXTRACT groupname, TRANLOG, EOF

### LSN: Positions to a given LSN.

LSN in MongoDB Capture is Operation Time in oplog which is unique for each record, time is represents as seconds with the increment as a 20 digit long value.

### Syntax:

ADD EXTRACT groupname, TRANLOG, LSN "06931975403544248321"

### Security and Authentication

MongoDB capture uses Oracle GoldenGate credential store to manage user IDs and their encrypted passwords (together known as credentials) that are used by Oracle GoldenGate processes to interact with the MongoDB database. The credential store eliminates the need to specify user names and clear-text passwords in the Oracle GoldenGate parameter files.

An optional alias can be used in the parameter file instead of the user ID to map to a userid and password pair in the credential store.

In Oracle GoldenGate for Big Data, you specify the alias and domain in the property file and not the actual user ID or password. User credentials are maintained in secure wallet storage.

To add CREDENTIAL STORE and DBLOGIN run the following commands in the adminclient:

adminclient> add credentialstore
adminclient> alter credentialstore add user "<userid>" password <pwd>
alias mongo

#### Example value of userid:

mongodb://myUserAdmin@localhost:27017/admin?replicaSet=rs0

Note:

Ensure that the userid value is in double quotes.

adminclient > dblogin useridalias mongo

To test DBLOGIN, run the following command

```
adminclient> list tables tcust*
```

On successful add of authentication to credential store, add the alias in the parameter file of extract.

Example:

SOURCEDB USERIDALIAS mongo

MongoDB Capture uses connection URI to connect to a MongoDB deployment. Authentication and Security is passed as query string as part of connection URI. See SSL Configuration Setup to configure SSL.

To specify access control use userid:

```
mongodb://<user>@<hostname1>:<port>, <hostname2>:<port>, <hostname3>:<port>/?
replicaSet=<replicatName>
```

### To specify TLS/SSL:

Using connection string prefix of "+srv" as mongodb+srv automatically sets the tls option to true.

```
mongodb+srv://server.example.com/
```

To disable TLS add tls=false in the query string.

mongodb:// >@<hostname1>:<port>/?replicaSet=<replicatName>&tls=false

### To specify Authentication:

### authSource:

mongodb://<user>@<hostname1>:<port>, <hostname2>:<port>, <hostname3>:<port>/?
replicaSet=<replicatName>&authSource=admin

#### authMechanism:

mongodb://<user>@<hostname1>:<port>, <hostname2>:<port>, <hostname3>:<port>/?
replicaSet=<replicatName>&authSource=admin&authMechanism=GSSAPI

For more information about Security and Authentication using Connection URL, see Mongo DB Documentation

SSL Configuration Setup

### SSL Configuration Setup

To configure SSL between the MongoDB instance and Oracle GoldenGate for Big Data MongoDB Capture, do the following:

#### Create certificate authority (CA)

```
openssl req -passout pass:password -new -x509 -days 3650 -extensions
v3_ca -keyout
ca_private.pem -out ca.pem -subj
"/CN=CA/OU=GOLDENGATE/O=ORACLE/L=BANGALORE/ST=KA/C=IN"
```

#### Create key and certificate signing requests (CSR) for client and all server nodes

```
openssl req -newkey rsa:4096 -nodes -out client.csr -keyout client.key
-subj
'/CN=certName/OU=OGGBDCLIENT/O=ORACLE/L=BANGALORE/ST=AP/C=IN'
openssl req -newkey rsa:4096 -nodes -out server.csr -keyout server.key
-subj
'/CN=slc13auo.us.oracle.com/OU=GOLDENGATE/O=ORACLE/L=BANGALORE/ST=TN/
C=IN'
```

#### Sign the certificate signing requests with CA

#### Create the privacy enhanced mail (PEM) file for mongod

```
cat client-signed.crt client.key > client.pem
cat server-signed.crt server.key > server.pem
```

#### Create trust store and keystore

```
openssl pkcs12 -export -out server.pkcs12 -in server.pem
openssl pkcs12 -export -out client.pkcs12 -in client.pem
```

```
bash-4.2$ ls
ca.pem ca_private.pem client.csr client.pem server-signed.crt
server.key server.pkcs12
ca.srl client-signed.crt client.key client.pkcs12 server.csr
server.pem
```

### Start instances of mongod with the following options:

```
--tlsMode requireTLS --tlsCertificateKeyFile ../opensslKeys/server.pem --
tlsCAFile ../opensslKeys/ca.pem
```

### credentialstore connectionString

### Note:

The Length of connectionString should not exceed 256.

For CDC Extract, add the key store and trust store as part of the JVM options.

### **JVM options**

```
-Xms512m -Xmx4024m -Xss32m -Djavax.net.ssl.trustStore=../mcopensslkeys /
server.pkcs12
                -Djavax.net.ssl.trustStorePassword=password
                -Djavax.net.ssl.keyStore =../mcopensslkeys/client.pkcs12
                -Djavax.net.ssl.keyStorePassword=password
```

### Mongo DB Configuration Reference

The following properties are used with MongoDB change data capture.

Properties	Req uire d/ Opti onal	Locati on	Default	Explanation

Properties	Req uire d/ Opti onal	Locati on	Default	Explanation
SOURCEDB USERIDALIAS <alias name=""></alias>	Req uire d	Extract param eter (.prm) file	None	This parameter is used by the extract process for authentication in to the source MongoDB database. The <i>alias name</i> refers to the alias that should exist in Oracle Wallet. See Security and Authentication.
ABEND_ON_DDL	Opti onal	CDC Extract param eter (.prm) file	None	This is a default behaviour of MongoDB Capture extract. On detection of CREATE collection, RENAME collection, and DROP collection, extract process will be abended.
NO_ABEND_ON_DD L	Opti onal	CDC Extract param eter (.prm) file	None	On detection of CREATE collection, RENAME collection, and DROP collection, extract process skips these operations and continue processing the next operation.
ABEND_ON_DROP_ DATABASE	Opti onal	CDC Extract param eter (.prm) file	None	This is a default behaviour of MongoDB Capture extract. On detection of Drop Database operation, extract process will be abended.
NO_ABEND_ON_DR OP_DATABASE	Opti onal	CDC Extract param eter (.prm) file.	None	On detection of Drop Database operation, extract process will skip these operations and continue processing the next operation.
BINARY_JSON_FO RMAT	Opti onal	prm	None	When configured BINARY_JSON_FORMAT, MongoDB Capture process represents documents in BSON format, and using BINARY_JSON_FORMAT is more performance efficient. If BINARY_JSON_FORMAT is not specified, then documents are represented in Extended JSON format which is human-readable and less performance efficient compared to using BINARY_JSON_FORMAT.
				When using BINARY_JSON_FORMAT - in the generated trail file, the column metadata has data_type as 64, sub_data_type as 4, and Remarks as JSON.
				When BINARY_JSON_FORMAT is not specified - in the generated trail file, the column metadata has data_type as 64, sub_data_type as 0, and Remarks as JSON.
				For more information, see Table Metadata.

Properties	Req uire d/ Opti onal	Locati on	Default	Explanation
TRANLOGOPTIONS FETCHPARTIALJS ON	Opti onal	CDC Extract param eter (.prm) file	None	On configuring tranlogoptions FETCHPARTIALJSON, the extract process does a DB lookup and fetches the full document for the given update operation. See Update Operation Behavior.

#### **Table Metadata**

When BINARY\_JSON\_FORMAT is configured, the column metadata should have data type as 64, sub data type as 4, and JSON as the Remarks.

#### Example:

# Columns in Trail File

Each trail records will have two columns:

- Column 0 as 'id', which identifies a document in a collection.
- Column 1 as 'payload', which holds all the columns (fields of a collection).

Based on property BINARY\_JSON\_FORMAT, columns are presented as a BSON format or Extended JSON format. When BINARY\_JSON\_FORMAT is configured, the captured documents are represented in the BSON format as follows.

```

# Update Operation Behavior

MongoDB Capture extract reads change records from the capped collection oplog.rs. For Update operations, the collection contains information on the modified fields only. Thus the MongoDB Capture extract will write only the modified fields in trail on Update operation as MongoDB native \$set and \$unset documents.

#### Example trail record:

# **Oplog Size Recommendations**

TokenID x36 '6' TRANID

By default, MongoDB uses 5% of disk space as oplog size.

Oplog should be long enough to hold all transactions for the longest downtime you expect on a secondary. At a minimum, an oplog should be able to hold minimum 72 hours of operations or even a week's work of operations.

Before mongod creates an oplog, you can specify its size with the --oplogSize option.

After you have started a replica set member for the first time, use the replSetResizeOplog administrative command to change the oplog size. replSetResizeOplog enables you to resize the oplog dynamically without restarting the mongod process.

### Workloads Requiring Larger Oplog Size

If you can predict your replica set's workload to resemble one of the following patterns, then you might want to create an oplog that is larger than the default. Conversely, if your application predominantly performs reads with a minimal amount of write operations, a smaller oplog may be sufficient.

The following workloads might require a larger oplog size.

### Updates to Multiple Documents at Once

The oplog must translate multi-updates into individual operations in order to maintain idempotency. This can use a great deal of oplog space without a corresponding increase in data size or disk use.

### Deletions Equal the Same Amount of Data as Inserts

If you delete roughly the same amount of data as you insert, then the database doesn't grow significantly in disk use, but the size of the operation log can be quite large.

### Significant Number of In-Place Updates

If a significant portion of the workload is updates that do not increase the size of the documents, then the database records a large number of operations but does not change the quantity of data on disk.

# Troubleshooting

• Error : com.mongodb.MongoQueryException: Query failed with error code 11600 and error message 'interrupted at shutdown' on server localhost:27018.

The MongoDB server is killed or closed. Restart the Mongod instances and MongoDB capture.

- Error: java.lang.IllegalStateException: state should be: open.
   The active session is closed due to the session's idle time-out value getting exceeded. Increase the mongod instance's logicalSessionTimeoutMinutes paramater value and restart the Mongod instances and MongoDB capture.
- Error:Exception in thread "main" com.mongodb.MongoQueryException: Query failed with error code 136 and error message 'CollectionScan died due to position in capped collection being deleted. Last seen record id: RecordId(6850088381712443337)' on server localhost:27018 at com.mongodb.internal.operation.QueryHelper.translateCommandException( QueryHelper.java:29) This Exception bannens when we have East writes to mongod and insufficient

This Exception happens when we have Fast writes to mongod and insufficient oplog size. See Oplog Size Recommendations.

- Error: not authorized on DB to execute command This error occurs due to insufficient privileges for the user. The user must be authenticated to run the specified command.
- Error: com.mongodb.MongoClientException: Sessions are not supported by the MongoDB cluster to which this client is connected.

Ensure that the Replica Set is available and accessible. In case of MongoDB instance migration from a different version, set the property FeatureCompatibilityVersion as follows:

```
db.adminCommand( { setFeatureCompatibilityVersion: "3.6" } ){ }
```

# MongoDB Capture Client Dependencies

What are the dependencies for the MongoDB Capture to connect to MongoDB databases?

Oracle GoldenGate requires that you use the 4.4.1 MongoDB reactive streams or higher integration with MongoDB. You can download this driver from: https://search.maven.org/artifact/org.mongodb/mongodb-driver-reactivestream

- MongoDB Capture Client Dependencies: Reactive Streams Java Driver 4.4.1
- MongoDB Reactive Streams Java Driver 4.4.1

## MongoDB Capture Client Dependencies: Reactive Streams Java Driver 4.4.1

The required dependent client libraries are: bson.jar, mongodb-driver-core.jar, mongodbdriver-reactivestreams.jar, and reactive-streams.jar and reactor-core.jar

You must include the path to the MongoDB reactivestreams Java driver in the gg.classpath property. To automatically download the Java driver from the Maven central repository, add the following Maven coordinates of these third party libraries that are needed to run MongoDB Change Data Capture in the pom.xml file:

```
<dependency>
    <groupId>org.mongodb</groupId>
    <artifactId>mongodb-driver-reactivestreams</artifactId>
    <version>4.4.1</version>
</dependency>
<dependency>
    <groupId>org.mongodb</groupId>
    <artifactId>bson</artifactId>
    <version>4.4.1</version>
</dependency>
<dependency>
      <groupId>org.mongodb</groupId>
     <artifactId>mongodb-driver-core</artifactId>
     <version>4.4.1</version>
</dependency>
<dependency>
     <proupId>org.reactivestreams</proupId>
     <artifactId>reactive-streams</artifactId>
     <version>1.0.3</version>
</dependency>
<dependency>
     <proupId>io.projectreactor</proupId>
     <artifactId>reactor-core</artifactId>
</dependency>
```

### Example

Download version 4.4.1 from Maven central at: https://mvnrepository.com/artifact/ org.mongodb/mongodb-driver-reactivestreams.

## MongoDB Reactive Streams Java Driver 4.4.1

You must include the path to the MongoDB reactivestreams Java driver in the gg.classpath property. To automatically download the Java driver from the Maven central repository, add the following lines in the pom.xml file, substituting your correct information:

```
<!-- https://search.maven.org/artifact/org.mongodb/mongodb-driver-
reactivestreams -->
<dependency>
<groupId>org.mongodb</groupId>
<artifactId>mongodb-driver-reactivestreams</artifactId>
<version>4.4.1</version>
</dependency>
<dependency>
<groupId>org.mongodb</groupId>
<artifactId>bson</artifactId>
<version>4.4.1</version>
</dependency>
<dependency>
<groupId>org.mongodb</groupId>
<artifactId>mongodb-driver-core</artifactId>
<version>4.4.1</version>
</dependency>
<dependency>
<groupId>org.reactivestreams</groupId>
<artifactId>reactive-streams</artifactId>
<version>1.0.3</version>
</dependency>
```

```
<dependency>
<groupId>io.projectreactor</groupId>
<artifactId>reactor-core</artifactId>
</dependency>
```

# **OCI** Streaming

To capture messages from OCI Streaming and parse into logical change records with Oracle GoldenGate for Big Data, you can use Kafka Extract. For more information, see Apache Kafka as source.

# Target

- Amazon Kinesis
   The Kinesis Streams Handler streams data to applications hosted on the Amazon
   Cloud or in your environment.
- Amazon MSK

### Amazon Redshift

Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. The purpose of the Redshift Event Handler is to apply operations into Redshift tables.

- Amazon S3 Learn how to use the S3 Event Handler, which provides the interface to Amazon S3 web services.
- Apache Cassandra

The Cassandra Handler provides the interface to Apache Cassandra databases.

Apache HBase

The HBase Handler is used to populate HBase tables from existing Oracle GoldenGate supported sources.

- Apache HDFS The HDFS Handler is designed to stream change capture data into the Hadoop Distributed File System (HDFS).
- Apache Kafka The Kafka Handler is designed to stream change capture data from an Oracle GoldenGate trail to a Kafka topic.
- Apache Hive
- Azure Blob Storage
- Azure Data Lake Storage
- Azure Event Hubs Kafka handler supports connectivity to Microsoft Azure Event Hubs.
- Azure Synapse Analytics Microsoft Azure Synapse Analytics is a limitless analytics service that brings together data integration, enterprise data warehousing and big data analytics.
- Confluent Kafka
- DataStax
- Elasticsearch
- Flat Files
- Google BigQuery
- Google Cloud Storage
- Java Message Service (JMS)

The Java Message Service (JMS) Handler allows operations from a trail file to be formatted in messages, and then published to JMS providers like Oracle Weblogic Server, Websphere, and ActiveMQ.

Java Database Connectivity

Learn how to use the Java Database Connectivity (JDBC) Handler, which can replicate source transactional data to a target or database.

- Map(R)
- MongoDB Learn how to use the MongoDB Handler, which can replicate transactional data from Oracle GoldenGate to a target MongoDB and Autonomous JSON databases (AJD and ATP).
- Netezza

OCI Streaming

Oracle Cloud Infrastructure Streaming (OCI Streaming) supports putting messages to and receiving messages using the Kafka client. Therefore, Oracle GoldenGate for Big Data can be used to publish change data capture operation messages to OCI Streaming.

#### Oracle NoSQL

The Oracle NoSQL Handler can replicate transactional data from Oracle GoldenGate to a target Oracle NoSQL Database.

#### OCI Autonomous Data Warehouse

Oracle Autonomous Data Warehouse (ADW) is a fully managed database tuned and optimized for data warehouse workloads with the market-leading performance of Oracle Database.

### Oracle Cloud Infrastructure Object Storage

The Oracle Cloud Infrastructure Event Handler is used to load files generated by the File Writer Handler into an Oracle Cloud Infrastructure Object Store.

#### Redis

Redis is an in-memory data structure store which supports optional durability. Redis is simply a key/value data store where a unique key identifies the data structure stored. The value is the data structure that is stored.

- Snowflake
- Additional Details

# Amazon Kinesis

The Kinesis Streams Handler streams data to applications hosted on the Amazon Cloud or in your environment.

This chapter describes how to use the Kinesis Streams Handler.

- Overview
- Detailed Functionality
- Setting Up and Running the Kinesis Streams Handler
- Kinesis Handler Performance Considerations
- Troubleshooting

# Overview

Amazon Kinesis is a messaging system that is hosted in the Amazon Cloud. Kinesis streams can be used to stream data to other Amazon Cloud applications such as Amazon S3 and Amazon Redshift. Using the Kinesis Streams Handler, you can also stream data to applications hosted on the Amazon Cloud or at your site. Amazon Kinesis streams provides functionality similar to Apache Kafka.

The logical concepts map is as follows:

- Kafka Topics = Kinesis Streams
- Kafka Partitions = Kinesis Shards

A Kinesis stream must have at least one shard.

# **Detailed Functionality**

- Amazon Kinesis Java SDK
- Kinesis Streams Input Limits

## Amazon Kinesis Java SDK

The Oracle GoldenGate Kinesis Streams Handler uses the AWS Kinesis Java SDK to push data to Amazon Kinesis, see *Amazon Kinesis Streams Developer Guide* at:

http://docs.aws.amazon.com/streams/latest/dev/developing-producers-with-sdk.html.

The Kinesis Steams Handler was designed and tested with the latest AWS Kinesis Java SDK version 1.11.107. These are the dependencies:

- Group ID: com.amazonaws
- Artifact ID: aws-java-sdk-kinesis
- Version: 1.11.107

Oracle GoldenGate for Big Data does not ship with the AWS Kinesis Java SDK. Oracle recommends that you use the AWS Kinesis Java SDK identified in the Certification Matrix, see Verifying Certification, System, and Interoparability Requirements.

## Note:

It is assumed by moving to the latest AWS Kinesis Java SDK that there are no changes to the interface, which can break compatibility with the Kinesis Streams Handler.

You can download the AWS Java SDK, including Kinesis from:

https://aws.amazon.com/sdk-for-java/

## **Kinesis Streams Input Limits**

The upper input limit for a Kinesis stream with a single shard is 1000 messages per second up to a total data size of 1MB per second. Adding streams or shards can increase the potential throughput such as the following:

- 1 stream with 2 shards = 2000 messages per second up to a total data size of 2MB per second
- 3 streams of 1 shard each = 3000 messages per second up to a total data size of 3MB per second

The scaling that you can achieve with the Kinesis Streams Handler depends on how you configure the handler. Kinesis stream names are resolved at runtime based on the configuration of the Kinesis Streams Handler.

Shards are selected by the hash the partition key. The partition key for a Kinesis message cannot be null or an empty string (""). A null or empty string partition key results in a Kinesis error that results in an abend of the Replicat process.

Maximizing throughput requires that the Kinesis Streams Handler configuration evenly distributes messages across streams and shards.

To achieve the best distribution across shards in a Kinesis stream, select a partitioning key which rapidly changes. You can select fprimaryKeys as it is unique per row in the source database. Additionally, operations for the same row are sent to the same Kinesis stream and shard. When the DEBUG logging is enabled, the Kinesis stream name, sequence number, and the shard number are logged to the log file for successfully sent messages.

# Setting Up and Running the Kinesis Streams Handler

Instructions for configuring the Kinesis Streams Handler components and running the handler are described in the following sections.

Use the following steps to set up the Kinesis Streams Handler:

- 1. Create an Amazon AWS account at https://aws.amazon.com/.
- 2. Log into Amazon AWS.
- 3. From the main page, select Kinesis (under the Analytics subsection).
- 4. Select Amazon Kinesis Streams **Go to Streams** to create Amazon Kinesis streams and shards within streams.
- Create a client ID and secret to access Kinesis. The Kinesis Streams Handler requires these credentials at runtime to successfully connect to Kinesis.
- 6. Create the client ID and secret:
  - a. Select your name in AWS (upper right), and then in the list select **My Security Credentials**.
  - b. Select Access Keys to create and manage access keys. Note your client ID and secret upon creation.

The client ID and secret can only be accessed upon creation. If lost, you have to delete the access key, and then recreate it.

- Set the Classpath in Kinesis Streams Handler
- Kinesis Streams Handler Configuration
- Using Templates to Resolve the Stream Name and Partition Name
- Resolving AWS Credentials
- Configuring the Proxy Server for Kinesis Streams Handler
- Configuring Security in Kinesis Streams Handler

## Set the Classpath in Kinesis Streams Handler

You must configure the gg.classpath property in the Java Adapter properties file to specify the JARs for the AWS Kinesis Java SDK as follows:

```
gg.classpath={download_dir}/aws-java-sdk-1.11.107/lib/*:{download_dir}/
aws-java-sdk-1.11.107/third-party/lib/*
```

# Kinesis Streams Handler Configuration

You configure the Kinesis Streams Handler operation using the properties file. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the Kinesis Streams Handler, you must first configure the handler type by specifying gg.handler.name.type=kinesis\_streams and the other Kinesis Streams properties as follows:

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .type	Required	kinesis_streams	None	Selects the Kinesis Streams Handler for streaming change data capture into Kinesis.
gg.handler.name .mode	Optional	op <b>or</b> tx	op	Choose the operating mode.
gg.handler.name .region	Required	The Amazon region name which is hosting your Kinesis instance.	None	Setting of the Amazon AWS region name is required.
gg.handler.name .proxyServer	Optional	The host name of the proxy server.	None	Set the host name of the proxy server if connectivity to AWS is required to go through a proxy server.
gg.handler.name .proxyPort	Optional	The port number of the proxy server.	None	Set the port name of the proxy server if connectivity to AWS is required to go through a proxy server.
gg.handler.name .proxyUsername	Optional	The username of the proxy server (if credentials are required).	None	Set the username of the proxy server if connectivity to AWS is required to go through a proxy server and the proxy server requires credentials.

## Table 8-2 Kinesis Streams Handler Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .proxyPassword	Optional	The password of the proxy server (if credentials are required).	None	Set the password of the proxy server if connectivity to AWS is required to go through a proxy server and the proxy server requires credentials.
gg.handler.name .deferFlushAtTx Commit	Optional	true false	false	When set to false, the Kinesis Streams Handler will flush data to Kinesis at transaction commit for write durability. However, it may be preferable to defer the flush beyond the transaction commit for performance purposes, see Kinesis Handler Performance Considerations.
gg.handler.name .deferFlushOpCo unt	Optional	Integer	None	Only applicable if gg.handler.name .deferFlushAtTx Commit is set to true. This parameter marks the minimum number of operations that must be received before triggering a flush to Kinesis. Once this number of operations are received, a flush will occur on the next transaction commit and all outstanding operations will be moved from the Kinesis Streams Handler to AWS Kinesis.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .formatPerOp	Optional	true   false	true	When set to true, it will send messages to Kinesis, once per operation (insert, delete, update). When set to false, operations messages will be concatenated for all the operations and a single message will be sent at the transaction level. Kinesis has a limitation of 1MB max massage size If 1MB is exceeded then transaction level message will be broken up into multiple messages

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .customMessageG rouper	Optional	oracle.goldenga te.handler.kine sis.KinesisJson TxMessageGroupe r	None	This configuration parameter provides the ability to group Kinesis messages using custom logic. Only one implementation is included in the distribution at this time. The oracle.goldenga te.handler.kine sis.KinesisJson TxMessageGroupe ris a custom message which groups JSON operation messages representing operations into a wrapper JSON message that encompasses the transaction. Setting of this value overrides the setting of the gg.handler.form atPerOp setting. Using this feature assumes that the customer is using the JSON formatter (that is gg.handler.name .format=json).
gg.handler.name .streamMappingT emplate	Required	A template string value to resolve the Kinesis message partition key (message key) at runtime.	None	See Using Templates to Resolve the Stream Name and Partition Name for more information.
gg.handler.name .partitionMappi ngTemplate	Required	A template string value to resolve the Kinesis message partition key (message key) at runtime.	None	See Using Templates to Resolve the Stream Name and Partition Name for more information.

Table 0.2	(Cont.) Kinocic Strooms Handler Configuration Properties
Table 8-2	(Cont.) Kinesis Streams Handler Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.hander.name. format	Required	Any supported pluggable formatter.	<pre>delimitedtext   json   json_row   xml   avro_row   avro_opt</pre>	Selects the operations message formatter. JSON is likely the best fit for Kinesis.
gg.hander.name. enableStreamCre ation	Optional	true	true false	By default, the Kinesis Handler automatically creates Kinesis streams if they do not already exist. Set to false to disable to automatic creation of Kinesis streams.
gg.hander.name. shardCount	Optional	Positive integer.	1	A Kinesis stream contains one or more shards. Controls the number of shards on Kinesis streams that the Kinesis Handler creates. Multiple shards can help improve the ingest performance to a Kinesis stream. Use only when gg.handler.name .enableStreamCr eation is set to true.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.hander.name. proxyProtocol	Optional	HTTP   HTTPS	HTTP	Sets the proxy protocol connection to the proxy server for additional level of security. The client first performs an SSL handshake with the proxy server, and then ar SSL handshake with Amazon AWS. This feature was added into the Amazon SDK in version 1.11.396 so you must use at least that version to use this property.
gg.handler.name .enableSTS	Optional	true   false	false	Set to true, to enable the Kinesis Handler to access Kinesis credentials from the AWS Security Token Service. Ensure that the AWS Security Token Service is enabled if you set this property to true.
gg.handler.name .STSRegion	Optional	Any legal AWS region specifier.	The region is obtained from the gg.handler.name .region property.	Use to resolve the region for the STS call. It's only valid if the gg.handler.name .enableSTS property is set to true. You can set a different AWS region for resolving credentials from STS than the configured Kinesis region.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .accessKeyId	Optional	A valid AWS access key.	None	Set this parameter to explicitly set the access key for AWS. This parameter has no effect if gg.handler.name .enableSTS is set to true. If unset, credentials resolution falls back to the AWS default credentials provider chain.
gg.handler.name .secretKey	Optional	A valid AWS secret key.	None	Set this parameter to explicitly set the secret key for AWS. This parameter has no effect if gg.handler.name .enableSTS is set to true. If unset, credentials resolution falls back to the AWS default credentials provider chain.

## Using Templates to Resolve the Stream Name and Partition Name

The Kinesis Streams Handler provides the functionality to resolve the stream name and the partition key at runtime using a template configuration value. Templates allow you to configure static values and keywords. Keywords are used to dynamically replace the keyword with the context of the current processing. Templates are applicable to the following configuration parameters:

gg.handler.name.streamMappingTemplate
gg.handler.name.partitionMappingTemplate

Source database transactions are made up of 1 or more individual operations which are the individual inserts, updates, and deletes. The Kinesis Handler can be configured to send one message per operation (insert, update, delete, Alternatively, it can be configured to group operations into messages at the transaction level. Many of the template keywords resolve data based on the context of an individual source database operation. Therefore, many of the keywords *do not work* when sending messages at the transaction level. For example \$ {fullyQualifiedTableName} does not work when sending messages at the transaction level. The \${fullyQualifiedTableName} property resolves to the qualified source table name for an operation. Transactions can contain multiple operations for many source tables. Resolving

the fully-qualified table name for messages at the transaction level is non-deterministic and so abends at runtime.

For more information about the Template Keywords, see Template Keywords.

#### Example Templates

The following describes example template configuration values and the resolved values.

Example Template	Resolved Value
<pre>\${groupName}_\$ {fullyQualifiedTableName}</pre>	KINESIS001_DBO.TABLE1
prefix_\${ <i>schemaName</i> }_\$ { <i>tableName</i> }_suffix	<pre>prefix_DBO_TABLE1_suffix</pre>
<pre>\${currentTimestamp[yyyy-mm-dd hh:MM:ss.SSS]}</pre>	2017-05-17 11:45:34.254

## **Resolving AWS Credentials**

### AWS Kinesis Client Authentication

The Kinesis Handler is a client connection to the AWS Kinesis cloud service. The AWS cloud must be able to successfully authenticate the AWS client in order in order to successfully interface with Kinesis.

## AWS Kinesis Client Authentication

The Kinesis Handler is a client connection to the AWS Kinesis cloud service. The AWS cloud must be able to successfully authenticate the AWS client in order in order to successfully interface with Kinesis.

The AWS client authentication has become increasingly complicated as more authentication options have been added to the Kinesis Stream Handler. This topic explores the different use cases for AWS client authentication.

### • Explicit Configuration of the Client ID and Secret

A client ID and secret are generally the required credentials for the Kinesis Handler to interact with Amazon Kinesis. A client ID and secret are generated using the Amazon AWS website.

Use of the AWS Default Credentials Provider Chain

If the gg.eventhandler.name.accessKeyId and

gg.eventhandler.name.secretKey are unset, then credentials resolution reverts to the AWS default credentials provider chain. The AWS default credentials provider chain provides various ways by which the AWS credentials can be resolved.

AWS Federated Login
 The use case is when you have your on-premise system login integrated with
 AWS. This means that when you log into an on-premise machine, you are also
 logged into AWS.

Explicit Configuration of the Client ID and Secret

A client ID and secret are generally the required credentials for the Kinesis Handler to interact with Amazon Kinesis. A client ID and secret are generated using the Amazon AWS website.

These credentials can be explicitly configured in the Java Adapter Properties file as follows:

gg.handler.name.accessKeyId=
gg.handler.name.secretKey=

Furthermore, the Oracle Wallet functionality can be used to encrypt these credentials.

### Use of the AWS Default Credentials Provider Chain

If the gg.eventhandler.name.accessKeyId and gg.eventhandler.name.secretKey are unset, then credentials resolution reverts to the AWS default credentials provider chain. The AWS default credentials provider chain provides various ways by which the AWS credentials can be resolved.

For more information about the default credential provider chain and order of operations for AWS credentials resolution, see Working with AWS Credentials.

When Oracle GoldenGate for Big Data runs on an AWS Elastic Compute Cloud (EC2) instance, the general use case is to resolve the credentials from the EC2 metadata service. The AWS default credentials provider chain provides resolution of credentials from the EC2 metadata service as one of the options.

#### AWS Federated Login

The use case is when you have your on-premise system login integrated with AWS. This means that when you log into an on-premise machine, you are also logged into AWS.

In this use case:

- You may not want to generate client IDs and secrets. (Some users disable this feature in the AWS portal).
- The client AWS applications need to interact with the AWS Security Token Service (STS) to obtain an authentication token for programmatic calls made to Kinesis.

This feature is enabled by setting the following: gg.eventhandler.name.enableSTS=true.

## Configuring the Proxy Server for Kinesis Streams Handler

Oracle GoldenGate can be used with a proxy server using the following parameters to enable the proxy server:

```
gg.handler.name.proxyServer=
gg.handler.name.proxyPort=80
gg.handler.name.proxyUsername=username
gg.handler.name.proxyPassword=password
```

#### Sample configurations:

```
gg.handlerlist=kinesis
gg.handler.kinesis.type=kinesis_streams
gg.handler.kinesis.mode=op
gg.handler.kinesis.format=json
gg.handler.kinesis.region=us-west-2
gg.handler.kinesis.partitionMappingTemplate=TestPartitionName
gg.handler.kinesis.streamMappingTemplate=TestStream
gg.handler.kinesis.deferFlushAtTxCommit=true
gg.handler.kinesis.deferFlushOpCount=1000
```

gg.handler.kinesis.formatPerOp=true
#gg.handler.kinesis.customMessageGrouper=oracle.goldengate.handler.kine
sis.KinesisJsonTxMessageGrouper
gg.handler.kinesis.proxyServer=www-proxy.myhost.com
gg.handler.kinesis.proxyPort=80

# Configuring Security in Kinesis Streams Handler

The Amazon Web Services (AWS) Kinesis Java SDK uses HTTPS to communicate with Kinesis. Mutual authentication is enabled. The AWS server passes a Certificate Authority (CA) signed certificate to the AWS client which allow the client to authenticate the server. The AWS client passes credentials (client ID and secret) to the AWS server which allows the server to authenticate the client.

# Kinesis Handler Performance Considerations

- Kinesis Streams Input Limitations
- Transaction Batching
- Deferring Flush at Transaction Commit

# **Kinesis Streams Input Limitations**

The maximum write rate to a Kinesis stream with a single shard to be 1000 messages per second up to a maximum of 1MB of data per second. You can scale input to Kinesis by adding additional Kinesis streams or adding shards to streams. Both adding streams and adding shards can linearly increase the Kinesis input capacity and thereby improve performance of the Oracle GoldenGate Kinesis Streams Handler.

Adding streams or shards can linearly increase the potential throughput such as follows:

- 1 stream with 2 shards = 2000 messages per second up to a total data size of 2MB per second.
- 3 streams of 1 shard each = 3000 messages per second up to a total data size of 3MB per second.

To fully take advantage of streams and shards, you must configure the Oracle GoldenGate Kinesis Streams Handler to distribute messages as evenly as possible across streams and shards.

Adding additional Kinesis streams or shards does nothing to scale Kinesis input if all data is sent to using a static partition key into a single Kinesis stream. Kinesis streams are resolved at runtime using the selected mapping methodology. For example, mapping the source table name as the Kinesis stream name may provide good distribution of messages across Kinesis streams if operations from the source trail file are evenly distributed across tables. Shards are selected by a hash of the partition key. Partition keys are resolved at runtime using the selected mapping methodology. Therefore, it is best to choose a mapping methodology to a partition key that rapidly changes to ensure a good distribution of messages across shards.

# **Transaction Batching**

The Oracle GoldenGate Kinesis Streams Handler receives messages and then batches together messages by Kinesis stream before sending them via synchronous

HTTPS calls to Kinesis. At transaction commit all outstanding messages are flushed to Kinesis. The flush call to Kinesis impacts performance. Therefore, deferring the flush call can dramatically improve performance.

The recommended way to defer the flush call is to use the GROUPTRANSOPS configuration in the replicat configuration. The GROUPTRANSOPS groups multiple small transactions into a single larger transaction deferring the transaction commit call until the larger transaction is completed. The GROUPTRANSOPS parameter works by counting the database operations (inserts, updates, and deletes) and only commits the transaction group when the number of operations equals or exceeds the GROUPTRANSOPS configuration setting. The default GROUPTRANSOPS setting for replicat is 1000.

Interim flushes to Kinesis may be required with the GROUPTRANSOPS setting set to a large amount. An individual call to send batch messages for a Kinesis stream cannot exceed 500 individual messages or 5MB. If the count of pending messages exceeds 500 messages or 5MB on a per stream basis then the Kinesis Handler is required to perform an interim flush.

## Deferring Flush at Transaction Commit

The messages are by default flushed to Kinesis at transaction commit to ensure write durability. However, it is possible to defer the flush beyond transaction commit. This is only advisable when messages are being grouped and sent to Kinesis at the transaction level (that is one transaction = one Kinesis message or chunked into a small number of Kinesis messages), when the user is trying to capture the transaction as a single messaging unit.

This may require setting the GROUPTRANSOPS replication parameter to 1 so as not to group multiple smaller transactions from the source trail file into a larger output transaction. This can impact performance as only one or few messages are sent per transaction and then the transaction commit call is invoked which in turn triggers the flush call to Kinesis.

In order to maintain good performance the Oracle GoldenGate Kinesis Streams Handler allows the user to defer the Kinesis flush call beyond the transaction commit call. The Oracle GoldenGate replicat process maintains the checkpoint in the .cpr file in the {GoldenGate Home}/dirchk directory. The Java Adapter also maintains a checkpoint file in this directory named .cpj. The Replicat checkpoint is moved beyond the checkpoint for which the Oracle GoldenGate Kinesis Handler can guarantee message loss will not occur. However, in this mode of operation the GoldenGate Kinesis Streams Handler maintains the correct checkpoint in the .cpj file. Running in this mode will not result in message loss even with a crash as on restart the checkpoint in the .cpj file is parsed if it is before the checkpoint in the .cpr file.

# Troubleshooting

## **Topics:**

- Java Classpath
- Kinesis Handler Connectivity Issues
- Logging

## Java Classpath

The most common initial error is an incorrect classpath to include all the required AWS Kinesis Java SDK client libraries and creates a ClassNotFound exception in the log file.

You can troubleshoot by setting the Java Adapter logging to DEBUG, and then rerun the process. At the debug level, the logging includes information about which JARs were added to the classpath from the gg.classpath configuration variable.

The gg.classpath variable supports the wildcard asterisk (\*) character to select all JARs in a configured directory. For example, /usr/kinesis/sdk/\*, see Setting Up and Running the Kinesis Streams Handler.

## Kinesis Handler Connectivity Issues

If the Kinesis Streams Handler is unable to connect to Kinesis when running on premise, the problem can be the connectivity to the public Internet is protected by a proxy server. Proxy servers act a gateway between the private network of a company and the public Internet. Contact your network administrator to get the URLs of your proxy server, and then follow the directions in Configuring the Proxy Server for Kinesis Streams Handler.

## Logging

The Kinesis Streams Handler logs the state of its configuration to the Java log file.

This is helpful because you can review the configuration values for the handler. Following is a sample of the logging of the state of the configuration:

```
**** Begin Kinesis Streams Handler - Configuration Summary ****
Mode of operation is set to op.
   The AWS region name is set to [us-west-2].
   A proxy server has been set to [www-proxy.us.oracle.com] using port [80].
   The Kinesis Streams Handler will flush to Kinesis at transaction commit.
   Messages from the GoldenGate source trail file will be sent at the operation
level.
   One operation = One Kinesis Message
The stream mapping template of [${fullyQualifiedTableName}] resolves to [fully
qualified table name].
   The partition mapping template of [${primaryKeys}] resolves to [primary keys].
**** End Kinesis Streams Handler - Configuration Summary ****
```

# Amazon MSK

Amazon MSK is a fully managed, secure, and a highly available Apache Kafka service. You can use Apache Kafka to replicate to Amazon MSK.

# Amazon Redshift

Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. The purpose of the Redshift Event Handler is to apply operations into Redshift tables.

See Flat Files.

- Detailed Functionality Ensure to use the Redshift Event handler as a downstream Event handler connected to the output of the S3 Event handler. The S3 Event handler loads files generated by the File Writer Handler into Amazon S3.
- Operation Aggregation

- Unsupported Operations and Limitations
- Uncompressed UPDATE records
   It is mandatory that the trail files used to apply to Redshift contain uncompressed
   UPDATE operation records, which means that the UPDATE operations contain full image of the row being updated.
- Error During the Data Load Proces Staging operation data from AWS S3 onto temporary staging tables and updating the target table occurs inside a single transaction. In case of any error(s), the entire transaction is rolled back and the replicat process will ABEND.

- INSERTALLRECORDS Support
- Redshift COPY SQL Authorization
   The Redshift event handler uses COPY SQL to read staged files in Amazon Web Services
   (AWS) S3 buckets. The COPY SQL query may need authorization credentials to access
   files in AWS S3.
- Co-ordinated Apply Support

# **Detailed Functionality**

Ensure to use the Redshift Event handler as a downstream Event handler connected to the output of the S3 Event handler. The S3 Event handler loads files generated by the File Writer Handler into Amazon S3.

Redshift Event handler uses the COPY SQL to bulk load operation data available in S3 into temporary Redshift staging tables. The staging table data is then used to update the target table. All the SQL operations are performed in batches providing better throughput.

# **Operation Aggregation**

## Aggregation In Memory

Before loading the operation data into S3, the operations in the trail file are aggregated. Operation aggregation is the process of aggregating (merging/compressing) multiple operations on the same row into a single output operation based on a threshold.

Aggregation using SQL post loading data into the staging table

In this aggregation operation, the in-memory operation aggregation need not be performed. The operation data loaded into the temporary staging table is aggregated using SQL queries, such that the staging table contains just one row per key.

# Aggregation In Memory

Before loading the operation data into S3, the operations in the trail file are aggregated. Operation aggregation is the process of aggregating (merging/ compressing) multiple operations on the same row into a single output operation based on a threshold.

Table 8-3 Configuration Properties

Properties	Require d/ Option al	Legal Values	Defau It	Explanation
gg.aggregate.o perations	Optional	true   false	false	Aggregate operations based on the primary key of the operation record.

# Aggregation using SQL post loading data into the staging table

In this aggregation operation, the in-memory operation aggregation need not be performed. The operation data loaded into the temporary staging table is aggregated using SQL queries, such that the staging table contains just one row per key.

Table 8-4 Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.name.aggre gateStagingTa bleRows	Optional	True  False	False	Use SQL to aggregate staging table data before updating the target table.

# Unsupported Operations and Limitations

The following operations are not supported by the Redshift Handler:

- DDL changes are not supported.
- Timestamp and Timestamp with Time zone data types: The maximum precision supported is up to microseconds, the nanoseconds portion will be truncated. This is a limitation we have observed with the Redshift COPY SQL.
- Redshift COPY SQL has a limitation on the maximum size of a single input row from any source is 4MB.

# Uncompressed UPDATE records

It is mandatory that the trail files used to apply to Redshift contain uncompressed UPDATE operation records, which means that the UPDATE operations contain full image of the row being updated.

If UPDATE records have missing columns, then such columns are updated in the target as null. By setting the parameter gg.abend.on.missing.columns=true, replicat can fail fast on detecting a compressed update trail record. This is the recommended setting.

# Error During the Data Load Proces

Staging operation data from AWS S3 onto temporary staging tables and updating the target table occurs inside a single transaction. In case of any error(s), the entire transaction is rolled back and the replicat process will ABEND.

If there are errors with the COPY SQL, then the Redshift system table stl\_load\_errors is also queried and the error traces are made available in the handler log file.

# Troubleshooting and Diagnostics

- Connectivity issues to Redshift
  - Validate JDBC connection URL, user name and password.
  - Check if http/https proxy is enabled. Generally, Redshift endpoints cannot be accessed via proxy.
- DDL and Truncate operations not applied on the target table: The Redshift handler will ignore DDL and truncate records in the source trail file.
- Target table existence: It is expected that the Redshift target table exists before starting the apply process. Target tables need to be designed with primary keys, sort keys, partition distribution key columns. Approximations based on the column metadata in the trail file may not be always correct. Therefore, Redshift apply will ABEND if the target table is missing.
- Operation aggregation in-memory (gg.aggregagte.operations=true) is memory intensive where as operation aggregation using SQL(gg.eventhandler.name.aggregateStagingTableRows=true) requires more SQL processing on the Redshift database. These configurations are mutually exclusive and only one of them should be enabled at a time. Tests within Oracle have revealed that operation aggregation in memory delivers better apply rate. This may not always be the case on all the customer deployments.
- Diagnostic information on the apply process is logged onto the handler log file.
  - Operation aggregation time (in milli-seconds) in-memory:

Stage and load processing time (in milli-seconds) for SQL queries

- Stage time (in milli-seconds) will also include additional statistics if operation aggregation using SQL is enabled.
- Co-existence of the components: The location/region of the machine where replicat process is running, AWS S3 bucket region and the Redshift cluster region would impact the overall throughput of the apply process. Data flow is as follows: GoldenGate => AWS S3 => AWS Redshift. For best throughput, the components need to be located as close as possible.

# Classpath

Redshift apply relies on the upstream File Writer handler and the S3 Event handler.

Include the required jars needed to run the S3 Event handler in gg.classpath. See Amazon S3. Redshift Event handler uses the Redshift JDBC driver. Ensure to include the jar file in gg.classpath as shown in the following example:

gg.classpath=aws-java-sdk-1.11.356/lib/\*:aws-java-sdk-1.11.356/thirdparty/lib/\*:./RedshiftJDBC42-no-awssdk-1.2.8.1005.jar

# Configuration

#### **Automatic Configuration**

AWS Redshift Data warehouse replication involves configuring of multiple components, such as file writer handler, S3 event handler and Redshift event handler. The Automatic Configuration feature auto configures these components so that you need to perform minimal configurations. The properties modified by auto configuration will also be logged in the handler log file.

To enable auto configuration to replicate to Redshift target, set the parameter: gg.target=redshift

gg.target Required Legal Value: redshift Default: None Explanation: Enables replication to Redshift target

When replicating to Redshift target, the customization of S3 event hander name and Redshift event handler name is not allowed.

#### **File Writer Handler Configuration**

File writer handler name is pre-set to the value redshift. The following is an example to edit a property of file writer handler: gg.handler.redshift.pathMappingTemplate=./dirout

## **S3 Event Handler Configuration**

S3 event handler name is pre-set to the value s3. The following is an example to edit a property of the S3 event handler: gg.eventhandler.s3.bucketMappingTemplate=bucket1.

### **Redshift Event Handler Configuration**

The Redshift event handler name is pre-set to the value redshift.

Properties	Required/ Optional	Legal Value	Default	Explanation
gg.eventhandler .redshift.conne ctionURL	Required	Redshift JDBC Connection URL	None	Sets the Redshift JDBC connection URL. Example: jdbc:redshift:/ /aws-redshift- instance.cjoaij 3df5if.us- east-2.redshift .amazonaws.com: 5439/mydb
gg.eventhandler .redshift.UserN ame	Required	JDBC User Name	None	Sets the Redshift database user name.
gg.eventhandler .redshift.Passw ord	Required	JDBC Password	None	Sets the Redshift database password.
gg.eventhandler .redshift.awsIa mRole	Optional	AWS role ARN in the format: arn:aws:iam:: <a ws_account_id&gt;: role/ <role_name></role_name></a 	None	AWS IAM role ARN that the Redshift cluster uses for authentication and authorization for executing COPY SQL to access objects in AWS S3 buckets.
gg.eventhandler .redshift.useAw sSecurityTokenS ervice	Optional	true   false	Value is set from the configuration property set in the upstream s3 Event handler gg.eventhandler .s3.enableSTS	see Redshift
gg.eventhandler .redshift.awsST SEndpoint	Optional	A valid HTTPS URL.	Value is set from the configuration property set in the upstream s3 Event handler gg.eventhandler .s3.stsURL.	The AWS STS endpoint string. For example: https:// sts.us- east-1.amazonaws .com. For more information, see Redshift COPY

Table 8-5Properties

SQL Authorization.

Properties	Required/ Optional	Legal Value	Default	Explanation
gg.eventhandler .redshift.awsST SRegion	Optional	A valid AWS region.	Value is set from the configuration property set in the upstream s3 Event handler gg.eventhandler .s3.stsRegion.	The AWS STS region. For example, us- east-1. For more information, see Redshift COPY SQL Authorization.
gg.initialLoad	Optional	true   false	false	If set to true, initial load mode is enabled. See INSERTALLRECO RDS Support.
gg.operation.ag gregator.valida te.keyupdate	Optional	true <b>or</b> false	false	If set to true, Operation Aggregator will validate key update operations (optype 115) and correct to normal update if no key values have changed. Compressed key update operations do not qualify for merge.

#### Table 8-5 (Cont.) Properties

#### **End-to-End Configuration**

The following is an end-end configuration example which uses auto configuration for FW handler, S3 and Redshift Event handlers.

The sample properties are available at the following location

- In an Oracle GoldenGate Classic install: <oggbd\_install\_dir>/AdapterExamples/ big-data/redshift-via-s3/rs.props
- In an Oracle GoldenGate Microservices install: <oggbd\_install\_dir>/opt/ AdapterExamples/big-data/redshift-via-s3/rs.props

# Configuration to load GoldenGate trail operation records

- # into Amazon Redshift by chaining
- # File writer handler -> S3 Event handler -> Redshift Event handler.
- # Note: Recommended to only edit the configuration marked as TODO

gg.target=redshift
#The S3 Event Handler
#TODO: Edit the AWS region
gg.eventhandler.s3.region=<aws region>
#TODO: Edit the AWS S3 bucket
gg.eventhandler.s3.bucketMappingTemplate<s3bucket>

#The Redshift Event Handler #TODO: Edit ConnectionUrl gg.eventhandler.redshift.connectionURL=jdbc:redshift://aws-redshift-

#TODO:Set the classpath to include AWS Java SDK and Redshift JDBC driver.
gg.classpath=aws-java-sdk-1.11.356/lib/*:aws-java-sdk-1.11.356/third-party/lib/*:./
RedshiftJDBC42-no-awssdk-1.2.8.1005.jar
jvm.bootoptions=-Xmx8g -Xms32m
```

# INSERTALLRECORDS Support

Stage and merge targets supports INSERTALLRECORDS parameter.

See INSERTALLRECORDS in *Reference for Oracle GoldenGate*. Set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm).

Setting this property directs the Replicat process to use bulk insert operations to load operation data into the target table. You can tune the batch size of bulk inserts using the File Writer property gg.handler.redshift.maxFileSize. The default value is set to 1GB. The frequency of bulk inserts can be tuned using the File Writer property gg.handler.redshift.fileRollInterval, the default value is set to 3m (three minutes).

# Redshift COPY SQL Authorization

The Redshift event handler uses COPY SQL to read staged files in Amazon Web Services (AWS) S3 buckets. The COPY SQL query may need authorization credentials to access files in AWS S3.

Authorization can be provided by using an AWS Identity and Access Management (IAM) role that is attached to the Redshift cluster or by providing a AWS access key and a secret for the access key. As a security consideration, it is a best practise to use role-based access when possible.

## **AWS Key-Based Authorization**

With key-based access control, you provide the access key ID and secret access key for an AWS IAM user that is authorized to access AWS S3. The access key id and secret access key are retrieved by looking up the credentials as follows:

- Environment variables AWS\_ACCESS\_KEY/AWS\_ACCESS\_KEY\_ID and AWS\_SECRET\_KEY/ AWS\_SECRET\_ACCESS\_KEY.
- 2. Java System Properties aws.accessKeyId and aws.secretKey.
- 3. Credential profiles file at the default location (~/.aws/credentials).
- 4. Amazon Elastic Container Service (ECS) container credentials loaded from Amazon ECS if the environment variable AWS CONTAINER CREDENTIALS RELATIVE URI is set.
- 5. Instance profile credentials retrieved from Amazon Elastic Compute Cloud (EC2) metadata service.

### **Running Replicat on an AWS EC2 Instance**

If the replicat process is started on an AWS EC2 instance, then the access key ID and secret access key are automatically retrieved by Oracle GoldenGate for BigData and no explicit user configuration is required.

### Temporary Security Credentials using AWS Security Token Service (STS)

If you use the key-based access control, then you can further limit the access users have to your data by retrieving temporary security credentials using AWS Security Token Service. The auto configure feature of the Redshift event handler automatically picks up the AWS Security Token Service (STS) configuration from S3 event handler.

Table 8-6S3 Event Handler Configuration and Redshift Event HandlerConfiguration

S3 Event Handler Configuration	Redshift Event Handler Configuration		
enableSTS	useAwsSTS		
stsURL	awsSTSEndpoint		
stsRegion	awsSTSRegion		

#### AWS IAM Role-based Authorization

With role-based authorization, Redshift cluster temporarily assumes an IAM role when executing COPY SQL. You need to provide the role Amazon Resource Number (ARN) as a configuration value as follows: gg.eventhandler.redshift.AwsIamRole. For example:

gg.eventhandler.redshift.AwsIamRole=arn:aws:iam::<aws\_account\_id>:role/ <role\_name>. The role needs to be authorized to read the respective S3 bucket. Ensure that the trust relationship of the role contains the AWS redshift service. Additionally, attach this role to the Redshift cluster before starting the Redshift cluster. For example, AWS IAM policy that can be used in the the trust relationship of the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
  {
    "Effect": "Allow",
    "Principal": {
    "Service": [
    "redshift.amazonaws.com"
    ]
    },
    "Action": "sts:AssumeRole"
  }
]
}
```

### If the role-based authorization is configured

(gg.eventhandler.redshift.AwsIamRole), then it is given priority over key-based authorization.

# Co-ordinated Apply Support

To enable co-ordinated apply for Redshift, ensure that the Redshift database's isolation level is set to SNAPSHOT. The Redshift SNAPSHOT ISOLATION option allows higher concurrency, where concurrent modifications to different rows in the same table can complete successfully.

### SQL Query to Alter the Database's Isolation Level

ALTER DATABASE <sampledb> ISOLATION LEVEL SNAPSHOT;

# Amazon S3

Learn how to use the S3 Event Handler, which provides the interface to Amazon S3 web services.

- Overview
- Detailing Functionality
- Configuring the S3 Event Handler

# Overview

Amazon S3 is object storage hosted in the Amazon cloud. The purpose of the S3 Event Handler is to load data files generated by the File Writer Handler into Amazon S3, see https://aws.amazon.com/s3/.

You can use any format that the File Writer Handler, see Flat Files.

# **Detailing Functionality**

The S3 Event Handler requires the Amazon Web Services (AWS) Java SDK to transfer files to S3 object storage.Oracle GoldenGate for Big Data does not include the AWS Java SDK. You have to download and install the AWS Java SDK from:

### https://aws.amazon.com/sdk-for-java/

Then you have to configure the gg.classpath variable to include the JAR files in the AWS Java SDK and are divided into two directories. Both directories must be in gg.classpath, for example:

```
gg.classpath=/usr/var/aws-java-sdk-1.11.240/lib/*:/usr/var/aws-java-sdk-1.11.240/third-
party/lib/
```

- Resolving AWS Credentials
- About the AWS S3 Buckets
- Troubleshooting

# **Resolving AWS Credentials**

Amazon Web Services Simple Storage Service Client Authentication

The S3 Event Handler is a client connection to the Amazon Web Services (AWS) Simple Storage Service (S3) cloud service. The AWS cloud must be able to successfully authenticate the AWS client in order in order to successfully interface with S3.

## Amazon Web Services Simple Storage Service Client Authentication

The S3 Event Handler is a client connection to the Amazon Web Services (AWS) Simple Storage Service (S3) cloud service. The AWS cloud must be able to successfully authenticate the AWS client in order in order to successfully interface with S3.

The AWS client authentication has become increasingly complicated as more authentication options have been added to the S3 Event Handler. This topic explores the different use cases for AWS client authentication.

### • Explicit Configuration of the Client ID and Secret

A client ID and secret are generally the required credentials for the S3 Event Handler to interact with Amazon S3. A client ID and secret are generated using the Amazon AWS website.

### Use of the AWS Default Credentials Provider Chain

If the gg.eventhandler.name.accessKeyId and

gg.eventhandler.name.secretKey are unset, then credentials resolution reverts to the AWS default credentials provider chain. The AWS default credentials provider chain provides various ways by which the AWS credentials can be resolved.

AWS Federated Login

The use case is when you have your on-premise system login integrated with AWS. This means that when you log into an on-premise machine, you are also logged into AWS.

### Explicit Configuration of the Client ID and Secret

A client ID and secret are generally the required credentials for the S3 Event Handler to interact with Amazon S3. A client ID and secret are generated using the Amazon AWS website.

These credentials can be explicitly configured in the Java Adapter Properties file as follows:

gg.eventhandler.name.accessKeyId=
gg.eventhandler.name.secretKey=

Furthermore, the Oracle Wallet functionality can be used to encrypt these credentials.

#### Use of the AWS Default Credentials Provider Chain

If the gg.eventhandler.name.accessKeyId and gg.eventhandler.name.secretKey are unset, then credentials resolution reverts to the AWS default credentials provider chain. The AWS default credentials provider chain provides various ways by which the AWS credentials can be resolved.

For more information about the default credential provider chain and order of operations for AWS credentials resolution, see Working with AWS Credentials. When Oracle GoldenGate for Big Data runs on an AWS Elastic Compute Cloud (EC2) instance, the general use case is to resolve the credentials from the EC2 metadata service. The AWS default credentials provider chain provides resolution of credentials from the EC2 metadata service as one of the options.

#### AWS Federated Login

The use case is when you have your on-premise system login integrated with AWS. This means that when you log into an on-premise machine, you are also logged into AWS.

In this use case:

- You may not want to generate client IDs and secrets. (Some users disable this feature in the AWS portal).
- The client AWS applications need to interact with the AWS Security Token Service (STS) to obtain an authentication token for programmatic calls made to S3.

This feature is enabled by setting the following: gg.eventhandler.name.enableSTS=true.

## About the AWS S3 Buckets

AWS divides S3 storage into separate file systems called **buckets**. The S3 Event Handler can write to pre-created buckets. Alternatively, if the S3 bucket does not exist, the S3 Event Handler attempts to create the specified S3 bucket. AWS requires that S3 bucket names are lowercase. Amazon S3 bucket names must be globally unique. If you attempt to create an S3 bucket that already exists in any Amazon account, it causes the S3 Event Handler to abend.

## Troubleshooting

#### **Connectivity Issues**

If the S3 Event Handler is unable to connect to the S3 object storage when running on premise, it's likely your connectivity to the public internet is protected by a proxy server. Proxy servers act a gateway between the private network of a company and the public internet. Contact your network administrator to get the URLs of your proxy server.

Oracle GoldenGate can be used with a proxy server using the following parameters to enable the proxy server:

```
gg.handler.name.proxyServer=
gg.handler.name.proxyPort=80
gg.handler.name.proxyUsername=username
gg.handler.name.proxyPassword=password
```

#### Sample configuration:

```
gg.eventhandler.s3.type=s3
gg.eventhandler.s3.region=us-west-2
gg.eventhandler.s3.proxyServer=www-proxy.us.oracle.com
gg.eventhandler.s3.proxyPort=80
gg.eventhandler.s3.proxyProtocol=HTTP
gg.eventhandler.s3.bucketMappingTemplate=yourbucketname
gg.eventhandler.s3.pathMappingTemplate=thepath
gg.eventhandler.s3.finalizeAction=none
```

# Configuring the S3 Event Handler

You can configure the S3 Event Handler operation using the properties file. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the S3 Event Handler, you must first configure the handler type by specifying gg.eventhandler.name.type=s3 and the other S3 Event properties as follows:

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r. <i>nam</i> e.type	Required	s3	None	Selects the S3 Event Handler for use with Replicat.
gg.eventhandle r. <i>name</i> .region	Required	The AWS region name that is hosting your S3 instance.	None	Setting the legal AWS region name is required.
gg.eventhandle r.name.cannedA CL	Optional	Accepts one of the following values: privat e public -read public -read- write aws- exec- read authe nticat ed- read bucke t- owner -read bucke t- owner -read bucke t- owner -full- contro l log- delive ry- write	None	Amazon S3 supports a set of predefined grants, known as canned Access Control Lists. Each canned ACL has a predefined set of grantees and permissions. For more information, see Managing access with ACLs
gg.eventhandle r. <i>name</i> .proxySe rver	Optional	The host name of your proxy server.	None	Sets the host name of your proxy server if connectivity to AWS is required use a proxy server.
gg.eventhandle r. <i>name</i> .proxyPo rt	Optional	The port number of the proxy server.	None	Sets the port number of the proxy server if connectivity to AWS is required use a proxy server.

Table 8-7	S3 Event Handler Configuration Properties
-----------	---

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r. <i>name</i> .proxyUs ername	Optional	The username of the proxy server.	None	Sets the user name of the proxy server if connectivity to AWS is required use a proxy server and the proxy server requires credentials.
gg.eventhandle r. <i>name</i> .proxyPa ssword	Optional	The password of the proxy server.	None	Sets the password for the user name of the proxy server if connectivity to AWS is required use a proxy server and the proxy server requires credentials.
gg.eventhandle r.name.bucketM appingTemplate	Required	A string with resolvable keywords and constants used to dynamicall y generate the path in the S3 bucket to write the file.	None	Use resolvable keywords and constants used to dynamically generate the S3 bucket name at runtime. The handler attempts to create the S3 bucket if it does not exist. AWS requires bucket names to be all lowercase. A bucket name with uppercase characters results in a runtime exception. See Template Keywords.
gg.eventhandle r. <i>nam</i> e.pathMap pingTemplate	Required	A string with resolvable keywords and constants used to dynamicall y generate the path in the S3 bucket to write the file.	None	Use keywords interlaced with constants to dynamically generate unique S3 path names at runtime. Typically, path names follow the format, ogg/data/\$ {groupName}/\$ {fullyQualifiedTableName} In S3, the convention is <i>not</i> to begin the path with the backslash (/) because it results in a root directory of "". See Template Keywords.
gg.eventhandle r. <i>name</i> .fileNam eMappingTempla te	Optional	A string with resolvable keywords and constants used to dynamicall y generate the S3 file name at runtime.	None	Use resolvable keywords and constants used to dynamically generate the S3 data file name at runtime. If not set, the upstream file name is used. See Template Keywords.

 Table 8-7
 (Cont.) S3 Event Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r.name.finaliz eAction	Optional	none   delete	None	Set to none to leave the S3 data file in place on the finalize action. Set to delete if you want to delete the S3 data file with the finalize action.
gg.eventhandle r. <i>name</i> .eventHa ndler	Optional	A unique string identifier cross referencin g a child event handler.	No event handler configu red.	Sets the event handler that is invoked on the file roll event. Event handlers can do file roll event actions like loading files to S3, converting to Parquet or ORC format, or loading files to HDFS.
gg.eventhandle r.name.url	Optional (unless Dell ECS, then required)	A legal URL to connect to cloud storage.	None	Not required for Amazon AWS S3. Required for Dell ECS. Sets the URL to connect to cloud storage.
gg.eventhandle r.name.proxyPr otocol	Optional	HTTP   HTTPS	HTTP	Sets the proxy protocol connection to the proxy server for additional level of security. The client first performs an SSL handshake with the proxy server, and then an SSL handshake with Amazon AWS. This feature was added into the Amazon SDK in version 1.11.396 so you must use at least that version to use this property.
gg.eventhandle r. <i>name</i> .SSEAlgo rithm	Optional	AES256   aws:kms	Empty	Set only if you are enabling S3 server side encryption. Use the parameters to set the algorithm for server side encryption in S3.
gg.eventhandle r. <i>name</i> .AWSKmsK eyId	Optional	A legal AWS key managem ent system server side managem ent key or the alias that represents that key.	Empty	Set only if you are enabling S3 server side encryption and the S3 algorithm is aws:kms. This is either the encryption key or the encryption alias that you set in the AWS Identity and Access Management web page. Aliases are prepended with alias/.
gg.eventhandle r.name.enableS TS	Optional	true  false	false	Set totrue, to enable the S3 Event Handler to access S3 credentials from the AWS Security Token Service. The AWS Security Token Service must be enabled if you set this property to true.

Table 8-7	(Cont.) S3 Event Handler Configuration Properties
	(cont.) 55 Event nandier configuration roperties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r.name.STSAssu meRole	Optional	AWS user and role in the following format: {user arn}:rol e/{role name}	None	Set configuration if you want to assume a different user/role. Only valid with STS enabled.
gg.eventhandle r.name.STSAssu meRoleSessionN ame	Optional	Any string.	RoleSe	The assumed role requires a session name for session logging. However this can be any value. Only valid if both gg.eventhandler.name.enableSTS=tr ue and gg.eventhandler.name.STSAssumeRol e are configured.
gg.eventhandle r.name.STSRegi on	Optional	Any legal AWS region specifier.	The region is obtaine d from the gg.eve nthand ler.na me.reg ion propert y.	Use to resolve the region for the STS call. It's only valid if the gg.eventhandler.name.enableSTS property is set to true. You can set a different AWS region for resolving credentials from STS than the configured S3 region.
gg.eventhandle r.name.enableB ucketAdmin	Optional	true  false	true	Set to false to disable checking if S3 buckets exist and automatic creation of buckets, if they do not exist. This feature requires S3 admin privileges on S3 buckets which some customers do not wish to grant.
gg.eventhandle r.name.accessK eyId	Optional	A valid AWS access key.	None	Set this parameter to explicitly set the access key for AWS. This parameter has no effect if gg.eventhandler.name.enableSTS is set to true. If this property is not set, then the credentials resolution falls back to the AWS default credentials provider chain.
gg.eventhandle r.name.secretK ey	Optional	A valid AWS secret key.	None	Set this parameter to explicitly set the secret key for AWS. This parameter has no effect if gg.eventhandler.name.enableSTS is set to true. If this property is not set, then credentials resolution falls back to the AWS default credentials provider chain.

 Table 8-7
 (Cont.) S3 Event Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r.s3.enableAcc elerateMode	•	true  false	false	Enable/Disable Amazon S3 Transfer Acceleration to transfer files quickly and securely over long distances between your client and an S3 bucket.

# Apache Cassandra

The Cassandra Handler provides the interface to Apache Cassandra databases.

This chapter describes how to use the Cassandra Handler.

- Overview
- Detailing the Functionality
- Setting Up and Running the Cassandra Handler
- About Automated DDL Handling

The Cassandra Handler performs the table check and reconciliation process the first time an operation for a source table is encountered. Additionally, a DDL event or a metadata change event causes the table definition in the Cassandra Handler to be marked as not suitable.

- Performance Considerations
- Additional Considerations
- Troubleshooting
- Cassandra Handler Client Dependencies
   What are the dependencies for the Cassandra Handler to connect to Apache Cassandra databases?

## Overview

Apache Cassandra is a NoSQL Database Management System designed to store large amounts of data. A Cassandra cluster configuration provides horizontal scaling and replication of data across multiple machines. It can provide high availability and eliminate a single point of failure by replicating data to multiple nodes within a Cassandra cluster. Apache Cassandra is open source and designed to run on low-cost commodity hardware.

Cassandra relaxes the axioms of a traditional relational database management systems (RDBMS) regarding atomicity, consistency, isolation, and durability. When considering implementing Cassandra, it is important to understand its differences from a traditional RDBMS and how those differences affect your specific use case.

Cassandra provides eventual consistency. Under the eventual consistency model, accessing the state of data for a specific row eventually returns the latest state of the data for that row as defined by the most recent change. However, there may be a latency period between the creation and modification of the state of a row and what is returned when the state of that row is queried. The benefit of eventual consistency is that the latency period is predicted based on your Cassandra configuration and the

level of work load that your Cassandra cluster is currently under, see http:// cassandra.apache.org/.

The Cassandra Handler provides some control over consistency with the configuration of the gg.handler.name.consistencyLevel property in the Java Adapter properties file.

# Detailing the Functionality

- About the Cassandra Data Types
- About Catalog, Schema, Table, and Column Name Mapping

Traditional RDBMSs separate structured data into tables. Related tables are included in higher-level collections called databases. Cassandra contains both of these concepts. Tables in an RDBMS are also tables in Cassandra, while database schemas in an RDBMS are keyspaces in Cassandra.

- About DDL Functionality
- How Operations are Processed
- About Compressed Updates vs. Full Image Updates
- About Primary Key Updates

## About the Cassandra Data Types

Cassandra provides a number of column data types and most of these data types are supported by the Cassandra Handler.

#### **Supported Cassandra Data Types**

ASCII BIGINT BLOB BOOLEAN DATE DECIMAL DOUBLE DURATION FLOAT INET INT SMALLINT TEXT TIME TIMESTAMP TIMEUUID TINYINT UUID VARCHAR VARINT

### **Unsupported Cassandra Data Types**

COUNTER MAP SET LIST UDT (user defined type) TUPLE CUSTOM\_TYPE

#### **Supported Database Operations**

INSERT UPDATE (captured as INSERT) DELETE

The Cassandra commit log files do *not* record any before images for the UPDATE or DELETE operations. So the captured operations never have a before image section. Oracle GoldenGate features that rely on before image records, such as Conflict Detection and Resolution, are not available.

#### **Unsupported Database Operations**

TRUNCATE DDL (CREATE, ALTER, DROP)

The data type of the column value in the source trail file must be converted to the corresponding Java type representing the Cassandra column type in the Cassandra Handler. This data conversion introduces the risk of a runtime conversion error. A poorly mapped field (such as varchar as the source containing alpha numeric data to a Cassandra int) may cause a runtime error and cause the Cassandra Handler to abend. You can view the Cassandra Java type mappings at:

#### **DataStax Documentation**

It is possible that the data may require specialized processing to get converted to the corresponding Java type for intake into Cassandra. If this is the case, you have two options:

• Try to use the general regular expression search and replace functionality to format the source column value data in a way that can be converted into the Java data type for use in Cassandra.

Or

• Implement or extend the default data type conversion logic to override it with custom logic for your use case. Contact Oracle Support for guidance.

### About Catalog, Schema, Table, and Column Name Mapping

Traditional RDBMSs separate structured data into tables. Related tables are included in higher-level collections called databases. Cassandra contains both of these concepts. Tables in an RDBMS are also tables in Cassandra, while database schemas in an RDBMS are keyspaces in Cassandra.

It is important to understand how data maps from the metadata definition in the source trail file are mapped to the corresponding keyspace and table in Cassandra. Source tables are generally either two-part names defined as schema.table,or three-part names defined as schema.table.

The following table explains how catalog, schema, and table names map into Cassandra. Unless you use special syntax, Cassandra converts all keyspace, table names, and column names to lower case.

Table Name in Source Trail File	Cassandra Keyspace Name	Cassandra Table Name	
QASOURCE.TCUSTMER	qasource	tcustmer	

Table Name in Source Trail File	Cassandra Keyspace Name	Cassandra Table Name
dbo.mytable	dbo	mytable
GG.QASOURCE.TCUSTORD	gg_qasource	tcustord

### About DDL Functionality

- About the Keyspaces
- About the Tables
- Adding Column Functionality
- Dropping Column Functionality

### About the Keyspaces

The Cassandra Handler does *not* automatically create keyspaces in Cassandra. Keyspaces in Cassandra define a replication factor, the replication strategy, and topology. The Cassandra Handler does not have enough information to create the keyspaces, so you must manually create them.

You can create keyspaces in Cassandra by using the CREATE KEYSPACE command from the Cassandra shell.

### About the Tables

The Cassandra Handler can automatically create tables in Cassandra if you configure it to do so. The source table definition may be a poor source of information to create tables in Cassandra. Primary keys in Cassandra are divided into:

- Partitioning keys that define how data for a table is separated into partitions in Cassandra.
- **Clustering keys** that define the order of items within a partition.

In the default mapping for automated table creation, the first primary key is the partition key, and any additional primary keys are mapped as clustering keys.

Automated table creation by the Cassandra Handler may be fine for proof of concept, but it may result in data definitions that do not scale well. When the Cassandra Handler creates tables with poorly constructed primary keys, the performance of ingest and retrieval may decrease as the volume of data stored in Cassandra increases. Oracle recommends that you analyze the metadata of your replicated tables, then manually create corresponding tables in Cassandra that are properly partitioned and clustered for higher scalability.

Primary key definitions for tables in Cassandra are immutable after they are created. Changing a Cassandra table primary key definition requires the following manual steps:

- **1.** Create a staging table.
- 2. Populate the data in the staging table from original table.
- 3. Drop the original table.
- 4. Re-create the original table with the modified primary key definitions.

- **5.** Populate the data in the original table from the staging table.
- 6. Drop the staging table.

### Adding Column Functionality

You can configure the Cassandra Handler to add columns that exist in the source trail file table definition but are missing in the Cassandra table definition. The Cassandra Handler can accommodate metadata change events of this kind. A reconciliation process reconciles the source table definition to the Cassandra table definition. When the Cassandra Handler is configured to add columns, any columns found in the source table definition process for a table occurs after application startup the first time an operation for the table is encountered. The reconciliation process reoccurs after a metadata change event on a source table, when the first operation for the source table is encountered.

### **Dropping Column Functionality**

You can configure the Cassandra Handler to drop columns that do not exist in the source trail file definition but exist in the Cassandra table definition. The Cassandra Handler can accommodate metadata change events of this kind. A reconciliation process reconciles the source table definition to the Cassandra table definition. When the Cassandra Handler is configured to drop, columns any columns found in the Cassandra table definition that are not in the source table definition are dropped.

### **Caution**:

Dropping a column permanently removes data from a Cassandra table. Carefully consider your use case before you configure this mode.

### Note:

Primary key columns cannot be dropped. Attempting to do so results in an abend.

### Note:

Column name changes are not well-handled because there is no DDL is processed. When a column name changes in the source database, the Cassandra Handler interprets it as dropping an existing column and adding a new column.

### How Operations are Processed

The Cassandra Handler pushes operations to Cassandra using either the asynchronous or synchronous API. In asynchronous mode, operations are flushed at

transaction commit (grouped transaction commit using GROUPTRANSOPS) to ensure write durability. The Cassandra Handler does not interface with Cassandra in a transactional way.

#### **Supported Database Operations**

INSERT UPDATE (captured as INSERT) DELETE

The Cassandra commit log files do *not* record any before images for the UPDATE or DELETE operations. So the captured operations never have a before image section. Oracle GoldenGate features that rely on before image records, such as Conflict Detection and Resolution, are not available.

#### **Unsupported Database Operations**

TRUNCATE DDL (CREATE, ALTER, DROP)

Insert, update, and delete operations are processed differently in Cassandra than a traditional RDBMS. The following explains how insert, update, and delete operations are interpreted by Cassandra:

- Inserts: If the row does not exist in Cassandra, then an insert operation is processed as an insert. If the row already exists in Cassandra, then an insert operation is processed as an update.
- Updates: If a row does not exist in Cassandra, then an update operation is processed as an insert. If the row already exists in Cassandra, then an update operation is processed as insert.
- Delete: If the row does not exist in Cassandra, then a delete operation has no effect. If the row exists in Cassandra, then a delete operation is processed as a delete.

The state of the data in Cassandra is idempotent. You can replay the source trail files or replay sections of the trail files. The state of the Cassandra database must be the same regardless of the number of times that the trail data is written into Cassandra.

## About Compressed Updates vs. Full Image Updates

Oracle GoldenGate allows you to control the data that is propagated to the source trail file in the event of an update. The data for an update in the source trail file is either a compressed or a full image of the update, and the column information is provided as follows:

#### Compressed

For the primary keys and the columns for which the value changed. Data for columns that have not changed is not provided in the trail file.

#### Full Image

For all columns, including primary keys, columns for which the value has changed, and columns for which the value has not changed.

The amount of information about an update is important to the Cassandra Handler. If the source trail file contains full images of the change data, then the Cassandra Handler can use prepared statements to perform row updates in Cassandra. Full images also allow the Cassandra Handler to perform primary key updates for a row in Cassandra. In Cassandra, primary keys are immutable, so an update that changes a primary key must be treated as a delete and an insert. Conversely, when compressed updates are used, prepared statements cannot be used for Cassandra row updates. Simple statements identifying the changing

values and primary keys must be dynamically created and then executed. With compressed updates, primary key updates are not possible and as a result, the Cassandra Handler will abend.

You must set the control properties gg.handler.name.compressedUpdates and gg.handler.name.compressedUpdatesfor so that the handler expects either compressed or full image updates.

The default value, true, sets the Cassandra Handler to expect compressed updates. Prepared statements are not be used for updates, and primary key updates cause the handler to abend.

When the value is false, prepared statements are used for updates and primary key updates can be processed. A source trail file that does not contain full image data can lead to corrupted data columns, which are considered null. As a result, the null value is pushed to Cassandra. If you are not sure about whether the source trail files contains compressed or full image data, set gg.handler.name.compressedUpdates to true.

CLOB and BLOB data types do not propagate LOB data in updates unless the LOB column value changed. Therefore, if the source tables contain LOB data, set gg.handler.name.compressedUpdates to true.

### About Primary Key Updates

Primary key values for a row in Cassandra are immutable. An update operation that changes any primary key value for a Cassandra row must be treated as a delete and insert. The Cassandra Handler can process update operations that result in the change of a primary key in Cassandra only as a delete and insert. To successfully process this operation, the source trail file *must* contain the complete before and after change data images for all columns. The gg.handler.name.compressed configuration property of the Cassandra Handler must be set to false for primary key updates to be successfully processed.

# Setting Up and Running the Cassandra Handler

Instructions for configuring the Cassandra Handler components and running the handler are described in the following sections.

Before you run the Cassandra Handler, you must install the Datastax Driver for Cassandra and set the gg.classpath configuration property.

### Get the Driver Libraries

The Cassandra Handler has been updated to use the newer 4.x versions of the Datastax Java Driver or 2.x versions of the Datastax Enterprise Java Driver. The Datastax Java Driver for Cassandra does not ship with Oracle GoldenGate for Big Data. For more information, see

#### Datastax Java Driver for Apache Cassandra.

You can use the Dependency Downloader scripts to download the Datastax Java Driver and its associated dependencies.

#### Set the Classpath

You must configure the gg.classpath configuration property in the Java Adapter properties file to specify the JARs for the Datastax Java Driver for Cassandra. Ensure that this JAR is first in the list.

gg.classpath=/path/to/4.x/cassandra-java-driver/\*

- Understanding the Cassandra Handler Configuration
- Review a Sample Configuration
- Configuring Security

## Understanding the Cassandra Handler Configuration

The following are the configurable values for the Cassandra Handler. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the Cassandra Handler, you must first configure the handler type by specifying gg.handler.name.type=cassandra and the other Cassandra properties as follows:

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handlerlist	Require d	Any string	None	Provides a name for the Cassandra Handler. The Cassandra Handler name then becomes part of the property names listed in this table.
gg.handler. <i>name.</i> type= cassandra	Require d	cassandr a	None	Selects the Cassandra Handler for streaming change data capture into name.
gg.handler. <i>name</i> .mode	Optional	op tx	op	The default is recommended. In op mode, operations are processed as received. In tx mode, operations are cached and processed at transaction commit. The txmode is slower and creates a larger memory footprint.
gg.handler.name.conta ctPoints=	Optional	A comma separated list of host names that the Cassandr a Handler will connect to.	localhost	A comma-separated list of the Cassandra host machines for the driver to establish an initial connection to the Cassandra cluster. This configuration property does <i>not</i> need to include all the machines enlisted in the Cassandra cluster. By connecting to a single machine, the driver can learn about other machines in the Cassandra cluster and establish connections to those machines as required.

### Table 8-8 Cassandra Handler Configuration Properties

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler. <i>name.</i> usern ame	Optional	A legal username string.	None	A user name for the connection to name. Required if Cassandra is configured to require credentials.
gg.handler. <i>name.</i> passw ord	Optional	A legal password string.	None	A password for the connection to name. Required if Cassandra is configured to require credentials.
gg.handler. <i>name.</i> compr essedUpdates	Optional	true  false	true	Sets the Cassandra Handler whether to expect full image updates from the source trail file. A value of true means that updates in the source trail file only contain column data for the primary keys and for columns that changed. The Cassandra Handler executes updates as simple statements updating only the columns that changed. A value of false means that updates in the source trail file contain column data for primary keys and all columns regardless of whether the column value has changed. The Cassandra Handler is able to use prepared statements for updates, which can provide better performance for streaming data to name.
gg.handler. <i>name.</i> ddlHa ndling	Optional	CREATE   ADD   DROP in any combinati on with values delimited by a comma	None	Configures the Cassandra Handler for the DDL functionality to provide. Options include CREATE, ADD, and DROP. These options can be set in any combination delimited by commas. When CREATE is enabled, the Cassandra Handler creates tables in Cassandra if a corresponding table does not exist. When ADD is enabled, the Cassandra Handler adds columns that exist in the source table definition that do <i>not</i> exist in the corresponding Cassandra table definition. When DROP is enabled, the handler drops columns that exist in the Cassandra table definition that do <i>not</i> exist in the corresponding source table definition.

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler. <i>nam</i> e.cassa ndraMode	Optional	async   sync	async	Sets the interaction between the Cassandra Handler and name. Set to async for asynchronous interaction. Operations are sent to Cassandra asynchronously and then flushed at transaction commit to ensure durability. Asynchronous provides better performance. Set to sync for synchronous interaction. Operations are sent to Cassandra synchronously.
gg.handler. <i>name</i> .consi stencyLevel	Optional	ALL   ANY   EACH_QUO RUM   LOCAL_ON E   LOCAL_QU ORUM   ONE   QUORUM   THREE   TWO	The Cassandra default.	Sets the consistency level for operations with name. It configures the criteria that must be met for storage on the Cassandra cluster when an operation is executed. Lower levels of consistency may provide better performance, while higher levels of consistency are safer.
gg.handler. <i>name</i> .port	Optional	Integer	9042	Set to configure the port number that the Cassandra Handler attempts to connect to Cassandra server instances. You can override the default in the Cassandra YAML files.
gg.handler.name.batch Type	Optional	String	unlogged	<ul> <li>Sets the type for Cassandra batch processing.</li> <li>unlogged - Does not use Cassandra's distributed batch log.</li> <li>logged - Cassandra first writes to its distributed batch log to ensure atomicity of the batch.</li> <li>counter - Use if counter types are updated in the batch.</li> </ul>

 Table 8-8
 (Cont.) Cassandra Handler Configuration Properties

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler.name.abend OnUnmappedColumns	Optional	Boolean	true	Only applicable when gg.handler.name.ddlHanding is not configured with ADD. When set to true, the replicat process will abend if a column exists in the source table, but does not exist in the target Cassandra table. When set to false, the replicat process will not abend if a column exists in the source table, but does not exist in the target Cassandra table. Instead, that column will not be replicated.
gg.handler.name.Datas taxJSSEConfigPath	Optional	String	None	Set the path and file name of a properties file containing the Cassandra driver configuration. Use when the Cassandra driver configuration needs to be configured for non-default values and potentially SSL connectivity. For more information, see Cassandra Driver Configuration Documentation. You need to follow the syntax of the configuration file for the driver version you are using. The suffix of the Cassandra driver configuration file must be .conf.
gg.handler.name.dataC enter	Optional	The datacente r name	datacenter 1	Set the datacenter name. If the datacenter name does not match the configured name on the server, then it will not connect to the database.

Table 8-8	(Cont.) Cassandra Handler	<sup>r</sup> Configuration Properties
-----------	---------------------------	---------------------------------------

# Review a Sample Configuration

The following is a sample configuration for the Cassandra Handler from the Java Adapter properties file:

gg.handlerlist=cassandra
#The handler properties
gg.handler.cassandra.type=cassandra
gg.handler.cassandra.mode=op
gg.handler.cassandra.contactPoints=localhost
gg.handler.cassandra.ddlHandling=CREATE,ADD,DROP
gg.handler.cassandra.compressedUpdates=true
gg.handler.cassandra.cassandraMode=async
gg.handler.cassandra.consistencyLevel=ONE

# **Configuring Security**

The Cassandra Handler connection to the Cassandra Cluster can be secured using user name and password credentials. These are set using the following configuration properties:

```
gg.handler.name.username
gg.handler.name.password
```

To configure SSL, the recommendation is to configure the SSL properties via the Datastax Java Driver configuration file and point to the configuration file via the

gg.handler.name.DatastaxJSSEConfigPath property. See https://docs.datastax.com/en/ developer/java-driver/4.14/manual/core/ssl/ for the SSL settings instructions.

Sample configuration file is as follows. Uncomment the relevant parameters and change to your required values.

```
datastax-java-driver {
 advanced.ssl-engine-factory {
   class = DefaultSslEngineFactory
    # This property is optional. If it is not present, the driver won't explicitly
enable cipher
    # suites on the engine, which according to the JDK documentations results in "a
minimum quality
    # of service".
    // cipher-suites = [ "TLS RSA WITH AES 128 CBC SHA",
"TLS RSA WITH AES 256 CBC SHA" ]
    # Whether or not to require validation that the hostname of the server
certificate's common
    # name matches the hostname of the server being connected to. If not set, defaults
to true.
    // hostname-validation = true
    # The locations and passwords used to access truststore and keystore contents.
    # These properties are optional. If either truststore-path or keystore-path are
specified,
    # the driver builds an SSLContext from these files. If neither option is
specified, the
    # default SSLContext is used, which is based on system property configuration.
    // truststore-path = /path/to/client.truststore
    // truststore-password = password123
    // keystore-path = /path/to/client.keystore
    // keystore-password = password123
  }
}
```

# About Automated DDL Handling

The Cassandra Handler performs the table check and reconciliation process the first time an operation for a source table is encountered. Additionally, a DDL event or a metadata change event causes the table definition in the Cassandra Handler to be marked as not suitable.

Therefore, the next time an operation for the table is encountered, the handler repeats the table check, and reconciliation process as described in this topic.

About the Table Check and Reconciliation Process

#### Capturing New Change Data

### About the Table Check and Reconciliation Process

The Cassandra Handler first interrogates the target Cassandra database to determine whether the target Cassandra keyspace exists. If the target Cassandra keyspace does not exist, then the Cassandra Handler abends. Keyspaces must be created by the user. The log file must contain the error of the exact keyspace name that the Cassandra Handler is expecting.

Next, the Cassandra Handler interrogates the target Cassandra database for the table definition. If the table does not exist, the Cassandra Handler either creates a table if gg.handler.name.ddlHandling includes the CREATE option or abends the process. A message is logged that shows you the table that does not exist in Cassandra.

If the table exists in Cassandra, then the Cassandra Handler reconciles the table definition from the source trail file and the table definition in Cassandra. This reconciliation process searches for columns that exist in the source table definition and not in the corresponding Cassandra table definition. If it locates columns fitting this criteria and the gg.handler.name.ddlHandling property includes ADD, then the Cassandra Handler adds the columns to the target table in Cassandra. Otherwise, it ignores these columns.

Next, the Cassandra Handler searches for columns that exist in the target Cassandra table but do not exist in the source table definition. If it locates columns that fit this criteria and the gg.handler.name.ddlHandling property includes DROP, then the Cassandra Handler removes these columns from the target table in Cassandra. Otherwise those columns are ignored.

Finally, the prepared statements are built.

### Capturing New Change Data

You can capture all of the new change data into your Cassandra database, including the DDL changes in the trail, for the target apply. Following is the acceptance criteria:

```
AC1: Support Cassandra as a bulk extract
AC2: Support Cassandra as a CDC source
AC4: All Cassandra supported data types are supported
AC5: Should be able to write into different tables based on any filter
conditions, like Updates to Update tables or based on primary keys
AC7: Support Parallel processing with multiple threads
AC8: Support Filtering based on keywords
AC9: Support for Metadata provider
AC10: Support for DDL handling on sources and target
AC11: Support for target creation and updating of metadata.
AC12: Support for error handling and extensive logging
AC13: Support for Conflict Detection and Resolution
AC14: Performance should be on par or better than HBase
```

# Performance Considerations

Configuring the Cassandra Handler for async mode provides better performance than sync mode. Set Replicat property GROUPTRANSOPS must be set to the default value of 1000.

Setting the consistency level directly affects performance. The higher the consistency level, the more work must occur on the Cassandra cluster before the transmission of a

given operation can be considered complete. Select the minimum consistency level that still satisfies the requirements of your use case.

The Cassandra Handler can work in either operation (op) or transaction (tx) mode. For the best performance operation mode is recommended:

gg.handler.name.mode=op

# Additional Considerations

- Cassandra database requires at least one primary key. The value of any primary key cannot be null. Automated table creation fails for source tables that do not have a primary key.
- When gg.handler.name.compressedUpdates=false is set, the Cassandra Handler expects to update full before and after images of the data.

# Note:

Using this property setting with a source trail file with partial image updates results in null values being updated for columns for which the data is missing. This configuration is incorrect and update operations pollute the target data with null values in columns that did not change.

• The Cassandra Handler does *not* process DDL from the source database, even if the source database provides DDL Instead, it reconciles between the source table definition and the target Cassandra table definition. A DDL statement executed at the source database that changes a column name appears to the Cassandra Handler as if a column is dropped from the source table and a new column is added. This behavior depends on how the gg.handler.name.ddlHandling property is configured.

gg.handler.name.ddlHandling Configuration	Behavior
Not configured for ADD or DROP	Old column name and data maintained in Cassandra. New column is not created in Cassandra, so no data is replicated for the new column name from the DDL change forward.
Configured for ADD only	Old column name and data maintained in Cassandra. New column iscreated in Cassandra and data replicated for the new column name from the DDL change forward. Column mismatch between the data is located before and after the DDL change.
Configured for DROP only	Old column name and data dropped in Cassandra. New column is not created in Cassandra, so no data replicated for the new column name.
Configured for ADD and DROP	Old column name and data dropped in Cassandra. New column is created in Cassandra, and data is replicated for the new column name from the DDL change forward.

# Troubleshooting

This section contains information to help you troubleshoot various issues.

- Java Classpath
- Write Timeout Exception
- Datastax Driver Error

# Java Classpath

When the classpath that is intended to include the required client libraries, a ClassNotFound exception appears in the log file. To troubleshoot, set the Java Adapter logging to DEBUG, and then run the process again. At the debug level, the log contains data about the JARs that were added to the classpath from the gg.classpath configuration variable. The gg.classpath variable selects the asterisk (\*) wildcard character to select all JARs in a configured directory. For example, /usr/cassandra/cassandra-java-driver4.9.0/\*:/usr/cassandra/cassandra-java-driver4.9.0/1ib/\*.

For more information about setting the classpath, see Setting Up and Running the Cassandra Handler and Cassandra Handler Client Dependencies.

## Write Timeout Exception

When running the Cassandra handler, you may experience a com.datastax.driver.core.exceptions.WriteTimeoutException exception that causes the Replicat process to abend. It is likely to occur under some or all of the following conditions:

- The Cassandra Handler processes large numbers of operations, putting the Cassandra cluster under a significant processing load.
- GROUPTRANSOPS is configured higher than the value of 1000 default.
- The Cassandra Handler is configured in asynchronous mode.
- The Cassandra Handler is configured with a consistency level higher than ONE.

When this problem occurs, the Cassandra Handler is streaming data faster than the Cassandra cluster can process it. The write latency in the Cassandra cluster finally exceeds the write request timeout period, which in turn results in the exception.

The following are potential solutions:

- Increase the write request timeout period. This is controlled with the write\_request\_timeout\_in\_ms property in Cassandra and is located in the cassandra.yaml file in the cassandra\_install/conf directory. The default is 2000 (2 seconds). You can increase this value to move past the error, and then restart the Cassandra node or nodes for the change to take effect.
- Decrease the GROUPTRANSOPS configuration value of the Replicat process. Typically, decreasing the GROUPTRANSOPS configuration decreases the size of transactions processed and reduces the likelihood that the Cassandra Handler can overtax the Cassandra cluster.

Reduce the consistency level of the Cassandra Handler. This in turn reduces the amount
of work the Cassandra cluster has to complete for an operation to be considered as
written.

### Datastax Driver Error

The Cassandra Handler has been changed to use the 4.x version of the Datastax Java Driver. ClassNotFound exceptions can occur under either of the following conditions:

- The gg.classpath configuration is set to point at the old 3.x version of the Java Driver.
- The gg.classpath has not been configured to include the 4.x version of the Java Driver.

# Cassandra Handler Client Dependencies

What are the dependencies for the Cassandra Handler to connect to Apache Cassandra databases?

The following Maven dependencies are required for the Cassandra Handler:

#### Artifact: java-driver-core

GroupId: com.datastax.oss

AtifactId: java-driver-core

Version: 4.x

Artifact: java-driver-query-builder

GroupId: com.datastax.oss

Artifact ID: java-driver-query-builder

Version: 4.x

- Cassandra Datastax Java Driver 4.12.0

# Apache HBase

The HBase Handler is used to populate HBase tables from existing Oracle GoldenGate supported sources.

This chapter describes how to use the HBase Handler.

- Overview
- Detailed Functionality
- Setting Up and Running the HBase Handler
- Security
- Metadata Change Events

The HBase Handler seamlessly accommodates metadata change events including adding a column or dropping a column. The only requirement is that the source trail file contains the metadata.

- Additional Considerations
- Troubleshooting the HBase Handler Troubleshooting of the HBase Handler begins with the contents for the Java log4j file. Follow the directions in the Java Logging Configuration to configure the runtime to correctly generate the Java log4j log file.
- HBase Handler Client Dependencies What are the dependencies for the HBase Handler to connect to Apache HBase databases?

# Overview

HBase is an open source Big Data application that emulates much of the functionality of a relational database management system (RDBMS). Hadoop is specifically designed to store large amounts of unstructured data. Conversely, data stored in databases and replicated through Oracle GoldenGate is highly structured. HBase provides a way to maintain the important structure of data while taking advantage of the horizontal scaling that is offered by the Hadoop Distributed File System (HDFS).

# **Detailed Functionality**

The HBase Handler takes operations from the source trail file and creates corresponding tables in HBase, and then loads change capture data into those tables.

### **HBase Table Names**

Table names created in an HBase map to the corresponding table name of the operation from the source trail file. Table name is case-sensitive.

#### HBase Table Namespace

For two-part table names (schema name and table name), the schema name maps to the HBase table namespace. For a three-part table name like Catalog.Schema.MyTable, the create HBase namespace would be Catalog\_Schema. HBase table namespaces are case sensitive. A null schema name is supported and maps to the default HBase namespace.

#### **HBase Row Key**

HBase has a similar concept to the database primary keys, called the HBase row key. The HBase row key is the unique identifier for a table row. HBase only supports a single row key per row and it cannot be empty or null. The HBase Handler maps the primary key value into the HBase row key value. If the source table has multiple primary keys, then the primary key values are concatenated, separated by a pipe delimiter (1). You can configure the HBase row key delimiter.

If there's no primary/unique keys at the source table, then Oracle GoldenGate behaves as follows:

- If KEYCOLS is specified, then it constructs the key based on the specifications defined in the KEYCOLS clause.
- If KEYCOLS is not specified, then it constructs a key based on the concatenation of all eligible columns of the table.

The result is that the value of every column is concatenated to generate the HBase rowkey. However, this is not a good practice.

Workaround: Use the replicat mapping statement to identify one or more primary key columns. For example: MAP QASOURCE.TCUSTORD, TARGET QASOURCE.TCUSTORD, KEYCOLS (CUST CODE);

#### **HBase Column Family**

HBase has the concept of a column family. A column family is a way to group column data. Only a single column family is supported. Every HBase column must belong to a single column family. The HBase Handler provides a single column family per table that defaults to cf. You can configure the column family name. However, after a table is created with a specific column family name, you cannot reconfigure the column family name in the HBase example, without first modifying or dropping the table results in an abend of the Oracle GoldenGateReplicat processes.

## Setting Up and Running the HBase Handler

HBase must run either collocated with the HBase Handler process or on a machine that can connect from the network that is hosting the HBase Handler process. The underlying HDFS single instance or clustered instance serving as the repository for HBase data must also run.

Instructions for configuring the HBase Handler components and running the handler are described in this topic.

- Classpath Configuration
- HBase Handler Configuration
- Sample Configuration

### • Performance Considerations

# **Classpath Configuration**

For the HBase Handler to connect to HBase and stream data, the hbase-site.xml file and the HBase client jars must be configured in gg.classpath variable. The HBase client jars must match the version of HBase to which the HBase Handler is connecting. The HBase client jars are not shipped with the Oracle GoldenGate for Big Data product.

HBase Handler Client Dependencies lists the required HBase client jars by version.

The default location of the hbase-site.xml file is HBase Home/conf.

The default location of the HBase client JARs is HBase Home/lib/\*.

If the HBase Handler is running on Windows, follow the Windows classpathing syntax.

The gg.classpath must be configured exactly as described. The path to the hbase-site.xml file must contain only the path with no wild card appended. The inclusion of the \* wildcard in the path to the hbase-site.xml file will cause it to be inaccessible. Conversely, the path to the dependency jars must include the (\*) wildcard character in order to include all the jar files in that directory, in the associated classpath. Do not use \*.jar. The following is an example of a correctly configured gg.classpath variable:

gg.classpath=/var/lib/hbase/lib/\*:/var/lib/hbase/conf

## HBase Handler Configuration

The following are the configurable values for the HBase Handler. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the HBase Handler, you must first configure the handler type by specifying gg.handler.jdbc.type=hbase and the other HBase properties as follows:

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handlerlist	Required	Any string.	None	Provides a name for the HBase Handler. The HBase Handler name is then becomes part of the property names listed in this table.
gg.handler. <i>name.</i> type	Required	hbase.	None	Selects the HBase Handler for streaming change data capture into HBase.
gg.handler. <i>name.</i> hBaseColumnFamil yName	Optional	Any string legal for an HBase column family name.	cf	Column family is a grouping mechanism for columns in HBase. The HBase Handler only supports a single column family.
gg.handler.name. HBase20Compatibl e	Optional	true  false	false (HBas e 1.0 compa tible)	HBase 2.x removed methods and changed object hierarchies. The result is that it broke the binary compatibility with HBase 1.x. Set this property to true to correctly interface with HBase 2.x, otherwise HBase 1.x compatibility is used.

 Table 8-9
 HBase Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler. <i>name.</i> includeTokens	Optional	true  false	false	Using true indicates that token values are included in the output to HBase. Using false means token values are not to be included.
gg.handler. <i>name.</i> keyValueDelimite r	Optional	Any string.	=	Provides a delimiter between key values in a map. For example, key=value, key1=value1, key2=value2. Tokens are mapped values. Configuration value supports CDATA[] wrapping.
gg.handler. <i>name.</i> keyValuePairDeli miter	Optional	Any string.	,	Provides a delimiter between key value pairs in a map. For example, key=value, key1=value1, key2=value2key= value, key1=value1, key2=value2. Tokens are mapped values. Configuration value supports CDATA[] wrapping.
gg.handler.name. encoding	Optional	Any encoding name or alias supported by Java. <sup>1</sup> For a list of supported options, see https:// docs.ora cle.com/ javase/8 /docs/ technote s/ guides/ intl/ encoding .doc.htm l.	the machi ne hostin g the Oracle Golde nGate	Determines the encoding of values written the HBase. HBase values are written as bytes.

Table 8-9	(Cont.) HBase Handler Configuration Properties
-----------	--

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler. <i>name.</i> pkUpdateHandling	Optional	abend  update  delete- insert	abend	<ul> <li>Provides configuration for how the HBase Handler should handle update operations that change a primary key. Primary key operations can be problematic for the HBase Handler and require special consideration by you.</li> <li>abend: indicates the process will end abnormally.</li> <li>update: indicates the process will treat this as a normal update</li> <li>delete-insert: indicates the process will treat this as a delete and an insert. The full before image is required for this feature to work properly. This can be achieved by using full supplemental logging in Oracle Database. Without full before and after row images the insert data will be incomplete.</li> </ul>
gg.handler. <i>name.</i> nullValueReprese ntation	Optional	Any string.	NULL	Allows you to configure what will be sent to HBase in the case of a NULL column value. The default is NULL. Configuration value supports CDATA[] wrapping.
gg.handler. <i>name.</i> authType	Optional	kerberos	None	Setting this property to kerberos enables Kerberos authentication.
gg.handler. <i>name.</i> kerberosKeytabFi le	-		-	The keytab file allows the HDFS Handler to access a password to perform a kinit operation for Kerberos security.
gg.handler. <i>name.</i> kerberosPrincipa l	•	-,	-	The Kerberos principal name for Kerberos authentication.
gg.handler. <i>nam</i> e. rowkeyDelimiter	Optional	Any string/	l	Configures the delimiter between primary key values from the source table when generating the HBase rowkey. This property supports CDATA[] wrapping of the value to preserve whitespace if the user wishes to delimit incoming primary key values with a character or characters determined to be whitespace.

Table 8-9	(Cont.) HBase Handler Configuration Properties
-----------	--

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler. <i>name</i> . setHBaseOperatio nTimestamp	Optional	true  false	true	Set to true to set the timestamp for HBase operations in the HBase Handler instead of allowing HBase to assign the timestamps on the server side. This property can be used to solve the problem of a row delete followed by an immediate reinsert of the row not showing up in HBase, see HBase Handler Delete-Insert Problem.
gg.handler. <i>name</i> . omitNullValues	Optional	true  false	false	Set to true to omit null fields from being written.
gg.handler.name. metaColumnsTempl ate	Optional	A legal string	None	A legal string specifying the metaColumns to be included. For more information, see Metacolumn Keywords.

Table 8-9	(Cont.) HBase Handler Configuration Properties
-----------	--

See Java Internalization Support at https://docs.oracle.com/javase/8/docs/ technotes/guides/intl/.

## Sample Configuration

The following is a sample configuration for the HBase Handler from the Java Adapter properties file:

```
gg.handlerlist=hbase
gg.handler.hbase.type=hbase
gg.handler.hbase.mode=tx
gg.handler.hbase.hBaseColumnFamilyName=cf
gg.handler.hbase.includeTokens=true
gg.handler.hbase.includeTokens=true
gg.handler.hbase.keyValueDelimiter=CDATA[=]
gg.handler.hbase.keyValueDelimiter=CDATA[,]
gg.handler.hbase.encoding=UTF-8
gg.handler.hbase.pkUpdateHandling=abend
gg.handler.hbase.nullValueRepresentation=CDATA[NULL]
gg.handler.hbase.authType=none
```

## Performance Considerations

At each transaction commit, the HBase Handler performs a flush call to flush any buffered data to the HBase region server. This must be done to maintain write durability. Flushing to the HBase region server is an expensive call and performance can be greatly improved by using the Replicat GROUPTRANSOPS parameter to group multiple smaller transactions in the source trail file into a larger single transaction applied to HBase. You can use Replicat base-batching by adding the configuration syntax in the Replicat configuration file.

Operations from multiple transactions are grouped together into a larger transaction, and it is only at the end of the grouped transaction that transaction is committed.

# Security

You can secure HBase connectivity using Kerberos authentication. Follow the associated documentation for the HBase release to secure the HBase cluster. The HBase Handler can connect to Kerberos secured clusters. The HBase hbase-site.xml must be in handlers classpath with the hbase.security.authentication property set to kerberos and hbase.security.authorization property set to true.

You have to include the directory containing the HDFS core-site.xml file in the classpath. Kerberos authentication is performed using the Hadoop UserGroupInformation class. This class relies on the Hadoop configuration property hadoop.security.authentication being set to kerberos to successfully perform the kinit command.

Additionally, you must set the following properties in the HBase Handler Java configuration file:

gg.handler.{name}.authType=kerberos
gg.handler.{name}.keberosPrincipalName={legal Kerberos principal name}
gg.handler.{name}.kerberosKeytabFile={path to a keytab file that contains the password
for the Kerberos principal so that the Oracle GoldenGate HDFS handler can
programmatically perform the Kerberos kinit operations to obtain a Kerberos ticket}.

You may encounter the inability to decrypt the Kerberos password from the keytab file. This causes the Kerberos authentication to fall back to interactive mode which cannot work because it is being invoked programmatically. The cause of this problem is that the Java Cryptography Extension (JCE) is not installed in the Java Runtime Environment (JRE). Ensure that the JCE is loaded in the JRE, see http://www.oracle.com/technetwork/java/ javase/downloads/jce8-download-2133166.html.

# Metadata Change Events

The HBase Handler seamlessly accommodates metadata change events including adding a column or dropping a column. The only requirement is that the source trail file contains the metadata.

# Additional Considerations

Classpath issues are common during the initial setup of the HBase Handler. The typical indicators are occurrences of the ClassNotFoundException in the Java log4j log file. The HBase client jars do not ship with Oracle GoldenGate for Big Data. You must resolve the required HBase client jars. HBase Handler Client Dependencies includes a list of HBase client jars for each supported version. Either the hbase-site.xml or one or more of the required client JARS are not included in the classpath. For instructions on configuring the classpath of the HBase Handler, see Classpath Configuration.

# Troubleshooting the HBase Handler

Troubleshooting of the HBase Handler begins with the contents for the Java  $\log 4j$  file. Follow the directions in the Java Logging Configuration to configure the runtime to correctly generate the Java  $\log 4j$  log file.

- Java Classpath
- HBase Connection Properties

- Logging of Handler Configuration
- HBase Handler Delete-Insert Problem

## Java Classpath

Issues with the Java classpath are common. A ClassNotFoundException in the Java log4j log file indicates a classpath problem. You can use the Java log4j log file to troubleshoot this issue. Setting the log level to DEBUG logs each of the jars referenced in the gg.classpath object to the log file. You can make sure that all of the required dependency jars are resolved by enabling DEBUG level logging, and then searching the log file for messages like the following:

2015-09-29 13:04:26 DEBUG ConfigClassPath:74 - ...adding to classpath: url="file:/ggwork/hbase/hbase-1.0.1.1/lib/hbase-server-1.0.1.1.jar"

### HBase Connection Properties

The contents of the HDFS hbase-site.xml file (including default settings) are output to the Java log4j log file when the logging level is set to DEBUG or TRACE. This file shows the connection properties to HBase. Search for the following in the Java log4j log file.

```
2015-09-29 13:04:27 DEBUG HBaseWriter:449 - Begin - HBase configuration object contents for connection troubleshooting.
Key: [hbase.auth.token.max.lifetime] Value: [604800000].
```

Commonly, for the hbase-site.xml file is not included in the classpath or the path to the hbase-site.xml file is incorrect. In this case, the HBase Handler cannot establish a connection to HBase, and the Oracle GoldenGate process abends. The following error is reported in the Java log4j log.

```
2015-09-29 12:49:29 ERROR HBaseHandler:207 - Failed to initialize the HBase handler. org.apache.hadoop.hbase.ZooKeeperConnectionException: Can't connect to ZooKeeper
```

Verify that the classpath correctly includes the hbase-site.xml file and that HBase is running.

### Logging of Handler Configuration

The Java log4j log file contains information on the configuration state of the HBase Handler. This information is output at the INFO log level. The following is a sample output:

```
2015-09-29 12:45:53 INFO HBaseHandler:194 - **** Begin HBase Handler -
Configuration Summary ****
Mode of operation is set to tx.
HBase data will be encoded using the native system encoding.
In the event of a primary key update, the HBase Handler will ABEND.
HBase column data will use the column family name [cf].
The HBase Handler will not include tokens in the HBase data.
The HBase Handler has been configured to use [=] as the delimiter between keys
and values.
The HBase Handler has been configured to use [,] as the delimiter between key
values pairs.
The HBase Handler has been configured to output [NULL] for null values.
Hbase Handler Authentication type has been configured to use [none]
```

## HBase Handler Delete-Insert Problem

### If you are using the HBase Handler with the

gg.handler.name.setHBaseOperationTimestamp=false configuration property, then the source database may get out of sync with data in the HBase tables. This is caused by the deletion of a row followed by the immediate reinsertion of the row. HBase creates a tombstone marker for the delete that is identified by a specific timestamp. This tombstone marker marks any row records in HBase with the same row key as deleted that have a timestamp before or the same as the tombstone marker. This can occur when the deleted row is immediately reinserted. The insert operation can inadvertently have the same timestamp as the delete operation so the delete operation causes the subsequent insert operation to incorrectly appear as deleted.

To work around this issue, you need to set the gg.handler.name.setHbaseOperationTimestamp=true, which does two things:

- Sets the timestamp for row operations in the HBase Handler.
- Detection of a delete-insert operation that ensures that the insert operation has a timestamp that is after the insert.

The default for gg.handler.name.setHbaseOperationTimestamp is true, which means that the HBase server supplies the timestamp for a row. This prevents the HBase delete-reinsert out-of-sync problem.

Setting the row operation timestamp in the HBase Handler can have these consequences:

- **1.** Since the timestamp is set on the client side, this could create problems if multiple applications are feeding data to the same HBase table.
- 2. If delete and reinsert is a common pattern in your use case, then the HBase Handler has to increment the timestamp 1 millisecond each time this scenario is encountered.

Processing cannot be allowed to get too far into the future so the HBase Handler only allows the timestamp to increment 100 milliseconds into the future before it attempts to wait the process so that the client side HBase operation timestamp and real time are back in sync. When a delete-insert is used instead of an update in the source database so this sync scenario would be quite common. Processing speeds may be affected by not allowing the HBase timestamp to go over 100 milliseconds into the future if this scenario is common.

# HBase Handler Client Dependencies

What are the dependencies for the HBase Handler to connect to Apache HBase databases?

The maven central repository artifacts for HBase databases are:

- Maven groupId: org.apache.hbase
- Maven atifactId: hbase-client
- Maven version: the HBase version numbers listed for each section

The hbase-client-x.x.iar file is not distributed with Apache HBase, nor is it mandatory to be in the classpath. The hbase-client-x.x.iar file is an empty Maven project whose purpose of aggregating all of the HBase client dependencies.

# Apache HDFS

The HDFS Handler is designed to stream change capture data into the Hadoop Distributed File System (HDFS).

This chapter describes how to use the HDFS Handler.

- Overview
- Writing into HDFS in SequenceFile Format The HDFS SequenceFile is a flat file consisting of binary key and value pairs. You can enable writing data in SequenceFile format by setting the gg.handler.name.format property to sequencefile.
- Setting Up and Running the HDFS Handler
- Writing in HDFS in Avro Object Container File Format
- Generating HDFS File Names Using Template Strings
- Metadata Change Events
- Partitioning

The partitioning functionality uses the template mapper functionality to resolve partitioning strings. The result is that the you have more control in how to partition source trail data. Starting Oracle GoldenGate for Big Data 21.1, all the keywords that are supported by the templating functionality are supported in HDFS partitioning.

- HDFS Additional Considerations
- Best Practices
- Troubleshooting the HDFS Handler Troubleshooting of the HDFS Handler begins with the contents for the Java log4j file.
   Follow the directions in the Java Logging Configuration to configure the runtime to correctly generate the Java log4j log file.
- HDFS Handler Client Dependencies

## Overview

The HDFS is the primary file system for Big Data. Hadoop is typically installed on multiple machines that work together as a Hadoop cluster. Hadoop allows you to store very large amounts of data in the cluster that is horizontally scaled across the machines in the cluster. You can then perform analytics on that data using a variety of Big Data applications.

# Writing into HDFS in SequenceFile Format

The HDFS SequenceFile is a flat file consisting of binary key and value pairs. You can enable writing data in SequenceFile format by setting the gg.handler.name.format property to sequencefile.

The key part of the record is set to null, and the actual data is set in the value part. For information about Hadoop SequenceFile, see https://cwiki.apache.org/confluence/display/HADOOP2/SequenceFile.

- Integrating with Hive
- Understanding the Data Format

#### Integrating with Hive

Oracle GoldenGate for Big Data release does not include a Hive storage handler because the HDFS Handler provides all of the necessary Hive functionality .

You can create a Hive integration to create tables and update table definitions in case of DDL events. This is limited to data formatted in Avro Object Container File format. For more information, see Writing in HDFS in Avro Object Container File Format and HDFS Handler Configuration.

For Hive to consume sequence files, the DDL creates Hive tables including STORED as sequencefile. The following is a sample create table script:

```
CREATE EXTERNAL TABLE table_name (
   coll string,
   ...
   col2 string)
ROW FORMAT DELIMITED
STORED as sequencefile
LOCATION '/path/to/hdfs/file';
```

#### Note:

If files are intended to be consumed by Hive, then the gg.handler.name.partitionByTable property should be set to true.

## Understanding the Data Format

The data written in the value part of each record and is in delimited text format. All of the options described in the Using the Delimited Text Row Formatter section are applicable to HDFS SequenceFile when writing data to it.

For example:

```
gg.handler.name.format=sequencefile
gg.handler.name.format.includeColumnNames=true
gg.handler.name.format.includeOpType=true
```

gg.handler.name.format.includeCurrentTimestamp=true
gg.handler.name.format.updateOpKey=U

# Setting Up and Running the HDFS Handler

To run the HDFS Handler, a Hadoop single instance or Hadoop cluster must be installed, running, and network-accessible from the machine running the HDFS Handler. Apache Hadoop is open source and you can download it from:

#### http://hadoop.apache.org/

Follow the Getting Started links for information on how to install a single-node cluster (for pseudo-distributed operation mode) or a clustered setup (for fully-distributed operation mode).

Instructions for configuring the HDFS Handler components and running the handler are described in the following sections.

- Classpath Configuration
- HDFS Handler Configuration
- Review a Sample Configuration
- Performance Considerations
- Security

#### **Classpath Configuration**

For the HDFS Handler to connect to HDFS and run, the HDFS <code>core-site.xml</code> file and the HDFS client jars must be configured in <code>gg.classpath</code> variable. The HDFS client jars must match the version of HDFS that the HDFS Handler is connecting. For a list of the required client jar files by release, see HDFS Handler Client Dependencies.

The default location of the core-site.xml file is Hadoop Home/etc/hadoop

The default locations of the HDFS client jars are the following directories:

Hadoop Home/share/hadoop/common/lib/\*

Hadoop Home/share/hadoop/common/\*

Hadoop Home/share/hadoop/hdfs/lib/\*

Hadoop Home/share/hadoop/hdfs/\*

The gg.classpath must be configured exactly as shown. The path to the core-site.xml file must contain the path to the directory containing the core-site.xmlfile with no wildcard appended. If you include a (\*) wildcard in the path to the core-site.xml file, the file is not picked up. Conversely, the path to the dependency jars must include the (\*) wildcard character in order to include all the jar files in that directory in the associated classpath. Do not use \*.jar.

The following is an example of a correctly configured gg.classpath variable:

gg.classpath=/ggwork/hadoop/hadoop-2.6.0/etc/hadoop:/ggwork/hadoop/hadoop-2.6.0/share/ hadoop/common/lib/\*:/ggwork/hadoop/hadoop-2.6.0/share/hadoop/common/\*:/ggwork/hadoop/ hadoop-2.6.0/share/hadoop/hdfs/\*:/ggwork/hadoop/hadoop-2.6.0/share/hadoop/hdfs/lib/\*

The HDFS configuration file hdfs-site.xml must also be in the classpath if Kerberos security is enabled. By default, the hdfs-site.xml file is located in the Hadoop\_Home/etc/hadoop directory. If the HDFS Handler is not collocated with Hadoop, either or both files can be copied to another machine.

## HDFS Handler Configuration

The following are the configurable values for the HDFS Handler. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the HDFS Handler, you must first configure the handler type by specifying gg.handler.name.type=hdfs and the other HDFS properties as follows:

Property	Optional / Require d	Legal Values	Default	Explanation
gg.handlerlist	Required	Any string	None	Provides a name for the HDFS Handler. The HDFS Handler name then becomes part of the property names listed in this table.
gg.handler. <i>nam</i> e.type	Required	hdfs	None	Selects the HDFS Handler for streaming change data capture into HDFS.
gg.handler. <i>nam</i> e.mode	Optional	tx   op	op	Selects operation (op) mode or transaction (tx) mode for the handler. In almost all scenarios, transaction mode results in better performance.
gg.handler. <i>nam</i> e.maxFileSize	Optional	The default unit of measure is bytes. You can use k, m, or g to specify kilobytes, megabytes, or gigabytes. Examples of legal values include 10000, 10k, 100m, 1.1g.	1g	Selects the maximum file size of the created HDFS files.
gg.handler. <i>nam</i> e.pathMappingT emplate	Optional	Any legal templated string to resolve the target write directory in HDFS. Templates can contain a mix of constants and keywords which are dynamically resolved at runtime to generate the HDFS write directory.	<pre>/ogg/\$ {toLower Case[\$ {fullyQu alifiedT ableName }]}</pre>	You can use keywords interlaced with constants to dynamically generate the HDFS write directory at runtime, see Generating HDFS File Names Using Template Strings.
gg.handler. <i>nam</i> e.fileRollInte rval	Optional	The default unit of measure is milliseconds. You can stipulate ms, s, m, h to signify milliseconds, seconds, minutes, or hours respectively. Examples of legal values include 10000, 10000ms, 10s, 10m, or 1.5h. Values of 0 or less indicate that file rolling on time is turned off.	File rolling on time is off.	The timer starts when an HDFS file is created. If the file is still open when the interval elapses, then the file is closed. A new file is not immediately opened. New HDFS files are created on a just-in-time basis.

Property	Optional / Require	Legal Values	Default	Explanation
	d			
gg.handler. <i>nam</i> e.inactivityRo llInterval	Optional	The default unit of measure is milliseconds. You can use ms, s, m, h to specify milliseconds, seconds, minutes, or hours. Examples of legal values include 10000, 10000ms, 10s, 10, 5m, or 1h. Values of 0 or less indicate that file inactivity rolling on time is turned off.	File inactivity rolling on time is off.	The timer starts from the latest write to an HDFS file. New writes to an HDFS file restart the counter. If the file is still open when the counter elapses, the HDFS file is closed. A new file is not immediately opened. New HDFS files are created on a just-in-time basis.
gg.handler. <i>nam</i> e.fileNameMapp ingTemplate	Optional	A string with resolvable keywords and constants used to dynamically generate HDFS file names at runtime.	<pre>\$ {fullyQu alifiedT ableName }_\$ {groupNa me}_\$ {current TimeStam p}.txt</pre>	You can use keywords interlaced with constants to dynamically generate unique HDFS file names at runtime, see Generating HDFS File Names Using Template Strings. File names typically follow the format, \$ {fullyQualifiedTableName}_\$ {groupName}_\${currentTimeStamp} {.txt}.
gg.handler. <i>nam</i> e.partitionByT able	Optional	true false	true (data is partitioned by table)	Determines whether data written into HDFS must be partitioned by table. If set to true, then data for different tables are written to different HDFS files. If set to false, then data from different tables is interlaced in the same HDFS file.
				Must be set to true to use the Avro Object Container File Formatter. If set to false, a configuration exception occurs at initialization.
gg.handler. <i>nam</i> e.rollOnMetada taChange	Optional	true false	true (HDFS files are rolled on a metadata change event)	Determines whether HDFS files are rolled in the case of a metadata change. True means the HDFS file is rolled, false means the HDFS file is not rolled. Must be set to true to use the Avro Object Container File Formatter. If set to false, a configuration exception occurs at initialization.

Property	Optional / Require d	Legal Values	Default	Explanation
gg.handler. <i>nam</i> e.format	Optional	<pre>delimitedtext json  json_row xml  avro_row avro_op  avro_row_ocf  avro_op_ocf  sequencefile</pre>	delimite dtext	<ul> <li>Selects the formatter for the HDFS Handler for how output data is formatted.</li> <li>delimitedtext: Delimited text</li> <li>json: JSON</li> <li>json_row: JSON output modeling row data</li> <li>xml: XML</li> <li>avro_row: Avro in row compact format</li> <li>avro_op: Avro in operation more verbose format.</li> <li>avro_row_ocf: Avro in the row compact format written into HDFS in the Avro Object Container File (OCF) format.</li> <li>avro_op_ocf: Avro in the more verbose format written into HDFS in the Avro Object Container File format.</li> <li>sequencefile: Delimited text written in sequence into HDFS is sequence file format.</li> </ul>
gg.handler. <i>nam</i> e.includeToken s	Optional	true false	false	Set to true to include the tokens field and tokens key/values in the output. Set to false to suppress tokens output.
gg.handler.nam e.partitioner. fully_qualifie d_table_ name	Optional	A mixture of templating keywords and constants to resolve a sub directory at runtime to partition the data.	-	The configuration resolves a sub directory or sub directories, which are appended to the resolved HDFS target path. These sub directories are used to partition the data. gg.handler.name.partitionByTable must be set to true.
gg.handler. <i>nam</i> e.authType	Optional	kerberos	none	Setting this property to kerberos enables Kerberos authentication.
gg.handler. <i>nam</i> e.kerberosKeyt abFile		Relative or absolute path to a Kerberos keytab file.	-	The keytab file allows the HDFS Handler to access a password to perform a kinit operation for Kerberos security.
gg.handler. <i>nam</i> e.kerberosPrin cipal	Optional (Require d if authTyp e=Kerbe ros)	A legal Kerberos principal name like user/ FQDN@MY.REALM.	-	The Kerberos principal name for Kerberos authentication.

Property	Optional / Require d	Legal Values	Default	Explanation
gg.handler. <i>nam</i> e.schemaFilePa th	Optional	-	null	Set to a legal path in HDFS so that schemas (if available) are written in that HDFS directory. Schemas are currently only available for Avro and JSON formatters. In the case of a metadata change event, the schema is overwritten to reflect the schema change.
gg.handler.nam e.compressionT ype Applicable to Sequence File Format only.	Optional	block   none   record	none	Hadoop Sequence File Compression Type. Applicable only if gg.handler.name.format is set to sequencefile
gg.handler.nam e.compressionC odec Applicable to Sequence File and writing to HDFS is Avro OCF formats only.	Optional	<pre>org.apache.hadoop.io .compress.DefaultCod ec   org.apache.hadoop.io .compress. BZip2Codec   org.apache.hadoop.io .compress.SnappyCode c   org.apache.hadoop.io .compress.GzipCodec</pre>	he.hadoo p.io.com	Hadoop Sequence File Compression Codec. Applicable only if gg.handler.name.format is set to sequencefile
gg.handler.nam e.compressionC odec	Optional	null   snappy   bzip2   xz   deflate	null	Avro OCF Formatter Compression Code. This configuration controls the selection of the compression library to be used for Avro OCF files. Snappy includes native binaries in the
				Snappy JAR file and performs a Java-native traversal when compressing or decompressing. Use of Snappy may introduce runtime issues and platform porting issues that you may not experience when working with Java. You may need to perform additional testing to ensure that Snappy works on all of your required platforms. Snappy is an open source library, so Oracle cannot guarantee its ability to operate on all of your required platforms.

Property	Optional / Require d	Legal Values	Default	Explanation
gg.handler. <i>nam</i> e.openNextFile AtRoll	Optional	true   false	false	Applicable only to the HDFS Handler that is not writing an Avro OCF or sequence file to support extract, load, transform (ELT) situations.
				When set to true, this property creates a new file immediately on the occurrence of a file roll.
				File rolls can be triggered by any one of the following:
				<ul><li>Metadata change</li><li>File roll interval elapsed</li></ul>
				<ul> <li>Inactivity interval elapsed</li> <li>Data files are being loaded into HDFS and a monitor program is monitoring the write directories waiting to consume the data. The monitoring programs use the appearance of a new file as a trigger so that the previous file can be consumed by the consuming application.</li> </ul>
gg.handler. <i>nam</i> e.hsync	Optional	true false	false	Set to use an hflush call to ensure that data is transferred from the HDFS Handler to the HDFS cluster. When set to false, hflush is called on open HDFS write streams at transaction commit to ensure write durability.
				Setting hsync to true calls hsync instead of hflush at transaction commit. Using hsync ensures that data has moved to the HDFS cluster and that the data is written to disk. This provides a higher level of write durability though it adversely effects performance. Also, it does not make the write data immediately available to analytic tools.
				For most applications setting this property to false is appropriate.

# Review a Sample Configuration

The following is a sample configuration for the HDFS Handler from the Java Adapter properties file:

```
gg.handlerlist=hdfs
gg.handler.hdfs.type=hdfs
gg.handler.hdfs.mode=tx
gg.handler.hdfs.includeTokens=false
gg.handler.hdfs.maxFileSize=1g
gg.handler.hdfs.pathMappingTemplate=/ogg/${fullyQualifiedTableName}
gg.handler.hdfs.fileRollInterval=0
gg.handler.hdfs.inactivityRollInterval=0
gg.handler.hdfs.partitionByTable=true
```

gg.handler.hdfs.rollOnMetadataChange=true
gg.handler.hdfs.authType=none
gg.handler.hdfs.format=delimitedtext

## Performance Considerations

The HDFS Handler calls the HDFS flush method on the HDFS write stream to flush data to the HDFS data nodes at the end of each transaction in order to maintain write durability. This is an expensive call and performance can adversely affect, especially in the case of transactions of one or few operations that result in numerous HDFS flush calls.

Performance of the HDFS Handler can be greatly improved by batching multiple small transactions into a single larger transaction. If you require high performance, configure batching functionality for the Replicat process. For more information, see Replicat Grouping.

The HDFS client libraries spawn threads for every HDFS file stream opened by the HDFS Handler. Therefore, the number of threads executing in the JMV grows proportionally to the number of HDFS file streams that are open. Performance of the HDFS Handler may degrade as more HDFS file streams are opened. Configuring the HDFS Handler to write to many HDFS files (due to many source replication tables or extensive use of partitioning) may result in degraded performance. If your use case requires writing to many tables, then Oracle recommends that you enable the roll on time or roll on inactivity features to close HDFS file streams. Closing an HDFS file stream causes the HDFS client threads to terminate, and the associated resources can be reclaimed by the JVM.

## Security

The HDFS cluster can be secured using Kerberos authentication. The HDFS Handler can connect to Kerberos secured cluster. The HDFS core-site.xml should be in the handlers classpath with the hadoop.security.authentication property set to kerberos and the hadoop.security.authorization property set to true. Additionally, you must set the following properties in the HDFS Handler Java configuration file:

gg.handler.*name*.authType=kerberos

gg.handler.name.kerberosPrincipalName=legal Kerberos principal name gg.handler.name.kerberosKeytabFile=path to a keytab file that contains the password for the Kerberos principal so that the HDFS Handler can programmatically perform the Kerberos kinit operations to obtain a Kerberos ticket

You may encounter the inability to decrypt the Kerberos password from the keytab file. This causes the Kerberos authentication to fall back to interactive mode which cannot work because it is being invoked programmatically. The cause of this problem is that the Java Cryptography Extension (JCE) is not installed in the Java Runtime Environment (JRE). Ensure that the JCE is loaded in the JRE, see http://www.oracle.com/technetwork/java/ javase/downloads/jce8-download-2133166.html.

# Writing in HDFS in Avro Object Container File Format

The HDFS Handler includes specialized functionality to write to HDFS in Avro Object Container File (OCF) format. This Avro OCF is part of the Avro specification and is detailed in the Avro documentation at:

https://avro.apache.org/docs/current/spec.html#Object+Container+Files

Avro OCF format may be a good choice because it:

integrates with Apache Hive (Raw Avro written to HDFS is not supported by Hive.)

provides good support for schema evolution.

Configure the following to enable writing to HDFS in Avro OCF format:

To write row data to HDFS in Avro OCF format, configure the gg.handler.name.format=avro\_row\_ocf property.

To write operation data to HDFS is Avro OCF format, configure the gg.handler.name.format=avro op ocf property.

The HDFS and Avro OCF integration includes functionality to create the corresponding tables in Hive and update the schema for metadata change events. The configuration section provides information on the properties to enable integration with Hive. The Oracle GoldenGate Hive integration accesses Hive using the JDBC interface, so the Hive JDBC server must be running to enable this integration.

# Generating HDFS File Names Using Template Strings

The HDFS Handler can dynamically generate HDFS file names using a template string. The template string allows you to generate a combination of keywords that are dynamically resolved at runtime with static strings to provide you more control of generated HDFS file names. You can control the template file name using the gg.handler.name.fileNameMappingTemplate configuration property. The default value for this parameters is:

\${fullyQualifiedTableName}\_\${groupName}\_\${currentTimestamp}.txt

#### See Template Keywords.

Following are examples of legal templates and the resolved strings:

#### Legal Template Replacement

\${schemaName}.\${tableName}\_\_\${groupName}\_\${currentTimestamp}.txt
TEST.TABLE1 HDFS001 2017-07-05 04-31-23.123.txt

\${fullyQualifiedTableName}--\${currentTimestamp}.avro
ORACLE.TEST.TABLE1-2017-07-05 04-31-23.123.avro

\${fullyQualifiedTableName}\_\${currentTimestamp[yyyy-MM-ddTHH-mmss.SSS]}.json ORACLE.TEST.TABLE1 2017-07-05T04-31-23.123.json

Be aware of these restrictions when generating HDFS file names using templates:

- Generated HDFS file names must be legal HDFS file names.
- Oracle strongly recommends that you use \${groupName} as part of the HDFS file
  naming template when using coordinated apply and breaking down source table
  data to different Replicat threads. The group name provides uniqueness of
  generated HDFS names that \${currentTimestamp} alone does not guarantee.
  HDFS file name collisions result in an abend of the Replicat process.

## Metadata Change Events

Metadata change events are now handled in the HDFS Handler. The default behavior of the HDFS Handler is to roll the current relevant file in the event of a metadata

change event. This behavior allows for the results of metadata changes to at least be separated into different files. File rolling on metadata change is configurable and can be turned off.

To support metadata change events, the process capturing changes in the source database must support both DDL changes and metadata in trail. Oracle GoldenGatedoes not support DDL replication for all database implementations. See the Oracle GoldenGateinstallation and configuration guide for the appropriate database to determine whether DDL replication is supported.

## Partitioning

The partitioning functionality uses the template mapper functionality to resolve partitioning strings. The result is that the you have more control in how to partition source trail data. Starting Oracle GoldenGate for Big Data 21.1, all the keywords that are supported by the templating functionality are supported in HDFS partitioning.

For more information, see Template Keywords. **Precondition** 

To use the partitioning functionality, ensure that the data is partitioned by the table. You cannot set the following configuration:

gg.handler.name.partitionByTable=false

#### **Path Configuration**

Assume that the path mapping template is configured as follows:

gg.handler.hdfs.pathMappingTemplate=/ogg/\${fullyQualifiedTableName}

At runtime the path resolves as follows for the source table DBO.ORDERS:

/ogg/DB0.ORDERS

#### **Partitioning Configuration**

Configure the HDFS partitioning as follows; any of the keywords that are legal for templating are now legal for partitioning:

```
gg.handler.name.partitioner.fully qualified table name=templating keywords and/or
```

constants

**Example 1**: The partitioning for the DBO. ORDERS table is set to the following:

```
gg.handler.hdfs.partitioner.DBO.ORDERS=par_sales_region=$
{columnValue[SALES REGION]}
```

This example can result in the following breakdown of files in HDFS:

```
/ogg/DB0.ORDERS/par_sales_region=west/data files
/ogg/DB0.ORDERS/par_sales_region=east/data files
```

/ogg/DB0.ORDERS/par\_sales\_region=north/data files
/ogg/DB0.ORDERS/par sales region=south/data files

**Example 2**: The partitioning for the DBO.ORDERS table is set to the following:

gg.handler.hdfs.partitioner.DBO.ORDERS=par\_sales\_region=\$
{columnValue[SALES REGION]}/par state=\${columnValue[STATE]}

This example can result in the following breakdown of files in HDFS:

```
/ogg/DBO.ORDERS/par_sales_region=west/par_state=CA/data files
/ogg/DBO.ORDERS/par_sales_region=east/par_state=FL/data files
/ogg/DBO.ORDERS/par_sales_region=north/par_state=MN/data files
/ogg/DBO.ORDERS/par_sales_region=south/par_state=TX/data files
```

Ensure to be extra vigilant while configuring HDFS partitioning. If you choose partitioning column values that have a very large range of data values, then it results in partitioning to a proportional number of output data files. The HDFS client spawns multiple threads to service each open HDFS write stream. Partitioning to very large numbers of HDFS files can result in resource exhaustion of memory and/or threads.

#### Note:

Starting Oracle GoldenGate for Big Data 21.1, the Automated Hive integration has been removed with the changes to support templating in control partitioning.

## HDFS Additional Considerations

The Oracle HDFS Handler requires certain HDFS client libraries to be resolved in its classpath as a prerequisite for streaming data to HDFS.

For a list of required client JAR files by version, see HDFS Handler Client Dependencies. The HDFS client jars do not ship with the Oracle GoldenGate for Big Dataproduct. The HDFS Handler supports multiple versions of HDFS, and the HDFS client jars must be the same version as the HDFS version to which the HDFS Handler is connecting. The HDFS client jars are open source and are freely available to download from sites such as the Apache Hadoop site or the maven central repository.

In order to establish connectivity to HDFS, the HDFS core-site.xml file must be in the classpath of the HDFS Handler. If the core-site.xml file is not in the classpath, the HDFS client code defaults to a mode that attempts to write to the local file system. Writing to the local file system instead of HDFS can be advantageous for troubleshooting, building a point of contact (POC), or as a step in the process of building an HDFS integration.

Another common issue is that data streamed to HDFS using the HDFS Handler may not be immediately available to Big Data analytic tools such as Hive. This behavior commonly occurs when the HDFS Handler is in possession of an open write stream to an HDFS file. HDFS writes in blocks of 128 MB by default. HDFS blocks under construction are not always visible to analytic tools. Additionally, inconsistencies between file sizes when using the -ls, -cat, and -get commands in the HDFS shell

may occur. This is an anomaly of HDFS streaming and is discussed in the HDFS specification. This anomaly of HDFS leads to a potential 128 MB per file blind spot in analytic data. This may not be an issue if you have a steady stream of replication data and do not require low levels of latency for analytic data from HDFS. However, this may be a problem in some use cases because closing the HDFS write stream finalizes the block writing. Data is immediately visible to analytic tools, and file sizing metrics become consistent again. Therefore, the new file rolling feature in the HDFS Handler can be used to close HDFS writes streams, making all data visible.

### Important:

The file rolling solution may present its own problems. Extensive use of file rolling can result in many small files in HDFS. Many small files in HDFS may result in performance issues in analytic tools.

You may also notice the HDFS inconsistency problem in the following scenarios.

- The HDFS Handler process crashes.
- A forced shutdown is called on the HDFS Handler process.
- A network outage or other issue causes the HDFS Handler process to abend.

In each of these scenarios, it is possible for the HDFS Handler to end without explicitly closing the HDFS write stream and finalizing the writing block. HDFS in its internal process ultimately recognizes that the write stream has been broken, so HDFS finalizes the write block. In this scenario, you may experience a short term delay before the HDFS process finalizes the write block.

## **Best Practices**

It is considered a Big Data best practice for the HDFS cluster to operate on dedicated servers called cluster nodes. Edge nodes are server machines that host the applications to stream data to and retrieve data from the HDFS cluster nodes. Because the HDFS cluster nodes and the edge nodes are different servers, the following benefits are seen:

- The HDFS cluster nodes do not compete for resources with the applications interfacing with the cluster.
- The requirements for the HDFS cluster nodes and edge nodes probably differ. This physical topology allows the appropriate hardware to be tailored to specific needs.

It is a best practice for the HDFS Handler to be installed and running on an edge node and streaming data to the HDFS cluster using network connection. The HDFS Handler can run on any machine that has network visibility to the HDFS cluster. The installation of the HDFS Handler on an edge node requires that the core-site.xml files, and the dependency jars are copied to the edge node so that the HDFS Handler can access them. The HDFS Handler can also run collocated on a HDFS cluster node if required.

## Troubleshooting the HDFS Handler

Troubleshooting of the HDFS Handler begins with the contents for the Java  $\log 4j$  file. Follow the directions in the Java Logging Configuration to configure the runtime to correctly generate the Java  $\log 4j$  log file.

- Java Classpath
- Java Boot Options
- HDFS Connection Properties
- Handler and Formatter Configuration

### Java Classpath

Problems with the Java classpath are common. The usual indication of a Java classpath problem is a ClassNotFoundException in the Java log4j log file. The Java log4j log file can be used to troubleshoot this issue. Setting the log level to DEBUG allows for logging of each of the jars referenced in the gg.classpath object to be logged to the log file. In this way, you can ensure that all of the required dependency jars are resolved by enabling DEBUG level logging and search the log file for messages, as in the following:

```
2015-09-21 10:05:10 DEBUG ConfigClassPath:74 - ...adding to classpath:
url="file:/ggwork/hadoop/hadoop-2.6.0/share/hadoop/common/lib/guava-11.0.2.jar
```

### Java Boot Options

When running HDFS replicat with JRE 11, StackOverflowError is thrown. You can fix this issue by editing the bootoptions property in the Java Adapter Properties file as follows:

jvm.bootoptions=-Djdk.lang.processReaperUseDefaultStackSize=true

## **HDFS** Connection Properties

The contents of the HDFS core-site.xml file (including default settings) are output to the Java log4j log file when the logging level is set to DEBUG or TRACE. This output shows the connection properties to HDFS. Search for the following in the Java log4j log file:

```
2015-09-21 10:05:11 DEBUG HDFSConfiguration:58 - Begin - HDFS configuration object contents for connection troubleshooting.
```

If the fs.defaultFS property points to the local file system, then the core-site.xml file is not properly set in the gg.classpath property.

Key: [fs.defaultFS] Value: [file:///].

This shows to the fs.defaultFS property properly pointed at and HDFS host and port.

Key: [fs.defaultFS] Value: [hdfs://hdfshost:9000].

#### Handler and Formatter Configuration

The Java log4j log file contains information on the configuration state of the HDFS Handler and the selected formatter. This information is output at the INFO log level. The output resembles the following:

```
2015-09-21 10:05:11 INFO AvroRowFormatter:156 - **** Begin Avro Row Formatter -
Configuration Summary ****
Operation types are always included in the Avro formatter output.
The key for insert operations is [I].
```

The key for update operations is [U]. The key for delete operations is [D]. The key for truncate operations is [T]. Column type mapping has been configured to map source column types to an appropriate corresponding Avro type. Created Avro schemas will be output to the directory [./dirdef]. Created Avro schemas will be encoded using the [UTF-8] character set. In the event of a primary key update, the Avro Formatter will ABEND. Avro row messages will not be wrapped inside a generic Avro message. No delimiter will be inserted after each generated Avro message. \*\*\*\* End Avro Row Formatter - Configuration Summary \*\*\*\* 2015-09-21 10:05:11 INFO HDFSHandler:207 - \*\*\*\* Begin HDFS Handler -Configuration Summary \*\*\*\* Mode of operation is set to tx. Data streamed to HDFS will be partitioned by table. Tokens will be included in the output. The HDFS root directory for writing is set to [/ogg]. The maximum HDFS file size has been set to 1073741824 bytes. Rolling of HDFS files based on time is configured as off. Rolling of HDFS files based on write inactivity is configured as off. Rolling of HDFS files in the case of a metadata change event is enabled. HDFS partitioning information: The HDFS partitioning object contains no partitioning information. HDFS Handler Authentication type has been configured to use [none] \*\*\*\* End HDFS Handler - Configuration Summary \*\*\*\*

# HDFS Handler Client Dependencies

This appendix lists the HDFS client dependencies for Apache Hadoop. The hadoop-client-x.x.x.jar is not distributed with Apache Hadoop nor is it mandatory to be in the classpath. The hadoop-client-x.x.x.jar is an empty maven project with the purpose of aggregating all of the Hadoop client dependencies.

Maven groupId: org.apache.hadoop

Maven atifactId: hadoop-client

Maven version: the HDFS version numbers listed for each section

Hadoop Client Dependencies

### Hadoop Client Dependencies

This section lists the Hadoop client dependencies for each HDFS version.

- HDFS 3.3.0
- HDFS 3.2.0
- HDFS 3.1.4
- HDFS 3.0.3
- HDFS 2.9.2
- HDFS 2.8.5
- HDFS 2.7.7
- HDFS 2.6.0

# Apache Kafka

The Kafka Handler is designed to stream change capture data from an Oracle GoldenGate trail to a Kafka topic.

This chapter describes how to use the Kafka Handler.

Apache Kafka

The Kafka Handler is designed to stream change capture data from an Oracle GoldenGate trail to a Kafka topic.

- Apache Kafka Connect Handler The Kafka Connect Handler is an extension of the standard Kafka messaging functionality.
- Apache Kafka REST Proxy The Kafka REST Proxy Handler to stream messages to the Kafka REST Proxy distributed by Confluent.

## Apache Kafka

The Kafka Handler is designed to stream change capture data from an Oracle GoldenGate trail to a Kafka topic.

This chapter describes how to use the Kafka Handler.

- Overview
- Detailed Functionality
- Setting Up and Running the Kafka Handler
- Schema Propagation
- Performance Considerations
- About Security
- Metadata Change Events
- Snappy Considerations
- Kafka Interceptor Support

The Kafka Producer client framework supports the use of Producer Interceptors. A Producer Interceptor is simply a user exit from the Kafka Producer client whereby the Interceptor object is instantiated and receives notifications of Kafka message send calls and Kafka message send acknowledgement calls.

Kafka Partition Selection

Kafka topics comprise one or more partitions. Distribution to multiple partitions is a good way to improve Kafka ingest performance, because the Kafka client parallelizes message sending to different topic/partition combinations. Partition selection is controlled by a following calculation in the Kafka client.

- Troubleshooting
- Kafka Handler Client Dependencies
   What are the dependencies for the Kafka Handler to connect to Apache Kafka databases?

#### Overview

The Oracle GoldenGate for Big Data Kafka Handler streams change capture data from an Oracle GoldenGate trail to a Kafka topic. Additionally, the Kafka Handler provides functionality to publish messages to a separate schema topic. Schema publication for Avro and JSON is supported.

Apache Kafka is an open source, distributed, partitioned, and replicated messaging service, see http://kafka.apache.org/.

Kafka can be run as a single instance or as a cluster on multiple servers. Each Kafka server instance is called a broker. A Kafka topic is a category or feed name to which messages are published by the producers and retrieved by consumers.

In Kafka, when the topic name corresponds to the fully-qualified source table name, the Kafka Handler implements a Kafka producer. The Kafka producer writes serialized change data capture, from multiple source tables to either a single configured topic or separating source operations, to different Kafka topics.

#### **Detailed Functionality**

#### **Transaction Versus Operation Mode**

The Kafka Handler sends instances of the Kafka ProducerRecord class to the Kafka producer API, which in turn publishes the ProducerRecord to a Kafka topic. The Kafka ProducerRecord effectively is the implementation of a Kafka message. The ProducerRecord has two components: a key and a value. Both the key and value are represented as byte arrays by the Kafka Handler. This section describes how the Kafka Handler publishes data.

#### **Transaction Mode**

The following configuration sets the Kafka Handler to transaction mode:

gg.handler.name.Mode=tx

In transaction mode, the serialized data is concatenated for every operation in a transaction from the source Oracle GoldenGate trail files. The contents of the concatenated operation data is the value of the Kafka ProducerRecord object. The key of the Kafka ProducerRecord object is NULL. The result is that Kafka messages comprise data from 1 to *N* operations, where *N* is the number of operations in the transaction.

For grouped transactions, all the data for all the operations are concatenated into a single Kafka message. Therefore, grouped transactions may result in very large Kafka messages that contain data for a large number of operations.

#### **Operation Mode**

The following configuration sets the Kafka Handler to operation mode:

```
gg.handler.name.Mode=op
```

In operation mode, the serialized data for each operation is placed into an individual ProducerRecord object as the value. The ProducerRecord key is the fully qualified table name of the source operation. The ProducerRecord is immediately sent using the Kafka Producer API. This means that there is a 1 to 1 relationship between the incoming operations and the number of Kafka messages produced.

#### **Topic Name Selection**

The topic is resolved at runtime using this configuration parameter:

```
gg.handler.topicMappingTemplate
```

You can configure a static string, keywords, or a combination of static strings and keywords to dynamically resolve the topic name at runtime based on the context of the current operation, see Using Templates to Resolve the Topic Name and Message Key.

#### Kafka Broker Settings

To configure topics to be created automatically, set the auto.create.topics.enable property to true. This is the default setting.

If you set the auto.create.topics.enable property to false, then you must manually create topics before you start the Replicat process.

#### **Schema Propagation**

The schema data for all tables is delivered to the schema topic that is configured with the schemaTopicName property. For more information, see Schema Propagation.

### Setting Up and Running the Kafka Handler

Instructions for configuring the Kafka Handler components and running the handler are described in this section.

You must install and correctly configure Kafka either as a single node or a clustered instance, see http://kafka.apache.org/documentation.html.

If you are using a Kafka distribution other than Apache Kafka, then consult the documentation for your Kafka distribution for installation and configuration instructions.

Zookeeper, a prerequisite component for Kafka and Kafka broker (or brokers), must be up and running.

Oracle recommends and considers it best practice that the data topic and the schema topic (if applicable) are preconfigured on the running Kafka brokers. You can create Kafka topics dynamically. However, this relies on the Kafka brokers being configured to allow dynamic topics.

If the Kafka broker is not collocated with the Kafka Handler process, then the remote host port must be reachable from the machine running the Kafka Handler.

- Classpath Configuration
- Kafka Handler Configuration
- Java Adapter Properties File
- Kafka Producer Configuration File
- Using Templates to Resolve the Topic Name and Message Key
   The Kafka Handler provides functionality to resolve the topic name and the
   message key at runtime using a template configuration value. Templates allow you
   to configure static values and keywords. Keywords are used to dynamically
   resolve content at runtime and inject that resolved value into the resolved string.
- Kafka Configuring with Kerberos
- Kafka SSL Support

Kafka support SSL connectivity between Kafka clients and the Kafka cluster. SSL connectivity provides both authentication and encryption of messages transported between the client and the server.

### Classpath Configuration

For the Kafka Handler to connect to Kafka and run, the Kafka Producer properties file and the Kafka client JARs must be configured in the gg.classpath configuration variable. The Kafka client JARs must match the version of Kafka that the Kafka Handler is connecting to. For a list of the required client JAR files by version, see Kafka Handler Client Dependencies.

The recommended storage location for the Kafka Producer properties file is the Oracle GoldenGate dirprm directory.

The default location of the Kafka client JARs is Kafka Home/libs/\*.

The gg.classpath must be configured precisely. The path of the Kafka Producer Properties file must contain the path with no wildcard appended. If the \* wildcard is included in the path to the Kafka Producer Properties file, the file is not picked up. Conversely, path to the dependency JARs must include the \* wild card character in order to include all the JAR files in that directory in the associated classpath. Do *not* use \*.jar. The following is an example of the correctly configured classpath:

gg.classpath={kafka install dir}/libs/\*

### Kafka Handler Configuration

The following are the configurable values for the Kafka Handler. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the Kafka Handler, you must first configure the handler type by specifying gg.handler.namr.type=kafka and the other Kafka properties as follows:

Property Name	Required / Optional	Property Value	Default	Description
gg.handlerlist	Required	name (choice of any name)	None	List of handlers to be used.
gg.handler. <i>nam</i> e.type	Required	kafka	None	Type of handler to use.
gg.handler. <i>nam</i> e.KafkaProduce rConfigFile	Optional	Any custom file name	kafka-producer- default.properti es	Filename in classpath that holds Apache Kafka properties to configure the Apache Kafka producer.
gg.handler. <i>nam</i> e.Format	Optional	Formatter class or short code.	delimitedtext	Formatter to use to format payload. Can be one of xml, delimitedtext, json, json_row, avro_row, avro_op
gg.handler. <i>nam</i> e.SchemaTopicN ame	Required when schema delivery is required.	Name of the schema topic.	None	Topic name where schema data will be delivered. If this property is not set, schema will not be propagated. Schemas will be propagated only for Avro formatters.
gg.handler. <i>nam</i> e.SchemaPrClas sName	Optional	Fully qualified class name of a custom class that implements Oracle GoldenGate for Big Data Kafka Handler's CreateProducerRe cord Java Interface.	Provided this implementation class: oracle.goldengat e.handler.kafka ProducerRecord	Schema is also propagated as a ProducerRecord. The default key is the fully qualified table name. If this needs to be changed for schema records, the custom implementation of the CreateProducerRecord interface needs to be created and this property needs to be set to point to the fully qualified name of the new class.

#### Table 8-10 Configuration Properties for Kafka Handler

Property Name	Required / Optional	Property Value	Default	Description
gg.handler. <i>nam</i> e.mode	Optional	tx/op	tx	With Kafka Handler operation mode, each change capture data record (Insert, Update, Delete, and so on) payload is represented as a Kafka Producer Record and is flushed one at a time. With Kafka Handler in transaction mode, all operations within a source transaction are represented as a single Kafka Producer record. This combined byte payload is flushed on a transaction Commit event.
gg.handler. <i>nam</i> e.topicMapping Template	Required	A template string value to resolve the Kafka topic name at runtime.	None	See Using Templates to Resolve the Topic Name and Message Key.
gg.handler. <i>nam</i> e.keyMappingTe mplate	Required	A template string value to resolve the Kafka message key at runtime.	None	See Using Templates to Resolve the Topic Name and Message Key.
gg.hander.name .logSuccessful lySentMessages	Optional	true false	true	Set to true, the Kafka Handler will log at the INFO level message that have been successfully sent to Kafka. Enabling this property has negative impact on performance.
gg.handler.nam e.metaHeadersT emplate	Optional	Comma delimited list of metacolumn keywords.	None	Allows the user to select metacolumns to inject context- based key value pairs into Kafka message headers using the metacolumn keyword syntax.

#### Table 8-10 (Cont.) Configuration Properties for Kafka Handler

### Java Adapter Properties File

The following is a sample configuration for the Kafka Handler from the Adapter properties file:

gg.handlerlist = kafkahandler
gg.handler.kafkahandler.Type = kafka
gg.handler.kafkahandler.KafkaProducerConfigFile =
custom\_kafka\_producer.properties
gg.handler.kafkahandler.topicMappingTemplate=oggtopic
gg.handler.kafkahandler.keyMappingTemplate=\${currentTimestamp}
gg.handler.kafkahandler.Format = avro\_op
gg.handler.kafkahandler.SchemaTopicName = oggSchemaTopic
gg.handler.kafkahandler.SchemaPrClassName = com.company.kafkaProdRec.SchemaRecord
gg.handler.kafkahandler.Mode = tx

You can find a sample Replicat configuration and a Java Adapter Properties file for a Kafka integration in the following directory:

GoldenGate install directory/AdapterExamples/big-data/kafka

### Kafka Producer Configuration File

The Kafka Handler must access a Kafka producer configuration file in order to publish messages to Kafka. The file name of the Kafka producer configuration file is controlled by the following configuration in the Kafka Handler properties.

gg.handler.kafkahandler.KafkaProducerConfigFile=custom\_kafka\_producer.properties

The Kafka Handler attempts to locate and load the Kafka producer configuration file by using the Java classpath. Therefore, the Java classpath must include the directory containing the Kafka Producer Configuration File.

The Kafka producer configuration file contains Kafka proprietary properties. The Kafka documentation provides configuration information for the 0.8.2.0 Kafka producer interface properties. The Kafka Handler uses these properties to resolve the host and port of the Kafka brokers, and properties in the Kafka producer configuration file control the behavior of the interaction between the Kafka producer client and the Kafka brokers.

A sample of configuration file for the Kafka producer is as follows:

```
bootstrap.servers=localhost:9092
acks = 1
compression.type = gzip
reconnect.backoff.ms = 1000
value.serializer = org.apache.kafka.common.serialization.ByteArraySerializer
key.serializer = org.apache.kafka.common.serialization.ByteArraySerializer
# 100KB per partition
batch.size = 102400
linger.ms = 0
max.request.size = 1048576
send.buffer.bytes = 131072
```

Encrypt Kafka Producer Properties

#### Encrypt Kafka Producer Properties

The sensitive properties within the Kafka Producer Configuration File can be encrypted using the Oracle GoldenGate Credential Store. For more information about how to use Credential Store, see Using Identities in Oracle GoldenGate Credential Store.

For example, the following kafka property:

```
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
required
username="alice" password="alice";
```

#### can be replaced with:

```
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
required
username=ORACLEWALLETUSERNAME[alias domain_name]
password=ORACLEWALLETPASSWORD[alias
domain name];
```

### Using Templates to Resolve the Topic Name and Message Key

The Kafka Handler provides functionality to resolve the topic name and the message key at runtime using a template configuration value. Templates allow you to configure static values and keywords. Keywords are used to dynamically resolve content at runtime and inject that resolved value into the resolved string.

The templates use the following configuration properties:

gg.handler.name.topicMappingTemplate
gg.handler.name.keyMappingTemplate

#### **Template Modes**

Source database transactions are made up of one or more individual operations that are the individual inserts, updates, and deletes. The Kafka Handler can be configured to send one message per operation (insert, update, delete), or alternatively can be configured to group operations into messages at the transaction level. Many template keywords resolve data based on the context of an individual source database operation. Therefore, many of the keywords do *not* work when sending messages at the transaction level. For example, using \${fullyQualifiedTableName} does not work when sending messages at the transaction level rather it resolves to the qualified source table name for an operation. However, transactions can contain multiple operations for many source tables. Resolving the fully qualified table name for messages at the transaction level is non-deterministic so abends at runtime.

For more information about the Template Keywords, see Template Keywords. See Example Templates.

#### Kafka Configuring with Kerberos

Use these steps to configure a Kafka Handler Replicat with Kerberos to enable a Cloudera instance to process an Oracle GoldenGate for Big Data trail to a Kafka topic:

1. In GGSCI, add a Kafka Replicat:

GGSCI> add replicat kafka, exttrail dirdat/gg

2. Configure a prm file with these properties:

```
replicat kafka
discardfile ./dirrpt/kafkax.dsc, purge
SETENV (TZ=PST8PDT)
GETTRUNCATES
GETUPDATEBEFORES
ReportCount Every 1000 Records, Rate
MAP qasource.*, target qatarget.*;
```

3. Configure a Replicat properties file as follows:

```
###KAFKA Properties file ###
gg.log=log4j
gg.log.level=info
gg.report.time=30sec
###Kafka Classpath settings ###
gg.classpath=/opt/cloudera/parcels/KAFKA-2.1.0-1.2.1.0.p0.115/lib/kafka/
libs/*
jvm.bootoptions=-Xmx64m -Xms64m -Djava.class.path=./ggjava/ggjava.jar -
```

Dlog4j.configuration=log4j.properties -Djava.security.auth.login.config=/scratch/ ydama/ogg/v123211/dirprm/jaas.conf -Djava.security.krb5.conf=/etc/krb5.conf

```
### Kafka handler properties ###
gg.handlerlist = kafkahandler
gg.handler.kafkahandler.type=kafka
gg.handler.kafkahandler.KafkaProducerConfigFile=kafka-producer.properties
gg.handler.kafkahandler.format=delimitedtext
gg.handler.kafkahandler.format.PkUpdateHandling=update
gg.handler.kafkahandler.format.includeCurrentTimestamp=false
gg.handler.kafkahandler.format.fieldDelimiter=|
gg.handler.kafkahandler.format.lineDelimiter=CDATA[\n]
gg.handler.kafkahandler.topicMappingTemplate=myoggtopic
gg.handler.kafkahandler.keyMappingTemplate=${position}
```

#### 4. Configure a Kafka Producer file with these properties:

```
bootstrap.servers=10.245.172.52:9092
acks=1
#compression.type=snappy
reconnect.backoff.ms=1000
value.serializer=org.apache.kafka.common.serialization.ByteArraySerializer
key.serializer=org.apache.kafka.common.serialization.ByteArraySerializer
batch.size=1024
linger.ms=2000
```

security.protocol=SASL\_PLAINTEXT

sasl.kerberos.service.name=kafka
sasl.mechanism=GSSAPI

5. Configure a jaas.conf file with these properties:

```
KafkaClient {
  com.sun.security.auth.module.Krb5LoginModule required
  useKeyTab=true
  storeKey=true
  keyTab="/scratch/ydama/ogg/v123211/dirtmp/keytabs/slc06unm/kafka.keytab"
  principal="kafka/slc06unm.us.oracle.com@HADOOPTEST.ORACLE.COM";
  };
```

- 6. Ensure that you have the latest key.tab files from the Cloudera instance to connect secured Kafka topics.
- 7. Start the Replicat from GGSCI and make sure that it is running with INFO ALL.
- 8. Review the Replicat report to see the total number of records processed. The report is similar to:

#### 9. Ensure that the secure Kafka topic is created:

```
/kafka/bin/kafka-topics.sh --zookeeper slc06unm:2181 --list
myoggtopic
```

#### 10. Review the contents of the secure Kafka topic:

a. Create a consumer.properties file containing:

```
security.protocol=SASL_PLAINTEXT
sasl.kerberos.service.name=kafka
```

b. Set this environment variable:

```
export KAFKA_OPTS="-Djava.security.auth.login.config="/scratch/ogg/v123211/
dirprm/jaas.conf"
```

c. Run the consumer utility to check the records:

```
/kafka/bin/kafka-console-consumer.sh --bootstrap-server sys06:9092 --topic
myoggtopic --new-consumer --consumer.config consumer.properties
```

### Kafka SSL Support

Kafka support SSL connectivity between Kafka clients and the Kafka cluster. SSL connectivity provides both authentication and encryption of messages transported between the client and the server.

SSL can be configured for server authentication (client authenticates server) but is generally configured for mutual authentication (both client and server authenticate each other). In an SSL mutual authentication, each side of the connection retrieves a certificate from its keystore and passes it to the other side of the connection, which verifies the certificate against the certificate in its truststore.

When you set up SSL, see the Kafka documentation for more information about the specific Kafka version that you are running. The Kafka documentation also provides information on how to do the following:

- Set up the Kafka cluster for SSL
- Create self signed certificates in a keystore/truststore file

Configure the Kafka clients for SSL

Oracle recommends you to implement the SSL connectivity using the Kafka producer and consumer command line utilities before attempting to use it with Oracle GoldenGate for Big Data. The SSL connectivity should be confirmed between the machine hosting Oracle GoldenGate for Big Data and the Kafka cluster. This action proves that SSL connectivity is correctly set up and working prior to introducing Oracle GoldenGate for Big Data.

The following is an example of Kafka producer configuration with SSL mutual authentication:

```
bootstrap.servers=localhost:9092
acks=1
value.serializer=org.apache.kafka.common.serialization.ByteArraySerializer
key.serializer=org.apache.kafka.common.serialization.ByteArraySerializer
security.protocol=SSL
ssl.keystore.location=/var/private/ssl/server.keystore.jks
ssl.keystore.password=test1234
ssl.key.password=test1234
ssl.truststore.location=/var/private/ssl/server.truststore.jks
ssl.truststore.password=test1234
```

# Schema Propagation

The Kafka Handler provides the ability to publish schemas to a schema topic. Currently, the Avro Row and Operation formatters are the only formatters that are enabled for schema publishing. If the Kafka Handler schemaTopicName property is set, then the schema is published for the following events:

- The Avro schema for a specific table is published the first time an operation for that table is encountered.
- If the Kafka Handler receives a metadata change event, the schema is flushed. The regenerated Avro schema for a specific table is published the next time an operation for that table is encountered.
- If the Avro wrapping functionality is enabled, then the generic wrapper Avro schema is published the first time that any operation is encountered. To enable the generic wrapper, Avro schema functionality is enabled in the Avro formatter configuration, see Avro Row Formatter and The Avro Operation Formatter.

The Kafka ProducerRecord value is the schema, and the key is the fully qualified table name.

Because Avro messages directly depend on an Avro schema, user of Avro over Kafka may encounter issues. Avro messages are not human readable because they are binary. To deserialize an Avro message, the receiver must first have the correct Avro schema, but because each table from the source database results in a separate Avro schema, this can be difficult. The receiver of a Kafka message cannot determine which Avro schema to use to deserialize individual messages when the source Oracle GoldenGate trail file includes operations from multiple tables. To solve this problem, you can wrap the specialized Avro messages in a generic Avro message wrapper. This generic Avro wrapper provides the fully-qualified table name, the hashcode of the schema string, and the wrapped Avro message. The receiver can use the fully-qualified table name and the hashcode of the schema string to resolve the associated schema of the wrapped message, and then use that schema to deserialize the wrapped message.

# Performance Considerations

For the best performance, Oracle recommends that you send the Kafka Handler to operate in operation mode.

gg.handler.*name*.mode = op

Additionally, Oracle recommends that you set the batch.size and linger.ms values in the Kafka Producer properties file. These values are highly dependent upon the use case scenario. Typically, higher values result in better throughput, but latency is increased. Smaller values in these properties reduces latency but overall throughput decreases.

Use of the Replicat variable GROUPTRANSOPS also improves performance. The recommended setting is 10000.

If the serialized operations from the source trail file must be delivered in individual Kafka messages, then the Kafka Handler must be set to operation mode.

gg.handler.*name*.mode = op

# About Security

Kafka version 0.9.0.0 introduced security through SSL/TLS and SASL (Kerberos). You can secure the Kafka Handler using one or both of the SSL/TLS and SASL security offerings. The Kafka producer client libraries provide an abstraction of security functionality from the integrations that use those libraries. The Kafka Handler is effectively abstracted from security functionality. Enabling security requires setting up security for the Kafka cluster, connecting machines, and then configuring the Kafka producer properties file with the required security properties. For detailed instructions about securing the Kafka cluster, see the Kafka documentation at

You may encounter the inability to decrypt the Kerberos password from the keytab file. This causes the Kerberos authentication to fall back to interactive mode which cannot work because it is being invoked programmatically. The cause of this problem is that the Java Cryptography Extension (JCE) is not installed in the Java Runtime Environment (JRE). Ensure that the JCE is loaded in the JRE, see http://www.oracle.com/technetwork/java/ javase/downloads/jce8-download-2133166.html.

# Metadata Change Events

Metadata change events are now handled in the Kafka Handler. This is relevant only if you have configured a schema topic and the formatter used supports schema propagation (currently Avro row and Avro Operation formatters). The next time an operation is encountered for a table for which the schema has changed, the updated schema is published to the schema topic.

To support metadata change events, the Oracle GoldenGate process capturing changes in the source database must support the Oracle GoldenGate metadata in trail feature, which was introduced in Oracle GoldenGate 12c (12.2).

# **Snappy Considerations**

The Kafka Producer Configuration file supports the use of compression. One of the configurable options is Snappy, an open source compression and decompression (codec) library that provides better performance than other codec libraries. The Snappy JAR does not run on all platforms. Snappy may work on Linux systems though may or may not work on

other UNIX and Windows implementations. If you want to use Snappy compression, test Snappy on all required systems before implementing compression using Snappy. If Snappy does not port to all required systems, then Oracle recommends using an alternate codec library.

### Kafka Interceptor Support

The Kafka Producer client framework supports the use of Producer Interceptors. A Producer Interceptor is simply a user exit from the Kafka Producer client whereby the Interceptor object is instantiated and receives notifications of Kafka message send calls and Kafka message send acknowledgement calls.

The typical use case for Interceptors is monitoring. Kafka Producer Interceptors must conform to the interface

org.apache.kafka.clients.producer.ProducerInterceptor. The Kafka Handler supports Producer Interceptor usage.

The requirements to using Interceptors in the Handlers are as follows:

- The Kafka Producer configuration property "interceptor.classes" must be configured with the class name of the Interceptor(s) to be invoked.
- In order to invoke the Interceptor(s), the jar files plus any dependency jars must be available to the JVM. Therefore, the jar files containing the Interceptor(s) plus any dependency jars must be added to the gg.classpath in the Handler configuration file.

For more information, see Kafka documentation.

### Kafka Partition Selection

Kafka topics comprise one or more partitions. Distribution to multiple partitions is a good way to improve Kafka ingest performance, because the Kafka client parallelizes message sending to different topic/partition combinations. Partition selection is controlled by a following calculation in the Kafka client.

(Hash of the Kafka message key) modulus (the number of partitions) = selected partition number

The Kafka message key is selected by the following configuration value:

gg.handler.{your handler name}.keyMappingTemplate=

If this parameter is set to a value which generates a static key, all messages will go to the same partition. The following is example of static keys:

gg.handler.{your handler name}.keyMappingTemplate=StaticValue

If this parameter is set to a value which generates a key that changes infrequently, partition selection changes infrequently. In the following example the table name is used as the message key. Every operation for a specific source table will have the same key and thereby route to the same partition:

gg.handler.{your handler name}.keyMappingTemplate=\${tableName}

A null Kafka message key distributes to the partitions on a round-robin basis. To do this, set the following:

gg.handler.{your handler name}.keyMappingTemplate=\${null}

The recommended setting for configuration of the mapping key is the following:

gg.handler.{your handler name}.keyMappingTemplate=\${primaryKeys}

This generates a Kafka message key that is the concatenated and delimited primary key values.

Operations for each row should have a unique primary key(s) thereby generating a unique Kafka message key for each row. Another important consideration is Kafka messages sent to different partitions are not guaranteed to be delivered to a Kafka consumer in the original order sent. This is part of the Kafka specification. Order is only maintained within a partition. Using primary keys as the Kafka message key means that operations for the same row, which have the same primary key(s), generate the same Kafka message key, and therefore are sent to the same Kafka partition. In this way, the order is maintained for operations for the same row.

At the DEBUG log level the Kafka message coordinates (topic, partition, and offset) are logged to the .log file for successfully sent messages.

# Troubleshooting

- Verify the Kafka Setup
- Classpath Issues
- Invalid Kafka Version
- Kafka Producer Properties File Not Found
- Kafka Connection Problem

#### Verify the Kafka Setup

You can use the command line Kafka producer to write dummy data to a Kafka topic, and you can use a Kafka consumer to read this data from the Kafka topic. Use this method to verify the setup and read/write permissions to Kafka topics on disk, see <a href="http://kafka.apache.org/documentation.html#quickstart">http://kafka.apache.org/documentation.html#quickstart</a>.

#### **Classpath Issues**

Java classpath problems are common. Such problems may include a ClassNotFoundException problem in the log4j log file or may be an error resolving the classpath because of a typographic error in the gg.classpath variable. The Kafka client libraries do *not* ship with the Oracle GoldenGate for Big Data product. You must obtain the correct version of the Kafka client libraries and properly configure the gg.classpath property in the Java Adapter Properties file to correctly resolve the Java the Kafka client libraries as described in Classpath Configuration.

### Invalid Kafka Version

The Kafka Handler does *not* support Kafka versions 0.8.2.2 or older. If you run an unsupported version of Kafka, a runtime Java exception, java.lang.NoSuchMethodError, occurs. It implies that the org.apache.kafka.clients.producer.KafkaProducer.flush() method cannot be found. If you encounter this error, migrate to Kafka version 0.9.0.0 or later.

### Kafka Producer Properties File Not Found

This problem typically results in the following exception:

ERROR 2015-11-11 11:49:08,482 [main] Error loading the kafka producer properties

Check the gg.handler.kafkahandler.KafkaProducerConfigFile configuration variable to ensure that the Kafka Producer Configuration file name is set correctly. Check the gg.classpath variable to verify that the classpath includes the path to the Kafka Producer properties file, and that the path to the properties file does not contain a \* wildcard at the end.

### Kafka Connection Problem

This problem occurs when the Kafka Handler is unable to connect to Kafka. You receive the following warnings:

```
WARN 2015-11-11 11:25:50,784 [kafka-producer-network-thread | producer-1] WARN (Selector.java:276) - Error in I/O with localhost/127.0.0.1 java.net.ConnectException: Connection refused
```

The connection retry interval expires, and the Kafka Handler process abends. Ensure that the Kafka Broker is running and that the host and port provided in the Kafka Producer Properties file are correct. You can use network shell commands (such as netstat -1) on the machine hosting the Kafka broker to verify that Kafka is listening on the expected port.

### Kafka Handler Client Dependencies

What are the dependencies for the Kafka Handler to connect to Apache Kafka databases?

The maven central repository artifacts for Kafka databases are:

Maven groupId: org.apache.kafka

Maven atifactId: kafka-clients

Maven version: the Kafka version numbers listed for each section

- Kafka 2.8.0
- Kafka 2.7.0
- Kafka 2.6.0
- Kafka 2.5.1
- Kafka 2.4.1
- Kafka 2.3.1

# Apache Kafka Connect Handler

The Kafka Connect Handler is an extension of the standard Kafka messaging functionality.

This chapter describes how to use the Kafka Connect Handler.

- Overview
- Detailed Functionality
- Setting Up and Running the Kafka Connect Handler

- Connecting to a Secure Schema Registry
- Kafka Connect Handler Performance Considerations
- Kafka Interceptor Support

The Kafka Producer client framework supports the use of Producer Interceptors. A Producer Interceptor is simply a user exit from the Kafka Producer client whereby the Interceptor object is instantiated and receives notifications of Kafka message send calls and Kafka message send acknowledgement calls.

Kafka Partition Selection

Kafka topics comprise one or more partitions. Distribution to multiple partitions is a good way to improve Kafka ingest performance, because the Kafka client parallelizes message sending to different topic/partition combinations. Partition selection is controlled by a following calculation in the Kafka client.

- Troubleshooting the Kafka Connect Handler
- Kafka Connect Handler Client Dependencies
   What are the dependencies for the Kafka Connect Handler to connect to Apache Kafka Connect databases?

### Overview

The Oracle GoldenGate Kafka Connect is an extension of the standard Kafka messaging functionality. Kafka Connect is a functional layer on top of the standard Kafka Producer and Consumer interfaces. It provides standardization for messaging to make it easier to add new source and target systems into your topology.

Confluent is a primary adopter of Kafka Connect and their Confluent Platform offering includes extensions over the standard Kafka Connect functionality. This includes Avro serialization and deserialization, and an Avro schema registry. Much of the Kafka Connect functionality is available in Apache Kafka. A number of open source Kafka Connect integrations are found at:

#### https://www.confluent.io/product/connectors/

The Kafka Connect Handler is a Kafka Connect source connector. You can capture database changes from any database supported by Oracle GoldenGate and stream that change of data through the Kafka Connect layer to Kafka. You can also connect to Oracle Event Hub Cloud Services (EHCS) with this handler.

Kafka Connect uses proprietary objects to define the schemas (org.apache.kafka.connect.data.Schema) and the messages (org.apache.kafka.connect.data.Struct). The Kafka Connect Handler can be configured to manage what data is published and the structure of the published data.

The Kafka Connect Handler does *not* support any of the pluggable formatters that are supported by the Kafka Handler.

#### **Topics:**

### **Detailed Functionality**

The Kafka Connect framework provides converters to convert in-memory Kafka Connect messages to a serialized format suitable for transmission over a network. These converters are selected using configuration in the Kafka Producer properties file.

#### **JSON Converter**

Kafka Connect and the JSON converter is available as part of the Apache Kafka download. The JSON Converter converts the Kafka keys and values to JSONs which are then sent to a Kafka topic. You identify the JSON Converters with the following configuration in the Kafka Producer properties file:

```
key.converter=org.apache.kafka.connect.json.JsonConverter
key.converter.schemas.enable=true
value.converter=org.apache.kafka.connect.json.JsonConverter
value.converter.schemas.enable=true
```

The format of the messages is the message schema information followed by the payload information. JSON is a self describing format so you should not include the schema information in each message published to Kafka.

To omit the JSON schema information from the messages set the following:

```
key.converter.schemas.enable=false
value.converter.schemas.enable=false
```

#### **Avro Converter**

Confluent provides Kafka installations, support for Kafka, and extended functionality built on top of Kafka to help realize the full potential of Kafka. Confluent provides both open source versions of Kafka (Confluent Open Source) and an enterprise edition (Confluent Enterprise), which is available for purchase.

A common Kafka use case is to send Avro messages over Kafka. This can create a problem on the receiving end as there is a dependency for the Avro schema in order to deserialize an Avro message. Schema evolution can increase the problem because received messages must be matched up with the exact Avro schema used to generate the message on the producer side. Deserializing Avro messages with an incorrect Avro schema can cause runtime failure, incomplete data, or incorrect data. Confluent has solved this problem by using a schema registry and the Confluent schema converters.

The following shows the configuration of the Kafka Producer properties file.

```
key.converter=io.confluent.connect.avro.AvroConverter
value.converter=io.confluent.connect.avro.AvroConverter
key.converter.schema.registry.url=http://localhost:8081
value.converter.schema.registry.url=http://localhost:8081
```

When messages are published to Kafka, the Avro schema is registered and stored in the schema registry. When messages are consumed from Kafka, the exact Avro schema used to create the message can be retrieved from the schema registry to deserialize the Avro message. This creates matching of Avro messages to corresponding Avro schemas on the receiving side, which solves this problem.

Following are the requirements to use the Avro Converters:

- This functionality is available in both versions of Confluent Kafka (open source or enterprise).
- The Confluent schema registry service must be running.

- Source database tables must have an associated Avro schema. Messages associated with different Avro schemas must be sent to different Kafka topics.
- The Confluent Avro converters and the schema registry client must be available in the classpath.

The schema registry keeps track of Avro schemas by topic. Messages must be sent to a topic that has the same schema or evolving versions of the same schema. Source messages have Avro schemas based on the source database table schema so Avro schemas are unique for each source table. Publishing messages to a single topic for multiple source tables will appear to the schema registry that the schema is evolving every time the message sent from a source table that is different from the previous message.

#### **Protobuf Converter**

The Protobul Converter allows Kafka Connect messages to be formatted as Google Protocol Buffers format. The Protobul Converter integrates with the Confluent schema registry and this functionality is available in both the open source and enterprise versions of Confluent. Confluent added the Protobul Converter starting in Confluent version 5.5.0.

The following shows the configuration to select the Protobul Converter in the Kafka Producer Properties file:

```
key.converter=io.confluent.connect.protobuf.ProtobufConverter
value.converter=io.confluent.connect.protobuf.ProtobufConverter
key.converter.schema.registry.url=http://localhost:8081
value.converter.schema.registry.url=http://localhost:8081
```

The requirements to use the Protobuf Converter are as follows:

- This functionality is available in both versions of Confluent Kafka (open source or enterprise) starting in 5.5.0.
- The Confluent schema registry service must be running.
- Messages with different schemas (source tables) should be sent to different Kafka topics.
- The Confluent Protobul converter and the schema registry client must be available in the classpath.

The schema registry keeps track of Protobuf schemas by topic. Messages must be sent to a topic that has the same schema or evolving versions of the same schema. Source messages have Protobuf schemas based on the source database table schema so Protobuf schemas are unique for each source table. Publishing messages to a single topic for multiple source tables will appear to the schema registry that the schema is evolving every time the message sent from a source table that is different from the previous message.

### Setting Up and Running the Kafka Connect Handler

Instructions for configuring the Kafka Connect Handler components and running the handler are described in this section.

#### **Classpath Configuration**

Two things must be configured in the gg.classpath configuration variable so that the Kafka Connect Handler can to connect to Kafka and run. The required items are the Kafka Producer properties file and the Kafka client JARs. The Kafka client JARs must match the version of Kafka that the Kafka Connect Handler is connecting to. For a listing of the required client JAR files by version, see Kafka Handler Client Dependencies Kafka Connect Handler Client Dependencies. The recommended storage location for the Kafka Producer properties file is the Oracle GoldenGate dirprm directory.

The default location of the Kafka Connect client JARs is the Kafka Home/libs/\* directory.

The gg.classpath variable must be configured precisely. Pathing to the Kafka Producer properties file should contain the path with no wildcard appended. The inclusion of the asterisk (\*) wildcard in the path to the Kafka Producer properties file causes it to be discarded. Pathing to the dependency JARs should include the \* wildcard character to include all of the JAR files in that directory in the associated classpath. Do not use \*.jar.

Following is an example of a correctly configured Apache Kafka classpath:

gg.classpath=dirprm:{kafka\_install\_dir}/libs/\*

Following is an example of a correctly configured Confluent Kafka classpath:

```
gg.classpath={confluent_install_dir}/share/java/kafka-serde-tools/*:
{confluent_install_dir}/share/java/kafka/*:{confluent_install_dir}/share/java/
confluent-common/*
```

- Kafka Connect Handler Configuration
   The automated output of meta-column fields in generated Kafka Connect messages has
   been removed as of Oracle GoldenGate for Big Data release 21.1.
- Using Templates to Resolve the Topic Name and Message Key
- Configuring Security in the Kafka Connect Handler

#### Kafka Connect Handler Configuration

The automated output of meta-column fields in generated Kafka Connect messages has been removed as of Oracle GoldenGate for Big Data release 21.1.

Meta-column fields can be configured as the following property:

gg.handler.name.metaColumnsTemplate

To output the metacolumns as in previous versions configure the following:

```
gg.handler.name.metaColumnsTemplate=${objectname[table]},${optype[op_type]},$
{timestamp[op ts]},${currenttimestamp[current ts]},${position[pos]}
```

To also include the primary key columns and the tokens configure as follows:

```
gg.handler.name.metaColumnsTemplate=${objectname[table]},${optype[op_type]},$
{timestamp[op_ts]},${currenttimestamp[current_ts]},${position[pos]},$
{primarykeycolumns[primary keys]},${alltokens[tokens]}
```

For more information see the configuration property:

```
gg.handler.name.metaColumnsTemplate
```

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>na</i> <i>me</i> .type	Required	kafkaconnect	None	The configuration to select the Kafka Connect Handler.
gg.handler. <i>na</i> me.kafkaProdu cerConfigFile	Required	string	None	Name of the properties file containing the properties of the Kafka and Kafka Connect configuration properties. This file must be part of the classpath configured by the gg.classpath property.
gg.handler. <i>na</i> <i>me</i> .topicMappi ngTemplate	Required	A template string value to resolve the Kafka topic name at runtime.	None	See Using Templates to Resolve the Topic Name and Message Key.
gg.handler. <i>na</i> <i>m</i> e.keyMapping Template	Required	A template string value to resolve the Kafka message key at runtime.	None	See Using Templates to Resolve the Topic Name and Message Key.
gg.handler. <i>na</i> me.includeTok ens	Optional	true false	false	Set to true to include a map field in output messages. The key is <b>tokens</b> and the value is a map where the keys and values are the token keys and values from the Oracle GoldenGate source trail file. Set to false to suppress this field.

# Table 8-11 Kafka Connect Handler Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>na</i> <i>me</i> .messageFor matting	Optional	row op	row	Controls how output messages are modeled. Selecting row and the output messages will be modeled as row. Set to op and the output messages will be modeled as operations messages.
gg.handler. <i>na</i> <i>m</i> e.insertOpKe Y	Optional	any string	I	The value of the field op_type to indicate an insert operation.
gg.handler. <i>na</i> <i>me</i> .updateOpKe Y	Optional	any string	U	The value of the field op_type to indicate an insert operation.
gg.handler. <i>na</i> <i>m</i> e.deleteOpKe Y	Optional	any string	D	The value of the field op_type to indicate a delete operation.
gg.handler. <i>na</i> me.truncateOp Key	Optional	any string	Т	The value of the field op_type to indicate a truncate operation.
gg.handler. <i>na</i> <i>me</i> .treatAllCo lumnsAsString s	Optional	true false	false	Set to true to treat all output fields as strings. Set to false and the Handler will map the corresponding field type from the source trail file to the best corresponding Kafka Connect data type.

Table 8-11	(Cont.) Kafka Connect Handler Configuration Properties
	(cond) rana connect handler conniguration roperties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>na</i> <i>me</i> .mapLargeNu mbersAsString s	Optional	true false	false	Large numbers are mapping to number fields as Doubles. It is possible to lose precision in certain scenarios
				If set to true these fields will be mapped as Strings in order to preserve precision.
gg.handler. <i>na</i> <i>me</i> .pkUpdateHa ndling	Optional	abend   update   delete-insert	abend	Only applicable if modeling row messages gg.handler.na me.messageFor matting=row. Not applicable if modeling operations messages as the before and after images are propagated to the message in the case of an update.
gg.handler. <i>na me</i> .metaColumn sTemplate	Optional	Any of the metacolumns keywords.	None	A comma- delimited string consisting of one or more templated values that represent the template, see Metacolumn Keywords.

Table 8-11	(Cont.) Kafka Connect Handler Configuration Properties
Table 0-11	(Cont.) Karka Connect Handler Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>na</i> me.includeIsM issingFields	Optional	true false	true	Set to true to include an extract { colum n_name}. Set this property for each column to allow downstream applications to differentiate if a null value is actually null in the source trail file or if it is missing in the source trail file.
gg.handler.na me.enableDeci malLogicalTyp e	Optional	true false	false	Set to true to enable decimal logical types in Kafka Connect. Decimal logical types allow numbers which will not fit in a 64 bit data type to be represented.
gg.handler.na me.oracleNumb erScale	Optional	Positive Integer	38	Only applicable if gg.handler.na me.enableDeci malLogicalTyp e=true. Some source data types do not have a fixed scale associated with them. Scale must be set for Kafka Connectdecimal logical types. In the case of source types which do not have a scalein the metadata, the value of this parameter is used to set the scale.

Table 8-11	(Cont.) Kafka Connect Handler Configuration Properties
	(contra connect narater conniguration r roperties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.na ne.EnableTime stampLogicalT ype	Optional	true false	false	Set to true to enable the Kafka Connect timestamp logica type. The Kafka connect timestamp logica time is a integer measurement ofmilliseconds since the Java epoch. This means precision greater thanmilliseconds is not possible if the timestamp logica type is used. Use of this property requires that the gg.format.tim estamp property be set. This property is the timestamp formatting string, which is used to determine the output of timestamps in string format. For example, gg.format.tim estamp=yyyy- MM-dd HH:mm:ss.SSS. Ensure that the goldengate.us erexit.timest amp property is not set in the configuration file. Setting this property prevents parsing the input timestamps.

Table 8-11 (	(Cont.) Kafka Connect Handler	<b>Configuration Properties</b>
--------------	-------------------------------	---------------------------------

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.na me.metaHeader sTemplate	Optional	Comma delimited list of metacolumn keywords.	None	Allows the user to select metacolumns to inject context- based key value pairs into Kafka message headers using the metacolumn keyword syntax. See Metacolumn Keywords.
gg.handler.na me.schemaName space	Optional	Any string without characters which violate the Kafka Connector Avro schema naming requirements.	None	Used to control the generated Kafka Connect schema name. If it is not set, then the schema name is the same as the qualified source table name. For example, if the source table is QASOURCE. TCUS TMER, then the Kafka Connect schema name will be the same. This property allows you to control the generated schema name. For example, if this property is set to com.example.c ompany, then the generated Kafka Connect schema name for the table QASOURCE. TCUS TMER is com.example.c ompany.TCUSTM ER.

Table 8-11	(Cont.) Kafka Connect Handler Configuration Properties
------------	--

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.na me.enableNonn ullable	Optional	true false	false	The default behavior is to set all fields as nullable in the generated Kafka Connect schema. Set this parameter to true to honor the nullable value configured in the target metadata provided by the metadata provider. Setting this property to true can have some adverse side effects.
				<ol> <li>Setting a field to non- nullable means the field must have a value to be valid. If a field is set as non- nullable and the value is null or missing in the source trail file, a runtime error will result.</li> </ol>
				2. Setting a field to non- nullable means that truncate operations cannot be propagated. Truncate operations have no field values. The result is that the Kafka Connect converter

<b>Table 8-11</b>	(Cont.) Kafka Connect Handler Configuration Properties
-------------------	--

Properties	Required/ Optional	Legal Values	Default	Explanation
				serialization will field because there is no value for the field.
				3. A schema change resulting in the addition of a non- nullable field will cause a schema backwards compatibility exception in the Confluen schema registry. If this occurs, users will need to adjust or disable the compatibility configuration of the Confluent schema registry.

Table 8-11 (Cont.) Kafka Connect Handler Configuration Properties

See Using Templates to Resolve the Stream Name and Partition Name for more information.

#### **Review a Sample Configuration**

```
gg.handlerlist=kafkaconnect
#The handler properties
gg.handler.kafkaconnect.type=kafkaconnect
gg.handler.kafkaconnect.kafkaProducerConfigFile=kafkaconnect.properties
gg.handler.kafkaconnect.mode=op
#The following selects the topic name based on the fully qualified table name
gg.handler.kafkaconnect.topicMappingTemplate=${fullyQualifiedTableName}
#The following selects the message key using the concatenated primary keys
gg.handler.kafkaconnect.keyMappingTemplate=${primaryKeys}
#The formatter properties
gg.handler.kafkaconnect.messageFormatting=row
gg.handler.kafkaconnect.insertOpKey=I
gg.handler.kafkaconnect.updateOpKey=U
gg.handler.kafkaconnect.deleteOpKey=D
gg.handler.kafkaconnect.truncateOpKey=T
gg.handler.kafkaconnect.treatAllColumnsAsStrings=false
gg.handler.kafkaconnect.pkUpdateHandling=abend
```

### Using Templates to Resolve the Topic Name and Message Key

The Kafka Connect Handler provides functionality to resolve the topic name and the message key at runtime using a template configuration value. Templates allow you to configure static values and keywords. Keywords are used to dynamically replace the keyword with the context of the current processing. Templates are applicable to the following configuration parameters:

gg.handler.name.topicMappingTemplate
gg.handler.name.keyMappingTemplate

#### **Template Modes**

The Kafka Connect Handler can only send operation messages. The Kafka Connect Handler cannot group operation messages into a larger transaction message.

For more information about the Template Keywords, see Template Keywords. For example templates, see Example Templates.

### Configuring Security in the Kafka Connect Handler

Kafka version 0.9.0.0 introduced security through SSL/TLS or Kerberos. The Kafka Connect Handler can be secured using SSL/TLS or Kerberos. The Kafka producer client libraries provide an abstraction of security functionality from the integrations utilizing those libraries. The Kafka Connect Handler is effectively abstracted from security functionality. Enabling security requires setting up security for the Kafka cluster, connecting machines, and then configuring the Kafka Producer properties file, that the Kafka Handler uses for processing, with the required security properties.

You may encounter the inability to decrypt the Kerberos password from the keytab file. This causes the Kerberos authentication to fall back to interactive mode which cannot work because it is being invoked programmatically. The cause of this problem is that the Java Cryptography Extension (JCE) is not installed in the Java Runtime Environment (JRE). Ensure that the JCE is loaded in the JRE, see http:// www.oracle.com/technetwork/java/javase/downloads/jce8-download-2133166.html.

### Connecting to a Secure Schema Registry

The customer topology for Kafka Connect may include a schema registry which is secured. This topic shows how to set the Kafka producer properties configured for connectivity to a secured schema registry.

#### SSL Mutual Auth

key.converter.schema.registry.ssl.truststore.location= key.converter.schema.registry.ssl.truststore.password= key.converter.schema.registry.ssl.keystore.location= key.converter.schema.registry.ssl.key.password= value.converter.schema.registry.ssl.truststore.location= value.converter.schema.registry.ssl.truststore.location= value.converter.schema.registry.ssl.truststore.location= value.converter.schema.registry.ssl.keystore.location= value.converter.schema.registry.ssl.keystore.location= value.converter.schema.registry.ssl.keystore.location= value.converter.schema.registry.ssl.keystore.password= value.converter.schema.registry.ssl.keystore.password=

#### SSL Basic Auth

```
key.converter.basic.auth.credentials.source=USER_INFO
key.converter.basic.auth.user.info=username:password
key.converter.schema.registry.ssl.truststore.location=
key.converter.basic.auth.credentials.source=USER_INFO
value.converter.basic.auth.user.info=username:password
value.converter.schema.registry.ssl.truststore.location=
value.converter.schema.registry.ssl.truststore.password=
```

# Kafka Connect Handler Performance Considerations

There are multiple configuration settings both for the Oracle GoldenGate for Big Data configuration and in the Kafka producer which affect performance.

The Oracle GoldenGate parameter have the greatest affect on performance is the Replicat GROUPTRANSOPS parameter. The GROUPTRANSOPS parameter allows Replicat to group multiple source transactions into a single target transaction. At transaction commit, the Kafka Connect Handler calls flush on the Kafka Producer to push the messages to Kafka for write durability followed by a checkpoint. The flush call is an expensive call and setting the Replicat GROUPTRANSOPS setting to larger amount allows the replicat to call the flush call less frequently thereby improving performance.

The default setting for GROUPTRANSOPS is 1000 and performance improvements can be obtained by increasing the value to 2500, 5000, or even 10000.

The Op mode gg.handler.kafkaconnect.mode=op parameter can also improve performance than the Tx mode gg.handler.kafkaconnect.mode=tx.

A number of Kafka Producer properties can affect performance. The following are the parameters with significant impact:

- linger.ms
- batch.size
- acks
- buffer.memory
- compression.type

Oracle recommends that you start with the default values for these parameters and perform performance testing to obtain a base line for performance. Review the Kafka documentation for each of these parameters to understand its role and adjust the parameters and perform additional performance testing to ascertain the performance effect of each parameter.

### Kafka Interceptor Support

The Kafka Producer client framework supports the use of Producer Interceptors. A Producer Interceptor is simply a user exit from the Kafka Producer client whereby the Interceptor object is instantiated and receives notifications of Kafka message send calls and Kafka message send acknowledgement calls.

The typical use case for Interceptors is monitoring. Kafka Producer Interceptors must conform to the interface org.apache.kafka.clients.producer.ProducerInterceptor. The Kafka Connect Handler supports Producer Interceptor usage.

The requirements to using Interceptors in the Handlers are as follows:

- The Kafka Producer configuration property "interceptor.classes" must be configured with the class name of the Interceptor(s) to be invoked.
- In order to invoke the Interceptor(s), the jar files plus any dependency jars must be available to the JVM. Therefore, the jar files containing the Interceptor(s) plus any dependency jars must be added to the gg.classpath in the Handler configuration file.

For more information, see Kafka documentation.

# Kafka Partition Selection

Kafka topics comprise one or more partitions. Distribution to multiple partitions is a good way to improve Kafka ingest performance, because the Kafka client parallelizes message sending to different topic/partition combinations. Partition selection is controlled by a following calculation in the Kafka client.

(Hash of the Kafka message key) modulus (the number of partitions) = selected partition number

The Kafka message key is selected by the following configuration value:

gg.handler.{your handler name}.keyMappingTemplate=

If this parameter is set to a value which generates a static key, all messages will go to the same partition. The following is example of static keys:

gg.handler.{your handler name}.keyMappingTemplate=StaticValue

If this parameter is set to a value which generates a key that changes infrequently, partition selection changes infrequently. In the following example the table name is used as the message key. Every operation for a specific source table will have the same key and thereby route to the same partition:

gg.handler.{your handler name}.keyMappingTemplate=\${tableName}

A null Kafka message key distributes to the partitions on a round-robin basis. To do this, set the following:

gg.handler.{your handler name}.keyMappingTemplate=\${null}

The recommended setting for configuration of the mapping key is the following:

gg.handler.{your handler name}.keyMappingTemplate=\${primaryKeys}

This generates a Kafka message key that is the concatenated and delimited primary key values.

Operations for each row should have a unique primary key(s) thereby generating a unique Kafka message key for each row. Another important consideration is Kafka messages sent to different partitions are not guaranteed to be delivered to a Kafka consumer in the original order sent. This is part of the Kafka specification. Order is only maintained within a partition. Using primary keys as the Kafka message key means that operations for the same row, which have the same primary key(s),

generate the same Kafka message key, and therefore are sent to the same Kafka partition. In this way, the order is maintained for operations for the same row.

At the DEBUG log level the Kafka message coordinates (topic, partition, and offset) are logged to the .log file for successfully sent messages.

Troubleshooting the Kafka Connect Handler

- Java Classpath for Kafka Connect Handler
- Invalid Kafka Version
- Kafka Producer Properties File Not Found
- Kafka Connection Problem

#### Java Classpath for Kafka Connect Handler

Issues with the Java classpath are one of the most common problems. The indication of a classpath problem is a ClassNotFoundException in the Oracle GoldenGate Java log4j log file or and error while resolving the classpath if there is a typographic error in the gg.classpath variable.

The Kafka client libraries do not ship with the Oracle GoldenGate for Big Data product. You are required to obtain the correct version of the Kafka client libraries and to properly configure the gg.classpath property in the Java Adapter Properties file to correctly resolve the Java the Kafka client libraries as described in Setting Up and Running the Kafka Connect Handler.

### Invalid Kafka Version

Kafka Connect was introduced in Kafka 0.9.0.0 version. The Kafka Connect Handler does not work with Kafka versions 0.8.2.2 and older. Attempting to use Kafka Connect with Kafka 0.8.2.2 version typically results in a ClassNotFoundException error at runtime.

#### Kafka Producer Properties File Not Found

Typically, the following exception message occurs:

ERROR 2015-11-11 11:49:08,482 [main] Error loading the kafka producer properties

Verify that the gg.handler.kafkahandler.KafkaProducerConfigFile configuration property for the Kafka Producer Configuration file name is set correctly.

Ensure that the gg.classpath variable includes the path to the Kafka Producer properties file and that the path to the properties file does not contain a \* wildcard at the end.

#### Kafka Connection Problem

Typically, the following exception message appears:

WARN 2015-11-11 11:25:50,784 [kafka-producer-network-thread | producer-1]

WARN (Selector.java:276) - Error in I/O with localhost/127.0.0.1 java.net.ConnectException: Connection refused

When this occurs, the connection retry interval expires and the Kafka Connection Handler process abends. Ensure that the Kafka Brokers are running and that the host and port provided in the Kafka Producer properties file is correct.

Network shell commands (such as, netstat -1) can be used on the machine hosting the Kafka broker to verify that Kafka is listening on the expected port.

### Kafka Connect Handler Client Dependencies

What are the dependencies for the Kafka Connect Handler to connect to Apache Kafka Connect databases?

The maven central repository artifacts for Kafka Connect databases are:

Maven groupid: org.apache.kafka

Maven artifactId: kafka-clients & connect-json

Maven version: the Kafka Connect version numbers listed for each section

- Kafka 2.8.0
- Kafka 2.7.1
- Kafka 2.6.0
- Kafka 2.5.1
- Kafka 2.4.1
- Kafka 2.3.1
- Kafka 2.2.1
- Kafka 2.1.1
- Kafka 2.0.1
- Kafka 1.1.1
- Kafka 1.0.2
- Kafka 0.11.0.0
- Kafka 0.10.2.0
- Kafka 0.10.2.0
- Kafka 0.10.0.0
- Kafka 0.9.0.1

Confluent Dependencies

#### **Confluent Dependencies**

The Confluent dependencies listed below are for the Kafka Connect Avro Converter and the assocated Avro Schema Registry client. When integrated with Confluent Kafka Connect, the below dependencies are required in addition to the Kafka Connect dependencies for the corresponding Kafka version which are listed in the previous sections.

- Confluent 6.2.0
- Confluent 6.1.0
- Confluent 6.0.0
- Confluent 5.5.0
- Confluent 5.4.0
- Confluent 5.3.0
- Confluent 5.2.1

## Apache Kafka REST Proxy

The Kafka REST Proxy Handler to stream messages to the Kafka REST Proxy distributed by Confluent.

This chapter describes how to use the Kafka REST Proxy Handler.

- Overview
- Setting Up and Starting the Kafka REST Proxy Handler Services
- Consuming the Records
- Performance Considerations
- Kafka REST Proxy Handler Metacolumns Template Property

### Overview

The Kafka REST Proxy Handler allows Kafka messages to be streamed using an HTTPS protocol. The use case for this functionality is to stream Kafka messages from an Oracle GoldenGate On Premises installation to cloud or alternately from cloud to cloud.

The Kafka REST proxy provides a RESTful interface to a Kafka cluster. It makes it easy for you to:

- produce and consume messages,
- view the state of the cluster,
- and perform administrative actions without using the native Kafka protocol or clients.

Kafka REST Proxy is part of the Confluent Open Source and Confluent Enterprise distributions. It is not available in the Apache Kafka distribution. To access Kafka through the REST proxy, you have to install the Confluent Kafka version see https://docs.confluent.io/ current/kafka-rest/docs/index.html.

## Setting Up and Starting the Kafka REST Proxy Handler Services

You have several installation formats to choose from including ZIP or tar archives, Docker, and Packages.

- Using the Kafka REST Proxy Handler
- Downloading the Dependencies
- Classpath Configuration
- Kafka REST Proxy Handler Configuration
- Review a Sample Configuration
- Security
- Generating a Keystore or Truststore
- Using Templates to Resolve the Topic Name and Message Key
- Kafka REST Proxy Handler Formatter Properties

## Using the Kafka REST Proxy Handler

You must download and install the Confluent Open Source or Confluent Enterprise Distribution because the Kafka REST Proxy is not included in Apache, Cloudera, or Hortonworks. You have several installation formats to choose from including ZIP or TAR archives, Docker, and Packages.

The Kafka REST Proxy has dependency on ZooKeeper, Kafka, and the Schema Registry

## Downloading the Dependencies

You can review and download the Jersey RESTful Web Services in Java client dependency from:

https://eclipse-ee4j.github.io/jersey/.

You can review and download the Jersey Apache Connector dependencies from the maven repository: https://mvnrepository.com/artifact/org.glassfish.jersey.connectors/ jersey-apache-connector.

## Classpath Configuration

The Kafka REST Proxy handler uses the Jersey project <code>jersey-client</code> version 2.27 and <code>jersey-connectors-apache</code> version 2.27 to connect to Kafka. Oracle GoldenGate for Big Data does not include the required dependencies so you must obtain them, see Downloading the Dependencies.

You have to configure these dependencies using the gg.classpath property in the Java Adapter properties file. This is an example of a correctly configured classpath for the Kafka REST Proxy Handler:

```
gg.classpath=dirprm:
{path_to_jersey_client_jars}/jaxrs-ri/lib/*:
{path_to_jersey_client_jars}
/jaxrs-ri/api/*
:{path_to_jersey_client_jars}/jaxrs-ri/ext/*:
{path_to_jersey_client_jars}
/connector/*
```

## Kafka REST Proxy Handler Configuration

The following are the configurable values for the Kafka REST Proxy Handler. Oracle recommend that you store the Kafka REST Proxy properties file in the Oracle GoldenGate dirprm directory.

To enable the selection of the Kafka REST Proxy Handler, you must first configure the handler type by specifying gg.handler.name.type=kafkarestproxy and the other Kafka REST Proxy Handler properties as follows:

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name</i> .type	Required	kafkarestproxy	None	The configuration to select the Kafka REST Proxy Handler.
gg.handler. <i>name</i> .topicMappingTe mplate	Required	A template string value to resolve the Kafka topic name at runtime.	None	See Using Templates to Resolve the Topic Name and Message Key.
gg.handler. <i>name</i> .keyMappingTemp late	Required	A template string value to resolve the Kafka message key at runtime.	None	See Using Templates to Resolve the Topic Name and Message Key.
gg.handler. <i>name</i> .postDataUrl	Required	The Listener address of the Rest Proxy.	None	Set to the URL of the Kafka REST proxy.
gg.handler. <i>name</i> .format	Required	avro json	None	Set to the REST proxy payload data format
gg.handler. <i>name</i> .payloadsize	Optional	A value representing the payload size in mega bytes.	5MB	Set to the maximum size of the payload of the HTTP messages.
gg.handler. <i>name</i> .apiVersion	Optional	v1   v2	v2	Sets the API version to use.
gg.handler. <i>name</i> .mode	Optional	op tx	op	Sets how operations are processed. In op mode, operations are processed as they are received. In tx mode, operations are cached and processed at the transaction commit.
gg.handler. <i>name</i> .trustStore	Optional	Path to the truststore.	None	Path to the truststore file that holds certificates from trusted certificate authorities (CA). These CAs are used to verify certificates presented by the server during an SSL connection, see Generating a Keystore or Truststore.

Properties	Required/ Optional	Legal Values	Default	Explanation
<pre>gg.handler.name .trustStorePass word</pre>	Optional	Password of the truststore.	None	The truststore password.
gg.handler. <i>name</i> .keyStore	Optional	Path to the keystore.	None	Path to the keystore file that the private key and identity certificate, which are presented to other parties (server or client) to verify its identity, see <u>Generating a</u> Keystore or Truststore.
gg.handler. <i>name</i> .keyStorePasswo rd	Optional	Password of the keystore.	None	The keystore password.
gg.handler. <i>name</i> .proxy	Optional	http:// host:port	None	Proxy URL in the following format: http:// host:port
gg.handler. <i>name</i> .proxyUserName	Optional	Any string.	None	The proxy user name.
gg.handler. <i>name</i> .proxyPassword	Optional	Any string.	None	The proxy password.
gg.handler. <i>name</i> .readTimeout	Optional	Integer value.	None	The amount of time allowed for the server to respond.
gg.handler. <i>name</i> .connectionTime out	Optional	Integer value.	None	The amount of time to wait to establish the connection to the host.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .format.metaCol umnsTemplate	-	<pre>\${alltokens}   \${token}   \$ {env}   \${sys}   \${javaprop}   \${optype}   \$ {position}   \$ {timestamp}   \$ {catalog}   \$ {catalog}   \$ {catalog}   \$ {schema}   \$ {table}   \$ {objectname}   \${cons   \$ {xid}   \$ {currenttimesta} mp}   \$ {currenttimesta} mpmicro}   \${txind}   \$ {currenttimesta} mpiso8601}\$ {static}\$ {segno}   \$ {rba}</pre>	None	<pre>\${alltokens}   \${loken}   \$ {env}   \${sys}   \${javaprop}   \${optype}   \$ {position}   \$ {timestamp}   \$ {catalog}   \$ {schema}   \$ {catalog}   \$ {schema}   \$ {table}   \$ {objectname}   \${csn}   \$ {vid}   \$ {currenttimestampicron} } \$ {timestampmicron}   \$ {currenttimestampmicron} } \$ {currenttimestampmicron} } \$ {currenttimestampmicron} } \$ {currenttimestampmicron} } \$ {currenttimestampmicron} } \$ {currenttimestampmicron} } \$ {txind}   \$ {currenttimestampmicron} } \$ {txind}   \$ {currenttimestampmicron} } \$ {txind}   \$ {currenttimestampicron} } \$ {txind}   \$ {currenttimestampicron} } \$ {txind}   \$ {currenttimestampicron} } \$ {currenttimestampicron} } \$ {consisting of one or more templated values that represent the template. For more information about the Metacolumn keywords, see Metacolumn keywords, see Metacolumn keywords. This is an example that would produce a list of metacolumns: \${optype}, \$ {token.ROWID}, \$ {sys.username}, \$ {currenttimestampicron} } } } } } {currenttimestampicron} } } } } } } } } } } } } } } } } } }</pre>

See Using Templates to Resolve the Stream Name and Partition Name for more information.

### **Review a Sample Configuration**

The following is a sample configuration for the Kafka REST Proxy Handler from the Java Adapter properties file:

```
gg.handlerlist=kafkarestproxy
#The handler properties
gg.handler.kafkarestproxy.type=kafkarestproxy
#The following selects the topic name based on the fully qualified table name
gg.handler.kafkarestproxy.topicMappingTemplate=${fullyQualifiedTableName}
#The following selects the message key using the concatenated primary keys
gg.handler.kafkarestproxy.keyMappingTemplate=${primaryKeys}
gg.handler.kafkarestproxy.postDataUrl=http://localhost:8083
gg.handler.kafkarestproxy.apiVersion=v1
gg.handler.kafkarestproxy.format=json
gg.handler.kafkarestproxy.payloadsize=1
gg.handler.kafkarestproxy.mode=tx
#Server auth properties
#gg.handler.kafkarestproxy.trustStore=/keys/truststore.jks
#gg.handler.kafkarestproxy.trustStorePassword=test1234
#Client auth properites
#gg.handler.kafkarestproxy.keyStore=/keys/keystore.jks
```

```
#gg.handler.kafkarestproxy.keyStorePassword=test1234
```

```
#Proxy properties
#gg.handler.kafkarestproxy.proxy=http://proxyurl:80
#gg.handler.kafkarestproxy.proxyUserName=username
#gg.handler.kafkarestproxy.proxyPassword=password
```

```
#The MetaColumnTemplate formatter properties
gg.handler.kafkarestproxy.format.metaColumnsTemplate=${optype},$
{timestampmicro},${currenttimestampmicro}
```

### Security

Security is possible between the following:

- Kafka REST Proxy clients and the Kafka REST Proxy server. The Oracle GoldenGate REST Proxy Handler is a Kafka REST Proxy client.
- The Kafka REST Proxy server and Kafka Brokers. Oracle recommends that you thoroughly review the security documentation and configuration of the Kafka REST Proxy server, see https://docs.confluent.io/current/kafka-rest/docs/index.html

REST Proxy supports SSL for securing communication between clients and the Kafka REST Proxy Handler. To configure SSL:

- 1. Generate a keystore using the scripts, see Generating a Keystore or Truststore.
- Update the Kafka REST Proxy server configuration in the kafkarest.properties file with these properties:

```
listeners=https://hostname:8083
confluent.rest.auth.propagate.method=SSL
```

```
Configuration Options for HTTPS
```

Chapter 8 Target

```
ssl.client.auth=true
ssl.keystore.location={keystore_file_path}/server.keystore.jks
ssl.keystore.password=test1234
ssl.key.password=test1234
ssl.truststore.location={keystore_file_path}/server.truststore.jks
ssl.truststore.password=test1234
ssl.keystore.type=JKS
ssl.truststore.type=JKS
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
```

3. Restart your server.

To disable mutual authentication, you update the ssl.client.auth= property from true to false.

### Generating a Keystore or Truststore

#### **Generating a Truststore**

You execute this script to generate the ca-cert, ca-key, and truststore.jks truststore files.

```
#!/bin/bash
PASSWORD=password
CLIENT_PASSWORD=password
VALIDITY=365
```

Then you generate a CA as in this example:

```
openssl req -new -x509 -keyout ca-key -out ca-cert -days $VALIDITY -passin
pass:$PASSWORD
    -passout pass:$PASSWORD -subj "/C=US/ST=CA/L=San Jose/O=Company/OU=Org/CN=FQDN"
    -nodes
```

Lastly, you add the CA to the server's truststore using keytool:

### Generating a Keystore

You run this script and pass the fqdn as argument to generate the ca-cert.srl, cert-file, cert-signed, and keystore.jks keystore files.

```
#!/bin/bash
PASSWORD=password
VALIDITY=365
if [ $# -lt 1 ];
then
echo "`basename $0` host fqdn|user_name|app_name"
exit 1
fi
CNAME=$1
ALIAS=`echo $CNAME|cut -f1 -d"."`
```

Then you generate the keystore with keytool as in this example:

keytool -noprompt ;keystore keystore.jks -alias \$ALIAS -keyalg RSA -validity \$VALIDITY
 -genkey -dname "CN=\$CNAME,OU=BDP,O=Company,L=San Jose,S=CA,C=US" -

storepass \$PASSWORD -keypass \$PASSWORD

Next, you sign all the certificates in the keystore with the CA:

```
keytool -keystore keystore.jks -alias $ALIAS -certreq -file cert-file -storepass
    $PASSWORDopenssl x509 -req -CA ca-cert -CAkey ca-key -in cert-file -out
    cert-signed -days $VALIDITY
        -CAcreateserial -passin pass:$PASSWORD
```

Lastly, you import both the CA and the signed certificate into the keystore:

```
keytool -keystore keystore.jks -alias CARoot -import -file ca-cert -storepass
    $PASSWORDkeytool -keystore keystore.jks -alias $ALIAS -import -file cert-
signed -storepass
    $PASSWORD
```

Using Templates to Resolve the Topic Name and Message Key

The Kafka REST Proxy Handler provides functionality to resolve the topic name and the message key at runtime using a template configuration value. Templates allow you to configure static values and keywords. Keywords are used to dynamically replace the keyword with the context of the current processing. The templates use the following configuration properties:

```
gg.handler.name.topicMappingTemplate
gg.handler.name.keyMappingTemplate
```

### **Template Modes**

The Kafka REST Proxy Handler can be configured to send one message per operation (insert, update, delete). Alternatively, it can be configured to group operations into messages at the transaction level.

For more information about the Template Keywords, see Template Keywords.

#### **Example Templates**

The following describes example template configuration values and the resolved values.

Example Template	Resolved Value
<pre>\${groupName}_\$ {fullyQualfiedTableName}</pre>	KAFKA001_dbo.table1
prefix_\${schemaName}_\$ {tableName}_suffix	<pre>prefix_dbo_table1_suffix</pre>
<pre>\${currentDate[yyyy-mm-dd hh:MM:ss.SSS]}</pre>	2017-05-17 11:45:34.254

### Kafka REST Proxy Handler Formatter Properties

The following are the configurable values for the Kafka REST Proxy Handler Formatter.

Properties	Optional/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format.include OpType	Optional	true   false	true	Set to true to create a field in the output messages called op_ts. The value is an indicator of the type of source database operation (for example, Ifor insert, Ufor update, Dfor delete).
				Set to false to omit this field in the output.
gg.handler. <i>name</i> .format.include OpTimestamp	Optional	true   false	true	Set to true to create a field in the output messages called op_type. The value is the operation timestamp (commit timestamp) from the source trail file.
				Set to false to omit this field in the output.
gg.handler. <i>name</i> .format.include CurrentTimestam p	Optional	true   false	true	Set to true to create a field in the output messages called current_ts. The value is the current timestamp of when the handler processes the operation. Set to false to omit this field in the output.

 Table 8-12
 Kafka REST Proxy Handler Formatter Properties

Properties	Optional/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format.include Position	Optional	true   false	true	Set to true to create a field in the output messages called pos. The value is the position (sequence number + offset) of the operation from the source trail file.
				Set to false to omit this field in the output.
gg.handler. <i>name</i> .format.include PrimaryKeys	Optional	true   false	true	Set to true to create a field in the output messages called primary_keys. The value is an array of the column names of the primary key columns.
				Set to false to omit this field in the output.
gg.handler. <i>name</i> .format.include Tokens	Optional	true   false	true	Set to true to include a map field in output messages. The key is tokens and the value is a map where the keys and values are the token keys and values from the Oracle GoldenGate source trail file.
				Set to false to suppress this field.
gg.handler. <i>name</i> .format.insertO pKey	Optional	Any string.	I	The value of the field op_type that indicates an insert operation.
gg.handler. <i>name</i> .format.updateO pKey	Optional	Any string.	U	The value of the field op_type that indicates an update operation.

<b>Table 8-12</b>	(Cont.) Kafka REST Proxy Handler Formatter Properties
	(

Properties	Optional/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format.deleteO pKey	Optional	Any string.	D	The value of the field op_type that indicates an delete operation.
gg.handler. <i>name</i> .format.truncat eOpKey	Optional	Any string.	Т	The value of the field op_type that indicates an truncate operation.
gg.handler. <i>name</i> .format.treatAl lColumnsAsStrin	Optional	true   false	false	Set to true treat all output fields as strings.
gs				Set to false and the handler maps the corresponding field type from the source trail file to the best corresponding Kafka data type.
gg.handler. <i>name</i> .format.mapLarg eNumbersAsStrin gs	Optional	true   false	false	Set to true and these fields are mapped as strings to preserve precision. This property is specific to the Avro Formatter; it cannot be used with other formatters.
gg.handler. <i>name</i> .format.iso8601 Format	Optional	true   false	false	Set to true to output the current date in the ISO8601 format.
gg.handler. <i>name</i> .format.pkUpdat eHandling	Optional	abend   update   delete-insert	abend	It is only applicable if you are modeling row messages with the . (gg.handler.nam e.format.messag eFormatting=row property. It is not applicable if you are modeling operations messages as the before and after images are propagated to the message with an update.

### Consuming the Records

A simple way to consume data from Kafka topics using the Kafka REST Proxy Handler is Curl.

### **Consume JSON Data**

### 1. Create a consumer for JSON data.

curl -k -X POST -H "Content-Type: application/vnd.kafka.v2+json"

https://localhost:8082/consumers/my\_json\_consumer

#### 2. Subscribe to a topic.

```
curl -k -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"topics":["topicname"]}' \
```

https://localhost:8082/consumers/my\_json\_consumer/instances/
my consumer instance/subscription

#### 3. Consume records.

curl -k -X GET -H "Accept: application/vnd.kafka.json.v2+json" \

```
https://localhost:8082/consumers/my_json_consumer/instances/
my_consumer_instance/records
```

### **Consume Avro Data**

1. Create a consumer for Avro data.

```
curl -k -X POST -H "Content-Type: application/vnd.kafka.v2+json" \
    --data '{"name": "my_consumer_instance", "format": "avro",
    "auto.offset.reset": "earliest"}' \
```

https://localhost:8082/consumers/my\_avro\_consumer

### 2. Subscribe to a topic.

curl -k -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"topics":["topicname"]}' \

https://localhost:8082/consumers/my\_avro\_consumer/instances/ my consumer instance/subscription

#### 3. Consume records.

curl -X GET -H "Accept: application/vnd.kafka.avro.v2+json" \

```
https://localhost:8082/consumers/my_avro_consumer/instances/
my consumer instance/records
```

### Note:

If you are using curl from the machine hosting the REST proxy, then unset the http\_proxy environmental variable before consuming the messages. If you are using curl from the local machine to get messages from the Kafka REST Proxy, then setting the http\_proxy environmental variable may be required.

### Performance Considerations

There are several configuration settings both for the Oracle GoldenGate for Big Data configuration and in the Kafka producer that affects performance.

The Oracle GoldenGate parameter that has the greatest affect on performance is the Replicat GROUPTRANSOPS parameter. It allows Replicat to group multiple source transactions into a single target transaction. At transaction commit, the Kafka REST Proxy Handler POST's the data to the Kafka Producer.

Setting the Replicat GROUPTRANSOPS to a larger number allows the Replicat to call the POST less frequently improving performance. The default value for GROUPTRANSOPS is 1000 and performance can be improved by increasing the value to 2500, 5000, or even 10000.

## Kafka REST Proxy Handler Metacolumns Template Property

### Problems Starting Kafka REST Proxy server

The script to start the Kafka REST Proxy server appends its CLASSPATH to the environment CLASSPATH variable. If set, the environment CLASSPATH can contain JAR files that conflict with the correct execution of the Kafka REST Proxy server and may prevent it from starting. Oracle recommends that you unset the CLASSPATH environmental variable before started your Kafka REST Proxy server. Reset the CLASSPATH to "" to overcome the problem.

## Apache Hive

### **Integrating with Hive**

Oracle GoldenGate for Big Data release does not include a Hive storage handler because the HDFS Handler provides all of the necessary Hive functionality .

You can create a Hive integration to create tables and update table definitions in case of DDL events. This is limited to data formatted in Avro Object Container File format. For more information, see Writing in HDFS in Avro Object Container File Format and HDFS Handler Configuration.

For Hive to consume sequence files, the DDL creates Hive tables including STORED as sequencefile. The following is a sample create table script:

```
CREATE EXTERNAL TABLE table_name (
   coll string,
    ...
   col2 string)
ROW FORMAT DELIMITED
STORED as sequencefile
LOCATION '/path/to/hdfs/file';
```

### Note:

If files are intended to be consumed by Hive, then the gg.handler.name.partitionByTable property should be set to true.

# Azure Blob Storage

### Topics:

- Overview
- Prerequisites
- Storage Account, Container, and Objects
- Configuration
- Troubleshooting and Diagnostics

## Overview

Azure Blob Storage (ABS) is a service for storing objects in Azure cloud. It is highly scalable and is a secure object storage for cloud-native workloads, archives, data lakes, high-performance computing, and machine learning. You can use the Azure Blob Storage Event handler to load files generated by the File Writer handler into ABS.

## Prerequisites

Ensure that the following are set:

- Azure cloud account set up.
- Java Software Development Kit (SDK) for Azure Blob Storage.

## Storage Account, Container, and Objects

- **Storage Account**: An Azure storage account contains all of your Azure Storage data objects: blobs, file shares, queues, tables, and disks.
- **Container**: A container organizes a set of blobs, similar to a directory in a file system. A storage account can include an unlimited number of containers, and a container can store an unlimited number of blobs.
- Objects/blobs: Objects or blobs are the individual pieces of data that you store in a storage account container.

## Configuration

To enable the selection of the ABS Event Handler, you must first configure the Event Handler type by specifying gg.eventhandler.name.type=abs and the following ABS properties:

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandler . <i>name</i> .type	Required	abs	None	Selects the ABS Event Handler for use with File Writer handler.
gg.eventhandler . <i>name</i> .bucketMap pingTemplate	Required	A string with resolvable keywords and constants used to dynamically generate a Azure storage account container name.	None	A container is created by the ABS Event handler if it does not exist using this name. See https:// docs.microsoft.com /en-us/rest/api/ storageservices/ naming-and- referencing- containersblobs and- metadata#containe r-names. For supported keywords, see Template Keywords
gg.eventhandler . <i>name</i> .pathMappi ngTemplate	Required	A string with resolvable keywords and constants used to dynamically generate the path in the Azure storage account container to write the file.	None	Use keywords interlaced with constants to dynamically generate a unique Azure storage account container path names at runtime. Sample path name: ogg/ data/\$ {groupName}/\$ {fullyQualified TableName}. For supported keywords, see Template Keywords
gg.eventhandler . <i>name</i> .fileNameM appingTemplate	Optional	A string with resolvable keywords and constants used to dynamically generate a file name for the Azure Blob object.	None	Use resolvable keywords and constants used to dynamically generate the Azure Blob object file name. If not set, the upstream file name is used. For supported keywords, see Template Keywords

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandler . <i>name</i> .finalizeA ction	Optional	none   delete	none	Set to none to leave the Azure Blob data file in place on the finalize action. Set to delete if you want to delete the Azure Blob data file with the finalize action.
gg.eventhandler . <i>name</i> .eventHand ler	Optional	A unique string identifier cross referencing a child event handler.	No event handler configured.	Sets the downstream event handler that is invoked on the file roll event.
gg.eventhandler .name.accountNa me	Required	String	None	Azure storage account name.
gg.eventhandler .name.accountKe Y	Optional	String	None	Azure storage account key.
gg.eventhandler .name.sasToken	Optional	String	None	Sets a credential that uses a shared access signature (SAS) to authenticate to an Azure Service.
gg.eventhandler .name.tenantId	Optional	String	None	Sets the Azure tenant ID of the application.
gg.eventhandler .name.clientId	Optional	String	None	Sets the Azure client ID of the application.
<pre>gg.eventhandler .name.clientSec ret</pre>	Optional	String	None	Sets the Azure client secret for the authentication.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandler .name.accessTie r	Optional	Hot   Cool   Archive	None	Sets the tier on a Azure blob/object. Azure storage offers different access tiers, allowing you to store blob object data in the most cost-effective manner. Available access tiers include Hot, Cool and Archive. For more information, see https:// docs.microsoft.com /en-us/azure/ storage/blobs/ storage-blob- storage-tiers.
gg.eventhandler .name.endpoint	Optional	String	https:// <accountname>.b lob.core.window s.net</accountname>	Sets the Azure Storage service endpoint. See Azure Government Cloud Configuration

- Classpath Configuration
- Dependencies
- Authentication
- Proxy Configuration
- Sample Configuration
- Azure Government Cloud Configuration

# Classpath Configuration

The ABS Event handler uses the Java SDK for Azure Blob Storage.

### Note:

Ensure that the classpath includes the path to the Azure Blob Storage Java SDK.

## Dependencies

Download the SDK using the following maven co-ordinates:

```
<dependencies>
    <dependency>
        <groupId>com.azure</groupId>
        <artifactId>azure-storage-blob</artifactId>
```

```
<version>12.13.0</version>
</dependency>
<dependency>
<groupId>com.azure</groupId>
<artifactId>azure-identity</artifactId>
<version>1.3.3</version>
</dependency>
</dependencies>
```

## Authentication

You can authenticate the Azure Storage device by configuring one of the following:

- accountKey
- sasToken
- tenandId, clientID, and clientSecret

accounkKey has the highest precedence, followed by sasToken. If accountKey and sasToken are not set, then the tuple tenantId, clientId, and clientSecret are used.

Azure Tenant ID, Client ID, and Client Secret

### Azure Tenant ID, Client ID, and Client Secret

You can authenticate the Azure Storage device by configuring one of the following: To obtain your Azure tenant ID:

- **1.** Go to the Microsoft Azure portal.
- 2. Select Azure Active Directory from the list on the left to view the Azure Active Directory panel.
- **3.** Select Properties in the Azure Active Directory panel to view the Azure Active Directory properties.

The Azure tenant ID is the field marked as Directory ID.

To obtain your Azure client ID and client secret:

- **1.** Go to the Microsoft Azure portal.
- 2. Select All Services from the list on the left to view the Azure Services Listing.
- 3. Enter App into the filter command box and select App Registrations from the listed services.
- 4. Select the App Registration you created to access Azure Storage.

The Application Id displayed for the App Registration is the client ID. The client secret is the generated key string when a new key is added. This generated key string is available only once when the key is created. If you do not know the generated key string, then create another key making sure you capture the generated key string.

## **Proxy Configuration**

When the process is run behind a proxy server, the jvm.bootoptions property can be used to set proxy server configuration using well-known Java proxy properties.

### For example:

```
jvm.bootoptions=-Dhttps.proxyHost=some-proxy-address.com -Dhttps.proxyPort=80
-Djava.net.useSystemProxies=true
```

## Sample Configuration

```
#The ABS Event Handler
    gg.eventhandler.abs.type=abs
    gg.eventhandler.abs.pathMappingTemplate=${fullyQualifiedTableName}
    #TODO: Edit the Azure Blob Storage container name
    gg.eventhandler.abs.bucketMappingTemplate=<abs-container-name>
    gg.eventhandler.abs.finalizeAction=none
    #TODO: Edit the Azure storage account name.
    gg.eventhandler.abs.accountName=<storage-account-name>
    #TODO: Edit the Azure storage account key.
    #gg.eventhandler.abs.accountKey=<storage-account-key>
    #TODO: Edit the Azure shared access signature(SAS) to authenticate to an Azure
Service.
    #gg.eventhandler.abs.sasToken=<sas-token>
    #TODO: Edit the the tenant ID of the application.
    gg.eventhandler.abs.tenantId=<azure-tenant-id>
    #TODO: Edit the the client ID of the application.
    gg.eventhandler.abs.clientId=<azure-client-id>
    #TODO: Edit the the client secret for the authentication.
    gg.eventhandler.abs.clientSecret=<azure-client-secret>
    gg.classpath=/path/to/abs-deps/*
    #TODO: Edit the proxy configuration.
    #jvm.bootoptions=-Dhttps.proxyHost=some-proxy-address.com -Dhttps.proxyPort=80 -
Djava.net.useSystemProxies=true
```

## Azure Government Cloud Configuration

Additional configuration is required if Oracle GoldenGate for BigData has to replicate data to storage accounts that reside in Azure Government cloud.

Set the environment variables AZURE\_AUTHORITY\_HOST and gg.eventhandler. {name}.endpoint as per the following table:

Government cloud	AZURE_AUTHORITY_HOST	gg.eventhandler. {name}.endpoint
Azure US Government Cloud	https:// login.microsoftonline.us.	<pre>https://<storage-account- name&gt;.blob.core.usgovclou dapi.net</storage-account- </pre>
Azure German Cloud	https:// login.microsoftonline.de	<pre>https://<storage-account- name&gt;.blob.core.cloudapi. de</storage-account- </pre>
Azure China Cloud	https:// login.chinacloudapi.cn	https:// <storage-account- name&gt;.blob.core.chinaclou dapi.cn</storage-account- 

The environment variable can be set in the replicat prm file using the Oracle GoldenGate setenv parameter.

### Example:

```
setenv (AZURE_AUTHORITY_HOST = "https://login.microsoftonline.us")
```

## Troubleshooting and Diagnostics

• **Error**: Confidential Client is not supported in Cross Cloud request. This indicates that the target Azure storage account resides in one of the Azure Government clouds. Set the required configuration as per Azure Government Cloud Configuration.

# Azure Data Lake Storage

- Azure Data Lake Gen1 (ADLS Gen1) Microsoft Azure Data Lake supports streaming data through the Hadoop client. Therefore, data files can be sent to Azure Data Lake using either the Oracle GoldenGate for Big Data Hadoop Distributed File System (HDFS) Handler or the File Writer Handler in conjunction with the HDFS Event Handler.
- Azure Data Lake Gen2 using Hadoop Client and ABFS Microsoft Azure Data Lake Gen 2 (using Hadoop Client and ABFS) supports streaming data via the Hadoop client. Therefore, data files can be sent to Azure Data Lake Gen 2 using either the Oracle GoldenGate for Big Data HDFS Handler or the File Writer Handler in conjunction with the HDFS Event Handler.
- Azure Data Lake Gen2 using BLOB endpoint

## Azure Data Lake Gen1 (ADLS Gen1)

Microsoft Azure Data Lake supports streaming data through the Hadoop client. Therefore, data files can be sent to Azure Data Lake using either the Oracle GoldenGate for Big Data Hadoop Distributed File System (HDFS) Handler or the File Writer Handler in conjunction with the HDFS Event Handler.

The preferred mechanism for ingest to Microsoft Azure Data Lake is the File Writer Handler in conjunction with the HDFS Event Handler.

Use these steps to connect to Microsoft Azure Data Lake from Oracle GoldenGate for Big Data.

- 1. Download Hadoop 2.9.1 from http://hadoop.apache.org/releases.html.
- 2. Unzip the file in a temporary directory. For example, /ggwork/hadoop/hadoop-2.9.
- 3. Edit the /ggwork/hadoop/hadoop-2.9/hadoop-env.sh file in the directory.
- 4. Add entries for the JAVA HOME and HADOOP CLASSPATH environment variables:

```
export JAVA_HOME=/usr/lib/jvm/java-1.8.0-openjdk-amd64
export HADOOP_CLASSPATH=/ggwork/hadoop/hadoop-2.9.1/share/hadoop/tools/lib/
*:$HADOOP CLASSPATH
```

This points to Java 8 and adds the share/hadoop/tools/lib to the Hadoop classpath. The library path is not in the variable by default and the required Azure libraries are in this directory.

5. Edit the /ggwork/hadoop/hadoop-2.9.1/etc/hadoop/core-site.xml file and add:

```
<configuration>
<property>
<name>fs.adl.oauth2.access.token.provider.type</name>
<value>ClientCredential</value>
</property>
<propert.v>
<name>fs.adl.oauth2.refresh.url</name>
<value>Insert the Azure https URL here to obtain the access token</value>
</property>
<property>
<name>fs.adl.oauth2.client.id</name>
<value>Insert the client id here</value>
</property>
<property>
<name>fs.adl.oauth2.credential</name>
<value>Insert the password here</value>
</property>
<property>
<name>fs.defaultFS</name>
<value>adl://Account Name.azuredatalakestore.net</value>
</property>
</configuration>
```

- 6. Open your firewall to connect to both the Azure URL to get the token and the Azure Data Lake URL. Or disconnect from your network or VPN. Access to Azure Data Lake does not currently support using a proxy server per the Apache Hadoop documentation.
- Use the Hadoop shell commands to prove connectivity to Azure Data Lake. For example, in the 2.9.1 Hadoop installation directory, execute this command to get a listing of the root HDFS directory.

./bin/hadoop fs -ls /

- 8. Verify connectivity to Azure Data Lake.
- Configure either the HDFS Handler or the File Writer Handler using the HDFS Event Handler to push data to Azure Data Lake, see Flat Files. Oracle recommends that you use the File Writer Handler with the HDFS Event Handler. Setting the gg.classpath example:

```
gg.classpath=/ggwork/hadoop/hadoop-2.9.1/share/hadoop/common/:/ggwork/hadoop/
hadoop-
2.9.1/share/hadoop/common/lib/:/ggwork/hadoop/hadoop-
2.9.1/share/hadoop/hdfs/:/ggwork/hadoop/hadoop-2.9.1/share/hadoop/hdfs/lib/:/
ggwork/hadoop/hadoop-
2.9.1/etc/hadoop:/ggwork/hadoop/hadoop-2.9.1/share/hadoop/tools/lib/*
```

See https://hadoop.apache.org/docs/current/hadoop-azure-datalake/index.html.

## Azure Data Lake Gen2 using Hadoop Client and ABFS

Microsoft Azure Data Lake Gen 2 (using Hadoop Client and ABFS) supports streaming data via the Hadoop client. Therefore, data files can be sent to Azure Data Lake Gen 2 using either the Oracle GoldenGate for Big Data HDFS Handler or the File Writer Handler in conjunction with the HDFS Event Handler.

Hadoop 3.3.0 (or higher) is recommended for connectivity to Azure Data Lake Gen 2. Hadoop 3.3.0 contains an important fix to correctly fire Azure events on file close using the "abfss" scheme. For more information, see Hadoop Jira issue Hadoop-16182.

Use the File Writer Handler in conjunction with the HDFS Event Handler. This is the preferred mechanism for ingest to Azure Data Lake Gen 2.

### Prerequisites

Part 1:

 Connectivity to Azure Data Lake Gen 2 assumes that the you have correctly provisioned an Azure Data Lake Gen 2 account in the Azure portal. From the Azure portal select Storage Accounts from the commands on the left to view/create/delete storage accounts.

In the Azure Data Lake Gen 2 provisioning process, it is recommended that the Hierarchical namespace is enabled in the **Advanced** tab.

It is not mandatory to enable Hierarchical namespace for Azure storage account.

2. Ensure that you have created a Web app/API App Registration to connect to the storage account.

From the Azure portal select All services from the list of commands on the left, type app into the filter command box and select App registrations from the filtered list of services. Create an App registration of type Web app/API.

Add permissions to access Azure Storage. Assign the App registration to an Azure account. Generate a Key for the App Registration as follows:

- a. Navigate to the respective App registration page.
- b. On the left pane, select Certificates & secrets.
- c. Click + New client secret (This should show a new key under the column Value).

The generated key string is your client secret and is only available at the time the key is created. Therefore, ensure you document the generated key string.

### Part 2:

1. In the Azure Data Lake Gen 2 account, ensure that the App Registration is given access.

In the **Azure** portal, select **Storage accounts** from the left panel. Select the Azure Data Lake Gen 2 account that you have created.

Select the Access Control (IAM) command to bring up the Access Control (IAM) panel. Select the Role Assignments tab and add a roll assignment for the created App Registration.

The app registration assigned to the storage account must be provided with read and write access into the Azure storage account.

You can use either of the following roles: the built-in Azure role Storage Blob Data Contributor or custom role with the required permissions.

2. Connectivity to Azure Data Lake Gen 2 can be routed through a proxy server. Three parameters need to be set in the Java boot options to enable:

```
jvm.bootoptions=-Xmx512m -Xms32m -Djava.class.path=ggjava/ggjava.jar -
DproxySet=true -Dhttps.proxyHost={insert your proxy server} -
Dhttps.proxyPort={insert your proxy port}
```

3. Two connectivity schemes to Azure Data Lake Gen 2 are supported: abfs and abfss.

The preferred method is abfss since it employs HTTPS calls thereby providing security and payload encryption.

### Connecting to Microsoft Azure Data Lake 2

To connect to Microsoft Azure Data Lake 2 from Oracle GoldenGate for Big Data:

- 1. Download Hadoop 3.3.0 from http://hadoop.apache.org/releases.html.
- 2. Unzip the file in a temporary directory. For example, /usr/home/hadoop/hadoop-3.3.0.
- 3. Edit the {hadoop install dir}/etc/hadoop/hadoop-env.sh file to point to Java 8 and add the Azure Hadoop libraries to the Hadoop classpath. These are entries in the hadoop-env.sh file:

```
export JAVA_HOME=/usr/lib/jvm/jdk1.8.0_202
export HADOOP OPTIONAL TOOLS="hadoop-azure"
```

4. Private networks often require routing through a proxy server to access the public internet. Therefore, you may have to configure proxy server settings for the hadoop command line utility to test the connectivity to Azure. To configure proxy server settings, set the following in the hadoop-env.sh file:

```
export HADOOP_CLIENT_OPTS="-Dhttps.proxyHost={insert your proxy server} -
Dhttps.proxyPort={insert your proxy port}"
```

## Note:

These proxy settings only work for the hadoop command line utility. The proxy server settings for Oracle GoldenGate for Big Data connectivity to Azure are set in the jvm.bootoptions as described in this point.

5. Edit the {hadoop install dir}/etc/hadoop/core-site.xml file and add the following configuration:

```
<configuration>
<property>
 <name>fs.azure.account.auth.type</name>
 <value>OAuth</value>
</property>
<property>
 <name>fs.azure.account.oauth.provider.type</name>
 <value>org.apache.hadoop.fs.azurebfs.oauth2.ClientCredsTokenProvider</value>
</property>
<property>
 <name>fs.azure.account.oauth2.client.endpoint</name>
 <value>https://login.microsoftonline.com/{insert the Azure Tenant id here}/
oauth2/token</value>
</property>
<property>
 <name>fs.azure.account.oauth2.client.id</name>
 <value>{insert your client id here}</value>
</property>
<property>
 <name>fs.azure.account.oauth2.client.secret</name>
 <value>{insert your client secret here}</value>
</property>
<property>
 <name>fs.defaultFS</name>
 <value>abfss://{insert your container name here}@{insert your ADL gen2 storage
account name here }.dfs.core.windows.net</value>
</property>
```

```
<property>
<name>fs.azure.createRemoteFileSystemDuringInitialization</name>
<value>true</value>
</property>
</configuration>
```

To obtain your Azure Tenant Id, go to the **Microsoft Azure** portal. Enter Azure Active Directory in the **Search** bar and select **Azure Active Directory** from the list of services. The Tenant Id is located in the center of the main **Azure Active Directory** service page.

To obtain your Azure Client Id and Client Secret go to the Microsoft Azure portal. Select **All Services** from the list on the left to view the Azure Services Listing. Type **App** into the filter command box and select **App Registrations** from the listed services. Select the App Registration that you have created to access Azure Storage. The Application Id displayed for the App Registration is the Client Id. The Client Secret is the generated key string when a new key is added. This generated key string is available only once when the key is created. If you do not know the generated key string, create another key making sure you capture the generated key string.

The ADL gen2 account name is the account name you generated when you created the Azure ADL gen2 account.

File systems are sub partitions within an Azure Data Lake Gen 2 storage account. You can create and access new file systems on the fly but only if the following Hadoop configuration is set:

```
<property>
<name>fs.azure.createRemoteFileSystemDuringInitialization</name>
<value>true</value>
</property>
```

6. Verify connectivity using Hadoop shell commands.

```
./bin/hadoop fs -ls /
./bin/hadoop fs -mkdir /tmp
```

 Configure either the HDFS Handler or the File Writer Handler using the HDFS Event Handler to push data to Azure Data Lake, see Flat Files. Oracle recommends that you use the File Writer Handler with the HDFS Event Handler.

Setting the gg.classpath example:

```
gg.classpath=/ggwork/hadoop/hadoop-3.3.0/share/hadoop/common/*:/ggwork/
hadoop/hadoop-3.3.0/share/hadoop/common/lib/*:/ggwork/hadoop/hadoop-3.3.0/
share/hadoop/hdfs/*:
/ggwork/hadoop/hadoop-3.3.0/share/hadoop/hdfs/lib/*:/ggwork/hadoop/
hadoop-3.3.0/etc/hadoop/:/ggwork/hadoop/hadoop-3.3.0/share/hadoop/tools/lib/*
```

See https://hadoop.apache.org/docs/current/hadoop-azure-datalake/index.html.

## Azure Data Lake Gen2 using BLOB endpoint

Oracle GoldenGate for Big Data can connect to ADLS Gen2 using BLOB endpoint. Oracle GoldenGate for Big Data ADLS Gen2 replication using BLOB endpoint does not require any Hadoop installation. For more information, see For more information, see Azure Blob Storage.

# Azure Event Hubs

Kafka handler supports connectivity to Microsoft Azure Event Hubs.

To connect to the Microsoft Azure Event Hubs:

- 1. For more information about connecting to Microsoft Azure Event Hubs, see Quickstart: Data streaming with Event Hubs using the Kafka protocol.
- 2. Update the Kafka Producer Configuration file as follows to connect to Micrososoft Azure Event Hubs using Secure Sockets Layer (SSL)/Transport Layer Security (TLS) protocols:

```
bootstrap.servers=NAMESPACENAME.servicebus.windows.net:9093
security.protocol=SASL_SSL
sasl.mechanism=PLAIN
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
required username="$ConnectionString"
password="{YOUR.EVENTHUBS.CONNECTION.STRING}";
```

### See Kafka Producer Configuration File.

Connectivity to the Azure Event Hubs cannot be routed through a proxy server. Therefore, when you run Oracle GoldenGate for Big Data on premise to push data to Azure Event Hubs, you need to open your firewall to allow connectivity.

# Azure Synapse Analytics

Microsoft Azure Synapse Analytics is a limitless analytics service that brings together data integration, enterprise data warehousing and big data analytics.

- Detailed Functionality
- Configuration
- Troubleshooting and Diagnostics

## **Detailed Functionality**

Replication to Synapse uses stage and merge data flow.

The change data is staged in a temporary location in micro-batches and eventually merged into the target table.

Azure Data Lake Storage (ADLS) Gen 2 is used as the staging area for change data.

The Synapse Event handler is used as a downstream Event handler connected to the output of the Parquet Event handler.

The Parquet Event handler loads files generated by the File Writer Handler into ADLS Gen2.

The Synapse Event handler executes SQL statements to merge the operation records staged in ADLS Gen2.

The SQL operations are performed in batches providing better throughput.

Oracle GoldenGate for BigData uses the MERGE SQL statement or a combination of DELETE and INSERT SQL statements to perform the merge operation.

- Database User Privileges
- Merge SQL Statement
- Prerequisites

## Database User Privileges

Database user used for replication has to be granted the following privileges:

- INSERT, UPDATE, DELETE, and TRUNCATE on the target tables.
- CREATE and DROP Synapse external file format.
- CREATE and DROP Synapse external data source.
- CREATE and DROP Synapse external table.

### Merge SQL Statement

The merge SQL statement for Azure Synapse Analytics was made generally available during the later part of the year 2022 and therefore Oracle GoldenGate for Big Data uses merge statement by default. To disable merge SQL, ensure that a Java System property is set in the jvm.bootoptions parameter.

### For example:

jvm.bootoptions=-Dsynapse.use.merge.sql=false

## Prerequisites

The following are the prerequisites:

- Uncompressed UPDATE records: If Oracle GoldenGate is configured to not use merge statement (see Merge SQL Statement), then it is mandatory that the trail files used to apply to Synapse contain uncompressed UPDATE operation records, which means that the UPDATE operations contain full image of the row being updated. If UPDATE records have missing columns, then replicat will ABEND on detecting a compressed UPDATE trail record.
- If Oracle GoldenGate is configured to use merge statement (see Merge SQL Statement), then the target table must be a hash distributed table.
- Target table existence: The target tables should exist on the Synapse database.
- Azure storage account: An Azure storage account and container should exist. Oracle recommends co-locating the Azure Synapse workspace, and the Azure storage account in the same azure region.
- If Oracle GoldenGate is configured to use merge statement, then the target table cannot define IDENTITY columns because Synapse merge statement does not support inserting data into IDENTITY columns. For more information about merging SQL statement, see Merge SQL Statement.

## Configuration

- Automatic Configuration
- Synapse Database Credentials
- Classpath Configuration

- INSERTALLRECORDS Support
- Large Object (LOB) Performance
- End-to-End Configuration

### Automatic Configuration

Synapse replication involves configuration of multiple components, such as File Writer handler, Parquet Event handler, and Synapse Event handler.

The Automatic Configuration functionality helps to auto configure these components so that the user configuration is minimal.

The properties modified by auto configuration will also be logged in the handler log file.

To enable auto-configuration to replicate to Synapse target we need to set the parameter as follows: gg.target=synapse.

When replicating to Synapse target, customization of Parquet Event handler name and Synapse Event handler name is not allowed.

- File Writer Handler Configuration
- Parquet Event Handler Configuration
- Synapse Event Handler Configuration

### File Writer Handler Configuration

File writer handler name is pre-set to the value synapse. The following is an example to edit a property of File Writer handler:

gg.handler.synapse.pathMappingTemplate=./dirout

### Parquet Event Handler Configuration

The Parquet Event Handler name is pre-set to the value parquet. The Parquet Event Handler is auto-configured to write to HDFS. The hadoop configuration file core-site.xml must be configured to write data files to the respective container in the Azure Data Lake Storage(ADLS) Gen2 account. See Azure Data Lake Gen2 using Hadoop Client and ABFS.

The following is an example to edit a property of Parquet Event handler:

gg.eventhandler.parquet.finalizeAction=delete

### Synapse Event Handler Configuration

Synapse Event Handler name is pre-set to the value synapse.

Properties	Required/ Optional	Legal Values	Default	Explanatio n
gg.eventh andler.sy napse.con nectionUR L	Required	<pre>jdbc:sqlserver://<synapse- workspace&gt;.sql.azuresynapse.net: 1433;database= <db-name>;encrypt=true; trustServerCertificate=false; hostNameInCertificate=*.sql.azur esynapse.net; loginTimeout=300;</db-name></synapse- </pre>	None	JDBC URL to connect to Synapse.
gg.eventh andler.sy napse.Use rName	Required	Database username.	None	Synapse database user in the Synapse workspace. The username has to be qualified with the Synapse workspace name. Example: sqladminu ser@synap seworkspa ce.
gg.eventh andler.sy napse.Pas sword	Required	Supported database string.	None	Synapse database password.
gg.eventh andler.sy napse.cre dential	Required	Credential name.	None	Synapse database credential name to access Azure Data Lake Gen2 files. See Synapse Database Credentials for steps to create credential.

Table 9-12	Synanse Event Handler Configuration
Table 8-13	Synapse Event Handler Configuration

Properties	Required/ Optional	Legal Values	Default	Explanatio n
gg.eventh andler.sy napse.max Connnecti ons	Optional	Integer value	10	Use this parameter to control the number of concurrent JDBC database connections to the target Synapse database.
gg.eventh andler.sy napse.dro pStagingT ablesOnSh utdown	Optional	true <b>or</b> false	false	If set to true, the temporary staging tables created by GoldenGate will be dropped on replicat graceful stop.
gg.maxInl ineLobSiz e	Optional	Integer Value	16000	This parameter can be used to set the maximum inline size of large object (LOB) columns in bytes. For more information, see Large Object (LOB) Performance

## Table 8-13 (Cont.) Synapse Event Handler Configuration

Properties	Required/ Optional	Legal Values	Default	Explanatio n
gg.aggreg ate.opera tions.flu sh.interv al	Optional	Integer	30000	The flush interval parameter determines how often the data gets mergeo into Synapse. The value is set in milliseconds Use with caution! The higher the value, larger data will have to be stored in the memory of the Replicat process. Use the flush interva parameter with caution Increasing its default value increases the amount of data stored in the internal memory of the Replicat This can cause out- of-memory errors and stop the Replicat if it runs out of memory.

 Table 8-13
 (Cont.) Synapse Event Handler Configuration

Properties	Required/ Optional	Legal Values	Default	Explanatio n
gg.operat ion.aggre gator.val idate.key update	Optional	true <b>or</b> false	false	If set to true, Operation Aggregator will validate key update operations (optype 115) and correct to normal update if no key values have changed. Compressed key update operations do not qualify for merge.

Table 8-13 (Cont.) Synapse Event Handler Configuration

### Synapse Database Credentials

To allow Synapse to access the data files in Azure Data Lake Gen2 storage account, follow the steps to create a database credential:

- Connect to the respective Synapse SQL dedicated pool using the Azure Web SQL console (https://web.azuresynapse.net/en-us/).
- 2. Create a DB master key if one does not already exist, using your own password.
- Create a database scoped credential. This credential allows Oracle GoldenGate replicat process to access Azure Storage Account.
   Provide the Azure Storage Account name and Access key when creating this credential.

Storage Account Access keys can be retrieved from the Azure cloud console.

#### For example:

```
CREATE MASTER KEY ENCRYPTION BY PASSWORD = 'Your own password';
CREATE DATABASE SCOPED CREDENTIAL OGGBD_ADLS_credential
WITH
-- IDENTITY = '<storage_account_name>',
IDENTITY = 'sanavaccountuseast',
-- SECRET = '<storage_account_key>'
SECRET = 'c8C0yR-this-is-a-fake-access-key-Gc9c5mENOJ1mLyx101vSRD1RG0/
Ke+tbAvi6xe73HAAhLtdMFZRA=='
;
```

## **Classpath Configuration**

Synapse Event handler relies on the upstream File Writer handler and the Parquet Event handler.

Dependencies

Classpath

## Dependencies

 Microsoft SQLServer JDBC driver: The JDBC driver can be downloaded from Maven central using the following co-ordinates.

```
<dependency>
        <groupId>com.microsoft.sqlserver</groupId>
        <artifactId>mssql-jdbc</artifactId>
        <version>8.4.1.jre8</version>
        <scope>provided</scope>
        </dependency>
```

Alternatively, the JDBC driver can also be downloaded using the script <OGGDIR>/ DependencyDownloader/synapse.sh.

Parquet Event handler dependencies: See Parquet Event Handler Configuration to configure classpath to include Parquet dependencies.

#### Classpath

Edit the gg.classpath configuration parameter to include the path to the Parquet Event Handler dependencies and Synapse JDBC driver.

#### For example:

```
gg.classpath=./synapse-deps/mssql-jdbc-8.4.1.jre8.jar:hadoop-3.2.1/share
/hadoop/common/*:hadoop-3.2.1/share/hadoop/common/lib/*:hadoop-3.2.1/share/
hadoop/hdfs/*:hadoop-3.2.1/share/hadoop/hdfs/lib/*:hadoop-3.2.1/etc/hadoop
/:hadoop-3.2.1/share/hadoop/tools/lib/*:/path/to/parquet-deps/*
```

## **INSERTALLRECORDS Support**

Stage and merge targets supports INSERTALLRECORDS parameter.

See INSERTALLRECORDS in *Reference for Oracle GoldenGate*. Set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm). Set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm)

Setting this property directs the Replicat process to use bulk insert operations to load operation data into the target table. You can tune the batch size of bulk inserts using the File Writer property gg.handler.synapse.maxFileSize. The default value is set to 1GB. The frequency of bulk inserts can be tuned using the File Writer property gg.handler.synapse.fileRollInterval, the default value is set to 3m (three minutes).

## Note:

• When using the Synapse internal stage, the staging files can be compressed by setting gg.handler.synapse.putSQLAutoCompress to true.

## Large Object (LOB) Performance

The presence of large object (LOB) columns can impact Replicat's apply performance. Any LOB column changes that exceed the inline threshold gg.maxInlineLobSize does not qualify for batch processing and such operations gets slower.

If the compute machine has sufficient RAM, you can increase this parameter to speed up processing.

## End-to-End Configuration

The following is an end-end configuration example which uses auto-configuration for FW handler, Parquet and Synapse Event handlers.

This sample properties file can also be found in the directory AdapterExamples/big-data/ synapse/synapse.props:

```
# Configuration to load GoldenGate trail operation records
# into Azure Synapse Analytics by chaining
# File writer handler -> Parquet Event handler -> Synapse Event handler.
# Note: Recommended to only edit the configuration marked as TODO
gg.target=synapse
#The Parquet Event Handler
# No properties are required for the Parquet Event handler. Configure core-site.xml to
point to ADLS Gen2.
#gg.eventhandler.parquet.finalizeAction=delete
#The Synapse Event Handler
#TODO: Edit JDBC ConnectionUrl
gg.eventhandler.synapse.connectionURL=jdbc:sqlserver://<synapse-
workspace>.sql.azuresynapse.net:1433;database=<db-
name>;encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.sql.azuresynaps
e.net;loginTimeout=300;
#TODO: Edit JDBC user name
gg.eventhandler.synapse.UserName=<db user name>@<synapse-workspace>
#TODO: Edit JDBC password
gg.eventhandler.synapse.Password=<db password>
#TODO: Edit Credential to access Azure storage.
gg.eventhandler.synapse.credential=OGGBD ADLS credential
#TODO: Edit the classpath to include Parquet Event Handler dependencies and Synapse
JDBC driver.
gg.classpath=./synapse-deps/mssql-jdbc-8.4.1.jre8.jar:hadoop-3.2.1/share/hadoop/common/
*:hadoop-3.2.1/share/hadoop/common/lib/*:hadoop-3.2.1/share/hadoop/hdfs/*:hadoop-3.2.1/
share/hadoop/hdfs/lib/*:hadoop-3.2.1/etc/hadoop/:hadoop-3.2.1/share/hadoop/
tools/lib/*:/path/to/parquet-deps/*
#TODO: Provide sufficient memory (at least 8GB).
jvm.bootoptions=-Xmx8g -Xms8g
```

## Troubleshooting and Diagnostics

- Connectivity Issues to Synapse:
  - Validate JDBC connection URL, username and password.
  - Check if http/https proxy is enabled. Synapse does not support connections over http(s) proxy.

- DDL not applied on the target table: Oracle GoldenGate for BigData does not support DDL replication.
- **Target table existence**: It is expected that the Synapse target table exists before starting the replicat process. replicat process will ABEND if the target table is missing.
- SQL Errors: In case there are any errors while executing any SQL, the entire SQL statement along with the bind parameter values are logged into the OGGBD handler log file.
- **Co-existence of the components**: The location/region of the machine where replicat process is running, Azure Data Lake Storage container region and the Synapse region would impact the overall throughput of the apply process. Data flow is as follows: Oracle GoldenGate -> Azure Data Lake Gen 2 -> Synapse. For best throughput, the components need to located as close as possible.
- Replicat ABEND due to partial LOB records in the trail file: Oracle GoldenGate for Big Data Synapse apply does not support replication of partial LOB. The trail file needs to be regenerated by Oracle Integrated capture using TRANLOGOPTIONS FETCHPARTIALLOB option in the extract parameter file.
- Error:com.microsoft.sqlserver.jdbc.SQLServerException: Conversion failed when converting date and/or time from character string: This occurs when the source datetime column and target datetime column are incompatible.

For example: A case where the source column is a timestamp type, and the target column is Synapse time.

- If the Synapse table or column names contain double quotes, then Oracle GoldenGate for Big Data replicat will ABEND.
- Error: com.microsoft.sqlserver.jdbc.SQLServerException: HdfsBridge::recordReaderFillBuffer. This indicates that the data in the external table backed by Azure Data Lake file is not readable. Contact Oracle support.
- IDENTITY column in the target table: The Synapse MERGE statement does not support inserting data into IDENTITY columns. Therefore, if MERGE statement is enabled using jvm.bootoptions=-Dsynapse.use.merge.sql=true, then Replicat will ABEND with following error message: Exception:

com.microsoft.sqlserver.jdbc.SQLServerException: Cannot update
identity column 'ORDER ID'

• Error: com.microsoft.sqlserver.jdbc.SQLServerException: Merge statements with a WHEN NOT MATCHED [BY TARGET] clause must target a hash distributed table:

This indicates that merge SQL statement is on and Synapse target table is not a hash distributed table. You need to create the target table with a hash distribution.

## Confluent Kafka

 Confluent is a primary adopter of Kafka Connect and their Confluent Platform offering includes extensions over the standard Kafka Connect functionality. This

includes Avro serialization and deserialization, and an Avro schema registry. Much of the Kafka Connect functionality is available in Apache Kafka.

- You can use Oracle GoldenGate for Big Data Kafka Connect Handler to replicate to Confluent Kafka. The Kafka Connect Handler is a Kafka Connect source connector. You can capture database changes from any database supported by Oracle GoldenGate and stream that change of data through the Kafka Connect layer to Kafka.
- Kafka Connect uses proprietary objects to define the schemas (org.apache.kafka.connect.data.Schema) and the messages (org.apache.kafka.connect.data.Struct). The Kafka Connect Handler can be configured to manage what data is published and the structure of the published data.
- The Kafka Connect Handler does not support any of the pluggable formatters that are supported by the Kafka Handler.

## DataStax

Datastax Enterprise is a NoSQL database built on Apache Cassandra. For more information, see Apache Cassandrafor configuring replication to Datastax Enterprise.

## Elasticsearch

- Elasticsearch with Elasticsearch 7x and 6x
   The Elasticsearch Handler allows you to store, search, and analyze large volumes of
- data quickly and in near real time.
  Elasticsearch 8x The Elasticsearch Handler allows you to store, search, and analyze large volumes of data quickly and in near real time.

## Elasticsearch with Elasticsearch 7x and 6x

The Elasticsearch Handler allows you to store, search, and analyze large volumes of data quickly and in near real time.

This article describes how to use the Elasticsearch handler.

## Note:

This section on the Elasticsearch Handler pertains to Oracle GoldenGate for Big Data versions 21.9.0.0.0 and before. Starting with Oracle GoldenGate for Big Data 21.10.0.0.0, the Elasticsearch client was changed in order to support Elasticsearch 8.x.

- Overview
- Detailing the Functionality
- Setting Up and Running the Elasticsearch Handler
- Troubleshooting
- Performance Consideration
- About the Shield Plug-In Support

- About DDL Handling
- Known Issues in the Elasticsearch Handler
- Elasticsearch Handler Transport Client Dependencies What are the dependencies for the Elasticsearch Handler to connect to Elasticsearch databases?
- Elasticsearch High Level REST Client Dependencies

## Overview

Elasticsearch is a highly scalable open-source full-text search and analytics engine. Elasticsearch allows you to store, search, and analyze large volumes of data quickly and in near real time. It is generally used as the underlying engine or technology that drives applications with complex search features.

The Elasticsearch Handler uses the Elasticsearch Java client to connect and receive data into Elasticsearch node, see https://www.elastic.co.

## Detailing the Functionality

This topic details the Elasticsearch Handler functionality.

- About the Elasticsearch Version Property
- About the Index and Type
- About the Document
- About the Primary Key Update
- About the Data Types
- Operation Mode
- Operation Processing Support
- About the Connection

## About the Elasticsearch Version Property

The Elasticsearch Handler supports two different clients to communicate with the Elasticsearch cluster: The Elasticsearch transport client and the Elasticsearch High Level REST client.

Elasticsearch Handler can also be configured for the two supported clients by specifying the appropriate version of Elasticsearch handler properties file. Older version of Elasticsearch (6.x) supports only Transport client and the Elasticsearch handler can be configured by setting the configurable property version value to 6.x. For the latest version of Elasticsearch (7.x), both the Transport client and the High Level REST client are supported. Therefore, in the latest version, the Elasticsearch Handler can be configured for Transport client by setting the value of configurable property version to 7.x and High Level REST client by setting the value to Rest7.x.

The configurable parameters for each of them are as follows:

1. Set the gg.handler.name.version configuration value to 6.x or 7.x to connect to the Elasticsearch cluster using the transport client using the respective version.

2. Set the gg.handler.name.version configuration value to REST7.0 to connect to the Elasticseach cluster using the Elasticsearch High Level REST client. The REST client support Elasticsearch versions 7.x.

## About the Index and Type

An Elasticsearch **index** is a collection of documents with similar characteristics. An index can only be created in lowercase. An Elasticsearch **type** is a logical group within an index. All the documents within an index or type should have same number and type of fields.

The Elasticsearch Handler maps the source trail schema concatenated with source trail table name to construct the index. For three-part table names in source trail, the index is constructed by concatenating source catalog, schema, and table name.

The Elasticsearch Handler maps the source table name to the Elasticsearch type. The type name is case-sensitive.

## Note:

Elasticsearch field names are case sensitive. If the field name in the data to be either updated or inserted are in uppercase and the existing fields in Elasticsearch server are in lowercase, then they are treated as new fields and not updated as existing fields. The workaround for this is using the parameter gg.schema.normalize=lowercase, which will update the field name to lowercase, thus resolving the issue.

Table 8-14	Elasticsearch Mapping
------------	-----------------------

Source Trail	Elasticsearch Index	Elasticsearch Type
schema.tablename	schema_tablename	tablename
catalog.schema.tablename	catalog_schema_tablename	tablename

If an index does not already exist in the Elasticsearch cluster, a new index is created when Elasticsearch Handler receives (INSERT or UPDATE operation in source trail) data.

## About the Document

An Elasticsearch document is a basic unit of information that can be indexed. Within an index or type, you can store as many documents as you want. Each document has an unique identifier based on the id field.

The Elasticsearch Handler maps the source trail primary key column value as the document identifier.

## About the Primary Key Update

The Elasticsearch document identifier is created based on the source table's primary key column value. The document identifier cannot be modified. The Elasticsearch handler processes a source primary key's update operation by performing a DELETE followed by an INSERT. While performing the INSERT, there is a possibility that the new document may contain fewer fields than required. For the INSERT operation to contain all the fields in the source table, enable trail Extract to capture the full data before images for update operations or use GETBEFORECOLS to write the required column's before images.

## About the Data Types

Elasticsearch supports the following data types:

- 32-bit integer
- 64-bit integer
- Double
- Date
- String
- Binary

## **Operation Mode**

The Elasticsearch Handler uses the operation mode for better performance. The gg.handler.name.mode property is not used by the handler.

## **Operation Processing Support**

The Elasticsearch Handler maps the source table name to the Elasticsearch type. The type name is case-sensitive.

For three-part table names in source trail, the index is constructed by concatenating source catalog, schema, and table name.

#### INSERT

The Elasticsearch Handler creates a new index if the index does not exist, and then inserts a new document.

#### UPDATE

If an Elasticsearch index or document exists, the document is updated. If an Elasticsearch index or document does not exist, a new index is created and the column values in the UPDATE operation are inserted as a new document.

#### DELETE

If an Elasticsearch index or document exists, the document is deleted. If Elasticsearch index or document does not exist, a new index is created with zero fields.

The TRUNCATE operation is not supported.

#### About the Connection

A **cluster** is a collection of one or more nodes (servers) that holds the entire data. It provides federated indexing and search capabilities across all nodes.

A **node** is a single server that is part of the cluster, stores the data, and participates in the cluster's indexing and searching.

The Elasticsearch Handler property gg.handler.name.ServerAddressList can be set to point to the nodes available in the cluster.

## Setting Up and Running the Elasticsearch Handler

You must ensure that the Elasticsearch cluster is setup correctly and the cluster is up and running, see <a href="https://www.elastic.co/guide/en/elasticsearch/reference/current/index.html">https://www.elastic.co/guide/en/elasticsearch/reference/current/index.html</a>. Alternatively, you can use Kibana to verify the setup.

#### Set the Classpath

The property gg.classpath must include all the jars required by the Java transport client. For a listing of the required client JAR files by version, see Elasticsearch Handler Transport Client Dependencies. For a listing of the required client JAR files for the Elatisticsearch High Level REST client, see Elasticsearch High Level REST Client Dependencies.

The inclusion of the \* wildcard in the path can include the \* wildcard character in order to include all of the JAR files in that directory in the associated classpath. Do not use \*.jar.

The following is an example of the correctly configured classpath:

gg.classpath=Elasticsearch\_Home/lib/\*

Configuring the Elasticsearch Handler

## Configuring the Elasticsearch Handler

Elasticsearch Handler can be configured for different version of Elasticsearch. For the latest version (7.x), two types of clients are supported: the Transport client and High-level REST client. When the configurable property version is set to the values 6.x or 7.x it uses Elasticsearch Transport client for connecting and performing all other operations of handler to Elasticsearch cluster. When the configurable property version is set to rest7.x, it uses Elasticsearch High Level REST client for connecting and performing other operations of handler to Elasticsearch 7.x cluster. The configurable parameters for each of them are separately given below:

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handlerlist	Required	Name (Any name of your choice for handler)	None	The list of handlers to be used.
gg.handler. <nam e&gt;.type</nam 	Required	elasticsearch	None	Type of handler to use. For example, Elasticsearch, Kafka, or Flume.
gg.handler.name .ServerAddressL ist	Optional	Server:Port[, Server:Port]	<ul> <li>localhost:9300 (for Transport Client)</li> <li>localhost:9200 (for High-Level REST Client)</li> </ul>	Comma separated list of contact points of the nodes. The allowed port for version REST7.x is 9200. For other version, it is 9300.

## Table 8-15 Common Configurable Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name</i> .version	Required	5.x 6.x 7.x  REST7.x	7.x	The version values 5.x, 6.x, and 7.x indicate using the Elasticsearch Transport client to communicate with Elasticsearch version 5.x, 6.x and 7.x respectively. The version REST7.x indicates using the Elasticsearch High Level REST client to communicate with Elasticsearch version 7.x.
gg.handler.name .version gg.handler.name .bulkWrite	Optional	true   false	false	When this property is true, the Elasticsearch Handler uses the bulk write API to ingest data into Elasticsearch cluster. The batch size of bulk write can be controlled using the MAXTRANSOPS Replicat parameter.
gg.handler. <i>name</i> .numberAsString	Optional	true   false	false	When this property is true, the Elasticsearch Handler receives all the number column values (Long, Integer, or Double) in the source trail as strings into the Elasticsearch cluster.
gg.handler.elas ticsearch.upser t	Optional	true   false	true	When this property is true, a new document is inserted if the document does no already exist when performing an UPDATE operation.

Table 8-15	(Cont.) Common Configurable Properties
	(cond) common comganasie i roperties

#### Example 8-1 Sample Handler Properties file:

Sample Replicat configuration and a Java Adapter Properties files can be found at the following directory:

#### **Common Configurable Properties**

The common configurable properties that are applicable for all the versions of Elasticsearch and applicable for both Transport client as well as High Level REST client of Elasticsearch handler are as shown in the following table:

Table 8-16	<b>Common Configurable Properties</b>
------------	---------------------------------------

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handlerlist	Required	Name (Any name of your choice for handler)	None	The list of handlers to be used.
gg.handler. <nam e&gt;.type</nam 	Required	elasticsearch	None	Type of handler to use. For example, Elasticsearch, Kafka, or Flume.
gg.handler.name .ServerAddressL ist	•	Server:Port[, Server:Port …]	<ul> <li>localhost:9300 (for Transport Client)</li> <li>localhost:9200 (for High-Level REST Client)</li> </ul>	list of contact points of the nodes. The allowed

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name</i> .version	Required	6.x 7.x REST7.x	7.x	The version values 6.x, and 7.x indicate using the Elasticsearch Transport client to communicate with Elasticsearch version 6.x and 7.x respectively. The version REST7.x indicates using the Elasticsearch High Level REST client to communicate with Elasticsearch version 7.x.
gg.handler.name .version gg.handler.name .bulkWrite	Optional	true   false	false	When this property is true, the Elasticsearch Handler uses the bulk write API to ingest data into Elasticsearch cluster. The batch size of bulk write can be controlled using the MAXTRANSOPS Replicat parameter.
gg.handler. <i>name</i> .numberAsString	Optional	true   false	false	When this property is true, the Elasticsearch Handler receives all the number column values (Long, Integer, or Double) in the source trail as strings into the Elasticsearch cluster.
gg.handler.elas ticsearch.upser t	Optional	true   false	true	When this property is true, a new document is inserted if the document does no already exist when performing an UPDATE operation.

Table 8-16	(Cont.) Common Configurable Properties
	(cond) continen congurable i reperties

#### **Transport Client Configurable Properties**

When the configurable property version is set to the value 6.x or 7.x, it uses Transport client to communicate with the corresponding version of Elasticsearch cluster. The configurable properties applicable when using Transport client only are as follows:

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .clientSettings File	Required	Transport client properties file.	None	The filename in classpath that holds Elasticsearch transport client properties used by the Elasticsearch Handler.

## Table 8-17 Transport Client Configurable Properties

Copygg.handlerlist=elasticsearch

gg.handler.elasticsearch.type=elasticsearch
gg.handler.elasticsearch.ServerAddressList=localhost:9300
gg.handler.elasticsearch.clientSettingsFile=client.properties
gg.handler.elasticsearch.version=[6.x | 7.x]
gg.classpath=/path/to/elastic/lib/\*:/path/to/elastic/modules/transport-netty4/\*:/
path/to/elastic/modules/reindex/\*: /path/to/elastic/plugins/x-pack/\*:

#### Transport Client Setting Properties File

The Elasticsearch Handler uses a Java Transport client to interact with Elasticsearch cluster. The Elasticsearch cluster may have additional plug-ins like shield or x-pack, which may require additional configuration.

The gg.handler.name.clientSettingsFile property should point to a file that has additional client settings based on the version of Elasticsearch cluster.

The Elasticsearch Handler attempts to locate and load the client settings file using the Java classpath. The Java classpath must include the directory containing the properties file. The client properties file for Elasticsearch (without any plug-in) is: cluster.name=Elasticsearch cluster name.

The Shield plug-in also supports additional capabilities like SSL and IP filtering. The properties can be set in the client.properties file, see https://www.elastic.co/guide/en/shield/current/\_using\_elasticsearch\_java\_clients\_with\_shield.html.

Example of client.properties file for Elasticsearch Handler with X-Pack plug-in:

Copycluster.name=Elasticsearch\_cluster\_name xpack.security.user=x-pack username:x-pack-password

The X-Pack plug-in also supports additional capabilities. The properties can be set in the client.properties file, see

https://www.elastic.co/guide/en/elasticsearch/client/java-api/5.1/transport-client.html and https://www.elastic.co/guide/en/x-pack/current/java-clients.html

#### **Classpath Settings for Transport Client**

The gg.classpath setting for Elasticsearch handler with Transport client should contain the path to jars from library (lib) and modules (transport-netty4 and reindex modules) folder inside Elasticsearch installation directory. If x-pack plugin is used for authentication purpose, then

the classpath should also include the jars inside the plugins (x-pack) folder inside Elasticsearch installation directory. See the path for jars as follows:

```
.
.
. [path/to/elastic/lib/*]
2. [/path/to/elastic/modules/transport-netty4/*]
3. [/path/to/elastic/modules/reindex/*]
4. [/path/to/elastic/plugins/x-pack/*] 
    This needs to be added only if x-
pack plugin is configured in Elasticsearch
```

#### **REST Client Configurable Properties**

When the configurable property version is set to value rest7.x, the handler uses Elasticsearch High Level REST client to connect to Elasticsearch 7.x cluster. The configurable properties that are supported for REST client only are as follows:

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.el asticsearch.r outingTemplat e	Optional	<pre>\$ {columnValue[ table1=column 1,table2=colu mn2,]</pre>	None	The template to be used for deciding the routing algorithm
gg.handler.na me.authType	Optional	none   basic   ssl	None	Controls the authentication type for the Elasticsearch REST client. • none - No authentication n • basic - Client authentication n using username and password without message encrytption. • ssl - Mutua authentication n. Client authenticate the server using a trust store. Serve authentication n client using username and password. Messages are encrypted.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.na me.authType gg.handler.na me.basicAuthU sername	Required (for auth-type basic.)	A valid username	None	The username for the server to authenticate the Elasticsearch REST client. Must be provided for auth types basic.
gg.handler.na me.basicAuthP assword	Required (for auth-type basic.)	A valid password	None	The password for the server to authenticate the Elasticsearch REST client. Must be provided for auth types basic.
gg.handler.na me.trustStore	Required (for auth-type SSL)	The fully qualified name (path + name) of trust- store file	None	The truststore for the Elasticsearch client to validate the certificate received from the Elasticsearch server. Must be provided if the auth type is set to ssl. Valid only for the Elasticsearch REST client
gg.handler.na me.trustStore Password	Required (for auth-type SSL)	A valid trust-store Password	None	The password for the truststore for the Elasticsearch REST client to validate the certificate received from the Elasticsearch server. Must be provided if the auth type is set to ssl.
gg.handler.na me.maxConnect Timeout	Optional	Positive integer	Default value of Apache HTTP Components framework.	Set the maximum wait period for a connection to be established from the Elasticsearch REST client to the Elasticsearch server. Valid only for the Elasticsearch REST client.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.na me.maxSocketT imeout	Optional	Positive Integer	Default value of Apache HTTP Components framework.	Sets the maximum wait period in milliseconds to wait for a response from the service after issuing a reques May need to be increased when pushing large data volumes. Valid only for the Elasticsearch REST client.
gg.handler.na me.proxyUsern ame	Optional	The proxy server username	None	If the connectivit to the Elasticsearch uses the REST client and routin through a proxy server, then this property sets the username of you proxy server. Most proxy servers do not require credentials.
gg.handler.na me.proxyPassw ord	Optional	The proxy server password	None	If the connectivit to the Elasticsearch uses the REST client and routin through a proxy server, then this property sets the password of you proxy server. Most proxy servers do not require credentials.
gg.handler.na me.proxyProto col	Optional	http   https	None	If the connectivit to the Elasticsearch uses the REST client and routin through a proxy server, then this property sets th protocol of your proxy server.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.na me.proxyPort	Optional	The port number of your proxy server.	None	If the connectivity to the Elasticsearch uses the REST client and routing through a proxy server, then this property sets the port number of your proxy server.
gg.handler.na me.proxyServe r	Optional	The host name of your proxy server.	None	If the connectivity to the Elasticsearch uses the REST client and routing through a proxy server, then this property sets the host name of your proxy server.

#### Sample Properties for Elasticsearch Handler using REST Client

```
gg.handlerlist=elasticsearch
```

```
\verb"gg.handler.elasticsearch.type=elasticsearch"
```

```
gg.handler.elasticsearch.ServerAddressList=localhost:9200
```

```
gg.handler.elasticsearch.version=rest7.x
```

```
gg.classpath=/path/to/elasticsearch/lib/*:/path/to/elasticsearch/modules/reindex/*:/
path/to/elasticsearch/modules/lang-mustache/*:/path/to/elasticsearch/modules/rank-
eval/*
```

#### Authentication for REST Client

The configurable property auth-type value SSL can be used to configure the SSL authentication mechanism for communicating with Elasticsearch cluster. This property can also be used to configure the basic authentication with SSL by providing configurable property basic username/password along with the trust-store properties.

#### Classpath Settings for REST Client

The Classpath for High Level REST client must contain the jars from the library (lib) folder and modules folders (reindex, lang-mustache and ran-eval) inside the Elasticsearch installation directory. The REST client are dependent on these libraries and should be included in gg.classpath for the handler to work. Following are the list of dependencies:

- 1. [/path/to/elasticsearch/lib/\*]
- 2. [/path/to/elasticsearch/modules/reindex/\*]
- 3. [/path/to/elasticsearch/modules/lang-mustache/\*]
- 4. [/path/to/elasticsearch/modules/rank-eval/\*]

## Troubleshooting

This section contains information to help you troubleshoot various issues.

#### **Transport Client Properties File Not Found**

This is applicable for Transport Client only when the property version is set to 6.x or 7.x.

#### Error:

```
ERROR 2017-01-30 22:33:10,058 [main] Unable to establish connection. Check handler properties and client settings configuration.
```

To resolve this exception, verify that the gg.handler.name.clientSettingsFile configuration property is correctly setting the Elasticsearch transport client settings file name. Verify that the gg.classpath variable includes the path to the correct file name and that the path to the properties file does not contain an asterisk (\*) wildcard at the end.

- Incorrect Java Classpath
- Elasticsearch Version Mismatch
- Transport Client Properties File Not Found
- Cluster Connection Problem
- Unsupported Truncate Operation
- Bulk Execute Errors

#### Incorrect Java Classpath

The most common initial error is an incorrect classpath to include all the required client libraries and creates a ClassNotFound exception in the log4j log file.

Also, it may be due to an error resolving the classpath if there is a typographic error in the gg.classpath variable.

The Elasticsearch transport client libraries do not ship with the Oracle GoldenGate for Big Data product. You should properly configure the gg.classpath property in the Java Adapter Properties file to correctly resolve the client libraries, see Setting Up and Running the Elasticsearch Handler.

## Elasticsearch Version Mismatch

The Elasticsearch Handler gg.handler.name.version property must beset to one of the following values: 6.x, 7.x or REST7.x to match the major version number of the Elasticsearch cluster. For example, gg.handler.name.version=7.x.

The following errors may occur when there is a wrong version configuration:

Error: NoNodeAvailableException[None of the configured nodes are available:]

ERROR 2017-01-30 22:35:07,240 [main] Unable to establish connection. Check handler properties and client settings configuration.

java.lang.IllegalArgumentException: unknown setting [shield.user]

Ensure that all required plug-ins are installed and review documentation changes for any removed settings.

## Transport Client Properties File Not Found

#### To resolve this exception:

ERROR 2017-01-30 22:33:10,058 [main] Unable to establish connection. Check handler properties and client settings configuration.

Verify that the gg.handler.name.clientSettingsFile configuration property is correctly setting the Elasticsearch transport client settings file name. Verify that the gg.classpath variable includes the path to the correct file name and that the path to the properties file does not contain an asterisk (\*) wildcard at the end.

#### **Cluster Connection Problem**

This error occurs when the Elasticsearch Handler is unable to connect to the Elasticsearch cluster:

Error: NoNodeAvailableException[None of the configured nodes are available:]

Use the following steps to debug the issue:

- **1**. Ensure that the Elasticsearch server process is running.
- 2. Validate the cluster.name property in the client properties configuration file.
- **3.** Validate the authentication credentials for the x-Pack or Shield plug-in in the client properties file.
- 4. Validate the gg.handler.name.ServerAddressList handler property.

## **Unsupported Truncate Operation**

The following error occurs when the Elasticsearch Handler finds a TRUNCATE operation in the source trail:

oracle.goldengate.util.GGException: Elasticsearch Handler does not support the operation: TRUNCATE

This exception error message is written to the handler log file before the RAeplicat process abends. Removing the GETTRUNCATES parameter from the Replicat parameter file resolves this error.

## **Bulk Execute Errors**

....

```
DEBUG [main] (ElasticSearch5DOTX.java:130) - Bulk execute status: failures:
[true] buildFailureMessage:[failure in bulk execution: [0]: index
[cs2cat_slsch_n1tab], type [N1TAB], id [83], message
[RemoteTransportException[[U0vac81][127.0.0.1:9300][indices:data/write/
bulk[s][p]]]; nested: EsRejectedExecutionException[rejected execution of
org.elasticsearch.transport.TransportService$7@43eddfb2 on
EsThreadPoolExecutor[bulk, queue capacity = 50,
org.elasticsearch.common.util.concurrent.EsThreadPoolExecutor@5ef5f412[Runnin
```

```
g, pool size = 4, active threads = 4, queued tasks = 50, completed
tasks = 84]]];]
```

It may be due to the Elasticsearch running out of resources to process the operation. You can limit the Replicat batch size using MAXTRANSOPS to match the value of the thread pool.bulk.queue size Elasticsearch configuration parameter.

## Note:

Changes to the Elasticsearch parameter, thread\_pool.bulk.queue\_size, are effective only after the Elasticsearch node is restarted.

## Performance Consideration

The Elasticsearch Handler gg.handler.name.bulkWrite property is used to determine whether the source trail records should be pushed to the Elasticsearch cluster one at a time or in bulk using the bulk write API. When this property is **true**, the source trail operations are pushed to the Elasticsearch cluster in batches whose size can be controlled by the MAXTRANSOPS parameter in the generic Replicat parameter file. Using the bulk write API provides better performance.

Elasticsearch uses different thread pools to improve how memory consumption of threads are managed within a node. Many of these pools also have queues associated with them, which allow pending requests to be held instead of discarded.

For bulk operations, the default queue size is 50 (in version 5.2) and 200 (in version 5.3).

To avoid bulk API errors, you must set the Replicat MAXTRANSOPS size to match the bulk thread pool queue size at a minimum. The configuration thread\_pool.bulk.queue\_size property can be modified in the elasticsearch.yaml file.

## About the Shield Plug-In Support

Elasticsearch versions 6.*x* and 7.*x* (X-Pack plug-in for Elasticsearch 6.*x* and 7.*x*) support a Shield plug-in which provides basic authentication, SSL and IP filtering. Similar capabilities exist in the X-Pack plug-in for Elasticsearch 6.*x* and 7.*x*. The additional transport client settings can be configured in the Elasticsearch Handler using the gg.handler.name.clientSettingsFile property.

## About DDL Handling

The Elasticsearch Handler does not react to any DDL records in the source trail. Any data manipulation records for a new source table results in auto-creation of index or type in the Elasticsearch cluster.

## Known Issues in the Elasticsearch Handler

#### Elasticsearch: Trying to input very large number

Very large numbers result in inaccurate values with Elasticsearch document. For example, 9223372036854775807, -9223372036854775808. This is an issue with the Elasticsearch server and not a limitation of the Elasticsearch Handler.

The workaround for this issue is to ingest all the number values as strings using the gg.handler.name.numberAsString=true property.

#### Elasticsearch: Issue with index

The Elasticsearch Handler is not able to input data into the same index if there are more than one table with similar column names and different column data types.

Index names are always lowercase though the catalog/schema/tablename in the trail may be case-sensitive.

## Elasticsearch Handler Transport Client Dependencies

What are the dependencies for the Elasticsearch Handler to connect to Elasticsearch databases?

The maven central repository artifacts for Elasticsearch databases are:

Maven groupId: org.elasticsearch.client

Maven atifactId: transport

Maven groupId: org.elasticsearch.client

Maven atifactId: x-pack-transport

## Elasticsearch High Level REST Client Dependencies

The maven coordinates for the Elasticsearch High Level REST client are:

Maven groupId: org.elasticsearch.client

Maven atifactId: elasticsearch-rest-high-level-client

Maven version: 7.13.3

## Note:

Ensure not to mix the versions in the jar files dependency stack for the Elasticsearch High Level REST Client. Mixing versions results in dependency conflicts.

## Elasticsearch 8x

The Elasticsearch Handler allows you to store, search, and analyze large volumes of data quickly and in near real time.

This article describes how to use the Elasticsearch handler (starting Oracle GoldenGate for Big Data 21.10.0.0). In Oracle GoldenGate for Big Data version 21.10.0.0, the Elasticsearch handler was modified to support a new Elasticsearch client. The new client supports Elasticsearch 8.x.

- Setting Up the Elasticsearch Handler
- Elasticsearch Handler Configuration
- Enabling Security for Elasticsearch

The Elasticsearch cluster must be accessed in secured manner in production environment. Security features must be first enabled in Elasticsearch cluster and those security configurations must be added to Elasticsearch handler properties file

Security Configuration for Elasticsearch Cluster

The latest version of Elasticsearch has the security auto-configured when it is installed and started. The logs will print security details for auto-configured cluster as follows:

- Security Configuration for Elasticsearch Handler
- Troubleshooting
- Elasticsearch Handler Client Dependencies What are the dependencies for the Elasticsearch Handler to connect to Elasticsearch databases?

## Overview

Elasticsearch is a highly scalable open-source full-text search and analytics engine. Elasticsearch allows you to store, search, and analyze large volumes of data quickly and in near real time. It is generally used as the underlying engine or technology that drives applications with complex search features.

The Elasticsearch Handler uses the Elasticsearch Java client to connect and receive data into Elasticsearch node, see https://www.elastic.co.

## Detailing the Functionality

This topic details the Elasticsearch Handler functionality.

## About the Index

An Elasticsearch **index** is a collection of documents with similar characteristics. An index can only be created in lowercase. An Elasticsearch **type** is a logical group within an index. All the documents within an index or type should have same number and type of fields. Index in Elasticsearch is equivalent to table in RDBMS.

For three-part table names in source trail, the index is constructed by concatenating source catalog, schema, and table name. The Elasticsearch Handler maps the source trail schema concatenated with source trail table name to construct the index when there is no catalog in source table.

## Table 8-18 Elasticsearch Mapping

Source Trail	Elasticsearch Index
schema.tablename	schema_tablename
catalog.schema.tablename	catalog_schema_tablename

If an index does not already exist in the Elasticsearch cluster, a new index is created when Elasticsearch Handler receives (INSERT or UPDATE operation in source trail) data.

If Handler receives DELETE operation in source trail but the index does not exist in Elasticsearch cluster, then the handler will ABEND.

## About the Document

An Elasticsearch document is a basic unit of information that can be indexed. Within an index or type, you can store as many documents as you want. Each document has an unique identifier based on the id field.

If Handler receives DELETE operation in source trail but the index does not exist in Elasticsearch cluster, then the handler will ABEND.

## About the Data Types

Elasticsearch supports the following data types:

- 32-bit integer
- 64-bit integer
- Double
- Date
- String
- Binary

## About the Connection

A **cluster** is a collection of one or more nodes (servers) that holds the entire data. It provides federated indexing and search capabilities across all nodes.

A **node** is a single server that is part of the cluster, stores the data, and participates in the cluster's indexing and searching.

The Elasticsearch Handler property gg.handler.name.ServerAddressList can be set to point to the nodes available in the cluster.

Elasticsearch Handler uses the Java API client to connect to Elasticsearch cluster nodes configured in above handler property via http/https protocol, even though the cluster nodes internally communicate with each other using transport layer protocol.

Port for http/https must be configured in handler property (instead of transport port) for connection via Elasticsearch client.

## About Supported Operation

The Elasticsearch Handler supports the following operations for replication to Elasticsearch cluster in the target.

#### INSERT

The Elasticsearch Handler creates a new index if the index does not exist, and then inserts a new document. If the  $_id$  is already present, it overwrites (replaces) the existing record with new record with same id.

#### UPDATE

If an Elasticsearch index or document exists, the document is updated. If an Elasticsearch index or document does not exist, then a new index is created and the column values in the UPDATE operation are inserted as a new document.

## DELETE

If an Elasticsearch index or \_id of document exists, then the document is deleted. If \_id of document does not exist, then it continues without doing anything. If Elasticsearch index is missing, then it will ABEND the handler.

The TRUNCATE operation is not supported.

## About DDL Handling

The Elasticsearch Handler does not react to any DDL records in the source trail. Any data manipulation records for a new source table results in auto-creation of index or type in the Elasticsearch cluster.

## About the Primary Key Update

The Elasticsearch document identifier is created based on the source table's primary key column value. The document identifier cannot be modified.

The Elasticsearch handler processes a source primary key's update operation by performing a DELETE followed by an INSERT. While performing the INSERT, there is a possibility that the new document may contain fewer fields than required.

For the INSERT operation to contain all the fields in the source table, enable trail Extract to capture the full data before images for update operations or use GETBEFORECOLS to write the required column's before images.

## About UPSERT

The Elasticsearch handler supports UPSERT mode for UPDATE operations. This mode can be enabled by setting the Elasticsearch handler property gg.handler.name.upsert as true. This is enabled by default.

The UPSERT mode ensures that for an UPDATE operation from source trail, if the index or the \_id of document is missing from Elasticsearch cluster, it will create the index and convert the operation to INSERT for adding it as a new record.

Elasticsearch Handler will ABEND for same scenario when UPSERT is false.

In future releases, this mechanism will be enhanced to be in line with HANDLECOLLISION mode Oracle GoldenGate where:

- An insert collision should result in duplicate error.
- A missing update or delete should result in not found error.

The corresponding error codes will be returned back to replicat and handled by it as per Oracle GoldenGate handle collision strategy.

## About Bulk Write

The Elasticsearch handler supports bulk operation mode where multiple operations can be grouped into a batch and whole batch can be applied to target Elasticsearch cluster in one shot. This improves the performance.

Bulk mode can be enabled by setting the value of Elasticsearch handler property gg.handler.name.bulkWrite as true. It is disabled by default.

Bulk mode has a few limitations. If there is any failure (exception thrown) for an operation in bulk, it can result in inconsistent data at target. For example, a delete operation where the index is missing from the target Elasticsearch cluster, it will result in exception. If such an operation is part of a batch in bulk mode, then the batch is not applied after the failure of that operation, resulting in inconsistency.

To avoid bulk API errors, you must set the handler MAXTRANSOPS size to match the bulk thread pool queue size at a minimum.

The configuration thread\_pool.bulk.queue\_size property can be modified in the elasticsearch.yaml file.

## About Routing

A document is routed to a particular shard in an index using the \_routing value. The default \_routing value is the document's \_id field. Custom routing patterns can be implemented by specifying a custom routing value per document.

Elasticsearch Handler supports custom routing by specifying the mapping field key in the property gg.handler.name.routingKeyMappingTemplate of Elasticsearch handler properties file.

## About Request Headers

Elasticsearch allows sending additional request headers (header name and value pair) along with the http requests of REST calls. The Elasticsearch Handler supports sending additional headers by specifying header name and value pairs in the Elasticsearch Handler property gg.handler.name.headers in the properties file.

## About Java API Client

Elasticsearch Handler now uses Java API Client to connect Elasticsearch cluster for performing all operations of replication. It internally uses Elasticsearch Rest Client and Transport Client to perform all the operations. The older clients like Rest High-Level Client and Transport Client are deprecated and hence removed.

#### Supported Versions of Elasticsearch Cluster

To configure this handler, Elasticsearch cluster version 7.16.x or above must be configured and running. To configure Elasticsearch cluster, see Get Elasticsearch up and running

## Setting Up the Elasticsearch Handler

You must ensure that the Elasticsearch cluster is setup correctly and the cluster is up and running. Supported versions of Elasticsearch cluster are 7.16.x and above. See https://www.elastic.co/guide/en/elasticsearch/reference/current/index.html. Alternatively, you can use Kibana to verify the setup.

## Elasticsearch Handler Configuration

To configure the Elasticsearch Handler, the parameter file (res.prm) and the properties (elasticsearch.props) file must be configured with valid values.

#### Parameter File:

Parameter file should point to the correct properties file for Elasticsearch Handler.

The following are the mandatory parameters for parameter file (res.prm) necessary for running Elasticsearch Handler:

- REPLICAT replicat-name
- TARGETDB LIBFILE libggjava.so SET property=dirprm/elasticsearch.props
- MAP schema-name.table-name, TARGET schema-name.table-name

#### **Properties File:**

The following are the mandatory properties for properties file (elasticsearch.props), which is necessary for running Elasticsearch handler:

- gg.handlerlist=elasticsearch
- gg.handler.elasticsearch.type=elasticsearch
- gg.handler.elasticsearch.ServerAddressList=127.0.0.1:9200

Property Name	Required (Yes/No)	Legal Values (Default value)	Explanation
gg.handler.name.Ser verAddressList	Yes	<pre>[<hostname  ip&gt;:<port>, <hostname  ip&gt;:<port>,] [localhost:9200]</port></hostname  </port></hostname  </pre>	List of valid hostnames (or IP) and port number separated by ':' of cluster nodes of Elasticsearch cluster.
gg.handler.name.Bul kWrite	No	[true   false] Default [false]	If Bulk Write mode is enabled (set true), the operations of transaction will be stored in batch and applied to target ES cluster in one shot for a batch (transaction) depending on batch size.
gg.handler.name.Ups ert	No	[true   false] [true]	If upsert mode is enabled (set to true), the update operation will be inserted as new document when it's missing on target ES cluster.
gg.handler.name.Num berAsString	I NO	[true   false] [false]	Set if the number will be stored as string.
gg.handler.name.Pro xyServer	No	[Proxy-Hostname   Proxy-IP]	Proxy server hostname (or IP) to connect to Elasticsearch cluster.
gg.handler.name.Pro xyPort	No	[Port number]	Port number of proxy server. Required if proxy is configured.
gg.handler.name.Pro xyProtocol	No	[http   https] [http]	Protocol for Proxy server connection.
gg.handler.name.Prc xyUsername	No	[Username of proxy server]	Username for connecting to Proxy server.
gg.handler.name.Pro xyPassword	No	[Password of proxy server]	Password for connecting to Proxy server. This can be encrypted using ORACLEWALLET.
gg.handler.name.Aut hType	No	[basic   ssl   none] [none]	Authentication type to be used for connecting to Elasticsearch cluster.
gg.handler.name.Bas icAuthUsername	No	[username of ES cluster]	Username credential for basic authentication to connect ES server. This can be encrypted using ORACLEWALLET.

## Table 8-19 Elasticsearch Handler Configuration Properties

Property Name	Required (Yes/No)	Legal Values (Default value)	Explanation
gg.handler.name.Bas icAuthPassword	No	[password of ES cluster]	Password credential for basic authentication to connect ES server. This can be encrypted using ORACLEWALLET.
gg.handler.name.Fin gerprint	No	[fingerprint hash code]	It is the hash of a certificate calculated on all certificate's data and its signature. Applicable for authentication type SSL. This can be encrypted using ORACLEWALLET.
gg.handler.name.Cer tFilePath	No	<pre>[/path/to/ CA_certificate_file .crt]</pre>	CA certificate file (.crt) for SSL/TLS authentication.
gg.handler.name.Tru stStore	No	[/Path/to/trust- store-file]	Path to Trust-store file in server for SSL / TLS server authentication. Applicable for authentication type SSL.
gg.handler.name.Tru stStorePassword	No	[trust-store password]	Password for Trust-store file for SSL/TLS authentication. Applicable for authentication type SSL. This can be encrypted using ORACLEWALLET.
gg.handler.name.Tru stStoreType	No	[jks   pkcs12] [jks]	The key-store type for SSL/TLS authentication. Applicable if authentication type is SSL.
gg.handler.name.Rou tingKeyMappingTempl ate	No	[Routing field-name]	This defines the field- name whose value will be mapped for routing to particular shard in an index of ES cluster.
gg.handler.name.Hea ders	No	[ <key>:<value>, <key>:<value>,]</value></key></value></key>	List of name and value pair of headers to be sent with REST calls.
gg.handler.name.Max ConnectTimeout	No	Time in seconds	Time in seconds that request will wait for connecting to Elasticsearch server.
gg.handler.name.Max SocketTimeout	No	Time in seconds	Time in seconds that request will wait for response to come from Elasticsearch server.
gg.handler.name.IOT hreadCount	No	Count	Count of thread to handle IO requests.

## Table 8-19 (Cont.) Elasticsearch Handler Configuration Properties

Property Name	Required (Yes/No)	Legal Values (Default value)	Explanation
gg.handler.name.Nod eSelector	No	ANY   SKIP_DEDICATED _MASTERS   [Fully qualified name of node selector class] [ANY]	Predefined strategy ANY or SKIP_DEDICATED_MAST ERS. Or fully qualified name of class that implements custom strategy (by implementing NodeSelector.java interface).

<b>Table 8-19</b>	(Cont.) Elasticsearch Handler Configuration Properties
-------------------	--

#### Set the Classpath

The Elasticsearch handler property gg.classpath must include all the dependency jars required by the Java API client. For a listing and downloading of the required client JAR files, use the Dependency Downloader script elasticsearch\_java.sh in OGG\_HOME/ DependencyDownloader directory and pass the version 8.7.0 as argument. For more information about Elasticsearch client dependencies, see Elasticsearch Handler Client Dependencies.

It creates a directory OGG\_HOME/DepedencyDownloader/dependencies/ elasticsearch\_rest\_8.7.0 and downloads all the dependency jars inside it. The client library version 8.7.0 can be used for all supported Elasticsearch clusters.

This location can be configured in classpath as: gg.classpath=/path/to/OGG\_HOME/ DepedencyDownloader/dependencies/elasticsearch rest 8.7.0/\*

The inclusion of the \* wildcard character at the end of the path can be used in order to include all of the JAR files in that directory in the associated classpath. Do not use \*.jar.

#### Sample Configuration of Elasticsearch Handler:

For reference, to configure Elasticsearch handler, sample parameter (res.prm) and sample properties file (elasticsearch.props) for Elasticsearch handler is available in directory:

OGG HOME/AdapterExamples/big-data/elasticsearch

## Enabling Security for Elasticsearch

The Elasticsearch cluster must be accessed in secured manner in production environment. Security features must be first enabled in Elasticsearch cluster and those security configurations must be added to Elasticsearch handler properties file

## Security Configuration for Elasticsearch Cluster

The latest version of Elasticsearch has the security auto-configured when it is installed and started. The logs will print security details for auto-configured cluster as follows:

Elasticsearch security features have been automatically configured!
 Authentication is enabled and cluster connections are encrypted.

ORACLE

Password for the elastic user (reset with `bin/elasticsearch-reset-password -u elastic`): nnh0LWKZMLkw\_QD5jxhE
 HTTP CA certificate SHA-256 fingerprint:
 862e3f117c386a63f8f43db88760d463900e4c814590b8920e1c0e25f6db4df4
 Configure Kibana to use this cluster:
 Run Kibana and click the configuration link in the terminal when Kibana starts.
 Copy the following enrollment token and paste it into Kibana in your browser (valid for the next 30 minutes):
 eyJ2ZXIiOiI4LjYuMiIsImFkciI6WyIxMDAuNzAuOTguNzM60TIwMCJdLCJmZ3IiOiI4NjJ
 IM2YxMTdjMzg2YTYzZjhmNDNkYjg4NzYwZDQ2MzkwMGU0YzgxNDU5MGI4OTIwZTFjMGUyNW
 Y2ZGI0ZGY0Iiwia2V5IjoiUTVCVF9vWUJ2TnZDVXBSSkNTWEM6NkJNc3ZXanBUYWUwa016V
 1pDU1JPQSJ9

These security parameter values must be noted down and used to configure Elasticsearch handler. All the auto-generated certificates are created inside ElasticSearch-install-directory/config/cert folder.

If security is not auto-configured for older versions of Elasticsearch, we need to manually enable the security features like basic and encrypted (SSL) authentication in below configuration file of Elasticsearch cluster before running it.

Elasticsearch-installation-directory/config/elasticsearch.yml Following parameters must be added to enable security features in elasticsearch.yml file and restarting the Elasticsearch cluster.

```
#----- BEGIN SECURITY AUTO CONFIGURATION
_____
# The following settings, TLS certificates and keys have been
# configured for SSL/TLS authentication.
#
_____
# Enable security features
xpack.security.enabled: true
xpack.security.enrollment.enabled: true
# Enable encryption for HTTP API client connections
xpack.security.http.ssl:
 enabled: true
 keystore.path: certs/http.p12
# Enable encryption and mutual authentication between cluster nodes
xpack.security.transport.ssl:
 enabled: true
 verification mode: certificate
 keystore.path: certs/transport.p12
 truststore.path: certs/transport.p12
# Create a new cluster with the current node only
# Additional nodes can still join the cluster later
cluster.initial master nodes: ["cluster-host-name"]
# Allow HTTP API connections from anywhere
# Connections are encrypted and require user authentication
```

```
http.host: 0.0.0.0
#----- END SECURITY AUTO CONFIGURATION -----
```

For more information about the security setting of Elasticsearch cluster, see https:// www.elastic.co/guide/en/elasticsearch/reference/current/manually-configure-security.html

## Security Configuration for Elasticsearch Handler

Elasticsearch handler supports three modes of security configuration which can be configured using the Elasticsearch Handler property gg.handler.name.authType with following values: Elasticsearch-installation-directory/config/elasticsearch.yml

- 1. **None**: This mode is used when no security feature is enabled in Elasticsearch stack. No other configuration is required for this mode and Elasticsearch can be accessed directly using http protocol.
- 2. **Basic**: This mode is used when only basic security feature is enabled for a user by setting a username and password for the user. The basic authentication username and password property must be provided in properties file in order to access the Elasticsearch cluster.

```
gg.handler.name.authType=basic
gg.handler.name.basicAuthUsername=elastic
gg.handler.name.basicAuthPassword=changeme
```

3. SSL: This mode mode is used when SSL/TLS authentication is configured for encryption in Elasticsearch stack. User must provide either of CA fingerprint hash, path to CA certificate file (.crt) OR path to trust-store file (along with trust-store type and trust-store password) for handler to be able to connect to Elasticsearch cluster. This mode also supports combination of SSL/TLS authentication and Basic authentication configured in Elasticsearch stack. User must configure both basic authentication properties (username and password) and SSL related properties (fingerprint or certificate file or trust-store), if both are configured in Elasticsearch cluster.

All the above security related properties that contains confidential information can be configured to use Oracle Wallet for encrypting their confidential values in properties file.

## Troubleshooting

- Error: org.elasticsearch.ElasticsearchException[Index [index-name] is not found] - This exception occurs when there is a delete operation and the corresponding index of delete operation is not present in the Elasticsearch cluster. This can also occur for the update operation if upsert=false and the index is missing.
- 2. Error: javax.net.ssl.SSLHandshakeException: [ Connection failed ] This can happen when properties for enabling authentication in the elasticsearch.yml file mentioned above are missing for authentication type SSL.
- Error: javax.net.ssl.SSLException: [Received fatal alert: bad\_certificate] - This issue comes when host validation fails. Check that certificates generated using cert-utils in Elasticsearch contains the host information.

## **Elasticsearch Handler Client Dependencies**

What are the dependencies for the Elasticsearch Handler to connect to Elasticsearch databases?

The maven central repository artifacts for Elasticsearch databases are:

Maven groupId: co.elastic.clients

Maven atifactId: elasticsearch-java

Version: 8.7.0

Elasticsearch 8.7.0

## Elasticsearch 8.7.0

```
commons-codec-1.15.jar
commons-logging-1.2.jar
elasticsearch-java-8.7.0.jar
elasticsearch-rest-client-8.7.0.jar
httpasyncclient-4.15.jar
httpclient-4.5.13.jar
httpcore-4.4.13.jar
httpcore-nio-4.4.13.jar
jakarta.json-api-2.0.1.jar
jsr305-3.0.2.jar
parsson-1.0.0.jar
```

## Flat Files

Oracle GoldenGate for Big Data supports writing data files to a local file system with File Writer Handler.

Oracle GoldenGate for Big Data supports loading data files created by File Writer into Cloud storage services. In these cases, File Writer Handler should be used with one of the following cloud storage configurations:

Amazon S3

- Azure Data Lake Storage
- File Writer Handler
- Google Cloud Storage
- Oracle Cloud Infrastructure Object Storage
- Overview You can use the File Writer Handler and the event handlers to transform data.
- Optimized Row Columnar (ORC) The Optimized Row Columnar (ORC) Event Handler to generate data files is in ORC format.
- Parquet Learn how to use the Parquet load files generated by the File Writer Handler into HDFS.

## Overview

You can use the File Writer Handler and the event handlers to transform data.

The File Writer Handler supports generating data files in delimited text, XML, JSON, Avro, and Avro Object Container File formats. It is intended to fulfill an extraction, load, and transform use case. Data files are staged on your local file system. Then when writing to a data file is complete, you can use a third party application to read the file to perform additional processing.

The File Writer Handler also supports the event handler framework. The event handler framework allows data files generated by the File Writer Handler to be transformed into other formats, such as Optimized Row Columnar (ORC) or Parquet. Data files can be loaded into third party applications, such as HDFS or Amazon S3. The event handler framework is extensible allowing more event handlers performing different transformations or loading to different targets to be developed. Additionally, you can develop a custom event handler for your big data environment.

Oracle GoldenGate for Big Data provides two handlers to write to HDFS. Oracle recommends that you use the HDFS Handler or the File Writer Handler in the following situations:

#### The HDFS Handler is designed to stream data directly to HDFS.

Use when no post write processing is occurring in HDFS. The HDFS Handler does not change the contents of the file, it simply uploads the existing file to HDFS. Use when analytical tools are accessing data written to HDFS in real time including data in files that are open and actively being written to.

# The File Writer Handler is designed to stage data to the local file system and then to load completed data files to HDFS when writing for a file is complete.

Analytic tools are not accessing data written to HDFS in real time.

Post write processing is occurring in HDFS to transform, reformat, merge, and move the data to a final location.

You want to write data files to HDFS in ORC or Parquet format.

- Detailing the Functionality
- Configuring the File Writer Handler
- Stopping the File Writer Handler
- Review a Sample Configuration

#### File Writer Handler Partitioning

Partitioning functionality had been added to the File Writer Handler in Oracle GoldenGate for Big Data 21.1. The partitioning functionality uses the template mapper functionality to resolve partitioning strings. The result is that you are afforded control in how to partition source trail data.

## Detailing the Functionality

- Using File Roll Events
- Automatic Directory Creation
- About the Active Write Suffix
- Maintenance of State

## Using File Roll Events

A **file roll event** occurs when writing to a specific data file is completed. No more data is written to that specific data file.

#### **Finalize Action Operation**

You can configure the finalize action operation to clean up a specific data file after a successful file roll action using the finalizeaction parameter with the following options:

#### none

Leave the data file in place (removing any active write suffix, see About the Active Write Suffix).

#### delete

Delete the data file (such as, if the data file has been converted to another format or loaded to a third party application).

#### move

Maintain the file name (removing any active write suffix), but move the file to the directory resolved using the movePathMappingTemplate property.

#### rename

Maintain the current directory, but rename the data file using the fileRenameMappingTemplate property.

#### move-rename

Rename the file using the file name generated by the fileRenameMappingTemplate property and move the file to the directory resolved using the movePathMappingTemplate property.

Typically, event handlers offer a subset of these same actions.

A sample Configuration of a finalize action operation:

```
gg.handlerlist=filewriter
#The File Writer Handler
gg.handler.filewriter.type=filewriter
gg.handler.filewriter.mode=op
gg.handler.filewriter.pathMappingTemplate=./dirout/evActParamS3R
gg.handler.filewriter.stateFileDirectory=./dirsta
```

```
gg.handler.filewriter.fileNameMappingTemplate=${fullyQualifiedTableName}_$
{currentTimestamp}.txt
gg.handler.filewriter.fileRollInterval=7m
gg.handler.filewriter.finalizeAction=delete
gg.handler.filewriter.inactivityRollInterval=7m
```

#### **File Rolling Actions**

Any of the following actions trigger a file roll event.

- A metadata change event.
- The maximum configured file size is exceeded
- The file roll interval is exceeded (the current time minus the time of first file write is greater than the file roll interval).
- The inactivity roll interval is exceeded (the current time minus the time of last file write is greater than the file roll interval).
- The File Writer Handler is configured to roll on shutdown and the Replicat process is stopped.

#### **Operation Sequence**

The file roll event triggers a sequence of operations to occur. It is important that you understand the order of the operations that occur when an individual data file is rolled:

- **1.** The active data file is switched to inactive, the data file is flushed, and state data file is flushed.
- 2. The configured event handlers are called in the sequence that you specified.
- 3. The finalize action is executed on all the event handlers in the reverse order in which you configured them. Any finalize action that you configured is executed.
- 4. The finalize action is executed on the data file and the state file. If all actions are successful, the state file is removed. Any finalize action that you configured is executed.

For example, if you configured the File Writer Handler with the Parquet Event Handler and then the S3 Event Handler, the order for a roll event is:

- **1.** The active data file is switched to inactive, the data file is flushed, and state data file is flushed.
- 2. The Parquet Event Handler is called to generate a Parquet file from the source data file.
- 3. The S3 Event Handler is called to load the generated Parquet file to S3.
- 4. The finalize action is executed on the S3 Parquet Event Handler. Any finalize action that you configured is executed.
- 5. The finalize action is executed on the Parquet Event Handler. Any finalize action that you configured is executed.
- 6. The finalize action is executed for the data file in the File Writer Handler

#### Automatic Directory Creation

You do not have to configure write directories before you execute the handler. The File Writer Handler checks to see if the specified write directory exists before creating a file and recursively creates directories as needed.

## About the Active Write Suffix

A common use case is using a third party application to monitor the write directory to read data files. Third party application can only read a data file when writing to that file has completed. These applications need a way to determine if writing to a data file is active or complete. The File Writer Handler allows you to configure an **active write suffix** using this property:

gg.handler.name.fileWriteActiveSuffix=.tmp

The value of this property is appended to the generated file name. When writing to the file is complete, the data file is renamed and the active write suffix is removed from the file name. You can set your third party application to monitor your data file names to identify when the active write suffix is removed.

## Maintenance of State

Previously, all Oracle GoldenGate for Big Data Handlers have been stateless. These stateless handlers only maintain state in the context of the Replicat process that it was running. If the Replicat process was stopped and restarted, then all the state was lost. With a Replicat restart, the handler began writing with no contextual knowledge of the previous run.

The File Writer Handler provides the ability of maintaining state between invocations of the Replicat process. By default with a restart:

- the state saved files are read,
- the state is restored,
- and appending active data files continues where the previous run stopped.

You can change this default action to require all files be rolled on shutdown by setting this property:

gg.handler.name.rollOnShutdown=true

## Configuring the File Writer Handler

Lists the configurable values for the File Writer Handler. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the File Writer Handler, you must first configure the handler type by specifying gg.handler.name.type=filewriter and the other File Writer properties as follows:

<b>Table 8-20</b>	File Writer Handler Configuration Properties
-------------------	--

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.type	Required	filewrit er	None	Selects the File Writer Handler for use.

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.maxFileSize	Optional	Default unit of measure is bytes. You can stipulate k, m, or g to signify kilobytes, megabytes, megabytes respectivel y. Examples of legal values include 10000, 10k, 100m, 1.1g.	1g	Sets the maximum file size of files generated by the File Writer Handler. When the file size is exceeded, a roll event is triggered.

 Table 8-20
 (Cont.) File Writer Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.fileRollInte rval	Optional	The default unit of measure is millisecon ds. You can stipulate ms, s, m, h to signify millisecon ds, seconds, minutes, or hours respectivel y. Examples of legal values include 10000, 10000ms, 10s, 10m, or 1.5h. Values of 0 or less indicate that file rolling on time is turned off.	File rolling on time is off.	The timer starts when a file is created. If the file is still open when the interval elapses then the a file roll event will be triggered.

 Table 8-20
 (Cont.) File Writer Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.inactivityRo llInterval		of measure is millisecon ds. You can stipulate ms, s, m, h to signify millisecon ds, seconds, minutes, or hours respectivel y. Examples of legal values include 10000, 10000ms, 10s, 10m, or 1.5h. Values of 0 or less indicate that file rolling on time is turned off.	y rolling is turned off.	The timer starts from the latest write to a generated file. New writes to a generated file restart the counter. If the file is still open when the timer elapses a roll event is triggered
gg.handler.nam e.fileNameMapp ingTemplate	Required	A string with resolvable keywords and constants used to dynamicall y generate File Writer Handler data file names at runtime.	None	Use keywords interlaced with constants to dynamically generate unique file names at runtime. Typically, file names follow the format, /some/path/\${tableName}_\$ {groupName}_\$ {currentTimestamp}.txt. See Template Keywords.

 Table 8-20
 (Cont.) File Writer Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.pathMappingT emplate	Required	A string with resolvable keywords and constants used to dynamicall y generate the directory to which a file is written.	None	Use keywords interlaced with constants to dynamically generate unique path names at runtime. Typically, path names follow the format, /some/path/\${tableName}. See Template Keywords.
gg.handler.nam e.fileWriteAct iveSuffix	Optional	A string.	None	An optional suffix that is appended to files generated by the File Writer Handler to indicate that writing to the file is active. At the finalize action the suffix is removed.
gg.handler.nam e.stateFileDir ectory	Required	A directory on the local machine to store the state files of the File Writer Handler.	None	Sets the directory on the local machine to store the state files of the File Writer Handler. The group name is appended to the directory to ensure that the functionality works when operating in a coordinated apply environment.
gg.handler.nam e.rollOnShutdo wn	Optional	true   false	false	Set to true, on normal shutdown of the Replicat process all open files are closed and a file roll event is triggered. If successful, the File Writer Handler has no state to carry over to a restart of the File Writer Handler.

Table 8-20	(Cont.) File Writer Handler Configuration Properties
	(cond) The Writer Handler Configuration (roperties)

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.finalizeActi on	Optional	none   delete   move   rename   move- rename	none	Indicates what the File Writer Handler should do at the finalize action. <b>none</b> Leave the data file in place (removing any active write suffix, see About the Active Write Suffix). <b>delete</b> Delete the data file (such as, if the data file has been converted to another format or loaded to a third party application). <b>move</b> Maintain the file name (removing any active write suffix), but move the file to the directory resolved using the movePathMappingTemplate property. <b>rename</b> Maintain the current directory, but rename the data file using the fileRenameMappingTemplate property. <b>move-rename</b> Rename the file using the file name generated by the fileRenameMappingTemplate property and move the file the file to the directory resolved using the
gg.handler.nam e.partitionByT able	Optional	true   false	true	Set to true so that data from different source tables is partitioned into separate files. Set to false to interlace operation data from all source tables into a single output file. It cannot be set to false if the file format is the Avro OCF (Object Container File) format.
gg.handler.nam e.eventHandler	Optional	HDFS   ORC   PARQUET   S3	No event handler configu red.	A unique string identifier cross referencing an event handler. The event handler will be

<b>Table 8-20</b>	(Cont.) File Writer Handler Configuration Propertie	es
-------------------	---	----

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.fileRenameMa ppingTemplate		A string with resolvable keywords and constants used to dynamicall y generate File Writer Handler data file names for file renaming in the finalize action.	None.	Use keywords interlaced with constants to dynamically generate unique file names at runtime. Typically, file names follow the format, \$ {fullyQualifiedTableName}_\$ {groupName}_\$ {currentTimestamp}.txt. See Template Keywords.
gg.handler.nam e.movePathMapp ingTemplate	Required if gg.hand ler.nam e.final izeActi on is set to rename or move- rename.	A string with resolvable keywords and constants used to dynamicall y generate the directory to which a file is written.	None	Use keywords interlaced with constants to dynamically generate a unique path names at runtime. Typically, path names typically follow the format, /ogg/data/\$ {groupName}/\$ {fullyQualifiedTableName}. See Template Keywords.

 Table 8-20
 (Cont.) File Writer Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.format	Optional	<pre>delimite dtext   json   json_row   xml   avro_row   avro_op   avro_row _ocf   avro_op_ ocf</pre>	delimi	Selects the formatter for the HDFS Handler for how output data will be formatted delimitedtext Delimited text. json JSON json_row JSON output modeling row data xml XML avro_row Avro in row compact format. avro_op Avro in operation more verbose format.
				<pre>avro_row_ocf Avro in the row compact format written into HDFS in the Avro Object Container File (OCF) format. avro_op_ocf Avro in the more verbose format written into HDFS in the Avro OCF format. If you want to use the Parquet or ORC Event Handlers, then the selected format must be avro row ocf or avro op ocf.</pre>
gg.handler.nam e.bom	Optional	An even number of hex characters	None	Enter an even number of hex characters where every two characters correspond to a single byte in the byte order mark (BOM). For example, the string efbbbf represents the 3-byte BOM for UTF-8.
gg.handler.nam e.createContro lFile	Optional	true   false	false	Set to true to create a control file. A <b>control file</b> contains all of the completed file names including the path separated by a delimiter. The name of the control file is {groupName}.control. For example, if the Replicat process name is fw, then the control file name is FW.control.
gg.handler.nam e.controlFileD elimiter	Optional	Any string	new line (\n)	Allows you to control the delimiter separating file names in the control file. You can useCDATA[] wrapping with this property.

 Table 8-20
 (Cont.) File Writer Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.controlFileD irectory	Optional	A path to a directory to hold the control file.	period (.) or	Set to specify where you want to write the control file.
gg.handler.nam e.createOwnerF ile	Optional	true   false	false	Set to true to create an owner file. The owner file is created when the Replicat process starts and is removed when it terminates normally. The owner file allows other applications to determine if the process is running. The owner file remains in place when the Replicat process ends abnormally. The name of the owner file is the {groupName}.owner. For example, if the replicat process is name fw, then the owner file name is FW.owner. The file is create in the . directory or the Oracle GoldenGate installation directory.
gg.handler.nam e.atTime	Optional	One or more times to trigger a roll action of all open files.	None	Configure one or more trigger times in the following format: HH:MM, HH:MM, HH:MM Entries are based on a 24 hour clock. For example, an entry to configure rolled actions at three discrete times of day is: gg.handler.fw.atTime=03:30,21:00,23: 51
gg.handler.nam e.avroCodec	Optional	null no compressi on.	<pre>null   bzip2   deflat e   snappy   xz</pre>	Enables the corresponding compression algorithm for generated Avro OCF files. The corresponding compression library must be added to the gg.classpath when compression is enabled.

Table 8-20	(Cont.) File Writer Handler	<b>Configuration Properties</b>
		ooningen allon i roportioo

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler.nam e.bufferSize	Optional	1024	Positive Integer >= 512	Sets the size the BufferedOutputStream for each active writestream. Setting to a larger value may improve performance especially when there are a few active write streams, but a large number of operations are being written to those streams. If there are a large number of active write streams, increasing the value with this property is likely undesirable and could result in an out of memory exception by exhausting the Java heap.
gg.handler.nam e.rollOnTrunca te	Optional	true   false	false	Controls whether the occurrence of truncate operation causes a rollover of the corresponding data file by the handler. The default is false, which means the corresponding data file is not rolled when a truncate operation is presented. Set to true to roll the data file on a truncate operation. To propagate truncate operations, ensure to set the replicat property GETTRUNCATES.
gg.handler.nam e.logEventHand lerStatus	Optional	true   false	false	When set to true, it logs the status of completed event handlers at the info logging level. Can be used for debugging and troubleshooting of the event handlers.
eventHandlerTi meoutMinutes	Optional	Long integer	120	The event handler thread timeout in minutes. The event handler threads spawned by the file writer handler are provided a max execution time to complete their work. If the timeout value is exceeded, then Replicat assumes that the Event handler thread is hung and will ABEND. For stage and merge use cases, Event handler threads may take longer to complete their work. The default value is set to 120 (2 hours).

Table 8-20	(Cont.) File Writer Handler Configuration Pro	operties
------------	---	----------

# Stopping the File Writer Handler

The replicat process running the File Writer Handler should only be stopped normally.

- Force stop should never be executed on the replicat process.
- The Unix kill command should never be used to kill the replicat process.

The File Writer is writing data files and using state files to track the progress and state. File writing is not transactional. Abnormal ending of the replicat process means that the state of the File Writer Handler can become inconsistent. The best practice is to stop the replicat process normally.

An inconsistent state may mean that the replicat process will abend on startup and require manual removal of state files.

The following is a typical error message for inconsistent state:

```
ERROR 2022-07-11 19:05:23.000367 [main] - Failed to
restore state for UUID [d35f117f-ffab-4e60-aa93-f7ef860bf280]
table name [QASOURCE.TCUSTORD]
data file name [QASOURCE.TCUSTORD_2022-07-11_19-04-27.900.txt]
```

The error means that the data file has been removed from the file system, but that the corresponding .state file has not yet been removed. Three scenarios can generally cause this problem:

- The replicat process was force stopped, was killed using the kill command, or crashed while it was in the processing window between when the data file was removed and when the associated .state file was removed.
- The user has manually removed the data file or files but left the associated .state file in place.
- There are two instances of the same replicat process running. A lock file is created to prevent this, but there is a window on replicat startup which allows multiple instances of a replicat process to be started.

If this problem occurs, then you should manually determine whether or not the data file associated with the .state file has been successfully processed. If the data has been successfully processed, then you can manually remove the .state file and restart the replicat process.

If data file associated with the problematic .state file has been determined not to have been processed, then do the following:

- 1. Delete all the .state files.
- Alter the seqno and rba of the replicat process to back it up to a period for which it was known that processing successfully occurred.
- 3. Restart the replicat process to reprocess the data.

### **Review a Sample Configuration**

This File Writer Handler configuration example is using the Parquet Event Handler to convert data files to Parquet, and then for the S3 Event Handler to load Parquet files into S3:

```
gg.handlerlist=filewriter
#The handler properties
gg.handler.name.type=filewriter
gg.handler.name.mode=op
gg.handler.name.pathMappingTemplate=./dirout
gg.handler.name.stateFileDirectory=./dirsta
gg.handler.name.fileNameMappingTemplate=${fullyQualifiedTableName}_$
{currentTimestamp}.txt
gg.handler.name.fileRollInterval=7m
gg.handler.name.finalizeAction=delete
gg.handler.name.format=avro_row_ocf
gg.handler.name.includetokens=true
gg.handler.name.partitionByTable=true
```

```
gg.handler.name.eventHandler=parquet
gg.handler.name.rollOnShutdown=true
gg.eventhandler.parguet.type=parguet
gg.eventhandler.parquet.pathMappingTemplate=./dirparquet
gg.eventhandler.parguet.writeToHDFS=false
gg.eventhandler.parguet.finalizeAction=delete
gg.eventhandler.parquet.eventHandler=s3
gg.eventhandler.parquet.fileNameMappingTemplate=${tableName} $
{currentTimestamp}.parquet
gq.handler.filewriter.eventHandler=s3
gg.eventhandler.s3.type=s3
gg.eventhandler.s3.region=us-west-2
qq.eventhandler.s3.proxyServer=www-proxy.us.oracle.com
gg.eventhandler.s3.proxyPort=80
gg.eventhandler.s3.bucketMappingTemplate=tomsfunbucket
gg.eventhandler.s3.pathMappingTemplate=thepath
gg.eventhandler.s3.finalizeAction=none
```

### File Writer Handler Partitioning

Partitioning functionality had been added to the File Writer Handler in Oracle GoldenGate for Big Data 21.1. The partitioning functionality uses the template mapper functionality to resolve partitioning strings. The result is that you are afforded control in how to partition source trail data.

All of the keywords that are supported by the templating functionality are now supported in File Writer Handler partitioning.

File Writer Handler Partitioning Precondition In order to use the partitioning functionality, data must first be partitioned by table. The following configuration cannot be set: gg.handler.filewriter.partitionByTable=false.

Path Configuration

Assume that the path mapping template is configured as follows: gg.handler.filewriter.pathMappingTemplate=/ogg/\${fullyQualifiedTableName}. At runtime the path resolves as follows for the DBO.ORDERS source table: /ogg/DBO.ORDERS.

• Partitioning Configuration Any of the keywords that are legal for templating are now legal for partitioning: gg.handler.filewriter.partitioner.fully qualified table name=templating keywords and/or constants.

 Partitioning Effect on Event Handler The resolved partitioning path is carried forward to the corresponding Event Handlers as well.

### File Writer Handler Partitioning Precondition

In order to use the partitioning functionality, data must first be partitioned by table. The following configuration cannot be set: gg.handler.filewriter.partitionByTable=false.

### Path Configuration

Assume that the path mapping template is configured as follows:

gg.handler.filewriter.pathMappingTemplate=/ogg/\${fullyQualifiedTableName}. At runtime the path resolves as follows for the DB0.ORDERS source table: /ogg/DB0.ORDERS.

### Partitioning Configuration

Any of the keywords that are legal for templating are now legal for partitioning: gg.handler.filewriter.partitioner.fully qualified table name=templating keywords and/or constants.

See Template Keywords. Example 1 Partitioning for the DBO.ORDERS table is set to the following:

```
gg.handler.filewriter.partitioner.DBO.ORDERS=par_sales_region=$
{columnValue[SALES REGION]}
```

This example can result in the following breakdown of files on the file system:

```
/ogg/DB0.ORDERS/par_sales_region=west/data files
/ogg/DB0.ORDERS/par_sales_region=east/data files
/ogg/DB0.ORDERS/par_sales_region=north/data files
/ogg/DB0.ORDERS/par_sales_region=south/data file
```

#### Example 2

Partitioning for the DBO.ORDERS table is set to the following:

```
gg.handler.filewriter.partitioner.DBO.ORDERS=par_sales_region=$
{columnValue[SALES REGION]}/par state=${columnValue[STATE]}
```

This example can result in the following breakdown of files on the file system:

```
/ogg/DBO.ORDERS/par_sales_region=west/par_state=CA/data files
/ogg/DBO.ORDERS/par_sales_region=east/par_state=FL/data files
/ogg/DBO.ORDERS/par_sales_region=north/par_state=MN/data files
/ogg/DBO.ORDERS/par_sales_region=south/par_state=TX/data files
```

## Caution:

Ensure to be extra vigilant while configuring partitioning. Choosing partitioning column values that have a very large range of data values result in partitioning to a proportional number of output data files.

### Partitioning Effect on Event Handler

The resolved partitioning path is carried forward to the corresponding Event Handlers as well.

#### Example 1

```
If partitioning is configured as follows:
gg.handler.filewriter.partitioner.DB0.ORDERS=par_sales_region=$
{columnValue[SALES_REGION]}, then the partition string might resolve to the following:
```

```
par_sales_region=west
par_sales_region=east
par_sales_region=north
par_sales_region=south
```

### Example 2

If S3 Event handler is used, then the path mapping template of the S3 Event Handler is configured as follows: gg.eventhandler.s3.pathMappingTemplate=output/dir. The target directories in S3 are as follows:

```
output/dir/par_sales_region=west/data files
output/dir/par_sales_region=east/data files
output/dir/par_sales_region=north/data files
output/dir/par_sales_region=south/data files
```

# Optimized Row Columnar (ORC)

The Optimized Row Columnar (ORC) Event Handler to generate data files is in ORC format.

This topic describes how to use the ORC Event Handler.

- Overview
- Detailing the Functionality
- Configuring the ORC Event Handler
- Optimized Row Columnar Event Handler Client Dependencies What are the dependencies for the Optimized Row Columnar (OCR) Handler?

### Overview

ORC is a row columnar format that can substantially improve data retrieval times and the performance of Big Data analytics. You can use the ORC Event Handler to write ORC files to either a local file system or directly to HDFS. For information, see https://orc.apache.org/.

### Detailing the Functionality

- About the Upstream Data Format
- About the Library Dependencies
- Requirements

### About the Upstream Data Format

The ORC Event Handler can only convert Avro Object Container File (OCF) generated by the File Writer Handler. The ORC Event Handler cannot convert other formats to ORC data files. The format of the File Writer Handler must be avro row ocf or avro op ocf, see Flat Files.

### About the Library Dependencies

Generating ORC files requires both the Apache ORC libraries and the HDFS client libraries, see Optimized Row Columnar Event Handler Client Dependencies and HDFS Handler Client Dependencies.

Oracle GoldenGate for Big Data does not include the Apache ORC libraries nor does it include the HDFS client libraries. You must configure the gg.classpath variable to include the dependent libraries.

### Requirements

The ORC Event Handler can write ORC files directly to HDFS. You must set the writeToHDFS property to true:

gg.eventhandler.orc.writeToHDFS=true

Ensure that the directory containing the HDFS core-site.xml file is in gg.classpath. This is so the core-site.xml file can be read at runtime and the connectivity information to HDFS can be resolved. For example:

gg.classpath=/{HDFS\_install\_directory}/etc/hadoop

If you enable Kerberos authentication is on the HDFS cluster, you have to configure the Kerberos principal and the location of the keytab file so that the password can be resolved at runtime:

gg.eventHandler.name.kerberosPrincipal=principal
gg.eventHandler.name.kerberosKeytabFile=path\_to\_the\_keytab\_file

### Configuring the ORC Event Handler

You configure the ORC Handler operation using the properties file. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

The ORC Event Handler works only in conjunction with the File Writer Handler.

To enable the selection of the ORC Handler, you must first configure the handler type by specifying gg.eventhandler.name.type=orc and the other ORC properties as follows:

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r. <i>name</i> .type	Required	ORC	None	Selects the ORC Event Handler.
gg.eventhandle r. <i>name</i> .writeTo HDFS	Optional	true   false	false	The ORC framework allows direct writing to HDFS. Set to false to write to the local file system. Set to true to write directly to HDFS.
gg.eventhandle r. <i>name</i> .pathMap pingTemplate	Required	A string with resolvable keywords and constants used to dynamicall y generate the path in the ORC bucket to write the file.	None	Use keywords interlaced with constants to dynamically generate unique ORC path names at runtime. Typically, path names follow the format, /ogg/data/\$ {groupName}/\$ {fullyQualifiedTableName}. See Template Keywords.

Table 8-21 ORC Event Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r. <i>name</i> .fileMap pingTemplate	Optional	A string with resolvable keywords and constants used to dynamicall y generate the ORC file name at runtime.	None	Use resolvable keywords and constants used to dynamically generate the ORC data file name at runtime. If not set, the upstream file name is used. See Template Keywords.
gg.eventhandle r. <i>name</i> .compres sionCodec	Optional	LZ4   LZO   NONE   SNAPPY   ZLIB	NONE	Sets the compression codec of the generated ORC file.
gg.eventhandle r. <i>nam</i> e.finaliz eAction	Optional	none   delete	none	Set to none to leave the ORC data file in place on the finalize action. Set to delete if you want to delete the ORC data file with the finalize action.
gg.eventhandle r. <i>name</i> .kerbero sPrincipal	Optional	The Kerberos principal name.	None	Sets the Kerberos principal when writing directly to HDFS and Kerberos authentication is enabled.
gg.eventhandle r. <i>name</i> .kerbero sKeytabFile	Optional	The path to the Keberos keytab file.	none	Sets the path to the Kerberos keytab file with writing directly to HDFS and Kerberos authentication is enabled.
gg.eventhandle r. <i>name</i> .blockPa dding	Optional	true   false	true	Set to true to enable block padding in generated ORC files or false to disable.
gg.eventhandle r. <i>name</i> .blockSi ze	Optional	long	The ORC default.	Sets the block size of generated ORC files.
gg.eventhandle r. <i>name</i> .bufferS ize	Optional	integer	The ORC default.	Sets the buffer size of generated ORC files.
gg.eventhandle r. <i>name</i> .encodin gStrategy	Optional	COMPRESS ION   SPEED	The ORC default.	Set if the ORC encoding strategy is optimized for compression or for speed

 Table 8-21
 (Cont.) ORC Event Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r. <i>name</i> .padding Tolerance	Optional	A percentag e represente d as a floating point number.	The ORC default.	Sets the percentage for padding tolerance of generated ORC files.
gg.eventhandle r. <i>nam</i> e.rowInde xStride	Optional	integer	The ORC default.	Sets the row index stride of generated ORC files.
gg.eventhandle r.name.stripeS ize	Optional	integer	The ORC default.	Sets the stripe size of generated ORC files.
gg.eventhandle r. <i>nam</i> e.eventHa ndler	Optional	A unique string identifier cross referencin g a child event handler.	No event handler configu red.	The event handler that is invoked on the file roll event. Event handlers can do file roll event actions like loading files to S3 or HDFS.
gg.eventhandle r. <i>nam</i> e.bloomFi lterFpp	Optional	The false positive probability must be greater than zero and less than one. For example, . 25 and .75 are both legal values, but 0 and 1 are not.	The Apache ORC default.	result indicating that the value being searched for is in the block, but the value is actually not in the block. needs to set which tables to set bloom filters and on which columns. The user selects on which tables and columns to set bloom filters with the following configuration syntax: gg.eventhandler.orc.bloomFilter.QASO URCE.TCUSTMER=CUST_CODE gg.eventhandler.orc.bloomFilter.QASO URCE.TCUSTORD=CUST_CODE, ORDER_DATE QASOURCE.TCUSTMER and QASOURCE.TCUSTORD are the fully qualified names of the source tables. The
gg.eventhandle r. <i>name</i> .bloomFi lterVersion	Optional	ORIGINAL   UTF8	ORIGIN AL	configured values are one or more columns on which to configure bloom filters. The columns names are delimited by a comma. Sets the version of the ORC bloom filter.

# Parquet

Learn how to use the Parquet load files generated by the File Writer Handler into HDFS.

See Flat Files.

- Overview
- Detailing the Functionality
- Configuring the Parquet Event Handler
- Parquet Event Handler Client Dependencies What are the dependencies for the Parquet Event Handler?

### Overview

The Parquet Event Handler enables you to generate data files in Parquet format. Parquet files can be written to either the local file system or directly to HDFS. Parquet is a columnar data format that can substantially improve data retrieval times and improve the performance of Big Data analytics, see https://parquet.apache.org/.

### Detailing the Functionality

- Configuring the Parquet Event Handler to Write to HDFS
- About the Upstream Data Format

### Configuring the Parquet Event Handler to Write to HDFS

The Apache Parquet framework supports writing directly to HDFS. The Parquet Event Handler can write Parquet files directly to HDFS. These additional configuration steps are required:

The Parquet Event Handler dependencies and considerations are the same as the HDFS Handler, see HDFS Additional Considerations.

Set the writeToHDFS property to true:

gg.eventhandler.parquet.writeToHDFS=true

Ensure that gg.classpath includes the HDFS client libraries.

Ensure that the directory containing the HDFS core-site.xml file is in gg.classpath. This is so the core-site.xml file can be read at runtime and the connectivity information to HDFS can be resolved. For example:

gg.classpath=/{HDFS install directory}/etc/hadoop

If Kerberos authentication is enabled on the HDFS cluster, you have to configure the Kerberos principal and the location of the keytab file so that the password can be resolved at runtime:

```
gg.eventHandler.name.kerberosPrincipal=principal
gg.eventHandler.name.kerberosKeytabFile=path_to_the_keytab_file
```

### About the Upstream Data Format

The Parquet Event Handler can only convert Avro Object Container File (OCF) generated by the File Writer Handler. The Parquet Event Handler cannot convert other formats to Parquet data files. The format of the File Writer Handler must be <a href="https://www.ocf.or.avro\_op\_ocf">avro\_op\_ocf</a>, see Flat Files.

# Configuring the Parquet Event Handler

You configure the Parquet Event Handler operation using the properties file. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

The Parquet Event Handler works only in conjunction with the File Writer Handler.

To enable the selection of the Parquet Event Handler, you must first configure the handler type by specifying gg.eventhandler.name.type=parquet and the other Parquet Event properties as follows:

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r. <i>name</i> .type	Required	parquet	None	Selects the Parquet Event Handler for use.
gg.eventhandle r. <i>name</i> .writeTo HDFS	Optional	true   false	false	Set to false to write to the local file system. Set to true to write directly to HDFS.
gg.eventhandle r.name.pathMap pingTemplate	Required	A string with resolvable keywords and constants used to dynamicall y generate the path to write generated Parquet files.	None	Use keywords interlaced with constants to dynamically generate unique path names at runtime. Typically, path names follow the format, /ogg/data/\${groupName}/\$ {fullyQualifiedTableName}. See Template Keywords.
gg.eventhandle r. <i>name</i> .fileNam eMappingTempla te	Optional	A string with resolvable keywords and constants used to dynamicall y generate the Parquet file name at runtime	None	Sets the Parquet file name. If not set, the upstream file name is used. See Template Keywords.
gg.eventhandle r.name.compres sionCodec	Optional	GZIP   LZO   SNAPPY   UNCOMPRE SSED		Sets the compression codec of the generated Parquet file.

 Table 8-22
 Parquet Event Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r. <i>name</i> .finaliz eAction	Optional	none   delete	none	Indicates what the Parquet Event Handler should do at the finalize action.
				none Leave the data file in place.
				delete Delete the data file (such as, if the data file has been converted to another format or loaded to a third party application).
gg.eventhandle r. <i>name</i> .diction aryEncoding	Optional	true   false	The Parquet default.	Set to true to enable Parquet dictionary encoding.
gg.eventhandle r. <i>name</i> .validat ion	Optional	true   false	The Parquet default.	Set to true to enable Parquet validation.
gg.eventhandle r. <i>name</i> .diction aryPageSize	Optional	Integer	The Parquet default.	Sets the Parquet dictionary page size.
gg.eventhandle r. <i>name</i> .maxPadd ingSize	Optional	Integer	The Parquet default.	Sets the Parquet padding size.
gg.eventhandle r. <i>name</i> .pageSiz e	Optional	Integer	The Parquet default.	Sets the Parquet page size.
gg.eventhandle r. <i>name</i> .rowGrou pSize	Optional	Integer	The Parquet default.	Sets the Parquet row group size.
gg.eventhandle r. <i>name</i> .kerbero sPrincipal	Optional	The Kerberos principal name.	None	Set to the Kerberos principal when writing directly to HDFS and Kerberos authentication is enabled.
gg.eventhandle r. <i>name</i> .kerbero sKeytabFile	Optional	The path to the Keberos keytab file.		Set to the path to the Kerberos keytab file with writing directly to HDFS and Kerberos authentication is enabled.
gg.eventhandle r. <i>name</i> .eventHa ndler	Optional	A unique string identifier cross referencin g a child event handler.	No event handler configu red.	The event handler that is invoked on the file roll event. Event handlers can do file roll event actions like loading files to S3, converting to Parquet or ORC format, or loading files to HDFS.

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r.name.writerV ersion	Optional	v1 v2	The Parquet library default which is up through Parquet version 1.11.0 is v1.	Allows the ability to set the Parquet writer version.

- Google BigQuery Stage and Merge

# Using Streaming API

Learn how to use the Google BigQuery Handler, which streams change data capture data from source trail files into Google BigQuery.

BigQuery is a RESTful web service that enables interactive analysis of massively large datasets working in conjunction with Google Storage, see <a href="https://cloud.google.com/bigquery/">https://cloud.google.com/bigquery/</a>.

- Detailing the Functionality
- Setting Up and Running the BigQuery Handler The Google BigQuery Handler uses the Java BigQuery client libraries to connect to Big Query.
- Google BigQuery Dependencies
   The Google BigQuery client libraries are required for integration with BigQuery.

### Detailing the Functionality

- Data Types
- Metadata Support
- Operation Modes
- Operation Processing Support
- Proxy Settings
- Mapping to Google Datasets
   A dataset is contained within a specific Google cloud project. Datasets are toplevel containers that are used to organize and control access to your tables and views.

### Data Types

The BigQuery Handler supports the standard SQL data types and most of these data types are supported by the BigQuery Handler. A data type conversion from the column value in the trail file to the corresponding Java type representing the BigQuery column type in the BigQuery Handler is required.

#### The following data types are supported:

STRING BYTES INTEGER FLOAT NUMERIC BOOLEAN TIMESTAMP DATE TIME DATETIME

The BigQuery Handler does not support complex data types, such as ARRAY and STRUCT.

### Metadata Support

The BigQuery Handler creates tables in BigQuery if the tables do not exist.

The BigQuery Handler alters tables to add columns which exist in the source metadata or configured metacolumns which do not exist in the target metadata. The BigQuery Handler also adds columns dynamically at runtime if it detects a metadata change.

The BigQuery Handler does not drop columns in the BigQuery table which do not exist into the source table definition. BigQuery neither supports dropping existing columns, nor supports changing the data type of existing columns. Once a column is created in BigQuery, it is immutable.

Truncate operations are not supported.

### **Operation Modes**

You can configure the BigQuery Handler in one of these two modes:

#### Audit Log Mode = true

#### gg.handler.name.auditLogMode=true

When the handler is configured to run with audit log mode true, the data is pushed into Google BigQuery without a unique row identification key. As a result, Google BigQuery is not able to merge different operations on the same row. For example, a source row with an insert operation, two update operations, and then a delete operation would show up in BigQuery as four rows, one for each operation.

Also, the order in which the audit log is displayed in the BigQuery data set is not deterministic.

To overcome these limitations, users should specify optype and postion in the meta columns template for the handler. This adds two columns of the same names in the schema for the table in Google BigQuery. For example: gg.handler.bigquery.metaColumnsTemplate = \$ {optype}, \${position}

The <code>optype</code> is important to determine the operation type for the row in the audit log. To view the audit log in order of the operations processed in the trail file, specify position which can be used in the ORDER BY clause while querying the table in Google BigQuery. For example:

SELECT \* FROM [projectId:datasetId.tableId] ORDER BY position

#### auditLogMode = false

#### gg.handler.name.auditLogMode=false

When the handler is configured to run with audit log mode false, the data is pushed into Google BigQuery using a unique row identification key. The Google BigQuery is able to merge different operations for the same row. However, the behavior is complex. The Google BigQuery maintains a finite deduplication period in which it will merge operations for a given row. Therefore, the results can be somewhat nondeterministic.

The trail source needs to have a full image of the records in order to merge correctly. Example 1

An insert operation is sent to BigQuery and before the deduplication period expires, an update operation for the same row is sent to BigQuery. The resultant is a single row in BigQuery for the update operation.

Example 2

An insert operation is sent to BigQuery and after the deduplication period expires, an update operation for the same row is sent to BigQuery. The resultant is that both the insert and the update operations show up in BigQuery.

This behavior has confounded many users, as this is the documented behavior when using the BigQuery SDK and a feature as opposed to a defect. The documented length of the deduplication period is at least one minute. However, Oracle testing has shown that the period is significantly longer. Therefore, unless users can guarantee that all operations for a give row occur within a very short period, it is likely there will be multiple entries for a given row in BigQuery. It is therefore just as important for users to configure meta columns with the optype and position so they can determine the latest state for a given row. To read more about audit log mode read the following Google BigQuery documentation:Streaming data into BigQuery.

#### Operation Processing Support

The BigQuery Handler pushes operations to Google BigQuery using synchronous API. Insert, update, and delete operations are processed differently in BigQuery than in a traditional RDBMS.

The following explains how insert, update, and delete operations are interpreted by the handler depending on the mode of operation:

#### auditLogMode = true

- insert Inserts the record with optype as an insert operation in the BigQuery table.
- update -Inserts the record with optype as an update operation in the BigQuery table.
- delete Inserts the record with optype as a delete operation in the BigQuery table.
- pkUpdate—When pkUpdateHandling property is configured as delete-insert, the handler sends out a delete operation followed by an insert operation. Both these rows have the same position in the BigQuery table, which helps to identify it as a primary key operation and not a separate delete and insert operation.

#### auditLogMode = false

- insert If the row does not already exist in Google BigQuery, then an insert operation is processed as an insert. If the row already exists in Google BigQuery, then an insert operation is processed as an update. The handler sets the deleted column to false.
- update If a row does not exist in Google BigQuery, then an update operation is processed as an insert. If the row already exists in Google BigQuery, then an update operation is processed as update. The handler sets the deleted column to false.
- delete If the row does not exist in Google BigQuery, then a delete operation is added. If the row exists in Google BigQuery, then a delete operation is processed as a delete. The handler sets the deleted column to true.
- pkUpdate—When pkUpdateHandling property is configured as delete-insert, the handler sets the deleted column to true for the row whose primary key is updated. It is followed by a separate insert operation with the new primary key and the deleted column set to false for this row.

Do not toggle the audit log mode because it forces the BigQuery handler to abend as Google BigQuery cannot alter schema of an existing table. The existing table needs to be deleted before switching audit log modes.

#### Note:

The BigQuery Handler does not support the truncate operation. It abends when it encounters a truncate operation.

### **Proxy Settings**

To connect to BigQuery using a proxy server, you must configure the proxy host and the proxy port in the properties file as follows:

```
jvm.bootoptions= -Dhttps.proxyHost=proxy_host_name -
Dhttps.proxyPort=proxy port number
```

### Mapping to Google Datasets

A dataset is contained within a specific Google cloud project. Datasets are top-level containers that are used to organize and control access to your tables and views.

A table or view must belong to a dataset, so you need to create at least one dataset before loading data into BigQuery.

The Big Query handler can use existing datasets or create datasets if not found.

The Big Query Handler maps the table's schema name to the dataset name. For three-part table names, the dataset is constructed by concatenating catalog and schema.

### Setting Up and Running the BigQuery Handler

The Google BigQuery Handler uses the Java BigQuery client libraries to connect to Big Query.

These client libraries are located using the following Maven coordinates:

- Group ID: com.google.cloud
- Artifact ID: google-cloud-bigquery
- Version: 2.7.1

The BigQuery Client libraries do not ship with Oracle GoldenGate for Big Data. Additionally, Google appears to have removed the link to download the BigQuery Client libraries. You can download the BigQuery Client libraries using Maven and the Maven coordinates listed above. However, this requires proficiency with Maven. The Google BigQuery client libraries can be downloaded using the Dependency downloading scripts. For more information, see Google BigQuery Dependencies.

For more information about Dependency Downloader, see Dependency Downloader.

- Schema Mapping for BigQuery
- Understanding the BigQuery Handler Configuration
- Review a Sample Configuration
- Configuring Handler Authentication

### Schema Mapping for BigQuery

The table schema name specified in the replicat map statement is mapped to the BigQuery dataset name. For example: map QASOURCE.\*, target "dataset\_US".\*;

This map statement replicates tables to the BigQuery dataset "dataset\_US". Oracle GoldenGate for Big Data normalizes schema and table names to uppercase. Lowercase and mixed case dataset and table names are supported, but need to be quoted in the Replicat mapping statement.

### Understanding the BigQuery Handler Configuration

The following are the configurable values for the BigQuery Handler. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the BigQuery Handler, you must first configure the handler type by specifying gg.handler.name.type=bigquery and the other BigQuery properties as follows:

Properties	Required/ Optional	Legal Value s	Defau It	Explanation
gg.handlerlist	Required	Any string	None	Provides a name for the BigQuery Handler. The BigQuery Handler name then becomes part of the property names listed in this table.
gg.handler. <i>nam</i> e.type=bigquer y	Required	bigqu ery	None	Selects the BigQuery Handler for streaming change data capture into Google BigQuery.

Properties	Required/ Optional	-	Defau It	Explanation
gg.handler. <i>nam</i> e.credentialsF ile	Optional	Relativ e or absolu te path to the creden tials file	None	The credentials file downloaded from Google BigQuery for authentication. If you do not specify the path to the credentials file, you need to set it as an environment variable, see Configuring Handler Authentication.
gg.handler. <i>nam</i> e.projectId	Required	Any string	None	The name of the project in Google BigQuery. The handler needs project ID to connect to Google BigQuery store.
gg.handler. <i>nam</i> e.batchSize	Optional	Any numbe r	500	The maximum number of operations to be batched together. This is applicable for all target table batches.
gg.handler. <i>nam</i> e.batchFlushFr equency	Optional	Any numbe r	1000	The maximum amount of time in milliseconds to wait before executing the next batch of operations. This is applicable for all target table batches.
gg.handler. <i>nam</i> e.skipInvalidR ows	Optional	true  false	false	Sets whether to insert all valid rows of a request, even if invalid rows exist. If not set, the entire insert request fails if it contains an invalid row.
gg.handler. <i>nam</i> e.ignoreUnknow nValues	Optional	true  false	false	Sets whether to accept rows that contain values that do not match the schema. If not set, rows with unknown values are considered to be invalid.
gg.handler. <i>nam</i> e.connectionTi meout	Optional	Positiv e integer	20000	The maximum amount of time, in milliseconds, to wait for the handler to establish a connection with Google BigQuery.
gg.handler. <i>nam</i> e.readTimeout	Optional	Positiv e integer	30000	The maximum amount of time in milliseconds to wait for the handler to read data from an established connection.
gg.handler. <i>nam</i> e.metaColumnsT emplate	Optional	A legal string	None	A legal string specifying the metaColumns to be included. If you set auditLogMode to true, it is important that you set the metaColumnsTemplate property to view the operation type for the row inserted in the audit log, see Metacolumn Keywords.
gg.handler. <i>nam</i> e.auditLogMode	Optional	true  false	false	Set to true, the handler writes each record to the target without any primary key. Everything is processed as insert. Set to false, the handler tries to merge incoming records into the target table if they have the same primary key. Primary keys are needed for this property. The trail source records need to have a full image updates to merge correctly.

Properties	Required/ Optional	Legal Value s	Defau It	Explanation
gg.handler. <i>nam</i> e.pkUpdateHand ling	Optional	abend   delet e- inser t	abend	<ul> <li>Sets how the handler handles update operations that change a primary key. Primary key operations can be problematic for the BigQuery Handler and require special consideration:</li> <li>abend- indicates the process abends.</li> <li>delete-insert- indicates the process treats the operation as a delete and an insert. The full before image is required for this property to work correctly. Without full before and after row images the insert data are incomplete. Oracle recommends this option.</li> </ul>
gg.handler. <i>nam</i> e.adjustScale	Optional	true  false	false	The BigQuery numeric data type supports a maximum scale of 9 digits. If a field is mapped into a BigQuery numeric data type, then it fails if the scale is larger than 9 digits. Set this property to true to round fields mapped to BigQuery numeric data types to a scale of 9 digits. Enabling this property results in a loss of precision for source data values with a scale larger than 9.
gg.handler.nam e.includeDelet edColumn	Optional	true  false	false	Set to true to include a boolean column in the output called deleted. The value of this column is set to false for insert and update operations, and is set to true for delete operations.
gg.handler. <i>nam</i> e.enableAlter	Optional	true  false	false	Set to true to enable altering the target BigQuery table. This will allow the BigQuery Handler to add columns or metacolumns configured on the source, which are not currently in the target BigQuery table.
gg.handler. <i>nam</i> e.clientId	Optional	String	None	Use to set the client id if the configuration property gg.handler.name.credentialsFile to resolve the Google BigQuery credentials is not set. You may wish to use this property instead of the credentials file in order to use Oracle Wallet to secure credentials.
gg.handler. <i>nam</i> e.clientEmail	Optional	String	None	Use to set the client email if the configuration property gg.handler.name.credentialsFile to resolve the Google BigQuery credentials is not set. You may wish to use this property instead of the credentials file inorder to use Oracle Wallet to secure credentials.

Properties	Required/ Optional	Legal Value s	Defau It	Explanation
gg.handler. <i>nam</i> e.privateKey	Optional	String	None	Use to set the private key if the configuration property gg.handler.name.credentialsFile to resolve the Google BigQuery credentials is not set. You may wish to use this property instead of the credentials file inorder to use Oracle Wallet to secure credentials.
gg.handler. <i>nam</i> e.privateKeyId	Optional	String	None	Use to set the private key id if the configuration property gg.handler.name.credentialsFile to resolve the Google BigQuery credentials is not set. You may wish use this property instead of the credentials file in order to use Oracle Wallet to secure credentials.
gg.eventhandle r.bq.clientId	Optional	Valid Big Query Crede ntials Client ID	It gets auto- config ured by copyin g the value from gg.ev entha ndler .gcs. clien tId proper ty.	Provides the client ID key from the credentials file for connecting to Google Big Query service account.
gg.eventhandle r.bq.clientEma il	Optional	Valid Big Query Crede ntials Client Email	It gets auto- config	Provides the client Email key from the credentials file for connecting to Google Big Query service account.

Properties	Required/ Optional	Legal Value s	Defau It	Explanation
gg.eventhandle r.bq.privateKe yId	Optional	Valid Big Query Crede ntials Privat e Key ID	It gets auto- config ured by copyin g the value from gg.ev entha ndler .gcs. priva teKey Id proper ty.	Provides the Private Key ID from the credentials file for connecting to Google Big Query service account.
gg.eventhandle r.bq.privateKe Y	Optional	Valid Big Query Crede ntials Privat e Key.	It gets auto- config ured by copyin g the value from gg.ev entha ndler .gcs. priva teKey proper ty.	Provides the Private Key from the credentials file for connecting to Google Big Query service account.
gg.operation.a ggregator.vali date.keyupdate	Optional	true <b>or</b> false	false	If set to true, Operation Aggregator will validate key update operations (optype 115) and correct to normal update if no key values have changed. Compressed key update operations do not qualify for merge.

To be able to connect GCS to the Google Cloud Service account, ensure that either of the following is configured: the credentials file property with the relative or absolute path to credentials JSON file or the properties for individual credentials keys. The configuration property that is used to individually add google service account credential key enables them to be encrypted using the Oracle wallet.

### Review a Sample Configuration

The following is a sample configuration for the BigQuery Handler:

gg.handlerlist = bigquery

```
#The handler properties
gg.handler.bigquery.type = bigquery
gg.handler.bigquery.projectId = festive-athlete-201315
gg.handler.bigquery.credentialsFile = credentials.json
gg.handler.bigquery.auditLogMode = true
gg.handler.bigquery.pkUpdateHandling = delete-insert
```

gg.handler.bigquery.metaColumnsTemplate =\${optype}, \${position}

### Configuring Handler Authentication

You have to configure the BigQuery Handler authentication using the credentials in the JSON file downloaded from Google BigQuery.

Download the credentials file:

- 1. Login into your Google account at cloud.google.com.
- 2. Click Console, and then to go to the Dashboard where you can select your project.
- 3. From the navigation menu, click APIs & Services then select Credentials.
- 4. From the Create Credentials menu, choose Service account key.
- 5. Choose the JSON key type to download the JSON credentials file for your system.

After you have the credentials file, you can authenticate the handler in one of the following methods listed here:

• Specify the path to the credentials file in the properties file with the gg.handler.name.credentialsFile configuration property.

The path of the credentials file must contain the path with no wildcard appended. If you include the \* wildcard in the path to the credentials file, the file is not recognized.

Or

- Set the credentials file keys (clientId, ClientEmail, privateKeyId, and privateKey) into the corresponding handler properties. Or
- Set the GOOGLE\_APPLICATION\_CREDENTIALS environment variable on your system. For example:

export GOOGLE APPLICATION CREDENTIALS = credentials.json

Then restart the Oracle GoldenGate manager process.

### Google BigQuery Dependencies

The Google BigQuery client libraries are required for integration with BigQuery.

The maven coordinates are as follows:

Maven groupId: com.google.cloud

Maven artifactId: google-cloud-bigquery

Version: 2.7.1

• BigQuery 2.7.1

### BigQuery 2.7.1

The required BigQuery Client libraries for the 2.7.1 version are as follows:

```
api-common-2.1.3.jar
checker-compat-qual-2.5.5.jar
checker-qual-3.21.1.jar
commons-codec-1.15.jar
commons-logging-1.2.jar
error prone annotations-2.11.0.jar
failureaccess-1.0.1.jar
gax-2.11.0.jar
gax-httpjson-0.96.0.jar
google-api-client-1.33.1.jar
google-api-services-bigguery-v2-rev20211129-1.32.1.jar
google-auth-library-credentials-1.4.0.jar
google-auth-library-oauth2-http-1.4.0.jar
google-cloud-bigquery-2.7.1.jar
google-cloud-core-2.4.0.jar
google-cloud-core-http-2.4.0.jar
google-http-client-1.41.2.jar
google-http-client-apache-v2-1.41.2.jar
google-http-client-appengine-1.41.2.jar
google-http-client-gson-1.41.2.jar
google-http-client-jackson2-1.41.2.jar
google-oauth-client-1.33.0.jar
grpc-context-1.44.0.jar
gson-2.8.9.jar

# Google BigQuery Stage and Merge

#### Topics:

Overview

BigQuery is Google Cloud's fully managed, petabyte-scale, and cost-effective analytics data warehouse that lets you run analytics over vast amounts of data in near real time.

- Detailed Functionality
- Prerequisites
- Differences between BigQuery Handler and Stage and Merge BigQuery Event Handler
- Authentication or Authorization

- Configuration
- Troubleshooting and Diagnostics

### Overview

BigQuery is Google Cloud's fully managed, petabyte-scale, and cost-effective analytics data warehouse that lets you run analytics over vast amounts of data in near real time.

### Detailed Functionality

The BigQuery Event handler uses the stage and merge data flow.

The change data is staged in a temporary location in microbatches and eventually merged into to the target table. Google Cloud Storage (GCS) is used as the staging area for change data.

This Event handler is used as a downstream Event handler connected to the output of the GCS Event handler.

The GCS Event handler loads files generated by the File Writer Handler into Google Cloud Storage.

The Event handler runs BigQuery Query jobs to execute MERGE SQL. The SQL operations are performed in batches providing better throughput.

### Note:

The BigQuery Event handler doesn't use the Google BigQuery streaming API.

## Prerequisites

- **Target table existence**: Ensure that the target tables exist in the BigQuery dataset.
- **Google Cloud Storage(GCS) bucket and dataset location**: Ensure that the GCS bucket and the BigQuery dataset exist in the same location/region.

Differences between BigQuery Handler and Stage and Merge BigQuery Event Handler

Table 8-23	<b>BigQuery Handler</b>	v/s Stage and Merge	BigQuery Event Handler
------------	-------------------------	---------------------	------------------------

Feature/Limitation	BigQuery Handler	Stage And Merge BigQuery Event Handler
Compressed update support	Partially supported with limitations.	YES
Audit log mode	Process all the operations as INSERT.	No need to enable audit log mode.
GCP Quotas/Limits	Maximum rows per second per table: 100000. See Google BigQuery Documentation.	Daily destination table update limit — 1500 updates per table per day. See Google BigQuery Documentation.

Feature/Limitation	BigQuery Handler	Stage And Merge BigQuery Event Handler
Approximate pricing with 1TB Storage (for exact pricing refer GCP Pricing calculator)	Streaming Inserts for 1TB costs ~72.71 USD per month	Query job for 1TB costs ~20.28 USD per month.
Duplicate rows replicated to BigQuery	YES	NO
Replication of TRUNCATE operation	Not supported	Supported
API used	BigQuery Streaming API	BigQuery Query job

#### Table 8-23 (Cont.) BigQuery Handler v/s Stage and Merge BigQuery Event Handler

### Authentication or Authorization

For more information about using the Google service account key, see Authentication and Authorization in the Google Cloud Service (GCS) Event Handler topic. In addition to the permissions needed to access GCS, the service account also needs permissions to access BigQuery. You may choose to use a pre-defined IAM role, such as roles/bigquery.dataEditor or roles/bigquery.dataOwner. When creating a custom role, the following are the IAM permissions used to run BigQuery Event handler. For more information, see Configuring Handler Authentication.

BigQuery Permissions

### **BigQuery Permissions**

Permission	Description
bigquery.connections.create	Create new connections in a project.
bigquery.connections.delete	Delete a connection.
bigquery.connections.get	Gets connection metadata. Credentials are excluded.
bigquery.connections.list	List connections in a project.
bigquery.connections.update	Update a connection and its credentials.
bigquery.connections.use	Use a connection configuration to connect to a remote data source.
bigquery.datasets.create	Create new datasets.
bigquery.datasets.get	Get metadata about a dataset.
bigquery.connections.export	Export table data out of BigQuery.
bigquery.connections.get	Get table metadata. To get table data, you need bigquery.tables.getData.
bigquery.connections.list	List connections in a project.
bigquery.connections.update	Update a connection and its credentials.
bigquery.datasets.create	Create new empty datasets.
bigquery.datasets.get	Get metadata about a dataset.
bigquery.datasets.getIamPolicy	Reserved for future use.

#### Table 8-24 BigQuery Permissions

Permission	Description
bigquery.datasets.update	Update metadata for a dataset.
bigquery.datasets.updateTag	Update tags for a dataset.
bigquery.jobs.create	Run jobs (including queries) within the project.
bigquery.jobs.get	Get data and metadata on any job.
bigquery.jobs.list	List all jobs and retrieve metadata on any job submitted by any user. For jobs submitted by other users, details and metadata are redacted.
bigquery.jobs.listAll	List all jobs and retrieve metadata on any job submitted by any user.
bigquery.jobs.update	Cancel any job.
bigquery.readsessions.create	Create a new read session via the BigQuery Storage API.
bigquery.readsessions.getData	Read data from a read session via the BigQuery Storage API.
bigquery.readsessions.update	Update a read session via the BigQuery Storage API.
bigquery.reservations.create	Create a reservation in a project.
bigquery.reservations.delete	Delete a reservation.
bigquery.reservations.get	Retrieve details about a reservation.
bigquery.reservations.list	List all reservations in a project.
bigquery.reservations.update	Update a reservation's properties.
<pre>bigquery.reservationAssignments.crea te</pre>	Create a reservation assignment. This permission is required on the owner project and assignee resource. To move a reservation assignment, you need bigquery.reservationAssignments.crea te on the new owner project and assignee resource.
bigquery.reservationAssignments.dele te	Delete a reservation assignment. This permission is required on the owner project and assignee resource. To move a reservation assignment, you need bigquery.reservationAssignments.dele te on the old owner project and assignee resource.
bigquery.reservationAssignments.list	List all reservation assignments in a project.
$\verb bigquery.reservationAssignments.sear  \\ \verb ch  $	Search for a reservation assignment for a given project, folder, or organization.
bigquery.routines.create	Create new routines (functions and stored procedures).
bigquery.routines.delete	Delete routines.
bigquery.routines.list	List routines and metadata on routines.
bigquery.routines.update	Update routine definitions and metadata.
bigquery.savedqueries.create	Create saved queries.
bigquery.savedqueries.delete	Delete saved queries.

Table 8-24 (Cont.) BigQuery Permissions

Permission	Description
bigquery.savedqueries.get	Get metadata on saved queries.
bigquery.savedqueries.list	Lists saved queries.
bigquery.savedqueries.update	Updates saved queries.
bigquery.tables.create	Create new tables.
bigquery.tables.delete	Delete tables
bigquery.tables.export	Export table data out of BigQuery.
bigquery.tables.get	Get table metadata. To get table data, you need bigquery.tables.getData.
bigquery.tables.getData	Get table data. This permission is required for querying table data. To get table metadata, you need bigquery.tables.get.
bigquery.tables.getIamPolicy	Read a table's IAM policy.
bigquery.tables.list	List tables and metadata on tables.
bigquery.tables.setCategory	Set policy tags in table schema.
bigquery.tables.setIamPolicy	Changes a table's IAM policy.
bigquery.tables.update	Update table metadata. To update table data, you need bigquery.tables.updateData.
bigquery.tables.updateData	Update table data. To update table metadata, you need bigquery.tables.update.
bigquery.tables.updateTag	Update tags for a table.

Table 8-24	(Cont.)	BigQuery	Permissions
------------	---------	----------	-------------

In addition to these permissions, ensure that resourcemanager.projects.get/list is always granted as a pair.

# Configuration

- Automatic Configuration
- Classpath Configuration The GCS Event handler and the BigQuery Event handler use the Java SDK provided by Google. Google does not provide a direct link to download the SDK.
- Proxy Configuration
- INSERTALLRECORDS Support
- BigQuery Dataset and GCP ProjectId Mapping
- End-to-End Configuration

### Automatic Configuration

Replication to BigQuery involves configuring of multiple components, such as File Writer handler, Google Cloud Storae (GCS) Event handler and BigQuery Event handler.

The Automatic Configuration functionality helps to auto configure these components so that the user configuration is minimal.

The properties modified by auto configuration is also logged in the handler log file. To enable auto configuration to replicate to BigQuery target, set the parameter gg.target=bq.

When replicating to BigQuery target, you cannot customize GCS Event handler name and BigQuery Event handler name.

File Writer Handler Configuration

File Writer handler name is preset to the value bq. The following is an example to edit a property of File Writer handler: gg.handler.bq.pathMappingTemplate=./dirout.

- GCS Event Handler Configuration The GCS Event handler name is preset to the value gcs. The following is an example to edit a property of GCS Event handler: gg.eventhandler.gcs.concurrency=5.
- BigQuery Event Handler Configuration

BigQuery Event handler name is preset to the value bq. There are no mandatory parameters required for BigQuery Event handler. Mostly, auto configure derives the required parameters.

#### File Writer Handler Configuration

File Writer handler name is preset to the value bq. The following is an example to edit a property of File Writer handler: gg.handler.bq.pathMappingTemplate=./dirout.

#### GCS Event Handler Configuration

The GCS Event handler name is preset to the value gcs. The following is an example to edit a property of GCS Event handler: gg.eventhandler.gcs.concurrency=5.

#### **BigQuery Event Handler Configuration**

BigQuery Event handler name is preset to the value bq. There are no mandatory parameters required for BigQuery Event handler. Mostly, auto configure derives the required parameters.

The following are the BigQuery Event handler configurations:

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.bq.credent ialsFile	Optional	Relative or absolute path to the service account key file.	Value from property gg.eventhandl er.gcs.creden tialsFile	Sets the path to the service account key file. Autoconfigure wil automatically configure this property based on the configuration gg.eventhandl er.gcs.creden tialsFile, unless the user wants to use a different service account key file for BigQuery access. Alternatively, if the environment variable GOOGLE_APPLIC ATION_CREDENT IALS is set to the path to the service account key file, this parameter need not be set.
gg.eventhandl er.bq.project Id	Optional	The Google project-id	project-id associated with the service account.	Sets the project- id of the Google Cloud project that houses BigQuery Autoconfigure will automatically configure this property by accessing the service account key file unless user wants to override this explicitly.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.bq.kmsKey	Optional	Key names in the format: projects/ <project>/ locations/ <location>/ keyRings/ <ring_name>/ cryptoKeys/ <key_name> • <project>: Google project-id • <location> : Location of the BigQuery dataset. • <ring_name &gt;: Google Cloud KMS key ring name. • <key_name> : Google Cloud KMS key name.</key_name></ring_name </location></project></key_name></ring_name></location></project>	Value from property gg.eventhandl er.gcs.kmsKey	Set a customer managed Cloud KMS key to encrypt data in BigQuery. Autoconfigure wi automatically configure this property based on the configuration gg.eventhandl er.gcs.kmsKey
gg.eventhandl er.bq.connect ionTimeout	Optional	Positive integer.	20000	The maximum amount of time, i milliseconds, to wait for the handler to establish a connection with Google BigQuery
gg.eventhandl er.bq.readTim eout	Optional	Positive integer.	30000	The maximum amount of time ir milliseconds to wait for the handler to read data from an established connection.
gg.eventhandl er.bq.totalTi meout	Optional	Positive integer.	120000	The total timeout parameter in seconds. The TotalTimeout parameter has the ultimate control over how long the logic should keep trying the remote call until it gives up completely.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.bq.retries	Optional	Positive integer.	3	The maximum number of retry attempts to perform.
gg.eventhandl er.bq.createD ataset	Optional	true false	true	Set to true to automatically create the BigQuery dataset if it does not exist.
gg.eventhandl er.bq.createT able	Optional	true false	true	Set to true to automatically create the BigQuery target table if it does not exist.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.aggregate. operations.fl ush.interval	Optional	Integer	30000	The flush interval parameter determines how often the data will be merged into Snowflake. The value is set in milliseconds.

## **Classpath Configuration**

The GCS Event handler and the BigQuery Event handler use the Java SDK provided by Google. Google does not provide a direct link to download the SDK.

You can download the SDKs using the following maven co-ordinates:

#### **Google Cloud Storage**

```
<dependency>
    <groupId>com.google.cloud</groupId>
    <artifactId>google-cloud-storage</artifactId>
```

Chapter 8 Target

```
<version>1.113.9</version>
</dependency>
```

To download the GCS dependencies, execute the following script <OGGDIR>/ DependencyDownloader/gcs.sh.

#### BigQuery

To download the BigQuery dependencies, execute the following script <OGGDIR>/ DependencyDownloader/bigquery.sh. For more information, see gcs.sh in Dependency Downloader Scripts.

Set the path to the GCS and BigQuery SDK in the gg.classpath configuration parameter. For example: gg.classpath=./gcs-deps/\*:./bq-deps/\*.

For more information, see Dependency Downloader Scripts.

#### **Proxy Configuration**

When the replicat process is run behind a proxy server, you can use the jvm.bootoptions property to set the proxy server configuration. For example: jvm.bootoptions=- Dhttps.proxyHost=some-proxy-address.com -Dhttps.proxyPort=80.

#### INSERTALLRECORDS Support

Stage and merge targets supports INSERTALLRECORDS parameter.

See INSERTALLRECORDS in *Reference for Oracle GoldenGate*. Set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm). Set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm)

Setting this property directs the Replicat process to use bulk insert operations to load operation data into the target table.

To process initial load trail files, set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm). Setting this property directs the Replicat process to use bulk insert operations to load operation data into the target table. You can tune the batch size of bulk inserts using the gg.handler.bq.maxFileSize File Writer property. The default value is set to 1GB.

The frequency of bulk inserts can be tuned using the File Writer gg.handler.bq.fileRollInterval property, the default value is set to 3m (three minutes).

#### BigQuery Dataset and GCP ProjectId Mapping

The BigQuery Event handler maps the table schema name to the BigQuery dataset. The table catalog name is mapped to the GCP projectId.

- Three-Part Table Names
- Mapping Table

#### Three-Part Table Names

If the tables use distinct catalog names, then the BigQuery datasets would reside in multiple GCP projects. The GCP service account key should have the required privileges in the respective GCP projects. See BigQuery Permissions.

#### Mapping Table

MAP statement in the Replicat parameter file	BigQuery Dataset	GCP ProjectId
<pre>MAP SCHEMA1.*, TARGET "bq-project-1".*.*;</pre>	SCHEMA1	bq-project-1
<pre>MAP "bq- project-2".SCHEMA2.*, TARGET *.*.*;</pre>	SCHEMA2	bq-project-2
<pre>MAP SCHEMA3.*, TARGET *.*;</pre>	SCHEMA3	The default projectId from the GCP service account key file or the configuration gg.eventhandler.bq.proj ectId.

Table 8-2	5 Mapp	oing T	able
-----------	--------	--------	------

### End-to-End Configuration

The following is an end-end configuration example which uses auto configuration for File Writer (FW) handler, GCS, and BigQuery Event handlers.

This sample properties file is located at: AdapterExamples/big-data/bigquery-via-gcs/bq.props.

```
# Configuration to load GoldenGate trail operation records
 # into Google Big Query by chaining
 # File writer handler -> GCS Event handler -> BQ Event handler.
 # Note: Recommended to only edit the configuration marked as TODO
 # The property gg.eventhandler.gcs.credentialsFile need not be set if
 # the GOOGLE APPLICATION CREDENTIALS environment variable is set.
gg.target=bq
 ## The GCS Event handler
 #TODO: Edit the GCS bucket name
gg.eventhandler.gcs.bucketMappingTemplate=<gcs-bucket-name>
 #TODO: Edit the GCS credentialsFile
gg.eventhandler.gcs.credentialsFile=/path/to/gcp/credentialsFile
## The BQ Event handler
## No mandatory configuration required.
#TODO: Edit to include the GCS Java SDK and BQ Java SDK.
gg.classpath=/path/to/gcs-deps/*:/path/to/bq-deps/*
#TODO: Edit to provide sufficient memory (at least 8GB).
jvm.bootoptions=-Xmx8g -Xms8g
#TODO: If running OGGBD behind a proxy server.
#jvm.bootoptions=-Xmx8g -Xms512m -Dhttps.proxyHost=<ip-address> -
Dhttps.proxyPort=<port>
```

## **Troubleshooting and Diagnostics**

- **DDL not applied on the target table**: Oracle GoldenGate for BigData does not support DDL replication.
- **SQL Errors**: In case there are any errors while executing any SQL, the entire SQL statement along with the bind parameter values are logged into the Oracle GoldenGate for Big Data handler log file.
- Co-existence of the components: The location/region of the machine where Replicat process is running and the BigQuery dataset/GCS bucket impacts the overall throughput of the apply process.
   Data flow is as follows: GoldenGate -> GCS bucket -> BigQuery. For best throughput, ensure that the components are located as close as possible.
- com.google.cloud.bigquery.BigQueryException: Access Denied: Project <anygcp-project>: User does not have bigquery.datasets.create permission in project <any-gcp-project>. The service account key used by Oracle GoldenGate for BigData does not have permission to create datasets in this project. Grant the permission bigquery.datasets.create and restart the Replicat process. The privileges are listed in BigQuery Permissions.

# **Google Cloud Storage**

### Topics:

- Overview
- Prerequisites
- Buckets and Objects
- Authentication and Authorization
- Configuration

## Overview

Google Cloud Storage (GCS) is a service for storing objects in Google Cloud Platform. You can use the GCS Event handler to load files generated by the File Writer handler into GCS.

# Prerequisites

Ensure to have the following set up:

- Google Cloud Platform (GCP) account set up.
- Google service account key with the relevant permissions.
- GCS Java Software Developement Kit (SDK)

# **Buckets and Objects**

Buckets are the basic containers in GCS that store data (objects). Objects are the individual pieces of data that you store in the Cloud Storage bucket.

# Authentication and Authorization

A Google Cloud Platform (GCP) service account is a special kind of account used by an application, not by a person. Oracle GoldenGate for BigData uses a service account key for accessing GCS service.

You need to create a service account key with the relevant Identity and Access Management (IAM) permissions.

Use the JSON key type to generate the service account key file.

You can either set the path to the service account key file in the environment variable GOOGLE\_APPLICATION\_CREDENTIALS or in the GCS Event handler property
gg.eventhandler.name.credentialsFile. You can also specify the individual keys of
credentials file like clientId, clientEmail, privateKeyId and privateKey into
corresponding handler properties instead of specifying the credentials file path directly.
This enables the credential keys to be encrypted using Oracle wallet.

For more information about creating a service account key, see GCP documentation. The following are the IAM permissions to be added into the service account used to run GCS Event handler.

- Bucket Permissions
- Object Permissions

## **Bucket Permissions**

Bucket Permission Name	Description
storage.bucke ts.create	Create new buckets in a project.
storage.bucke ts.delete	Delete buckets.
storage.bucke ts.get	Read bucket metadata, excluding IAM policies.
storage.bucke ts.list	List buckets in a project. Also read bucket metadata, excluding IAM policies, when listing.
storage.bucke ts.update	Update bucket metadata, excluding IAM policies.

#### Table 8-26 Bucket Permissions

# **Object Permissions**

Table 8-27	<b>Object Permissions</b>
------------	---------------------------

Object Permission Name	Description
<pre>storage.objects .create</pre>	Add new objects to a bucket.
storage.objects .delete	Delete objects.
<pre>storage.objects .get</pre>	Read object data and metadata, excluding ACLs.
storage.objects .list	List objects in a bucket. Also read object metadata, excluding ACLs, when listing.
storage.objects .update	Update object metadata, excluding ACLs.

# Configuration

Table 8-28 Object Permissions

Properties	Required/ Optional	Legal Values	Default	Explanatio n
gg.eventh andler. <i>na</i> <i>me</i> .type	Required	gcs	None	Selects the GCS Event Handler for use with File Writer handler.

Properties	Required/ Optional	Legal Values	Default	Explanatio n
gg.eventh andler. <i>na</i> <i>me</i> .locati on		A valid GCS location.	None	If the GCS bucket does not exist, a new bucket will be created in this GCS location. If location is not specified, new bucket creation will fail. GCS location reference: GCS locations.
gg.eventh andler. <i>na</i> <i>me</i> .bucket MappingTe mplate	Required	A string with resolvable keywords and constants used to dynamicall y generate a GCS bucket name.	None	A GCS bucket is created by the GCS Event handler if it does not exist using this name. See Bucket Naming Guidelines. . For more information about supported keywords, see Template Keywords.

Table 8-28 (Cont.) Object Permissions

Properties	Required/ Optional	Legal Values	Default	Explanatio n
gg.eventh andler.na me.pathMa ppingTemp late		A string with resolvable keywords and constants used to dynamicall y generate the path in the GCS bucket to write the file.	None	Use keywords interlaced with constants to dynamicall y generate a unique GCS path names at runtime. Example path name: ogg/ data/\$ {groupNam e}/\$ {fullyQua lifiedTab leName}. For more information about supported keywords, see Template Keywords.
gg.eventh andler. <i>na</i> me.fileNa meMapping Template	Optional	A string with resolvable keywords and constants used to dynamicall y generate a file name for the GCS object.	None	Use resolvable keywords and constants used to dynamicall y generate the GCS object file name. If not set, the upstream file name is used. For more information about supported keywords, see Template Keywords

 Table 8-28
 (Cont.) Object Permissions

Properties	Required/ Optional	Legal Values	Default	Explanatio n
gg.eventh andler. <i>na</i> me.finali zeAction	Optional	A unique string identifier cross referencing a child event handler.	No event handler configured.	Sets the downstrea m event handler that is invoked on the file roll event. A typical example would be use a downstrea m to load the GCS data into Google BigQuery using the BigQuery Event handler.
gg.eventh andler. <i>na</i> <i>m</i> e.creden tialsFile	Optional	Relative or absolute path to the service account key file.	Noe	Sets the path to the service account key file. Alternativel y, if the environme nt variable GOOGLE_AP PLICATION _CREDENTI ALS is set to the path to the service account key file, then you need not set this parameter.

				greater than 10

Table 8-28	(Cont.)	Object	Permissions
------------	---------	--------	-------------

Properties	Required/ Optional	Legal Values	Default	Explanatio n
				mega bytes.
gg.eventh andler.gc s.clientI d	Optional	Valid Big Query Credentials Client Id	NA	Provides the client ID key from the credentials file for connecting to Google Big Query service account.
gg.eventh andler.gc s.clientE mail	Optional	Valid Big Query Credentials Client Email	NA	Provides the client Email key from the credentials file for connecting to Google Big Query service account.
gg.eventh andler.gc s.private KeyId	Optional	Valid Big Query Credentials Client Email	NA	Provides the client Email key from the credentials file for connecting to Google Big Query service account.
gg.eventh andler.gc s.private Key	Optional	Valid Big Query Credentials Private Key.	NA	Provides the Private Key from the credentials file for connecting to Google Big Query service account.

Table 8-28	(Cont.) Object Permissions

Properties	Required/ Optional	Legal Values	Default	Explanatio n
gg.eventh andler.na me.projec tId	Optional	The Google project- id   project- id associated with the service account.	NA	Sets the project- id of the Google Cloud project that houses the storage bucket. Auto configure will automatical ly configure this property by accessing the service account key file unless user wants to override this explicitly.

Table 8-28	(Cont.)	Object	Permissions
------------	---------	--------	-------------

### Note:

To be able to connect GCS to the Google Cloud Service account, ensure that either of the following is configured: the credentials file property with the relative or absolute path to credentials JSON file or the properties for individual credentials keys. The configuration property to individually add google service account credential key enables them to encrypt using the Oracle wallet.

- Sample Configuration

## **Classpath Configuration**

The GCS Event handler uses the Java SDK for Google Cloud Storage. The classpath must include the path to the GCS SDK.

• Dependencies

## Dependencies

You can download the SDK using the following maven co-ordinates:

<dependency> <groupId>com.google.cloud</groupId> <artifactId>google-cloud-storage</artifactId> <version>1.113.9</version> </dependency>

Alternatively, you can download the GCS dependencies by running the script: <OGGDIR>/ DependencyDownloader/gcs.sh.

Edit the gg.classpath configuration parameter to include the path to the GCS SDK.

## **Proxy Configuration**

When the Replicat process runs behind a proxy server, you can use the jvm.bootoptions property to set proxy server configuration. For Example:

```
jvm.bootoptions=-Dhttps.proxyHost=some-proxy-address.com
-Dhttps.proxyPort=80
```

## Sample Configuration

```
#The GCS Event handler
gg.eventhandler.gcs.type=gcs
gg.eventhandler.gcs.pathMappingTemplate=${fullyQualifiedTableName}
#TODO: Edit the GCS bucket name
gg.eventhandler.gcs.bucketMappingTemplate=<gcs-bucket-name>
#TODO: Edit the GCS credentialsFile
gg.eventhandler.gcs.credentialsFile=/path/to/gcs/credentials-file
gg.eventhandler.gcs.finalizeAction=none
gg.classpath=/path/to/gcs-deps/*
jvm.bootoptions=-Xmx8g -Xms8g
```

# Java Message Service (JMS)

The Java Message Service (JMS) Handler allows operations from a trail file to be formatted in messages, and then published to JMS providers like Oracle Weblogic Server, Websphere, and ActiveMQ.

This chapter describes how to use the JMS Handler.

- Overview
- Setting Up and Running the JMS Handler
- JMS Dependencies

## Overview

The Java Message Service is a Java API that allows applications to create, send, receive, and read messages. The JMS API defines a common set of interfaces and associated semantics that allow programs written in the Java programming language to communicate with other messaging implementations.

The JMS Handler captures the Oracle GoldenGate trail and sends those messages to the configured JMS providers.

## Note:

The Java Message Service (JMS) Handler does not support DDL operations. In case of DDL operations, replicat/extract is expected to fail.

# Setting Up and Running the JMS Handler

The JMS Handler setup (JNDI configuration) depends on the JMS provider that you use.

The following sections provide instructions for configuring the JMS Handler components and running the handler.

#### **Runtime Prerequisites**

The JMS provider should be up and running with the required ConnectionFactory and QueueConnectionFactory and TopicConnectionFactory configured.

#### Security

Configure the SSL according to the JMS Provider used.

- Classpath Configuration
- Java Naming and Directory Interface Configuration
- Handler Configuration
- Sample Configuration Using Oracle WebLogic Server

## Classpath Configuration

Oracle recommends that you store the JMS Handler properties file in the Oracle GoldenGate dirprm directory. The JMS Handler requires the JMS Provider client JARs are in the classpath in order to execute. The location of the providers client JARs is similar to:

## Java Naming and Directory Interface Configuration

You configure the Java Naming and Directory Interface (JNDI) properties to connect to an Initial Context to look up the connection factory and initial destination.

Properties	Requir ed/ Option al	Legal Values	Default	Explanation
java.naming.pr ovider.url	Require d	Valid provider URL with port	None	Specifies the URL that the handler uses to look up objects on the server. For example, t3://localhost:7001 or if SSL is enabled t3s://localhost:7002.

#### Table 8-29 JNDI Configuration Properties

gg.classpath= path\_to\_the\_providers\_client\_jars

Properties	Requir ed/ Option al	Legal Values	Default	Explanation
java.naming.fa ctory.initial	Require d	Initial Context factory class name	None	Specifies which initial context factory to use when creating a new initial context object. For Oracle WebLogic Server, the value is weblogic.jndi.WLInitialContextFac tory.
java.naming.se curity.princip al		Valid user name	None	Specifies the user name to use.
java.naming.se curity.credent ials		Valid password	None	Specifies the password for the user.

	Table 8-29 (	(Cont.)	) JNDI Configuration Properties
--	--------------	---------	---------------------------------

# Handler Configuration

You configure the JMS Handler operation using the properties file. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the JMS Handler, you must first configure the handler type by specifying gg.handler.name.type=jms and the other JMS properties as follows:

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler. <i>name</i> .type	Require d	JMS	None	Set to jms to send transactions, operations, and metadata as formatted text messages to a JMS provider. Set to jms_map to send JMS map messages.
gg.handler. <i>name</i> .destination	Require d	Valid queue or topic name	None	Sets the queue or topic to which the message is sent. This must be correctly configured on the JMS server. For example, queue/A, queue.Test, example.MyTopic.
gg.handler. <i>name</i> .destinationTyp e	Optional	queue  topic	queue	Specifies whether the handler is sending to a queue (a single receiver) or a topic (publish/ subscribe). The gg.handler.name.queueOrTopic property is an alias of this property. Set to queue removes a message from the queue once it has been read. Set to topic publishes messages and can be delivered to multiple subscribers.

 Table 8-30
 JMS Handler Configuration Properties

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler. <i>name</i> .connectionFact ory	Require d	Valid connectio n factory name	None	Specifies the name of the connection factory to lookup using JNDI. The gg.handler.name.ConnectionFactoryJND IName property is an alias of this property
gg.handler. <i>name</i> .useJndi	Optional	true  false	true	Set to false, then JNDI is not used to configure the JMS client. Instead, factories and connections are explicitly constructed.
gg.handler. <i>name</i> .connectionUrl	Optional	Valid connectio n URL	None	Specify only when you are not using JNDI to explicitly create the connection.
gg.handler. <i>name</i> .connectionFact oryClass	Optional	Valid connecti onFactor yClass	None	Set to access a factory only when not using JNDI. The value of this property is the Java class name to instantiate, which constructs a factory object explicitly.
gg.handler. <i>name</i> .physicalDestin ation	Optional	Name of the queue or topic object obtained through the Connecti onFactor y API instead of the JNDI provider	None	The physical destination is important when JMS is configured to use JNDI. The ConnectionFactory is resolved through a JNDI lookup. Setting the physical destination means that the queue or topic is resolved by invoking a method on the ConnectionFactory instead of invoking JNDI.
gg.handler. <i>name</i> .user	Optional	Valid user name	None	The user name to send messages to the JMS server.
gg.handler. <i>name</i> .password	Optional	Valid password	None	The password to send messages to the JMS server.

Table 8-30	(Cont.)	<b>JMS Handler Configuration Properties</b>
	(00111)	ome nanaler comiguration roperties

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler. <i>name</i> .sessionMode	Optional	auto  client  dupsok	auto	Sets the JMS session mode, these values equate to the standard JMS values: Session.AUTO_ACKNOWLEDGE The session automatically acknowledges a client's receipt of a message either when the session has successfully returned from a call to receive or when the message listener the session has called to process the message successfully returns. Session.CLIENT_ACKNOWLEDGE The client acknowledges a consumed message by calling the message's acknowledge method. Session.DUPS_OK_ACKNOWLEDGE This acknowledgment mode instructs the session to lazily acknowledge the delivery of messages.
gg.handler. <i>name</i> .localTX	Optional	true  false	true	Sets whether local transactions are used when sending messages. Local transactions are enabled by default, unless sending and committing single messages one at a time. Set to false to disable local transactions.
gg.handler. <i>name</i> .persistent	Optional	true  false	true	Sets the delivery mode to persistent or not. If you want the messages to be persistent, the JMS provider must be configured to log the message to stable storage as part of the client's send operation.
gg.handler. <i>name</i> .priority	Optional	Valid integer between 0-10	4	The JMS server defines a 10 level priority value, with 0 as the lowest and 9 as the highest.
gg.handler. <i>name</i> .timeToLive	Optional	Time in millisecon ds	0	Sets the length of time in milliseconds from its dispatch time that a produced message is retained by the message system. Set to zero specifies that the time is unlimited.

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler. <i>name</i> .custom	Optional	Class names implement ing oracle.g oldengat e.messag ing.hand ler.GGMe ssageLif eCycleLi stener	None	Configures a message listener allowing properties to be set on the message before it is delivered.

Table 8-30	(Cont.) JMS Handler Configuration Properties
------------	--

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format	Optional	<pre>xml  tx2ml  xml2  minxml  csv  fixed  text  logdump  json </pre>	delimite dtext	Specifies the format used to transform operations and transactions into messages sent to the JMS server.
				The velocity template should point to the location of the template file. Samples are available under: AdapterExamples/ java-delivery/sample-dirprm/. Example: format_op2xml.vm
		json_op  json_row   delimite dtext  Velocity template		<pre>&lt;\$op.TableName sqlType='\$op.sqlType' opType='\$op.opType' txInd='\$op.txState' ts='\$op.Timestamp' numCols='\$op.NumColumns' pos='\$op.Position'&gt; #foreach(\$col in \$op ) #if(! \$col.isMissing()) &lt;\$col.Name colIndex='\$col.Index'&gt; #if(\$col.hasBefore()) #if(\$col.hasBeforeNull()) <before><isnull></isnull></before> #else <before><![CDATA[\$col.before]]><!-- before--> #{end}## if col has 'before' value #{end}## if col 'before' is null #if( \$col.isNull()) <after><isnull></isnull></after> #{else} <after><![CDATA[\$col.value]]><!-- after--> #{end}## if col is null #if( \$col.hasValue()) #if( \$col.hasValue()] #if( \$col.hasValue()] #if( \$col.hasValue()] #if( \$col.hasVal</after></before></pre>

Table 8-30	(Cont.) JMS Handler	Configuration	Properties
------------	---------------------	---------------	------------

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler. <i>name</i> .includeTables	Optional	List of valid table names	None	Specifies a list of tables the handler will include.
				If the schema (or owner) of the table is specified, then only that schema matches the table name. Otherwise, the table name matches any schema. A comma separated list of tables can be specified. For example, to have the handler only process tables foo.customer and bar.orders.
				If the catalog and schema (or owner) of the table are specified, then only that catalog and schema matches the table name. Otherwise, the table name matches any catalog and schema. A comma separated list of tables can be specified. For example, to have the handler only process tables dbo.foo.customer and dbo.bar.orders.
				If any table matches the include list of tables, the transaction is included.
				The list of table names specified are case sensitive.
gg.handler. <i>name</i> .excludeTables	Optional	List of valid table names	None	Specifies a list of tables the handler will exclude.
				To selectively process operations on a table by table basis, the handler must be processing in operation mode. If the handler is processing in transaction mode, then when a single transaction contains several operations spanning several tables. If any table matches the exclude list of tables, the transaction is excluded.
				The list of table names specified are case sensitive.
gg.handler. <i>name</i> .mode	Optional	op tx	op	Specifies whether to output one operation per message (op) or one transaction per message (tx).

# Sample Configuration Using Oracle WebLogic Server

#JMS Handler Template

#TODO: Set the path the jms client library wlthint3client.jar
gg.classpath=
jvm.bootoptions=-Xmx512m -Xms32m
```

## **JMS** Dependencies

The Java EE Specification APIs have moved out of the JDK in Java 8. JMS is a part of this specification, and therefore this dependency is required.

Maven groupId: javax

Maven artifactId: javaee-api

Version: 8.0

You can download the jar from Maven Central Repository.

• JMS 8.0

JMS 8.0

javaee-api-8.0.jar

# Java Database Connectivity

Learn how to use the Java Database Connectivity (JDBC) Handler, which can replicate source transactional data to a target or database.

This chapter describes how to use the JDBC Handler.

Overview

#### Detailed Functionality

The JDBC Handler replicates source transactional data to a target or database by using a JDBC interface.

- Setting Up and Running the JDBC Handler Use the JDBC Metadata Provider with the JDBC Handler to obtain column mapping features, column function features, and better data type mapping.
- Sample Configurations

# Overview

The Generic Java Database Connectivity (JDBC) Handler lets you replicate source transactional data to a target system or database by using a JDBC interface. You can use it with targets that support JDBC connectivity.

You can use the JDBC API to access virtually any data source, from relational databases to spreadsheets and flat files. JDBC technology also provides a common base on which the JDBC Handler was built. The JDBC handler with the JDBC metadata provider also lets you use Replicat features such as column mapping and column functions. For more information about using these features, see Metadata Providers

For more information about using the JDBC API, see http://docs.oracle.com/javase/8/ docs/technotes/guides/jdbc/index.html.

# **Detailed Functionality**

The JDBC Handler replicates source transactional data to a target or database by using a JDBC interface.

- Single Operation Mode
- Oracle Database Data Types
- MySQL Database Data Types
- Netezza Database Data Types
- Redshift Database Data Types

## Single Operation Mode

The JDBC Handler performs SQL operations on every single trail record (row operation) when the trail record is processed by the handler. The JDBC Handler does not use the BATCHSQL feature of the JDBC API to batch operations.

## Oracle Database Data Types

The following column data types are supported for Oracle Database targets:

NUMBER DECIMAL INTEGER FLOAT REAL DATE TIMESTAMP INTERVAL YEAR TO MONTH INTERVAL DAY TO SECOND CHAR

VARCHAR2 NCHAR NVARCHAR2 RAW CLOB NCLOB BLOB TIMESTAMP WITH TIMEZONE<sup>1</sup> TIME WITH TIMEZONE<sup>2</sup>

# MySQL Database Data Types

The following column data types are supported for MySQL Database targets:

INT REAL FLOAT DOUBLE NUMERIC DATE DATETIME TIMESTAMP TINYINT BOOLEAN SMALLINT BIGINT MEDIUMINT DECIMAL BIT YEAR ENUM CHAR VARCHAR

## Netezza Database Data Types

The following column data types are supported for Netezza database targets:

byteint
smallint
integer
bigint
numeric(p,s)
numeric(p)
float(p)
Real
double
char

 $<sup>^{1}\;</sup>$  Time zone with a two-digit hour and a two-digit minimum offset.

<sup>&</sup>lt;sup>2</sup> Time zone with a two-digit hour and a two-digit minimum offset.

varchar nchar nvarchar date time Timestamp

## Redshift Database Data Types

The following column data types are supported for Redshift database targets:

SMALLINT INTEGER BIGINT DECIMAL REAL DOUBLE CHAR VARCHAR DATE TIMESTAMP

## Setting Up and Running the JDBC Handler

Use the JDBC Metadata Provider with the JDBC Handler to obtain column mapping features, column function features, and better data type mapping.

The following topics provide instructions for configuring the JDBC Handler components and running the handler.

- Java Classpath
- Handler Configuration
- Statement Caching
- Setting Up Error Handling

## Java Classpath

The JDBC Java Driver location must be included in the class path of the handler using the gg.classpath property.

For example, the configuration for a MySQL database could be:

```
gg.classpath= /path/to/jdbc/driver/jar/mysql-connector-java-5.1.39-
bin.jar
```

### Handler Configuration

You configure the JDBC Handler operation using the properties file. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the JDBC Handler, you must first configure the handler type by specifying gg.handler.name.type=jdbc and the other JDBC properties as follows:

Properties	Require d/ Optiona I	Legal Values	Default	Explanation
gg.handler. <i>name</i> .type	Require d	jdbc	None	Selects the JDBC Handler for streaming change data capture into name.
gg.handler. <i>name</i> .connectionURL	Require d	A valid JDBC connectio n URL	None	The target specific JDBC connection URL.
gg.handler. <i>name</i> .DriverClass	Target databas e depende nt.	The target specific JDBC driver class name	None	The target specific JDBC driver class name.
gg.handler. <i>name</i> .userName	Target databas e depende nt.	A valid user name	None	The user name used for the JDBC connection to the target database.
gg.handler. <i>name</i> .password	Target databas e depende nt.	A valid password	None	The password used for the JDBC connection to the target database.
gg.handler. <i>name</i> .maxActiveState ments	Optional	Unsigned integer	Target database dependen t	If this property is not specified, the JDBC Handler queries the target dependent database metadata indicating maximum number of active prepared SQL statements. Some targets do not provide this metadata so then the default value of 256 active SQL statements is used.
				If this property is specified, the JDBC Handler will not query the target database for such metadata and use the property value provided in the configuration.
				In either case, when the JDBC handler finds that the total number of active SQL statements is about to be exceeded, the oldest SQL statement is removed from the cache to add one new SQL statement.

#### Table 8-31 JDBC Handler Configuration Properties

## Statement Caching

To speed up DML operations, JDBC driver implementations typically allow multiple statements to be cached. This configuration avoids repreparing a statement for operations that share the same profile or template.

The JDBC Handler uses statement caching to speed up the process and caches as many statements as the underlying JDBC driver supports. The cache is implemented by using an LRU cache where the key is the profile of the operation (stored internally in the memory as an instance of StatementCacheKey class), and the value is the PreparedStatement object itself.

DML operation type	StatementCacheKey contains a tuple of:
INSERT	(table name, operation type, ordered after-image column indices)
UPDATE	(table name, operation type, ordered after-image column indices)
DELETE	(table name, operation type)
TRUNCATE	(table name, operation type)

A StatementCacheKey object contains the following information for the various DML profiles that are supported in the JDBC Handler:

## Setting Up Error Handling

The JDBC Handler supports using the REPERROR and HANDLECOLLISIONS Oracle GoldenGate parameters. See *Reference for Oracle GoldenGate*.

You must configure the following properties in the handler properties file to define the mapping of different error codes for the target database.

#### gg.error.duplicateErrorCodes

A comma-separated list of error codes defined in the target database that indicate a duplicate key violation error. Most of the drivers of the JDBC drivers return a valid error code so, REPERROR actions can be configured based on the error code. For example:

gg.error.duplicateErrorCodes=1062,1088,1092,1291,1330,1331,1332,1333

#### $\verb+gg.error.notFoundErrorCodes+$

A comma-separated list of error codes that indicate missed DELETE or UPDATE operations on the target database.

In some cases, the JDBC driver errors occur when an UPDATE or DELETE operation does not modify any rows in the target database so, no additional handling is required by the JDBC Handler.

Most JDBC drivers do not return an error when a DELETE or UPDATE is affecting zero rows so, the JDBC Handler automatically detects a missed UPDATE or DELETE operation and triggers an error to indicate a not-found error to the Replicat process. The Replicat process can then execute the specified REPERROR action.

The default error code used by the handler is zero. When you configure this property to a non-zero value, the configured error code value is used when the handler triggers a not-found error. For example:

gg.error.notFoundErrorCodes=1222

#### gg.error.deadlockErrorCodes

A comma-separated list of error codes that indicate a deadlock error in the target database. For example:

```
gg.error.deadlockErrorCodes=1213
```

#### **Setting Codes**

Oracle recommends that you set a non-zero error code for the gg.error.duplicateErrorCodes, gg.error.notFoundErrorCodes, and gg.error.deadlockErrorCodes properties because Replicat does not respond to REPERROR and HANDLECOLLISIONS configuration when the error code is set to zero.

#### Sample Oracle Database Target Error Codes

```
gg.error.duplicateErrorCodes=1
gg.error.notFoundErrorCodes=0
gg.error.deadlockErrorCodes=60
```

#### Sample MySQL Database Target Error Codes

```
gg.error.duplicateErrorCodes=1022,1062
gg.error.notFoundErrorCodes=1329
gg.error.deadlockErrorCodes=1213,1614
```

## Sample Configurations

The following topics contain sample configurations for the databases supported by the JDBC Handler from the Java Adapter properties file.

- Sample Oracle Database Target
- Sample Oracle Database Target with JDBC Metadata Provider
- Sample MySQL Database Target
- Sample MySQL Database Target with JDBC Metadata Provider

### Sample Oracle Database Target

```
gg.handlerlist=jdbcwriter
gg.handler.jdbcwriter.type=jdbc
#Handler properties for Oracle database target
gg.handler.jdbcwriter.DriverClass=oracle.jdbc.driver.OracleDriver
gg.handler.jdbcwriter.connectionURL=jdbc:oracle:thin:@<DBServer
address>:1521:<database name>
gg.handler.jdbcwriter.userName=<dbuser>
gg.handler.jdbcwriter.password=<dbpassword>
gg.classpath=/path/to/oracle/jdbc/driver/ojdbc5.jar
goldengate.userexit.timestamp=utc
goldengate.userexit.writers=javawriter
javawriter.stats.display=TRUE
javawriter.stats.full=TRUE
gg.log=log4j
gg.log.level=INFO
gg.report.time=30sec
javawriter.bootoptions=-Xmx512m -Xms32m -Djava.class.path=.:ggjava/
ggjava.jar:./dirprm
```

## Sample Oracle Database Target with JDBC Metadata Provider

```
gg.handlerlist=jdbcwriter
gg.handler.jdbcwriter.type=jdbc
#Handler properties for Oracle database target with JDBC Metadata
provider
gg.handler.jdbcwriter.DriverClass=oracle.jdbc.driver.OracleDriver
gg.handler.jdbcwriter.connectionURL=jdbc:oracle:thin:@<DBServer
address>:1521:<database name>
gg.handler.jdbcwriter.userName=<dbuser>
gg.handler.jdbcwriter.password=<dbpassword>
gg.classpath=/path/to/oracle/jdbc/driver/ojdbc5.jar
#JDBC Metadata provider for Oracle target
gg.mdp.type=jdbc
gq.mdp.ConnectionUrl=jdbc:oracle:thin:@<DBServer</pre>
address>:1521:<database name>
gg.mdp.DriverClassName=oracle.jdbc.driver.OracleDriver
gg.mdp.UserName=<dbuser>
gg.mdp.Password=<dbpassword>
goldengate.userexit.timestamp=utc
goldengate.userexit.writers=javawriter
javawriter.stats.display=TRUE
javawriter.stats.full=TRUE
gg.log=log4j
gg.log.level=INFO
gg.report.time=30sec
javawriter.bootoptions=-Xmx512m -Xms32m -Djava.class.path=.:ggjava/
ggjava.jar:./dirprm
```

## Sample MySQL Database Target

```
gg.handlerlist=jdbcwriter
gg.handler.jdbcwriter.type=jdbc
#Handler properties for MySQL database target
gg.handler.jdbcwriter.DriverClass=com.mysgl.jdbc.Driver
gg.handler.jdbcwriter.connectionURL=jdbc:<a target=" blank"
href="mysql://">mysql://</a><DBServer address>:3306/<database name>
gg.handler.jdbcwriter.userName=<dbuser>
gg.handler.jdbcwriter.password=<dbpassword>
gg.classpath=/path/to/mysql/jdbc/driver//mysql-connector-java-5.1.39-
bin.jar
goldengate.userexit.timestamp=utc
goldengate.userexit.writers=javawriter
javawriter.stats.display=TRUE
javawriter.stats.full=TRUE
gg.log=log4j
gg.log.level=INFO
gg.report.time=30sec
```

```
javawriter.bootoptions=-Xmx512m -Xms32m -Djava.class.path=.:ggjava/ggjava.jar:./dirprm
```

## Sample MySQL Database Target with JDBC Metadata Provider

```
gg.handlerlist=jdbcwriter
gq.handler.jdbcwriter.type=jdbc
#Handler properties for MySQL database target with JDBC Metadata provider
gg.handler.jdbcwriter.DriverClass=com.mysql.jdbc.Driver
gg.handler.jdbcwriter.connectionURL=jdbc:<a target=" blank"
href="mysql://">mysql://</a><DBServer address>:3306/<database name>
gg.handler.jdbcwriter.userName=<dbuser>
gg.handler.jdbcwriter.password=<dbpassword>
gg.classpath=/path/to/mysql/jdbc/driver//mysql-connector-java-5.1.39-bin.jar
#JDBC Metadata provider for MySQL target
gg.mdp.type=jdbc
gg.mdp.ConnectionUrl=jdbc:<a target=" blank" href="mysgl://">mysgl://</
a><DBServer address>:3306/<database name>
gg.mdp.DriverClassName=com.mysql.jdbc.Driver
gg.mdp.UserName=<dbuser>
gg.mdp.Password=<dbpassword>
goldengate.userexit.timestamp=utc
goldengate.userexit.writers=javawriter
javawriter.stats.display=TRUE
javawriter.stats.full=TRUE
qq.loq=loq4j
gg.log.level=INFO
gg.report.time=30sec
javawriter.bootoptions=-Xmx512m -Xms32m -Djava.class.path=.:ggjava/
ggjava.jar:./dirprm
```

# Map(R)

Oracle GoldenGate for Big Data supports MapR over HDFS handler. For more information, see HDFS Event Handler

# MongoDB

Learn how to use the MongoDB Handler, which can replicate transactional data from Oracle GoldenGate to a target MongoDB and Autonomous JSON databases (AJD and ATP) .

- Overview
- MongoDB Wire Protocol
- Supported Target Types
- Detailed Functionality
- Setting Up and Running the MongoDB Handler
- Security and Authentication
- Reviewing Sample Configurations

- MongoDB to AJD/ATP Migration
- MongoDB Handler Client Dependencies
   What are the dependencies for the MongoDB Handler to connect to MongoDB databases?

## Overview

Mongodb Handler can used to replicate data from RDMS as well as document based databases like Mongodb or Cassandra to the following target databases using MongoDB wire protocol

## MongoDB Wire Protocol

The MongoDB Wire Protocol is a simple socket-based, request-response style protocol. Clients communicate with the database server through a regular TCP/IP socket, see https://docs.mongodb.com/manual/reference/mongodb-wire-protocol/.

## Supported Target Types

- MongoDB is an open-source document database that provides high performance, high availability, and automatic scaling, see https://www.mongodb.com/.
- Oracle Autonomous JSON Database (AJD) is a cloud document database service that makes it simple to develop JSON-centric applications, see Autonomous JSON Database | Oracle.
- Autonomous Database for transaction processing and mixed workloads (ATP) is a fully automated database service optimized to run transactional, analytical, and batch workloads concurrently, see Autonomous Transaction Processing | Oracle.
- On-premises Oracle Database 21c with Database API for MongoDB is also a supported target. See Installing Database API for MongoDB for any Oracle Database.

## **Detailed Functionality**

The MongoDB Handler takes operations from the source trail file and creates corresponding documents in the target MongoDB or Autonomous databases (AJD and ATP).

A record in MongoDB is a Binary JSON (BSON) document, which is a data structure composed of field and value pairs. A BSON data structure is a binary representation of JSON documents. MongoDB documents are similar to JSON objects. The values of fields may include other documents, arrays, and arrays of documents.

A collection is a grouping of MongoDB or AJD/ATP documents and is the equivalent of an RDBMS table. In MongoDB or AJD/ATP databases, a collection holds collection of documents. Collections do not enforce a schema. MongoDB or AJD/ATP documents within a collection can have different fields.

- Document Key Column
- Primary Key Update Operation
- MongoDB Trail Data Types

## Document Key Column

MongoDB or AJD/ATP databases require every document (row) to have a column named \_id whose value should be unique in a collection (table). This is similar to a primary key for RDBMS tables. If a document does not contain a top-level \_id column during an insert, the MongoDB driver adds this column.

The MongoDB Handler builds custom  $\_id$  field values for every document based on the primary key column values in the trail record. This custom  $\_id$  is built using all the key column values concatenated by a : (colon) separator. For example:

KeyColValue1:KeyColValue2:KeyColValue3

The MongoDB Handler enforces uniqueness based on these custom \_id values. This means that every record in the trail must be unique based on the primary key columns values. Existence of non-unique records for the same table results in a MongoDB Handler failure and in Replicat abending with a duplicate key error.

The behavior of the id field is:

- By default, MongoDB creates a unique index on the column during the creation of a collection.
- It is always the first column in a document.
- It may contain values of any BSON data type except an array.

### Primary Key Update Operation

MongoDB or AJD/ATP databases do not allow the \_id column to be modified. This means a primary key update operation record in the trail needs special handling. The MongoDB Handler converts a primary key update operation into a combination of a DELETE (with old key) and an INSERT (with new key). To perform the INSERT, a complete before-image of the update operation in trail is recommended. You can generate the trail to populate a complete before image for update operations by enabling the Oracle GoldenGate GETUPDATEBEFORES and NOCOMPRESSUPDATES parameters, see *Reference for Oracle GoldenGate*.

## MongoDB Trail Data Types

The MongoDB Handler supports delivery to the BSON data types as follows:

- 32-bit integer
- 64-bit integer
- Double

- Binary data

## Setting Up and Running the MongoDB Handler

The following topics provide instructions for configuring the MongoDB Handler components and running the handler.

- Classpath Configuration
- MongoDB Handler Configuration
- Using Bulk Write
- Using Write Concern
- Using Three-Part Table Names
- Using Undo Handling

### Classpath Configuration

The MongoDB Java Driver is required for Oracle GoldenGate for Big Data to connect and stream data to MongoDB. If the Oracle GoldenGate for Big Data version is 21.7.0.0.0 and below, then you need to use 3.x (MongoDB Java Driver 3.12.8). If the Oracle GoldenGate for Big Data version is 21.8.0.0.0 and above, then you need to use MongoDB Java Driver 4.6.0. The MongoDB Java Driver is not included in the Oracle GoldenGate for Big Data product. You must download the driver from: mongo java driver.

Select **mongo-java-driver** and the version to download the recommended driver JAR file.

You must configure the gg.classpath variable to load the MongoDB Java Driver JAR at runtime. For example: gg.classpath=/home/mongodb/mongo-java-driver-3.12.8.jar.

Oracle GoldenGate for Big Data supports the MongoDB Decimal 128 data type that was added in MongoDB 3.4. Use of a MongoDB Java Driver prior to 3.12.8 results in a ClassNotFound exception.

### MongoDB Handler Configuration

You configure the MongoDB Handler operation using the properties file. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the MongoDB Handler, you must first configure the handler type by specifying gg.handler.name.type=mongodb and the other MongoDB properties as follows:

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler. <i>nam</i> e.type	Required	mongodb	None	Selects the MongoDB Handler for use with Replicat.

### Table 8-32 MongoDB Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler. <i>nam</i> e.bulkWrite	Optional	true  false	true	Set to true, the handler caches operations until a commit transaction event is received. When committing the transaction event, all the cached operations are written out to the target MongoDB, AJD and ATP databases, which provides improved throughput.
				Set to false, there is no caching within the handler and operations are immediately written to the MongoDB, AJD and ATP databases.
gg.handler. <i>nam</i> e.WriteConcern	Optional	{"w": "value"	None	Sets the required write concern for all the operations performed by the MongoDB Handler.
		<pre>"wtimeou t": "number" }</pre>		The property value is in JSON format and can only accept keys as w and wtimeout, see https://docs.name.com/manual/ reference/write-concern/.
gg.handler. <i>nam</i> e.clientURI	Optional	Valid MongoDB client URI	None	Sets the MongoDB client URI. A client URI can also be used to set other MongoDB connection properties, such as authentication and WriteConcern. For example, mongodb:// localhost:27017/, see: https:// mongodb.github.io/mongo-java-driver/3.7/ javadoc/com/mongodb/ MongoClientURI.html.
gg.handler. <i>nam</i> e.CheckMaxRowS izeLimit	Optional	true  false	false	When set to true, the handler verifies that the size of the BSON document inserted or modified is within the limits defined by the MongoDB database. Calculating the size involves the use of a default codec to generate a RawBsonDocument, leading to a small degradation in the throughput of the MongoDB Handler. If the size of the document exceeds the MongoDB limit, on exception accurs and
				MongoDB limit, an exception occurs and Replicat abends.
gg.handler. <i>nam</i> e.upsert	Optional	true  false	false	Set to true, a new Mongo document is inserted if there are no matches to the query filter when performing an UPDATE operation.

Table 8-32	(Cont.) MongoDB	Handler Configuration Properties
	(Conta) mongobb	nandier Gonngaradon i roperdes

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.handler. <i>nam</i> e.enableDecima 1128	Optional	true  false	true	MongoDB version 3.4 added support for a 128-bit decimal data type called Decimal128. This data type was needed since Oracle GoldenGate for Big Data supports both integer and decimal data types that do not fit into a 64-bit Long or Double. Setting this property to true enables mapping into the Double128 data type for source data types that require it. Set to false to process these source data types as 64-bit Doubles.
gg.handler. <i>nam</i> e.enableTransa ctions	Optional	true  false	false	Set to true, to enable transactional processing in MongoDB 4.0 and higher.
				Note: MongoDB added support for transactions in MongoDB version 4.0. Additionally, the minimum version of the MongoDB client driver is 3.10.1.

Table 8-32	(Cont.) MongoDB	Handler Configuration	Properties
------------	-----------------	-----------------------	------------

### Using Bulk Write

Bulk write is enabled by default. For better throughput, Oracle recommends that you use bulk write.

You can also enable bulk write by using the BulkWrite handler property. To enable or disable bulk write use the gg.handler.handler.BulkWrite=true | false. The MongoDB Handler does not use the gg.handler.handler.mode=op | tx property that is used by Oracle GoldenGate for Big Data.

With bulk write, the MongoDB Handler uses the GROUPTRANSOPS parameter to retrieve the batch size. The handler converts a batch of trail records to MongoDB documents, which are then written to the database in one request.

### Using Write Concern

Write concern describes the level of acknowledgement that is requested from MongoDB for write operations to a standalone MongoDB, replica sets, and sharded-

clusters. With sharded-clusters, Mongo instances pass the write concern on to the shards, see https://docs.mongodb.com/manual/reference/write-concern/.

Use the following configuration:

w: value wtimeout: number

### Using Three-Part Table Names

An Oracle GoldenGate trail may have data for sources that support three-part table names, such as *Catalog.Schema.Table*. MongoDB only supports two-part names, such as *DBName.Collection*. To support the mapping of source three-part names to MongoDB two-part names, the source *Catalog* and *Schema* is concatenated with an underscore delimiter to construct the Mongo *DBName*.

For example, Catalog.Schema.Table would become catalog1 schema1.table1.

### Using Undo Handling

The MongoDB Handler can recover from bulk write errors using a lightweight undo engine. This engine works differently from typical RDBMS undo engines, rather the best effort to assist you in error recovery. Error recovery works well when there are primary violations or any other bulk write error where the MongoDB database provides information about the point of failure through BulkWriteException.

Table 8-33Table 1 lists the requirements to make the best use of this functionality.

<b>Table 8-33</b>	Undo Handling Requirements
-------------------	----------------------------

Operation to Undo	Require Full Before Image in the Trail?
INSERT	No
DELETE	Yes
UPDATE	No (before image of fields in the SET clause.)

If there are errors during undo operations, it may be not possible to get the MongoDB collections to a consistent state. In this case, you must manually reconcile the data.

## Security and Authentication

MongoDB Handler uses Oracle GoldenGate credential store to manage user IDs and their encrypted passwords (together known as credentials) that are used by Oracle GoldenGate processes to interact with the MongoDB database. The credential store eliminates the need to specify user names and clear-text passwords in the Oracle GoldenGate parameter files.

An optional alias can be used in the parameter file instead of the user ID to map to a userid and password pair in the credential store.

In Oracle GoldenGate for Big Data, you specify the alias and domain in the property file and not the actual user ID or password. User credentials are maintained in secure wallet storage.

To add CREDENTIAL STORE and DBLOGIN run the following commands in the adminclient:

```
adminclient> add credentialstore
adminclient> alter credentialstore add user <userid> password <pwd>
alias mongo
```

#### Example value of userid:

```
mongodb://myUserAdmin@localhost:27017/admin?replicaSet=rs0
```

adminclient > dblogin useridalias mongo

To test DBLOGIN, run the following command

```
adminclient> list tables tcust*
```

On successful add of authentication to credential store, add the alias in the parameter file of extract.

Example:

SOURCEDB USERIDALIAS mongo

MongoDB Handler uses connection URI to connect to a MongoDB deployment. Authentication and Security is passed as query string as part of connection URI. See SSL Configuration Setup to configure SSL.

To specify access control use userid:

```
mongodb://
<user>@<hostname1>:<port>,<hostname2>:<port>,<hostname3>:<port>/?
replicaSet=<replicatName>
```

#### To specify TLS/SSL:

Using connection string prefix of "+srv" as mongodb+srv automatically sets the tls option to true.

```
mongodb+srv://server.example.com/
```

#### To disable TLS add tls=false in the query string.

mongodb:// >@<hostname1>:<port>/?replicaSet=<replicatName>&tls=false

To specify Authentication:

#### authSource:

```
mongodb://<user>@<hostname1>:<port>, <hostname2>:<port>, <hostname3>:<port>/?
replicaSet=<replicatName>&authSource=admin
```

#### authMechanism:

mongodb://<user>@<hostname1>:<port>, <hostname2>:<port>, <hostname3>:<port>/?
replicaSet=<replicatName>&authSource=admin&authMechanism=GSSAPI

For more information about Security and Authentication using Connection URL, see Mongo DB Documentation

SSL Configuration Setup

## SSL Configuration Setup

To configure SSL between the MongoDB instance and Oracle GoldenGate for Big Data MongoDB Handler, do the following:

#### Create certificate authority (CA)

```
openssl req -passout pass:password -new -x509 -days 3650 -extensions v3_ca -
keyout
ca_private.pem -out ca.pem -subj
"/CN=CA/OU=GOLDENGATE/O=ORACLE/L=BANGALORE/ST=KA/C=IN"
```

#### Create key and certificate signing requests (CSR) for client and all server nodes

```
openssl req -newkey rsa:4096 -nodes -out client.csr -keyout client.key -subj
'/CN=certName/OU=OGGBDCLIENT/O=ORACLE/L=BANGALORE/ST=AP/C=IN'
openssl req -newkey rsa:4096 -nodes -out server.csr -keyout server.key -subj
'/CN=slc13auo.us.oracle.com/OU=GOLDENGATE/O=ORACLE/L=BANGALORE/ST=TN/C=IN'
```

#### Sign the certificate signing requests with CA

#### Create the privacy enhanced mail (PEM) file for mongod

```
cat client-signed.crt client.key > client.pem
cat server-signed.crt server.key > server.pem
```

#### Create trust store and keystore

openssl pkcs12 -export -out server.pkcs12 -in server.pem openssl pkcs12 -export -out client.pkcs12 -in client.pem bash-4.2\$ ls ca.pem ca\_private.pem client.csr client.pem serversigned.crt server.key server.pkcs12 ca.srl client-signed.crt client.key client.pkcs12 server.csr server.pem

#### Start instances of mongod with the following options:

```
--tlsMode requireTLS --tlsCertificateKeyFile ../opensslKeys/server.pem
--tlsCAFile
../opensslKeys/ca.pem
```

#### credentialstore connectionString

#### Note:

The Length of connectionString should not exceed 256.

For CDC Extract, add the key store and trust store as part of the JVM options.

#### **JVM options**

```
-Xms512m -Xmx4024m -Xss32m -Djavax.net.ssl.trustStore=../
mcopensslkeys /server.pkcs12
        -Djavax.net.ssl.trustStorePassword=password
        -Djavax.net.ssl.keyStore =../mcopensslkeys/client.pkcs12
        -Djavax.net.ssl.keyStorePassword=password
```

## **Reviewing Sample Configurations**

#### **Basic Configuration**

The following is a sample configuration for the MongoDB Handler from the Java adapter properties file:

```
gg.handlerlist=mongodb
gg.handler.mongodb.type=mongodb
```

```
#The following handler properties are optional.
#Refer to the Oracle GoldenGate for BigData documentation
#for details about the configuration.
#gg.handler.mongodb.clientURI=mongodb://localhost:27017/
#gg.handler.mongodb.WriteConcern={w:value, wtimeout: number }
#gg.handler.mongodb.BulkWrite=false
#gg.handler.mongodb.CheckMaxRowSizeLimit=true
```

```
goldengate.userexit.timestamp=utc
goldengate.userexit.writers=javawriter
javawriter.stats.display=TRUE
javawriter.stats.full=TRUE
gg.log=log4j
gg.log.level=INFO
gg.report.time=30sec
```

#Path to MongoDB Java driver. # maven co-ordinates # <dependency> # <groupId>org.mongodb</groupId> # <artifactId>mongo-java-driver</artifactId> # <version>3.10.1</version> # </dependency> gg.classpath=/path/to/mongodb/java/driver/mongo-java-driver-3.10.1.jar javawriter.bootoptions=-Xmx512m -Xms32m -Djava.class.path=.:ggjava/ggjava.jar:./dirprm

#### Oracle or MongDB Database Source to MongoDB, AJD, and ATP Target

You can map an Oracle or MongDB Database source table name in uppercase to a table in MongoDB that is in lowercase. This applies to both table names and schemas. There are two methods that you can use:

#### Create a Data Pump

You can create a data pump before the Replicat, which translates names to lowercase. Then you configure a MongoDB Replicat to use the output from the pump:

```
extract pmp
exttrail ./dirdat/le
map RAMOWER.EKKN, target "ram"."ekkn";
```

#### **Convert When Replicating**

You can convert table column names to lowercase when replicating to the MongoDB table by adding this parameter to your MongoDB properties file:

gg.schema.normalize=lowercase

## MongoDB to AJD/ATP Migration

- Overview
- Configuring MongoDB handler to Write to AJD/ATP
- Steps for Migration
- Best Practices

### Overview

Oracle Autonomous JSON Database (AJD) and Autonomous Database for transaction processing also uses wire protocol to connect. Wire protocol has the same MongoDB CRUD APIs.

### Configuring MongoDB handler to Write to AJD/ATP

Basic configuration remains the same including optional properties mentioned in this chapter.

The handler uses same protocol (mongodb wire protocol) and same driver jar for Autonomous databases as that of mongodb for performing all operation in target agnostic manner for performing the replication. The properties can also be used for any of the supported targets.

The following is a sample configuration for the MongoDB Handler for AJD/ATP from the Java adapter properties file:

```
gg.handlerlist=mongodb
gg.handler.mongodb.type=mongodb
#URL mentioned below should be an AJD instance URL
gg.handler.mongodb.clientURI=mongodb://[username]:[password]@[url]?
authSource=$external&authMechanism=PLAIN&ssl=true
#Path to MongoDB Java driver. Maven co-ordinates
# <dependency>
# <groupId>org.mongodb</groupId>
# <artifactId>mongo-java-driver</artifactId>
# <version>3.10.1</version>
# </dependency>
gg.classpath=/path/to/mongodb/java/driver/mongo-java-driver-3.10.1.jar
javawriter.bootoptions=-Xmx512m -Xms32m -Djava.class.path=.:ggjava/ggjava.jar:./
dirprm
```

### Steps for Migration

To migrate from MongoDB to AJD, first it is required to run initial load. Initial load comprises inserts operations only. After running initial load, start CDC which keeps the source and target database synchronized.

1. Start CDC extract and generate trails. Do not start replicat to consume these trail files.

- 2. Start Initial load extract and wait for initial load to complete.
- 3. Create a new replicat to consume the initial load trails generated in Step 2. Wait for completion and then stop replicat.
- 4. Create a new replicate to consume the CDC trails. Configure this replicat to use HANDLECOLLISIONS and then start replicat.
- 5. Wait for the CDC replicat (Step 4) to consume all the trails, check replicat lag, and replicat RBA to ensure that the CDC replicat has caught up. At this point, the source and target databases should be in sync.
- 6. Stop the CDC replicat, remove HANDLECOLLISIONS parameter, and then restart the CDC replicat.

### **Best Practices**

For migration from mongoDB to Oracle Autonomous Database (AJD/ATP), following are the best practices:

- 1. Before running CDC, ensure to run initial load, which loads the initial data using insert operations.
- 2. Use bulk mode for running mongoDB handler in order to achieve better throughput.
- 3. Enable handle-collision while migration to allow replicat to handle any collision error automatically.
- 4. In order to insert missing update, ensure to add the INSERTMISSINGUPDATES property in the.prm file.

## MongoDB Handler Client Dependencies

What are the dependencies for the MongoDB Handler to connect to MongoDB databases?

Oracle GoldenGate requires version 4.6.0 MongoDB reactive streams for integration with MongoDB. You can download this driver from: https://search.maven.org/artifact/org.mongodb/ mongodb-driver-reactivestreams

### Note:

If the Oracle GoldenGate for Big Data version is 21.7.0.0.0 and below, the driver version is MongoDB Java Driver 3.12.8. For Oracle GoldenGate for Big Data versions 21.8.0.0.0 and above, the driver version is MongoDB Java Driver 4.6.0.

- MongoDB Java Driver 4.6.0
- MongoDB Java Driver 3.12.8

## MongoDB Java Driver 4.6.0

The required dependent client libraries are:

- bson-4.6.0.jar
- bson-record-codec-4.6.0.jar
- mongodb-driver-core-4.6.0.jar

- mongodb-driver-legacy-4.6.0.jar
- mongodb-driver-legacy-4.6.0.jar
- mongodb-driver-sync-4.6.0.jar

The Maven coordinates of these third-party libraries that are needed to run MongoDB replicat are:

<dependency>

```
<groupId>org.mongodb</groupId>
<artifactId>mongodb-driver-legacy</artifactId>
<version>4.6.0</version>
</dependency>
<dependency>
<groupId>org.mongodb</groupId>
<artifactId>mongodb-driver-sync</artifactId>
<version>4.6.0</version>
</dependency>
```

#### Example

Download the latest version from Maven central at: https://central.sonatype.com/ artifact/org.mongodb/mongodb-driver-reactivestreams/4.6.0.

### MongoDB Java Driver 3.12.8

You must include the path to the MongoDB Java driver in the gg.classpath property. To automatically download the Java driver from the Maven central repository, add the following lines in the pom.xml file, substituting your correct information:

## Netezza

You can replicate to Netezza using Command event Handler in conjunction with Flat Files.

# **OCI** Streaming

Oracle Cloud Infrastructure Streaming (OCI Streaming) supports putting messages to and receiving messages using the Kafka client. Therefore, Oracle GoldenGate for Big Data can be used to publish change data capture operation messages to OCI Streaming.

You can use either the Kafka Handler or the Kafka Connect Handler. The Kafka Connect Handler only supports using the JSON Kafka Connect converter. The Kafka Connect Avro converter is not supported because the Avro converter requires connectivity to a schema registry.

## Note: The Oracle Streaming Service currently does not have a schema registry to which the Kafka Connect Avro converter can connect. Streams to which the Kafka Handlers or the Kafka Connect Handlers publish messages must be pre-created in Oracle Cloud Infrastructure (OCI). Using the Kafka Handler to publish messages to a stream in OSS which does not already exist results in a runtime exception.

• To create a stream in OCI, in the OCI console. select **Analytics**, click **Streaming**, and then click **Create Stream**. Streams are created by default in the **DefaultPool**.

# Oracle NoSQL

The Oracle NoSQL Handler can replicate transactional data from Oracle GoldenGate to a target Oracle NoSQL Database.

This chapter describes how to use the Oracle NoSQL Handler.

- Overview
- On-Premise Connectivity
- OCI Cloud Connectivity
- Oracle NoSQL Types
- Oracle NoSQL Handler Configuration
- Performance Considerations
- Operation Processing Support
- Column Processing
- Table Check and Reconciliation Process
- Oracle NoSQL SDK Dependencies

## Overview

Oracle NoSQL Database is a NoSQL-type distributed key-value database. It provides a powerful and flexible transaction model that greatly simplifies the process of developing a NoSQL-based application. It scales horizontally with high availability and transparent load balancing even when dynamically adding new capacity.

Starting from the Oracle GoldenGate for Big Data 21.3.0.0.0 release, the Oracle NoSQL Handler has been changed to use the Oracle NoSQL Java SDK to communicate with Oracle NoSQL. The Oracle NoSQL Java SDK supports both on-premise and OCI cloud instances of Oracle NoSQL. Make sure to read the documentation because connecting to on-premise verses OCI cloud instances of Oracle NoSQL both require specialized configuration parameters and possibly some setup.

For more information about Oracle NoSQL Java SDK, see Oracle NoSQL SDK for Java.

## **On-Premise Connectivity**

The Oracle NoSQL Java SDK requires that connectivity route through the Oracle NoSQL Database Proxy. The Oracle NoSQL Database Proxy is a separate process which enables the http/https interface of Oracle NoSQL. The Oracle NoSQL Java SDK uses the http/https interface. Oracle GoldenGate effectively communicates with the on-premise Oracle NoSQL instance through the Oracle NoSQL Database Proxy process.

For more information on the Oracle NoSQL Database Proxy including setup instructions, see Connecting to the Oracle NoSQL Database On-premise.

Connectivity to the Oracle NoSQL Database Proxy requires mutual authentication whereby the client authenticates the server and the server authenticates the client.

- Server Authentication
- Client Authentication
- Sample On-Premise Oracle NoSQL Configuration

### Server Authentication

Upon initial connection, the Oracle NoSQL Database Proxy process passes a certificate to the Oracle NoSQL Java SDK (Oracle NoSQL Handler). The Oracle NoSQL Java SDK then verifies the certificate against a certificate in a configured trust store. After the certificate received from the proxy has been verified against the trust store, the client has authenticated the server.

### **Client Authentication**

Upon initial connection, the Oracle NoSQL Java SDK (Oracle NoSQL Handler) passes credentials (username and password) to the Oracle NoSQL Database Proxy. These credentials are used for the NoSQL On-Premise instance to client.

### Sample On-Premise Oracle NoSQL Configuration

gg.handlerlist=nosql
gg.handler.nosql.type=nosql
gg.handler.nosql.nosqlURL=https://localhost:5555
gg.handler.nosql.ddlHandling=CREATE,ADD,DROP
gg.handler.nosql.interactiveMode=false
#Client Credentials
gg.handler.nosql.username={your username}
gg.handler.nosql.password={your password}
gg.handler.nosql.mode=op
# Set the gg.classpath to pick up the Oracle NoSQL Java SDK
gg.classpath=/path/to/the/SDK/\*

```
# Set the -D options in the bootoptions to resolve the trust store
location and password
jvm.bootoptions=-Xmx512m -Xms32m -Djavax.net.ssl.trustStore=/usr/nosql/
kv-20.3.17/USER/security/driver.trust -
Djavax.net.ssl.trustStorePassword={your trust store password}
```

## OCI Cloud Connectivity

Connectivity to an OCI Cloud instance of Oracle NoSQL is easier as it does not require the Oracle NoSQL Database Proxy required by the on-premise instance. Again, there is mutual authentication whereby the client authenticates the server and the server authenticates the client.

- Server Authentication
- Client Authentication
- Sample Cloud Oracle NoSQL Configuration
- Sample OCI Configuration file

### Server Authentication

Upon initial connection, the Oracle NoSQL cloud instance passes a CA signed certificate to the client. The client then authenticates this CA signed certificate with the Certificate Authority. Once complete, the client has authenticated the server.

### **Client Authentication**

Upon initial connection, the fingerprint, keyfile, and pass\_phrase properties are used for the server to authenticate the client.

### Sample Cloud Oracle NoSQL Configuration

```
gg.handlerlist=nosql
gg.handler.nosql.type=nosqlNoSQLSdkHandler
#gg.handler.nosql.type=nosql
gg.handler.nosql.ddlHandling=CREATE,ADD,DROP
gg.handler.nosql.interactiveMode=false
gg.handler.nosql.region=us-sanjose-1
gg.handler.nosql.configFilePath=/path/to/the/OCI/conf/file/nosql.conf
gg.handler.nosql.compartmentId=ocidl.compartment.ocl..aaaaaaaae2aedhka4
jlb3h6zhpaonaoktmg53adwkhwjflvv6hihz5cvwfeq
gg.handler.nosql.storageGb=10
gg.handler.nosql.readUnits=50
gg.handler.nosql.writeUnits=50
gg.handler.nosql.mode=op
# Set the gg.classpath to pick up the Oracle NoSQL Java SDK
gg.classpath=/path/to/the/SDK/*
```

## Sample OCI Configuration file

```
[DEFAULT]
user=ocid1.user.oc1..aaaaaaaaammf6u5h4wsmiuk52us5vnqhnnyzexkn56cqijlyo4vaao2j
zi3a
fingerprint=77:53:2c:e5:31:81:48:c3:3d:af:60:cf:e0:42:5c:7f
tenancy=ocid1.tenancy.oc1..aaaaaaaaattuxbj75pnn3nksvzyidshdbrfmmeflv4kkemajroz
2thvca4kba
region=us-sanjose-1
key_file=/home/username/OracleNoSQL/lastname.firstname-04-13-18-51.pem
openssl rsa -aes256 -in in.pem -out out.pem
```

#### tenancy

The Tenancy ID is displayed at the bottom of the Console page.

region

The region is displayed with the header session drop-down menu in the Console.

#### fingerprint

To generate the fingerprint, use the *How to Get the Key's Fingerprint* instructions at: https://docs.cloud.oracle.com/iaas/Content/API/Concepts/apisigningkey.htm

#### key\_file

You need to share the public and private key to establish a connection with Oracle Cloud Infrastructure. To generate the keys, use the *How to Generate an API Signing Keyat*: https://docs.cloud.oracle.com/iaas/Content/API/Concepts/apisigningkey.htm

#### pass\_phrase

This is an optional property. It is used to configure the passphrase if the private key in the pem file is protected with a passphase. The following openssl command can be used to take an unprotected private key pem file and add a passphrase. The following command prompts the user for the passphrase:

openssl rsa -aes256 -in in.pem -out out.pem

For more information, see Configuring Credentials for Oracle Cloud Infrastructure.

## Oracle NoSQL Types

Oracle NoSQL provides a number of column data types and most of these data types are supported by the Oracle NoSQL Handler. A data type conversion from the column value in the trail file to the corresponding Java type representing the Oracle NoSQL column type in the Oracle NoSQL Handler is required.

The Oracle NoSQL Handler does not support Array, Map and Record data types by default. To support them, you can implement a custom data converter and override the default data type conversion logic to override it with your own custom logic to support your use case. Contact Oracle Support for guidance.

The following Oracle NoSQL data types are supported:

- Binary
- Boolen

- Double
- Integer
- Number
- String
- Timestamp

The following Oracle NoSQL data types are not supported:

- Array
- Map

# Oracle NoSQL Handler Configuration

Properties	-	Legal Values	Default	Explanation
gg.handler.nam e.type	Req uire d	nosql	None	Selects the Oracle NoSQL Handler.
gg.handler.nam e.interactiveM ode	•	true  false	true	When set to true, the NoSQL handler will process one operation at a time. When set to false, the NoSQL Handler will process the batch perations at transaction commit. Batching has limitations. Batched operations must be separated by table and all batch operations for a table must have a common shared key(s).
gg.handler.nam e.ddlHandling	Opti onal	CREAT E, ADD, DROP in any combin ation separa ted by a comma delimit er	None	<ul> <li>Configure the Oracle NoSQL Handler for the DDL functionality to provide. Options include CREATE, ADD, and DROP.</li> <li>When CREATE is enabled, the handler creates tables in Oracle NoSQL if a corresponding table does not exist.</li> <li>When ADD is enabled, the handler adds columns that exist in the source table definition, but do not exist in the corresponding target Oracle NoSQL table definition.</li> <li>When DROP is enabled, the handler drops columns that exist in the Oracle NoSQL table definition, but do not exist in the corresponding target Oracle NoSQL table definition.</li> </ul>
gg.handler.nam e.retries	Opti onal	Positiv e Integer	3	The number of retries on any read or write exception that the Oracle NoSQL Handler encounters.
gg.handler.nam e.requestTimeo ut	Opti onal	Positiv e Integer	30000	The maximum time in milliseconds for a NoSQL request to wait for a response. If the timeout is exceeded, the call is assumed to have failed.

Properties	-	Legal Values	Default	Explanation
gg.handler.nam e.noSQLURL	Opti onal	A valid URL includi ng protoc ol.	None	On-premise only. Used to set the connectivity URL for the NoSQL proxy instance.
gg.handler.nam e.username	Opti onal	String	None	On-premise only. Used to set the username for connectivity to an on-premise NoSQL instance through the NoSQL proxy process.
gg.handler.nam e.password	Opti onal	String	None	On-premise only. Used to set the password for connectivity to an on-premise NoSQL instance through the NoSQL proxy process.
gg.handler.nam e.compartmentI d	Opti onal	The OCID of an Oracle NoSQL compa rtment on OCI.	None	Cloud only. The OCID of an Oracle NoSQL cloud instance compartment on OCI.
gg.handler.nam e.region	-	Legal Oracle OCI region name.	None	Cloud only. The OCI region name of an Oracle NoSQL cloud instance.
gg.handler.nam e.configFilePa th	Opti onal	A legal path and file name.	None	Cloud only. Set the path and file name of the config file containing the Oracle OCI information on the user, fingerprint, tenancy, region, and key-file.
gg.handler.nam e.profile	Opti onal	None	"DEFAUL T"	Cloud only. Sets the named sub-section in the gg.handler.name.configFilePath. OCI config files can contain multiple entries and the naming specifies which entry to use.
gg.handler.nam e.storageGb	Opti onal	Positiv e Integer	10	Cloud only. Oracle NoSQL tables created in a cloud instance must be configured with a maximum storage size. This sets that configuration for tables created by the Oracle NoSQL Handler.
gg.handler.nam e.readUnits	Opti onal	Positiv e Integer	50	Cloud only. Oracle NoSQL tables created in an OCI cloud instance must be configured with read units which is the maximum read throughput. Each unit is 1KB per second.
gg.handler.nam e.writeUnits	Opti onal	Positiv e Integer	50	Cloud only. Oracle NoSQL tables created in an OCI cloud instance must be configured with write units which is the maximum write throughput. Each unit is 1KB per second.

Properties	-	Legal Values	Default	Explanation
gg.handler.nam e.abendOnUnmap pedColumns	Opti onal	true  false	true	Set to true if the desired behavior of the handler is to abend when a column is found in the source table but the column does not exist in the target NoSQL table. Set to false if the desired behavior is for the handler to ignore columns found in the source table for which no corresponding column exists in the target NoSQL table.
gg.handler.nam e.dataConverte rClass	Opti onal	The fully qualifie d data convert er class name.	The default data converter.	The custom data converter can be implemented to override the default data conversion logic to support your specific use case. Must be included in the gg.classpath to be used.
gg.handler.nam e.timestampPat tern	Opti onal	-	HH:mm:s	This feature can be used to parse source field data into timestamps for timestamp target fields. The pattern needs to follow the Java convention for timestamp patterns and source data needs to conform to the pattern.
gg.handler.nam e.proxyServer	Opti onal	None	The proxy server host name.	Used to configure the forwarding proxy server host name for connectivity of on-premise Oracle GoldenGate for Big Data to Oracle Cloud Infrastructure (OCI) cloud instances of Oracle NoSQL. You must use at least version 5.2.27 of the Oracle NoSQL Java SDK.
gg.handler.nam e.proxyPort	Opti onal	80	Positive Integer	Used to configure the forwarding proxy server port number for connectivity of on-premise Oracle GoldenGate for Big Data to OCI cloud instances of Oracle NoSQL. You must use at least version 5.2.27 of the Oracle NoSQL Java SDK.
gg.handler.nam e.proxyUsernam e	Opti onal	None	String	Used to configure the username of the forwarding proxy for connectivity of on-premise Oracle GoldenGate for Big Data to OCI cloud instances of Oracle NoSQL if applicable. Most proxy servers do not require credentials. You must use at least version 5.2.27 of the Oracle NoSQL Java SDK.

Properties	Req uire d/ Opti ona I	Legal Values	Default	Explanation
gg.handler.nam e.proxyPasswor d	• •	None	String	Used to configure the password of the forwarding proxy for connectivity of on-premise Oracle GoldenGate for Big Data to OCI cloud instances of Oracle NoSQL if applicable. Most proxy servers do not require credentials. Must use at least version 5.2.27 of the Oracle NoSQL Java SDK.

## Performance Considerations

When then NoSQL Handler is processing in interactive mode, operations are processing one at a time as they are received by the NoSQL Handler.

The NoSQL Handler will process in bulk mode if the following parameter is set.

gg.handler.name.interactiveMode=false

The NoSQL SDK allows bulk processing of operations for operations which meet the following criteria:

- 1. Operations must be for the same NoSQL table.
- 2. Operations mush be in the same NoSQL shard (have the same shard key or shard key values).
- 3. Only one operation per row exists in the batch.

When interactive mode is set to false, the NoSQL handler group operations by table and shard key, and deduplicates operations for the same row.

An example of Deduplication: If there is an insert and an update for a row, then only the update operation is processed if the operations fall within the same transaction or replicat grouped transaction.

The NoSQL handler may provide better performance when interactive mode is set to false. However, for the interactive mode to provide better performance, operations need to be groupable by the above criteria. If operations are not groupable by the above criteria or if operations or bulk mode only provide grouping into very small batches, then bulk mode may not provide much or any improvement in performance.

## **Operation Processing Support**

The Oracle NoSQL Handler moves operations to Oracle NoSQL using synchronous API. The insert, update, and delete operations are processed differently in Oracle NoSQL databases rather than in a traditional RDBMS:

The following explains how insert, update, and delete operations are interpreted by the handler depending on the mode of operation:

 insert: If the row does not exist in your database, then an insert operation is processed as an insert. If the row exists, then an insert operation is processed as an update.

- update: If a row does not exist in your database, then an update operation is processed as an insert. If the row exists, then an update operation is processed as update.
- delete: If the row does not exist in your database, then a delete operation has no effect. If the row exists, then a delete operation is processed as a delete.

The state of the data in Oracle NoSQL databases is idempotent. You can replay the source trail files or replay sections of the trail files. Ultimately, the state of an Oracle NoSQL database is the same regardless of the number of times the trail data was written into Oracle NoSQL.

Primary key values for a row in Oracle NoSQL databases are immutable. An update operation that changes any primary key value for a Oracle NoSQL row must be treated as a delete and insert. The Oracle NoSQL Handler can process update operations that result in the change of a primary key in an Oracle NoSQL database only as a delete and insert. To successfully process this operation, the source trail file must contain the complete before and after change data images for all columns.

## **Column Processing**

You can configure the Oracle NoSQL Handler to add columns that exist in the source trail file table definition though are missing in the Oracle NoSQL table definition. The Oracle NoSQL Handler can accommodate metadata change events of adding a column. A reconciliation process occurs that reconciles the source table definition to the Oracle NoSQL table definition. When configured to add columns, any columns found in the source table definition that do not exist in the Oracle NoSQL table definition are added. The reconciliation process for a table occurs after application start up the first time an operation for the table is encountered. The reconciliation process reoccurs after a metadata change event on a source table, when the first operation for the source table is encountered after the change event. **Drop Column Functionality** 

Similar to adding, you can configure the Oracle NoSQL Handler to drop columns. The Oracle NoSQL Handler can accommodate metadata change events of dropping a column. A reconciliation process occurs that reconciles the source table definition to the Oracle NoSQL table definition. When configured to drop columns, any columns found in the Oracle NoSQL table definition that are not in the source table definition are dropped.

### Caution:

Dropping a column is potentially dangerous because it is permanently removing data from an Oracle NoSQL Database. Carefully consider your use case before configuring dropping.

Primary key columns cannot be dropped.

Column name changes are not handled well because there is no DDL-processing. The Oracle NoSQL Handler can handle any case change for the column name. A column name change event on the source database appears to the handler like dropping an existing column and adding a new column.

## Table Check and Reconciliation Process

- The Oracle NoSQL Handler interrogates the target Oracle NoSQL database for the table definition. If the table does not exist, the Oracle NoSQL Handler does one of two things. If gg.handler.name.ddlHandling includes CREATE, then a table is created in the database. Otherwise, the process abends and a message is logged that tells you the table that does not exist.
- 2. If the table exists in the Oracle NoSQL database, then the Oracle NoSQL Handler performs a reconciliation between the table definition from the source trail file and the table definition in the database. This reconciliation process searches for columns that exist in the source table definition and not in the corresponding database table definition. If it locates columns fitting this criteria and the gg.handler.name.ddlHandling property includes ADD, then the Oracle NoSQL Handler alters the target table in the database to add the new columns. Otherwise the columns missing in the target will not be added. If the property gg.handler.name.abendOnUnmappedColumns is set to true, then the NoSQL Handler will abend. Else, if the configuration propery gg.handler.name.abendOnUnmappedColumns is set to false, then the NoSQL Handler will continue the process and will not replicat data for the columns which exist in the source table and do not exist in the target NoSQL table.
- 3. The reconciliation process searches for columns that exist in the target Oracle NoSQL and do not exist in the source table definition. If it locates columns fitting this criteria and the gg.handler.name.ddlHandling property includes DROP, then the Oracle NoSQL Handler alters the target table in Oracle NoSQL to drop these columns. Otherwise, those columns are ignored.
- Full Image Data Requirements

### Full Image Data Requirements

In Oracle NoSQL, update operations perform a complete reinsertion of the data for the entire row. This Oracle NoSQL feature improves ingest performance, but in turn levies a critical requirement. Updates must include data for all columns, also known as full image updates. Partial image updates are not supported (updates with just the primary key information and data for the columns that changed). Using the Oracle NoSQL Handler with partial image update information results in incomplete data in the target NoSQL table.

## Oracle NoSQL SDK Dependencies

The maven coordinates are as follows:

Maven groupId: com.oracle.nosql.sdk

Maven artifactId: nosqldriver

Version: 5.2.27

Oracle NoSQL SDK Dependencies 5.2.27

Oracle NoSQL SDK Dependencies 5.2.27

```

# OCI Autonomous Data Warehouse

Oracle Autonomous Data Warehouse (ADW) is a fully managed database tuned and optimized for data warehouse workloads with the market-leading performance of Oracle Database.

```
    Detailed Functionality
```

The ADW Event handler is used as a downstream Event handler connected to the output of the OCI Object Storage Event handler. The OCI Event handler loads files generated by the File Writer Handler into Oracle OCI Object storage. All the SQL operations are performed in batches providing better throughput.

ADW Database Credential to Access OCI ObjectStore File

#### ADW Database User Privileges

ADW databases come with a predefined database role named DWROLE. If the ADW 'admin' user is not being used, then the database user needs to be granted the role DWROLE.

- Unsupported Operations/ Limitations
- Troubleshooting and Diagnostics
- Classpath

ADW apply relies on the upstream File Writer handler and the OCI Event handler. Include the required jars needed to run the OCI Event handler in gg.classpath.

Configuration

## **Detailed Functionality**

The ADW Event handler is used as a downstream Event handler connected to the output of the OCI Object Storage Event handler. The OCI Event handler loads files generated by the File Writer Handler into Oracle OCI Object storage. All the SQL operations are performed in batches providing better throughput.

## ADW Database Credential to Access OCI ObjectStore File

To access the OCI ObjectStore File:

 A PL/SQL procedure needs to be run to create a credential to access Oracle Cloud Infrastructure (OCI) Object store files.

2. An OCI authentication token needs to be generated under User settings from the OCI console. See CREATE\_CREDENTIAL in Using Oracle Autonomous Data WareHouse on Shared Exadata Infrastructure. For example:

```
BEGIN DBMS_CLOUD.create_credential
  (    credential_name =>
    'OGGBD-CREDENTIAL', username => 'oci-user', password =>
    'oci-user');
    END;
    /
```

3. The credential name can be configured using the followng property: gg.eventhandler.adw.objectStoreCredential. For example: gg.eventhandler.adw.objectStoreCredential=OGGBD-CREDENTIAL.

## ADW Database User Privileges

ADW databases come with a predefined database role named DWROLE. If the ADW 'admin' user is not being used, then the database user needs to be granted the role DWROLE.

This role provides the privileges required for data warehouse operations. For example, the following command grants DWROLE to the user dbuser-1:

```
GRANT DWROLE TO dbuser-1;
```

### Note:

Ensure that you do not use Oracle-created database user ggadmin for ADW replication, because this user lacks the INHERIT privilege.

## **Unsupported Operations/ Limitations**

- DDL changes are not supported.
- Replication of Oracle Object data types are not supported.
- If the GoldenGate trail is generated by Oracle Integrated capture, then for the UPDATE operations on the source LOB column, only the changed portion of the LOB is written to the trail file. Oracle GoldenGate for Big Data Autonomous Data Warehouse (ADW) apply doesn't support replication of partial LOB columns in the trail file.

## **Troubleshooting and Diagnostics**

- Connectivity Issues to ADW
  - Validate JDBC connection URL, user name and password.
  - Check if http/https proxy is enabled. See ADW proxy configuration: Prepare for Oracle Call Interface (OCI), ODBC, and JDBC OCI Connections in Using Oracle Autonomous Data Warehouse on Shared Exadata Infrastructure.
- DDL not applied on the target table: The ADW handler will ignore DDL.
- **Target table existence**: It is expected that the ADW target table exists before starting the apply process. Target tables need to be designed with appropriate primary keys, indexes

and partitions. Approximations based on the column metadata in the trail file may not be always correct. Therefore, replicat will ABEND if the target table is missing.

 Diagnostic throughput information on the apply process is logged into the handler log file.
 For example:

```
File Writer finalized 29525834 records
```

```
(rate: 31714) (start time: 2020-02-10 01:25:32.000579) (end time: 2020-02-10 01:41:03.000606).
```

In this sample log message:

- This message provides details about the end-end throughput of File Writer handler and the downstream event handlers (OCI Event handler and ADW event handler).
- The throughput rate also takes into account the wait-times incurred before rolling over files.
- The throughput rate also takes into account the time taken by the OCI event handler and the ADW event handler to process operations.
- The above examples indicates that 29525834 operations were finalized at the rate of 31714 operations per second between start time: [2020-02-10 01:25:32.000579] and end time: [2020-02-10 01:41:03.000606].

Example:

```
INFO 2019-10-01 00:36:49.000490 [pool-8-thread-1] - Begin DWH Apply
stage and load statistics
INFO 2019-10-01 00:36:49.000490 [pool-8-thread-1] - Time spent for
staging process [2074 ms]
INFO 2019-10-01 00:36:49.000490 [pool-8-thread-1] - Time spent for
merge process [992550 ms]
INFO 2019-10-01 00:36:49.000490 [pool-8-thread-1] - [31195516]
operations processed, rate[31,364]operations/sec.
INFO 2019-10-01 00:36:49.000490 [pool-8-thread-1] - End DWH Apply
stage and load statistics
INFO 2019-10-01 00:37:18.000230 [pool-6-thread-1] - Begin OCI Event
handler upload statistics
INFO 2019-10-01 00:37:18.000230 [pool-6-thread-1] - Time spent
loading files into ObjectStore [71789 ms]
INFO 2019-10-01 00:37:18.000230 [pool-6-thread-1] - [31195516]
operations processed, rate[434,545] operations/sec.
INFO 2019-10-01 00:37:18.000230 [pool-6-thread-1] - End OCI Event
handler upload statistics
```

In this example:

ADW Event handler throughput:

- In the above log message, the statistics for the ADW event handler is reported as DWH Apply stage and load statistics. ADW is classified as a Data Ware House (DWH), and therefore, this name.
- Here 31195516 operations from the source trail file were applied to ADW database at the rate of 31364 operations per second.
- ADW uses stage and merge. The time spent on staging is 2074 milliseconds and the time spent on executing merge SQL is 992550 milliseconds.

OCI Event handler throughput:

- In the above log message, the statistics for the OCI event handler is reported as OCI Event handler upload statistics.
- Here 31195516 operations from the source trail file were uploaded to the OCI object store at the rate of 434545 operations per second.
- Errors due to ADW credential missing grants to read OCI object store files:
  - A SQL exception indicating authorization failure is logged in the handler log file. For example:

```
java.sql.SQLException: ORA-20401:
Authorization failed for URI -
https://objectstorage.us-ashburn-1.oraclecloud.com/n/some_namespace/b/
some_bucket/o/ADMIN.NLS_AllTypes/
ADMIN.NLS_AllTypes_2019-12-16_11-44-01.237.avro
```

### Errors in file format/column data:

In case the ADW Event handler is unable to read data from the external staging table due to column data errors, the Oracle GoldenGate for Big Data handler log file provides diagnostic information to debug the issue.

The following details are available in the log file:

- JOB ID
- SID
- SERIAL #
- ROWS\_LOADED
- START TIME
- UPDATE TIME
- STATUS
- TABLE NAME
- OWNER NAME
- FILE\_URI\_LIST
- LOGFILE\_TABLE
- BADFILE\_TABLE

The contents of the LOGFILE\_TABLE and BADFILE\_TABLE should indicate the specific record and the column(s) in the record which have error and the cause of the error. This information is also queried automatically by the ADW Event handler and logged into the OGGBD FW handler log file. Based on the root cause of the error, customer can take action. In many cases, customers would have to modify the target table definition based on the

source column data types and restart replicat. In other cases, customers may also want to modify the mapping in the replicat prm file. For this, Oracle recommends that they re-position replicat to start from the beginning.

#### Any other SQL Errors:

In case there are any errors while executing any SQL, the entire SQL statement along with the bind parameter values are logged into the OGGBD handler log file.

#### Co-existence of the components:

The location/region of the machine where replicat process is running, OCI Objects storage bucket region and the ADW region would impact the overall throughput of the apply process. Data flow is as follows: **GoldenGate** I **OCI Object store** I **ADW**. For best throughput, the components need to located as close as possible.

#### Debugging row count mismatch on the target table

For better throughput, ADW event handler does not validate the row counts modified on the target table. We can enable row count matching by using the Java System property: disable.row.count.validation. To enable row count validation, provide this property in the jvm.bootoptions as follows: jvm.bootoptions=-Xmx512m -Xms32m -Djava.class.path=.:ggjava/ggjava.jar:./dirprm - Ddisable.row.count.validation=false

#### Replicat ABEND due to partial LOB records in the trail file:

Oracle GoldenGate for Big Data ADW apply does not support replication of partial LOB. The trail file needs to be regenerated by Oracle Integrated capture using TRANLOGOPTIONS FETCHPARTIALLOB option in the extract parameter file.

#### Throughput gain with uncompressed UPDATE trails:

If the source trail files contain the full image (all the column values of the respective table) of the row being updated, then you can include the JVM boot option -Dcompressed.update=false in the configuration property jvm.bootoptions.

For certain workloads and ADW instance shapes, this configuration may provide a better throughput. You may need to test the throughput gain on your environment.

# Classpath

ADW apply relies on the upstream File Writer handler and the OCI Event handler. Include the required jars needed to run the OCI Event handler in gg.classpath.

ADW Event handler uses the Oracle JDBC driver and its dependencies. The Autonomous Data Warehouse JDBC driver and other required dependencies are packaged with Oracle GoldenGate for Big Data.

For example: gg.classpath=./oci-java-sdk/lib/\*:./oci-java-sdk/thirdparty/lib/\*

# Configuration

#### Automatic Configuration

Autonomous Data Warehouse (ADW) replication involves configuring of multiple components, such as file writer handler, OCI event handler and ADW event handler.

- File Writer Handler Configuration File writer handler name is pre-set to the value adw. The following is an example to edit a property of file writer handler: gg.handler.adw.pathMappingTemplate=./dirout
- OCI Event Handler Configuration
   OCI event handler name is pre-set to the value 'oci'.
- ADW Event Handler Configuration ADW event handler name is pre-set to the value adw.
- INSERTALLRECORDS Support
- End-to-End Configuration

### Automatic Configuration

Autonomous Data Warehouse (ADW) replication involves configuring of multiple components, such as file writer handler, OCI event handler and ADW event handler.

The Automatic Configuration functionality helps to auto configure these components so that the user configuration is minimal. The properties modified by auto configuration will also be logged in the handler log file.

To enable auto configuration to replicate to ADW target we need to set the parameter

gg.target=adw

```
gg.target
Required
Legal Value: adw
Default: None
Explanation: Enables replication to ADW target
```

When replicating to ADW target, customization of OCI event hander name and ADW event handler name is not allowed.

### File Writer Handler Configuration

File writer handler name is pre-set to the value adw. The following is an example to edit a property of file writer handler: gg.handler.adw.pathMappingTemplate=./dirout

### **OCI Event Handler Configuration**

OCI event handler name is pre-set to the value 'oci'.

The following is an example to edit a property of the OCI event handler: gg.eventhandler.oci.profile=DEFAULT

### ADW Event Handler Configuration

ADW event handler name is pre-set to the value adw.

The following are the ADW event handler configurations:

Property	Required/ Optional	Legal Value s	Defau It	Explanationtes
gg.eventhandle r.adw.connecti onURL	Required	ADW	None	Sets the ADW JDBC connection URL. Example: jdbc:oracle:thin:@adw20190410ns_m edium?TNS_ADMIN=/home/sanav/ projects/adw/wallet
gg.eventhandle r.adw.UserName	Required	JDBC User name	None	Sets the ADW database user name.
gg.eventhandle r.adw.Password	Required	JDBC Passw ord	None	Sets the ADW database password.
gg.eventhandle r.adw.maxState ments	Optional	betwe	The default value is 250.	Use this parameter to control the number of prepared SQL statements that can be used.
gg.eventhandle r.adw.maxConnn ections	Optional	Intege r value.	10	Use this parameter to control the number of concurrent JDBC database connections to the target ADW database.
gg.eventhandle r.adw.dropStag ingTablesOnShu tdown	Optional	true   false	false	If set to true, the temporary staging tables created by the ADW event handler is dropped on replicat graceful stop.
gg.eventhandle r.adw.objectSt oreCredential	Required	A databa se creden tial name.	None	ADW Database credential to access OCI object-store files.
gg.initialLoad	Optional	true   false	false	If set to true, initial load mode is enabled. See INSERTALLRECORDS Support.
gg.operation.a ggregator.vali date.keyupdate	Optional	true or false	false	If set to true, Operation Aggregator will validate key update operations (optype 115) and correct to normal update if no key values have changed. Compressed key update operations do not qualify for merge.

## INSERTALLRECORDS Support

Stage and merge targets supports INSERTALLRECORDS parameter.

See INSERTALLRECORDS in *Reference for Oracle GoldenGate*. Set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm). Set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm)

Setting this property directs the Replicat process to use bulk insert operations to load operation data into the target table.

You can tune the batch size of bulk inserts using the File writer property gg.handler.adw.maxFileSize. The default value is set to 1GB. The frequency of bulk

inserts can be tuned using the File writer property gg.handler.adw.fileRollInterval, the default value is set to 3m (three minutes).

To process initial load trail files, set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm). Setting this property directs the Replicat process to use bulk insert operations to load operation data into the target table.

You can tune the batch size of bulk inserts using the File Writer property gg.handler.adw.maxFileSize. The default value is set to 1GB. The frequency of bulk inserts can be tuned using the File Writer property gg.handler.adw.fileRollInterval, the default value is set to 3m (three minutes).

### End-to-End Configuration

The following is an end-end configuration example which uses auto configuration for FW handler, OCI and ADW Event handlers. The sample properties file is available at the following location:

- In an Oracle GoldenGate Classic install: <oggbd\_install\_dir>/AdapterExamples/ big-data/adw-via-oci/adw.props.
- In an Oracle GoldenGate Microservices install: <oggbd\_install\_dir>/opt/ AdapterExamples/big-data/adw-via-oci/adw.props.

# Configuration to load GoldenGate trail operation records # into Autonomous Data Warehouse (ADW) by chaining # File writer handler -> OCI Event handler -> ADW Event handler. # Note: Recommended to only edit the configuration marked as TODO gg.target=adw ##The OCI Event handler # TODO: Edit the OCI config file path. gg.eventhandler.oci.configFilePath=<path/to/oci/config> # TODO: Edit the OCI profile name. gg.eventhandler.oci.profile=DEFAULT # TODO: Edit the OCI namespace. gg.eventhandler.oci.namespace=<OCI namespace> # TODO: Edit the OCI region. gg.eventhandler.oci.region=<oci-region> # TODO: Edit the OCI compartment identifier. gg.eventhandler.oci.compartmentID=<OCI compartment id> gg.eventhandler.oci.pathMappingTemplate=\${fullyQualifiedTableName} # TODO: Edit the OCI bucket name. gg.eventhandler.oci.bucketMappingTemplate=<ogg-bucket> ##The ADW Event Handler # TODO: Edit the ADW JDBC connectionURL gg.eventhandler.adw.connectionURL=jdbc:oracle:thin:@adw20190410ns medium?TNS ADMIN=/ path/to/ /adw/wallet # TODO: Edit the ADW JDBC user gg.eventhandler.adw.UserName=<db user> # TODO: Edit the ADW JDBC password gg.eventhandler.adw.Password=<db password> # TODO: Edit the ADW Credential that can access the OCI Object Store. gg.eventhandler.adw.objectStoreCredential=<ADW Object Store credential> # TODO:Set the classpath to include OCI Java SDK. gg.classpath=./oci-java-sdk/lib/\*:./oci-java-sdk/third-party/lib/\* #TODO: Edit to provide sufficient memory (at least 8GB). jvm.bootoptions=-Xmx8g -Xms8g

# Oracle Cloud Infrastructure Object Storage

The Oracle Cloud Infrastructure Event Handler is used to load files generated by the File Writer Handler into an Oracle Cloud Infrastructure Object Store.

The Oracle Cloud Infrastructure Event Handler is used to load files generated by the Flat Files into an Oracle Cloud Infrastructure Object Store. This topic describes how to use the OCI Event Handler.

- Overview
- Detailing the Functionality
- Configuration
- Configuring Credentials for Oracle Cloud Infrastructure
- Troubleshooting
- OCI Dependencies

## Overview

The Oracle Cloud Infrastructure Object Storage service is an internet-scale, highperformance storage platform that offers reliable and cost-efficient data durability. The Object Storage service can store an unlimited amount of unstructured data of any content type, including analytic data and rich content, like images and videos, see https://cloud.oracle.com/en\_US/cloud-infrastructure.

You can use any format handler that the File Writer Handler supports.

# Detailing the Functionality

The Oracle Cloud Infrastructure Event Handler requires the Oracle Cloud Infrastructure Java software development kit (SDK) to transfer files to Oracle Cloud Infrastructure Object Storage. Oracle GoldenGate for Big Data does not include the Oracle Cloud Infrastructure Java SDK, see https://docs.cloud.oracle.com/iaas/ Content/API/Concepts/sdkconfig.htm.

You must download the Oracle Cloud Infrastructure Java SDK at:

https://docs.us-phoenix-1.oraclecloud.com/Content/API/SDKDocs/javasdk.htm

Extract the JAR files to a permanent directory. There are two directories required by the handler, the JAR library directory that has Oracle Cloud Infrastructure SDK JAR and a third-party JAR library. Both directories must be in the gg.classpath.

Specify the gg.classpath environment variable to include the JAR files of the Oracle Cloud Infrastructure Java SDK.

#### Example

gg.classpath=/usr/var/oci/lib/\*:/usr/var/oci/third-party/lib/\*

Setting of the proxy server settings requires additional dependency libraries identified by the following Maven coordinates:

Group ID: com.oracle.oci.sdk

Artifact ID: oci-java-sdk-addons-apache

The best way to get all of the dependencies is to use the Dependency Downloading utility scripts. The OCI script downloads both the OCI Java SDK and the Apache Addons libraries.

For more information on this dependency, see OCI Documentation - README.

# Configuration

You configure the Oracle Cloud Infrastructure Event Handler operation using the properties file. These properties are located in the Java Adapter properties file (and not in the Replicat properties file).

The Oracle Cloud Infrastructure Event Handler works only in conjunction with the File Writer Handler.

To enable the selection of the Oracle Cloud Infrastructure Event Handler, you must first configure the handler type by specifying gg.eventhandler.name.type=oci and the other Oracle Cloud Infrastructure properties as follows:

Table 8-34         Oracle Cloud Infrastructure Event Handler C	Configuration Properties
--	--------------------------

Properties	Required / Optional	Legal Values	Default	Explanation
<pre>gg.eventhandler .name.type</pre>	Required	oci	None	Selects the Oracle Cloud Infrastructure Event Handler.
gg.eventhandler .name.contentTy pe	Optional	Valid content type value which is used to indicate the media type of the resource.	applic ation/ octet- stream	The content type of the object.
gg.eventhandler .name.contentEn coding	Optional	Valid values indicate which encoding to be applied.	utf-8	The content encoding of the object.
gg.eventhandler .name.contentLa nguage	Optional	Valid language intended for the audience.	en	The content language of the object.

Properties	Required / Optional	Legal Values	Default	Explanation
gg.eventhandler . <i>name</i> .configFil ePath	Optional	Path to the event handler config file.	None	<pre>The configuration file name and location. If gg.eventhandler.name.configFilePath is not set, then the following authentication parameters are required:     gg.eventhandler.name.userId     gg.eventhandler.name.tenancyID     gg.eventhandler.name.region     gg.eventhandler.name.privateKeyF     ile     gg.eventhandler.name.publicKeyFi     ngerprint These parameters take precedence over gg.eventhandler.name.configFilePath.</pre>
gg.eventhandler . <i>nam</i> e.userId	Optional	Valid user ID	None	OCID of the user calling the API. To get the value, see (Required Keys and OCIDs)https:// docs.oracle.com/en-us/iaas/Content/API/ Concepts/ apisigningkey.htm#Required_Keys_and_OCID s. Example: ocid1.user.oc1 <unique_id> (shortened for brevity)</unique_id>
gg.eventhandler . <i>name</i> .tenancyId	Optional	Valid tenancy ID	None	OCID of your tenancy. To get the value, see (Required Keys and OCIDs)https:// docs.oracle.com/en-us/iaas/Content/API/ Concepts/ apisigningkey.htm#Required_Keys_and_OCID s. in Oracle Cloud Infrastructure documentation. <b>Example</b> : ocid1.tenancy.oc1 <unique_id></unique_id>

Properties	Required / Optional	Legal Values	Default	Explanation	
gg.eventhandler .name.privateKe	Optional	A valid path to the file	None	Full path and filename of the private key.	
yFile				💉 Note:	
				The key pair must be in PEM format. For more information about generating a key pair in PEM format, see (Required Keys and OCIDs)https:// docs.oracle.com/ en-us/iaas/ Content/API/ Concepts/ apisigningkey.ht m#Required_Ke ys_and_OCIDs in Oracle Cloud Infrastructure documentation. <b>Example</b> : / home/opc/.oci / oci_api_key.p em	
gg.eventhandler . <i>name</i> .publicKey Fingerprint	Optional	String	None	Fingerprint for the public key that was added to this user. To get the value, see (Required Keys and OCIDs) https://docs.oracle.com/en- us/iaas/Content/API/Concepts/ apisigningkey.htm#Required_Keys_and_OCID s in Oracle Cloud Infrastructure documentation.	
gg.eventhandler . <i>name</i> .profile	Required	Valid string representin g the profile name.	DEFAUL T	documentation. In the Oracle Cloud Infrastructure config file the entries are identified by the profile name. The default profile is DEFAULT. You can have an additional profile like ADMIN_USER. Any value that isn't explicitly defined for the ADMIN_USER profile (or any other profiles that you add to the config file) is inherited from the DEFAULT profile.	

Properties	Required / Optional	Legal Values	Default	Explanation
gg.eventhandler . <i>nam</i> e.region	Required	Oracle Cloud Infrastructu re region	None	Oracle Cloud Infrastructure Servers and Data is hosted in a region and is a localized geographic area. The valid Region Identifiers are listed at Oracle Cloud Infrastructure Documentation - Regions and Availability Domains.
gg.eventhandler . <i>name</i> .compartme ntID	Required	Valid compartme nt id.	None	A compartment is a logical container to organize Oracle Cloud Infrastructure resources. The compartmentID is listed in Bucket Details while using the Oracle Cloud Infrastructure Console.
gg.eventhandler . <i>name</i> .pathMappi ngTemplate	Required	A string with resolvable keywords and constants used to dynamically generate the path in the Oracle Cloud Infrastructu re bucket to write the file.	None	Use keywords interlaced with constants to dynamically generate unique Oracle Cloud Infrastructure path names at runtime. See Template Keywords.
gg.eventhandler . <i>name</i> .fileNameM appingTemplate	Optional	A string with resolvable keywords and constants used to dynamically generate the Oracle Cloud Infrastructu re file name at runtime.	None	Use resolvable keywords and constants to dynamically generate the Oracle Cloud Infrastructure data file name at runtime. If not set, the upstream file name is used. See Template Keywords.

Properties	Required / Optional	Legal Values	Default	Explanation
gg.eventhandler . <i>name</i> .bucketMap pingTemplate	Required	A string with resolvable keywords and constants used to dynamically generate the path in the Oracle Cloud Infrastructu re bucket to write the file.	None	Use resolvable keywords and constants used to dynamically generate the Oracle Cloud Infrastructure bucket name at runtime. The event handler attempts to create the Oracle Cloud Infrastructure bucket if it does not exist. See Template Keywords.
gg.eventhandler . <i>name</i> .finalizeA ction	Optional	none  delete	None	Set to none to leave the Oracle Cloud Infrastructure data file in place on the finalize action. Set to delete if you want to delete the Oracle Cloud Infrastructure data file with the finalize action.
gg.eventhandler . <i>name</i> .eventHand ler	Optional	A unique string identifier cross referencing a child event handler.	No event handler is configur ed.	Sets the event handler that is invoked on the file roll event. Event handlers can do file roll event actions like loading files to S3, converting to Parquet or ORC format, loading files to HDFS, loading files to Oracle Cloud Infrastructure Storage Classic, or loading file to Oracle Cloud Infrastructure.
gg.eventhandler .name.proxyServ er	Optional	The host name of your proxy server.	None	Set to the host name of the proxy server if OCI connectivity requires routing through a proxy server.
gg.eventhandler .name.proxyPort	Optional	The port number of the proxy server.	None	Set to the port number of the proxy server if OCI connectivity requires routing through a proxy server.
gg.eventhandler .name.proxyProt ocol	Optional	HTTP   HTTPS	HTTP	Sets the proxy protocol connection to the proxy server for additional level of security. The majority of proxy servers support HTTP. Only set this if the proxy server supports HTTPS and HTTPS is required.
gg.eventhandler .name.proxyUser name	Optional	The username for the proxy server.	None	Sets the username for connectivity to the proxy server if credentials are required. Most proxy servers do not require credentials.

Properties	Required / Optional	Legal Values	Default	Explanation
gg.eventhandler .name.proxyPass word	Optional	The password for the proxy server.	None	Sets the password for connectivity to the proxy server if credentials are required. Most proxy servers do not require credentials.
gg.handler.name .SSEKey	Optional	A legal Base64 encoded OCI server side encryption key.	None	Allows you to control the encryption of data files loaded to OCI. OCI encrypts by default. This property allows an additional level of control by supporting encryption with a specific key. That key must also be used to decrypt data files.

#### **Sample Configuration**

```
gg.eventhandler.oci.type=oci
gg.eventhandler.oci.configFilePath=~/.oci/config
gg.eventhandler.oci.profile=DEFAULT
gg.eventhandler.oci.namespace=dwcsdemo
gg.eventhandler.oci.region=us-ashburn-1
gg.eventhandler.oci.compartmentID=ocid1.compartment.oc1..aaaaaaaajdg6iblwgqlyqpeg
f6kwdais2gyx3guspboa7fsi72tfihz2wrba
gg.eventhandler.oci.pathMappingTemplate=${schemaName}
gg.eventhandler.oci.fileNameMappingTemplate=${tableName}_${currentTimestamp}.txt
gg.eventhandler.oci.finalizeAction=NONE
goldengate.userexit.writers=javawriter
```

Automatic Configuration

### Automatic Configuration

OCI Object storage replication involves configuring multiple components, such as the File Writer Handler, formatter, and the target OCI Object Storage Event Handler.

The Automatic Configuration functionality helps you to auto configure these components so that the manual configuration is minimal.

The properties modified by auto-configuration is also logged in the handler log file.

To enable auto configuration to replicate to the OCI Object Storage target, set the parameter gg.target=oci.

- File Writer Handler Configuration
- Formatter Configuration

#### File Writer Handler Configuration

The File Writer Handler name is pre set to the value oci.

You can add or edit a property of the File Writer Handler. For example: gg.handler.oci.pathMappingTemplate=./dirout

#### Formatter Configuration

The json row formatter is set by default.

You can add or edit a property of the formatter. For example: gg.handler.oci.format=json\_row

# Configuring Credentials for Oracle Cloud Infrastructure

Basic configuration information like user credentials and tenancy Oracle Cloud IDs (OCIDs) of Oracle Cloud Infrastructure is required for the Java SDKs to work, see <a href="https://docs.cloud.oracle.com/iaas/Content/General/Concepts/identifiers.htm">https://docs.cloud.oracle.com/iaas/Content/General/Concepts/identifiers.htm</a>.

The ideal configuration file include keys user, fingerprint, key\_file, tenancy, and region with their respective values. The default configuration file name and location is  $\sim/.oci/config.$ 

Create the config file as follows:

- 1. Create a directory called .oci in the Oracle GoldenGate for Big Data home directory
- 2. Create a text file and name it config.
- 3. Obtain the values for these properties:

#### user

- a. Login to the Oracle Cloud Infrastructure Console https://console.usashburn-1.oraclecloud.com.
- b. Click Username.
- c. Click User Settings.

The User's OCID is displayed and is the value for the key user.

#### tenancy

The Tenancy ID is displayed at the bottom of the Console page.

#### region

The region is displayed with the header session drop-down menu in the Console.

#### fingerprint

To generate the fingerprint, use the How to Get the Key's Fingerprint instructions at:

https://docs.cloud.oracle.com/iaas/Content/API/Concepts/apisigningkey.htm

#### key\_file

You need to share the public and private key to establish a connection with Oracle Cloud Infrastructure. To generate the keys, use the *How to Generate an API Signing Key*at:

https://docs.cloud.oracle.com/iaas/Content/API/Concepts/apisigningkey.htm

#### pass\_phrase

This is an optional property. It is used to configure the passphrase if the private key in the pem file is protected with a passphase. The following openssl command can be used to take an unprotected private key pem file and add a passphrase.

#### The following command prompts the user for the passphrase:

openssl rsa -aes256 -in in.pem -out out.pem

#### **Sample Configuration File**

```
user=ocidl.user.oc1..aaaaaaaat5nvwcna5j6aqzqedqw3rynjq
fingerprint=20:3b:97:13::4e:c5:3a:34
key_file=~/.oci/oci_api_key.pem
tenancy=ocidl.tenancy.oc1..aaaaaaaaba3pv6wkcr44h25vqstifs
```

# Troubleshooting

#### **Connectivity Issues**

If the OCI Event Handler is unable to connect to the OCI object storage when running on premise, it's likely your connectivity to the public internet is protected by a proxy server. Proxy servers act a gateway between the private network of a company and the public internet. Contact your network administrator to get the URL of your proxy server.

Oracle GoldenGate for Big Data connectivity to OCI can be routed through a proxy server by setting the following configuration properties:

gg.eventhandler.name.proxyServer={insert your proxy server name}
gg.eventhandler.name.proxyPort={insert your proxy server port number}

#### ClassNotFoundException Error

The most common initial error is an incorrect classpath that does not include all the required client libraries so results in a ClassNotFoundException error. Specify the gg.classpath variable to include all of the required JAR files for the Oracle Cloud Infrastructure Java SDK, see Detailing the Functionality.

# **OCI** Dependencies

The maven coordinates for OCI are as follows:

Maven groupId: com.oracle.oci.sdk

Maven artifactId: oci-java-sdk-full

Version: 1.34.0

The following are the Apache add-ons to which, support routing through a proxy server:

Maven groupId: com.oracle.oci.sdk

Maven artifactId: oci-java-sdk-addons-apache

Version: 1.34.0

OCI 1.34.0

# OCI 1.34.0

# Redis

Redis is an in-memory data structure store which supports optional durability. Redis is simply a key/value data store where a unique key identifies the data structure stored. The value is the data structure that is stored.

The Redis Handler supports the replication of change data capture to Redis and the storage of that data in three different data structures: Hash Maps, Streams, JSONs.

- Data Structures Supported by the Redis Handler
- Redis Handler Configuration Properties
- Security
- Authentication Using Credentials
- SSL Basic Auth
- SSL Mutual Auth
- Redis Handler Dependencies The Redis Handler uses the Jedis client libraries to connect to the Redis server.
- Redis Handler Client Dependencies The Redis Handler uses the Jedis client to connect to Redis.

# Data Structures Supported by the Redis Handler

- Hash Maps
- Streams
- JSONs

### Hash Maps

The is the most common user use case. The key is a unique identifier for the table and row of the data which is being pushed to Redis. The data structure stored at each key location is a hash map. The key in the hash map is the column name and the value is the column value.

#### Behavior on Inserts, Updates, and Deletes

The source trail file will contain insert, update. and delete operations for which the data can be pushed into Redis. The Redis Handler will process inserts, updates, and deletes as follows:

Inserts – The Redis Handler will create a new key in Redis the value of which is a hash map for which the hash map key is the column name and the hash map value is the column value.

Updates – The Redis Handler will update an existing hash map structure in Redis. The existing hash map will be updated with the column names and values from the update operation processed. Because hash map data is updated and not replace, full image updates are not required.

Primary Key Updates – The Redis Handler will move the old key to the new key name alone with the data structure, then an update will be performed on the hash map.

Deletes – The Redis Handler will delete the key and its corresponding data structure from Redis.

#### Handling of Null Values

Redis hash maps cannot store null as a value. A Redis hash map must have a nonnull value. The default behavior is to omit columns with a null value from the generated hash map. If an update changes a column value from a non-null value to a null value, then the column key and value is removed from the hash map.

Users may wish to propagate null values to Redis. But, because Redis hash maps cannot store null values, a representative value will need to be configured to be propagated instead. This is configured by setting the following two parameters:

```
gg.handler.redis.omitNullValues=false
gg.handler.redis.nullValueRepresentation=null
```

The user will need to designate some value as null. But the following are legal too.

In this case the null value representation is an empty string or "".

gg.handler.redis.nullValueRepresentation=CDATA[]
In this case the null value representation is set to a tab.

gg.handler.redis.nullValueRepresentation=CDATA[\t]

#### **Support for Binary Values**

The default functionality is to push all data into Redis hash maps as Java strings. Binary values must be converted to Base64 to be represented as a Java String. Consequently, binary values will be represented as Base64. Alternatively, users can push bytes into Redis hash maps to retain the original bytes values by setting the following configuration property.

gg.handler.redis.dataType=bytes
Example hash map data in Redis:

127.0.0.1:6379> hgetall TCUSTMER:JANE

- 1) "optype"
- 2) "I"
- 3) "CITY"
- 4) "DENVER"
- 5) "primarykeycolumns"
- 6) "CUST CODE"
- 7) "STATE"
- 8) "CO"
- 9) "CUST CODE"
- 10) "JANE"
- 11) "position"
- 12) "00000000000000002126"
- 13) "NAME"
- 14) "ROCKY FLYER INC."

#### **Example Configuration**

```
gg.handlerlist=redis
gg.handler.redis.type=redis
gg.handler.redis.hostPortList= localhost:6379
gg.handler.redis.createIndexes=true
gg.handler.redis.mode=op
gg.handler.redis.metacolumnsTemplate=${position},${optype},${primarykeycolumns}
```

### Streams

Redis streams are analogs the Kafka topics. The Redis key is the stream name. The value of the stream are the individual messages pushed to the Redis stream. Individual messages are identified by a timestamp and offset of when the message was pushed to Redis. The value of each individual message is a hash map for which the key is the column name and value is the column value.

#### Behavior on Inserts, Updates, and Deletes

Each and every operation and its associated data is propagated to Redis Streams. Therefore, every operation will show up as a new message in Redis Streams.

#### Handling of Null Values

Redis streams stores hash maps as the value for each message. A Redis hash map cannot store null as a value. Null values work exactly as they do in hash maps functionality.

#### **Support for Binary Values**

The default functionality is to push all data into Redis hash maps as Java strings. Binary values must be converted to Base64 to be represented as a Java String. Consequently, binary values will be represented as Base64. Alternatively, users can push bytes into Redis hash maps to retain the original bytes values by setting the following configuration property.

```
gg.handler.redis.dataType=bytes
Steam data appears in Redis as follows:
```

```
127.0.0.1:6379> xread STREAMS TCUSTMER 0-0
1) 1) "TCUSTMER"
   2) 1) 1) "1664399290398-0"
         2) 1) "optype"
            2) "I"
             3) "CITY"
             4) "SEATTLE"
             5) "primarykeycolumns"
             6) "CUST CODE"
             7) "STATE"
             8) "WA"
            9) "CUST CODE"
            10) "WILL"
            11) "position"
            12) "000000000000001956"
            13) "NAME"
            14) "BG SOFTWARE CO."
2) 1) "1664399290398-1"
         2) 1) "optype"
```

- 3) "CITY"
- 4) "DENVER"
- 5) "primarykeycolumns"

- 6) "CUST CODE"
- 7) "STATE"
- 8) "CO"
- 9) "CUST CODE"
- 10) "JANE"
- 11) "position"
- 12) "0000000000000002126"
- 13) "NAME"
- 14) "ROCKY FLYER INC."

#### **Example Configuration**

```
gg.handlerlist=redis
gg.handler.redis.type=redis
gg.handler.redis.hostportlist=localhost:6379
gg.handler.redis.mode=op
gg.handler.redis.integrationType=streams
gg.handler.redis.metacolumnsTemplate=${position},${optype},${primarykeycolumns}
```

# JSONs

The key is a unique identifier for the table and row of the data which is being pushed to Redis. The value is a JSON object. The keys in the JSON object are the column names while the values in the JSON object are the column values.

The source trail file will contain inserts update and delete operations for which the data can be pushed into Redis. The Redis Handler will process inserts, updates, and deletes as follows:

Inserts – The Redis Handler will create a new JSON at the key.

Updates – The Redis Handler will replace the JSON at the given key with the new JSON reflecting the data of update. Because the JSON is replaced, full image updates are recommended in the source trail file.

Deletes – The key in Redis along with its corresponding JSON data structure are deleted.

#### Handling of Null Values

The JSON specification supports null values as JSON null. Therefore, null values in the data will be propagated as JSON null. Null value replacement is not supported since the JSON specification supports null values. Neither

```
gg.handler.redis.omitNullValues nor
```

gg.handler.redis.nullValueRepresentation configuration properties have any effect when the Redis Handler is configured to send JSONs. JSON per the specification is represented as follows: "fieldname": null

#### **Support for Binary Values**

Per the JSON specification, binary values are represented as Base64. Therefore, all binary values will be converted and propagated as Base64. Setting the property gg.handler.redis.dataType has no effect. JSONs will generally appear in Redis as follows:

```
127.0.0.1:6379> JSON.GET
TCUSTMER:JANE"{\"position\":\"00000000000000002126\",\"optype\":\"I\",\"pr
```

```
imarykeycolumns\":[\"CUST_CODE\"],\"CUST_CODE\":\"JANE\",\"NAME\":\"ROCKY FLYER
INC.\",\"CITY\":\"DENVER\",\"STATE\":\"CO\"}"
```

#### Example Configuration:

```
gg.handlerlist=redis
gg.handler.redis.type=redis
gg.handler.redis.hostportlist=localhost:6379
gg.handler.redis.mode=op
gg.handler.redis.integrationType=jsons
gg.handler.redis.createIndexes=true
gg.handler.redis.metacolumnsTemplate=${position},${optype},${primarykeycolumns}
```

# **Redis Handler Configuration Properties**

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handlerlist= name	Required	Any String	none	Provides the name for the Redis Handler.
gg.handler.name .type	Required	redis	none	Selects the Redis Handler.
gg.handler.name .mode	Optional	op   tx	op	The default is recommended. In op mode, operations are processed as received. In tx mode, operations are cached and processed at transaction commit. The tx mode is slower and creates a larger memory footprint.
gg.handler.name .integrationTyp e	Optional	hashmaps   streams   jsons	hashmaps	Sets the integration type for Redis. Select hashmaps and the data will be pushed into Redis as hashmaps. Select streams and data will be pushed into Redis streams. Select jsons and the data will be pushed into Redis as JSONs.

### Table 8-35 Redis Handler Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .dataType	Optional	string   bytes	string	Only valid for hashmap and streams integration types. Controls if string data or byte data is pushed to Redis. If string is selected, all binary data will be pushed to Redis Base64 encoded. If bytes is selected, binary data is pushed to Redis without conversion.
gg.handler.name .keyMappingTemp ate	Optional	Any combination of string and templating keywords.	For hashmaps and jsons: \$ {tableName}:\$ {primaryKeys} For streams: \$	Redis is a key value data store. The resolved value of this template determines the key for an operation.
gg.handler.name .createIndexes	Optional	true   false	{tableName}	Will automatically create an index for each replicated table for the following integration types: hashmaps   jsons User can delete these indexes or create additional indexes. Information on created indexes is logged to the replicat <replicat name&gt;.log file.</replicat 

## Table 8-35 (Cont.) Redis Handler Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .omitNullValues	Optional	true   false	true	Null values cannot be stored as values in a Redis hashmap structure. Both the intetgation types hashmaps and streams store hashmaps. By default, if a column value is null it cannot be replicated to Redis. By default, if a column value is changed to null, it has to be removed from a hashmap. Setting this to false will replicate a configured value representing a null value to Redis.
gg.handler.name .nullValueRepre sentation	Optional	Any String	"" (empty string)	Only valid if integration type is hashmaps or streams. Only valid if gg.handler.name .omitNullValues is set to false. This configured value here is the value that will be replicated to Redis instead of a null.
gg.handler.name .metaColumnsTem plate		Any string of comma separated metacolumn keywords.	none	This can be configured to select one or more metacolumns to be added to the output to Redis. See Metacolumn Keywords.
gg.handler.name .insertOpKey	Optional	Any string	"I."	This is the value of the operation type for inserts which is replicated if the metacolumn \$ {optype} is configured.

## Table 8-35 (Cont.) Redis Handler Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .updateOpKey	Optional	Any sting	"U"	This is the value of the operation type for updates which is replicated if the metacolumn \$ {optype} is configured.
gg.handler.name .deleteOpKey	Optional	Any string	"D"	This is the value of the operation type for deletes which is replicated if the metacolumn \$ {optype} is configured.
gg.handler.name .trucateOpKey	Optional	Any string	"T"	This is the value of the operation type for truncate which is replicated if the metacolumn \$ {optype} is configured.
gg.handler.name .maxStreamLengt h	Optional	Positive Integer	0	Sets the maximum length of steams. If more messages are pushed to a steam than this value, then the oldest messages will be deleted so that the maximum stream size is enforced. The default value is 0 which means no limit on the maximum stream length.
gg.handler.name .username	Optional	Any string	None	Used to set the username, if required, for connectivity to Redis.
gg.handler.name .password	Optional	Any string	None	Used to set the password, if required, for connectivity to Redis.

## Table 8-35 (Cont.) Redis Handler Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler.name .timeout	Optional	integer	15000	Property to set the both the connection and socket timeouts in milliseconds.
gg.handler.name .enableSSL	Optional	true   false	false	Set to true if connecting to a Redis that has been SSL enabled. SSL can be basic auth (certificate passes from server to client) or mutual auth (certificate passes from server to client and then a certificate passes from client to the server). Basic auth is generally combined with use of credentials (username and password) so that both sides of the connection can authenticate the other. SSL provides encryption of in flight messages.

#### Table 8-35 (Cont.) Redis Handler Configuration Properties

# Security

Connectivity to Redis can be secured in multiple ways. It is the Redis server which is configured for, and thereby selects, the type of security. The Redis Handler, which is the Redis client, must be configured to match the security of the server.

Redis server – connection listener – This is the Redis application.

Redis client – connection caller – This is the Oracle GoldenGate Redis Handler.

Check with your Redis administrator as to what security has been configured on the Redis server. Then, configure the Redis Handler to follow the security configuration of the Redis server.

# Authentication Using Credentials

This is a simple security that requires the Redis client-provided credentials (username and password) for the Redis server to authenticate the Redis client. This security does not provide any encryption of inflight messages.

```
gg.handler.name.username=<username>
gg.handler.name.password=<password>
```

# SSL Basic Auth

In this use case the Redis server passes a certificate to the Redis client. This allows the client to authenticate the server. The client passes credentials to the server, which allows the Redis server to authenticate the client. This connection is SSL and provides encryption of inflight messages.

```
gg.handler.name.enableSSL=true
gg.handler.name.username=<username>
gg.handler.name.password=<password>
```

If the Redis server passes an unsigned certificate to the Redis client, then the Redis Handler will need to be configured with a truststore. If the Redis server passes a certificate signed by a Certificate Authority, then a truststore is not required.

To configure a truststore on the Redis Handler:

```
jvm.bootoptions=-Djavax.net.ssl.trustStore=<absolute path to
truststore> -Djavax.net.ssl.trustStorePassword=<truststore password>
```

# SSL Mutual Auth

In this use case the Redis server passes a certificate to the Redis client. This allows the client to authenticate the server. The Redis client then passes a certificate to the Redis server. This allows the server to authenticate the Redis client. This connection is SSL and provides encryption of inflight messages.

```
gg.handler.name.enableSSL=true
```

Typically with this setup, the Redis client will need both a truststore and a keystore. The configuration is as follows:

To configure a truststore on the Redis Handler:

```
jvm.bootoptions=-Djavax.net.ssl.keyStore=<absolute path to keystore> -
Djavax.net.ssl.keyStorePassword=<keystore password> -
Djavax.net.ssl.trustStore=<absolute path to truststore> -
Djavax.net.ssl.trustStorePassword=<truststore password>
```

# **Redis Handler Dependencies**

The Redis Handler uses the Jedis client libraries to connect to the Redis server.

The following is a link to Jedis: https://github.com/redis/jedis

The Jedis libraries do not ship with Oracle GoldenGate for Big Data and will need to be obtained and then the gg.classpath configuration property will need to be configured to resolved the Jedis client. The dependency downloader utility which ships with Oracle GoldenGate for Big Data can be used to download Jedis. The Redis Handler was developed using Jedis 4.2.3. The following shows example configuration of the gg.classpath: gg.classpath=/OGGBDinstall/DependencyDownloader/dependencies/jedis 4.2.3/\*

# **Redis Handler Client Dependencies**

The Redis Handler uses the Jedis client to connect to Redis.

Group ID: redis.clients

# Snowflake

### Topics:

- Overview
- Detailed Functionality
- Configuration
- Troubleshooting and Diagnostics

# Overview

Snowflake is a serverless data warehouse that runs on any of the following cloud providers: Amazon Web Services (AWS), Google Cloud Platform (GCP), or Microsoft Azure.

The Snowflake Event Handler is used to replicate data into Snowflake.

# **Detailed Functionality**

Replication to Snowflake uses the stage and merge data flow.

- The change data from the Oracle GoldenGate trails is staged in micro-batches at a temporary staging location (internal or external stage).
- The staged records are then merged into the Snowflake target tables using a merge SQL statement.

This topic contains the following:

- Staging Location
- Database User Privileges
- Prerequisites

### Staging Location

The change data records from the Oracle GoldenGate trail files are formatted into Avro OCF (Object Container Format) and are then uploaded to the staging location.

Change data can be staged in one of the following object stores:

- Snowflake internal stage
- Snowflake external stage
  - AWS Simple Storage Service (S3)
  - Azure Data Lake Storage (ADLS) Gen2
  - Google Cloud Storage (GCS)

### Database User Privileges

The database user used for replicating into Snowflake has to be granted the following privileges:

- INSERT, UPDATE, DELETE, and TRUNCATE on the target tables.
- CREATE and DROP on Snowflake named stage and external stage.
- If using external stage (S3, ADLS, GCS), CREATE, ALTER, and DROP external table.

### Prerequisites

- Verify that the target tables exist on the Snowflake database.
- You must have Amazon Web Services, Google Cloud Platform, or Azure cloud accounts set up if you intend to use any of the external stage locations such as, S3, ADLS Gen2, or GCS.
- Snowflake JDBC driver

# Configuration

The configuration of the Snowflake replication properties is stored in the Replicat properties file.

### Note:

Ensure to specify the path to the properties file in the parameter file only when using Coordinated Replicat. Add the following line to the parameter file:

TARGETDB LIBFILE libggjava.so SET property=<parameter file directory>/<properties file name>

- Automatic Configuration
- Snowflake Storage Integration
- Classpath Configuration
- Proxy Configuration
- INSERTALLRECORDS Support
- Snowflake Key Pair Authentication
- Mapping Source JSON/XML to Snowflake VARIANT
- End-to-End Configuration

### Automatic Configuration

Snowflake replication involves configuring multiple components, such as the File Writer Handler, S3 or HDFS or GCS Event Handler, and the target Snowflake Event Handler.

The Automatic Configuration functionality helps you to auto-configure these components so that the manual configuration is minimal.

The properties modified by auto-configuration is also logged in the handler log file.

To enable auto-configuration to replicate to the Snowflake target, set the parameter gg.target=snowflake.

The Java system property SF\_STAGE determines the staging location. If SF\_STAGE is not set, then Snowflake internal stage is used.

If  $SF\_STAGE$  is set to either s3, hdfs, or gcs, then AWS S3, ADLS Gen2, or GCS are respectively used as the staging locations.

The JDBC Metadata provider is also automatically enabled to retrieve target table metadata from Snowflake.

- File Writer Handler Configuration
- S3 Handler Configuration
- HDFS Event Handler Configuration
- Google Cloud Storage Event Handler Configuration
- Snowflake Event Handler Configuration

#### File Writer Handler Configuration

The File Writer Handler name is pre-set to the value snowflake and its properties are automatically set to the required values for Snowflake.

You can add or edit a property of the File Writer Handler. For example:

gg.handler.snowflake.pathMappingTemplate=./dirout

#### S3 Handler Configuration

The S3 Event Handler name is pre-set to the value s3 and must be configured to match your S3 configuration.

#### The following is an example of editing a property of the S3 Event Handler:

gg.eventhandler.s3.bucketMappingTemplate=bucket1

For more information, see Amazon S3.

#### HDFS Event Handler Configuration

The Hadoop Distributed File System (HDFS) Event Handler name is pre-set to the value hdfs and it is auto-configured to write to HDFS.

Ensure that the Hadoop configuration file core-site.xml is configured to write data files to the respective container in the Azure Data Lake Storage (ADLS) Gen2 storage account. For more information, see Azure Data Lake Gen2 using Hadoop Client and ABFS.

The following is an example of editing a property of the HDFS Event handler:

gg.eventhandler.hdfs.finalizeAction=delete

#### Google Cloud Storage Event Handler Configuration

The Google Cloud Storage (GCS) Event Handler name is pre-set to the value gcs and must be configured to match your GCS configuration.

The following is an example of editing a GCS Event Handler property:

gg.eventhandler.gcs.bucketMappingTemplate=bucket1

#### Snowflake Event Handler Configuration

The Snowflake Event Handler name is pre-set to the value snowflake.

The following are configuration properties available for the Snowflake Event handler, the required ones must be changed to match your Snowflake configuration:

Table 8-36 Snowflake Event Handler Configuration

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.snowflake. connectionURL	Required	<pre>jdbc:snowflak e:// <account_name>.snowflakeco mputing.com/? warehouse=<wa rehouse="name">&amp;db=<dat abase-name=""></dat></wa></account_name></pre>	None	JDBC URL to connect to Snowflake. Snowflake account name, warehouse and database must be set in the JDBC URL.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.snowflake. connectionURL	Required	Supported connection URL.	None	JDBC URL to connect to Snowflake. Snowflake account name, warehouse and database must be set in the JDBC URL. The warehouse can be set using `warehouse= <war ehouse name&gt;`, database can set using `db=<db name&gt;`. In some cases for authorization, a role should be set using `role=<rolename>`.</rolename></db </war 
gg.eventhandl er.snowflake. UserName	Required	Supported database user name string.	None	Snowflake database user.
gg.eventhandl er.snowflake. Password	Required	Supported database password string.	None	Snowflake database password.
gg.eventhandl er.snowflake. storageIntegr ation	Optional	Storage integration name.	None	This parameter is required when using an external stage such as ADLS Gen2 or GCS or S3. This is the credential for Snowflake data warehouse to access the respective Object store files. For more information, see Snowflake Storage Integration.

Table 0.26	(Cont) Snowflake Event Handler Configuration
Table 8-36	(Cont.) Snowflake Event Handler Configuration

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.snowflake. maxConnection s	Optional	Integer Value	10	Use this parameter to control the number of concurrent JDBC database connections to the target Snowflake database.
gg.eventhandl er.snowflake. dropStagingTa blesOnShutdow n	Optional	true false	false	If set to true, the temporary staging tables created by Oracle GoldenGate are dropped on replicat graceful stop.

 Table 8-36
 (Cont.) Snowflake Event Handler Configuration

🖍 N

o t

е 2 U s е t h е f T u s h i n t е r v а L

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.aggregate. operations.fl ush.interval	Optional	Integer	30000	The flush interval parameter determines how often the data will be merged into Snowflake. The value is set in milliseconds. Use with caution, the higher this value is the more data will need to be stored in the memory of the Replicat process.

## Table 8-36 (Cont.) Snowflake Event Handler Configuration

p a r

a m e t

operties	Required/ Optional	Legal Values	Default	Explanation

Properties	Required/ Optional	Legal Values	Default	Explanation

roperties	Required/ Optional	Legal Values	Default	Explanation

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.snowflake. putSQLThreads	Optional	Integer Value	4	Specifies the number of threads ('PARALLEL' clause) to use for uploading files using PUT SQL. This is only relevant when Snowflake internal stage (named stage) is used.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.snowflake. putSQLAutoCom press	Optional	true   false	false	Specifies whether Snowflake uses gzip to compress files (AUTO_COMPRESS clause) during upload using PUT SQL. true: Files are compressed (if they are not
				already compressed).
				false: Files are not compressed (which means, the files are uploaded as is). This is only relevant when Snowflake internal stage (named stage) is used.
gg.eventhandl er.snowflake. useCopyForIni tialLoad	Optional	true   false	true	If set to true, COPY SQL statement will be used during initial load. If set to false, INSERT SQL statement will be used during initial load.
gg.operation. aggregator.va lidate.keyupd ate	Optional	true <b>or</b> false	false	If set to true, Operation Aggregator will validate key update operations (optype 115) and correct to normal update if no key values have changed. Compressed key update operations do not qualify for merge.

Table 8-36	(Cont.) Snowflake Event Handler Configuration
	(Cont.) Chownake Event nander Conngaration

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.eventhandl er.snowflake. useCopyForIni tialLoad	Optional	true <b>or</b> false	true	If set to true, then COPY SQL statement will be used during initial load. If set to false, then INSERT SQL statement will be used during initial load.

Table 8-36 (Cont.) Snowflake Event Handler Configuration

### Snowflake Storage Integration

When you use an external staging location, ensure to setup Snowflake storage integration to grant Snowflake database read permission to the files located in the cloud object store.

If the Java system property SF\_STAGE is not set, then the storage integration is not required, and Oracle GoldenGate defaults to internal stage.

 Azure Data Lake Storage (ADLS) Gen2 Storage Integration: For more information about creating the storage integration for Azure, see Snowflake documentation to create the storage integration for Azure.

#### Example:

```
-- AS ACCOUNTADMIN
create storage integration azure int
type = external stage
storage_provider = azure
enabled = true
azure tenant id = '<azure tenant id>'
storage allowed locations = ('azure://<azure-account-name>.blob.core.windows.net/
<azure-container>/');
desc storage integration azure int;
-- Read AZURE CONSENT URL and accept the terms and conditions specified in the
link.
-- Read AZURE MULTI TENANT APP NAME to get the Snowflake app name to be granted
Blob Read permission.
grant create stage on schema <schema name> to role <role name>;
grant usage on integration azure int to role <role name>;
Google Cloud Storage (GCS) Storage Integration: For more information about creating
the storage integration for GCS, see Snowflake Documentation.
```

```
Example:
```

```
create storage integration gcs_int
type = external_stage
storage_provider = gcs
enabled = true
storage_allowed_locations = ('gcs://<gcs-bucket-name>/');
```

```
desc storage integration gcs_int;
```

-- Read the column STORAGE\_GCP\_SERVICE\_ACCOUNT to get the GCP Service Account email for Snowflake.
-- Create a GCP role with storage read permission and assign the role to the Snowflake Service account.

grant create stage on schema <schema name> to role <role name>;
grant usage on integration gcs\_int to role <role name>;

 AWS S3 Storage Integration: For more information about creating the storage integration for S3, see Snowflake Documentation.

### Note:

When you use S3 as the external stage, you don't need to create storage integration if you already have access to the following AWS credentials: AWS Access Key Id and Secret key. You can set AWS credentials in the jvm.bootoptions property.

• The storage integration name must start with an alphabetic character and cannot contain spaces or special characters unless the entire identifier string is enclosed in double quotes for example, My object. Identifiers enclosed in double quotes are also case-sensitive.

### **Classpath Configuration**

Snowflake Event Handler uses the Snowflake JDBC driver. Ensure that the classpath includes the path to the JDBC driver. If an external stage is used, then you need to also include the respective object store Event Handler's dependencies in the classpath.

Dependencies

### Dependencies

Snowflake JDBC driver: You can use the Dependency Downloader tool to download the JDBC driver by running the following script: <OGGDIR>/DependencyDownloader/ snowflake.sh.

For more information about Dependency Downloader, see Dependency Downloader in the *Installing and Upgrading Oracle GoldenGate for Big Data* guide.

Alternatively, you can also download the JDBC driver from Maven central using the following co-ordinates:

```
<dependency>
   <groupId>net.snowflake</groupId>
   <artifactId>snowflake-jdbc</artifactId>
    <version>3.13.19</version>
</dependency>
```

- If staging location is set to S3, then the classpath should include the S3 Event handler dependencies. See S3 Handler Configuration.
- If staging location is set to HDFS, then the classpath should include the HDFS Event handler dependencies. See HDFS Event Handler Configuration.

 If staging location is set to Google Cloud Storage (GCS), then the classpath should include the GCS Event handler dependencies. See Google Cloud Storage Event Handler Configuration.

Edit the gg.classpath configuration parameter to include the path to the object store Event Handler dependencies (if external stage is in use) and the Snowflake JDBC driver.

### **Proxy Configuration**

When the Replicat process runs behind a proxy server, you can use the jvm.bootoptions property proxy server configuration.

### Example:

```
jvm.bootoptions=-Dhttp.useProxy=true -Dhttps.proxyHost=<some-proxy-address.com>
-Dhttps.proxyPort=80 -Dhttp.proxyHost=<some-proxy-address.com> -Dhttp.proxyPort=80
```

### INSERTALLRECORDS Support

Stage and merge targets supports INSERTALLRECORDS parameter.

See INSERTALLRECORDS in *Reference for Oracle GoldenGate*. Set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm). Set the INSERTALLRECORDS parameter in the Replicat parameter file (.prm)

Setting this property directs the Replicat process to use bulk insert operations to load operation data into the target table. You can tune the batch size of bulk inserts using the File Writer property gg.handler.snowflake.maxFileSize. The default value is set to 1GB. The frequency of bulk inserts can be tuned using the File writer property gg.handler.snowflake.fileRollInterval, the default value is set to 3m (three minutes).

### Note:

• When using the Snowflake internal stage, the staging files can be compressed by setting gg.eventhandler.snowflake.putSQLAutoCompress to true.

### Snowflake Key Pair Authentication

Snowflake supports key pair authentication as an alternative to basic authentication using username and password.

The path to the private key file must be set in the JDBC connection URL using the property: private\_key\_file.

If the private key file is encrypted, then the connection URL should also include the property: private\_key\_file\_pwd.

Additionally, the connection URL should also include the Snowflake user that is assigned the respective public key by setting the property user.

### Example JDBC connection URL:

```
jdbc:snowflake://<account_name>.snowflakecomputing.com/?warehouse=<warehouse-name>
&db=<database-name>&private_key_file=/path/to/private/key/rsa_key.p8
&private key file pwd=<private-key-password>&user=<db-user>
```

ORACLE

When using key pair authentication, ensure that the Snowflake event handler parameters Username and Password are not set.

### Note:

Oracle recommends you to upgrade Oracle GoldenGate for Big Data to version 21.10.0.0.0. In case you cannot upgrade to 21.10.0.0.0, then modify the JDBC URL to replace '\' characters with '/'.

### Mapping Source JSON/XML to Snowflake VARIANT

The JSON and XML source column types in the Oracle GoldenGate trail gets automatically detected and mapped into Snowflake VARIANT. You can inspect the metadata in the Oracle GoldenGate trail file for JSON and XML types using logdump.

Example: logdump output showing JSON and XML types:

```
022/01/06 01:38:54.717.464 Metadata

End of definition
```

In this example, COL and COL2 are JSON columns and COL3 is an XML column.

Additionally, mapping to Snowflake VARIANT is supported only if the source columns are stored as text.

## End-to-End Configuration

The following is an end-end configuration example which uses auto-configuration.

Location of the sample properties file: <OGGDIR>/AdapterExamples/big-data/snowflake/

- sf.props: Configuration using internal stage
- sf-s3.props: Configuration using S3 stage.
- sf-az.props: Configuration using ADLS Gen2 stage.
- sf-gcs.props: Configuration using GCS stage.

# Note: Recommended to only edit the configuration marked as TODO

gg.target=snowflake

```
#The Snowflake Event Handler

```

# Troubleshooting and Diagnostics

- Connectivity issues to Snowflake:
  - Validate JDBC connection URL, username, and password.
  - Check HTTP(S) proxy configuration if running Replicat process behind a proxy.
- **DDL not applied on the target table**: Oracle GoldenGate for Big Data does not support DDL replication.
- Target table existence: It is expected that the target table exists before starting the Replicat process.
   Replicat process will ABEND if the target table is missing.
- **SQL Errors**: In case there are any errors while executing any SQL, the SQL statements along with the bind parameter values are logged into the Oracle GoldenGate for Big Data handler log file.
- Co-existence of the components: When using an external stage location (S3, ADLS Gen 2 or GCS), the location/region of the machine where the Replicat process is running and the object store's region have an impact on the overall throughput of the apply process.
   For the best possible throughput, the components need to be located ideally in the same region or as close as possible.
- Replicat ABEND due to partial LOB records in the trail file: Oracle GoldenGate for Big Data does not support replication of partial LOB data. The trail file needs to

be regenerated by Oracle Integrated capture using TRANLOGOPTIONS FETCHPARTIALLOB option in the Extract parameter file.

• When replicating to more than ten target tables, the parameter maxConnnections can be increased to a higher value which can improve throughput.

### Note:

When tuning this, increasing the parameter value would create more JDBC connections on the Snowflake data warehouse.You can consult your Snowflake Database administrators so that the data warehouse health is not compromised.

The Snowflake JDBC driver uses the standard Java log utility. The log levels of the JDBC driver can be set using the JDBC connection parameter tracing. The tracing level can be set in the Snowflake Event handler property
 gg.eventhandler.snowflake.connectionURL.
 The following is an example of editing this property:

jdbc:snowflake://<account\_name>.snowflakecomputing.com/? warehouse=<warehouse-name>&db=<database-name>&tracing=SEVERE

For more information, see https://docs.snowflake.com/en/user-guide/jdbc-parameters.html#tracing.

- Exception: net.snowflake.client.jdbc.SnowflakeReauthenticationRequest: Authentication token has expired. The user must authenticate again. This error occurs when are extended periods of inactivity. To resolve this, you can set the JDBC parameter CLIENT\_SESSION\_KEEP\_ALIVE to force the database user to login after a period of inactivity in the session. For example, jdbc:snowflake:// <account\_name>.snowflakecomputing.com/?warehouse=<warehousename>&db=<database-name>&CLIENT\_SESSION\_KEEP\_ALIVE=true
- Replicat stops with an out of memory error: Decrease the gg.aggregate.operations.flush.interval value if you are not using its default value (30000).
- Performance issue while replicating Large Object (LOB) column values: LOB processing can lead to slowness. For every LOB column that exceeds the inline LOB threshold, an UPDATE SQL is executed. Look for the following message to tune throughput during LOB processing: The current operation at position [<segno>/<rba>] for table [<tablename>] contains a LOB column [<column name>] of length [<N>] bytes that exceeds the threshold of maximum inline LOB size [<N>]. Operation Aggregator will flush merged operations, which can degrade performance. The maximum inline LOB size in bytes can be tuned using the configuration gg.maxInlineLobSize. Check the trail files that contain LOB data and get a maximum size of BLOB/CLOB columns. Alternatively, check the source table definitions to determine the maximum size of LOB data. The default inline LOB size is set to 16000 bytes, which can be increased to a higher value so that all LOB column updates are processed in batches. The configuration property is gg.maxInlineLobSize`. For example: In gg.maxInlineLobSize=24000000 -->, all LOBs up to 24 MB are processed inline. You need to reposition the Replicat, purge the state files, data directory, and start over, so that bigger staging files are generated.

Error message: No database is set in the current session. Please set a database in the JDBC connection url
 [gg.eventhandler.snowflake.connectionURL] using the option 'db=<database
 name>'.`
 Resolution: Set the database name in the configuration property

gg.eventhandler.snowflake.connectionURL.

- Warning message: No role is set in the current session. Please set a custom role name in the JDBC connection url
   [gg.eventhandler.snowflake.connectionURL] using the option 'role=<role
   name>' if the warehouse [{}] requires a custom role to access it.
   Resolution: In some cases a custom role is required to access the Snowflake
   warehouse, set the role in the configuration property
   gg.eventhandler.snowflake.connectionURL.
- Error message: No active warehouse selected in the current session. Please set the warehouse name (and custom role name if required to access the respective warehouse) in the JDBC connection url [gg.eventhandler.snowflake.connectionURL] using the options 'warehouse=<warehouse name>' and 'role=<role name>'. Resolution: Set the warehouse and role in the configuration property gg.eventhandler.snowflake.connectionURL.

# Additional Details

Command Event Handler

This chapter describes how to use the Command Event Handler. The Command Event Handler provides the interface to synchronously execute an external program or script.

- HDFS Event Handler The HDFS Event Handler is used to load files generated by the File Writer Handler into HDFS.
- Metacolumn Keywords
- Metadata Providers

The Metadata Providers can replicate from a source to a target using a Replicat parameter file.

Pluggable Formatters

The pluggable formatters are used to convert operations from the Oracle GoldenGate trail file into formatted messages that you can send to Big Data targets using one of the Oracle GoldenGate for Big Data Handlers.

- Stage and Merge Data Warehouse Replication
   Data warehouse targets typically support Massively Parallel Processing (MPP).
   The cost of a single Data Manipulation Language (DML) operation is comparable to the cost of execution of batch DMLs.
- Template Keywords
- Velocity Dependencies Starting Oracle GoldenGate for Big Data release 21.1.0.0.0, the Velocity jar files have been removed from the packaging.

# **Command Event Handler**

This chapter describes how to use the Command Event Handler. The Command Event Handler provides the interface to synchronously execute an external program or script.

- Overview Command Event Handler The purpose of the Command Event Handler is to load data files generated by the File Writer Handler into respective targets by executing an external program or a script provided.
- Configuring the Command Event Handler You can configure the Command Event Handler operation using the File Writer Handler properties file.
- Using Command Argument Template Strings
   Command Argument Templated Strings consists of keywords that are dynamically resolved at runtime. Command Argument Templated strings are passed as arguments to the script in the same order mentioned in the commandArgumentTemplate property.

### **Overview - Command Event Handler**

The purpose of the Command Event Handler is to load data files generated by the File Writer Handler into respective targets by executing an external program or a script provided.

### Configuring the Command Event Handler

You can configure the Command Event Handler operation using the File Writer Handler properties file.

The Command Event Handler works only in conjunction with the File Writer Handler.

To enable the selection of the Command Event Handler, you must first configure the handler type by specifying gg.eventhandler.name.type=command and the other Command Event properties as follows:

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandler. name.type	Required	command	None	Selects the Command Event Handler for use with Replicat
gg.eventhandler. name.command	Required	Valid path of external program or a script to be executed.	None	The script or an external program that should be executed by the Command Event Handler.
gg.eventhandler. name.cmdWaitMill i	Optional	Integer value representi ng milli seconds	Indefin itely	The Command Event Handler will wait for a period of time for the called commands in the script or external program to complete. If the Command Event Handler fails to complete the command within the configured timout period of time, process will get Abend.

Table 8-37 Command Event Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandler. name.multithread ed	Optional	true  false	true	If true, the configured commands in the script or external program will be executed multithreaded way. Else executed in single thread.
gg.eventhandler. name.commandArgu mentTemplate	Optional	See Using Command Argument Templated Strings.	None	The Command Event Handler uses the command argument template strings during script or external program execution as input arguments. For a list of valid argument strings, see Using Command Argument Templated Strings.

#### Table 8-37 (Cont.) Command Event Handler Configuration Properties

#### Sample Configuration

gg.eventhandler.command.type=command

gg.eventhandler.command.command=<path of the script to be executed>

#gg.eventhandler.command.cmdWaitMilli=10000

gg.eventhandler.command.multithreaded=true

```
gg.eventhandler.command.commandArgumentTemplate=${tablename},$
{datafilename},${countoperations}
```

### Using Command Argument Template Strings

Command Argument Templated Strings consists of keywords that are dynamically resolved at runtime. Command Argument Templated strings are passed as arguments to the script in the same order mentioned in the commandArgumentTemplate property.

The valid tokens used as a command Argument Template strings are as follows: UUID, TableName, DataFileName, DataFileDir, DataFileDirandName, Offset, Format, CountOperations, CountInserts, CountUpdates, CountDeletes, CountTruncates. Invalid Templated string results in an Abend.

#### **Supported Template Strings**

#### \${uuid}

The File Writer Handler assigns a uuid to internally track the state of generated files. The usefulness of the uuid may be limited to troubleshooting scenarios.

#### \${tableName}

The individual source table name. For example, MYTABLE.

#### \${dataFileName}

The generated data file name.

### \${dataFileDirandName}

The source file name with complete path and filename along with the file extension.

### \${offset}

The offset (or size in bytes) of the data file.

### \${format}

The format of the file. For example: delimitedtext | json | json\_row | xml | avro\_row | avro\_op | avro\_row\_ocf | avro\_op\_ocf

### \${countOperations}

The total count of operations in the data file. It must be either renamed or used by the event handlers or it becomes zero (0) because nothing is written. For example, 1024.

### \${countInserts}

The total count of insert operations in the data file. It must be either renamed or used by the event handlers or it becomes zero (0) because nothing is written. For example, 125.

### \${countUpdates}

The total count of update operations in the data file. It must be either renamed or used by the event handlers or it becomes zero (0) because nothing is written. For example, 265.

### \${countDeletes}

The total count of delete operations in the data file. It must be either renamed or used by the event handlers or it becomes zero (0) because nothing is written. For example, 11.

### \${countTruncates}

The total count of truncate operations in the data file. It must be used either on rename or by the event handlers or it will be zero (0) because nothing is written yet. For example, 5.

### Note:

The Command Event Handler on successful execution of the script or the commnad logs a message with the following statement: The command completed successfully, along with the statement of command that gets executed. If there's an error when the command gets executed, the Command Event Handler abends the Replicat process and logs the error message.

## HDFS Event Handler

The HDFS Event Handler is used to load files generated by the File Writer Handler into HDFS.

This topic describes how to use the HDFS Event Handler. See Flat Files.

Detailing the Functionality

### Detailing the Functionality

- Configuring the Handler
- Configuring the HDFS Event Handler

### Configuring the Handler

The HDFS Event Handler can can upload data files to HDFS. These additional configuration steps are required:

The HDFS Event Handler dependencies and considerations are the same as the HDFS Handler, see HDFS Additional Considerations.

Ensure that gg.classpath includes the HDFS client libraries.

Ensure that the directory containing the HDFS core-site.xml file is in gg.classpath. This is so the core-site.xml file can be read at runtime and the connectivity information to HDFS can be resolved. For example:

gg.classpath=/{HDFSinstallDirectory}/etc/hadoop

If Kerberos authentication is enabled on the HDFS cluster, you have to configure the Kerberos principal and the location of the keytab file so that the password can be resolved at runtime:

gg.eventHandler.name.kerberosPrincipal=principal gg.eventHandler.name.kerberosKeytabFile=pathToTheKeytabFile

### Configuring the HDFS Event Handler

You configure the HDFS Handler operation using the properties file. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

To enable the selection of the HDFS Event Handler, you must first configure the handler type by specifying gg.eventhandler.name.type=hdfs and the other HDFS Event properties as follows:

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r.name.type	Required	hdfs	None	Selects the HDFS Event Handler for use.
gg.eventhandle r.name.pathMap pingTemplate	Required	A string with resolvable keywords and constants used to dynamicall y generate the path in HDFS to write data files.	None	Use keywords interlaced with constants to dynamically generate unique path names at runtime. Path names typically follow the format, /ogg/data/\${groupName}/\$ {fullyQualifiedTableName}. See Template Keywords.

Table 8-38 HDFS Event Handler Configuration Properties

Properties	Require d/ Optional	Legal Values	Defaul t	Explanation
gg.eventhandle r.name.fileNam eMappingTempla te	Optional	A string with resolvable keywords and constants used to dynamicall y generate the HDFS file name at runtime.	None	Use keywords interlaced with constants to dynamically generate unique file names at runtime. If not set, the upstream file name is used. See Template Keywords.
gg.eventhandle r.name.finaliz eAction	Optional	none   delete	none	Indicates what the File Writer Handler should do at the finalize action.
				Leave the data file in place (removing any active write suffix, see About the Active Write Suffix).
				delete Delete the data file (such as, if the data file has been converted to another format or loaded to a third party application).
gg.eventhandle r.name.kerbero sPrincipal	Optional	The Kerberos principal name.	None	Set to the Kerberos principal when HDFS Kerberos authentication is enabled.
gg.eventhandle r.name.keberos KeytabFile	Optional	The path to the Keberos keytab file.	None	Set to the path to the Kerberos keytab file when HDFS Kerberos authentication is enabled.
gg.eventhandle r.name.eventHa ndler	Optional	A unique string identifier cross referencin g a child event handler.	No event handler configu red.	

Table 8-38	(Cont.) HDFS Event Handler Configuration Properties
------------	---

# Metacolumn Keywords

This appendix describes the metacolumn keywords.

The metacolumns functionality allows you to select the metadata fields that you want to see in the generated output messages. The format of the metacolumn syntax is:

#### \${keyword[fieldName].argument}

The keyword is fixed based on the metacolumn syntax. Optionally, you can provide a field name between the square brackets. If a field name is not provided, then the default field name is used.

Keywords are separated by a comma. Following is an example configuration of metacolumns:

```
gg.handler.filewriter.format.metaColumnsTemplate=${objectname[table]},$
{optype[op_type]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]}
```

An argument may be required for a few metacolumn keywords. For example, it is required where specific token values are resolved or specific environmental variable values are resolved.

#### \${alltokens}

All of the tokens for an operation delivered as a map where the token keys are the keys in the map and the token values are the map values.

#### \${token}

The value of a specific Oracle GoldenGate token. The token key should follow token key should follow the token using the period (.) operator. For example:

\${token.MYTOKEN}

### \${sys}

A system environmental variable. The variable name should follow sys using the period (.) operator.

### \${sys.MYVAR}

An Oracle GoldenGate environment variable. The variable name should follow env using the period (.) operator.

### \${env}

An Oracle GoldenGate environment variable. The variable name should follow env using the period (.) operator. For example:

\${env.someVariable}

### \${javaprop}

A Java JVM variable. The variable name should follow javaprop using the period (.) operator. For example:

\${javaprop.MYVAR}

#### \${optype}

The operation type. This is generally  ${\tt I}$  for inserts,  ${\tt U}$  for updates,  ${\tt D}$  for deletes, and  ${\tt T}$  for truncates.

#### \${position}

The record position. This is location of the record in the source trail file. It is a 20 character string. The first 10 characters is the trail file sequence number. The last 10 characters is the offset or rba of the record in the trail file.

#### \${timestamp}

Record timestamp.

\${catalog} Catalog name.

\${schema} Schema name.

\${table} Table name.

\${objectname}
The fully qualified table name.

\${csn}
Source Commit Sequence Number.

\${xid}
Source transaction ID.

\${currenttimestamp}
Current timestamp.

\${currenttimestampiso8601}
Current timestamp in ISO 8601 format.

\${opseqno} Record sequence number within the transaction.

\${timestampmicro}
Record timestamp in microseconds after epoch.

### \${currenttimestampmicro}

Current timestamp in microseconds after epoch.

### \${txind}

The is the transactional indicator from the source trail file. The values of a transaction are B for the first operation, M for the middle operations, E for the last operation, or W for whole if there is only one operation. Filtering operations or the use of coordinated apply negate the usefulness of this field.

### \${primarykeycolumns}

Use to inject a field with a list of the primary key column names.

### \${static}

Use to inject a field with a static value into the output. The value desired should be the argument. If the desired value is abc, then the syntax is f(static.abc) or f(static[FieldName].abc].

### \${seqno}

Used to inject a field containing the sequence number of the source trail file for the given operation.

### \${rba}

Used to inject a field containing the rba (offset) of the operation in the source trail file for the given operation.

### \${metadatachanged}

A boolean field which gets set to true on the first operation following a metadata change for the source table definition.

#### \${groupname}

A string field which the value is the group name of the replicat process. Group name is effectively the replicat process name as it is referred to in ggsci or the Oracle GoldenGate Microservices UI.

### Metadata Providers

The Metadata Providers can replicate from a source to a target using a Replicat parameter file.

This chapter describes how to use the Metadata Providers.

- About the Metadata Providers
- Avro Metadata Provider

The Avro Metadata Provider is used to retrieve the table metadata from Avro Schema files. For every table mapped in Replicat using COLMAP, the metadata is retrieved from Avro Schema. Retrieved metadata is then used by Replicat for column mapping.

- Java Database Connectivity Metadata Provider
- Hive Metadata Provider

The Hive Metadata Provider is used to retrieve the table metadata from a Hive metastore. The metadata is retrieved from Hive for every target table that is mapped in the Replicat properties file using the COLMAP parameter. The retrieved target metadata is used by Replicat for the column mapping functionality.

 Google BigQuery Metadata Provider
 Google metadata provider uses the Google Query Job to retrieve the metadata schema information from the Google BigQuery Table. The Table should already be created on the target for BigQuery to fetch the metadata.

### About the Metadata Providers

Metadata Providers work only if handlers are configured to run with a Replicat process.

The Replicat process maps source table to target table and source column to target column mapping using syntax in the Replicat configuration file. The source metadata definitions are included in the Oracle GoldenGate trail file (or by source definitions files in Oracle GoldenGate releases 12.2 and later). When the replication target is a database, the Replicat process obtains the target metadata definitions from the target database. However, this is a shortcoming when pushing data to Big Data applications or during Java delivery in general. Typically, Big Data applications provide no target metadata, so Replicat mapping is not possible. The metadata providers exist to address this deficiency. You can use a metadata provider to define target metadata using either Avro or Hive, which enables Replicat mapping of source table to target table and source column to target column.

The use of the metadata provider is optional and is enabled if the gg.mdp.type property is specified in the Java Adapter Properties file. If the metadata included in the source Oracle GoldenGate trail file is acceptable for output, then do not use the metadata provider. Use a metadata provider should be used in the following cases:

- You need to map source table names into target table names that do not match.
- You need to map source column names into target column name that do not match.
- You need to include certain columns from the source trail file and omit other columns.

A limitation of Replicat mapping is that the mapping defined in the Replicat configuration file is static. Oracle GoldenGate provides functionality for DDL propagation when using an Oracle database as the source. The proper handling of schema evolution can be problematic when the Metadata Provider and Replicat mapping are used. Consider your use cases for schema evolution and plan for how you want to update the Metadata Provider and the Replicat mapping syntax for required changes.

For every table mapped in Replicat using COLMAP, the metadata is retrieved from a configured metadata provider and retrieved metadata then be used by Replicat for column mapping.

Only the Hive and Avro Metadata Providers are supported and you must choose one or the other to use in your metadata provider implementation.

#### Scenarios - When to use a metadata provider

1. The following scenarios do not require a metadata provider to be configured:

A mapping in which the source schema named GG is mapped to the target schema named GGADP.\*

A mapping in which the schema and table name whereby the schema GG.TCUSTMER is mapped to the table name GGADP.TCUSTMER NEW

```
MAP GG.*, TARGET GGADP.*;
(OR)
MAP GG.TCUSTMER, TARGET GG_ADP.TCUSTMER_NEW;
```

2. The following scenario requires a metadata provider to be configured:

A mapping in which the source column name does not match the target column name. For example, a source column of CUST\_CODE mapped to a target column of CUST\_CODE\_NEW.

```
MAP GG.TCUSTMER, TARGET GG_ADP.TCUSTMER_NEW, COLMAP(USEDEFAULTS,
CUST CODE NEW=CUST CODE, CTTY2=CITY);
```

### Avro Metadata Provider

The Avro Metadata Provider is used to retrieve the table metadata from Avro Schema files. For every table mapped in Replicat using COLMAP, the metadata is retrieved from Avro Schema. Retrieved metadata is then used by Replicat for column mapping.

- Detailed Functionality
- Runtime Prerequisites
- Classpath Configuration
- Avro Metadata Provider Configuration
- Review a Sample Configuration
- Metadata Change Events
- Limitations
- Troubleshooting

### **Detailed Functionality**

The Avro Metadata Provider uses Avro schema definition files to retrieve metadata. Avro schemas are defined using JSON. For each table mapped in the *process\_name*. prm file, you must create a corresponding Avro schema definition file.

### Avro Metadata Provider Schema Definition Syntax

```
{"namespace": "[$catalogname.]$schemaname",
"type": "record",
"name": "$tablename",
"fields": [
     {"name": "$col1", "type": "$datatype"},
     {"name": "$col2 ", "type": "$datatype ", "primary_key":true},
{"name": "$col3", "type": "$datatype ", "primary_key":true},
     {"name": "$col4", "type": ["$datatype", "null"]}
   1
}
                     - name of catalog/schema being mapped
namespace
                    - name of the table being mapped
name
fields.name
                    - array of column names
fields.type
                    - datatype of the column
fields.primary_key - indicates the column is part of primary key.
Representing nullable and not nullable columns:
"type":"$datatype" - indicates the column is not nullable, where "$datatype" is
the actual datatype.
"type": ["$datatype", "null"] - indicates the column is nullable, where
```

The names of schema files that are accessed by the Avro Metadata Provider must be in the following format:

[\$catalogname.]\$schemaname.\$tablename.mdp.avsc

\$catalogname - name of the catalog if exists \$schemaname - name of the schema \$tablename - name of the table .mdp.avsc - constant, which should be appended always

### Supported Avro Primitive Data Types

"\$datatype" is the actual datatype

- boolean
- bytes
- double
- float
- int
- long
- string

See https://avro.apache.org/docs/1.7.5/spec.html#schema\_primitive.

### Supported Avro Logical Data Types

- decimal
- timestamp

### Example Avro for decimal logical type

```
{"name":"DECIMALFIELD","type":
{"type":"bytes","logicalType":"decimal","precision":15,"scale":5}}
```

### Example of Timestamp logical type

```
{"name":"TIMESTAMPFIELD","type":
{"type":"long","logicalType":"timestamp-micros"}}
```

### **Runtime Prerequisites**

Before you start the Replicat process, create Avro schema definitions for all tables mapped in Replicat's parameter file.

### Classpath Configuration

The Avro Metadata Provider requires no additional classpath setting.

### Avro Metadata Provider Configuration

Property	Required/ Optional	Legal Values	Default	Explanation
gg.mdp.type	Required	avro	-	Selects the Avro Metadata Provider
gg.mdp.schema FilesPath	Required	<b>Example</b> :/home/ user/ggadp/ avroschema/	-	The path to the Avro schema files directory
gg.mdp.charse t	Optional	Valid character set	UTF-8	Specifies the character set of the column with character data type. Used to convert the source data from the trail file to the correct target character set.
gg.mdp.nation alCharset	Optional	Valid character set	UTF-8	Specifies the character set of the column with character data type. Used to convert the source data from the trail file to the correct target character set.
				Example: Used to indicate character set of columns, such as NCHAR, NVARCHAR in an Oracle database.

### **Review a Sample Configuration**

This is an example for configuring the Avro Metadata Provider. Consider a source that includes the following table:

```
TABLE GG.TCUSTMER {
    CUST_CODE VARCHAR(4) PRIMARY KEY,
    NAME VARCHAR(100),
    CITY VARCHAR(200),
    STATE VARCHAR(200)
}
```

This table maps the (CUST\_CODE (GG.TCUSTMER) in the source to CUST\_CODE2 (GG\_AVRO.TCUSTMER\_AVRO) on the target and the column CITY (GG.TCUSTMER) in source to CITY2 (GG\_AVRO.TCUSTMER\_AVRO) on the target. Therefore, the mapping in the *process name*. prm file is:

```
MAP GG.TCUSTMER, TARGET GG_AVRO.TCUSTMER_AVRO, COLMAP(USEDEFAULTS,
CUST CODE2=CUST CODE, CITY2=CITY);
```

In this example the mapping definition is as follows:

- Source schema GG is mapped to target schema GG\_AVRO.
- Source column CUST CODE is mapped to target column CUST CODE2.
- Source column CITY is mapped to target column CITY2.
- USEDEFAULTS specifies that rest of the columns names are same on both source and target (NAME and STATE columns).

This example uses the following Avro schema definition file:

File path: /home/ggadp/avromdpGG\_AVRO.TCUSTMER\_AVRO.mdp.avsc

```
{"namespace": "GG_AVRO",
"type": "record",
"name": "TCUSTMER_AVRO",
"fields": [
        {"name": "NAME", "type": "string"},
        {"name": "CUST_CODE2", "type": "string", "primary_key":true},
        {"name": "CITY2", "type": "string"},
        {"name": "STATE", "type": ["string", "null"]}
]
```

The configuration in the Java Adapter properties file includes the following:

```
gg.mdp.type = avro
gg.mdp.schemaFilesPath = /home/ggadp/avromdp
```

The following sample output uses a delimited text formatter with a semi-colon as the delimiter:

```
I;GG_AVRO.TCUSTMER_AVRO;2013-06-02 22:14:36.000000;NAME;BG SOFTWARE
CO;CUST CODE2;WILL;CITY2;SEATTLE;STATE;WA
```

Oracle GoldenGate for Big Data includes a sample Replicat configuration file, a sample Java Adapter properties file, and sample Avro schemas at the following location:

GoldenGate install directory/AdapterExamples/big-data/metadata provider/avro

### Metadata Change Events

If the DDL changes in the source database tables, you may need to modify the Avro schema definitions and the mappings in the Replicat configuration file. You may also want to stop or suspend the Replicat process in the case of a metadata change event. You can stop the Replicat process by adding the following line to the Replicat configuration file (process\_name. prm):

DDL INCLUDE ALL, EVENTACTIONS (ABORT)

Alternatively, you can suspend the Replicat process by adding the following line to the Replication configuration file:

DDL INCLUDE ALL, EVENTACTIONS (SUSPEND)

### Limitations

Avro bytes data type cannot be used as primary key.

The source-to-target mapping that is defined in the Replicat configuration file is static. Oracle GoldenGate 12.2 and later support DDL propagation and source schema evolution for Oracle Databases as replication source. If you use DDL propagation and source schema evolution, you lose the ability to seamlessly handle changes to the source metadata.

#### Troubleshooting

This topic contains the information about how to troubleshoot the following issues:

- Invalid Schema Files Location
- Invalid Schema File Name
- Invalid Namespace in Schema File
- Invalid Table Name in Schema File

#### Invalid Schema Files Location

The Avro schema files directory specified in the gg.mdp.schemaFilesPath configuration property must be a valid directory. If the path is not valid, you encounter following exception:

oracle.goldengate.util.ConfigException: Error initializing Avro metadata provider Specified schema location does not exist. {/path/to/schema/files/dir}

#### Invalid Schema File Name

For every table that is mapped in the *process\_name.prm* file, you must create a corresponding Avro schema file in the directory that is specified in gg.mdp.schemaFilesPath.

For example, consider the following scenario:

Mapping:

```
MAP GG.TCUSTMER, TARGET GG_AVRO.TCUSTMER_AVRO, COLMAP(USEDEFAULTS,
cust_code2=cust_code, CITY2 = CITY);
```

Property:

gg.mdp.schemaFilesPath=/home/usr/avro/

In this scenario, you must create a file called GG\_AVRO.TCUSTMER\_AVRO.mdp.avsc in the /home/usr/avro/ directory.

If you do not create the /home/usr/avro/GG\_AVRO.TCUSTMER\_AVRO.mdp.avsc file, you encounter the following exception:

java.io.FileNotFoundException: /home/usr/avro/GG AVRO.TCUSTMER AVRO.mdp.avsc

#### Invalid Namespace in Schema File

The target schema name specified in Replicat mapping must be same as the namespace in the Avro schema definition file.

For example, consider the following scenario:

#### Mapping:

```
MAP GG.TCUSTMER, TARGET GG_AVRO.TCUSTMER_AVRO, COLMAP(USEDEFAULTS, cust_code2 =
cust_code, CITY2 = CITY);
```

```
Avro Schema Definition:
{
    "namespace": "GG_AVRO",
    ..
}
```

In this scenario, Replicat abends with following exception:

```
Unable to retrieve table matadata. Table : GG_AVRO.TCUSTMER_AVRO
Mapped [catalogname.]schemaname (GG_AVRO) does not match with the schema
namespace {schema namespace}
```

#### Invalid Table Name in Schema File

The target table name that is specified in Replicat mapping must be same as the name in the Avro schema definition file.

For example, consider the following scenario:

Mapping:

```
MAP GG.TCUSTMER, TARGET GG_AVRO.TCUSTMER_AVRO, COLMAP(USEDEFAULTS, cust_code2 =
cust code, CITY2 = CITY);
```

#### Avro Schema Definition:

```
{
"namespace": "GG_AVRO",
"name": "TCUSTMER_AVRO",
...
}
```

In this scenario, if the target table name specified in Replicat mapping does not match with the Avro schema name, then REPLICAT abends with following exception:

```
Unable to retrieve table matadata. Table : GG_AVRO.TCUSTMER_AVRO
Mapped table name (TCUSTMER_AVRO) does not match with the schema table name
{table name}
```

### Java Database Connectivity Metadata Provider

The Java Database Connectivity (JDBC) Metadata Provider is used to retrieve the table metadata from any target database that supports a JDBC connection and has a database schema. The JDBC Metadata Provider is the preferred metadata provider for any target database that is an RDBMS, although various other non-RDBMS targets also provide a JDBC driver.

### **Topics:**

- JDBC Detailed Functionality
- Java Classpath
- JDBC Metadata Provider Configuration
- Review a Sample Configuration

### JDBC Detailed Functionality

The JDBC Metadata Provider uses the JDBC driver that is provided with your target database. The DBC driver retrieves the metadata for every target table that is mapped in the Replicat properties file. Replicat processes use the retrieved target metadata to map columns.

You can enable this feature for JDBC Handler by configuring the REPERROR property in your Replicat parameter file. In addition, you need to define the error codes specific to your RDBMS JDBC target in the JDBC Handler properties file as follows:

Property	Value	Required
gg.error.duplicateErrorCodes	Comma-separated integer values of error codes that indicate duplicate errors	No
gg.error.notFoundErrorCodes	Comma-separated integer values of error codes that indicate Not Found errors	No
gg.error.deadlockErrorCodes	Comma-separated integer values of error codes that indicate deadlock errors	No

### Table 8-39 JDBC REPERROR Codes

### For example:

```
#ErrorCode
gg.error.duplicateErrorCodes=1062,1088,1092,1291,1330,1331,1332,1333
gg.error.notFoundErrorCodes=0
gg.error.deadlockErrorCodes=1213
```

To understand how the various JDBC types are mapped to database-specific SQL types, see https://docs.oracle.com/javase/6/docs/technotes/guides/jdbc/getstart/mapping.html#table1.

### Java Classpath

The JDBC Java Driver location must be included in the class path of the handler using the  $\tt gg.classpath$  property.

For example, the configuration for a MySQL database might be:

gg.classpath= /path/to/jdbc/driver/jar/mysql-connector-java-5.1.39-bin.jar

### JDBC Metadata Provider Configuration

The following are the configurable values for the JDBC Metadata Provider. These properties are located in the Java Adapter properties file (not in the Replicat properties file).

Table 8-40 JDBC Metadata Provider Properties

Properties	Required / Optional	Legal Values	Default	Explanation
gg.mdp.type	Required	jdbc	None	Entering jdbc at a command prompt activates the use of the JDBC Metadata Provider.
gg.mdp.Conne ctionUrl	Required	jdbc:sub protocol :subname	None	The target database JDBC URL.
gg.mdp.Drive rClassName	Required	Java class name of the JDBC driver	None	The fully qualified Java class name of the JDBC driver.
gg.mdp.userN ame	Optional	A legal username string.	None	The user name for the JDBC connection. Alternatively, you can provide the user name using the ConnectionURL property.
gg.mdp.passw ord	Optional	A legal password string	None	The password for the JDBC connection. Alternatively, you can provide the password using the ConnectionURL property.

### Review a Sample Configuration

### **MySQL Driver Configuration**

```
gg.mdp.type=jdbc
gg.mdp.ConnectionUrl=jdbc:oracle:thin:@myhost:1521:orcl
gg.mdp.DriverClassName=oracle.jdbc.driver.OracleDriver
gg.mdp.UserName=username
gg.mdp.Password=password
```

#### **Netezza Driver Configuration**

```
gg.mdp.type=jdbc
gg.mdp.ConnectionUrl=jdbc:netezza://hostname:port/databaseName
gg.mdp.DriverClassName=org.netezza.Driver
```

gg.mdp.UserName=username gg.mdp.Password=password

### **Oracle OCI Driver configuration**

```
ggg.mdp.type=jdbc
gg.mdp.ConnectionUrl=jdbc:oracle:oci:@myhost:1521:orcl
gg.mdp.DriverClassName=oracle.jdbc.driver.OracleDriver
gg.mdp.UserName=username
gg.mdp.Password=password
```

### **Oracle Teradata Driver configuration**

```
gg.mdp.type=jdbc
gg.mdp.ConnectionUrl=jdbc:teradata://10.111.11.111/USER=username,PASSWORD=password
gg.mdp.DriverClassName=com.teradata.jdbc.TeraDriver
gg.mdp.UserName=username
gg.mdp.Password=password
```

#### **Oracle Thin Driver Configuration**

```
gg.mdp.type=jdbc
gg.mdp.ConnectionUrl=jdbc:mysql://localhost/databaseName?
user=username&password=password
gg.mdp.DriverClassName=com.mysql.jdbc.Driver
gg.mdp.UserName=username
gg.mdp.Password=password
```

#### **Redshift Driver Configuration**

```
gg.mdp.type=jdbc
gg.mdp.ConnectionUrl=jdbc:redshift://hostname:port/databaseName
gg.mdp.DriverClassName=com.amazon.redshift.jdbc42.Driver
gg.mdp.UserName=username
gg.mdp.Password=password
```

### Hive Metadata Provider

The Hive Metadata Provider is used to retrieve the table metadata from a Hive metastore. The metadata is retrieved from Hive for every target table that is mapped in the Replicat properties file using the COLMAP parameter. The retrieved target metadata is used by Replicat for the column mapping functionality.

- Detailed Functionality
- Configuring Hive with a Remote Metastore Database
- Classpath Configuration
- Hive Metadata Provider Configuration Properties
- Review a Sample Configuration
- Security
- Metadata Change Event
- Limitations
- Additional Considerations
- Troubleshooting

### **Detailed Functionality**

The Hive Metadata Provider uses both Hive JDBC and HCatalog interfaces to retrieve metadata from the Hive metastore. For each table mapped in the *process\_name.prm* file, a corresponding table is created in Hive.

The default Hive configuration starts an embedded, local metastore Derby database. Because, Apache Derby is designed to be an embedded database, it allows only a single connection. The limitation of the Derby Database means that it cannot function when working with the Hive Metadata Provider. To workaround this limitation this, you must configure Hive with a remote metastore database. For more information about how to configure Hive with a remote metastore database, see https://cwiki.apache.org/ confluence/display/Hive/AdminManual+Metastore+Administration.

Hive does not support Primary Key semantics, so the metadata retrieved from Hive metastore does not include a primary key definition. When you use the Hive Metadata Provider, use the Replicat KEYCOLS parameter to define primary keys.

### **KEYCOLS**

Use the KEYCOLS parameter must be used to define primary keys in the target schema. The Oracle GoldenGate HBase Handler requires primary keys. Therefore, you must set primary keys in the target schema when you use Replicat mapping with HBase as the target.

The output of the Avro formatters includes an Array field to hold the primary column names. If you use Replicat mapping with the Avro formatters, consider using KEYCOLS to identify the primary key columns.

For example configurations of KEYCOLS, see Review a Sample Configuration.

### **Supported Hive Data types**

- BIGINT
- BINARY
- BOOLEAN
- CHAR
- DATE
- DECIMAL
- DOUBLE
- FLOAT
- INT
- SMALLINT
- STRING
- TIMESTAMP
- TINYINT
- VARCHAR

See https://cwiki.apache.org/confluence/display/Hive/LanguageManual+Types.

### Configuring Hive with a Remote Metastore Database

You can find a list of supported databases that you can use to configure remote Hive metastore can be found at https://cwiki.apache.org/confluence/display/Hive/ AdminManual+MetastoreAdmin#AdminManualMetastoreAdmin-SupportedBackendDatabasesforMetastore.

The following example shows a MySQL database is configured as the Hive metastore using properties in the  $f(HIVE_HOME)/conf/hive-site.xml$  Hive configuration file.

### Note:

The ConnectionURL and driver class used in this example are specific to MySQL database. If you use a database other than MySQL, then change the values to fit your configuration.

```
<property>
         <name>javax.jdo.option.ConnectionURL</name>
         <value>jdbc:mysql://MYSQL DB IP:MYSQL DB PORT/DB NAME?
createDatabaseIfNotExist=false</value>
 </property>
 <property>
        <name>javax.jdo.option.ConnectionDriverName</name>
        <value>com.mysql.jdbc.Driver</value>
 </property>
 <property>
          <name>javax.jdo.option.ConnectionUserName</name>
     <value>MYSQL CONNECTION USERNAME</value>
 </property>
 <property>
         <name>javax.jdo.option.ConnectionPassword</name>
         <value>MYSQL CONNECTION PASSWORD</value>
 </property>
```

To see a list of parameters to configure in the hive-site.xml file for a remote metastore, see https://cwiki.apache.org/confluence/display/Hive/ AdminManual+MetastoreAdmin#AdminManualMetastoreAdmin-RemoteMetastoreDatabase.

### Classpath Configuration

For the Hive Metadata Provider to connect to Hive, you must configure thehivesite.xml file and the Hive and HDFS client jars in the gg.classpath variable. The client JARs must match the version of Hive to which the Hive Metadata Provider is connecting.

For example, if the hive-site.xml file is created in the /home/user/oggadp/dirprm directory, then gg.classpath entry is gg.classpath=/home/user/oggadp/dirprm/

1. Create a hive-site.xml file that has the following properties:

```
<configuration>
<!-- Mandatory Property -->
<property>
<name>hive.metastore.uris</name>
<value>thrift://HIVE SERVER HOST IP:9083</value>
<property>
<!-- Optional Property. Default value is 5 -->
<property>
<name>hive.metastore.connect.retries</name>
<value>3</value>
</property>
<!-- Optional Property. Default value is 1 -->
<property>
<name>hive.metastore.client.connect.retry.delay</name>
<value>10</value>
</property>
<!-- Optional Property. Default value is 600 seconds -->
<property>
<name>hive.metastore.client.socket.timeout</name>
<value>50</value>
</property>
```

</configuration>

2. By default, the following directories contain the Hive and HDFS client jars:

```
HIVE_HOME/hcatalog/share/hcatalog/*
HIVE_HOME/lib/*
```

HIVE\_HOME/hcatalog/share/webhcat/java-client/\*
HADOOP\_HOME/share/hadoop/common/\*
HADOOP\_HOME/share/hadoop/common/lib/\*
HADOOP\_HOME/share/hadoop/mapreduce/\*

Configure the gg.classpath exactly as shown in the step 1. The path to the hivesite.xml file must be the path with no wildcard appended. If you include the \* wildcard in the path to the hive-site.xml file, it will not be located. The path to the dependency JARs must include the \* wildcard character to include all of the JAR files in that directory in the associated classpath. Do *not* use \*.jar.

### Hive Metadata Provider Configuration Properties

Property	Required/ Optional	Legal Values	Default	Explanation
gg.mdp.type	Required	hive	-	Selects the Hive Metadata Provider
gg.mdp.connec tionUrl	Required	Format without Kerberos Authentication: jdbc:hive2:// HIVE_SERVER_IP:HIVE_JDBC_ PORT/HIVE_DB Format with Kerberos Authentication: jdbc:hive2:// HIVE_SERVER_IP:HIVE_JDBC_ PORT/HIVE_DB; principal=user/ FQDN@MY.REALM	-	The JDBC connection URL of the Hive server
gg.mdp.driver ClassName	Required	org.apache.hive.jdbc.Hive Driver	-	The fully qualified Hive JDBC driver class name
gg.mdp.userNa me	Optional	Valid username	11 11	The user name for connecting to the Hive database. The userName property is not required when Kerberos authentication is used. The Kerberos principal should be specified in the connection URL as specified in connectionUrl property's legal values.
gg.mdp.passwo rd	Optional	Valid Password	""	The password for connecting to the Hive database
gg.mdp.charse t	Optional	Valid character set	UTF-8	The character set of the column with the character data type. Used to convert the source data from the trail file to the correct target character set.

Property	Required/ Optional	Legal Values	Default	Explanation
gg.mdp.nation alCharset	Optional	Valid character set	UTF-8	The character set of the column with the national character data type. Used to convert the source data from the trail file to the correct target character set.
				For example, this property may indicate the character set of columns, such as NCHAR and NVARCHAR in an Oracle database.
gg.mdp.authTy pe	Optional	Kerberos	none	Allows you to designate Kerberos authentication to Hive.
gg.mdp.kerber osKeytabFile	Optional (Required if authType= kerberos)	Relative or absolute path to a Kerberos keytab file.	_	The keytab file allows Hive to access a password to perform the kinit operation for Kerberos security.
gg.mdp.kerber osPrincipal	Optional (Required if authType= kerberos)	A legal Kerberos principal name(user/FQDN@MY.REALM)	_	The Kerberos principal name for Kerberos authentication.

### **Review a Sample Configuration**

This is an example for configuring the Hive Metadata Provider. Consider a source with following table:

```
TABLE GG.TCUSTMER {
	CUST_CODE VARCHAR(4) PRIMARY KEY,
	NAME VARCHAR(100),
	CITY VARCHAR(200),
	STATE VARCHAR(200)}
```

The example maps the column CUST\_CODE (GG.TCUSTMER) in the source to CUST\_CODE2 (GG\_HIVE.TCUSTMER\_HIVE) on the target and column CITY (GG.TCUSTMER) in the source to CITY2 (GG HIVE.TCUSTMER HIVE) on the target.

Mapping configuration in the *process\_name*. prm file includes the following configuration:

```
MAP GG.TCUSTMER, TARGET GG_HIVE.TCUSTMER_HIVE, COLMAP(USEDEFAULTS,
CUST_CODE2=CUST_CODE, CITY2=CITY) KEYCOLS(CUST_CODE2);
```

#### In this example:

- The source schema GG is mapped to the target schema GG HIVE.
- The source column CUST CODE is mapped to the target column CUST CODE2.
- The source column CITY is mapped to the target column CITY2.

- USEDEFAULTS specifies that rest of the column names are same on both source and target (NAME and STATE columns).
- KEYCOLS is used to specify that CUST CODE2 should be treated as primary key.

Because primary keys cannot be specified in the Hive DDL, the KEYCOLS parameter is used to specify the primary keys.

### Note:

You can choose any schema name and are not restricted to the gg\_hive schema name. The Hive schema can be pre-existing or newly created. You do this by modifying the connection URL (gg.mdp.connectionUrl) in the Java Adapter properties file and the mapping configuration in the Replicat.prm file. Once the schema name is changed, update the connection URL (gg.mdp.connectionUrl) and mapping in the Replicat.prm file.

You can create the schema and tables for this example in Hive by using the following commands. You can create the schema and tables for this example in Hive by using the following commands. To start the Hive CLI use the following command:

```
HIVE HOME/bin/hive
```

To create the GG HIVE schema, in Hive, use the following command:

hive> create schema gg\_hive; OK Time taken: 0.02 seconds

To create the TCUSTMER HIVE table in the GG HIVE database, use the following command:

Configure the .properties file in a way that resembles the following:

```
gg.mdp.type=hive
gg.mdp.connectionUrl=jdbc:hive2://HIVE_SERVER_IP:10000/gg_hive
gg.mdp.driverClassName=org.apache.hive.jdbc.HiveDriver
```

The following sample output uses the delimited text formatter, with a comma as the delimiter:

```
I;GG_HIVE.TCUSTMER_HIVE;2015-10-07T04:50:47.519000;cust_code2;WILL;name;BG SOFTWARE
C0;city2;SEATTLE;state;WA
```

A sample Replicat configuration file, Java Adapter properties file, and Hive create table SQL script are included with the installation at the following location:

GoldenGate install directory/AdapterExamples/big-data/metadata provider/hive

### Security

You can secure the Hive server using Kerberos authentication. For information about how to secure the Hive server, see the Hive documentation for the specific Hive release. The Hive Metadata Provider can connect to a Kerberos secured Hive server.

Make sure that the paths to the HDFS core-site.xml file and the hive-site.xml file are in the handler's classpath.

Enable the following properties in the core-site.xml file:

```
<property>
<name>hadoop.security.authentication</name>
<value>kerberos</value>
</property>
<property>
```

```
<name>hadoop.security.authorization</name>
<value>true</value>
</property>
```

Enable the following properties in the hive-site.xml file:

```
<property>
<name>hive.metastore.sasl.enabled</name>
<value>true</value>
</property>
<property>
<name>hive.metastore.kerberos.keytab.file</name>
<value>/path/to/keytab</value> <!-- Change this value -->
</property>
<property>
<name>hive.metastore.kerberos.principal</name>
<value>Kerberos Principal</value> <!-- Change this value -->
</property>
<property>
   <name>hive.server2.authentication</name>
    <value>KERBEROS</value>
</property>
<property>
   <name>hive.server2.authentication.kerberos.principal</name>
    <value>Kerberos Principal</value> <!-- Change this value -->
</property>
<property>
    <name>hive.server2.authentication.kerberos.keytab</name>
    <value>/path/to/keytab</value> <!-- Change this value -->
</property>
```

### Metadata Change Event

Tables in Hive metastore should be updated, altered, or created manually if the source database tables change. In the case of a metadata change event, you may wish to terminate or suspend the Replicat process. You can terminate the Replicat process by adding the following to the Replicat configuration file (*process\_name.prm*):

DDL INCLUDE ALL, EVENTACTIONS (ABORT)

You can suspend, the Replicat process by adding the following to the Replication configuration file:

DDL INCLUDE ALL, EVENTACTIONS (SUSPEND)

### Limitations

Columns with binary data type cannot be used as primary keys.

The source-to-target mapping that is defined in the Replicat configuration file is static. Oracle GoldenGate 12.2 and later versions supports DDL propagation and source schema evolution for Oracle databases as replication sources. If you use DDL propagation and source schema evolution, you lose the ability to seamlessly handle changes to the source metadata.

### Additional Considerations

The most common problems encountered are the Java classpath issues. The Hive Metadata Provider requires certain Hive and HDFS client libraries to be resolved in its classpath.

The required client JAR directories are listed in Classpath Configuration. Hive and HDFS client JARs do not ship with Oracle GoldenGate for Big Data. The client JARs should be of the same version as the Hive version to which the Hive Metadata Provider is connecting.

To establish a connection to the Hive server, the hive-site.xml file must be in the classpath.

### Troubleshooting

If the mapped target table is not present in Hive, the Replicat process will terminate with a "Table metadata resolution exception".

For example, consider the following mapping:

```
MAP GG.TCUSTMER, TARGET GG_HIVE.TCUSTMER_HIVE, COLMAP(USEDEFAULTS,
CUST CODE2=CUST CODE, CITY2=CITY) KEYCOLS(CUST CODE2);
```

This mapping requires a table called TCUSTMER\_HIVE to be created in the schema GG\_HIVE in the Hive metastore. If this table is not present in Hive, then the following exception occurs:

```
ERROR [main) - Table Metadata Resolution Exception
Unable to retrieve table matadata. Table : GG_HIVE.TCUSTMER_HIVE
NoSuchObjectException(message:GG_HIVE.TCUSTMER_HIVE table not found)
```

### Google BigQuery Metadata Provider

Google metadata provider uses the Google Query Job to retrieve the metadata schema information from the Google BigQuery Table. The Table should already be created on the target for BigQuery to fetch the metadata.

Google BigQuery does not support primary key semantics, so the metadata retrieved from BigQuery Table does not include any primary key definition. You can identify the primary keys using the KEYCOLS syntax in the replicat mapping statement. If KEYCOLS is not present, then the key information from the source table is used.

- Authentication
- Supported BigQuery Datatypes

### Parameterized BigQuery Datatypes

The BigQuery datatypes that can be parameterized to add constraints are STRING, BYTES, NUMERIC, and BIGNUMERIC. The STRING and BYTES datatypes can have length constraints.NUMERIC and BIGNUMERIC can have scale and precision constraints.

- Unsupported BigQuery Datatypes
- Configuring BigQuery Metadata Provider
- Sample Configuration
- Proxy Settings
- Classpath Settings
- Limitations

### Authentication

Google BigQuery cloud service account can be connected either using the credentials JSON file by setting the path to the file in MDP property or setting the individual keys of credentials JSON into BigQuery MDP properties. The individual properties of BigQuery metadata provider for configuring the service account credential keys can be encrypted using Oracle wallet.

### Supported BigQuery Datatypes

The following table lists the Google BigQuery datatypes that are supported and their default scale and precision values:

Data Type	Range	Max Scale	Max Preci sion	Max Bytes
BOOL	TRUE  FALSE NIL	NA	NA	1
INT64	[-2^64] to [+ 2^64 -1]	NA	NA	8
FLOAT64	NA	NA	None	8
NUMERIC	Min: 9.99999999 9999999999 99999999999 999999	9	38	64
	<b>Max:</b> 9.99999999 9999999999 9999999999 999999			

Data Type	Range	Max Scale	Max Preci sion	Max Bytes
BIG NUMERIC	Min: 5.78960446 1865809771 1785492504 3439539266	38	77	255
	3499233282 0282019728 7920039565 64819968E+ 38			
	Max: 5.78960446 1865809771 1785492504 3439539266			
	3499233282 0282019728 7920039565 64819967E+ 38			
STRING	Unlimited	NA	NA	2147483647L
BYTES	Unlimited	NA	NA	2147483647L
DATE	0001-01-01 to 9999-12-31	NA	NA	ΝΑ
TIME	00:00:00 to 23:59:59.9 99999	NA	NA	NA
TIMESTAMP	0001-01-01 00:00:00 to 9999-12-31 23:59:59.9 99999 UTC	NA	NA	NA

### Parameterized BigQuery Datatypes

The BigQuery datatypes that can be parameterized to add constraints are STRING, BYTES, NUMERIC, and BIGNUMERIC. The STRING and BYTES datatypes can have length constraints.NUMERIC and BIGNUMERIC can have scale and precision constraints.

- **1.** STRING(L): L is the maximum number of Unicode characters allowed.
- 2. BYTES(L): L is the maximum number of bytes allowed.
- **3.** NUMERIC(P[, S]) or BIGNUMERIC(P[, S]): P is maximum precision (total number of digits) and S is maximum scale (number of digits after decimal) that is allowed.

The parameterized datatypes are supported in BigQuery Metadata Provider. If there is a datatype with user-defined precision, scale or max-length, then metadata provider calculates the data based on those values.

## Unsupported BigQuery Datatypes

The following table lists the Google BigQuery datatypes that are supported and their default scale and precision values:

The BigQuery datatypes that are not supported by metadata provider are complex datatypes, such as GEOGRAPHY, JSON, ARRAY, INTERVAL, and STRUCT. The metadata provider is going to abend with invalid datatype exception if it encounters them.

# Configuring BigQuery Metadata Provider

The following table lists the configuration properties for BigQuery metadata provider:

Property	Required/ Optional	Legal Value s	Defau It	Explanationtes
gg.mdp.type	Required	bq	NA	Select BigQuery Metadata Provider
gg.mdp.credent ialsFile	Optional	File path to creden tials JSON file.	NA	Provides path to the credentials JSON file for connecting to Google BigQuery Service account.
gg.mdp.clientI d	Optional	Valid BigQu ery Crede ntials Client Id	NA	Provides the client Id key from the credentials file for connecting to Google BigQuery service account.
gg.mdp.clientE mail	Optional	Valid BigQu ery Crede ntials Client Email	NA	Provides the client Email key from the credentials file for connecting to Google BigQuery service account.
gg.mdp.private KeyId	Optional	Valid BigQu ery Crede ntials Privat e Key ID	NA	Provides the Private Key ID from the credentials file for connecting to Google BigQuery service account.
gg.mdp.private Key	Optional	Valid BigQu ery Crede ntials Privat e Key	NA	Provides the Private Key from the credentials file for connecting to Google BigQuery service account.

Property	Required/ Optional	Legal Value s	Defau It	Explanationtes
gg.mdp.project Id	Optional	Uniqu e BigQu ery project Id	NA	Unique project Id of BigQuery.
gg.mdp.connect ionTimeout	Optional	Time in sec	5	Connect Timeout for BigQuery connection.
gg.mdp.readTim eout	Optional	Time in sec	6	Timeout to read from BigQuery connection.
gg.mdp.totalTi meout	Optional	Time in sec	9	Total timeout for BigQuery connection.
gg.mdp.retryCo unt	Optional	Maxim um numbe r of retries.	-	Maximum number of reties for connecting to BigQuery.

Either of the property to set the path to credentials JSON file or the properties to set the credential file keys are mandatory for connecting to Google Service account for accessing the BigQuery. Setting the individual credentials parameter enables them to be encrypted using Oracle wallet.

## Sample Configuration

Sample properties file content:

The following are sample properties that are added to BigQuery Handler properties file or BigQuery Event Handler properties file along with their own properties in order to configure the metadata provider.

```
gg.mdp.type=bq
gg.mdp.credentialsFile=/path/to/credFile.json
```

#### Sample parameter file:

There is no change in parameter file for configuring metadata provider. This sample parameter file is similar to the BigQuery Event Handler parameter file.

```
REPLICAT bqeh
TARGETDB LIBFILE libggjava.so SET property=dirprm/bqeh.props
MAP schema.tableName, TARGET schema.tableName;
```

## **Proxy Settings**

The proxy settings can be added as java virtual machine (JVM) arguments when we are trying to access the BigQuery server from behind a proxy. For example, for oracle proxy server connection cab be added in properties file as follows:

```
jvm.bootoptions= -Dhttps.proxyHost=www-proxy.us.oracle.com -
Dhttps.proxyPort=80
```

## **Classpath Settings**

The dependency of BigQuery metadata provider is same as the Google BigQuery stage-and-merge Event Handler dependency. The dependencies added to the Oracle GoldenGate class-path for BigQuery event Handler is sufficient for running the BigQuery metadata provider, and no extra dependency need to be configured.

## Limitations

The complex BigQuery datatypes are not yet supported by the metadata provider. It will abend in case any of unsupported datatypes are encountered.

If the BigQuery handler or event-handler is configured to auto create table and dataspace, then the metadata provider expects table to exist in order to fetch the metadata. The feature to auto-create table and dataspace of BigQuery handler and event handler does not work with BigQuery metadata provider. Metadata change event is not supported by Big Query metadata provider. It can be configured to abend or suspend in case there is a metadata change.

# Pluggable Formatters

The pluggable formatters are used to convert operations from the Oracle GoldenGate trail file into formatted messages that you can send to Big Data targets using one of the Oracle GoldenGate for Big Data Handlers.

This chapter describes how to use the pluggable formatters.

- Using Operation-Based versus Row-Based Formatting The Oracle GoldenGate for Big Data formatters include operation-based and rowbased formatters.
- Using the Avro Formatter

Apache Avro is an open source data serialization and deserialization framework known for its flexibility, compactness of serialized data, and good serialization and deserialization performance. Apache Avro is commonly used in Big Data applications.

- Using the Delimited Text Formatter
- Using the JSON Formatter
- Using the Length Delimited Value Formatter
   The Length Delimited Value (LDV) Formatter is a row-based formatter. It formats database operations from the source trail file into a length delimited value output.
   Each insert, update, delete, or truncate operation from the source trail is formatted into an individual length delimited message.

### • Using the XML Formatter

The XML Formatter formats before-image and after-image data from the source trail file into an XML document representation of the operation data. The format of the XML document is effectively the same as the XML format in the previous releases of the Oracle GoldenGate Java Adapter.

# Using Operation-Based versus Row-Based Formatting

The Oracle GoldenGate for Big Data formatters include operation-based and row-based formatters.

The operation-based formatters represent the individual insert, update, and delete events that occur on table data in the source database. Insert operations only provide after-change data (or images), because a new row is being added to the source database. Update operations provide both before-change and after-change data that shows how existing row data is modified. Delete operations only provide before-change data to identify the row being deleted. The operation-based formatters model the operation as it is exists in the source trail file. Operation-based formats include fields for the before-change and after-change images.

The row-based formatters model the row data as it exists after the operation data is applied. Row-based formatters contain only a single image of the data. The following sections describe what data is displayed for both the operation-based and the row-based formatters.

- Operation Formatters
- Row Formatters
- Table Row or Column Value States

## **Operation Formatters**

The formatters that support operation-based formatting are JSON, Avro Operation, and XML. The output of operation-based formatters are as follows:

- Insert operation: Before-image data is null. After image data is output.
- Update operation: Both before-image and after-image data is output.
- Delete operation: Before-image data is output. After-image data is null.
- Truncate operation: Both before-image and after-image data is null.

### **Row Formatters**

The formatters that support row-based formatting are Delimited Text and Avro Row. Rowbased formatters output the following information for the following operations:

- Insert operation: After-image data only.
- Update operation: After-image data only. Primary key updates are a special case which will be discussed in individual sections for the specific formatters.
- Delete operation: Before-image data only.
- Truncate operation: The table name is provided, but both before-image and after-image data are null. Truncate table is a DDL operation, and it may not support different database implementations. Refer to the *Oracle GoldenGate* documentation for your database implementation.

## Table Row or Column Value States

In an RDBMS, table data for a specific row and column can only have one of two states: either the data has a value, or it is null. However; when data is transferred to the Oracle GoldenGate trail file by the Oracle GoldenGate capture process, the data can have three possible states: it can have a value, it can be null, or it can be missing.

For an insert operation, the after-image contains data for all column values regardless of whether the data is null.. However, the data included for update and delete operations may not always contain complete data for all columns. When replicating data to an RDBMS for an update operation only the primary key values and the values of the columns that changed are required to modify the data in the target database. In addition, only the primary key values are required to delete the row from the target database. Therefore, even though values are present in the source database, the values may be missing in the source trail file. Because data in the source trail file may have three states, the Plugable Formatters must also be able to represent data in all three states.

Because the row and column data in the Oracle GoldenGate trail file has an important effect on a Big Data integration, it is important to understand the data that is required. Typically, you can control the data that is included for operations in the Oracle GoldenGate trail file. In an Oracle database, this data is controlled by the supplemental logging level. To understand how to control the row and column values that are included in the Oracle GoldenGate trail file, see the *Oracle GoldenGate* documentation for your source database implementation.

# Using the Avro Formatter

Apache Avro is an open source data serialization and deserialization framework known for its flexibility, compactness of serialized data, and good serialization and deserialization performance. Apache Avro is commonly used in Big Data applications.

- Avro Row Formatter
- The Avro Operation Formatter
- Avro Object Container File Formatter

## Avro Row Formatter

The Avro Row Formatter formats operation data from the source trail file into messages in an Avro binary array format. Each individual insert, update, delete, and truncate operation is formatted into an individual Avro message. The source trail file contains the before and after images of the operation data. The Avro Row Formatter takes the before-image and after-image data and formats it into an Avro binary representation of the operation data.

The Avro Row Formatter formats operations from the source trail file into a format that represents the row data. This format is more compact than the output from the Avro Operation Formatter for the Avro messages model the change data operation.

The Avro Row Formatter may be a good choice when streaming Avro data to HDFS. Hive supports data files in HDFS in an Avro format.

This section contains the following topics:

### Operation Metadata Formatting Details

The automated output of meta-column fields in generated Avro messages has been removed as of Oracle GoldenGate for Big Data release 21.1. Meta-column fields can still be output; however, they need to explicitly configured as the following property: gg.handler.name.format.metaColumnsTemplate.

- Operation Data Formatting Details
- Sample Avro Row Messages
- Avro Schemas
- Avro Row Configuration Properties
- Review a Sample Configuration
- Metadata Change Events
- Special Considerations

#### **Operation Metadata Formatting Details**

The automated output of meta-column fields in generated Avro messages has been removed as of Oracle GoldenGate for Big Data release 21.1. Meta-column fields can still be output; however, they need to explicitly configured as the following property: gg.handler.name.format.metaColumnsTemplate.

To output the metacolumns configure the following:

```
gg.handler.name.format.metaColumnsTemplate=${objectname[table]},$
{optype[op_type]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]}
```

To also include the primary key columns and the tokens configure as follows:

```
gg.handler.name.format.metaColumnsTemplate=${objectname[table]},$
{optype[op_type]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]},${primarykeycolumns[primary keys]},${alltokens[tokens]}
```

```
For more information see the configuration property:
```

gg.handler.name.format.metaColumnsTemplate.

Table 0-41 Avio I officiation	Table 8-41	Avro	Formatter	Metadata
-------------------------------	------------	------	-----------	----------

Value	Description
table	The fully qualified table in the format is: CATALOG_NAME.SCHEMA_NAME.TABLE_NAME
op_type	The type of database operation from the source trail file. Default values are ${\mathbb I}$ for insert, ${\mathbb U}$ for update, ${\mathbb D}$ for delete, and ${\mathbb T}$ for truncate.
op_ts	The timestamp of the operation from the source trail file. Since this timestamp is from the source trail, it is fixed. Replaying the trail file results in the same timestamp for the same operation.
current_ts	The time when the formatter processed the current operation record. This timestamp follows the ISO-8601 format and includes microsecond precision. Replaying the trail file will <i>not</i> result in the same timestamp for the same operation.

Value	Description
pos	The concatenated sequence number and the RBA number from the source trail file. This trail position lets you trace the operation back to the source trail file. The sequence number is the source trail file number. The RBA number is the offset in the trail file.
primary_keys	An array variable that holds the column names of the primary keys of the source table.
tokens	A map variable that holds the token key value pairs from the source trail file.

### **Operation Data Formatting Details**

The operation data follows the operation metadata. This data is represented as individual fields identified by the column names.

Column values for an operation from the source trail file can have one of three states: the column has a value, the column value is null, or the column value is missing. Avro attributes only support two states, the column has a value or the column value is null. Missing column values are handled the same as null values. Oracle recommends that when you use the Avro Row Formatter, you configure the Oracle GoldenGate capture process to provide full image data for all columns in the source trail file.

By default, the setting of the Avro Row Formatter maps the data types from the source trail file to the associated Avro data type. Because Avro provides limited support for data types, source columns map into Avro long, double, float, binary, or string data types. You can also configure data type mapping to handle all data as strings.

#### Sample Avro Row Messages

Because Avro messages are binary, they are not human readable. The following sample messages show the JSON representation of the messages.

- Sample Insert Message
- Sample Update Message
- Sample Delete Message
- Sample Truncate Message

#### Sample Insert Message

```
{"table": "GG.TCUSTORD",
"op_type": "I",
"op_ts": "2013-06-02 22:14:36.000000",
"current_ts": "2015-09-18T10:13:11.172000",
"pos": "000000000000001444",
"primary_keys": ["CUST_CODE", "ORDER_DATE", "PRODUCT_CODE", "ORDER_ID"],
"tokens": {"R": "AADPkvAAEAAEqL2AAA"},
"CUST_CODE": "WILL",
"ORDER_DATE": "1994-09-30:15:33:00",
"PRODUCT_CODE": "CAR",
"ORDER_ID": "144",
"PRODUCT_PRICE": 17520.0,
"PRODUCT_AMOUNT": 3.0,
"TRANSACTION ID": "100"}
```

### Sample Update Message

```
{"table": "GG.TCUSTORD",
"op_type": "U",
"op_ts": "2013-06-02 22:14:41.000000",
"current_ts": "2015-09-18T10:13:11.492000",
"pos": "00000000000002891",
"primary_keys": ["CUST_CODE", "ORDER_DATE", "PRODUCT_CODE", "ORDER_ID"], "tokens":
    {"R": "AADPkvAAEAAEqLZAAA"},
"CUST_CODE": "BILL",
"ORDER_DATE": "1995-12-31:15:00:00",
"PRODUCT_CODE": "CAR",
"ORDER_ID": "765",
"PRODUCT_PRICE": 14000.0,
"PRODUCT_AMOUNT": 3.0,
"TRANSACTION ID": "100"}
```

#### Sample Delete Message

```
{"table": "GG.TCUSTORD",
"op_type": "D",
"op_ts": "2013-06-02 22:14:41.000000",
"current_ts": "2015-09-18T10:13:11.512000",
"pos": "000000000000004338",
"primary_keys": ["CUST_CODE", "ORDER_DATE", "PRODUCT_CODE", "ORDER_ID"], "tokens":
{"L": "206080450", "6": "9.0.80330", "R": "AADPkvAAEAAEqLZAAC"}, "CUST_CODE":
"DAVE",
"ORDER_DATE": "1993-11-03:07:51:35",
"PRODUCT_CODE": "PLANE",
"ORDER_ID": "600",
"PRODUCT_PRICE": null,
"PRODUCT_AMOUNT": null,
"TRANSACTION ID": null}
```

### Sample Truncate Message

```
{"table": "GG.TCUSTORD",
"op_type": "T",
"op_ts": "2013-06-02 22:14:41.000000",
"current_ts": "2015-09-18T10:13:11.514000",
"pos": "000000000000004515",
"primary_keys": ["CUST_CODE", "ORDER_DATE", "PRODUCT_CODE", "ORDER_ID"], "tokens":
{"R": "AADPkvAAEAAEqL2AAB"},
"CUST_CODE": null,
"ORDER_DATE": null,
"PRODUCT_CODE": null,
"PRODUCT_CODE": null,
"PRODUCT_PRICE": null,
"PRODUCT_AMOUNT": null,
"TRANSACTION ID": null}
```

#### Avro Schemas

Avro uses JSONs to represent schemas. Avro schemas define the format of generated Avro messages and are required to serialize and deserialize Avro messages. Schemas are generated on a just-in-time basis when the first operation for a table is encountered. Because generated Avro schemas are specific to a table definition, a separate Avro schema is generated for every table encountered for processed operations. By default, Avro schemas are written to the *GoldenGate\_Home/dirdef* directory, although the write location is configurable. Avro schema file names adhere to the following naming convention: *Fully\_Qualified\_Table\_Name.avsc.* 

The following is a sample Avro schema for the Avro Row Format for the references examples in the previous section:

```
{
 "type" : "record",
 "name" : "TCUSTORD",
 "namespace" : "GG",
 "fields" : [ {
   "name" : "table",
   "type" : "string"
 }, {
   "name" : "op_type",
    "type" : "string"
 }, {
   "name" : "op_ts",
   "type" : "string"
 }, {
   "name" : "current ts",
    "type" : "string"
 }, {
    "name" : "pos",
    "type" : "string"
 }, {
    "name" : "primary keys",
    "type" : {
     "type" : "array",
     "items" : "string"
   }
 }, {
    "name" : "tokens",
    "type" : {
     "type" : "map",
     "values" : "string"
   },
   "default" : { }
 }, {
    "name" : "CUST CODE",
    "type" : [ "null", "string" ],
    "default" : null
 }, {
    "name" : "ORDER DATE",
    "type" : [ "null", "string" ],
    "default" : null
 }, {
    "name" : "PRODUCT CODE",
    "type" : [ "null", "string" ],
    "default" : null
 }, {
    "name" : "ORDER ID",
    "type" : [ "null", "string" ],
    "default" : null
 }, {
   "name" : "PRODUCT PRICE",
    "type" : [ "null", "double" ],
    "default" : null
 }, {
    "name" : "PRODUCT AMOUNT",
    "type" : [ "null", "double" ],
    "default" : null
 }, {
    "name" : "TRANSACTION ID",
   "type" : [ "null", "string" ],
   "default" : null
```

}]

# Avro Row Configuration Properties

Properties	Optio nal/ Requ ired	Value		Explanation
gg.handler.name.format.insertOpKey	Optio nal	Any string	I	Indicator to be inserted into the output record to indicate an insert operation.
gg.handler.name.format.updateOpKey	Optio nal	Any string	U	Indicator to be inserted into the output record to indicate an update operation.
gg.handler.name.format.deleteOpKey	Optio nal	Any string	D	Indicator to be inserted into the output record to indicate a delete operation.
gg.handler. <i>name</i> .format.truncateOpKey	Optio nal	Any string	Т	Indicator to be inserted into the output record to indicate a truncate operation.
gg.handler.name.format.encoding	Optio nal	Any legal encod ing name or alias suppo rted by Java.	-8 (the JSO N	Controls the output encoding of generated JSON Avro schema. The JSON default is UTF-8. Avro messages are binary and support their own internal representation of encoding.
gg.handler. <i>name.</i> format.treatAllColumnsAsSt rings	Optio nal	true  fals e	fal se	Controls the output typing of generated Avro messages. If set to false then the formatter will attempt to map Oracle GoldenGate types to the corresponding AVRO type. If set to true then all data will be treated as Strings in the generated Avro messages and schemas.

 Table 8-42
 Avro Row Configuration Properties

Properties	Optio nal/ Requ ired	Value		Explanation
gg.handler. <i>name</i> .format.pkUpdateHandling	Optio nal	aben d  upda te  dele te- inse rt	abe nd	<ul> <li>Specifies how the formatter handles update operations that change a primary key. Primary key operations for the Avro Row formatter require special consideration.</li> <li>abend: the process terminates.</li> <li>update: the process handles the update as a normal update.</li> <li>delete or insert: the process handles the update as a delete and an insert. Full supplemental logging must be enabled. Without full before and after row images, the insert data will be incomplete.</li> </ul>
gg.handler. <i>name</i> .format.lineDelimiter	Optio nal	Any string	no valu e	Inserts a delimiter after each Avro message. This is not a best practice, but in certain cases you may want to parse a stream of data and extract individual Avro messages from the stream. Select a unique delimiter that cannot occur in any Avro message. This property supports CDATA[] wrapping.

Properties	Optio nal/ Requ ired	Value		Explanation
gg.handler. <i>nam</i> e.format.versionSchemas	Optio nal	true  fals e	fal se	Avro schemas always follow the fully_qualified_t able_name.avsc convention. Setting this property to true creates an additional Avro schema named fully_qualified_tab le_name_current_tim estamp.avsc in the schema directory. Because the additional Avro schema is not destroyed or removed, provides a history of schema evolution.
gg.handler. <i>name</i> .format.wrapMessageInGeneri cAvroMessage	Optio nal	true  fals e	fal se	Wraps the Avro messages for operations from the source trail file in a generic Avro wrapper message. For more information, see Generic Wrapper Functionality.
gg.handler.name.format.schemaDirectory	Optio nal	Any legal, existin g file syste m path.	./ dir def	The output location of generated Avro schemas.
gg.handler.name.format.schemaFilePath	Optio nal	Any legal encod ing name or alias suppo rted by Java.	./ dir def	The directory in the HDFS where schemas are output. A metadata change overwrites the schema during the next operation for the associated table. Schemas follow the same naming convention as schemas written to the local file system:catalog.schem a.table.avsc.

Properties	Optio nal/ Requ ired	Value		Explanation
gg.handler. <i>name</i> .format.iso8601Format	Optio nal	true  fals e	tru e	The format of the current timestamp. The default is the ISO 8601 format. A setting of false removes the T between the date and time in the current timestamp, which outputs a space instead.
gg.handler.name.format.includeIsMissingFie lds	Optio nal	true  fals e	fal se	Set to true to include a {column_name}_isMis sing boolean field for each source field. This field allows downstream applications to differentiate if a null value is null in the source trail file (value is false) or is missing in the source trail file (value is true).
gg.handler. <i>name</i> .format.enableDecimalLogica lType	Optio nal	true  fals e	fal se	Enables the use of Avro decimal logical types. The decimal logical type represents numbers as a byte array and can provide support for much larger numbers than can fit in the classic 64-bit long or double data types.

Propertie	s Optio nal/ Requ ired	Value	Explanation
.handler.name.format.oracleNumberScal	e Optio nal	Any intege r	Allows you to set the scale on the Avro decimal data type.Only
	nal		decimal data type.Onl applicable when you see enableDecimalLogic 1Type=true. The Oracle NUMBER is a proprietary numeric data type of Oracle Databass that supports variable precision and scale. Precision and scale are variable on a per instance of the Oracle NUMBER data type. Precision and scale are required parameters when generating the Avro decimal logical type. This makes mapping of Oracle NUMBER data types into Avro difficult because there is no way to deterministically know the precision and scale of an Oracle NUMBER data type when the Avro schema is generated. The best alternative is to generate a large Avro decimal data type a precision of 164 and a scale of 38, which should hold any legal instance of Oracle NUMBER. While this solves the problem of
			precision loss when converting Oracle Number data types to Avro decimal data
			types, you may not like that Avro decimal data types when retrieved from Avro messages downstream have 38 digits trailing the decima
			 downs

Properties	Optio nal/ Requ ired	Value		Explanation
gg.handler.name.format.mapOracleNumbersAsS trings	Optio nal	true  fals e	fal se	This property is only applicable if decimal logical types are enabled via the property gg.handler.name.for mat.enableDecimalLo gialType=true. Oracle numbers are especially problematic because they have a large precision (168) and floating scale of up to 38 Some analytical tools, such as Spark cannot read numbers that large. This property allows you to map those Oracle numbers as strings while still mapping the smaller numbers as decimal logical types.
gg.handler.name.format.enableTimestampLogi calType	Optio nal	true  fals e	fal se	Set to true to map source date and time data types into the Avro TimestampMicros logical data type. The variable gg.format.timestamp must be configured to provide a mask for the source date and time data types to make sense of them. The Avro TimestampMicros is part of the Avro 1.8 specification.
gg.handler.name.format.mapLargeNumbersAsSt rings	Optio nal	true  fals e	fal se	Oracle GoldenGate supports the floating point and integer source datatypes. Some of these datatypes may not fit into the Avro primitive double or long datatypes. Set this property to true to map the fields that do not fit into the Avro primitive double or long datatypes to Avro string.

Properties	Optio nal/ Requ ired	Value	Explanation
gg.handler.name.format.metaColumnsTemplate	Optio nal	See Metac olumn Keyw ords.	 The current meta column information can be configured in a simple manner and removes the explicit need to use:
			<pre>insertOpKey   updateOpKey   deleteOpKey   truncateOpKey   includeTableName   includeOpTimestamp   includeOpType   includePosition   includeCurrentTimes tamp, useIso8601Format It is a comma-delimited string consisting of one or more templated values that represent the template. For more information</pre>
			about the Metacolumn keywords, see Metacolumn Keywords.

Properties	Optio nal/ Requ ired	Value		Explanation	
gg.handler.name.format.maxPrecision	Optio nal	None	Posi tive Inte ger	Allows you to set the maximum precision for Avro decimal logical types. Consuming applications may have limitations on Avro precision (that is, Apache Spark supports a maximum precision of 38).

## Table 8-42 (Cont.) Avro Row Configuration Properties

### The NUMBER type in an Oracle RDBMS supports a maximum precision of 164. Configuration of this property likely means you are casting larger source numeric types to smaller target numeric types. If the precision of the source value is greater than the configured precision, then a runtime exception will occur and the replicat process will abend. That behavior is not a bug. That is the expected behavior.

#### **Review a Sample Configuration**

The following is a sample configuration for the Avro Row Formatter in the Java Adapter properties file:

```
gg.handler.hdfs.format=avro_row
gg.handler.hdfs.format.insertOpKey=I
gg.handler.hdfs.format.updateOpKey=U
gg.handler.hdfs.format.deleteOpKey=D
gg.handler.hdfs.format.truncateOpKey=T
gg.handler.hdfs.format.encoding=UTF-8
```

gg.handler.hdfs.format.pkUpdateHandling=abend
gg.handler.hdfs.format.wrapMessageInGenericAvroMessage=false

#### Metadata Change Events

If the replicated database and upstream Oracle GoldenGate replication process can propagate metadata change events, the Avro Row Formatter can take action when metadata changes. Because Avro messages depend closely on their corresponding schema, metadata changes are important when you use Avro formatting.

An updated Avro schema is generated as soon as a table operation occurs after a metadata change event. You must understand the impact of a metadata change event and change downstream targets to the new Avro schema. The tight dependency of Avro messages to Avro schemas may result in compatibility issues. Avro messages generated before the schema change may not be able to be deserialized with the newly generated Avro schema.

Conversely, Avro messages generated after the schema change may not be able to be deserialized with the previous Avro schema. It is a best practice to use the same version of the Avro schema that was used to generate the message. For more information, consult the Apache Avro documentation.

#### **Special Considerations**

This sections describes these special considerations:

- Troubleshooting
- Primary Key Updates
- Generic Wrapper Functionality

#### Troubleshooting

Because Avro is a binary format, it is not human readable. Since Avro messages are in binary format, it is difficult to debug any issue, the Avro Row Formatter provides a special feature to help debug issues. When the log4j Java logging level is set to TRACE, Avro messages are deserialized and displayed in the log file as a JSON object, letting you view the structure and contents of the created Avro messages. Do not enable TRACE in a production environment as it has substantial negative impact on performance. To troubleshoot content, you may want to consider switching to use a formatter that produces human-readable content. The XML or JSON formatters both produce content in human-readable format.

#### Primary Key Updates

In Big Data integrations, primary key update operations require special consideration and planning. Primary key updates modify one or more of the primary keys of a given row in the source database. Because data is appended in Big Data applications, a primary key update operation looks more like a new insert than like an update without special handling. You can use the following properties to configure the Avro Row Formatter to handle primary keys:

Value	Description
abend	The formatter terminates. This behavior is the default behavior.
update	With this configuration the primary key update is treated like any other update operation. Use this configuration only if you can guarantee that the primary key is not used as selection criteria row data from a Big Data system.

<b>Table 8-43</b>	Configurable behavior
-------------------	-----------------------

Value	Description
delete-insert	The primary key update is treated as a special case of a delete, using the before image data and an insert using the after-image data. This configuration may more accurately model the effect of a primary key update in a Big Data application. However, if this configuration is selected, it is important to have full supplemental logging enabled on Replication at the source database. Without full supplemental logging the delete operation will be correct, but insert operation will not contain all of the data for all of the columns for a full representation of the row data in the Big Data application.

#### Table 8-43 (Cont.) Configurable behavior

#### Generic Wrapper Functionality

Because Avro messages are not self describing, the receiver of the message must know the schema associated with the message before the message can be deserialized. Avro messages are binary and provide no consistent or reliable way to inspect the message contents in order to ascertain the message type. Therefore, Avro can be troublesome when messages are interlaced into a single stream of data such as Kafka.

The Avro formatter provides a special feature to wrap the Avro message in a generic Avro message. You can enable this functionality by setting the following configuration property.

gg.handler.name.format.wrapMessageInGenericAvroMessage=true

The generic message is Avro message wrapping the Avro payload message that is common to all Avro messages that are output. The schema for the generic message is name generic\_wrapper.avsc and is written to the output schema directory. This message has the following three fields:

- table name : The fully qualified source table name.
- schema\_fingerprint : The fingerprint of the Avro schema of the wrapped message. The fingerprint is generated using the Avro SchemaNormalization.parsingFingerprint64 (schema) call.
- payload: The wrapped Avro message.

The following is the Avro Formatter generic wrapper schema.

```
"type" : "record",
"name" : "generic_wrapper",
"namespace" : "oracle.goldengate",
"fields" : [ {
    "name" : "table_name",
    "type" : "string"
}, {
    "name" : "schema_fingerprint",
    "type" : "long"
}, {
    "name" : "payload",
    "type" : "bytes"
} ]
```

}

## The Avro Operation Formatter

The Avro Operation Formatter formats operation data from the source trail file into messages in an Avro binary array format. Each individual insert, update, delete, and truncate operation is formatted into an individual Avro message. The source trail file contains the before and after images of the operation data. The Avro Operation Formatter formats this data into an Avro binary representation of the operation data.

This format is more verbose than the output of the Avro Row Formatter for which the Avro messages model the row data.

- Operation Data Formatting Details
- Sample Avro Operation Messages
- Avro Schema
- Avro Operation Formatter Configuration Properties
- Review a Sample Configuration
- Metadata Change Events
- Special Considerations

### **Operation Metadata Formatting Details**

The automated output of meta-column fields in generated Avro messages has been removed as of Oracle GoldenGate for Big Data release 21.1. Meta-column fields can still be output; however, they need to explicitly configured as the following property:

gg.handler.name.format.metaColumnsTemplate

To output the metacolumns as in previous versions configure the following:

```
gg.handler.name.format.metaColumnsTemplate=${objectname[table]},$
{optype[op_type]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]}
```

To also include the primary key columns and the tokens configure as follows:

```
gg.handler.name.format.metaColumnsTemplate=${objectname[table]},$
{optype[op_type]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]},${primarykeycolumns[primary keys]},${alltokens[tokens]}
```

For more information see the configuration property: gg.handler.name.format.metaColumnsTemplate

### Table 8-44 Avro Messages and its Metadata

Fields	Description
table	The fully qualified table name, in the format: CATALOG_NAME.SCHEMA NAME.TABLE NAME
op_type	The type of database operation from the source trail file. Default values are ${\tt I}$ for insert, ${\tt U}$ for update, ${\tt D}$ for delete, and ${\tt T}$ for truncate.

Fields	Description
op_ts	The timestamp of the operation from the source trail file. Since this timestamp is from the source trail, it is fixed. Replaying the trail file results in the same timestamp for the same operation.
current_ts	The time when the formatter processed the current operation record. This timestamp follows the ISO-8601 format and includes microsecond precision. Replaying the trail file will <i>not</i> result in the same timestamp for the same operation.
pos	The concatenated sequence number and rba number from the source trail file. The trail position provides traceability of the operation back to the source trail file. The sequence number is the source trail file number. The rba number is the offset in the trail file.
primary_keys	An array variable that holds the column names of the primary keys of the source table.
tokens	A map variable that holds the token key value pairs from the source trail file.

#### Table 8-44 (Cont.) Avro Messages and its Metadata

### **Operation Data Formatting Details**

The operation data is represented as individual fields identified by the column names.

Column values for an operation from the source trail file can have one of three states: the column has a value, the column value is null, or the column value is missing. Avro attributes only support two states: the column has a value or the column value is null. The Avro Operation Formatter contains an additional Boolean field *COLUMN\_NAME\_isMissing* for each column to indicate whether the column value is missing or not. Using *COLUMN\_NAME* field together with the *COLUMN\_NAME\_isMissing* field, all three states can be defined.

• State 1: The column has a value

COLUMN NAME field has a value

COLUMN NAME isMissing field is false

State 2: The column value is null

COLUMN NAME field value is null

COLUMN\_NAME\_isMissing field is false

State 3: The column value is missing

COLUMN NAME field value is null

COLUMN NAME isMissing field is true

By default the Avro Row Formatter maps the data types from the source trail file to the associated Avro data type. Because Avro supports few data types, this functionality usually results in the mapping of numeric fields from the source trail file to members typed as numbers. You can also configure this data type mapping to handle all data as strings.

#### Sample Avro Operation Messages

Because Avro messages are binary, they are not human readable. The following topics show example Avro messages in JSON format:

• Sample Insert Message

- Sample Update Message
- Sample Delete Message
- Sample Truncate Message

#### Sample Insert Message

```
{"table": "GG.TCUSTORD",

"current_ts": "2015-09-18T10:17:49.900000",
"pos": "0000000000000004515",
"primary_keys": ["CUST_CODE", "ORDER_DATE", "PRODUCT_CODE", "ORDER_ID"], "tokens":
    {"R": "AADPkvAAEAAEqL2AAB"},
"before": null,
"after": null}
```

#### Avro Schema

Avro schemas are represented as JSONs. Avro schemas define the format of generated Avro messages and are required to serialize and deserialize Avro messages. Avro schemas are generated on a just-in-time basis when the first operation for a table is encountered. Because Avro schemas are specific to a table definition, a separate Avro schema is generated for every table encountered for processed operations. By default, Avro schemas are written to the *GoldenGate\_Home/dirdef* directory, although the write location is configurable. Avro schema file names adhere to the following naming convention: *Fully Qualified Table Name.avsc*.

The following is a sample Avro schema for the Avro Operation Format for the samples in the preceding sections:

```
{
 "type" : "record",
 "name" : "TCUSTORD",
 "namespace" : "GG",
 "fields" : [ {
   "name" : "table",
   "type" : "string"
 }, {
   "name" : "op_type",
    "type" : "string"
 }, {
   "name" : "op ts",
    "type" : "string"
 }, {
   "name" : "current ts",
    "type" : "string"
 }, {
    "name" : "pos",
    "type" : "string"
 }, {
    "name" : "primary keys",
   "type" : {
     "type" : "array",
     "items" : "string"
   }
 }, {
    "name" : "tokens",
    "type" : {
     "type" : "map",
     "values" : "string"
   },
    "default" : { }
 }, {
    "name" : "before",
    "type" : [ "null", {
     "type" : "record",
      "name" : "columns",
      "fields" : [ {
       "name" : "CUST CODE",
        "type" : [ "null", "string" ],
        "default" : null
      }, {
        "name" : "CUST_CODE_isMissing",
        "type" : "boolean"
      }, {
       "name" : "ORDER DATE",
        "type" : [ "null", "string" ],
       "default" : null
      }, {
       "name" : "ORDER DATE isMissing",
        "type" : "boolean"
      }, {
        "name" : "PRODUCT_CODE",
        "type" : [ "null", "string" ],
        "default" : null
      }, {
       "name" : "PRODUCT CODE isMissing",
        "type" : "boolean"
     }, {
        "name" : "ORDER_ID",
        "type" : [ "null", "string" ],
```

```
"default" : null
    }, {
      "name" : "ORDER ID isMissing",
      "type" : "boolean"
    }, {
      "name" : "PRODUCT PRICE",
      "type" : [ "null", "double" ],
      "default" : null
    }, {
      "name" : "PRODUCT PRICE isMissing",
      "type" : "boolean"
    }, {
      "name" : "PRODUCT_AMOUNT",
      "type" : [ "null", "double" ],
      "default" : null
    }, {
      "name" : "PRODUCT_AMOUNT_isMissing",
      "type" : "boolean"
    }, {
      "name" : "TRANSACTION ID",
      "type" : [ "null", "string" ],
      "default" : null
    }, {
      "name" : "TRANSACTION ID isMissing",
      "type" : "boolean"
   } ]
  }],
  "default" : null
}, {
  "name" : "after",
  "type" : [ "null", "columns" ],
  "default" : null
} ]
```

Avro Operation Formatter Configuration Properties

}

## Table 8-45 Configuration Properties

Properties	Optional Y/N	Legal Values	Default	Explanation
gg.handler. <i>name</i> .form at.insertOpKey	Optional	Any string	I	Indicator to be inserted into the output record to indicate an insert operation
gg.handler. <i>name</i> .form at.updateOpKey	Optional	Any string	U	Indicator to be inserted into the output record to indicate an update operation.
gg.handler. <i>name</i> .form at.deleteOpKey	Optional	Any string	D	Indicator to be inserted into the output record to indicate a delete operation.
gg.handler. <i>name</i> .form at.truncateOpKey	Optional	Any string	Т	Indicator to be inserted into the output record to indicate a truncate operation.

Properties	Optional Y/N	Legal Values	Default	Explanation
gg.handler. <i>name.</i> form at.encoding	Optional	Any legal encoding name or alias supported by Java	UTF-8 (the JSON default)	Controls the output encoding of generated JSON Avro schema. The JSON default is UTF-8. Avro messages are binary and support their own internal representation of encoding.
gg.handler. <i>name.</i> form at.treatAllColumnsAs Strings	Optional	true false	false	Controls the output typing of generated Avro messages. If set to false, then the formatter attempts to map Oracle GoldenGate types to the corresponding Avro type. If set to true, then all data is treated as Strings in the generated Avro messages and schemas.
gg.handler. <i>name.</i> form at.lineDelimiter	Optional	Any string	no value	Inserts delimiter after each Avro message. This is not a best practice, but in certain cases you may want to parse a stream of data and extract individual Avro messages from the stream, use this property to help. Select a unique delimiter that cannot occur in any Avro message. This property supports CDATA [] wrapping.
gg.handler. <i>name.</i> form at.schemaDirectory	Optional	Any legal, existing file system path.	./dirdef	The output location of generated Avro schemas.
gg.handler. <i>name</i> .form at.wrapMessageInGene ricAvroMessage	Optional	true false	false	Wraps Avro messages for operations from the source trail file in a generic Avro wrapper message. For more information, see Generic Wrapper Functionality.
gg.handler. <i>name</i> .form at.iso8601Format	Optional	true false	true	The format of the current timestamp. By default the ISO 8601 is set to false, removes the $T$ between the date and time in the current timestamp, which outputs a space instead.
gg.handler.name.form at.includeIsMissingF ields	Optional	true false	false	Set to true to include a { column_name }_isMissing boolean field for each source field. This field allows downstream applications to differentiate if a null value is null in the source trail file (value is false) or is missing in the the source trail file (value is true).

Table 8-45	(Cont.) Configuration Properties
------------	----------------------------------

Properties	Optional Y/N	Legal Values	Default	Explanation
gg.handler.name.form at.oracleNumberScale	Optional	Any integer value from 0 to 38.	None	Allows you to set the scale on the Avro decimal data type.Only applicable when you set enableDecimalLogicalType =true. The Oracle NUMBER is a proprietary numeric data type of Oracle Database that supports variable precision and scale. Precision and scale are variable on a per instance of the Oracle NUMBER data type. Precision and scale are required parameters when generating the Avro decimal logical type. This makes mapping of Oracle NUMBER data types into Avro difficult because there is no way to deterministically know the precision and scale of an Oracle NUMBER data type when the Avro schema is generated. The best alternative is to generate a large Avro decimal data type a precision of 164 and a scale of 38, which should hold any legal instance of Oracle NUMBER. While this solves the problem of precision loss when converting Oracle Number data types, you may not like that Avro decimal data types when retrieved from Avro messages downstream have 38 digits trailing the decimal point.

Table 8-45	(Cont.)	Configuration	Properties
------------	---------	---------------	------------

Properties	Optional Y/N	Legal Values	Default	Explanation
gg.handler.name.form at.mapOracleNumbersA sStrings	Optional	true false	false	This property is only applicable if decimal logical types are enabled via the property gg.handler.name.format.e nableDecimalLogialType=t rue. Oracle numbers are especially problematic because they have a large precision (168) and floating scale of up to 38. Some analytical tools, such as Spark cannot read numbers that large. This property allows you to map those Oracle numbers as strings while still mapping the smaller numbers as decimal logical types.
gg.handler.name.form at.enableTimestampLo gicalType	Optional	true false	false	Set to true to map source date and time data types into the Avro TimestampMicros logical data type. The variable gg.format.timestamp must be configured to provide a mask for the source date and time data types to make sense of them. The Avro TimestampMicros is part of the Avro 1.8 specification.
gg.handler.name.form at.enableDecimalLogi calType	Optional	true false	false	Enables the use of Avro decimal logical types. The decimal logical type represents numbers as a byte array and can provide support for much larger numbers than can fit in the classic 64-bit long or double data types.
gg.handler.name.form at.mapLargeNumbersAs Strings	Optional	true false	false	Oracle GoldenGate supports the floating point and integer source datatypes. Some of these datatypes may not fit into the Avro primitive double or long datatypes. Set this property to true to map the fields that do not fit into the Avro primitive double or long datatypes to Avro string.

Table 8-45	(Cont.)	Configuration	Properties
------------	---------	---------------	------------

Properties	Optional Y/N	Legal Values	Default	Explanation
gg.handler.name.form at.metaColumnsTempla te	Optional	See Metacolumn Keywords	None	The current meta column information can be configured in a simple manner and removes the explicit need to use:
				<pre>insertOpKey   updateOpKey   deleteOpKey   truncateOpKey   includeTableName   includeOpTimestamp   includeOpType   includePosition   includeCurrentTimestamp, useIso8601Format It is a comma-delimited string consisting of one or more templated values that represent the template.</pre>
				For more information about the Metacolumn keywords, see Metacolumn Keywords.

Table 8-45	(Cont.)	Configuration	Properties
------------	---------	---------------	------------

Properties	Optional Y/N	Legal Values	Default	Explanation	
gg.handler.name.form at.maxPrecision	Optional	None	Positive Integer	Allows you to set the precision for Avro de logical types. Consu applications may ha limitations on Avro p (that is, Apache Spa a maximum precisio	ecimal Iming ve precision Irk suppor

# Table 8-45 (Cont.) Configuration Properties

The NUMBER type in an Oracle RDBMS supports a

Properties	Optional Y/N	Legal Values	Default	Explanation
				maximum precision of 164. Configuration of this property likely means you are casting larger source numeric types to smaller target numeric types. If the precision of the source value is greater than the configured precision, a runtime exception occurs and the replicat process will abend. That behavior is not a bug. That is the expected behavior.

Table 8-45	(Cont.)	Configuration	Properties
------------	---------	---------------	------------

### Review a Sample Configuration

The following is a sample configuration for the Avro Operation Formatter in the Java Adapter properg.handlerties file:

gg.handler.hdfs.format=avro\_op
gg.handler.hdfs.format.insertOpKey=I
gg.handler.hdfs.format.updateOpKey=U
gg.handler.hdfs.format.deleteOpKey=D
gg.handler.hdfs.format.truncateOpKey=T
gg.handler.hdfs.format.encoding=UTF-8
gg.handler.hdfs.format.wrapMessageInGenericAvroMessage=false

#### Metadata Change Events

If the replicated database and upstream Oracle GoldenGate replication process can propagate metadata change events, the Avro Operation Formatter can take action when metadata changes. Because Avro messages depend closely on their corresponding schema, metadata changes are important when you use Avro formatting.

An updated Avro schema is generated as soon as a table operation occurs after a metadata change event.

You must understand the impact of a metadata change event and change downstream targets to the new Avro schema. The tight dependency of Avro messages to Avro schemas may result in compatibility issues. Avro messages generated before the schema change may not be able to be deserialized with the newly generated Avro schema. Conversely, Avro messages generated after the schema change may not be able to be deserialized with the previous Avro schema. It is a best practice to use the same version of the Avro schema that was used to generate the message

For more information, consult the Apache Avro documentation.

#### **Special Considerations**

This section describes these special considerations:

- Troubleshooting
- Primary Key Updates
- Generic Wrapper Message

#### Troubleshooting

Because Avro is a binary format, it is not human readable. However, when the log4j Java logging level is set to TRACE, Avro messages are deserialized and displayed in the log file as a JSON object, letting you view the structure and contents of the created Avro messages. Do not enable TRACE in a production environment, as it has a substantial impact on performance.

#### Primary Key Updates

The Avro Operation Formatter creates messages with complete data of before-image and after-images for update operations. Therefore, the Avro Operation Formatter requires no special treatment for primary key updates.

### Generic Wrapper Message

Because Avro messages are not self describing, the receiver of the message must know the schema associated with the message before the message can be deserialized. Avro messages are binary and provide no consistent or reliable way to inspect the message contents in order to ascertain the message type. Therefore, Avro can be troublesome when messages are interlaced into a single stream of data such as Kafka.

The Avro formatter provides a special feature to wrap the Avro message in a generic Avro message. You can enable this functionality by setting the following configuration property:

gg.handler.name.format.wrapMessageInGenericAvroMessage=true

The generic message is Avro message wrapping the Avro payload message that is common to all Avro messages that are output. The schema for the generic message is name generic\_wrapper.avsc and is written to the output schema directory. This message has the following three fields:

- table name: The fully qualified source table name.
- schema\_fingerprint : The fingerprint of the of the Avro schema generating the messages. The fingerprint is generated using the parsingFingerprint64 (Schema s) method on the org.apache.avro.SchemaNormalization class.
- payload: The wrapped Avro message.

The following is the Avro Formatter generic wrapper schema:

```
{
  "type" : "record",
  "name" : "generic_wrapper",
  "namespace" : "oracle.goldengate",
  "fields" : [ {
    "name" : "table_name",
    "type" : "string"
  }, {
    "name" : "schema_fingerprint",
    "type" : "long"
  }, {
    "name" : "payload",
    "type" : "bytes"
  } ]
}
```

## Avro Object Container File Formatter

Oracle GoldenGate for Big Data can write to HDFS in Avro Object Container File (OCF) format. Avro OCF handles schema evolution more efficiently than other formats. The Avro OCF Formatter also supports compression and decompression to allow more efficient use of disk space.

The HDFS Handler integrates with the Avro formatters to write files to HDFS in Avro OCF format. The Avro OCF format is required for Hive to read Avro data in HDFS. The Avro OCF format is detailed in the Avro specification, see http://avro.apache.org/docs/current/spec.html#Object+Container+Files.

You can configure the HDFS Handler to stream data in Avro OCF format, generate table definitions in Hive, and update table definitions in Hive in the case of a metadata change event.

### • Avro OCF Formatter Configuration Properties

### Avro OCF Formatter Configuration Properties

Properties	Optional / Required	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format.insertO pKey	Optional	Any string	I	Indicator to be inserted into the output record to indicate an insert operation.
gg.handler. <i>name</i> .format.updateO pKey	Optional	Any string	U	Indicator to be inserted into the output record to indicate an update operation.
gg.handler. <i>name</i> .format.truncat eOpKey	Optional	Any string	Т	Indicator to be truncated into the output record to indicate a truncate operation.
gg.handler. <i>name</i> .format.deleteO pKey	Optional	Any string	D	Indicator to be inserted into the output record to indicate a truncate operation.
gg.handler. <i>name</i> .format.encodin g	Optional	Any legal encoding name or alias supported by Java.	UTF-8	Controls the output encoding of generated JSON Avro schema. The JSON default is UTF-8. Avro messages are binary and support their own internal representation of encoding.

Properties	Optional / Required	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format.treatAl lColumnsAsStrin gs	Optional	true false	false	Controls the output typing of generated Avro messages. When the setting is false, the formatter attempts to map Oracle GoldenGate types to the corresponding Avro type. When the setting is true, all data is treated as strings in the generated Avro messages and schemas.

Properties	Optional / Required	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format.pkUpdat eHandling	Optional	abend   update   delete-insert	abend	Controls how the formatter should handle update operations that change a primary key. Primary key operations can be problematic for the Avro Row formatte and require specia consideration by you. • abend : the process will terminates. • update : the process handles this as a normal update • delete and insert: the process handles thins operation as a delete and an insert. The full before image is required for this feature to work properly This can be achieved by using full supplemental logging in Oracle. Without full before and after row images the insert data wi be incomplete
gg.handler. <i>name</i> .format.generat eSchema	Optional	true false	true	Because schemas must be generated for Avro serialization to false to suppress the writing of the generated schemas to the local file system.

Properties	Optional / Required	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format.schemaD irectory	Optional	Any legal, existing file system path	./dirdef	The directory where generated Avro schemas are saved to the local file system. This property does not control where the Avro schema is written to in HDFS; that is controlled by an HDFS Handler property.
gg.handler. <i>name</i> .format.iso8601 Format	Optional	true false	true	By default, the value of this property is true, and the format for the current timestamp is ISO8601. Set to false to remove the T between the date and time in the current timestamp and output a space instead.
gg.handler. <i>name</i> .format.version Schemas	Optional	true false	false	If set to true, an Avro schema is created in the schema directory and versioned by a time stamp. The schema uses the following format: fully_qualified table_name_time stamp.avsc

# Using the Delimited Text Formatter

The Delimited Text Formatter formats database operations from the source trail file into a delimited text output. Each insert, update, delete, or truncate operation from the source trail is formatted into an individual delimited message. Delimited text output includes a fixed number of fields for each table separated by a field delimiter and terminated by a line delimiter. The fields are positionally relevant. Many Big Data analytical tools including Hive work well with HDFS files that contain delimited text. Column values for an operation from the source trail file can have one of three states: the column has a value, the column value is null, or the column value is missing. By default, the delimited text maps these column value states into the delimited text output as follows:

• Column has a value: The column value is output.

- Column value is null: The default output value is NULL. The output for the case of a null column value is configurable.
- Column value is missing: The default output value is an empty string (""). The output for the case of a missing column value is configurable.
- Using the Delimited Text Row Formatter The Delimited Text Row Formatter is the Delimited Text Formatter that was included a release prior to the Oracle GoldeGate for Big Data 19.1.0.0 release. It writes the after change data for inserts and updates, and before change data for deletes.
- Delimited Text Operation Formatter

The Delimited Text Operation Formatter is new functionality in the Oracle GoldenGate for Big Data 19.1.0.0.0 release. It outputs both before and after change data for insert, update and delete operations.

# Using the Delimited Text Row Formatter

The Delimited Text Row Formatter is the Delimited Text Formatter that was included a release prior to the Oracle GoldeGate for Big Data 19.1.0.0 release. It writes the after change data for inserts and updates, and before change data for deletes.

- Configuration
- Metadata Change Events
- Additional Considerations

#### Message Formatting Details

The automated output of meta-column fields in generated delimited text messages has been removed as of Oracle GoldenGate for Big Data release 21.1. Meta-column fields can still be output; however, they need to explicitly configured as the following property:

gg.handler.name.format.metaColumnsTemplate

To output the metacolumns as in previous versions configure the following:

```
gg.handler.name.format.metaColumnsTemplate=${optype[op_type]},$
{objectname[table]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]}
```

#### To also include the primary key columns and the tokens configure as follows:

```
gg.handler.name.format.metaColumnsTemplate=${optype[op_type]},$
{objectname[table]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]},${primarykeycolumns[primary keys]},${alltokens[tokens]}
```

For more information, see

see the configuration property gg.handler.name.format.metaColumnsTemplate in the Delimited Text Formatter Configuration Properties table.

Formatting details:

- **Operation Type** : Indicates the type of database operation from the source trail file. Default values are I for insert, U for update, D for delete, T for truncate. Output of this field is suppressible.
- **Fully Qualified Table Name**: The fully qualified table name is the source database table including the catalog name, and the schema name. The format of the fully qualified table name is *catalog\_name.schema\_name.table\_name*. The output of this field is suppressible.
- **Operation Timestamp** : The commit record timestamp from the source system. All operations in a transaction (unbatched transaction) will have the same operation timestamp. This timestamp is fixed, and the operation timestamp is the same if the trail file is replayed. The output of this field is suppressible.
- **Current Timestamp** : The timestamp of the current time when the delimited text formatter processes the current operation record. This timestamp follows the ISO-8601 format and includes microsecond precision. Replaying the trail file does *not* result in the same timestamp for the same operation. The output of this field is suppressible.
- **Trail Position** :The concatenated sequence number and RBA number from the source trail file. The trail position lets you trace the operation back to the source trail file. The sequence number is the source trail file number. The RBA number is the offset in the trail file. The output of this field is suppressible.
- **Tokens** : The token key value pairs from the source trail file. The output of this field in the delimited text output is suppressed unless the includeTokens configuration property on the corresponding handler is explicitly set to true.

#### Sample Formatted Messages

The following sections contain sample messages from the Delimited Text Formatter. The default field delimiter has been changed to a pipe character, |, to more clearly display the message.

### **Output Format Summary Log**

If INFO level logging is enabled, the Java log4j logging logs a summary of the delimited text output format . A summary of the delimited fields is logged for each source table encountered and occurs when the first operation for that table is received by the Delimited Text formatter. This detailed explanation of the fields of the delimited text output may be useful when you perform an initial setup. When a metadata change event occurs, the summary of the delimited fields is regenerated and logged again at the first subsequent operation for that table.

# Configuration

Review a Sample Configuration

#### **Review a Sample Configuration**

The following is a sample configuration for the Delimited Text formatter in the Java Adapter configuration file:

gg.handler.name.format.includeColumnNames=false gg.handler.name.format.insertOpKey=I gg.handler.name.format.updateOpKey=U gg.handler.name.format.deleteOpKey=D gg.handler.name.format.truncateOpKey=T gg.handler.name.format.encoding=UTF-8 gg.handler.name.format.fieldDelimiter=CDATA[\u0001] gg.handler.name.format.lineDelimiter=CDATA[\n] gg.handler.name.format.keyValueDelimiter=CDATA[=] gg.handler.name.format.kevValuePairDelimiter=CDATA[] gg.handler.name.format.pkUpdateHandling=abend gg.handler.name.format.missingValueRepresentation=CDATA[] gg.handler.name.format.missingValueRepresentation=CDATA[] gg.handler.name.format.includeGroupCols=false gg.handler.name.format=delimitedtext

#### Metadata Change Events

Oracle GoldenGate for Big Data now handles metadata change events at runtime. This assumes that the replicated database and upstream replication processes are propagating metadata change events. The Delimited Text Formatter changes the output format to accommodate the change and the Delimited Text Formatter continue running.

# Note:

A metadata change may affect downstream applications. Delimited text formats include a fixed number of fields that are positionally relevant. Deleting a column in the source table can be handled seamlessly during Oracle GoldenGate runtime, but results in a change in the total number of fields, and potentially changes the positional relevance of some fields. Adding an additional column or columns is probably the least impactful metadata change event, assuming that the new column is added to the end. Consider the impact of a metadata change event before executing the event. When metadata change events are frequent, Oracle recommends that you consider a more flexible and self-describing format, such as JSON or XML.

# Additional Considerations

Exercise care when you choose field and line delimiters. It is important to choose delimiter values that will not occur in the content of the data.

The Java Adapter configuration trims leading and trailing characters from configuration values when they are determined to be whitespace. However, you may want to choose field delimiters, line delimiters, null value representations, and missing value representations that include or are fully considered to be whitespace. In these cases, you must employ specialized syntax in the Java Adapter configuration file to preserve the whitespace. To preserve the whitespace, when your configuration values contain leading or trailing characters that are considered whitespace, wrap the configuration value in a CDATA[] wrapper. For example, a configuration value of n should be configured as CDATA[n].

You can use regular expressions to search column values then replace matches with a specified value. You can use this search and replace functionality together with the Delimited Text Formatter to ensure that there are no collisions between column value contents and field and line delimiters. For more information, see Using Regular Expression Search and Replace.

Big Data applications sore data differently from RDBMSs. Update and delete operations in an RDBMS result in a change to the existing data. However, in Big Data applications, data is appended instead of changed. Therefore, the current state of a given row consolidates all of the existing operations for that row in the HDFS system. This leads to some special scenarios as described in the following sections.

- Primary Key Updates
- Data Consolidation

# **Primary Key Updates**

In Big Data integrations, primary key update operations require special consideration and planning. Primary key updates modify one or more of the primary keys for the given row from the source database. Because data is appended in Big Data applications, a primary key update operation looks more like an insert than an update without any special handling. You can configure how the Delimited Text formatter handles primary key updates. These are the configurable behaviors:

Value	Description
abend	By default the delimited text formatter terminates in the case of a primary key update.
update	The primary key update is treated like any other update operation. Use this configuration alternative only if you can guarantee that the primary key is not used as selection criteria to select row data from a Big Data system.

# Table 8-46 Configurable Behavior

Table 8-46	(Cont.) Configurable Behavior
------------	-------------------------------

Value	Description
delete-insert	The primary key update is treated as a special case of a delete, using the before-image data and an insert using the after-image data. This configuration may more accurately model the effect of a primary key update in a Big Data application. However, if this configuration is selected it is important to have full supplemental logging enabled on replication at the source database. Without full supplemental logging, the delete operation will be correct, but the insert operation will not contain all of the data for all of the columns for a full representation of the row data in the Big Data application.

# Data Consolidation

Big Data applications append data to the underlying storage. Analytic tools generally spawn MapReduce programs that traverse the data files and consolidate all the operations for a given row into a single output. Therefore, it is important to specify the order of operations. The Delimited Text formatter provides a number of metadata fields to do this. The operation timestamp may be sufficient to fulfill this requirement. Alternatively, the current timestamp may be the best indicator of the order of operations. In this situation, the trail position can provide a tie-breaking field on the operation timestamp. Lastly, the current timestamp may provide the best indicator of order of operations in Big Data.

# **Delimited Text Operation Formatter**

The Delimited Text Operation Formatter is new functionality in the Oracle GoldenGate for Big Data 19.1.0.0.0 release. It outputs both before and after change data for insert, update and delete operations.

Oracle GoldenGate for Big Data now handles metadata change events at runtime. This assumes that the replicated database and upstream replication processes are propagating metadata change events. The Delimited Text Formatter changes the output format to accommodate the change and the Delimited Text Formatter continue running.

Additional Considerations

Exercise care when you choose field and line delimiters. It is important to choose delimiter values that do not occur in the content of the data.

#### Message Formatting Details

The automated output of meta-column fields in generated delimited text messages has been removed as of Oracle GoldenGate for Big Data release 21.1. Meta-column fields can still be output; however, they need to explicitly configured as the following property: gg.handler.name.format.metaColumnsTemplate. For more information, see the configuration property gg.handler.name.format.metaColumnsTemplate in the Delimited Text Formatter Configuration Properties table.

To output the metacolumns as in previous versions configure the following:

```
gg.handler.name.format.metaColumnsTemplate=${optype[op_type]},$
{objectname[table]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]}
```

To also include the primary key columns and the tokens configure as follows:

```
gg.handler.name.format.metaColumnsTemplate=${optype[op_type]},$
{objectname[table]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]},${primarykeycolumns[primary keys]},${alltokens[tokens]}
```

Formatting details:

- Operation Type :Indicates the type of database operation from the source trail file. Default values are I for insert, U for update, D for delete, T for truncate. Output of this field is suppressible.
- **Fully Qualified Table Name**: The fully qualified table name is the source database table including the catalog name, and the schema name. The format of the fully qualified table name is catalog\_name.schema\_name.table\_name. The output of this field is suppressible.
- **Operation Timestamp** : The commit record timestamp from the source system. All operations in a transaction (unbatched transaction) will have the same operation timestamp. This timestamp is fixed, and the operation timestamp is the same if the trail file is replayed. The output of this field is suppressible.
- **Current Timestamp** : The timestamp of the current time when the delimited text formatter processes the current operation record. This timestamp follows the ISO-8601 format and includes microsecond precision. Replaying the trail file does not result in the same timestamp for the same operation. The output of this field is suppressible.
- **Trail Position** :The concatenated sequence number and RBA number from the source trail file. The trail position lets you trace the operation back to the source trail file. The sequence number is the source trail file number. The RBA number is the offset in the trail file. The output of this field is suppressible.
- **Tokens** : The token key value pairs from the source trail file. The output of this field in the delimited text output is suppressed unless the includeTokens configuration property on the corresponding handler is explicitly set to true.

**Delimited Text Formatter Configuration Properties** 

Properties	Optio nal / Requi red	Legal Values	Default	Explanation
gg.handler.name.format	Requir ed	delimit edtext_ op	None	Selects the Delimited Text Operation Formatter as the formatter.
gg.handler. <i>name</i> .format.includ eColumnNames	Option al	true  false	false	Controls the output of writing the column names as a delimited field preceding the column value. When true, the output resembles:
				COL1_Name COL1_Before_Value  COL1_After_Value COL2_Name  COL2_Before_Value  COL2_After_Value
				When false, the output resembles: COL1_Before_Value  COL1_After_Value  COL2_Before_Value  COL2_After_Value

# Table 8-47 Delimited Text Formatter Configuration Properties

Properties	Optio nal / Requi red	Legal Values	Default	Explanation
gg.handler.name.format.disabl eEscaping	Option al	true  false	false	Set to true to disable the escaping of characters which conflict with the configured delimiters. Ensure that it is set to true if gg.handler.name.format.fieldDel imiter is set to a value of multiple characters.
gg.handler. <i>name.</i> format.insert OpKey	Option al	Any string	I	Indicator to be inserted into the output record to indicate an insert operation.
gg.handler. <i>name.</i> format.update OpKey	Option al	Any string	U	Indicator to be inserted into the output record to indicate an update operation.
gg.handler. <i>name.</i> format.delete OpKey	Option al	Any string	D	Indicator to be inserted into the output record to indicate a delete operation.
gg.handler. <i>name.</i> format.trunca teOpKey	Option al	Any string	Т	Indicator to be inserted into the output record to indicate a truncate operation.
gg.handler. <i>name</i> .format.encodi ng	Option al	Any encoding name or alias supporte d by Java.	The native system encoding of the machine hosting the Oracle GoldenGate process.	Determines the encoding of the output delimited text.
gg.handler. <i>name.</i> format.fieldD elimiter	Option al	Any String	ASCII 001 (the default Hive delimiter)	The delimiter used between delimited fields. This value supports CDATA[] wrapping. If a delimiter of more than one character is configured, then escaping is automatically disabled.
gg.handler. <i>name.</i> format.lineDe limiter	Option al	Any String	Newline (the default Hive delimiter)	The delimiter used between delimited fields. This value supports CDATA[] wrapping.
gg.handler. <i>name.</i> format.keyVal ueDelimiter	Option al	Any string	=	Specifies a delimiter between keys and values in a map. Key1=value1. Tokens are mapped values. Configuration value supports CDATA[] wrapping.
gg.handler. <i>name.</i> format.keyVal uePairDelimiter	Option al	Any string	,	Specifies a delimiter between key value pairs in a map. Key1=Value1,Key2=Value2. Tokens are mapped values. Configuration value supports CDATA[] wrapping.
gg.handler. <i>name</i> .format.nullVa lueRepresentation	Option al	Any string	NULL	Specifies what is included in the delimited output in the case of a NULL value. Configuration value supports CDATA[] wrapping.

# Table 8-47 (Cont.) Delimited Text Formatter Configuration Properties

Properties	Optio nal / Requi red	Legal Values	Default	Explanation
gg.handler. <i>name.</i> format.missin gValueRepresentation	Option al	Any string	""(no value)	Specifies what is included in the delimited text output in the case of a missing value. Configuration value supports CDATA[] wrapping.
gg.handler. <i>name.</i> format.includ eMetaColumnNames	Option al	true  false	false	Set to true, a field is included prior to each metadata column value, which is the column name of the metadata column. You can use it to make delimited messages more self-describing.
gg.handler. <i>name.</i> format.wrapSt ringsInQuotes	Option al	true  false	false	Set to true to wrap string value output in the delimited text format in double quotes (").
gg.handler.name.format.includ eGroupCols	Option al	true  false	false	If set to true, the columns are grouped into sets of all names, all before values, and all after values
				U,QASOURCE.TCUSTMER,2015-11-05 18:45:39.000000,2019-04-17T05:19:3 0.556000,0000000000000005100,R=AA KifQAAKAAAFDHAAE,CUST_CODE,NAME,CI TY,STATE,ANN,ANN'S BOATS,SEATTLE,WA,ANN,,NEW YORK,NY
gg.handler.name.format.enable FieldDescriptorHeaders	Option al	true   false	false	Set to true to add a descriptive header to each data file for delimited text output. The header will be the individual field names separated by the field delimiter.

# Table 8-47 (Cont.) Delimited Text Formatter Configuration Properties

Properties	Optio nal / Requi red	Legal Values	Default	Explanation
gg.handler.name.format.metaCo lumnsTemplate	Option al	Metacolu mn Keyword	None	The current meta column information can be configured in a simple manner and removes the explicit need to use:
		S.		<pre>insertOpKey   updateOpKey   deleteOpKey  </pre>
				It is a comma-delimited string consisting of one or more templated values that represent the template. For more information about the Metacolumn keywords, see Metacolumn Keywords. This is an example that would produce a list of metacolumns: \${optype}, \$ {token.ROWID}, \$ {sys.username}, \$ {currenttimestamp}

#### Table 8-47 (Cont.) Delimited Text Formatter Configuration Properties

#### **Review a Sample Configuration**

The following is a sample configuration for the Delimited Text formatter in the Java Adapter configuration file:

```
gg.handler.name.format.includeColumnNames=false
gg.handler.name.format.insertOpKey=I
gg.handler.name.format.updateOpKey=U
gg.handler.name.format.deleteOpKey=D
gg.handler.name.format.truncateOpKey=T
gg.handler.name.format.fieldDelimiter=CDATA[\u0001]
gg.handler.name.format.lineDelimiter=CDATA[\u0001]
gg.handler.name.format.keyValueDelimiter=CDATA[=]
gg.handler.name.format.nullValueRepresentation=NULL
gg.handler.name.format.includeGroupCols=false
gg.handler.name.format=delimitedtext op
```

#### Metadata Change Events

Oracle GoldenGate for Big Data now handles metadata change events at runtime. This assumes that the replicated database and upstream replication processes are propagating metadata change events. The Delimited Text Formatter changes the

output format to accommodate the change and the Delimited Text Formatter continue running.

# Note:

A metadata change may affect downstream applications. Delimited text formats include a fixed number of fields that are positionally relevant. Deleting a column in the source table can be handled seamlessly during Oracle GoldenGate runtime, but results in a change in the total number of fields, and potentially changes the positional relevance of some fields. Adding an additional column or columns is probably the least impactful metadata change event, assuming that the new column is added to the end. Consider the impact of a metadata change event before executing the event. When metadata change events are frequent, Oracle recommends that you consider a more flexible and self-describing format, such as JSON or XML.

# Additional Considerations

Exercise care when you choose field and line delimiters. It is important to choose delimiter values that do not occur in the content of the data.

The Java Adapter configuration trims leading and trailing characters from configuration values when they are determined to be whitespace. However, you may want to choose field delimiters, line delimiters, null value representations, and missing value representations that include or are fully considered to be whitespace. In these cases, you must employ specialized syntax in the Java Adapter configuration file to preserve the whitespace. To preserve the whitespace, when your configuration values contain leading or trailing characters that are considered whitespace, wrap the configuration value in a CDATA[] wrapper. For example, a configuration value of \n should be configured as CDATA[\n].

You can use regular expressions to search column values then replace matches with a specified value. You can use this search and replace functionality together with the Delimited Text Formatter to ensure that there are no collisions between column value contents and field and line delimiters. For more information, see Using Regular Expression Search and Replace.

Big Data applications sore data differently from RDBMSs. Update and delete operations in an RDBMS result in a change to the existing data. However, in Big Data applications, data is appended instead of changed. Therefore, the current state of a given row consolidates all of the existing operations for that row in the HDFS system. This leads to some special scenarios as described in the following sections.

# Using the JSON Formatter

The JavaScript Object Notation (JSON) formatter can output operations from the source trail file in either row-based format or operation-based format. It formats operation data from the source trail file into a JSON objects. Each insert, update, delete, and truncate operation is formatted into an individual JSON message.

# • Operation Metadata Formatting Details

The automated output of meta-column fields in generated JSONs has been removed as of Oracle GoldenGate for Big Data release 21.1. Meta-column fields can still be output. However, they need to explicitly configured as the following property:

gg.handler.name.format.metaColumnsTemplate.

- Operation Data Formatting Details
- Row Data Formatting Details
- Sample JSON Messages
- JSON Schemas
- JSON Formatter Configuration Properties
- Review a Sample Configuration
- Metadata Change Events
- JSON Primary Key Updates
- Integrating Oracle Stream Analytics

# **Operation Metadata Formatting Details**

The automated output of meta-column fields in generated JSONs has been removed as of Oracle GoldenGate for Big Data release 21.1. Meta-column fields can still be output. However, they need to explicitly configured as the following property: gg.handler.name.format.metaColumnsTemplate.

To output the metacolumns as in previous versions configure the following:

gg.handler.name.format.metaColumnsTemplate=\${objectname[table]},\$
{optype[op\_type]},\${timestamp[op\_ts]},\${currenttimestamp[current\_ts]},\$
{position[pos]}

To also include the primary key columns and the tokens configure as follows:

```
gg.handler.name.format.metaColumnsTemplate=${objectname[table]},$
{optype[op_type]},${timestamp[op_ts]},${currenttimestamp[current_ts]},$
{position[pos]},${primarykeycolumns[primary keys]},${alltokens[tokens]}
```

For more information see the configuration property: gg.handler.name.format.metaColumnsTemplate.

# **Operation Data Formatting Details**

JSON messages begin with the operation metadata fields, which are followed by the operation data fields. This data is represented by before and after members that are objects. These objects contain members whose keys are the column names and whose values are the column values.

Operation data is modeled as follows:

- Inserts: Includes the after-image data.
- Updates: Includes both the before-image and the after-image data.
- Deletes: Includes the before-image data.

Column values for an operation from the source trail file can have one of three states: the column has a value, the column value is null, or the column value is missing. The JSON Formatter maps these column value states into the created JSON objects as follows:

• The column has a value: The column value is output. In the following example, the member STATE has a value.

"after":{ "CUST\_CODE":"BILL", "NAME":"BILL'S USED
CARS", "CITY":"DENVER", "STATE":"CO" }

• The column value is null: The default output value is a JSON NULL. In the following example, the member STATE is null.

```
"after":{ "CUST_CODE":"BILL", "NAME":"BILL'S USED CARS",
"CITY":"DENVER", "STATE":null }
```

• The column value is missing: The JSON contains no element for a missing column value. In the following example, the member STATE is missing.

```
"after":{ "CUST_CODE":"BILL", "NAME":"BILL'S USED CARS",
"CITY":"DENVER", }
```

The default setting of the JSON Formatter is to map the data types from the source trail file to the associated JSON data type. JSON supports few data types, so this functionality usually results in the mapping of numeric fields from the source trail file to members typed as numbers. This data type mapping can be configured treat all data as strings.

# Row Data Formatting Details

JSON messages begin with the operation metadata fields, which are followed by the operation data fields. For row data formatting, this are the source column names and source column values as JSON key value pairs. This data is represented by before and after members that are objects. These objects contain members whose keys are the column names and whose values are the column values.

Row data is modeled as follows:

- Inserts: Includes the after-image data.
- Updates: Includes the after-image data.
- Deletes: Includes the before-image data.

Column values for an operation from the source trail file can have one of three states: the column has a value, the column value is null, or the column value is missing. The JSON Formatter maps these column value states into the created JSON objects as follows:

• The column has a value: The column value is output. In the following example, the member STATE has a value.

```
"CUST_CODE":"BILL", "NAME":"BILL'S USED CARS",
"CITY":"DENVER", "STATE":"CO" }
```

 The column value is null :The default output value is a JSON NULL. In the following example, the member STATE is null.

```
"CUST_CODE":"BILL", "NAME":"BILL'S USED CARS",
"CITY":"DENVER", "STATE":null }
```

• The column value is missing: The JSON contains no element for a missing column value. In the following example, the member STATE is missing.

```
"CUST_CODE":"BILL", "NAME":"BILL'S USED CARS",
"CITY":"DENVER", }
```

The default setting of the JSON Formatter is to map the data types from the source trail file to the associated JSON data type. JSON supports few data types, so this functionality usually results in the mapping of numeric fields from the source trail file to members typed as numbers. This data type mapping can be configured to treat all data as strings.

# Sample JSON Messages

The following topics are sample JSON messages created by the JSON Formatter for insert, update, delete, and truncate operations.

- Sample Operation Modeled JSON Messages
- Sample Flattened Operation Modeled JSON Messages
- Sample Row Modeled JSON Messages
- Sample Primary Key Output JSON Message

    }
}
```

# JSON Schemas

By default, JSON schemas are generated for each source table encountered. JSON schemas are generated on a just in time basis when an operation for that table is first encountered. A JSON schema is not required to parse a JSON object. However, many JSON parsers can use a JSON schema to perform a validating parse of a JSON object. Alternatively, you can review the JSON schemas to understand the layout of output JSON objects. By default, the JSON schemas are created in the *GoldenGate Home*/dirdef directory and are named by the following convention:

```
FULLY QUALIFIED TABLE NAME.schema.json
```

The generation of the JSON schemas is suppressible.

The following JSON schema example is for the JSON object listed in Sample Operation Modeled JSON Messages.

```
"CUST_CODE":{
                     "type":[
                         "string",
                         "null"
                     ]
                 },
                 "ORDER DATE":{
                     "type":[
                         "string",
                         "null"
                     ]
                 },
                 "PRODUCT CODE":{
                     "type":[
                         "string",
                         "null"
                     ]
                 },
                 "ORDER ID":{
                     "type":[
                         "number",
                         "null"
                     1
                 },
                 "PRODUCT_PRICE":{
                     "type":[
                         "number",
                         "null"
                     ]
                 },

# JSON Formatter Configuration Properties

}

Table 8-48	JSON Formatter Configuration Properties
------------	---

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format	Optional	json  json_row	None	Controls whether the generated JSON output messages are operation modeled or row modeled. Set to json for operation modeled orjson_row for row modeled.
<pre>gg.handler.name.format .insertOpKey</pre>	Optional	Any string	I	Indicator to be inserted into the output record to indicate an insert operation.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name.</i> format .updateOpKey	Optional	Any string	U	Indicator to be inserted into the output record to indicate an update operation.
gg.handler. <i>name</i> .format .deleteOpKey	Optional	Any string	D	Indicator to be inserted into the output record to indicate a delete operation.
gg.handler. <i>name</i> .format .truncateOpKey	Optional	Any string	Т	Indicator to be inserted into the output record to indicate a truncate operation.
gg.handler. <i>name.</i> format .prettyPrint	Optional	true false	false	Controls the output format of the JSON data. True formats the data with white space for easy reading. False generates more compact output that is difficult to read
gg.handler. <i>nam</i> e.format .jsonDelimiter	Optional	Any string	"" (no value)	Inserts a delimiter between generated JSONs so that they can be more easily parsed in a continuous stream of data. Configuration value supports CDATA[] wrapping.
gg.handler. <i>name</i> .format .generateSchema	Optional	true false	true	Controls the generation of JSON schemas for the generated JSON documents. JSON schemas are generated on a table-by-table basis. A JSON schema is not required to parse a JSON document. However, a JSON schemahelp indicate what the JSON documents look like and can be used for a validating JSON parse.
gg.handler. <i>name</i> .format .schemaDirectory	Optional	Any legal, existing file system path	./dirdef	Controls the output location of generated JSON schemas.
gg.handler. <i>name.</i> format .treatAllColumnsAsStri ngs		true   false	false	Controls the output typing of generated JSON documents. When false, the formatter attempts to map Oracle GoldenGate types to the corresponding JSON type. When true, all data is treated as strings in the generated JSONs and JSON schemas.
gg.handler. <i>name.</i> format .encoding	Optional	Any legal encoding name or alias supported by Java.	UTF-8 (the JSON default)	Controls the output encoding of generated JSON schemas and documents.
gg.handler. <i>name</i> .format .versionSchemas	Optional	true   false	false	Controls the version of created schemas. Schema versioning creates a schema with a timestamp in the schema directory on the local file system every time a new schema is created. True enables schema versioning. False disables schema versioning.

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format .iso8601Format	Optional	true false	true	Controls the format of the current timestamp. The default is the ISO 8601 format. A setting of false removes the "T" between the date and time in the current timestamp, which outputs a single space ("") instead.
gg.handler. <i>name</i> .format .flatten	Optional	true false	false	Controls sending flattened JSON formatted data to the target entity. Must be set to true for the flatten Delimiter property to work.
				This property is applicable only to Operation Formatted JSON (gg.handler.name.format=json).
gg.handler. <i>name</i> .format .flattenDelimiter	Optional	Any legal character or character string for a JSON field name.		Controls the delimiter for concatenated JSON element names. This property supports CDATA[] wrapping to preserve whitespace. It is only relevant when gg.handler.name.format.flatten is set to true.
gg.handler. <i>name</i> .format .beforeObjectName	Optional	Any legal character or character string for a JSON field name.	Any legal JSON attribute name.	Allows you to set whether the JSON element-before, that contains the change column values, can be renamed. This property is only applicable to Operation Formatted JSON (gg.handler.name.format=json).
gg.handler. <i>name</i> .format .afterObjectName	Optional	Any legal character or character string for a JSON field name.	Any legal JSON attribute name.	Allows you to set whether the JSON element, that contains the after-change column values, can be renamed. This property is only applicable to Operation Formatted JSON (gg.handler.name.format=json).

Table 8-48	(Cont.) JSON Formatter Configuration Properties
------------	---

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name.</i> format .pkUpdateHandling	Optional	abend  update  delete- insert	abend	Specifies how the formatter handles update operations that change a primary key. Primary key operations can be problematic for the JSON formatter and you need to speacially consider it. You can only use this property in conjunction with the row modeled JSON output messages.
				<ul> <li>This property is only applicable to Row Formatted JSON (gg.handler.name.format=json_row).</li> <li>abend: indicates that the process terminates.</li> <li>update: the process handles the operation as a normal update.</li> <li>delete or insert: the process handles the operation as a delete and an insert. Full supplemental logging must be enabled. Without full before and after row images, the insert data will be incomplete.</li> </ul>
<pre>gg.handler.name.format .omitNullValues</pre>	Optional	true   false	false	Set to true to omit fields that have null values from being included in the generated JSON output.
gg.handler.name.format .omitNullValuesSpecial UpdateHandling	Optional	true   false	false	Only applicable if gg.handler.name.format.omitNull Values=true. When set to true, it provides special handling to propagate the null value on the update after image if the before image data is missing or has a value.
gg.handler.name.format .enableJsonArrayOutput	Optional	true   false	false	Set to true to nest JSON documents representing the operation data into a JSON array. This works for file output and Kafka messages in transaction mode.

 Table 8-48
 (Cont.) JSON Formatter Configuration Properties

Properties	Required/ Optional	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format .metaColumnsTemplate	Optional	See Metacolumn Keywords	None	The current meta column information can be configured in a simple manner and removes the explicit need to use:
				<pre>insertOpKey   updateOpKey   deleteOpKey   truncateOpKey   includeTableName   includeOpTimestamp   includeOpType   includePosition   includeCurrentTimestamp, useIso8601Format It is a comma-delimited string consisting of one or more templated values that represent the template.</pre>
				For more information about the Metacolumn keywords, see Metacolumn Keywords.
				<pre>This is an example that would produce a list of metacolumns: \${optype}, \$ {token.ROWID}, \$ {sys.username}, \$ {currenttimestamp}</pre>

 Table 8-48
 (Cont.) JSON Formatter Configuration Properties

# **Review a Sample Configuration**

The following is a sample configuration for the JSON Formatter in the Java Adapter configuration file:

```
gg.handler.hdfs.format=json
gg.handler.hdfs.format.insertOpKey=I
gg.handler.hdfs.format.updateOpKey=U
gg.handler.hdfs.format.deleteOpKey=D
gg.handler.hdfs.format.truncateOpKey=T
gg.handler.hdfs.format.prettyPrint=false
gg.handler.hdfs.format.jsonDelimiter=CDATA[]
gg.handler.hdfs.format.generateSchema=true
gg.handler.hdfs.format.schemaDirectory=dirdef
gg.handler.hdfs.format.treatAllColumnsAsStrings=false
```

# Metadata Change Events

Metadata change events are handled at runtime. When metadata is changed in a table, the JSON schema is regenerated the next time an operation for the table is encountered. The content of created JSON messages changes to reflect the metadata change. For example, if an additional column is added, the new column is included in created JSON messages after the metadata change event.

# JSON Primary Key Updates

When the JSON formatter is configured to model operation data, primary key updates require no special treatment and are treated like any other update. The before and after values reflect the change in the primary key.

When the JSON formatter is configured to model row data, primary key updates must be specially handled. The default behavior is to abend. However, by using thegg.handler.name.format.pkUpdateHandling configuration property, you can configure the JSON formatter to model row data to treat primary key updates as either a regular update or as delete and then insert operations. When you configure the formatter to handle primary key updates as delete and insert operations, Oracle recommends that you configure your replication stream to contain the complete before-image and after-image data for updates. Otherwise, the generated insert operation for a primary key update will be missing data for fields that did not change.

# Integrating Oracle Stream Analytics

You can integrate Oracle GoldenGate for Big Data with Oracle Stream Analytics (OSA) by sending operation-modeled JSON messages to the Kafka Handler. This works only when the JSON formatter is configured to output operation-modeled JSON messages.

Because OSA requires flattened JSON objects, a new feature in the JSON formatter generates flattened JSONs. To use this feature, set the

gg.handler.*name*.format.flatten=false to true. (The default setting is false). The following is an example of a flattened JSON file:

```
{
    "table":"QASOURCE.TCUSTMER",
    "op_type":"U",
    "op_ts":"2015-11-05 18:45:39.000000",
    "current_ts":"2016-06-22T13:38:45.335001",
    "pos":"000000000000005100",
    "before.CUST_CODE":"ANN",
    "before.NAME":"ANN'S BOATS",
    "before.CITY":"SEATTLE",
    "before.STATE":"WA",
    "after.CUST_CODE":"ANN",
    "after.CITY":"NEW YORK",
    "after.STATE":"NY"
}
```

# Using the Length Delimited Value Formatter

The Length Delimited Value (LDV) Formatter is a row-based formatter. It formats database operations from the source trail file into a length delimited value output. Each insert, update, delete, or truncate operation from the source trail is formatted into an individual length delimited message.

With the length delimited, there are no field delimiters. The fields are variable in size based on the data.

By default, the length delimited maps these column value states into the length delimited value output. Column values for an operation from the source trail file can have one of three states:

- Column has a value The column value is output with the prefix indicator P.
- Column value is NULL —The default output value is N. The output for the case of a NULL column value is configurable.

- Column value is missing The default output value is M. The output for the case of a missing column value is configurable.
- Formatting Message Details
- Sample Formatted Messages
- LDV Formatter Configuration Properties
- Additional Considerations

# Formatting Message Details

The default format for output of data is the following:

# First is the row Length followed by metadata:

<ROW LENGTH><PRESENT INDICATOR><FIELD LENGTH><OPERATION TYPE><PRESENT
INDICATOR><FIELD LENGTH><FULLY QUALIFIED TABLE NAME><PRESENT INDICATOR><FIELD
LENGTH><OPERATION TIMESTAMP><PRESENT INDICATOR><FIELD LENGTH><CURRENT
TIMESTAMP><PRESENT INDICATOR><FIELD LENGTH><TRAIL POSITION><PRESENT INDICATOR><FIELD
LENGTH><TOKENS>

#### Or

<ROW LENGTH><FIELD LENGTH><FULLY QUALIFIED TABLE NAME><FIELD LENGTH><OPERATION
TIMESTAMP><FIELD LENGTH><CURRENT TIMESTAMP><FIELD LENGTH><TRAIL POSITION><FIELD
LENGTH><TOKENS>

#### Next is the row data:

<present INDICATOR><FIELD LENGTH><COLUMN 1 VALUE><PRESENT INDICATOR><FIELD LENGTH><COLUMN N VALUE>

# LDV Formatter Configuration Properties

Properties	Require d/ Option al	Legal Values	Defau It	Explanation
gg.handler. <i>nam</i> e.format.binar yLengthMode	Optional	true  false	false	The output can be controlled to display the field or record length in either binary or ASCII format. If set to true, the record or field length is represented in binary format else in ASCII.
gg.handler. <i>nam</i> e.format.recor dLength	Optional	4   8	true	Set to true, the record length is represented using either a 4 or 8-byte big Endian integer. Set to false, the string representation of the record length with padded value with configured length of 4 or 8 is used.
gg.handler. <i>nam</i> e.format.field Length	Optional	2   4	true	Set to true, the record length is represented using either a 2 or 4-byte big Endian integer. Set to false, the string representation of the record length with padded value with configured length of 2 or 4 is used.
gg.handler. <i>nam</i> e.format.forma t	Optional	true  false	true	Use to configure the Pindicator with MetaColumn. Set to false, enables the indicator P before the MetaColumns. If set to true, disables the indicator.
gg.handler. <i>nam</i> e.format.prese ntValue	Optional	Any string	Ρ	Use to configure what is included in the output when a column value is present. This value supports CDATA[] wrapping.
gg.handler. <i>nam</i> e.format.missi ngValue	Optional	Any string	М	Use to configure what is included in the output when a missing value is present. This value supports CDATA[] wrapping.
gg.handler. <i>nam</i> e.format.nullV alue	Optional	Any string	N	Use to configure what is included in the output when a NULL value is present. This value supports CDATA[] wrapping.
gg.handler. <i>nam</i> e.format.metaC olumnsTemplate	Optional	See Metacolu mn Keywords	None	Use to configure the current meta column information in a simple manner and removes the explicit need of insertOpKey, updateOpKey, deleteOpKey, truncateOpKey, includeTableName, includeOpTimestamp, includeOpType, includePosition, includeCurrentTimestamp and useIso8601Format. A comma-delimited string consisting of one or more templated values represents the template. This example produces a list of meta columns: \${optype}, \${token.ROWID},\$ {sys.username},\${currenttimestamp} See Metacolumn Keywords.

 Table 8-49
 LDV Formatter Configuration Properties

Properties	Require d/ Option al	Legal Values	Defau It	Explanation
gg.handler. <i>nam</i> e.format.pkUpd ateHandling	Optional	abend  update  delete- insert	abend	<ul> <li>Specifies how the formatter handles update operations that change a primary key.</li> <li>Primary key operations can be problematic for the text formatter and require special consideration by you.</li> <li>abend : indicates the process will abend</li> <li>update : indicates the process will treat this as a normal update</li> <li>delete-insert: indicates the process handles this as a delete and an insert. Full supplemental logging must be enabled for this to work. Without full before and after row images, the insert data will be incomplete.</li> </ul>
gg.handler. <i>nam</i> e.format.encod ing	Optional	Any encoding name or alias supporte d by Java.	The native syste m encod ing of the machi ne hostin g the Oracl e Golde nGate proce ss.	Use to set the output encoding for character data and columns.

Table 8-49 (Cont.) LDV Formatter Configuration Propertie
--

For more information about the Metacolumn keywords, see Metacolumn Keywords. This is an example that would produce a list of metacolumns:

\${optype}, \${token.ROWID}, \${sys.username}, \${currenttimestamp}

#### **Review a Sample Configuration**

```
#The LDV Handler
gg.handler.filewriter.format=binary
gg.handler.filewriter.format.binaryLengthMode=false
gg.handler.filewriter.format.recordLength=4
gg.handler.filewriter.format.fieldLength=2
gg.handler.filewriter.format.legacyFormat=false
gg.handler.filewriter.format.presentValue=CDATA[P]
gg.handler.filewriter.format.missingValue=CDATA[M]

gg.handler.filewriter.format.metaColumnsTemplate=${optype},${timestampmicro},$
{currenttimestampmicro},${timestamp}
gg.handler.filewriter.format.pkUpdateHandling=abend
```

# Additional Considerations

Big Data applications differ from RDBMSs in how data is stored. Update and delete operations in an RDBMS result in a change to the existing data. Data is not changed in Big Data applications, it is simply appended to existing data. The current state of a given row becomes a consolidation of all of the existing operations for that row in the HDFS system.

# **Primary Key Updates**

Primary key update operations require special consideration and planning for Big Data integrations. Primary key updates are update operations that modify one or more of the primary keys for the given row from the source database. Since data is simply appended in Big Data applications, a primary key update operation looks more like a new insert than an update without any special handling. The Length Delimited Value Formatter provides specialized handling for primary keys that is configurable to you. These are the configurable behaviors:

Value	Description
Abend	The default behavior is that the length delimited value formatter will abend in the case of a primary key update.
Update	With this configuration the primary key update will be treated just like any other update operation. This configuration alternative should only be selected if you can guarantee that the primary key that is being changed is not being used as the selection criteria when selecting row data from a Big Data system.
Delete- Insert	Using this configuration the primary key update is treated as a special case of a delete using the before image data and an insert using the after image data. This configuration may more accurately model the effect of a primary key update in a Big Data application. However, if this configuration is selected it is important to have full supplemental logging enabled on replication at the source database. Without full supplemental logging, the delete operation will be correct, but the insert operation do not contain all of the data for all of the columns for a full representation of the row data in the Big Data application.

# **Consolidating Data**

Big Data applications simply append data to the underlying storage. Typically, analytic tools spawn map reduce programs that traverse the data files and consolidate all the operations for a given row into a single output. It is important to have an indicator of the order of operations. The Length Delimited Value Formatter provides a number of metadata fields to fulfill this need. The operation timestamp may be sufficient to fulfill this requirement. However, two update operations may have the same operation timestamp especially if they share a common transaction. The trail position can provide a tie breaking field on the operation timestamp. Lastly, the current timestamp may provide the best indicator of order of operations in Big Data.

# Using the XML Formatter

The XML Formatter formats before-image and after-image data from the source trail file into an XML document representation of the operation data. The format of the XML document is effectively the same as the XML format in the previous releases of the Oracle GoldenGate Java Adapter.

- Sample XML Messages
- XML Schema
- XML Formatter Configuration Properties
- Review a Sample Configuration
- Metadata Change Events
- Primary Key Updates

# Message Formatting Details

The XML formatted messages contain the following information:

Table 8-51	XML formatting details
------------	------------------------

Value	Description
table	The fully qualified table name.
type	The operation type.
current_ts	The current timestamp is the time when the formatter processed the current operation record. This timestamp follows the ISO-8601 format and includes micro second precision. Replaying the trail file does not result in the same timestamp for the same operation.
pos	The position from the source trail file.
numCols	The total number of columns in the source table.
col	The $col$ element is a repeating element that contains the before and after images of operation data.
tokens	The tokens element contains the token values from the source trail file.

### XML Schema

The XML Formatter does not generate an XML schema (XSD). The XSD applies to all messages generated by the XML Formatter. The following XSD defines the structure of the XML documents that are generated by the XML Formatter.

```
<xs:schema attributeFormDefault="unqualified"</pre>
elementFormDefault="qualified" xmlns:xs="http://www.w3.org/2001/XMLSchema">
   <xs:element name="operation">
     <xs:complexType>
       <xs:sequence>
          <xs:element name="col" maxOccurs="unbounded" minOccurs="0">
           <xs:complexType>
             <xs:sequence>
               <xs:element name="before" minOccurs="0">
                 <xs:complexType>
                   <xs:simpleContent>
                      <xs:extension base="xs:string">
                        <xs:attribute type="xs:string" name="missing"</pre>
use="optional"/>
                      </xs:extension>
                   </xs:simpleContent>
                 </xs:complexType>
               </xs:element>
               <xs:element name="after" minOccurs="0">
                 <xs:complexType>
                   <xs:simpleContent>
                     <xs:extension base="xs:string">
                       <xs:attribute type="xs:string" name="missing"</pre>
use="optional"/>
                      </xs:extension>
                   </xs:simpleContent>
                 </xs:complexType>
               </xs:element>
               <xs:element type="xs:string" name="missing" minOccurs="0"/>
```

```
</xs:sequence>
             <xs:attribute type="xs:string" name="name"/>
             <xs:attribute type="xs:short" name="index"/>
           </xs:complexType>
         </xs:element>
         <xs:element name="tokens" minOccurs="0">
           <xs:complexType>
             <xs:sequence>
               <xs:element name="token" maxOccurs="unbounded" minOccurs="0">
                 <xs:complexType>
                  <xs:sequence>
                     <xs:element type="xs:string" name="Name"/>
                     <xs:element type="xs:string" name="Value"/>
                  </xs:sequence>
                 </xs:complexType>
               </xs:element>
             </xs:sequence>
           </xs:complexType>
         </xs:element>
       </xs:sequence>
       <xs:attribute type="xs:string" name="table"/>
      <xs:attribute type="xs:string" name="type"/>
      <xs:attribute type="xs:string" name="ts"/>
      <xs:attribute type="xs:dateTime" name="current ts"/>
      <xs:attribute type="xs:long" name="pos"/>
      <xs:attribute type="xs:short" name="numCols"/>
    </xs:complexType>
   </xs:element>
</xs:schema>
```

### XML Formatter Configuration Properties

Properties	Optional	Legal	Default	Explanation
	Y/N	Values		
gg.handler. <i>name</i> .format.insertO pKey	Optional	Any string	I	Indicator to be inserted into the output record to indicate an insert operation.
gg.handler. <i>name</i> .format.updateO pKey	Optional	Any string	U	Indicator to be inserted into the output record to indicate an update operation.
gg.handler. <i>name</i> .format.deleteO pKey	Optional	Any string	D	Indicator to be inserted into the output record to indicate a delete operation.
gg.handler. <i>name</i> .format.truncat eOpKey	Optional	Any string	Т	Indicator to be inserted into the output record to indicate a truncate operation.
gg.handler. <i>name</i> .format.encodin g	Optional	Any legal encoding name or alias supported by Java.	UTF-8 (the XML default)	The output encoding of generated XML documents.

### Table 8-52 XML Formatter Configuration Properties

Properties	Optional Y/N	Legal Values	Default	Explanation
gg.handler. <i>name</i> .format.include Prolog	Optional	true false	false	Determines whether an XML prolog is included in generated XML documents. An XML prolog is optional for well-formed XML. An XML prolog resembles the following: xml version='1.0'<br encoding='UTF-8'?>
gg.handler. <i>name</i> .format.iso8601 Format	Optional	true false	true	Controls the format of the current timestamp in the XML message. The default adds a T between the date and time. Set to false to suppress the T between the date and time and instead include blank space.
gg.handler. <i>name</i> .format.missing	Optional	true false	true	Set to true, the XML output displays the missing column value of the before and after image.
gg.handler. <i>name</i> .format.missing After	Optional	true false	true	Set to true, the XML output displays the missing column value of the after image.
gg.handler. <i>name</i> .format.missing Before	Optional	true false	true	Set to true, the XML output displays the missing column value of the before image.
gg.handler. <i>name</i> .format.metaCol umnsTemplate	Optional	See Metacolumn Keywords.	None	The current meta column information can be configured in a simple manner and removes the explicit need to use:
				<pre>insertOpKey   updateOpKey   deleteOpKey   truncateOpKey   includeTableName   includeOpTimestamp   includeOpType   includeCurrentTimestamp, useIso8601Format It is a comma-delimited string consisting of one or more templated values that represent the template. For more information about the Metacolumn keywords, see Metacolumn Keywords.</pre>

 Table 8-52
 (Cont.) XML Formatter Configuration Properties

### Review a Sample Configuration

The following is a sample configuration for the XML Formatter in the Java Adapter properties file:

```
gg.handler.hdfs.format=xml
gg.handler.hdfs.format.insertOpKey=I
gg.handler.hdfs.format.updateOpKey=U
```

gg.handler.hdfs.format.deleteOpKey=D
gg.handler.hdfs.format.truncateOpKey=T
gg.handler.hdfs.format.encoding=ISO-8859-1
gg.handler.hdfs.format.includeProlog=false

### Metadata Change Events

The XML Formatter seamlessly handles metadata change events. A metadata change event does not result in a change to the XML schema. The XML schema is designed to be generic so that the same schema represents the data of any operation from any table.

If the replicated database and upstream Oracle GoldenGate replication process can propagate metadata change events, the XML Formatter can take action when metadata changes. Changes in the metadata are reflected in messages after the change. For example, when a column is added, the new column data appears in XML messages for the table.

### **Primary Key Updates**

Updates to a primary key require no special handling by the XML formatter. The XML formatter creates messages that model database operations. For update operations, this includes before and after images of column values. Primary key changes are represented in this format as a change to a column value just like a change to any other column value.

### Stage and Merge Data Warehouse Replication

Data warehouse targets typically support Massively Parallel Processing (MPP). The cost of a single Data Manipulation Language (DML) operation is comparable to the cost of execution of batch DMLs.

Therefore, for better throughput the change data from the Oracle GoldenGate trails can be staged in micro batches at a temporary staging location, and the staged data records are merged into the data warehouse target table using the respective data warehouse's merge SQL statement. This section outlines an approach to replicate change data records from source databases to target data warehouses using stage and merge. The solution uses Command Event handler to invoke custom bash-shell scripts.

This chapter contains examples of what you can do with command event handler feature.

- Steps for Stage and Merge
- Hive Stage and Merge

Hive is a data warehouse infrastructure built on top of Hadoop. It provides tools to enable easy data ETL, a mechanism to put structures on the data, and the capability for querying and analysis of large data sets stored in Hadoop files.

### Steps for Stage and Merge

Stage

In this step the change data records in the Oracle GoldenGate trail files are pushed into a staging location. The staging location is typically a cloud object store such as OCI, AWS S3, Azure Data Lake, or Google Cloud Storage.

Merge

In this step the change data files in the object store are viewed as an external table defined in the data warehouse. The data in the external staging table is merged onto the target table.

### Configuration of Handlers

File Writer(FW) handler needs to be configured to generate local staging files that contain change data from the GoldenGate trail files.

- File Writer Handler File Writer (FW) handler is typically configured to generate files partitioned by table using the configuration gg.handler.{name}.partitionByTable=true.
- Operation Aggregation

Operation aggregation is the process of aggregating (merging/compressing) multiple operations on the same row into a single output operation based on a threshold.

• Object Store Event handler

The File Writer handler needs to be chained with an object store Event handler. Oracle GoldenGate for BigData supports uploading files to most cloud object stores such as OCI, AWS S3, and Azure Data Lake.

### • JDBC Metadata Provider

If the data warehouse supports JDBC connection, then the JDBC metadata provider needs to be enabled.

### Command Event handler Merge Script

Command Event handler is configured to invoke a bash-shell script. Oracle provides a bash-shell script that can execute the SQL statements so that the change data in the staging files are merged into the target tables.

Stage and Merge Sample Configuration
 A working configuration for the respective data warehouse is available under the directory AdapterExamples/big-data/data-warehouse-utils/<target>/.

### • Variables in the Merge Script

Typically, variables appear at the beginning of the Oracle provided script. There are lines starting with #TODO: that document the changes required for variables in the script.

SQL Statements in the Merge Script

The SQL statements in the shell script needs to be customized. There are lines starting with #TODO: that document the changes required for SQL statements.

- Merge Script Functions
- Prerequisites
- Limitations

### Stage

In this step the change data records in the Oracle GoldenGate trail files are pushed into a staging location. The staging location is typically a cloud object store such as OCI, AWS S3, Azure Data Lake, or Google Cloud Storage.

This can be achieved using File Writer handler and one of the Oracle GoldenGate for Big Data object store Event handlers.

### Merge

In this step the change data files in the object store are viewed as an external table defined in the data warehouse. The data in the external staging table is merged onto the target table.

Merge SQL uses the external table as the staging table. The merge is a batch operation leading to better throughput.

### Configuration of Handlers

File Writer(FW) handler needs to be configured to generate local staging files that contain change data from the GoldenGate trail files.

The FW handler needs to be chained to an object store Event handler that can upload the staging files into a staging location.

The staging location is typically a cloud object store, such as AWS S3 or Azure Data Lake.

The output of the object store event handler is chained with the Command Event handler that can invoke custom scripts to execute merge SQL statements on the target data warehouse.

### File Writer Handler

File Writer (FW) handler is typically configured to generate files partitioned by table using the configuration gg.handler.{name}.partitionByTable=true.

In most cases FW handler is configured to use the Avro Object Container Format (OCF) formatter.

The output file format could change based on the specific data warehouse target.

### Operation Aggregation

Operation aggregation is the process of aggregating (merging/compressing) multiple operations on the same row into a single output operation based on a threshold.

Operation Aggregation needs to be enabled for stage and merge replication using the configuration gg.aggregate.operations=true.

### **Object Store Event handler**

The File Writer handler needs to be chained with an object store Event handler. Oracle GoldenGate for BigData supports uploading files to most cloud object stores such as OCI, AWS S3, and Azure Data Lake.

### JDBC Metadata Provider

If the data warehouse supports JDBC connection, then the JDBC metadata provider needs to be enabled.

### Command Event handler Merge Script

Command Event handler is configured to invoke a bash-shell script. Oracle provides a bashshell script that can execute the SQL statements so that the change data in the staging files are merged into the target tables.

The shell script needs to be customized as per the required configuration before starting the replicat process.

### Stage and Merge Sample Configuration

A working configuration for the respective data warehouse is available under the directory AdapterExamples/big-data/data-warehouse-utils/<target>/.

This directory contains the following:

- replicat parameter (.prm) file.
- replicat properties file that contains the FW handler and all the Event handler configuration.
- DDL file for the sample table used in the merge script.
- Merge script for the specific data warehouse. This script contains SQL statements tested using the sample table defined in the DDL file.

### Variables in the Merge Script

Typically, variables appear at the beginning of the Oracle provided script. There are lines starting with #TODO: that document the changes required for variables in the script.

#### Example:

```
#TODO: Edit this. Provide the replicat group name.
repName=RBD
#TODO: Edit this. Ensure each replicat uses a unique prefix.
stagingTablePrefix=${repName}_STAGE_
#TODO: Edit the AWS S3 bucket name.
bucket=<AWS S3 bucket name>
#TODO: Edit this variable as needed.
s3Location="'s3://${bucket}/${dir}/'"
#TODO: Edit AWS credentials awsKeyId and awsSecretKey
awsKeyId=<AWS Access Key Id>
```

awsSecretKey=<AWS Secret key>

The variables repName and stagingTablePrefix are relevant for all the data warehouse targets.

### SQL Statements in the Merge Script

The SQL statements in the shell script needs to be customized. There are lines starting with #TODO: that document the changes required for SQL statements.

In most cases, we need to double quote " identifiers in the SQL statement. The double quote needs to be escaped in the script using backslash. For example: ".

Oracle provides a working example of SQL statements for a single table with a predefined set of columns defined in the sample DDL file. You need to add new sections for your own tables as part of *if-else* code block in the script.

#### Example:

```
if [ "${tableName}" == "DBO.TCUSTORD" ]
then
```

```
#TODO: Edit all the column names of the staging and target tables.
# The merge SQL example here is configured for the example table defined in the DDL
file.
# Oracle provided SQL statements
# TODO: Add similar SQL queries for each table.
elif [ "${tableName}" == "DBO.ANOTHER_TABLE" ]
then
#Edit SQLs for this table.
fi
```

### Merge Script Functions

The script is coded to include the following shell functions:

- main
- validateParams
- process
- processTruncate
- processDML
- dropExternalTable
- createExternalTable
- merge

The script has code comments for you to infer the purpose of each function.

#### Merge Script main function

The function main is the entry point of the script. The processing of the staged changed data file begin here.

This function invokes two functions: validateParams and process.

The input parameters to the script is validated in the function: validateParams.

Processing resumes in the process function if validation is successful.

### Merge Script process function

This function processes the operation records in the staged change data file and invokes processTruncate or processDML as needed.

Truncate operation records are handled in the function processTruncate. Insert, Update, and Delete operation records are handled in the function processDML.

#### Merge Script merge function

The merge function invoked by the function processDML contains the merge SQL statement that will be executed for each table.

The key columns to be used in the merge SQL's ON clause needs to be customized.

To handle key columns with null values, the ON clause uses data warehouse specific NVL functions. Example for a single key column "COlkey":

ON ((NVL(CAST(TARGET.\"C01Key\" AS VARCHAR(4000)),'\$
{uuid}')=NVL(CAST(STAGE.\"C01Key\" AS VARCHAR(4000)),'\${uuid}')))`

The column names in the merge statement's update and insert clauses also needs to be customized for every table.

#### Merge Script createExternalTable function

The createExternalTable function invoked by the function processDML creates an external table that is backed by the file in the respective object store file.

In this function, the DDL SQL statement for the external table should be customized for every target table to include all the target table columns.

In addition to the target table columns, the external table definition also consists of three meta-columns: optype, position, and fieldmask.

The data type of the meta-columns should not be modified. The position of the metacolumns should not be modified in the DDL statement.

### Prerequisites

- The Command handler merge scripts are available, starting from Oracle GoldenGate for BigData release 19.1.0.0.8.
- The respective data warehouse's command line programs to execute SQL queries must be installed on the machine where GoldenGate for Big Data is installed.

### Limitations

Primary key update operations are split into delete and insert pair. In case the Oracle GoldenGate trail file doesn't contain column values for all the columns in the respective table, then the missing columns gets updated to null on the target table.

### Hive Stage and Merge

Hive is a data warehouse infrastructure built on top of Hadoop. It provides tools to enable easy data ETL, a mechanism to put structures on the data, and the capability for querying and analysis of large data sets stored in Hadoop files.

This topic contains examples of what you can do with the Hive command event handler

- Data Flow
- Configuration

The directory AdapterExamples/big-data/data-warehouse-utils/hive/ in the Oracle GoldenGate BigData install contains all the configuration and scripts needed needed for replication to Hive using stage and merge.

- Merge Script Variables
- Prerequisites

### Data Flow

- File Writer (FW) handler is configured to generate files in Avro Object Container Format (OCF).
- The HDFS Event handler is used to push the Avro OCF files into Hadoop.

• The Command Event handler passes the Hadoop file metadata to the hive.sh script.

### Configuration

The directory AdapterExamples/big-data/data-warehouse-utils/hive/ in the Oracle GoldenGate BigData install contains all the configuration and scripts needed needed for replication to Hive using stage and merge.

The following are the files:

- hive.prm: The replicat parameter file.
- hive.props: The replicat properties file that stages data to Hadoop and runs the Command Event handler.
- hive.sh: The bash-shell script that reads data staged in Hadoop and merges data to Hive target table.
- hive-ddl.sql: The DDL statement that contains sample target table used in the script hive.sh.

Edit the properties indicated by the #TODO: comments in the properties file hive.props.

The bash-shell script function merge() contains SQL statements that needs to be customized for your target tables.

### Merge Script Variables

#### Modify the variables needs as needed:

```
#TODO: Modify the location of the OGGBD dirdef directory where the Avro schema files
exist.
avroSchemaDir=/opt/ogg/dirdef
```

#TODO: Edit the JDBC URL to connect to hive. hiveJdbcUrl=jdbc:hive2://localhost:10000/default #TODO: Edit the JDBC user to connect to hive. hiveJdbcUser=APP #TODO: Edit the JDBC password to connect to hive. hiveJdbcPassword=mine

#TODO: Edit the replicat group name. repName=HIVE #TODO: Edit this. Ensure each replicat uses a unique prefix.

### Prerequisites

The following are the prerequisites:

stagingTablePrefix=\${repName} STAGE

- The merge script hive.sh requires command line program beeline to be installed on the machine where Oracle GoldenGate for BigData replicat is installed.
- The custom script hive.sh uses the merge SQL statement. Hive Query Language (Hive QL) introduced support for merge in Hive version 2.2.

# **Template Keywords**

The templating functionality allows you to use a mix of constants and/or keywords for context based resolution of string values at runtime. The templating functionality is used extensively in the Oracle GoldenGate for Big Data to resolve file paths, file names, topic names, or message keys. This appendix describes the keywords and their associated arguments if applicable. Additionally, there are examples showing templates and resolved values.

### **Template Keywords**

This table includes a column if the keyword is supported for transaction level messages.

Keyword	Explanation	Transaction Message Support
\$ {fullyQualifiedTableNam e}	Resolves to the fully qualified table name including the period (.) delimiter between the catalog, schema, and table names.	No
	For example, TEST.DBO.TABLE1.	
<pre>\${catalogName}</pre>	Resolves to the catalog name.	No
\${schemaName}	Resolves to the schema name.	No
\${tableName}	Resolves to the short table name.	No
\${opType}	Resolves to the type of the operation: (INSERT, UPDATE, DELETE, or TRUNCATE)	No
<pre>\${primaryKeys[]}</pre>	The first parameter is optional and allows you to set the delimiter between primary key values. The default is	No
\${position}	The sequence number of the source trail file followed by the offset (RBA).	Yes
\${opTimestamp}	The operation timestamp from the source trail file.	Yes
<pre>\${emptyString}</pre>	Resolves to "".	Yes
\${groupName}	Resolves to the name of the Replicat process. If using coordinated delivery, it resolves to the name of the Replicat process with the Replicate thread number appended.	Yes

Keyword	Explanation	Transaction Message Support
<pre>\${staticMap[]} or \${staticMap[][]}</pre>	Resolves to a static value where the key is the fully- qualified table name. The keys and values are designated inside of the square brace in the following format: \$ {staticMap[DB0.TABLE1=v alue1,DB0.TABLE2=value2 ]} The second parameter is an optional default value. If the	No
	value cannot be located using the lookup by the table name, then the default value will be used instead.	
\${xid}	Resolves the transaction id.	Yes
<pre>\${columnValue[][]} or \${columnValue[][]]}</pre>	Resolves to a column value where the key is the fully- qualified table name and the value is the column name to be resolved. For example:	No
	<pre>\$ {columnValue[DB0.TABLE1 =COL1, DB0.TABLE2=COL2]} The second parameter is optional and allows you to set the value to use if the column value is null. The default is an</pre>	
	empty string "". The third parameter is optional and allows you to set the value to use if the column value is missing. The default is an empty string "".	
	If the \${columnValue} keyword is used in partitioning, then only the column name needs to be set. Only the HDFS Handler and the File Writer Handler support partitioning. In the case of partitioning, the table name is already known because partitioning configuration is separate for each and every source table. The following is an example of \$ {columnValue} when used in the context of partitioning:	
	<pre>\${columnValue[COL1]} or \${columnValue[COL2] [NULL][MISSING]}</pre>	

Keyword	Explanation	Transaction Message Support
<pre>\${currentTimestamp} Or \${currentTimestamp[]}</pre>	Resolves to the current timestamp. You can control the format of the current timestamp using the Java based formatting as described in the SimpleDateFormat class, see https:// docs.oracle.com/javase/8/ docs/api/java/text/ SimpleDateFormat.html	Yes
	Examples:	
	<pre>\${currentTimestamp}\$ {currentTimestamp[yyyy- MM-dd HH:mm:ss.SSS]}</pre>	
\${null}	Resolves to a NULL string.	Yes
\${custom[]}	It is possible to write a custom value resolver. If required, contact Oracle Support.	Implementation dependent
\${token[]}	Resolves a token value.	No
<pre>\${toLowerCase[]}</pre>	Keyword to convert to argument to lower case. Argument can be constants, keywords, or combination of both.	Yes
<pre>\${toUpperCase[]}</pre>	Keyword to convert to argument to upper case. Argument can be constants, keywords, or combination of both.	Yes

Keyword	Ex	planation		Transaction Message Support
<pre>\${substring[][]} Or \${substring[][]]}</pre>	sub	word to perform ostring operation ofigured content.	on the	Yes
	<ol> <li>The string on which the substring functionality i acting. Can be nested keywords, constants, o combination of both.</li> </ol>		tionality is nested stants, or a	
	2.	The starting in	dex.	
	3.	The ending inc provided then the input string {substring[ ][4]} returns {substring[ ][4][6]} retu	the end of J.) \$ thisisfun isfun. \$ thisisfun

<pre>\${truncateCount}</pre>	Keyword to resolve the count of truncate operations.	Yes
\${uuid}	Keyword to resolve a universally unique identifier (UUID). This is a 36 character string guaranteed to be unique. An example UUID: 7f6e4529-e387-48c1- a1b6-3e7a4146b211	Yes

### **Example Templates**

The following describes example template configuration values and the resolved values.

Example Template	Resolved Value
<pre>\${groupName}_\$ {fullyQualfiedTableName}</pre>	KAFKA001_DBO.TABLE1
<pre>prefix_\${schemaName}_\$ {tableName}_suffix</pre>	prefix_DBO_TABLE1_suffix
<pre>\${currentTimestamp[yyyy-MM-dd HH:mm:ss.SSS]}</pre>	2017-05-17 11:45:34.254
A_STATIC_VALUE	A_STATIC_VALUE

### **Velocity Dependencies**

Starting Oracle GoldenGate for Big Data release 21.1.0.0.0, the Velocity jar files have been removed from the packaging.

For the Velocity formatting to work, you need to download the jars and include them in their runtime by modifying the gg.classpath.

The maven coordinates for Velocity are as follows:

Maven groupId: org.apache.velocity

Maven artifactId: velocity

Version: 1.7

# 9 Administer

- Automatic Heartbeat for Big Data This chapter describes how to enable Heartbeat for Oracle GoldenGate for Big Data and how to manage and modify heartbeat across the replication environment.

- Oracle GoldenGate Java Delivery

# Automatic Heartbeat for Big Data

This chapter describes how to enable Heartbeat for Oracle GoldenGate for Big Data and how to manage and modify heartbeat across the replication environment.

- Overview
- Automatic Heartbeat Tables

# Overview

To enable HEARTBEATTABLE for Oracle GoldenGate for BigData, you need to:

- Specify GGSCHEMA in GLOBALS with any value, for example, GGSCHEMA GGADMIN.
- **Execute** ADD HEARTBEATTABLE from GGSCI.

In Oracle GoldenGate for RDBMS, the HEARTBEATTABLE records are applied to the following target HEARTBEATTABLE tables: GGADMIN.GG HEARTBEAT and GGADMIN.GG HEARBEAT HISTORY.

### Two Modes of HEARTBEATTABLE in Oracle GoldenGate for Big Data

In mode1, the records that are handled by Oracle GoldenGate for Big Data are written to HEARTBEATTABLE files. For example,

Table GGADMIN.GG\_HEARTBEAT is stored in file dirtmp/<replicat name>-hb.json. Here, the records are written to the replicat file hb.json.

Table GGADMIN.GG\_HEARTBEAT\_HISTORY is stored in dirtmp/<replicat-name>-hb-<date>.json. Here, the History records re written to the hb-<date>.json file.

Mode 2 is *passthrough* that enables you to send a statement directly to a non-Oracle system, such as Kafka without first being interpreted by Big Data.

To apply HEARTBEATTABLE as user data:

- Disable HEARTBEATTABLE by specifying DISABLEHEARTBEATTABLE in the replicat parameter file.
- Specify HEARTBEATTABLE tables in the replicat MAP statements:

```
MAP GGADMIN.GG_HEARTBEAT, TARGET
GGADMIN.GG_HEARTBEAT;
MAP GGADMIN.GG_HEARTBEAT_HISTORY, TARGET
GGADMIN.GG_HEARTBEAT_HISTORY;
```

When applied as user data, the HEARTBEAT records GG\_HEARTBEAT and GG\_HEARTBEAT\_HISTORY are written to the handler as if they are user tables. The HEARTBEAT records are not stored in tables like RDBMS, but in .json files.

# Automatic Heartbeat Tables

- ADD HEARTBEATTABLE
- ALTER HEARTBEAT TABLE
- INFO HEARTBEATTABLE
- LAG
- DELETE HEARTBEATTABLE

### ADD HEARTBEATTABLE

#### ADD HEARTBEATTABLE

- [, RETENTION\_TIME number in days] |
- [, PURGE\_FREQUENCY number in days]

### **RETENTION\_TIME**

Specifies when heartbeat entries older than the retention time in the history table are purged. The default is 30 days.

### PURGE FREQUENCY

Specifies how often the purge scheduler is run to delete table entries that are older than the retention time from the heartbeat history. The default is 1 day.

### Example:

```
GGSCI > ADD HEARTBEATTABLE
HEARTBEAT is now enabled:
HEARTBEAT configuration file in dirprm\heartbeat.properties
heartbeat.enabled=true
heartbeat.frequency=60
heartbeat.retention_time=30
heartbeat.purge.frequency=1
heartbeat.db.name=BigData
```

### Note:

Ensure to run the ADD HEARTBEATTABLE command before processing the trail file through the replicat.

# ALTER HEARTBEAT TABLE

#### ALTER HEARTBEATTABLE

- [, RETENTION\_TIME number in days] |
- [, PURGE FREQUENCY number in days]

### **RETENTION\_TIME**

Update heartbeat.retention\_time in dirprm/heartbeat.properties; will take affect on the next restart.

### PURGE\_FREQUENCY

Specifies how often entries older than the retention time are purged from the GG\_HEARTBEAT\_HISTORY. The default is 1 day.

### INFO HEARTBEATTABLE

#### Example

```
HEARTBEAT configuration file dirprm\heartbeat.properties
heartbeat.enabled=true
heartbeat.frequency=60
heartbeat.retention_time=30
heartbeat.purge.frequency=1
heartbeat.db.name=BigData
```

### LAG

#### LAG <replicat name>

#### Example

GGSCI> LAG rtpc				
Lag Information F	rom Heartbeat Table			
LAG	AGE	FROM	TO	PATH
5.77s	10m 22.87s	ORCL	BIGDATA	ETPC ==> PTPC ==> RTPC

### LAG <replicat name> HISTORY

GGSCI> LAG rtpc HISTORY

### Example

Lag Inf	ormation Fro	om Heartbeat	Table

2018-07-04	8.77s	9.90s	9.20s

# DELETE HEARTBEATTABLE

### DELETE HEARTBEATTABLE

#### Example

GGSCI> DELETE HEARTBEATTABLE

# Java Message Service (JMS)

This article explains using the Oracle GoldenGate for Big Data to capture Java Message Service (JMS) messages to be written to an Oracle GoldenGate trail.

- Prerequisites
- Configuring Message Capture

# Prerequisites

• Set up Credential Store Entry to Detect Source Type

### Set up Credential Store Entry to Detect Source Type

### **JMS Capture**

Similar to Kafka, for the sake of detecting the source type, user can create a credential store entry with the prefix: jms://. **Example** 

alter credentialstore add user jms:// password <anypassword> alias jms

If the extract parameter file does not specify SOURCEDB parameter with USERIDALIAS option, then the source type will be assumed to be JMS, and a warning message will be logged to indicate this.

## Configuring Message Capture

This chapter explains how to configure the VAM Extract to capture JMS messages.

- Configuring the VAM Extract
- Connecting and Retrieving the Messages

### Configuring the VAM Extract

JMS Capture only works with the Oracle GoldenGate Extract process. To run the Java message capture application you need the following:

- Oracle GoldenGate for Java Adapter
- Extract process
- Extract parameter file configured for message capture

- Description of the incoming data format, such as a source definitions file.
- Java 8 installed on the host machine
- Adding the Extract
- Configuring the Extract Parameters
- Configuring Message Capture

### Adding the Extract

To add the message capture VAM to the Oracle GoldenGate installation, add an Extract and the trail that it will create using GGSCI commands:

```
ADD EXTRACT jmsvam, VAM
ADD EXTTRAIL dirdat/id, EXTRACT jmsvam, MEGABYTES 100
```

The process name (jmsvam) can be replaced with any process name that is no more than 8 characters. The trail identifier (id) can be any two characters.

### Note:

Commands to position the Extract, such as BEGIN or EXTRBA, are not supported for message capture. The Extract will always resume by reading messages from the end of the message queue.

### Configuring the Extract Parameters

The Extract parameter file contains the parameters needed to define and invoke the VAM. Sample Extract parameters for communicating with the VAM are shown in the table.

Parameter	Description
EXTRACT jmsvam	The name of the Extract process.
VAM ggjava_vam.dll, PARAMS dirprm/jmsvam.properties	Specifies the name of the VAM library and the location of the properties file. The VAM properties should be in the dirprm directory of the Oracle GoldenGate installation location.
TRANLOGOPTIONS VAMCOMPATIBILITY 1	Specifies the original (1) implementation of the VAM is to be used.
TRANLOGOPTIONS GETMETADATAFROMVAM	Specifies that metadata will be sent by the VAM.
EXTTRAIL dirdat/id	Specifies the identifier of the target trail Extract creates.

### Configuring Message Capture

Message capture is configured by the properties in the VAM properties file (Adapter Properties file. This file is identified by the PARAMS option of the Extract VAM parameter and used to determine logging characteristics, parser mappings and JMS connection settings.

# Connecting and Retrieving the Messages

To process JMS messages you must configure the connection to the JMS interface, retrieve and parse the messages in a transaction, write each message to a trail, commit the transaction, and remove its messages from the queue.

- Connecting to JMS
- Retrieving Messages
- Completing the Transaction

### Connecting to JMS

Connectivity to JMS is through a generic JMS interface. Properties can be set to configure the following characteristics of the connection:

- Java classpath for the JMS client
- Name of the JMS queue or topic source destination
- · Java Naming and Directory Interface (JNDI) connection properties
  - Connection properties for Initial Context
  - Connection factory name
  - Destination name
- Security information
  - JNDI authentication credentials
  - JMS user name and password

The Extract process that is configured to work with the VAM (such as the jmsvam in the example) will connect to the message system. when it starts up.

### Note:

The Extract may be included in the Manger's AUTORESTART list so it will automatically be restarted if there are connection problems during processing.

Currently the Oracle GoldenGate for Java message capture adapter supports only JMS text messages.

### **Retrieving Messages**

The connection processing performs the following steps when asked for the next message:

- Start a local JMS transaction if one is not already started.
- Read a message from the message queue.
- If the read fails because no message exists, return an end-of-file message.
- Otherwise return the contents of the message.

### Completing the Transaction

Once all of the messages that make up a transaction have been successfully retrieved, parsed, and written to the Oracle GoldenGate trail, the local JMS transaction is committed and the messages removed from the queue or topic. If there is an error the local transaction is rolled back leaving the messages in the JMS queue.

# Parsing the Message

- Parsing Overview
- Fixed Width Parsing
- Delimited Parsing
- XML Parsing
- Source Definitions Generation Utility

# Parsing Overview

The role of the parser is to translate JMS text message data and header properties into an appropriate set of transactions and operations to pass into the VAM interface. To do this, the parser always must find certain data:

- Transaction identifier
- Sequence identifier
- Timestamp
- Table name
- Operation type
- Column data specific to a particular table name and operation type

Other data will be used if the configuration requires it:

- Transaction indicator
- Transaction name
- Transaction owner

The parser can obtain this data from JMS header properties, system generated values, static values, or in some parser-specific way. This depends on the nature of the piece of information.

- Parser Types
- Source and Target Data Definitions
- Required Data
- Optional Data

### Parser Types

The Oracle GoldenGate message capture adapter supports three types of parsers:

Fixed – Messages contain data presented as fixed width fields in contiguous text.

- Delimited Messages contain data delimited by field and end of record characters.
- XML Messages contain XML data accessed through XPath expressions.

### Source and Target Data Definitions

There are several ways source data definitions can be defined using a combination of properties and external files.

There are several properties that configure how the selected parser gets data and how the source definitions are converted to target definitions.

### **Required Data**

The following information is required for the parsers to translate the messages:

- Transaction Identifier
- Sequence Identifier
- Timestamp
- Table Name
- Operation Type
- Column Data

### **Transaction Identifier**

The transaction identifier (txid) groups operations into transactions as they are written to the Oracle GoldenGate trail file. The Oracle GoldenGate message capture adapter supports only contiguous, non-interleaved transactions. The transaction identifier can be any unique value that increases for each transaction. A system generated value can generally be used.

### Sequence Identifier

The sequence identifier (seqid) identifies each operation internally. This can be used during recovery processing to identify operations that have already been written to the Oracle GoldenGate trail. The sequence identifier can be any unique value that increases for each operation. The length should be fixed.

The JMS Message ID can be used as a sequence identifier if the message identifier for that provider increases and is unique. However, there are cases (for example, using clustering, failed transactions) where JMS does not guarantee message order or when the ID may be unique but not be increasing. The system generated Sequence ID can be used, but it can cause duplicate messages under some recovery situations. The recommended approach is to have the JMS client that adds messages to the queue set the Message ID, a header property, or some data element to an application-generated unique value that is increasing.

### Timestamp

The timestamp (timestamp) is used as the commit timestamp of operations within the Oracle GoldenGate trail. It should be increasing but this is not required, and it does not

have to be unique between transactions or operations. It can be any date format that can be parsed.

### Table Name

The table name is used to identify the logical table to which the column data belongs. The adapter requires a two part table name in the form <code>SCHEMA\_NAME.TABLE\_NAME</code>. This can either be defined separately (schema and table) or as a combination of schema and table (schemaandtable).

A single field may contain both schema and table name, they may be in separate fields, or the schema may be included in the software code so only the table name is required. How the schema and table names can be specified depends on the parser. In any case the two part logical table name is used to write records in the Oracle GoldenGate trail and to generate the source definitions file that describes the trail.

### **Operation Type**

The operation type (optype) is used to determine whether an operation is an insert, update or delete when written to the Oracle GoldenGate trail. The operation type value for any specific operation is matched against the values defined for each operation type.

The data written to the Oracle GoldenGate trail for each operation type depends on the Extract configuration:

- Inserts
  - The after values of all columns are written to the trail.
- Updates
  - Default The after values of keys are written. The after values of columns that have changed are written if the before values are present and can be compared. If before values are not present then all columns are written.
  - NOCOMPRESSUPDATES The after values of all columns are written to the trail.
  - GETUPDATEBEFORES The before and after values of columns that have changed are written to the trail if the before values are present and can be compared. If before values are not present only after values are written.
  - If both NOCOMPRESSUPDATES and GETUPDATEBEFORES are included, the before and after values of all columns are written to the trail if before values are present
- Deletes
  - Default The before values of all keys are written to the trail.
  - NOCOMPRESSDELETES The before values of all columns are written to the trail.

Primary key update operations may also be generated if the before values of keys are present and do not match the after values.

### Column Data

All parsers retrieve column data from the message text and write it to the Oracle GoldenGate trail. In some cases the columns are read in index order as defined by the source definitions, in other cases they are accessed by name.

Depending on the configuration and original message text, both before and after or only after images of the column data may be available. For updates, the data for nonupdated columns may or may not be available.

All column data is retrieved as text. It is converted internally into the correct data type for that column based on the source definitions. Any conversion problem will result in an error and the process will abend.

### **Optional Data**

The following data may be included, but is not required.

- Transaction Indicator
- Transaction Name
- Transaction Owner

### **Transaction Indicator**

The relationship of transactions to messages can be:

One transaction per message

This is determined automatically by the scope of the message.

Multiple transactions per message

This is determined by the transaction indicator (txind). If there is no transaction indicator, the XML parser can create transactions based on a matching transaction rule.

Multiple messages per transaction

The transaction indicator (txind) is required to specify whether the operation is the beginning, middle, end or the whole transaction. The transaction indicator value for any specific operation is matched against the values defined for each transaction indicator type. A transaction is started if the indicator value is beginning or whole, continued if it is middle, and ended if it is end or whole.

### **Transaction Name**

The transaction name (txname) is optional data that can be used to associate an arbitrary name to a transaction. This can be added to the trail as a token using a GETENV function.

### **Transaction Owner**

The transaction owner (txowner) is optional data that can be used to associate an arbitrary user name to a transaction. This can be added to the trail as a token using a GETENV function, or used to exclude certain transactions from processing using the EXCLUDEUSER Extract parameter.

# **Fixed Width Parsing**

Fixed width parsing is based on a data definition that defines the position and the length of each field. This is in the format of a Cobol copybook. A set of properties

define rules for mapping the copybook to logical records in the Oracle GoldenGate trail and in the source definitions file.

The incoming data should consist of a standard format header followed by a data segment. Both should contain fixed width fields. The data is parsed based on the PIC definition in the copybook. It is written to the trail translated as explained in Header and Record Data Type Translation.

- Header
- Header and Record Data Type Translation
- Key identification
- Using a Source Definition File

### Header

The header must be defined by a copybook 01 level record that includes the following:

- A commit timestamp or a change time for the record
- · A code to indicate the type of operation: insert, update, or delete
- The copybook record name to use when parsing the data segment

Any fields in the header record that are not mapped to Oracle GoldenGate header fields are output as columns.

The following example shows a copybook definition containing the required header values

### Example 9-1 Specifying a Header

```
01 HEADER.
20 Hdr-Timestamp PIC X(23)
20 Hdr-Source-DB-Function PIC X
20 Hdr-Source-DB-Rec-ID PIC X(8)
```

For the preceding example, you must set the following properties:

```
fixed.header=HEADER
fixed.timestamp=Hdr-Timestamp
fixed.optype=Hdr-Source-DB-Function
fixed.table=Hdr-Source-DB-Rec-Id
```

The logical name table output in this case will be the value of Hdr-Source-DB-Rec-Id.

- Specifying Compound Table Names
- Specifying timestamp Formats
- Specifying the Function

### Specifying Compound Table Names

More than one field can be used for a table name. For example, you can define the logical schema name through a static property such as:

fixed.schema=MYSCHEMA

You can then add a property that defines the data record as multiple fields from the copybook header definition.

### Example 9-2 Specifying Compound Table Names

HEA	DER.		
20	Hdr-Source-DB	PIC X(8).	
20	Hdr-Source-DB-Rec-Id	PIC X(8).	
20	Hdr-Source-DB-Rec-Version	PIC 9(4).	
20	Hdr-Source-DB-Function	PIC X.	
20	Hdr-Timestamp	PIC X(22)	•
	20 20 20 20	HEADER. 20 Hdr-Source-DB 20 Hdr-Source-DB-Rec-Id 20 Hdr-Source-DB-Rec-Version 20 Hdr-Source-DB-Function 20 Hdr-Timestamp	20Hdr-Source-DBPIC X(8).20Hdr-Source-DB-Rec-IdPIC X(8).20Hdr-Source-DB-Rec-VersionPIC 9(4).20Hdr-Source-DB-FunctionPIC X.

#### For the preceding example, you must set the following properties:

```
fixed.header=HEADER
fixed.table=Hdr-Source-DB-Rec-Id,Hdr-Source-DB-Rec-Version
fixed.schema=MYSCHEMA
```

The fields will be concatenated to result in logical schema and table names of the form:

MYSCHEMA.Hdr-Source-DB-Rec-Id+Hdr-Source-DB-Rec-Version

### Specifying timestamp Formats

A timestamp is parsed using the default format YYYY-MM-DD HH:MM:SS.FFF, with FFF depending on the size of the field.

Specify different incoming formats by entering a comment before the datetime field as shown in the next example.

#### Example 9-3 Specifying timestamp formats

```
01 HEADER.
* DATEFORMAT YYYY-MM-DD-HH.MM.SS.FF
20 Hdr-Timestamp PIC X(23)
```

### Specifying the Function

Use properties to map the standard Oracle GoldenGate operation types to the optype values. The following example specifies that the operation type is in the Hdr-Source-DB-Function field and that the value for insert is A, update is U and delete is D.

### Example 9-4 Specifying the Function

```
fixed.optype=Hdr-Source-DB-Function
fixed.optype.insert=A
fixed.optype.update=U
fixed.optype.delete=D
```

### Header and Record Data Type Translation

The data in the header and the record data are written to the trail based on the translated data type.

- A field definition preceded by a date format comment is translated to an Oracle GoldenGate datetime field of the specified size. If there is no date format comment, the field will be defined by its underlying data type.
- A PIC X field is translated to the CHAR data type of the indicated size.

• A PIC 9 field is translated to a NUMBER data type with the defined precision and scale. Numbers that are signed or unsigned and those with or without decimals are supported.

The following examples show the translation for various  ${\tt PIC}$  definitions.

Input	Output
PIC XX	CHAR (2)
PIC X(16)	CHAR(16)
PIC 9(4)	NUMBER(4)
* YYMMDD PIC 9(6)	DATE(10) YYYY-MM-DD
PIC 99.99	NUMBER(4,2)

In the example an input YYMMDD date of 100522 is translated to 2010-05-22. The number 1234567 with the specified format PIC 9(5)V99 is translated to a seven digit number with two decimal places, or 12345.67.

### Key identification

A comment is used to identify key columns within the data record.

In the following example Account has been marked as a key column for TABLE1.

```
01 TABLE1
* KEY
20 Account PIC X(19)
20 PAN_Seq_Num PIC 9(3)
```

### Using a Source Definition File

You can use fixed width parsing based on a data definition that comes from an Oracle GoldenGate source definition file. This is similar to Cobol copybook because a source definition file contains the position and the length of each field of participating tables. To use a source definition file, you must set the following properties:

```
fixed.userdefs.tables=qasource.HEADER
fixed.userdefs.qasource.HEADER.columns=optype,schemaandtable
fixed.userdefs.qasource.HEADER.optype=vchar 3
fixed.userdefs.qasource.HEADER.schemaandtable=vchar 30
```

```
fixed.header=qasource.HEADER
```

The following example defines a header section of a total length of 33 characters; the first 3 characters are the operation type, and the last 30 characters is the table name. The layout of all records to be parsed must start with the complete header section as defined in the fixed.userdefs properties. For each record, the header section is immediately followed by the content of all column data for the corresponding table. The column data must be strictly

laid out according to its offset and length defined in the source definition file. Specifically, the offset information is the fourth field (Fetch Offset) of the column definition and the length information is the third field (External Length) of the column definition. The following is an example of a definition for GG.JMSCAP\_TCUSTMER:

```
Definition for table GG.JMSCAP TCUSTMER
Record length: 78
Syskey: 0
Columns: 4
CUST CODE
                 4
                                             4
                                                    0 0 0 0 0
          64
                        0 0 0 1 0
                                        4
1 0 1 0
                                             30
NAME
          64
                30
                        10 0 0 1 0
                                       30
                                                    0 0 0 0 0

```

The fixed width data for GG.JMSCAP\_TCUSTMER may be similar to the following where the offset guides have been added to each section for clarity:

0 1 2 3 0 1 2 5 7 3 4 6 8 01234567890123456789012345678901201234567890123456789012345678901234567 8901234567890123456789012345678901234567890 I GG.JMSCAP TCUSTMER WILL BG SOFTWARE SEATTLE WA JANE ROCKY FLYER CO. I GG.JMSCAP TCUSTMER DENVER INC. СО DAVE'S PLANES DAVE I GG.JMSCAP TCUSTMER INC. TALLAHASSEE FL BILL BILL'S USED I GG.JMSCAP TCUSTMER CARS DENVER CO I GG.JMSCAP TCUSTMER ANN ANN'S SEATTLE BOATS WA U GG.JMSCAP TCUSTMER ANN ANN'S BOATS NEW YORK NY

You can choose to specify shorter data records, which means that only some of the earlier columns are present. To do this, the following requirements must be met:

- None of the missing or omitted columns are part of the key and
- all columns that are present contain complete data according to their respective External Length information

# **Delimited Parsing**

Delimited parsing is based a preexisting source definitions files and a set of properties. The properties specify the delimiters to use and other rules, such as whether there are column names and before values. The source definitions file determines the valid tables to be processed and the order and data type of the columns in the tables.

#### The format of the delimited message is:

 $\textit{METACOLS}^{n}[,\textit{COLNAMES}]^{m}[,\textit{COLBEFOREVALS}]^{m}, \{\textit{COLVALUES}\}^{m} \backslash n$ 

#### Where:

- There can be *n* metadata columns each followed by a field delimiter such as the comma shown in the format statement.
- There can be *m* column values. Each of these are preceded by a field delimiter such as a comma.
- The column name and before value are optional.
- Each record is terminated by an end of line delimiter, such as \n.

The message to be parsed *must* contain at least the header and metadata columns. If the number of columns is fewer than the number of header and meta columns, then the capture process terminates and provides an error message.

The remaining number of columns after the header and metadata columns are the column data for the corresponding table, specified in the order of the columns in the resolved metadata. Ideally, the number of table columns present in the message is exactly the same as the expected number of columns according to the metadata. However, missing columns in the message towards the end of message is allowed and the parser marks those last columns (not present in the rest of the message) as missing column data.

Although missing data is allowed from parser perspective, if the key @ column(s) is/are missing, then the capture process will also terminate.

Oracle GoldenGate primary key updates and unified updates are not supported. The only supported operations are inserts, updates, deletes, and truncates.

- Metadata Columns
- Parsing Properties
- Parsing Steps

## Metadata Columns

The metadata columns correspond to the header and contain fields that have special meaning. Metadata columns should include the following information.

- **optype** contains values indicating if the record is an insert, update, or delete. The default values are I, U, and D.
- **timestamp** indicates type of value to use for the commit timestamp of the record. The format of the timestamp defaults to YYYY-DD-MM HH:MM:SS.FFF.
- schemaandtable is the full table name for the record in the format SCHEMA.TABLE.
- schema is the record's schema name.
- **table** is the record's table name.
- **txind** is a value that indicates whether the record is the beginning, middle, end or the only record in the transaction. The default values are 0, 1, 2, 3.
- **id** is the value used as the sequence number (RSN or CSN) of the record. The id of the first record (operation) in the transaction is used for the sequence number of the transaction.

# **Parsing Properties**

Properties can be set to describe delimiters, values, and date and time formats.

- Properties to Describe Delimiters
- Properties to Describe Values
- Properties to Describe Date and Time

### Properties to Describe Delimiters

The following properties determine the parsing rules for delimiting the record.

- **fielddelim** specifies one or more ASCII or hexadecimal characters as the value for the field delimiter
- **recorddelim** specifies one or more ASCII or hexadecimal characters as the value for the record delimiter
- quote specifies one or more ASCII or hexadecimal characters to use for quoted values
- nullindicator specifies one or more ASCII or hexadecimal characters to use for NULL values

You can define escape characters for the delimiters so they will be replaced if the characters are found in the text. For example if a backslash and apostrophe (\') are specified, then the input "They used Mike\'s truck" is translated to "They used Mike's truck". Or if two quotes ("") are specified, "They call him ""Big Al""" is translated to "They call him "Big Al"".

Data values may be present in the record without quotes, but the system only removes escape characters within quoted values. A non-quoted string that matches a null indicator is treated as null.

### Properties to Describe Values

The following properties provide more information:

- hasbefores indicates before values are present for each record
- hasnames indicates column names are present for each record
- afterfirst indicates column after values come before column before values
- **isgrouped** indicates all column names, before values and after values are grouped together in three blocks, rather than alternately per column

### Properties to Describe Date and Time

The default format YYYY-DD-MM HH:MM:SS.FFF is used to parse dates. You can use properties to override this on a global, table or column level. Examples of changing the format are shown below.

delim.dateformat.default=MM/DD/YYYY-HH:MM:SS
delim.dateformat.MY.TABLE=DD/MMM/YYYY
delim.dateformat.MY.TABLE.COL1=MMYYYY

# Parsing Steps

The steps in delimited parsing are:

- 1. The parser first reads and validates the metadata columns for each record.
- 2. This provides the table name, which can then be used to look up column definitions for that table in the source definitions file.
- 3. If a definition cannot be found for a table, the processing will stop.
- 4. Otherwise the columns are parsed and output to the trail in the order and format defined by the source definitions.

# XML Parsing

XML parsing is based on a preexisting source definitions file and a set of properties. The properties specify rules to determine XML elements and attributes that correspond to transactions, operations and columns. The source definitions file determines the valid tables to be processed and the ordering and data types of columns in those tables.

- Styles of XML
- XML Parsing Rules
- XPath Expressions
- Other Value Expressions
- Transaction Rules
- Operation Rules
- Column Rules
- Overall Rules Example

## Styles of XML

The XML message is formatted in either dynamic or static XML. At runtime the contents of dynamic XML are data values that cannot be predetermined using a sample XML or XSD document. The contents of static XML that determine tables and column element or attribute names can be predetermined using those sample documents.

The following two examples contain the same data.

#### Example 9-5 An Example of Static XML

```
<NewMyTableEntries>

<NewMyTableEntry>

<CreateTime>2010-02-05:10:11:21</CreateTime>

<KeyCol>keyval</KeyCol>

<Col1>col1val</Col1>

</NewMyTableEntry>

</NewMyTableEntries>
```

The NewMyTableEntries element marks the transaction boundaries. The NewMyTableEntry indicates an insert to MY.TABLE. The timestamp is present in an element text value, and the column names are indicated by element names.

You can define rules in the properties file to parse either of these two styles of XML through a set of XPath-like properties. The goal of the properties is to map the XML to a predefined source definitions file through XPath matches.

#### Example 9-6 An Example of Dynamic XML

```
<transaction id="1234" ts="2010-02-05:10:11:21">
<operation table="MY.TABLE" optype="I">
<column name="keycol" index="0">
<aftervalue><![CDATA[keyval]]></aftervalue>
</column>
<column name="col1" index="1">
<aftervalue><![CDATA[col1val]]></aftervalue>
</column>
</operation>
</transaction>
```

Every operation to every table has the same basic message structure consisting of transaction, operation and column elements. The table name, operation type, timestamp, column names, column values, etc. are obtained from attribute or element text values.

## XML Parsing Rules

Independent of the style of XML, the parsing process needs to determine:

- Transaction boundaries
- Operation entries and metadata including:
  - Table name
  - Operation type
  - Timestamp
- Column entries and metadata including:
  - Either the column name or index; if both are specified the system will check to see if the column with the specified data has the specified name.
  - Column before or after values, sometimes both.

This is done through a set of interrelated rules. For each type of XML message that is to be processed you name a rule that will be used to obtain the required data. For each of these named rules you add properties to:

- Specify the rule as a transaction, operation, or column rule type. Rules of any type are required to have a specified name and type.
- Specify the XPath expression to match to see if the rule is active for the document being processed. This is optional; if not defined the parser will match the node of the parent rule or the whole document if this is the first rule.
- List detailed rules (subrules) that are to be processed in the order listed. Which subrules are valid is determined by the rule type. Subrules are optional.

In the following example the top-level rule is defined as genericrule. It is a transaction type rule. Its subrules are defined in oprule and they are of the type operation.

```
xmlparser.rules=genericrule
xmlparser.rules.genericrule.type=tx
```

```
xmlparser.rules.genericrule.subrules=oprule
xmlparser.rules.oprule.type=op
```

# **XPath Expressions**

The XML parser supports a subset of XPath expressions necessary to match elements and Extract data. An expression can be used to match a particular element or to Extract data.

When doing data extraction most of the path is used to match. The tail of the expression is used for extraction.

- Supported Constructs:
- Supported Expressions
- Obtaining Data Values

## Supported Constructs:

Supported Constructs	Description	
/e	Use the absolute path from the root of the document to match $\ensuremath{e}.$	
./e or e	Use the relative path from current node being processed to match $\ensuremath{\mathrm{e}}.$	
/e	Use a path based on the parent of the current node (can be repeated) to match $\ensuremath{e}.$	
//e	Match e wherever it occurs in a document.	
*	Match any element. Note: Partially wild-carded names are not supported.	
[n]	Match the nth occurrence of an expression.	
[x=v]	Match when x is equal to some value v where x can be:	
	• @att - some attribute value	
	• text() - some text value	
	• name() - some name value	
	• position() - the element position	

## Supported Expressions

Supported Expressions	Descriptions	
Match root element	/My/Element	
Match sub element to current node	./Sub/Element	
Match nth element	/My/*[n]	

Supported Expressions	Descriptions
Match nth Some element	/My/Some[n]
Match any text value	<pre>/My/*[text() ='value']</pre>
Match the text in Some element	<pre>/My/Some[text() = 'value']</pre>
Match any attribute	<pre>/My/*[@att = 'value']</pre>
Match the attribute in Some element	<pre>/My/Some[@att = 'value']</pre>

## **Obtaining Data Values**

In addition to matching paths, the XPath expressions can also be used to obtain data values, either absolutely or relative to the current node being processed. Data value expressions can contain any of the path elements in the preceding table, but must end with one of the value accessors listed below.

Value Accessors	Description
@att	Some attribute value.
text()	The text content (value) of an element.
content()	The full content of an element, including any child XML nodes.
name()	The name of an element.
position()	The position of an element in its parent.

#### Example 9-7 Examples of Extracting Data Values

To extract the relative element text value:

/My/Element/text()

To extract the absolute attribute value:

/My/Element/@att

#### To extract element text value with a match:

/My/Some[@att = 'value']/Sub/text()

### Note:

Path accessors, such as ancestor/descendent/self, are not supported.

# Other Value Expressions

The values extracted by the XML parser are either column values or properties of the transaction or operation, such as table or timestamp. These values are either obtained from XML using XPath or through properties of the JMS message, system values, or hard coded values. The XML parser properties specify which of these options are valid for obtaining the values for that property.

The following example specifies that timestamp can be an XPath expression, a JMS property, or the system generated timestamp.

{txrule}.timestamp={xpath-expression}|\${jms-property}|\*ts

The next example specifies that table can be an XPath expression, a JMS property, or hard coded value.

{oprule}.table={xpath-expression}|\${jms-property}|"value"

The last example specifies that name can be a XPath expression or hard coded value.

{colrule}.timestamp={xpath-expression}|"value"

## **Transaction Rules**

The rule that specifies the boundary for a transaction is at the highest level. Messages may contain a single transaction, multiple transactions, or a part of a transaction that spans messages. These are specified as follows:

- **single** The transaction rule match is not defined.
- multiple Each transaction rule match defines new transaction.
- **span** No transaction rule is defined; instead a transaction indicator is specified in an operation rule.

For a transaction rule, the following properties of the rule may also be defined through XPath or other expressions:

- timestamp The time at which the transaction occurred.
- txid The identifier for the transaction.

Transaction rules can have multiple subrules, but each must be of type operation.

The following example specifies a transaction that is the whole message and includes a timestamp that comes from the JMS property.

#### Example 9-8 JMS Timestamp

singletxrule.timestamp=\$JMSTimeStamp

The following example matches the root element transaction and obtains the timestamp from the  ${\tt ts}$  attribute.

#### Example 9-9 ts Timestamp

```
dyntxrule.match=/Transaction
dyntxrule.timestamp=@ts
```

# **Operation Rules**

An operation rule can either be a sub rule of a transaction rule, or a highest level rule (if the transaction is a property of the operation).

In addition to the standard rule properties, an operation rule should also define the following through XPath or other expressions:

- timestamp The timestamp of the operation. This is optional if the transaction rule is defined.
- **table** The name of the table on which this is an operation. Use this with schema.
- schema The name of schema for the table.
- schemaandtable Both schema and table name together in the form SCHEMA.TABLE. This can be used in place of the individual table and schema properties.
- optype Specifies whether this is an insert, update or delete operation based on optype values:
  - optype.insertval The value indicating an insert. The default is I.
  - optype.updateval The value indicating an update. The default is U.
  - optype.deleteval The value indicating a delete. The default is D.
- **seqid** The identifier for the operation. This will be the transaction identifier if txid has not already been defined at the transaction level.
- **txind** Specifies whether this operation is the beginning of a transaction, in the middle or at the end; or if it is the whole operation. This property is optional and not valid if the operation rule is a sub rule of a transaction rule.

Operation rules can have multiple sub rules of type operation or column.

The following example dynamically obtains operation information from the /Operation element of a /Transaction.

#### Example 9-10 Operation

```
dynoprule.match=./Operation
dynoprule.schemaandtable=@table
dynoprule.optype=@type
```

The following example statically matches /NewMyTableEntry element to an insert operation on the MY.TABLE table.

#### Example 9-11 Operation example

```
statoprule.match=./NewMyTableEntry
statoprule.schemaandtable="MY.TABLE"
statoprule.optype="I"
statoprule.timestamp=./CreateTime/text()
```

## Column Rules

A column rule must be a sub rule of an operation rule. In addition to the standard rule properties, a column rule should also define the following through XPath or other expressions.

- **name** The name of the column within the table definition.
- index The index of the column within the table definition.

#### Note:

If only one of name and index is defined, the other will be determined.

- before.value The before value of the column. This is required for deletes, but is optional for updates.
- **before.isnull** Indicates whether the before value of the column is null.
- before.ismissing Indicates whether the before value of the column is missing.
- after.value The before value of the column. This is required for deletes, but is optional for updates.
- after.isnull Indicates whether the before value of the column is null.
- after.ismissing Indicates whether the before value of the column is missing.
- **value** An expression to use for both before.value and after.value unless overridden by specific before or after values. Note that this does not support different before values for updates.
- isnull An expression to use for both before.isnull and after.isnull unless overridden.
- ismissing An expression to use for both before.ismissing and after.ismissing unless overridden.

The following example dynamically obtains column information from the  $/{\tt Column}$  element of an /Operation

#### Example 9-12 Dynamic Extraction of Column Information

```
dyncolrule.match=./Column
dyncolrule.name=@name
dyncolrule.before.value=./beforevalue/text()
dyncolrule.after.value=./aftervalue/text()
```

The following example statically matches the /KeyCol and /Coll elements to columns in MY.TABLE.

#### Example 9-13 Static Matching of Elements to Columns

```
statkeycolrule.match=/KeyCol
statkeycolrule.name="keycol"
statkeycolrule.value=./text()
statcollrule.match=/Coll
statcollrule.name="coll"
statcollrule.value=./text()
```

## **Overall Rules Example**

The following example uses the XML samples shown earlier with appropriate rules to generate the same resulting operation on the MY.TABLE table.

#### Dynamic XML

```
<transaction id="1234"
    ts="2010-02-05:10:11:21">
  <operation table="MY.TABLE"</pre>
optype="I">
    <column name="keycol" index="0">
      <aftervalue>
<! [CDATA[keyval]]>
     </aftervalue>
    </column>
    <column name="col1" index="1">
      <aftervalue>
         <![CDATA[col1val]]>
      </aftervalue>
    </column>
  </operation>
</transaction>
```

#### Static XML

```
NewMyTableEntries>
   <NewMyTableEntry>
        <CreateTime>
            2010-02-05:10:11:21
            </CreateTime>
            <KeyCol>keyval</KeyCol>
            <Coll>collval</Coll>
            </NewMyTableEntry>
        </NewMyTableEntries>
```

Dynamic	Static	
dyntxrule.match=/Transaction	stattxrule.match=/NewMyTableEntries	
dyntxrule.timestamp=@ts	<pre>stattxrule.subrules= statoprule</pre>	
dyntxrule.subrules=dynoprule	statoprule.match=./NewMyTableEntry	
dynoprule.match=./Operation	statoprule.schemaandtable="MY.TABLE"	
dynoprule.schemaandtable=@table	statoprule.optype="I"	
dynoprule.optype=@type	<pre>statoprule.timestamp=./CreateTime/text()</pre>	
dynoprule.subrules=dyncolrule	<pre>statoprule.subrules= statkeycolrule,</pre>	
dyncolrule.match=./Column	statcol1rule	
dyncolrule.name=@name	statkeycolrule.match=/KeyCol	

INSERT INTO MY.TABLE (KEYCOL, COL1)
VALUES ('keyval', 'col1val')

# Source Definitions Generation Utility

By default, the JMS capture process writes metadata information in the produced trail files, allowing trail file consumers to understand the structure of the trail records without any help from an external definition file.

The output source definitions file can then be used in a pump or delivery process to interpret the trail data created through the VAM.

# Message Capture Properties

- Logging and Connection Properties
- Parser Properties

# Logging and Connection Properties

The following properties control the connection to JMS and the log file names, error handling, and message output.

- Logging Properties
- JMS Connection Properties
- JNDI Properties

# **Logging Properties**

Logging is controlled by the following properties.

- gg.log
- gg.log.level
- gg.log.file
- gg.log.classpath

## gg.log

Specifies the type of logging that is to be used. The default implementation is the JDK option. This is the built-in Java logging called java.util.logging (JUL). The other logging options are log4j or logback. The syntax is:

gg.log={JDK|log4j|logback}

For example, to set the type of logging to log4j:

gg.log=log4j

The log file is created in the report subdirectory of the installation. The default log file name includes the group name of the associated Extract and the file extension is log.

## gg.log.level

Specifies the overall log level for all modules. The syntax is:

```
gg.log.level={ERROR|WARN|INFO|DEBUG}
```

The log levels are defined as follows:

- ERROR Only write messages if errors occur
- WARN Write error and warning messages
- INFO Write error, warning and informational messages
- DEBUG Write all messages, including debug ones.

The default logging level is INFO. The messages in this case will be produced on startup, shutdown and periodically during operation. If the level is switched to DEBUG, large volumes of messages may occur which could impact performance. For example, the following sets the global logging level to INFO:

```
# global logging level
gg.log.level=INFO
```

## gg.log.file

Specifies the path to the log file. The syntax is:

```
gg.log.file=path_to_file
```

Where the *path\_to\_file* is the fully defined location of the log file. This allows a change to the name of the log, but you must include the Replicat name if you have more than one Replicat to avoid one overwriting the log of the other.

### gg.log.classpath

Specifies the classpath to the JARs used to implement logging.

```
gg.log.classpath=path_to_jars
```

## **JMS Connection Properties**

The JMS connection properties set up the connection, such as how to start up the JVM for JMS integration.

- jvm.boot options
- jms.report.output
- jms.report.time
- jms.report.records
- jms.id
- jms.destination
- jms.connectionFactory
- jms.user, jms.password

### jvm.boot options

Specifies the classpath and boot options that will be applied when the JVM starts up. The path needs colon (:) separators for UNIX/Linux and semicolons (;) for Windows.

The syntax is:

```
jvm.bootoptions=option[, option][. . .]
```

The *options* are the same as those passed to Java executed from the command line. They may include classpath, system properties, and JVM memory options (such as maximum memory or initial memory) that are valid for the version of Java being used. Valid options may vary based on the JVM version and provider.

For example (all on a single line):

```
jvm.bootoptions= -Djava.class.path=ggjava/ggjava.jar
-Dlog4j.configuration=my-log4j.properties
```

The log4j.configuration property could be a fully qualified URL to a log4j properties file; by default this file is searched for in the classpath. You may use your own log4j configuration, or one of the pre-configured log4j settings: log4j.properties (default level of logging), debug-log4j.properties (debug logging) or trace-log4j.properties (very verbose logging).

### jms.report.output

Specifies where the JMS report is written. The syntax is:

```
jms.report.output={report|log|both}
```

Where:

- report sends the JMS report to the Oracle GoldenGate report file. This is the default.
- log will write to the Java log file (if one is configured)
- both will send to both locations.

### jms.report.time

Specifies the frequency of report generation based on time.

jms.report.time=time\_specification

The following examples write a report every 30 seconds, 45 minutes and eight hours.

```
jms.report.time=30sec
jms.report.time=45min
jms.report.time=8hr
```

### jms.report.records

Specifies the frequency of report generation based on number of records. The syntax is:

jms.report.records=number

The following example writes a report every 1000 records.

jms.report.records=1000

### jms.id

Specifies that a unique identifier with the indicated format is passed back from the JMS integration to the message capture VAM. This may be used by the VAM as a unique sequence ID for records.

jms.id={ogg|time|wmq|activemq|message\_header|custom java class}

Where:

- ogg returns the message header property GG\_ID which is set by Oracle GoldenGate JMS delivery.
- time uses a system timestamp as a starting point for the message ID
- wmq reformats a WebSphere MQ Message ID for use with the VAM
- activemq reformats an ActiveMQ Message ID for use with the VAM
- message\_header specifies your customized JMS message header to be included, such as JMSMessageID, JMSCorrelationID, or JMSTimestamp.
- custom\_java\_class specifies a custom Java class that creates a string to be used as an ID.

For example:

jms.id=time
jms.id=JMSMessageID

The ID returned must be unique, incrementing, and fixed-width. If there are duplicate numbers, the duplicates are skipped. If the message ID changes length, the Extract process will abend.

## jms.destination

Specifies the queue or topic name to be looked up using JNDI.

jms.destination=jndi\_name

#### For example:

jms.destination=sampleQ

### jms.connectionFactory

Specifies the connection factory name to be looked up using JNDI.

jms.connectionFactory=jndi\_name

#### For example

jms.connectionFactory=ConnectionFactory

### jms.user, jms.password

Sets the user name and password of the JMS connection, as specified by the JMS provider.

jms.user=user\_name
jms.password=password

This is not used for JNDI security. To set JNDI authentication, see the JNDI java.naming.security properties.

#### For example:

```
jms.user=myuser
jms.password=mypasswd
```

## **JNDI** Properties

In addition to specific properties for the message capture VAM, the JMS integration also supports setting JNDI properties required for connection to an Initial Context to look up the connection factory and destination. The following properties must be set:

```
java.naming.provider.url=url
java.naming.factory.initial=java_class_name
```

If JNDI security is enabled, the following properties may be set:

```
java.naming.security.principal=user_name
java.naming.security.credentials=password_or_other_authenticator
```

#### For example:

```
java.naming.provider.url= t3://localhost:7001
java.naming.factory.initial=weblogic.jndi.WLInitialContextFactory
java.naming.security.principal=jndiuser
java.naming.security.credentials=jndipw
```

# **Parser Properties**

Properties specify the formats of the message and the translation rules for each type of parser: fixed, delimited, or XML. Set the parser.type property to specify which parser to use. The remaining properties are parser specific.

- Setting the Type of Parser
- Fixed Parser Properties
- Delimited Parser Properties
- XML Parser Properties

# Setting the Type of Parser

The following property sets the parser type.

• parser.type

### parser.type

#### Specifies the parser to use.

```
parser.type={fixed|delim|xml}
```

Where:

- fixed invokes the fixed width parser
- delim invokes the delimited parser
- xml invokes the XML parser

For example:

parser.type=delim

# **Fixed Parser Properties**

The following properties are required for the fixed parser.

- fixed.schematype
- fixed.sourcedefs
- fixed.copybook
- fixed.header
- fixed.seqid
- fixed.timestamp
- fixed.timestamp.format
- fixed.txid
- fixed.txowner
- fixed.txname
- fixed.optype

- fixed.optype.insertval
- fixed.optype.updateval
- fixed.optype.deleteval
- fixed.table
- fixed.schema
- fixed.txind
- fixed.txind.beginval
- fixed.txind.middleval
- fixed.txind.endval
- fixed.txind.wholeval

## fixed.schematype

Specifies the type of file used as metadata for message capture. The two valid options are sourcedefs and copybook.

fixed.schematype={sourcedefs|copybook}

#### For example:

fixed.schematype=copybook

The value of this property determines the other properties that must be set in order to successfully parse the incoming data.

### fixed.sourcedefs

If the fixed.schematype=sourcedefs, this property specifies the location of the source definitions file that is to be used.

```
fixed.sourcedefs=file_location
```

#### For example:

fixed.sourcedefs=dirdef/hrdemo.def

## fixed.copybook

If the fixed.schematype=copybook, this property specifies the location of the copybook file to be used by the message capture process.

fixed.copybook=file\_location

#### For example:

fixed.copybook=test\_copy\_book.cpy

### fixed.header

Specifies the name of the sourcedefs entry or copybook record that contains header information used to determine the data block structure:

```
fixed.header=record_name
```

#### For example:

fixed.header=HEADER

## fixed.seqid

Specifies the name of the header field, JMS property, or system value that contains the seqid used to uniquely identify individual records. This value must be continually incrementing and the last character must be the least significant.

fixed.seqid={field\_name|\$jms\_property|\*seqid}

Where:

- field name indicates the name of a header field containing the seqid
- jms\_property uses the value of the specified JMS header property. A special value of this is \$jmsid which uses the value returned by the mechanism chosen by the jms.id property
- seqid indicates a simple incrementing 64-bit integer generated by the system

#### For example:

fixed.seqid=\$jmsid

## fixed.timestamp

Specifies the name of the field, JMS property, or system value that contains the timestamp.

fixed.timestamp={field\_name|\$jms\_property|\*ts}

#### For example:

fixed.timestamp=TIMESTAMP
fixed.timestamp=\$JMSTimeStamp
fixed.timestamp=\*ts

### fixed.timestamp.format

Specifies the format of the timestamp field.

fixed.timestamp.format=format

Where the format can include punctuation characters plus:

- YYYY four digit year
- YY two digit year
- M[M] one or two digit month
- D[D] one or two digit day
- HH hours in twenty four hour notation
- MI minutes
- SS seconds
- Fn n number of fractions

The default format is "YYYY-MM-DD:HH:MI:SS.FFF"

#### For example:

fixed.timestamp.format=YYYY-MM-DD-HH.MI.SS

## fixed.txid

Specifies the name of the field, JMS property, or system value that contains the txid used to uniquely identify transactions. This value must increment for each transaction.

```
fixed.txid={field name|$jms_property|*txid}
```

For most cases using the system value of \*txid is preferred.

For example:

fixed.txid=\$JMSTxId
fixed.txid=\*txid

### fixed.txowner

Specifies the name of the field, JMS property, or static value that contains a user name associated with a transaction. This value may be used to exclude certain transactions from processing. This is an optional property.

fixed.txowner={field\_name|\$jms property|"value"}

#### For example:

```
fixed.txowner=$MessageOwner
fixed.txowner="jsmith"
```

## fixed.txname

Specifies the name of the field, JMS property, or static value that contains an arbitrary name to be associated with a transaction. This is an optional property.

fixed.txname={field\_name|\$jms\_property|"value"}

#### For example:

fixed.txname="fixedtx"

### fixed.optype

Specifies the name of the field, or JMS property that contains the operation type, which is validated against the fixed.optype values specified in the next sections.

fixed.header.optype={field\_name|\$jms\_property}

#### For example:

fixed.header.optype=FUNCTION

### fixed.optype.insertval

This value identifies an insert operation. The default is I.

fixed.optype.insertval={value|\xhex\_value}

For example:

fixed.optype.insertval=A

## fixed.optype.updateval

#### This value identifies an update operation. The default is U.

fixed.optype.updateval={value|\xhex\_value}

#### For example:

fixed.optype.updateval=M

### fixed.optype.deleteval

#### This value identifies a delete operation. The default is D.

fixed.optype.deleteval={value|\xhex\_value}

#### For example:

fixed.optype.deleteval=R

### fixed.table

Specifies the name of the table. This enables the parser to find the data record definition needed to translate the non-header data portion.

fixed.table=field\_name|\$jms\_property[, . . .]

More than one comma delimited field name may be used to determine the name of the table Each field name corresponds to a field in the header record defined by the fixed.header property or JMS property. The values of these fields are concatenated to identify the data record.

#### For example:

fixed.table=\$JMSTableName
fixed.table=SOURCE\_Db,SOURCE\_Db\_Rec\_Version

### fixed.schema

Specifies the static name of the schema when generating SCHEMA. TABLE table names.

fixed.schema="value"

#### For example:

fixed.schema="OGG"

### fixed.txind

Specifies the name of the field or JMS property that contains a transaction indicator that is validated against the transaction indicator values. If this is not defined, all operations within a single message will be seen to have occurred within a whole transaction. If defined, then it determines the beginning, middle and end of transactions. Transactions defined in this way can span messages. This is an optional property.

fixed.txind={field\_name|\$jms\_property}

#### For example:

fixed.txind=\$TX\_IND

## fixed.txind.beginval

This value identifies an operation as the beginning of a transaction. The defaults is B.

fixed.txind.beginval={value|\xhex\_value}

#### For example:

fixed.txind.beginval=0

## fixed.txind.middleval

This value identifies an operation as the middle of a transaction. The default is M.

fixed.txind.middleval={value|\xhex\_value}

#### For example:

fixed.txind.middleval=1

## fixed.txind.endval

This value identifies an operation as the end of a transaction. The default is *E*.

fixed.txind.endval={value|\xhex\_value}

#### For example:

fixed.txind.endval=2

### fixed.txind.wholeval

This value identifies an operation as a whole transaction. The default is W.

fixed.txind.wholeval={value|\xhex\_value}

### For example:

fixed.txind.wholeval=3

# **Delimited Parser Properties**

The following properties are required for the delimited parser except where otherwise noted.

- delim.sourcedefs
- delim.header
- delim.seqid
- delim.timestamp
- delim.timestamp.format
- delim.txid
- delim.txowner

- delim.txname
- delim.optype
- delim.optype.insertval
- delim.optype.updateval
- delim.optype.deleteval
- delim.schemaandtable
- delim.schema
- delim.table
- delim.txind
- delim.txind.beginval
- delim.txind.middleval
- delim.txind.endval
- delim.txind.wholeval
- delim.fielddelim
- delim.linedelim
- delim.quote
- delim.nullindicator
- delim.fielddelim.escaped
- delim.linedelim.escaped
- delim.quote.escaped
- delim.nullindicator.escaped
- delim.hasbefores
- delim.hasnames
- delim.afterfirst
- delim.isgrouped
- delim.dateformat | delim.dateformat.table | delim.dateform.table.column

## delim.sourcedefs

#### Specifies the location of the source definitions file to use.

```
\texttt{delim.sourcedefs} = \textit{file\_location}
```

#### For example:

```
delim.sourcedefs=dirdef/hrdemo.def
```

## delim.header

Specifies the list of values that come before the data and assigns names to each.

```
delim.header=name[,name2][. . .]
```

The names must be unique. They can be referenced in other delim properties or wherever header fields can be used.

#### For example:

delim.header=optype, tablename, ts
delim.timestamp=ts

### delim.seqid

Specifies the name of the header field, JMS property, or system value that contains the seqid used to uniquely identify individual records. This value must increment and the last character must be the least significant.

```
delim.seqid={field_name|$jms_property|*seqid}
```

Where:

- field name indicates the name of a header field containing the seqid
- jms\_property uses the value of the specified JMS header property, a special value of this is \$jmsid which uses the value returned by the mechanism chosen by the jms.id property
- seqid indicates a simple continually incrementing 64-bit integer generated by the system

For example:

delim.seqid=\$jmsid

### delim.timestamp

Specifies the name of the JMS property, header field, or system value that contains the timestamp.

delim.timestamp={field\_name|\$jms\_property|\*ts}

#### For example:

```
delim.timestamp=TIMESTAMP
delim.timestamp=$JMSTimeStamp
delim.timestamp=*ts
```

### delim.timestamp.format

Specifies the format of the timestamp field.

delim.timestamp.format=format

Where the *format* can include punctuation characters plus:

- YYYY four digit year
- YY two digit year
- M[M] one or two digit month
- D[D] one or two digit day
- HH hours in twenty four hour notation

- MI minutes
- SS seconds
- Fn n number of fractions

The default format is "YYYY-MM-DD:HH:MI:SS.FFF"

#### For example:

delim.timestamp.format=YYYY-MM-DD-HH.MI.SS

### delim.txid

Specifies the name of the JMS property, header field, or system value that contains the txid used to uniquely identify transactions. This value must increment for each transaction.

```
delim.txid={field_name|$jms_property|*txid}
```

For most cases using the system value of \*txid is preferred.

#### For example:

delim.txid=\$JMSTxId
delim.txid=\*txid

### delim.txowner

Specifies the name of the JMS property, header field, or static value that contains an arbitrary user name associated with a transaction. This value may be used to exclude certain transactions from processing. This is an optional property.

```
delim.txowner={field name|$jms_property|"value"}
```

#### For example:

delim.txowner=\$MessageOwner
delim.txowner="jsmith"

### delim.txname

Specifies the name of the JMS property, header field, or static value that contains an arbitrary name to be associated with a transaction. This is an optional property.

delim.txname={field\_name|\$jms\_property|"value"}

#### For example:

delim.txname="fixedtx"

## delim.optype

Specifies the name of the JMS property or header field that contains the operation type. This is compared to the values for delim.optype.insertval, delim.optype.updateval and delim.optype.deleteval to determine the operation.

delim.optype={field\_name|\$jms\_property}

#### For example:

delim.optype=optype

## delim.optype.insertval

### This value identifies an insert operation. The default is I.

delim.optype.insertval={value|\xhex value}

#### For example:

delim.optype.insertval=A

## delim.optype.updateval

#### This value identifies an update operation. The default is U.

delim.optype.updateval={value|\xhex\_value}

#### For example:

delim.optype.updateval=M

## delim.optype.deleteval

This value identifies a delete operation. The default is D.

delim.optype.deleteval={value|\xhex\_value}

#### For example:

delim.optype.deleteval=R

### delim.schemaandtable

Specifies the name of the JMS property or header field that contains the schema and table name in the form <code>SCHEMA.TABLE</code>.

delim.schemaandtable={field\_name|\$jms\_property}

#### For example:

delim.schemaandtable=\$FullTableName

## delim.schema

Specifies the name of the JMS property, header field, or hard-coded value that contains the schema name.

delim.schema={field\_name|\$jms\_property|"value"}

#### For example:

delim.schema="OGG"

## delim.table

Specifies the name of the JMS property or header field that contains the table name.

delim.table={field\_name|\$jms\_property}

For example:

delim.table=TABLE\_NAME

## delim.txind

Specifies the name of the JMS property or header field that contains the transaction indicator to be validated against beginval, middleval, endval or wholeval. All operations within a single message will be seen as within one transaction if this property is not set. If it is set it determines the beginning, middle and end of transactions. Transactions defined in this way can span messages. This is an optional property.

delim.txind={field\_name|\$jms\_property}

For example:

delim.txind=txind

## delim.txind.beginval

The value that identifies an operation as the beginning of a transaction. The default is B.

delim.txind.beginval={value|\xhex\_value}

#### For example:

delim.txind.beginval=0

### delim.txind.middleval

The value that identifies an operation as the middle of a transaction. The default is M.

delim.txind.middleval={value|\xhex\_value}

#### For example:

```
delim.txind.middleval=1
```

## delim.txind.endval

The value that identifies an operation as the end of a transaction. The default is E.

delim.txind.endval={value|\xhex\_value}

#### For example:

delim.txind.endval=2

## delim.txind.wholeval

The value that identifies an operation as a whole transaction. The default is w.

delim.txind.wholeval={value|\xhex\_value}

#### For example:

delim.txind.wholeval=3

### delim.fielddelim

Specifies the delimiter value used to separate fields (columns) in the data. This value is defined through characters or hexadecimal values:

delim.fielddelim={value|\xhex\_value}

#### For example:

delim.fielddelim=,
delim.fielddelim=\xc7

### delim.linedelim

Specifies the delimiter value used to separate lines (records) in the data. This value is defined using characters or hexadecimal values.

delim.linedelim={value|\xhex\_value}

#### For example:

delim.linedelim=|| delim.linedelim=\xOa

## delim.quote

Specifies the value used to identify quoted data. This value is defined using characters or hexadecimal values.

```
delim.quote={value|\xhex_value}
```

#### For example:

delim.quote="

## delim.nullindicator

Specifies the value used to identify NULL data. This value is defined using characters or hexadecimal values.

```
delim.nullindicator={value|\xhex_value}
```

#### For example:

delim.nullindicator=NULL

### delim.fielddelim.escaped

Specifies the value that will replace the field delimiter when the field delimiter occurs in the input field. The syntax is:

delim.fielddelim.escaped={value|\xhex value}

For example, given the following property settings:

```
delim.fielddelim=-
delim.fielddelim.escaped=$#$
```

If the data does not contain the hyphen delimiter within any of the field values:

one two three four

The resulting delimited data is:

one-two-three-four

If there are hyphen (-) delimiters within the field values:

one two three four-fifths two-fifths

The resulting delimited data is:

one-two-three-four\$#\$fifths-two\$#\$fifths

## delim.linedelim.escaped

Specifies the value that will replace the line delimiter when the line delimiter occurs in the input data. The syntax is:

delim.linedelim.escaped={value|\xhex\_value}

For example, given the following property settings:

delim.linedelim=\
delim.linedelim.escaped=%/%

#### If the input lines are:

These are the lines and they do not contain the delimiter.

Because the lines do not contain the backslash (\), the result is:

These are the lines and they  $\$  do not contain the delimiter.  $\$ 

However, if the input lines do contain the delimiter:

These are the lines\data values and they do contain the delimiter.

#### So the results are:

```
These are the lines%/%data values\
and they do contain the delimiter.\
```

### delim.quote.escaped

Specifies the value that will replace a quote delimiter when the quote delimiter occurs in the input data. The syntax is:

delim.quote.escaped={value|\xhex\_value}

For example, given the following property settings:

delim.quote="
delim.quote.escaped="'"

If the input data does not contain the quote (") delimiter:

```
It was a very original play.
```

#### The result is:

"It was a very original play."

However, if the input data does contain the quote delimiter:

It was an "uber-original" play.

#### The result is:

"It was an "'"uber-original"'" play."

### delim.nullindicator.escaped

Specifies the value that will replace a null indicator when a null indicator occurs in the input data. The syntax is:

```
delim.nullindicator.escaped={value|\xhex value}
```

For example, given the following property settings:

```
delim.fielddelim=,
delim.nullindicator=NULL
delim.nullindicator.escaped=$NULL$
```

When the input data does not contain a NULL value or a NULL indicator:

1 2 3 4 5

The result is

1,2,3,4,5

When the input data contains a NULL value:

1 2 4 5

The result is

1,2,NULL,4,5

When the input data contains a NULL indicator:

1 2 NULL 4 5

The result is:

1,2,\$NULL\$,4,5

### delim.hasbefores

Specifies whether before values are present in the data.

```
delim.hasbefores={true|false}
```

The default is false. The parser expects to find before and after values of columns for all records if delim.hasbefores is set to true. The before values are used for updates and deletes, the after values for updates and inserts. The afterfirst property specifies whether the before images are before the after images or after them. If delim.hasbefores is false, then no before values are expected.

#### For example:

delim.hasbefores=true

### delim.hasnames

Specifies whether column names are present in the data.

delim.hasnames={true|false}

The default is false. If true, the parser expects to find column names for all records. The parser validates the column names against the expected column names. If false, no column names are expected.

For example:

delim.hasnames=true

### delim.afterfirst

Specifies whether after values are positioned before or after the before values.

```
delim.afterfirst={true|false}
```

The default is false. If true, the parser expects to find the after values before the before values. If false, the after values are before the before values.

For example:

delim.afterfirst=true

## delim.isgrouped

Specifies whether the column names and before and after images should be expected grouped together for all columns or interleaved for each column.

```
delim.isgrouped={true|false}
```

The default is false. If true, the parser expects find a group of column names (if hasnames is true), followed by a group of before values (if hasbefores), followed by a group of after values (the afterfirst setting will reverse the before and after value order). If false, the parser will expect to find a column name (if hasnames), before value (if hasbefores) and after value for each column.

For example:

delim.isgrouped=true

## delim.dateformat | delim.dateformat.table | delim.dateform.table.column

Specifies the date format for column data. This is specified at a global level, table level or column level. The format used to parse the date is a subset of the formats used for parser.timestamp.format.

```
delim.dateformat=format
delim.dateformat.TABLE=format
delim.dateformat.TABLE.COLUMN=format
```

Where:

- *format* is the format defined for parser.timestamp.format.
- *table* is the fully qualified name of the table that is currently being processed.
- *column* is a column of the specified table.

#### For example:

```
delim.dateformat=YYYY-MM-DD HH:MI:SS
delim.dateformat.MY.TABLE=DD/MM/YY-HH.MI.SS
delim.dateformat.MY.TABLE.EXP_DATE=YYMM
```

## **XML** Parser Properties

The following properties are used by the XML parser.

- xml.sourcedefs
- xml.rules
- rulename.type
- rulename.match
- rulename.subrules
- txrule.timestamp
- txrule.timestamp.format
- txrule.seqid
- txrule.txid
- txrule.txowner
- txrule.txname
- oprule.timestamp
- oprule.timestamp.format
- oprule.seqid
- oprule.txid
- oprule.txowner
- oprule.txname
- oprule.schemandtable
- oprule.schema
- oprule.table
- oprule.optype
- oprule.optype.insertval
- oprule.optype.updateval
- oprule.optype.deleteval
- oprule.txind
- oprule.txind.beginval
- oprule.txind.middleval
- oprule.txind.endval

- oprule.txind.wholeval
- colrule.name
- colrule.index
- colrule.value
- colrule.isnull
- colrule.ismissing
- colrule.before.value
- colrule.before.isnull
- colrule.before.ismissing
- colrule.after.value
- colrule.after.isnull
- colrule.after.ismissing

### xml.sourcedefs

Specifies the location of the source definitions file.

xml.sourcedefs=file\_location

#### For example:

xml.sourcedefs=dirdef/hrdemo.def

### xml.rules

Specifies the list of XML rules for parsing a message and converting to transactions, operations and columns:

```
xml.rules=xml_rule_name[, . . .]
```

The specified XML rules are processed in the order listed. All rules matching a particular XML document may result in the creation of transactions, operations and columns. The specified XML rules should be transaction or operation type rules.

#### For example:

xml.rules=dyntxrule, statoprule

## rulename.type

#### Specifies the type of XML rule.

```
rulename.type={tx|op|col}
```

Where:

- tx indicates a transaction rule
- op indicates an operation rule
- col indicates a column rule

For example:

dyntxrule.type=tx
statoprule.type=op

### rulename.match

Specifies an XPath expression used to determine whether the rule is activated for a particular document or not.

```
rulename.match=xpath_expression
```

If the XPath expression returns any nodes from the document, the rule matches and further processing occurs. If it does not return any nodes, the rule is ignored for that document.

The following example activates the dyntxrule if the document has a root element of Transaction

```
dyntxrule.match=/Transaction
```

Where statoprule is a sub rule of stattxtule, the following example activates the statoprule if the parent rule's matching nodes have child elements of NewMyTableEntry.

```
statoprule.match=./NewMyTableEntry
```

### rulename.subrules

Specifies a list of rule names to check for matches if the parent rule is activated by its match.

```
rulename.subrules=xml rule name[, . . .]
```

The specified XML rules are processed in the order listed. All matching rules may result in the creation of transactions, operations and columns.

Valid sub-rules are determined by the parent type. Transaction rules can only have operation sub-rules. Operation rules can have operation or column sub-rules. Column rules cannot have sub-rules.

For example:

```
dyntxrule.subrules=dynoprule
statoprule.subrules=statkeycolrule, statcol1rule
```

### txrule.timestamp

Controls the transaction timestamp by instructing the adapter to 1) use the transaction commit timestamp contained in a specified XPath expression or JMS property or 2) use the current system time. This is an optional property.

txrule.timestamp={xpath\_expression|\$jms\_property|\*ts}

The timestamp for the transaction may be overridden at the operation level, or may only be present at the operation level. Any XPath expression must end with a value, accessor, such as @att or text().

#### For example:

dyntxrule.timestamp=@ts

## txrule.timestamp.format

Specifies the format of the timestamp field.

txrule.timestamp.format=format

Where the format can include punctuation characters plus:

- YYYY four digit year
- YY two digit year
- M[M] one or two digit month
- D[D] one or two digit day
- HH hours in twenty four hour notation
- MI minutes
- SS seconds
- Fn n number of fractions

The default format is "YYYY-MM-DD:HH:MI:SS.FFF"

#### For example:

dyntxrule.timestamp.format=YYYY-MM-DD-HH.MI.SS

### *txrule*.seqid

Specifies the seqid for a particular transaction. This can be used when there are multiple transactions per message. Determines the XPath expression, JMS property, or system value that contains the transactions seqid. Any XPath expression must end with a value accessor such as @att or text().

txrule.seqid={xpath expression|\$jms property|\*seqid}

For example:

dyntxrule.seqid=@seqid

## txrule.txid

Specifies the XPath expression, JMS property, or system value that contains the txid used to unique identify transactions. This value must increment for each transaction.

txrule.txid={xpath\_expression|\$jms\_property|\*txid}

For most cases using the system value of \*txid is preferred.

For example:

dyntxrule.txid=\$JMSTxId
dyntxrule.txid=\*txid

### txrule.txowner

Specifies the XPath expression, JMS property, or static value that contains an arbitrary user name associated with a transaction. This value may be used to exclude certain transactions from processing.

txrule.txowner={xpath expression|\$jms property|"value"}

#### For example:

dyntxrule.txowner=\$MessageOwner
dyntxrule.txowner="jsmith"

### txrule.txname

Specifies the XPath expression, JMS property, or static value that contains an arbitrary name to be associated with a transaction. This is an optional property.

txrule.txname={xpath expression|\$jms property|"value"}

For example:

dyntxrule.txname="fixedtx"

## oprule.timestamp

Controls the operation timestamp by instructing the adapter to 1) use the transaction commit timestamp contained in a specified XPath expression or JMS property or 2) use the current system time. This is an optional property.

oprule.timestamp={xpath\_expression|\$jms\_property|\*ts}

The timestamp for the operation will override a timestamp at the transaction level.

Any XPath expression must end with a value accessor such as @att or text().

For example:

statoprule.timestamp=./CreateTime/text()

### oprule.timestamp.format

Specifies the format of the timestamp field.

oprule.timestamp.format=format

Where the *format* can include punctuation characters plus:

- YYYY four digit year
- YY two digit year
- M[M] one or two digit month
- D[D] one or two digit day
- HH hours in twenty four hour notation
- MI minutes
- SS seconds

• Fn - n number of fractions

The default format is "YYYY-MM-DD:HH:MI:SS.FFF"

For example:

statoprule.timestamp.format=YYYY-MM-DD-HH.MI.SS

## oprule.seqid

Specifies the seqid for a particular operation. Use the XPath expression, JMS property, or system value that contains the operation seqid. This overrides any seqid defined in parent transaction rules. Must be present if there is no parent transaction rule.

Any XPath expression must end with a value accessor such as @att or text().

oprule.seqid={xpath expression|\$jms property|\*seqid}

#### For example:

dynoprule.seqid=@seqid

### oprule.txid

Specifies the XPath expression, JMS property, or system value that contains the txid used to uniquely identify transactions. This overrides any txid defined in parent transaction rules and is required if there is no parent transaction rule. The value must be incremented for each transaction.

oprule.txid={xpath expression|\$jms property|\*txid}

For most cases using the system value of \*txid is preferred.

For example:

dynoprule.txid=\$JMSTxId
dynoprule.txid=\*txid

### oprule.txowner

Specifies the XPath expression, JMS property, or static value that contains an arbitrary user name associated with a transaction. This value may be used to exclude certain transactions from processing. This is an optional property.

oprule.txowner={xpath\_expression|\$jms\_property|"value"}

#### For example:

```
dynoprule.txowner=$MessageOwner
dynoprule.txowner="jsmith"
```

### oprule.txname

Specifies the XPath expression, JMS property, or static value that contains an arbitrary name to be associated with a transaction. This is an optional property.

oprule.txname={xpath expression|\$jms property|"value"}

For example:

```
dynoprule.txname="fixedtx"
```

## oprule.schemandtable

Specifies the XPath expression JMS property or hard-coded value that contains the schema and table name in the form <code>SCHEMA.TABLE</code>. Any XPath expression must end with a value accessor such as <code>@att</code> or <code>text()</code>. The value is verified to ensure the table exists in the source definitions.

oprule.schemaandtable={xpath\_expression|\$jms\_property|"value"}

#### For example:

statoprule.schemaandtable="MY.TABLE"

## oprule.schema

Specifies the XPath expression, JMS property or hard-coded value that contains the schema name. Any XPath expression must end with a value accessor such as @att or text().

```
oprule.schema={xpath expression|$jms property|"value"}
```

#### For example:

statoprule.schema=@schema

## oprule.table

Specifies the XPath expression, JMS property or hard-coded value that contains the table name. Any XPath expression must end with a value accessor such as @att or text().

```
oprule.table={xpath_expression|$jms_property|"value"}
```

#### For example:

statoprule.table=\$TableName

## oprule.optype

Specifies the XPath expression, JMS property or literal value that contains the <code>optype</code> to be validated against an <code>optype insertval</code>. Any XPath expression must end with a value accessor such as <code>@att or text()</code>.

```
oprule.optype={xpath_expression|$jms_property|"value"}
```

#### For example:

```
dynoprule.optype=@type
statoprule.optype="I"
```

## oprule.optype.insertval

Specifies the value that identifies an insert operation. The default is I.

```
oprule.optype.insertval={value|\xhex_value}
```

For example:

```
dynoprule.optype.insertval=A
```

## oprule.optype.updateval

#### Specifies the value that identifies an update operation. The default is U.

oprule.optype.updateval={value|\xhex\_value}

#### For example:

dynoprule.optype.updateval=M

## oprule.optype.deleteval

#### Specifies the value that identifies a delete operation. The default is D.

oprule.optype.deleteval={value|\xhex\_value}

#### For example:

dynoprule.optype.deleteval=R

## oprule.txind

Specifies the XPath expression or JMS property that contains the transaction indicator to be validated against <code>beginval</code> or other value that identifies the position within the transaction. All operations within a single message are regarded as occurring within a whole transaction if this property is not defined. Specifies the begin, middle and end of transactions. Any XPath expression must end with a value accessor such as <code>@att or text()</code>. Transactions defined in this way can span messages. This is an optional property.

oprule.txind={xpath\_expression|\$jms\_property}

For example:

dynoprule.txind=@txind

## oprule.txind.beginval

Specifies the value that identifies an operation as the beginning of a transaction. The default is  $\ensuremath{\mathtt{B}}.$ 

```
oprule.txind.beginval={value|\xhex_value}
```

#### For example:

dynoprule.txind.beginval=0

## oprule.txind.middleval

Specifies the value that identifies an operation as the middle of a transaction. The default is M.

oprule.txind.middleval={value|\xhex\_value}

#### For example:

dynoprule.txind.middleval=1

## oprule.txind.endval

Specifies the value that identifies an operation as the end of a transaction. The default is  $\ensuremath{\mathbb{E}}$  .

oprule.txind.endval={value|\xhex value}

#### For example:

dynoprule.txind.endval=2

## oprule.txind.wholeval

Specifies the value that identifies an operation as a whole transaction. The default is W.

oprule.txind.wholeval={value|\xhex\_value}

#### For example:

dynoprule.txind.wholeval=3

#### colrule.name

Specifies the XPath expression or hard-coded value that contains a column name. The column index must be specified if this is not and the column name will be resolved from that. If specified the column name will be verified against the source definitions file. Any XPath expression must end with a value accessor such as <code>@att ortext()</code>.

colrule.name={xpath expression|"value"}

#### For example:

dyncolrule.name=@name
statkeycolrule.name="keycol"

## colrule.index

Specifies the XPath expression or hard-coded value that contains a column index. If not specified then the column name must be specified and the column index will be resolved from that. If specified the column index will be verified against the source definitions file. Any XPath expression must end with a value accessor such as <code>@att</code> or <code>text()</code>.

colrule.index={xpath expression| "value"}

#### For example:

```
dyncolrule.index=@index
statkeycolrule.index=1
```

### colrule.value

Specifies the XPath expression or hard-coded value that contains a column value. Any XPath expression must end with a value accessor such as @att or text(). If the XPath expression fails to return any data because a node or attribute does not exist, the column value will be deemed as null. To differentiate between null and missing

values (for updates) the isnull and ismissing properties should be set. The value returned is used for delete before values, and update/insert after values.

colrule.value={xpath expression| "value"}

#### For example:

statkeycolrule.value=./text()

## colrule.isnull

Specifies the XPath expression used to discover if a column value is null. The XPath expression must end with a value accessor such as <code>@att or text()</code>. If the XPath expression returns any value, the column value is null. This is an optional property.

```
colrule.isnull=xpath_expression
```

For example:

dyncolrule.isnull=@isnull

## colrule.ismissing

Specifies the XPath expression used to discover if a column value is missing. The XPath expression must end with a value accessor such as @att or text(). If the XPath expression returns any value, then the column value is missing. This is an optional property.

```
colrule.ismissing=xpath expression
```

#### For example:

dyncolrule.ismissing=./missing

## colrule.before.value

Overrides *colrule*.value to specifically say how to obtain before values used for updates or deletes. This has the same format as *colrule*.value. This is an optional property.

#### For example:

```
dyncolrule.before.value=./beforevalue/text()
```

#### colrule.before.isnull

Overrides *colrule*.isnull to specifically say how to determine if a before value is null for updates or deletes. This has the same format as *colrule*.isnull. This is an optional property.

#### For example:

dyncolrule.before.isnull=./beforevalue/@isnull

## colrule.before.ismissing

Overrides *colrule*.ismissing to specifically say how to determine if a before value is missing for updates or deletes. This has the same format as *colrule*.ismissing. This is an optional property.

For example:

dyncolrule.before.ismissing=./beforevalue/missing

## colrule.after.value

Overrides *colrule*.value to specifically say how to obtain after values used for updates or deletes. This has the same format as *colrule*.value. This is an optional property.

For example:

dyncolrule.after.value=./aftervalue/text()

## colrule.after.isnull

Overrides *colrule*.isnull to specifically say how to determine if an after value is null for updates or deletes. This has the same format as *colrule*.isnull. This is an optional property.

For example:

dyncolrule.after.isnull=./aftervalue/@isnull

## colrule.after.ismissing

Overrides *colrule*.ismissing to specifically say how to determine if an after value is missing for updates or deletes. This has the same format as *colrule*.ismissing. This is an optional property.

#### For example:

dyncolrule.after.ismissing=./aftervalue/missing

# Oracle GoldenGate Java Delivery

This part of the book contains information on using Oracle GoldenGate for Big Data to process transaction records and apply it to various targets by means of Java module.

For more information, see Understanding the Java Adapter and Oracle GoldenGate for Big Data.

- Configuring Java Delivery
- Running Java Delivery
- Configuring Event Handlers
- Java Delivery Properties
- Developing Custom Filters, Formatters, and Handlers

# **Configuring Java Delivery**

- Configuring the JRE in the Properties File
- Configuring Oracle GoldenGate for Java Delivery
- Configuring the Java Handlers

# Configuring the JRE in the Properties File

The current release of Oracle GoldenGate Java Delivery requires Java 8. Refer to the section on configuring Java for how to correctly access Java and the required Java shared libraries. Modify the Adapter Properties file to point to the location of the Oracle GoldenGate for Java main JAR (ggjava.jar) and set any additional JVM runtime boot options as required (these are passed directly to the JVM at startup):

jvm.bootoptions=-Djava.class.path=.:ggjava/ggjava.jar -Xmx512m -Xmx64m

Note the following options in particular:

- java.class.path must include pathing to the core application (ggjava/ggjava.jar). The current directory (.) should be included as well in the classpath. Logging initializes when the JVM is loaded therefore the java.class.path variable should including any pathing to logging properties files (such as log4j properties files). The dependency JARs required for logging functionality are included in ggjava.jar and do not need to be explicitly included. Pathing can reference files and directories relative to the Oracle GoldenGate install directory, to allow storing Java property files, Velocity templates and other classpath resources in the dirprm subdirectory. It is also possible to append to the classpath in the Java application properties file. Pathing to be a better practice to use the gg.classpath variable to include any handler dependencies.
- The jvm.bootoptions property also allows you to control the initial heap size of the JVM (Xms) and the maximum heap size of the JVM (Xmx). Increasing the maximum heap size can improve performance by requiring less frequent garbage collections. Additionally, you may need to increase the maximum heap size if a Java out of memory exception occurs.

Once the properties file is correctly configured for your system, it usually remains unchanged. See Common Properties, for additional configuration options.

## Configuring Oracle GoldenGate for Java Delivery

Java Delivery is compatible with the Oracle GoldenGate Replicat process. Transaction data is read from the Oracle GoldenGate trail files and delivered to the Oracle GoldenGate Java Delivery module across JNI interface. The data is transferred to the Oracle GoldenGate Java Delivery module using the JNI interface. The Java Delivery module is configurable to allow data to be streamed into various targets. The supported targets for the Oracle GoldenGate Java Java Adapter product include JMS, file writing, and custom integrations. The Oracle GoldenGate to Big Data product includes all of those integrations and streaming capabilities to Big Data targets.

Configuring a Replicat for Java Delivery

## Configuring a Replicat for Java Delivery

The Oracle GoldenGate Replicat process can be configured to send transaction data to the Oracle GoldenGate for Java module. Replicat consumes a local trail (for example dirdat/aa) and sends the data to the Java Delivery module. The Java module is responsible for processing all the data and applying it to the desired target.

Following is an example of adding a Replicat process:

ADD REPLICAT javarep, EXTTRAIL ./dirdat/aa

The process names and trail names used in the preceding example can be replaced with any valid name. Process names must be 8 characters or less, trail names must to be two characters. In the Replicat parameter file (javarep.prm), specify the location of the user exit library.

The Replicat process has transaction grouping built into the application. Transaction grouping can significantly improve performance when streaming data to a target database. Transaction grouping can also significantly improve performance when streaming data to Big Data applications. The Replicat parameter to control transaction grouping is the GROUPTRANSOPS variable in the Replicat configuration file. The default value of this variable is 1000 which means the Replicat process will attempt to group 1000 operations into single target transaction. Performance testing has generally shown that the higher the GROUPTRANSOPS the better the performance when streaming data to Big Data applications. Setting the GROUPTRANSOPS variable to 1 means that the original transaction boundaries from the source trail file (source database) will be maintained.

Parameter	Explanation	
REPLICAT javarep	All Replicat parameter files start with the Replicat name	
SOURCEDEFS ./dirdef/tcust.def	(Optional) If the input trail files do not contain the metadata records, the Replicat process requires metadata describing the trail data. This can come from a database or a source definitions file. This metadata defines the column names and data types in the trail being read (./dirdat/aa).	
TARGETDB LIBFILE libggjava.so SET properties= dirprm/ javarep.properties	The TARGETDB LIBFILE libggjava.so parameter serves as a trigger to initialize the Java module. The SET clause to specify the Java properties file is optional. If specified, it should contain an absolute or relative path (relative to the Replicat executable) to the properties file for the Java module. The default value is <i>replicat_name</i> .properties in the dirprm directory.	
MAP schema.*, TARGET *.*;	The tables to pass to the Java module; tables not included will be skipped. If mapping from source to target tables is required, one can use the MAP source_specification TARGET target_specification as describe in "Mapping and Manipulating Data" in Administering Oracle GoldenGate.	

#### Table 9-1 User Exit Replicat Parameters

Parameter	Explanation
GROUPTRANSOPS 1000	Group source transactions into a single larger target transaction for improved performance. GROUPTRANSOPS of 1000 is the default setting. GROUPTRANSOPS sets a minimum value rather than an absolute value, to avoid splitting apart source transactions. Replicat waits until it receives all operations from the last source transaction in the group before applying the target transaction.
	For example, if transaction 1 contains 200 operations and transaction 2 contains 400 operations, and transaction 3 contains 500 operations, then Replicat transaction contains all 1,100 operations even though GROUPTRANSOPS is set to the default of 1,000. Conversely, Replicat might apply a transaction before reaching the value set by GROUPTRANSOPS if there is no more data in the trail to process.

Table 9-1	(Cont.)	<b>User Exit Replicat Parar</b>	neters
-----------	---------	---------------------------------	--------

## Configuring the Java Handlers

The Handlers are integrations with target applications which plug into the Oracle GoldenGate Java Delivery module. It is the Java Handlers which provide the functionality to push data to integration targets such as JMS or Big Data applications. The Java Adapter properties file is used to configure Java Delivery and Java handlers. To test the configuration, users may use the built-in file handler. Here are some example properties, followed by explanations of the properties (comment lines start with #):

```
# the list of active handlers
gg.handlerlist=myhandler
# set properties on 'myhandler'
gg.handler.myhandler.type=file
gg.handler.myhandler.format=tx2xml.vm
gg.handler.myhandler.file=output.xml
```

This property file declares the following:

• Active event handlers. In the example a single event handler is active, called myhandler. Multiple handlers may be specified, separated by commas. For example: gg.handlerlist=myhandler, yourhandler

Starting Oracle GoldenGate for Big Data 23c release, you will be able to specify only a single handler.

• Configuration of the handlers. In the example myhandler is declared to be a file type of handler: gg.handler.myhandler.type=file

Note:

See the documentation for each type of handler (for example, the JMS handler or the file writer handler) for the list of valid properties that can be set.

• The format of the output is defined by the Velocity template tx2xml.vm. You may specify your own custom template to define the message format; just specify the path to your template relative to the Java classpath.

This property file is actually a complete example that will write captured transactions to the output file <code>output.xml</code>. Other handler types can be specified using the keywords: <code>jms\_text</code> (or <code>jms</code>), <code>jms\_map</code>, <code>singlefile</code> (a file that does not roll), and others. Custom handlers can be implemented, in which case the type would be the fully qualified name of the Java class for the handler. Oracle GoldenGate Big Data package also contains built in Big Data target types.

#### Note:

See the documentation for each type of handler (for example, the JMS handler or the file writer handler) for the list of valid properties that can be set.

## Running Java Delivery

- Starting the Application
- Restarting the Java Delivery

# Starting the Application

To run the Java Delivery and execute the Java application, you only need an existing Oracle GoldenGate trail file. If the trail file does not contain metadata records, a source definitions file is also required to describe the schema for operations in the trail file. For the examples that follow, a simple TCUSTMER and TCUSTORD trail is used (matching the demo SQL provided with the Oracle GoldenGate software download).

Starting Using Replicat

## Starting Using Replicat

To run Java Delivery using Replicat, simply start the Replicat process from GGSCI:

GGSCI> START REPLICAT javarep GGSCI> INFO REPLICAT javarep

The INFO command returns information similar to the following:

 REPLICAT JAVAREP
 Last Started 2015-09-10 17:25 Status RUNNING

 Checkpoint Lag
 00:00:00 (updated 00:00:00 ago)

 Log Read Checkpoint File
 ./dirdat/aa0000002015-09-10 17:50:41.000000

 RBA 2702
 RBA 2702

## Restarting the Java Delivery

There are two possible checkpoint files when running with Replicat, the Replicat process checkpoint file and the Java Delivery checkpoint file. Both files are located in the dirchk directory and created using the following naming conventions.

#### **Replicat checkpoint file**

group\_name.cpr

#### Java delivery checkpoint file:

group\_name.cpj

To suppress the creation and use of the Java Delivery checkpoint the Replicat process should be created using the following syntax:

ADD REPLICAT myrep EXTTRAIL ./dirdat/tr NODBCHECKPOINT

It is the NODBCHECKPOINT syntax that disables the creation and use of the Java Delivery checkpoint file.

Restarting Java Delivery in Replicat

## Restarting Java Delivery in Replicat

The checkpoint handling in Replicat is more straightforward as it includes logic to pick which one out of the two checkpoint information is of higher priority. The logic is as follows:

- If the Java Delivery is started after user manually performed an ADD or ALTER REPLICAT, then the checkpoint information held by Replicat process will be used as the starting position.
- If the Java Delivery is started without prior manual intervention to alter checkpoint (for example, upon graceful stop or an abend), then the checkpoint information held by Java module will be used as the starting position.

For example, restarting a Java Delivery using Replicat at the beginning of a trail looks like the following:

**1.** Reset the Replicat to the beginning of the trail data:

GGSCI> ALTER REPLICAT JAVAREP, EXTSEQNO 0, EXTRBA 0

2. Reset the Replicat

```
GGSCI> START JAVAREP

GGSCI> INFO JAVAREP

REPLICAT JAVAREP Last Started 2015-09-10 17:25 Status RUNNING

Checkpoint Lag 00:00:00 (updated 00:00:00 ago)

Log Read Checkpoint File ./dirdat/aa000000

2015-09-10 17:50:41.000000 RBA 2702
```

It may take a few seconds for the Replicat process status to report itself as running. Check the report file to see if it abended or is still in the process of starting:

GGSCI> VIEW REPORT JAVAREP

In the case where the Java Delivery is restarted after a crash or an abend, the last position kept by the Java module will be used when the application restarts.

# **Configuring Event Handlers**

This chapter discusses types of event handlers explaining how to specify the event handler to use and what your options are. It explains how to format the output and what you can expect from the Oracle GoldenGate Report file.

- Specifying Event Handlers
- JMS Handler
- File Handler
- Custom Handlers
- Formatting the Output
- Reporting

## Specifying Event Handlers

Processing transaction, operation and metadata events in Java works as follows:

- The Oracle GoldenGate Replicat or Extract process reads local trail data and passes the transactions, operations and database metadata to the Java Delivery Module. Metadata can come from the trail itself, a source definitions file.
- Events are fired by the Java framework, optionally filtered by custom Event Filters.
- Handlers (event listeners) process these events, and process the transactions, operations and metadata. Custom formatters may be applied for certain types of targets.

There are several existing handlers:

- Various built in Big Data handlers to apply records to supported Big Data targets, see Replicate Data to configure various handlers supported in Oracle GoldenGate for Big Data.
- JMS message handlers to send to a JMS provider using either a MapMessage, or using a TextMessage with customized formatters.
- A specialized message handler to send JMS messages to Oracle Advanced Queuing (AQ).
- A file writer handler, for writing to a single file, or a rolling file.

## Note:

The file writer handler is particularly useful as development utility, since the file writer can take the exact same formatter as the JMS TextMessage handler. Using the file writer provides a simple way to test and tune the formatters for JMS without actually sending the messages to JMS

Event handlers can be configured using the main Java property file or they may optionally read in their own properties directly from yet another property file (depending on the handler implementation). Handler properties are set using the following syntax:

```
gg.handler.{name}.someproperty=somevalue
```

This will cause the property *someproperty* to be set to the value *somevalue* for the handler instance identified in the property file by *name*. This *name* is used in the property file to define active handlers and set their properties; it is user-defined.

Implementation note (for Java developers): Following the preceding example: when the handler is instantiated, the method void setSomeProperty(String value) will be called on the handler instance, passing in the String value *somevalue*. A JavaBean PropertyEditor may also be defined for the handler, in which case the string can be automatically converted to the appropriate type for the setter method. For example, in the Java application properties file, we may have the following:

```
# the list of active handlers: only two are active
gg.handlerlist=one, two
# set properties on 'one'
gg.handler.one.type=file
gg.handler.one.format=com.mycompany.MyFormatter
gg.handler.one.file=output.xml
# properties for handler 'two'
gg.handler.two.type=jms_text
gg.handler.two.format=com.mycompany.MyFormatter
gg.handler.two.properties=jboss.properties
# set properties for handler 'foo'; this handler is ignored
gg.handler.foo.type=com.mycompany.MyHandler
gg.handler.foo.someproperty=somevalue
```

The type identifies the handler class; the other properties depend on the type of handler created. If a separate properties file is used to initialize the handler (such as the JMS handlers), the properties file is found in the classpath. For example, if properties file is at: {gg\_install\_dir}/dirprm/foo.properties, then specify in the properties file as follows: gg.handler.name.properties=foo.properties.

## **JMS Handler**

The main Java property file identifies active handlers. The JMS handler may optionally use a separate property file for JMS-specific configuration. This allows more than one JMS handler to be configured to run at the same time.

There are examples included for several JMS providers (JBoss, TIBCO, Solace, ActiveMQ, WebLogic). For a specific JMS provider, you can choose the appropriate properties files as a starting point for your environment. Each JMS provider has slightly different settings, and your environment will have unique settings as well.

The installation directory for the Java JARs (ggjava) contains the core application JARs (ggjava.jar) and its dependencies in resources/lib/\*.jar. The resources directory contains all dependencies and configuration, and is in the classpath.

If the JMS client JARs already exist somewhere on the system, they can be referenced directly and added to the classpath without copying them.

The following types of JMS handlers can be specified:

• **jms** – sends text messages to a topic or queue. The messages may be formatted using Velocity templates or by writing a formatter in Java. The same formatters can be used for a jms text message as for writing to files. (jms text is a synonym for jms.)

- aq sends text messages to Oracle Advanced Queuing (AQ). The aq handler is a jms handler configured for delivery to AQ. The messages can be formatted using Velocity templates or a custom formatter.
- **jms\_map** sends a JMS MapMessage to a topic or queue. The JMSType of the message is set to the name of the table. The body of the message consists of the following metadata, followed by column name and column value pairs:
  - GG ID position of the record, uniquely identifies this operation
  - GG OPTYPE type of SQL (insert/update/delete),
  - GG TABLE table name on which the operation occurred
  - GG TX TIMESTAMP timestamp of the operation

## File Handler

The file handler is often used to verify the message format when the actual target is JMS, and the message format is being developed using custom Java or Velocity templates. Here is a property file using a file handler:

```
# one file handler active, using Velocity template formatting
gg.handlerlist=myfile
gg.handler.myfile.type=file
gg.handler.myfile.rollover.size=5M
gg.handler.myfile.format=sample2xml.vm
gg.handler.myfile.file=output.xml
```

This example uses a single handler (though, a JMS handler and the file handler could be used at the same time), writing to a file called output.xml, using a Velocity template called sample2xml.vm. The template is found using the classpath.

## **Custom Handlers**

For information on coding a custom handler, see Coding a Custom Handler in Java.

## Formatting the Output

As previously described, the existing JMS and file output handlers can be configured through the properties file. Each handler has its own specific properties that can be set: for example, the output file can be set for the file handler, and the JMS destination can be set for the JMS handler. Both of these handlers may also specify a custom formatter. The same formatter may be used for both handlers. As an alternative to writing Java code for custom formatting, a Velocity template may be specified For further information, see Filtering Events.

## Reporting

Summary statistics about the throughput and amount of data processed are generated when the Replicat or Extract process stops. Additionally, statistics can be written periodically either after a specified amount of time or after a specified number of records have been processed. If both time and number of records are specified, then the report is generated for whichever event happens first. These statistical summaries are written to the Oracle GoldenGate report file and the log files.

# Java Delivery Properties

- Common Properties
- Delivery Properties
- Java Application Properties

## **Common Properties**

The following properties are common to Java Delivery using either Replicat or Extract.

- Logging Properties
- JVM Boot Options

## Logging Properties

Logging is controlled by the following properties.

- gg.log
- gg.log.level
- gg.log.file
- gg.log.classpath

## gg.log

Specifies the type of logging that is to be used. The default implementation for the Oracle GoldenGate for Big Data is the jdk option. This is the built-in Java logging called java.util.logging (JUL). The other logging options are log4j or logback.

For example, to set the type of logging to log4j:

gg.log=log4j

The recommended setting is log4j. The log file is created in the dirrpt subdirectory of the installation. The default log file name includes the group name of the associated Extract and the file extension is .log.

<process name>\_<log level>\_log4j.log

Therefore if the Oracle GoldenGate Replicat process is called javaue, and the gg.log.level is set to debug, the resulting log file name will be:

javaue debug log4j.log

#### gg.log.level

Specifies the overall log level for all modules. The syntax is:

gg.log.level={ERROR|WARN|INFO|DEBUG|TRACE}

The log levels are defined as follows:

- ERROR Only write messages if errors occur
- WARN Write error and warning messages

- INFO Write error, warning and informational messages
- DEBUG Write all messages, including debug ones.
- TRACE Highest level of logging, includes all messages.

The default logging level is INFO. The messages in this case will be produced on startup, shutdown and periodically during operation. If the level is switched to DEBUG, large volumes of messages may occur which could impact performance. For example, the following sets the global logging level to INFO:

# global logging level
gg.log.level=INFO

## gg.log.file

Specifies the path to the log file. The syntax is:

```
gg.log.file=path_to_file
```

Where the *path\_to\_file* is the fully defined location of the log file. This allows a change to the name of the log, but you must include the Replicat name if you have more than one Replicat to avoid one overwriting the log of the other.

#### gg.log.classpath

Specifies the classpath to the JARs used to implement logging. This configuration property is not typically used as the ggjava.jar library includes the required logging dependency libraries.

```
gg.log.classpath=path_to_jars
```

## JVM Boot Options

The following options configure the Java Runtime Environment. Java classpath and memory options are configurable.

jvm.bootoptions

#### jvm.bootoptions

Specifies the initial Java classpath and other boot options that will be applied when the JVM starts. The java.class.path needs colon (:) separators for UNIX/Linux and semicolons (;) for Windows. This is where to specify various options for the JVM, such as initial and maximum heap size and classpath; for example:

- -Xms: initial java heap size
- -Xmx: maximum java heap size
- -Djava.class.path: classpath specifying location of at least the main application JAR, ggjava.jar. Other JARs, such as JMS provider JARs, may also be specified here as well; alternatively, these may be specified in the Java application properties file. If using a separate log4j properties file then the location of the properties file must be included in the bootoptions java.class.path included in the bootoptions variable.
- -verbose:jni: run in verbose mode (for JNI)

For example (all on a single line):

```
jvm.bootoptions= -Djava.class.path=ggjava/ggjava.jar
-Dlog4j.configuration=my-log4j.properties -Xmx512m
```

The log4j.configuration property identifies a log4j properties file that is resolved by searching the classpath. You may use your own log4j configuration, or one of the preconfigured log4j settings: log4j.properties (default level of logging), debug-log4j.properties (debug logging) or trace-log4j.properties (very verbose logging). To use log4j logging with the Replicat process gg.log=log4j must be set.

Use of the one of the preconfigured log4j settings does not require any change to the classpath since those files are already included in the classpath. The -Djava.class.path variable must include the path to the directory containing a custom log4j configuration file without the \* wild card appended.

## **Delivery Properties**

The following properties are available to Java Delivery:

- General Properties
- Statistics and Reporting

Disables or enables the checkpoint file handling. This causes the standard Oracle GoldenGate reporting to be incomplete. Oracle GoldenGate for Java adds its own reporting to handle this issue.

## **General Properties**

The following properties apply to all writer configurations:

- goldengate.userexit.writers
- goldengate.userexit.chkptprefix
- goldengate.userexit.nochkpt
- goldengate.userexit.usetargetcols

#### goldengate.userexit.writers

Specifies the name of the writer. This is always jvm and should not be modified.

For example:

```
goldengate.userexit.writers=jvm
```

All other properties in the file should be prefixed by the writer name, jvm.

#### goldengate.userexit.chkptprefix

Specifies a string value for the prefix added to the Java checkpoint file name. For example:

goldengate.userexit.chkptprefix=javaue\_

#### goldengate.userexit.nochkpt

Disables or enables the checkpoint file. The default is false, the checkpoint file is enabled. Set this property to true if transactions are supported and enabled on the target.

For example, Java Adapter Properties if JMS is the target and JMS local transactions are enabled (the default), set goldengate.userexit.nochkpt=true to disable the user exit

checkpoint file. If JMS transactions are disabled by setting <code>localTx=false</code> on the handler, the checkpoint file should be enabled by setting <code>goldengate.userexit.nochkpt=false</code>.

```
goldengate.userexit.nochkpt=true|false
```

#### goldengate.userexit.usetargetcols

Specifies whether or not mapping to target columns is allowed. The default is false, no target mapping.

goldengate.userexit.usetargetcols=true|false

## Statistics and Reporting

Disables or enables the checkpoint file handling. This causes the standard Oracle GoldenGate reporting to be incomplete. Oracle GoldenGate for Java adds its own reporting to handle this issue.

Statistics can be reported every t seconds or every n records - or if both are specified, whichever criteria is met first.

There are two sets of statistics recorded: those maintained by the Replicat module and those obtained from the Java module. The reports received from the Java side are formatted and returned by the individual handlers.

The statistics include the total number of operations, transactions and corresponding rates.

- jvm.stats.display
- jvm.stats.full
- jvm.stats.time | jvm.stats.numrecs

#### jvm.stats.display

Controls the output of statistics to the Oracle GoldenGate report file and to the user exit log files.

The following example outputs these statistics.

jvm.stats.display=true

#### jvm.stats.full

Controls the output of statistics from the Java side, in addition to the statistics from the C side.

Java side statistics are more detailed but also involve some additional overhead, so if statistics are reported often and a less detailed summary is adequate, it is recommended that stats.full property is set to false.

The following example will output Java statistics in addition to C.

jvm.stats.full=true

#### *jvm*.stats.time | *jvm*.stats.numrecs

Specifies a time interval, in seconds or a number of records, after which statistics will be reported. The default is to report statistics every hour or every 10000 records (which ever occurs first).

For example, to report ever 10 minutes or every 1000 records, specify:

```
jvm.stats.time=600
jvm.stats.numrecs=1000
```

The Java application statistics are handler-dependent:

- For the all handlers, there is at least the total elapsed time, processing time, number of operations, transactions;
- For the JMS handler, there is additionally the total number of bytes received and sent.
- The report can be customized using a template.

## Java Application Properties

The following defines the properties which may be set in the Java application property file.

- Properties for All Handlers
- Properties for Formatted Output
- Properties for CSV and Fixed Format Output
- File Writer Properties
- JMS Handler Properties
- JNDI Properties
- General Properties
- Java Delivery Transaction Grouping

## **Properties for All Handlers**

The following properties apply to all handlers:

- gg.handlerlist
- gg.handler.name.type

#### gg.handlerlist

The handler list is a list of active handlers separated by commas. These values are used in the rest of the property file to configure the individual handlers. For example:

```
gg.handlerlist=name1, name2
gg.handler.name1.propertyA=value1
gg.handler.name1.propertyB=value2
gg.handler.name1.propertyC=value3
gg.handler.name2.propertyA=value1
gg.handler.name2.propertyB=value2
gg.handler.name2.propertyC=value3
```

Using the handlerlist property, you may include completely configured handlers in the property file and just disable them by removing them from the handlerlist.

#### gg.handler.*name*.type

This type of handler. This is either a predefined value for built-in handlers, or a fully qualified Java class name. The syntax is:

gg.handler.name.type={jms|jms\_map|aq|singlefile|rollingfile|custom\_java\_class}

Where:

All but the last are pre-defined handlers:

- jms Sends transactions, operations, and metadata as formatted messages to a JMS provider
- aq Sends transactions, operations, and metadata as formatted messages to Oracle Advanced Queuing (AQ)
- jms\_map Sends JMS map messages
- singlefile Writes to a single file on disk, but does not roll the file
- **rollingfile** Writes transactions, operations, and metadata to a file on disk, rolling the file over after a certain size, amount of time, or both. For example:

```
gg.handler.name1.rolloverSize=5000000
gg.handler.name1.rolloverTime=1m
```

 custom\_java\_class – Any class that extends the Oracle GoldenGate for Java AbstractHandler class and can handle transaction, operation, or metadata events

The Oracle GoldenGate foe Big Data package also contains more predefined handlers to write to various Big Data targets.

## **Properties for Formatted Output**

The following properties apply to all handlers capable of producing formatted output; this includes:

- The jms text handler (but not the jms map handler)
- The aq handler
- The singlefile and rolling handlers, for writing formatted output to files
- The predefined Big Data handlers
- gg.handler.name.format
- gg.handler.name.includeTables
- gg.handler.name.excludeTables
- gg.handler.name.mode, gg.handler.name.format.mode

#### gg.handler.name.format

Specifies the format used to transform operations and transactions into messages sent to JMS, to the Big Data target or to a file. The format is specified uniquely for each handler. The value may be:

- Velocity template
- Java class name (fully qualified the class specified must be a type of formatter)
- csv for delimited values (such as comma separated values; the delimiter can be customized)
- fixed for fixed-length fields
- Built-in formatter, such as:
  - xml demo XML format
  - xml2 internal XML format

For example, to specify a custom Java class:

```
gg.handlerlist=abc
gg.handler.abc.format=com.mycompany.MyFormat
```

#### Or, for a Velocity template:

```
gg.handlerlist=xyz
gg.handler.xyz.format=path/to/sample.vm
```

If using templates, the file is found relative to some directory or JAR that is in the classpath. By default, the Oracle GoldenGate installation directory is in the classpath, so the preceding template could be placed in the dirprm directory of the Oracle GoldenGate installation location.

The default format is to use the built-in XML formatter.

#### gg.handler.name.includeTables

Specifies a list of tables this handler will include.

If the schema (or owner) of the table is specified, then only that schema matches the table name; otherwise, the table name matches any schema. A comma separated list of tables can be specified. For example, to have the handler only process tables foo.customer and bar.orders:

gg.handler.myhandler.includeTables=foo.customer, bar.orders

If the catalog and schema (or owner) of the table are specified, then only that catalog and schema matches the table name; otherwise, the table name matches any catalog and schema. A comma separated list of tables can be specified. For example, to have the handler only process tables dbo.foo.customer and dbo.bar.orders:

gg.handler.myhandler.includeTables=dbo.foo.customer, dbo.bar.orders

#### Note:

In order to selectively process operations on a table by table basis, the handler must be processing in operation mode. If the handler is processing in transaction mode, then when a single transaction contains several operations spanning several tables, if any table matches the include list of tables, the transaction will be included.

#### gg.handler.name.excludeTables

Specifies a list of tables this handler will exclude.

If the schema (or owner) of the table is specified, then only that schema matches the table name; otherwise, the table name matches any schema. A list of tables may be specified, comma-separated. For example, to have the handler process all operations on all tables except table date modified in all schemas:

gg.handler.myhandler.excludeTables=date\_modified

If the catalog and schema (or owner) of the table are specified, then only that catalog and schema matches the table name; otherwise, the table name matches any catalog and schema. A list of tables may be specified, comma-separated. For example, to have the handler process all operations on all tables except table date\_modified in catalog dbo and schema bar:

gg.handler.myhandler.excludeTables=dbo.bar.date\_modified

#### gg.handler.name.mode, gg.handler.name.format.mode

Specifies whether to output one operation per message (op) or one transaction per message (tx). The default is op. Use gg.handler.name.format.mode when you have a custom formatter.

## Properties for CSV and Fixed Format Output

If the handler is set to use either comma separated values (CSV) CSV or fixed format output, the following properties may also be set.

- gg.handler.name.format.delim
- gg.handler.name.format.quote
- gg.handler.name.format.metacols
- gg.handler.name.format.missingColumnChar
- gg.handler.name.format.presentColumnChar
- gg.handler.name.format.nullColumnChar
- gg.handler.name.format.beginTxChar
- gg.handler.name.format.middleTxChar
- gg.handler.name.format.endTxChar
- gg.handler.name.format.wholeTxChar
- gg.handler.name.format.insertChar

- gg.handler.name.format.updateChar
- gg.handler.name.format.deleteChar
- gg.handler.name.format.truncateChar
- gg.handler.name.format.endOfLine
- gg.handler.name.format.justify
- gg.handler.name.format.includeBefores

#### gg.handler.name.format.delim

Specifies the delimiter to use between fields. Set this to no value to have no delimiter used. For example:

```
gg.handler.handler1.format.delim=,
```

#### gg.handler.name.format.quote

Specifies the quote character to be used if column values are quoted. For example:

gg.handler.handler1.format.quote='

#### gg.handler.name.format.metacols

Specifies the metadata column values to appear at the beginning of the record, before any column data. Specify any of the following, in the order they should appear:

- position unique position indicator of records in a trail
- **opcode** I, U, **or** D **for insert**, **update**, **or delete records (see**: insertChar, updateChar, deleteChar)
- **txind** transaction indicator such as 0=begin, 1=middle, 2=end, 3=whole tx (see beginTxChar, middleTxChar, endTxChar, wholeTxChar)
- opcount position of a record in a transaction, starting from 0
- catalog catalog of the schema for the record
- schema schema/owner of the table for the record
- **tableonly** just table (no schema/owner)
- table full name of table, catalog.schema.table
- timestamp commit timestamp of record

For example:

gg.handler.handler1.format.metacols=opcode, table, txind, position

#### gg.handler.name.format.missingColumnChar

Specifies a special column prefix for a column value that was not captured from the source database transaction log. The column value is not in trail and it is unknown if it has a value or is <code>NULL</code>

The character used to represent the missing state of the column value can be customized. For example:

gg.handler.handler1.format.missingColumnChar=M

By default, the missing column value is set to an empty string and does not show.

#### gg.handler.name.format.presentColumnChar

Specifies a special column prefix for a column value that exists in the trail and is not  $\ensuremath{\mathtt{NULL}}$  .

The character used to represent the state of the column can be customized. For example:

gg.handler.handler1.format.presentColumnChar=P

By default, the present column value is set to an empty string and does not show.

#### gg.handler.name.format.nullColumnChar

Specifies a special column prefix for a column value that exists in the trail and is set to  $\ensuremath{\mathtt{NULL}}$  .

The character used to represent the state of the column can be customized. For example:

gg.handler.handler1.format.nullColumnChar=N

By default, the null column value is set to an empty string and does not show.

#### gg.handler.name.format.beginTxChar

Specifies the header metadata character (see metacols) used to identify a record as the begin of a transaction. For example:

gg.handler.handler1.format.beginTxChar=B

## gg.handler.name.format.middleTxChar

Specifies the header metadata characters (see metacols) used to identify a record as the middle of a transaction. For example:

gg.handler.handler1.format.middleTxChar=M

#### gg.handler.name.format.endTxChar

Specifies the header metadata characters (see metacols) used to identify a record as the end of a transaction. For example:

gg.handler.handler1.format.endTxChar=E

#### gg.handler.name.format.wholeTxChar

Specifies the header metadata characters (see metacols) used to identify a record as a complete transaction; referred to as a whole transaction. For example:

gg.handler.handler1.format.wholeTxChar=W

#### gg.handler.name.format.insertChar

Specifies the character to identify an insert operation. The default I.

For example, to use INS instead of I for insert operations:

gg.handler.handler1.format.insertChar=INS

#### gg.handler.name.format.updateChar

Specifies the character to identify an update operation. The default is U.

For example, to use UPD instead of U for update operations:

gg.handler.handler1.format.updateChar=UPD

#### gg.handler.name.format.deleteChar

Specifies the character to identify a delete operation. The default is D.

For example, to use DEL instead of D for delete operations:

gg.handler.handler1.format.deleteChar=DEL

#### gg.handler.name.format.truncateChar

Specifies the character to identify a truncate operation. The default is T.

For example, to use TRUNC instead of T for truncate operations:

gg.handler.handler1.format.truncateChar=TRUNC

#### gg.handler.name.format.endOfLine

#### Specifies the end-of-line character as:

- EOL Native platform
- CR Neutral (UNIX-style \n)
- CRLF Windows (\r\n)

For example:

gg.handler.handler1.format.endOfLine=CR

#### gg.handler.name.format.justify

Specifies the left or right justification of fixed fields. For example:

gg.handler.handler1.format.justify=left

## gg.handler.name.format.includeBefores

Controls whether before images should be included in the output. There must be before images in the trail. For example:

gg.handler.handler1.format.includeBefores=false

## **File Writer Properties**

The following properties only apply to handlers that write their output to files: the file handler and the singlefile handler.

- gg.handler.name.file
- gg.handler.name.append

#### gg.handler.name.rolloverSize

#### gg.handler.name.file

Specifies the name of the output file for the given handler. If the handler is a rolling file, this name is used to derive the rolled file names. The default file name is output.xml.

#### gg.handler.name.append

Controls whether the file should be appended to (true) or overwritten upon restart (false).

#### gg.handler.name.rolloverSize

If using the file handler, this specifies the size of the file before a rollover should be attempted. The file size will be at least this size, but will most likely be larger. Operations and transactions are not broken across files. The size is specified in bytes, but a suffix may be given to identify MB or KB. For example:

```
gg.handler.myfile.rolloverSize=5MB
```

The default rollover size is 10MB.

#### JMS Handler Properties

The following properties apply to the JMS handlers. Some of these values may be defined in the Java application properties file using the name of the handler. Other properties may be placed into a separate JMS properties file, which is useful if using more than one JMS handler at a time. For example:

```
gg.handler.myjms.type=jms_text
gg.handler.myjms.format=xml
gg.handler.myjms.properties=weblogic.properties
```

Just as with Velocity templates and formatting property files, this additional JMS properties file is found in the classpath. The preceding properties file weblogic.properties would be found in {gg\_install\_dir}/dirprm/ weblogic.properties, since the dirprm directory is included by default in the classpath.

Settings that can be made in the Java application properties file will override the corresponding value set in the supplemental JMS properties file (weblogic.properties in the preceding example). In the following example, the destination property is specified in the Java application properties file. This allows the same default connection information for the two handlers myjms1 and myjms2, but customizes the target destination queue.

```
gg.handlerlist=myjms1,myjms2
gg.handler.myjms1.type=jms_text
gg.handler.myjms1.destination=queue.sampleA
gg.handler.myjms1.format=sample.vm
gg.handler.myjms1.properties=tibco-default.properties
gg.handler.myjms2.type=jms_map
gg.handler.myjms2.destination=queue.sampleB
gg.handler.myjms2.properties=tibco-default.properties
```

To set a property, specify the handler name as a prefix; for example:

- gg.handlerlist=sample
  gg.handler.sample.type=jms\_text
  gg.handler.sample.format=my template.vm
- gg.handler.sample.destination=gg.myqueue
- gg.handler.sample.queueortopic=queue
- gg.handler.sample.connectionUrl=tcp://host:61616?jms.useAsyncSend=true
- gg.handler.sample.useJndi=false
- gg.handler.sample.connectionFactory=ConnectionFactory
- gg.handler.sample.connectionFactoryClass=\
- org.apache.activemq.ActiveMQConnectionFactory
- gg.handler.sample.timeToLive=50000
- Standard JMS Settings
- Group Transaction Properties

#### Standard JMS Settings

The following outlines the JMS properties which may be set, and the accepted values. These apply for both JMS handler types: jms text (TextMessage) and jms map (MapMessage).

- gg.handler.name.destination
- gg.handler.name.user
- gg.handler.name.password
- gg.handler.name.queueOrTopic
- gg.handler.name.persistent
- gg.handler.name.priority
- gg.handler.name.timeToLive
- gg.handler.name.connectionFactory
- gg.handler.name.useJndi
- gg.handler.name.connectionUrl
- gg.handler.name.connectionFactoryClass
- gg.handler.name.localTX
- gg.handlerlist.nop
- gg.handler.name.physicalDestination

#### gg.handler.name.destination

The queue or topic to which the message is sent. This must be correctly configured on the JMS server. Typical values may be: queue/A, queue.Test, example.MyTopic, etc.

gg.handler.name.destination=queue or topic

#### gg.handler.name.user

(Optional) User name required to send messages to the JMS server.

gg.handler.name.user=user name

#### gg.handler.name.password

(Optional) Password required to send messages to the JMS server

gg.handler.name.password=password

#### gg.handler.name.queueOrTopic

Whether the handler is sending to a queue (a single receiver) or a topic (publish / subscribe). This must be correctly configured in the JMS provider. This property is an alias of gg.handler.name.destination. The syntax is:

gg.handler.name.queueOrTopic=queue|topic

Where:

- queue a message is removed from the queue once it has been read. This is the default.
- topic messages are published and may be delivered to multiple subscribers.

#### gg.handler.name.persistent

If the delivery mode is set to persistent or not. If the messages are to be persistent, the JMS provider must be configured to log the message to stable storage as part of the client's send operation. The syntax is:

gg.handler.name.persistent={true|false}

#### gg.handler.name.priority

JMS defines a 10 level priority value, with 0 as the lowest and 9 as the highest. Priority is set to 4 by default. The syntax is:

gg.handler.name.priority=integer

#### For example:

gg.handler.name.priority=5

#### gg.handler.name.timeToLive

The length of time in milliseconds from its dispatch time that a produced message should be retained by the message system. A value of zero specifies the time is unlimited. The default is zero. The syntax is:

gg.handler.name.timeToLive=milliseconds

For example:

gg.handler.name.timeToLive= 36000

#### gg.handler.name.connectionFactory

Name of the connection factory to lookup using JNDI. ConnectionFactoryJNDIName is an alias. The syntax is:

gg.handler.name.connectionFactory=JNDI name

#### gg.handler.name.useJndi

If gg.handler.name.usejndi is false, then JNDI is not used to configure the JMS client. Instead, factories and connections are explicitly constructed. The syntax is:

gg.handler.name.useJndi=true|false

#### gg.handler.name.connectionUrl

Connection URL is used only when not using JNDI to explicitly create the connection. The syntax is:

gg.handler.name.connectionUrl=url

#### gg.handler.name.connectionFactoryClass

The Connection Factory Class is used to access a factory only when not using JNDI. The value of this property is the Java class name to instantiate; constructing a factory object explicitly.

gg.handler.name.connectionFactoryClass=java class name

#### gg.handler.name.localTX

Specifies whether or not local transactions are used. The default is true, local transactions are used. The syntax is:

gg.handler.name.localTX=true|false

#### gg.handlerlist.nop

Disables the sending of JMS messages to allow testing of message generation. This is a global property used only for testing. The events are still generated and handled and the message is constructed. The default is false; do not disable message send. The syntax is:

gg.handlerlist.nop=true|false

Users can take advantage of this option to measure the performance of trail records processing without involving the handler module. This approach can narrow down the possible culprits of a suspected performance issue while applying trail records to the target system.

#### gg.handler.name.physicalDestination

Name of the queue or topic object, obtained through the ConnectionFactory API instead of the JNDI provider.

gg.handler.name.physicalDestination=queue name

#### **Group Transaction Properties**

These properties set limits for grouping transactions.

#### JNDI Properties

These JNDI properties are required for connection to an Initial Context to look up the connection factory and initial destination.

```
java.naming.provider.url=url
java.naming.factory.initial=java-class-name
```

#### If JNDI security is enabled, the following properties may be set:

```
java.naming.security.principal=user-name
java.naming.security.credentials=password-or-other-authenticator
```

#### For example:

```
java.naming.provider.url= t3://localhost:7001
java.naming.factory.initial=weblogic.jndi.WLInitialContextFactory
java.naming.security.principal=jndiuser
java.naming.security.credentials=jndipw
```

## **General Properties**

The following are general properties that are used for the Java framework:

- gg.classpath
- gg.report.time
- gg.binaryencoding

#### gg.classpath

Specifies a comma delimited list of additional paths to directories or JARs to add to the classpath. Optionally, the list can be delimited by semicolons for Windows systems or by colons for UNIX. For example:

gg.classpath=C:\Program Files\MyProgram\bin;C:\Program Files\ProgramB\app\bin;

This Adapter properties file configuration property should be used to configure pathing to custom Java JARs or to the external dependencies of Big Data applications.

#### gg.report.time

Specifies how often statistics are calculated and sent to Extract for the processing report. If Extract is configured to print a report, these statistics are included. The syntax is:

```
gg.report.time=report interval{s|m|h}
```

#### Where:

- report interval is an integer
- The valid time units are:
  - s seconds
  - m minutes
  - h hours

If no value is entered, the default is to calculate and send every 24 hours.

#### gg.binaryencoding

Specifies the binary encoding type. The desired output encoding for binary data can be configured using this property. For example:

gg.binaryencoding=base64|hex

The default value is base64. The valid values to represent binary data are:

- base64 a base64 string
- hex a hexadecimal string

## Java Delivery Transaction Grouping

Transaction grouping can significantly improve the performance of Java integrations especially Big Data integrations. Java Delivery provides functionality to perform transaction grouping. When Java Delivery is hosted by a Replicat process then the GROUPTRANSOPS Replicat configuration should be used to perform transaction grouping.

# Developing Custom Filters, Formatters, and Handlers

- Filtering Events
- Custom Formatting
- Coding a Custom Handler in Java
- Additional Resources

## Filtering Events

By default, all transactions, operations and metadata events are passed to the DataSourceListener event handlers. An event filter can be implemented to filter the events sent to the handlers. The filter could select certain operations on certain tables containing certain column values, for example

Filters are additive: if more than one filter is set for a handler, then all filters must return true in order for the event to be passed to the handler.

You can configure filters using the Java application properties file:

```
# handler "foo" only receives certain events
gg.handler.one.type=jms
gg.handler.one.format=mytemplate.vm
gg.handler.one.filter=com.mycompany.MyFilter
```

To activate the filter, you write the filter and set it on the handler; no additional logic needs to be added to specific handlers.

## **Custom Formatting**

You can customize the output format of a built-in handler by:

- Writing a custom formatter in Java or
- Using a velocity template
- Coding a Custom Formatter in Java
- Using a Velocity Template

## Coding a Custom Formatter in Java

The preceding examples show a JMS handler and a file output handler using the same formatter (com.mycompany.MyFormatter). The following is an example of how this formatter may be implemented.

#### Example 9-14 Custom Formatting Implementation

```
package com.mycompany.MyFormatter;
import oracle.goldengate.datasource.DsOperation;
import oracle.goldengate.datasource.DsTransaction;
import oracle.goldengate.datasource.format.DsFormatterAdapter;
import oracle.goldengate.datasource.meta.ColumnMetaData;
import oracle.goldengate.datasource.meta.DsMetaData;
import oracle.goldengate.datasource.meta.TableMetaData;
import java.io.PrintWriter;
public class MyFormatter extends DsFormatterAdapter {
```

```
public MyFormatter() { }
        @Override
        public void formatTx(DsTransaction tx,
DsMetaData meta,
PrintWriter out)
        {
            out.print("Transaction: " );
            out.print("numOps=\'" + tx.getSize() + "\' " );
            out.println("ts=\'" + tx.getStartTxTimeAsString() + "\'");
            for(DsOperation op: tx.getOperations()) {
TableName currTable = op.getTableName();
TableMetaData tMeta = dbMeta.getTableMetaData(currTable);
String opType = op.getOperationType().toString();
String table = tMeta.getTableName().getFullName();
out.println(opType + " on table \"" + table + "\":" );
int colNum = 0;
for(DsColumn col: op.getColumns())
{
ColumnMetaData cMeta = tMeta.getColumnMetaData( colNum++ );
out.println(
cMeta.getColumnName() + " = " + col.getAfterValue() );
}
        }
        ROverride
        public void formatOp(DsTransaction tx,
DsOperation op,
TableMetaData tMeta,
PrintWriter out)
        {
            // not used...
        }
}
```

The formatter defines methods for either formatting complete transactions (after they are committed) or individual operations (as they are received, before the commit). If the formatter is in operation mode, then formatOp(...) is called; otherwise, formatTx(...) is called at transaction commit.

To compile and use this custom formatter, include the Oracle GoldenGate for Java JARs in the classpath and place the compiled .class files in gg install dir/dirprm:

```
javac -d gg_install_dir/dirprm
-classpath ggjava/ggjava.jar MyFormatter.java
```

The resulting class files are located in resources/classes (in correct package structure):

gg install dir/dirprm/com/mycompany/MyFormatter.class

Alternatively, the custom classes can be put into a JAR; in this case, either include the JAR file in the JVM classpath using the user exit properties (using java.class.path in the jvm.bootoptions property), or by setting the Java application properties file to include your custom JAR:

```
# set properties on 'one'
gg.handler.one.type=file
gg.handler.one.format=com.mycompany.MyFormatter
gg.handler.one.file=output.xml
gg.classpath=/path/to/my.jar,/path/to/directory/of/jars/*
```

#### Using a Velocity Template

As an alternative to writing Java code for custom formatting, Velocity templates can be a good alternative to quickly prototype formatters. For example, the following template could be specified as the format of a JMS or file handler:

```
Transaction: numOps='$tx.size' ts='$tx.timestamp'
#for each( $op in $tx )
operation: $op.sqlType, on table "$op.tableName":
#for each( $col in $op )
$op.tableName, $col.meta.columnName = $col.value
#end
#end
```

If the template were named sample.vm, it could be placed in the classpath, for example:

```
gg install dir/dirprm/sample.vm
```

Update the Java application properties file to use the template:

```
# set properties on 'one'
gg.handler.one.type=file
gg.handler.one.format=sample.vm
gg.handler.one.file=output.xml
```

When modifying templates, there is no need to recompile any Java source; simply save the template and re-run the Java application. When the application is run, the following output would be generated (assuming a table named SCHEMA.SOMETABLE, with columns TESTCOLA and TESTCOLB):

```
Transaction: numOps='3' ts='2008-12-31 12:34:56.000'
operation: UPDATE, on table "SCHEMA.SOMETABLE":
SCHEMA.SOMETABLE, TESTCOLA = value 123
SCHEMA.SOMETABLE, TESTCOLB = value abc
operation: UPDATE, on table "SCHEMA.SOMETABLE":
SCHEMA.SOMETABLE, TESTCOLA = value 456
SCHEMA.SOMETABLE, TESTCOLB = value def
operation: UPDATE, on table "SCHEMA.SOMETABLE":
SCHEMA.SOMETABLE, TESTCOLA = value 789
SCHEMA.SOMETABLE, TESTCOLB = value ghi
```

## Coding a Custom Handler in Java

A custom handler can be implemented by extending <code>AbstractHandler</code> as in the following example:

```
import oracle.goldengate.datasource.*;
import static oracle.goldengate.datasource.GGDataSource.Status;
```

```
public class SampleHandler extends AbstractHandler {
        @Override
        public void init(DsConfiguration conf, DsMetaData metaData) {
            super.init(conf, metaData);
            // ... do additional config...
        1
        @Override
       public Status operationAdded(DsEvent e, DsTransaction tx, DsOperation
op) { ... }
        @Override
        public Status transactionCommit(DsEvent e, DsTransaction tx) { ... }
        @Override
        public Status metaDataChanged(DsEvent e, DsMetaData meta) { .... }
        @Override
        public void destroy() { /* ... do cleanup ... */ }
        @Override
        public String reportStatus() { return "status report..."; }
        @Override
        public Status ddlOperation(OpType opType, ObjectType objectType, String
objectName, String ddlText) }
```

The method in AbstractHandler is not abstract rather it has a body. In the body it performs cached metadata invalidation by marking the metadata object as dirty. It also provides TRACE-level logging of DDL events when the ddlOperation method is specified. You can override this method in your custom handler implementations. You should always call the super method before any custom handling to ensure the functionality in AbstractHandler is executed

When a transaction is processed from the Extract, the order of calls into the handler is as follows:

- 1. Initialization:
  - First, the handler is constructed.
  - Next, all the "setters" are called on the instance with values from the property file.
  - Finally, the handler is initialized; the init(...) method is called before any transactions are received. It is important that the init(...) method call super.init(...) to properly initialize the base class.
- 2. Metadata is then received. If the Java module is processing an operation on a table not yet seen during this run, a metadata event is fired, and the metadataChanged(...) method is called. Typically, there is no need to implement this method. The DsMetaData is automatically updated with new data source metadata as it is received.
- A transaction is started. A transaction event is fired, causing the transactionBegin(...) method on the handler to be invoked (this is not shown). This is typically not used, since the transaction has zero operations at this point.
- 4. Operations are added to the transaction, one after another. This causes the operationAdded(...) method to be called on the handler for each operation added. The containing transaction is also passed into the method, along with the data source metadata that contains all processed table metadata. The transaction has not yet been committed, and could be aborted before the commit is received.

Each operation contains the column values from the transaction (possibly just the changed values when Extract is processing with compressed updates.) The column values may contain both before and after values.

For the ddlOperation method, the options are:

- opType Is an enumeration that identifies the DDL operation type that is occurring (CREATE, ALTER, and so on).
- objectType Is an enumeration that identifies the type of the target of the DDL (TABLE, VIEW, and so on).
- objectName Is the fully qualified source object name; typically a fully qualified table name.
- ddlText Is the raw DDL text executed on the source relational database.
- 5. The transaction is committed. This causes the transactionCommit(...) method to be called.
- 6. Periodically, reportStatus may be called; it is also called at process shutdown. Typically, this displays the statistics from processing (the number of operations andtransactions processed and other details).

An example of a simple printer handler, which just prints out very basic event information for transactions, operations and metadata follows. The handler also has a property myoutput for setting the output file name; this can be set in the Java application properties file as follows:

```
gg.handlerlist=sample
# set properties on 'sample'
gg.handler.sample.type=sample.SampleHandler
gg.handler.sample.myoutput=out.txt
```

To use the custom handler,

- 1. Compile the class
- 2. Include the class in the application classpath,
- 3. Add the handler to the list of active handlers in the Java application properties file.

To compile the handler, include the Oracle GoldenGate for Java JARs in the classpath and place the compiled .class files in *gg install dirl*javaue/resources/classes:

```
javac -d gg_install_dir/dirprm
-classpath ggjava/ggjava.jar SampleHandler.java
```

The resulting class files would be located in resources/classes, in correct package structure, such as:

gg install dir/dirprm/sample/SampleHandler.class

#### Note:

For any Java application development beyond *hello world* examples, either Ant or Maven would be used to compile, test and package the application. The examples showing javac are for illustration purposes only.

Alternatively, custom classes can be put into a JAR and included in the classpath. Either include the custom JAR files in the JVM classpath using the Java properties (using java.class.path in the jvm.bootoptions property), or by setting the Java application properties file to include your custom JAR:

```
# set properties on 'one'
gg.handler.one.type=sample.SampleHandler
gg.handler.one.myoutput=out.txt
gg.classpath=/path/to/my.jar,/path/to/directory/of/jars/*
```

The classpath property can be set on any handler to include additional individual JARs, a directory (which would contain resources or extracted class files) or a whole directory of JARs. To include a whole directory of JARs, use the Java 6 style syntax:

c:/path/to/directory/\* (or on UNIX: /path/to/directory/\* )

Only the wildcard \* can be specified; a file pattern cannot be used. This automatically matches all files in the directory ending with the .jar suffix. To include multiple JARs or multiple directories, you can use the system-specific path separator (on UNIX, the colon and on Windows the semicolon) or you can use platform-independent commas, as shown in the preceding example.

If the handler requires many properties to be set, just include the property in the parameter file, and your handler's corresponding "setter" will be called. For example:

```
gg.handler.one.type=com.mycompany.MyHandler
gg.handler.one.myOutput=out.txt
gg.handler.one.myCustomProperty=12345
```

The preceding example would invoke the following methods in the custom handler:

```
public void setMyOutput(String s) {
    // use the string...
} public void setMyCustomProperty(int j) {
    // use the int...
}
```

Any standard Java type may be used, such as int, long, String, boolean. For custom types, you may create a custom property editor to convert the String to your custom type.

## Additional Resources

There is Javadoc available for the Java API. The Javadoc has been intentionally reduced to a set of core packages, classes and interfaces in order to only distribute the relevant interfaces and classes useful for customizing and extension.

In each package, some classes have been intentionally omitted for clarity. The important classes are:

- oracle.goldengate.datasource.DsTransaction: represents a database transaction. A transaction contains zero or more operations.
- oracle.goldengate.datasource.DsOperation: represents a database operation (insert, update, delete). An operation contains zero or more column values representing the data-change event. Columns indexes are offset by zero in the Java API.
- oracle.goldengate.datasource.DsColumn: represents a column value. A column value is a composite of a before and an after value. A column value may be 'present' (having a value or be null) or 'missing' (is not included in the source trail).

- oracle.goldengate.datasource.DsColumnComposite is the composite
- oracle.goldengate.datasource.DsColumnBeforeValue is the column value before the operation (this is optional, and may not be included in the operation)
- oracle.goldengate.datasource.DsColumnAfterValue is the value after the operation
- oracle.goldengate.datasource.meta.DsMetaData: represents all database metadata seen; initially, the object is empty. DsMetaData contains a hash map of zero or more instances of TableMetaData, using the TableName as a key.
- oracle.goldengate.datasource.meta.TableMetaData: represents all metadata for a single table; contains zero or more ColumnMetaData.
- oracle.goldengate.datasource.meta.ColumnMetaData: contains column names and data types, as defined in the database and/or in the Oracle GoldenGate source definitions file.

See the Javadoc for additional details.

# 10 Troubleshoot

Troubleshooting the Java Adapters

# Troubleshooting the Java Adapters

This chapter includes the following sections:

#### **Topics:**

- Checking for Errors
- Reporting Issues

# Checking for Errors

There are two types of errors that can occur in the operation of Oracle GoldenGate for Java:

- The Replicat process running or VAM does not start or abends
- The process runs successfully, but the data is incorrect or nonexistent

If the Replicat or Extract process does not start or abends, check the error messages in order from the beginning of processing through to the end:

1. Check the Oracle GoldenGate event log for errors, and view the Extract report file:

```
GGSCI> VIEW GGSEVT
GGSCI> VIEW REPORT {replicat/extract name}
```

2. Check the applicable log file.

For the native log file:

• Look at the last messages reported in the log file for the native library. The file name is the log file prefix (log.logname) set in the property file and the current date.

shell> more {log.logname}\_{yyyymmdd}.log

## Note:

This is the only log file for the shared library, not the Java application.

3. If the Replicat, or VAM was able to launch the Java runtime, then a log4j log file will exist.

The name of the log file is defined in your <code>log4j.properties</code> file. By default, the log file name is <code>ggjava-version-log4j.log</code>, where version is the version number of the JAR file being used. For example:

```
shell> more ggjava-*log4j.log
```

To set a more detailed level of logging for the Java application, either:

- Edit the current log4j properties file to log at a more verbose level or
- Re-use one of the existing log4j configurations by editing properties file:

```
jvm.bootoptions=-Djava.class.path=ggjava/ggjava.jar
-Dlog4j.configuration=debug-log4j.properties -Xmx512m
```

These pre-configured log4j property files are found in the classpath, and are installed in:

./ggjava/resources/classes/\*log4j.properties

4. If one of these log files does not reveal the source of the problem, run the native process directly from the shell (outside of GGSCI) so that stderr and stdout can more easily be monitored and environmental variables can be verified. For example:

shell> REPLICAT PARAMFILE dirprm/javaue.prm

If the process runs successfully, but the data is incorrect or nonexistent, check for errors in any custom filter, formatter or handler you have written.

To restart the Replicat from the beginning of a trail, see Restarting the Java Delivery.

## Reporting Issues

If you have a support account for Oracle GoldenGate, submit a support ticket and include the following:

Operating system and Java versions

The version of the Java Runtime Environment can be displayed by:

- \$ java -version
- Configuration files:
  - Parameter file for the Replicat
  - All properties files used, including any JMS or JNDI properties files
  - Velocity templates for formatting purposes
  - If applicable, also include the target-specific configuration file
- Log files:

In the Oracle GoldenGate install directory, all <code>.log</code> files: the Java <code>log4j</code> log files and the native module or VAM log file.
