Preface

Oracle Linux: Administering SELinux provides an overview of the SELinux feature and includes tasks for administering SELinux on Oracle Linux systems.

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
monospace	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at https://www.oracle.com/corporate/accessibility/.

For information about the accessibility of the Oracle Help Center, see the Oracle Accessibility Conformance Report at https://www.oracle.com/corporate/accessibility/templates/t2-11535.html.

Access to Oracle Support for Accessibility

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit https://www.oracle.com/corporate/accessibility/learning-support.html#support-tab.

Diversity and Inclusion

Oracle is fully committed to diversity and inclusion. Oracle respects and values having a diverse workforce that increases thought leadership and innovation. As part of our initiative to build a more inclusive culture that positively impacts our employees, customers, and partners, we are working to remove insensitive terms from our products and documentation. We are also mindful of the necessity to maintain compatibility with our customers' existing technologies and the need to ensure continuity of service as Oracle's offerings and industry

standards evolve. Because of these technical constraints, our effort to remove insensitive terms is ongoing and will take time and external cooperation.

1 About Administering SELinux in Oracle Linux

This chapter describes the SELinux feature and provides tasks for administering SELinux on Oracle Linux systems.

Note:

The content in this document was tested against Oracle Linux 8 and Oracle Linux 9, but also applies to most Oracle Linux releases, and might also apply to other distributions.

Traditional Linux security is based on a Discretionary Access Control (DAC) policy, which provides minimal protection from broken software or from malware that's running as a normal user or as root. Access to files and devices is based solely on user identity and ownership. Malware or broken software can do anything with files and resources that the user that started the process can do. If the user is root or the application is setuid or setgid to root, the process can have root-access control over the entire file system.

The National Security Agency created Security Enhanced Linux (SELinux) to provide a finergrained level of control over files, processes, users, and applications in the Linux OS. The SELinux enhancement to the Linux kernel implements the Mandatory Access Control (MAC) policy, which enables you to define a security policy that provides granular permissions for all users, programs, processes, files, and devices. The kernel's access control decisions are based on all the security relevant information available, and not solely on the authenticated user identity.

When security-relevant access occurs, such as when a process opens a file, SELinux intercepts the operation in the kernel. If a MAC policy rule allows the operation, it continues. Otherwise, SELinux blocks the operation and returns an error to the process. The kernel checks and enforces DAC policy rules before MAC rules, so it doesn't check SELinux policy rules if DAC rules have already denied access to a resource.

SELinux Package Descriptions

SELinux contains several packages, each of which contain specific utilities that you can use to administer SELinux on Oracle Linux systems. Some packages are installed by default, while other packages are optional.

The following table describes the SELinux packages that are installed by default with Oracle Linux.

Package	Description
policycoreutils	Provides utilities such as load_policy, restorecon, secon, setfiles,
	semodule, sestatus, and setsebool for operating and managing SELinux.
libselinux	Provides the API that SELinux applications use to get and set process and file security contexts, and to obtain security policy decisions.
python3-libselinux	Contains Python bindings for developing SELinux applications.
selinux-policy	Provides the SELinux Reference Policy, which is used as the basis for other policies, such as the SELinux targeted policy.
selinux-policy-targeted	Provides the SELinux targeted policy, where objects outside the targeted domains run under DAC.
libselinux-utils	<pre>Provides the avcstat, getenforce, getsebool, matchpathcon, selinuxconlist, selinuxdefcon, selinuxenabled, setenforce, and togglesebool utilities.</pre>

The following table describes useful SELinux packages that aren't installed by default.

Package	Description
mcstrans	Translates SELinux levels, such as s0- s0:c0.c1023, to an easier-to-read form, such as SystemLow-SystemHigh.
policycoreutils-python-utils	<pre>Provides Python utilities for operating SELinux, such as audit2allow, audit2why, chcat, and semanage.</pre>
selinux-policy-mls	Provides a strict Multi-Level Security (MLS) policy as an alternative to the SELinux targeted policy.
selinux-policy-doc	Provides manual pages for many SELinux policy elements.
setroubleshoot	Enables you to view setroubleshoot- server messages by using the sealert command.
setroubleshoot-server	Translates access-denial messages from SELinux into detailed descriptions that you can view on the command line using the sealert command.

Package	Description	
setools-console	Provides the Tresys Technology SETools distribution of tools and libraries, which you can use to analyze and query policies monitor and report audit logs, and to manage file context.	

Use the dnf command or another suitable package manager to install SELinux packages that you require for the system.

For more information, see the SELinux Project Wiki, the selinux (8) manual page, and other manual pages for the SELinux commands.

Using SELinux Utilities

The following table describes the utilities that you can use to administer SELinux and information about the packages that contain each utility.

Utility	Package	Description	
audit2allow	policycoreutils-python- utils	Generates SELinux policy allow_audit rules from logs of denied operations.	
audit2why	policycoreutils-python- utils	Generates SELinux policy don't_audit rules from logs of denied operations.	
avcstat	libselinux-utils	Displays statistics for the SELinux Access Vector Cache (AVC).	
chcat	policycoreutils-python- utils	Changes or removes the security category for a file or user.	
findcon	setools-console	Searches for file context.	
fixfiles	policycoreutils	Fixes the security context for file systems.	
getenforce	libselinux-utils	Reports the current SELinux mode.	
getsebool	libselinux-utils	Reports SELinux Boolean values.	
indexcon	setools-console	Indexes file context.	
load_policy	policycoreutils	Loads a new SELinux policy into the kernel.	
matchpathcon	libselinux-utils	Queries the system policy and displays the default security context that's associated with the file path.	
replcon	setools-console	Replaces file context.	
restorecon	policycoreutils	Resets the security context on one or more files.	

Utility	Package	Description	
restorecond	policycoreutils	Daemon that watches for file creation and sets the default file context.	
sandbox	policycoreutils-python- utils	Runs a command in an SELinux sandbox.	
sealert	setroubleshoot-server, setroubleshoot	Acts as the user interface to the setroubleshoot system for diagnosing and explaining SELinux AVC denials and providing recommendations on how to prevent such denials.	
sechecker	setools-console	Checks SELinux policies.	
secon	policycoreutils	Displays the SELinux context from a file, program, or user input.	
sediff	setools-console	Compares SELinux polices.	
seinfo	setools-console	Queries SELinux policies.	
selinuxconlist	libselinux-utils	Displays all SELinux contexts that are reachable by a user.	
selinuxdefcon	libselinux-utils	Displays the default SELinux context for a user.	
selinuxenabled	libselinux-utils	Indicates whether SELinux is enabled.	
semanage	policycoreutils-python- utils	Manages SELinux policies.	
semodule	policycoreutils	Manages SELinux policy modules.	
semodule_deps	policycoreutils	Displays the dependencies between SELinux policy packages.	
semodule_expand	policycoreutils	Expands a SELinux policy module package.	
semodule_link	policycoreutils	Links SELinux policy module packages together.	
semodule_package	policycoreutils	Creates a SELinux policy module package.	
sesearch	setools-console	Queries SELinux policies.	
sestatus	policycoreutils	Displays the SELinux mode and the SELinux policy that are in use.	
setenforce	libselinux-utils	Changes the SELinux mode.	
setsebool	policycoreutils	Sets SELinux Boolean values.	
setfiles	policycoreutils	Sets the security context for one or more files.	

Utility	Package	Description
togglesebool	libselinux-utils	Flips the current value of an SELinux Boolean.

Setting SELinux Modes

SELinux runs in one of three modes:

Disabled

The kernel uses only DAC rules for access control. SELinux doesn't enforce any security policy because no policy is loaded into the kernel.

Enforcing

The kernel denies access to users and programs if they aren't granted permissions by SELinux security policy rules. All denial messages are logged as AVC (Access Vector Cache) denials. This is the default mode that enforces SELinux security policy.

Permissive

The kernel doesn't enforce security policy rules but SELinux sends denial messages to a log file. In this manner, you can see what actions would have been denied if SELinux were running in enforcing mode. This mode is intended to be used for diagnosing the behavior of SELinux.

To display current SELinux mode:

getenforce

To set the current mode to Enforcing:

sudo setenforce enforcing

To set the current mode to Permissive:

sudo setenforce permissive

The current value that you set for a mode using setenforce doesn't persist across reboots. To configure the default SELinux mode, edit the configuration file for SELinux, /etc/selinux/ config, and set the value of the SELINUX directive to disabled, enforcing, or permissive.

Getting More Information

SELinux is complex. You can obtain information about different policies more easily by installing the selinux-policy-doc package and then navigating the associated manual pages.

1. Install the package:

sudo dnf install -y selinux-policy-doc

2. Update the manual page database:

sudo mandb

3. Start searching through the new SELinux policy manual pages. To get a complete listing of all the SELinux manual documentation, run:

man -k _selinux

The policy documentation contains information about users and roles. For example, you can read more about the SELinux unprivileged <code>user_u</code> user and the <code>user_r</code> role in the <code>user_selinux(8)</code> manual page. The policy documentation outlines the restrictions applied for different security contexts and what Boolean options are available to you to customize the policy for an environment.

2 Administering SELinux Policies

An SELinux policy describes the access permissions for all users, programs, processes, and files, and for the devices upon which they act. You can configure SELinux to implement either Targeted Policy or Multi-Level Security (MLS) Policy. This chapter describes SELinux policies and how to administer them.

Targeted Policy

A targeted policy applies access controls to a limited number of processes that are believed to be most likely to be the targets of an attack on the system. Targeted processes run in their own SELinux domain, known as a *confined domain*, which restricts access to files that an attacker could exploit. If SELinux detects that a targeted process is trying to access resources outside the confined domain, it denies access to those resources and logs the denial. Only specific services run in confined domains. Examples are services that listen on a network for client requests, such as httpd, named, and sshd, and processes that run as root to perform tasks on behalf of users, such as passwd. Other processes, including most user processes, run in an unconfined domain where only DAC rules apply. If an attack compromises an unconfined process, SELinux doesn't prevent access to system resources and data.

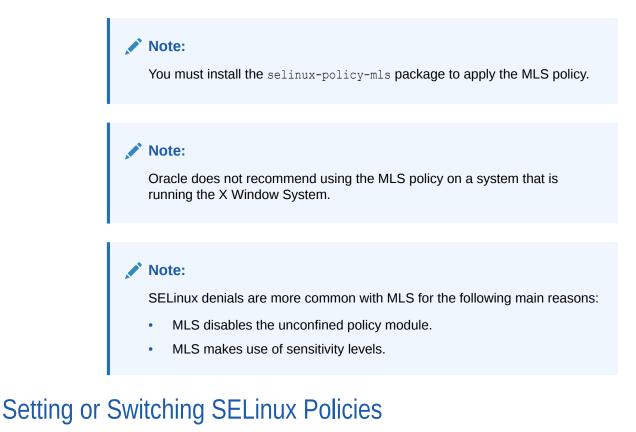

The following table shows examples of SELinux domains.

Domain	Description
init_t	systemd
httpd_t	HTTP daemon threads
kernel_t	Kernel threads
syslogd_t	journald and rsyslogd logging daemons
unconfined_t	Processes that are started by Oracle Linux users run in the unconfined domain

Multi-Level Security Policy

A Multi-Level Security (MLS) policy applies access controls to multiple levels of processes with each level having different rules for user access. Users can't obtain access to information if they don't have the correct authorization to run a process at a specific level. In SELinux, MLS implements the Bell-LaPadula (BLP) model for system security, which applies labels to files, processes, and other system objects to control the flow of information between security levels. In a typical implementation, the labels for security levels might range from the most secure, top secret, through secret, and classified, to the least secure, unclassified. For example, under MLS, you might configure a program labeled secret that can write to a file that's labeled top secret, but can't read from it. Similarly, you would configure the same program to read from and write to a file labeled secret, but only to read classified or unclassified files. So, information that passes through the program can flow upwards through the hierarchy of security levels, but not downwards.

Note:

You can't change the policy type of a running system.

You can configure the default policy type by editing the /etc/selinux/config file and setting the value of the the SELINUXTYPE directive to targeted or mls.

Before switching from one policy to another, change the SELinux mode to permissive. Relabeling while in enforcing mode may prevent confined domains from accessing files, which would also prevent your system from starting correctly.

Customizing SELinux Policies

You can customize an SELinux policy by enabling or disabling the members of a set of Boolean values. Any changes that you make take effect immediately and do not require a reboot.

To display the Boolean values and their descriptions, use the following command:

semanage boolean -1
SELinux boolean State Default Description
ftp_home_dir (off , off)
Determine whether ftpd can read and write files in user home directories.
smartmon_3ware (off , off)
Determine whether smartmon can support devices on 3ware controllers.

```
mpd_enable_homedirs (off , off)
Determine whether mpd can traverse user home directories.
...
```

You can use the getsebool and setsebool commands to display and set the value of a specific Boolean.

```
getsebool boolean sudo setsebool boolean on|off
```

The following example shows how you to display and set the value of the $\tt ftp_home_dir$ Boolean:

```
getsebool ftp_home_dir
ftp_home_dir --> off
sudo setsebool ftp_home_dir on
getsebool ftp_home_dir
ftp_home_dir --> on
```

To switch the value of a Boolean, use the togglesebool command, as shown in the following example:

```
sudo togglesebool ftp_home_dir
ftp home dir: inactive
```

To make the value of a Boolean persist across reboots, specify the -P option to setsebool, for example:

```
sudo setsebool -P ftp_home_dir on
getsebool ftp_home_dir
ftp home dir --> on
```

Administering SELinux Security Context

Under SELinux, all file systems, files, directories, devices, and processes have an associated security context. For files, SELinux stores a context label in the extended attributes of the file system. The context contains more information about a system object: the SELinux user, their role, their type, and the security level. SELinux uses this context information to control access by processes, Linux users, and files. This chapter provides information about how to administer SELinux Security Context

You can specify the -z option with certain commands (1s, ps, and id) to display the SELinux context by using the following syntax:

SELinux user:Role:Type:Level

SELinux user

An SELinux user account compliments a regular Linux user account. SELinux maps every Linux user to an SELinux user identity that is used in the SELinux context for the processes in a user session.

Role

In the Role-Based Access Control (RBAC) security model, a role acts as an intermediary abstraction layer between SELinux process domains or file types and an SELinux user. Processes run in specific SELinux domains, and file system objects are assigned SELinux file types. SELinux users are authorized to perform specified roles, and roles are authorized for specified SELinux domains and file types. A user's role defines which process domains and file types the user can access, and hence which processes and files the user can access.

Туре

A type defines an SELinux file type or an SELinux process domain. Processes are separated from each other by running in their own domains. This separation prevents processes from accessing files that other processes use, and prevents processes from accessing other processes. The SELinux policy rules define the access that process domains have to file types and to other process domains.

Level

A level is an attribute of Multi-Level Security (MLS) and Multi-Category Security (MCS). An MLS range is a pair of sensitivity levels, written as $low_level_high_level$. The range can be abbreviated as low_level if the levels are identical. For example, s0 is the same as s0-s0. Each level has an optional set of security categories to which it applies. If the set is contiguous, it can be abbreviated. For example, s0:c0.c3 is the same as s0:c0,c1,c2,c3.

Displaying SELinux User Mapping

Display the mapping between SELinux and Linux user accounts by using the semanage command.

semanage login -1

Login Name

SELinux User

MLS/MCS Range

Service

*

*

__default__ unconfined_u s0-s0:c0.c1023 root unconfined_u s0-s0:c0.c1023 system_u system_u s0-s0:c0.c1023

By default, SELinux maps Linux users other than root and the default system-level user, system_u, to the Linux __default__ user, and in turn to the SELinux unconfined_u user. The MLS/MCS Range is the security level used by Multi-Level Security (MLS) and Multi-Category Security (MCS).

Displaying SELinux Context Information

To display the context information that's associated with files, use the ls -z command:

```
ls -Z
```

```
-rw-----. root root system_u:object_r:admin_home_t:s0 anaconda-ks.cfg
-rw-r--r-. root root unconfined_u:object_r:admin_home_t:s0 config
-rw-r--r-. root root system_u:object_r:admin_home_t:s0 initial-setup-ks.cfg
drwxr-xr-x. root root unconfined_u:object_r:admin_home_t:s0 jail
-rw-r--r-. root root unconfined_u:object r:admin_home_t:s0 team0.cfg
```

To display the context information that's associated with a specified file or directory, type:

```
ls -Z /etc/selinux/config
```

-rw-r--r-. root root system_u:object_r:selinux_config_t:s0 /etc/selinux/config

To display the context information that's associated with processes, use the ${\tt ps}$ $-{\tt Z}$ command:

ps -Z

```
LABEL PID TTY TIME CMD
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023 3038 pts/0 00:00:00 su
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023 3044 pts/0 00:00:00 bash
unconfined u:unconfined r:unconfined t:s0-s0:c0.c1023 3322 pts/0 00:00:00 ps
```

To display the context information that's associated with the current user, use the ${\tt id}$ – ${\tt z}$ command:

```
id -Z
```

unconfined u:unconfined r:unconfined t:s0-s0:c0.c1023

Changing the Default File Type

Under some circumstances, you might need to change the default file type for a file system hierarchy. For example, you might want to use a DocumentRoot directory other than /var/www/html with httpd.

To change the default file type of the directory hierarchy /var/webcontent to httpd sys content t:

 Use the semanage command to define the file type httpd_sys_content_t for the directory hierarchy:

sudo /usr/sbin/semanage fcontext -a -t httpd_sys_content_t "/var/webcontent(/.*)?"

This command adds the following entry to the file /etc/selinux/targeted/contexts/ files/file contexts.local:

/var/webcontent(/.*)? system_u:object_r:httpd_sys_content_t:s0

2. Use the restorecon command to apply the new file type to the entire directory hierarchy.

```
sudo /sbin/restorecon -R -v /var/webcontent
```

Restoring the Default File Type

The following steps restore the default file type of the directory hierarchy /var/webcontent that has the httpd sys content t setting:

 Use the semanage command to delete the file type definition for the directory hierarchy from the file /etc/selinux/targeted/contexts/files/file_contexts.local:

sudo /usr/sbin/semanage fcontext -d "/var/webcontent(/.*)?"

2. Use the restorecon command to apply the default file type to the entire directory hierarchy.

sudo /sbin/restorecon -R -v /var/webcontent

Relabeling a File System

If you see an error message that contains the string file_t, the problem typically lies with a file system having an incorrect context label.

To relabel a file system by using the command line:

- 1. Create the file /.autorelabel and reboot the system.
- 2. Run the fixfiles onboot command, then reboot the system.

4 Administering SELinux Users

As described in Administering SELinux Security Context, each SELinux user account compliments a regular Oracle Linux user account. SELinux maps every Oracle Linux user to an SELinux user identity that's used in the SELinux context for the processes in a user session.

SELinux users form part of a SELinux policy that's authorized for a specific set of roles and for a specific MLS (Multi-Level Security) range, and each Oracle Linux user is mapped to an SELinux user as part of the policy. As a result, Linux users inherit the restrictions and security rules and mechanisms placed on SELinux users. To define the roles and levels of users, the mapped SELinux user identity is used in the SELinux context for processes in a session.

By default, users are mapped to the unconfined_u SELinux user when they're created, unless otherwise specified. With that setting, SELinux functions in a nonrestrictive capacity. To improve system security, you can change the default user mapping and start applying different user mappings for different user requirements on the system.

Understanding Confined SELinux Users

SELinux includes several confined users that are restricted to different security domains and that have predefined security rules and mechanisms to control what a user is allowed to do. SELinux policies include rules that apply to the different roles that a user can belong to, and these are used to enforce what operations are allowed to for each SELinux user.

By convention, SELinux users have the suffix u, such as user u.

Oracle Linux includes several SELinux users that are already set up through which you can restrict system access immediately:

unconfined_u

A largely unrestricted SELinux user often set as the default SELinux user mapping for system user accounts on new systems in a less restrictive environment. In a hardened environment, no system user accounts must map to this user.

root

The SELinux user meant for the root account.

sysadm_u

The SELinux user with direct system administrative role assigned. This user isn't intended to run nonadministrative commands.

staff_u

The SELinux user for users that need to run both nonadministrative commands (through the staff r role) and administrative commands (through the sysadm r role).

user_u

The SELinux user for nonprivileged accounts that don't need to run any administrative commands.

system_u

The SELinux user for system services.

xguest_u

The SELinux user for guest access to a system and provisioned with limited access.

Users are confined to their SELinux domains, and policies control the types of things that they can do on the system. The following table illustrates how certain predefined security rules work for different users.

SELinux User	SELinux Domain	Permit Running su and sudo?	Permit Network Access?	Permit Logging in Using X Window System?	Permit Executing Applications in \$HOME and /tmp?
guest_u	guest_t	No	Yes	No	No
staff_u	staff_t	sudo	Yes	Yes	Yes
system_u	ssystem_t	Yes	Yes	Yes	Yes
user_u	user_t	No	Yes	Yes	Yes
xguest_x	xguest_t	No	Firefox only	Yes	No

SELinux users are distinct and managed separately from standard Oracle Linux system users within SELinux. You can map Oracle Linux system user accounts to different SELinux users to apply a more restrictive security policy framework to any of the system user accounts.

Mapping Oracle Linux Users to SELinux Confined Users

By default, users are mapped to the unconfined_u SELinux user when they're created, unless otherwise specified. Users can check their security context by running:

id -Z

Output might be similar to the following example:

unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023

A system administrator can map an Oracle Linux user to an SELinux confined user to apply different levels of access. For example, to map the *oracle* user to the SELinux user u user, use the semanage command:

sudo semanage login -a -s user_u oracle

When you create a user, you can specify the SELinux user mapping when you run the useradd command. For example, to add a privileged *oracleadmin* user that maps onto the SELinux staff u user, run:

sudo useradd -Z staff_u oracleadmin

Setting the Default User Mapping

On most newly installed systems, the default user mapping is set to the unconfined_u SELinux user to provide a less restrictive environment for general use. In some

environments where strict policy enforcement is required, such as when conforming to a Security Technical Implementation Guide (STIG), you might need to map all Oracle Linux user accounts to appropriate confined SELinux users so that a system is better protected by the SELinux policy rules that you're enforcing.

1. To change the default user mapping so that any user accounts that don't have explicit SELinux user mappings are confined to the SELinux user u user, run:

sudo semanage login -m -s user_u -r s0 __default__

2. Verify that the __default__ user mapping is no longer set to the unconfined_u SELinux user by running:

semanage login -1

Note that the unconfined security context continues to apply to users after this change until the user session or the process is restarted under the new context. To enforce this change at a system-wide level, reboot the system.

Configuring the Behavior of Application Execution for Users

To help prevent flawed or malicious applications from revising a user's files, you can use Boolean values to specify whether users are permitted to run applications in directories for which they have write access, such as the user's home directory hierarchy and /tmp.

To enable Oracle Linux users in the <code>guest_t</code> and <code>xguest_t</code> domains to run applications in directories to which they have write access, thpe:

```
sudo setsebool -P allow_guest_exec_content on
sudo setsebool -P allow_xguest_exec_content on
```

The following example shows how to prevent users in the staff_t and user_t domains from running applications in directories to which they have write access:

```
sudo setsebool -P allow_staff_exec_content off
sudo setsebool -P allow user exec content off
```

For more information, see Customizing SELinux Policies.

5

Extending SELinux Policies with Multi-Category Security

Multi-Category Security (MCS) extends the SELinux targeted and Multi-Level Security (MLS) policies so you can assign category labels to processes and files. With MCS, files can be accessed only by processes or users that are assigned to the same categories that apply to the file. MCS is applied after all other security checks have been performed. Thus MCS is typically used to further restrict access. Category tags range from c0 to c1023, but you can define text labels for these category values to make them easier to work with. The mcstrans service can be used to translate between the category values and text labels when handling system inputs and outputs.

While MLS can be used to define different security levels or sensitivity for data, MCS can be used to group data for different purposes. For example, you might run the same service for several different projects on a system and data within each project that might have different levels of sensitivity. Users must only be granted access to data that meets their sensitivity clearance for a particular project. MCS enforces this restriction by associating a category tag with each project. The resulting security context of a file or process is a combination of SELinux user, SELinux role, SELinux type, MLS sensitivity level, and MCS category.

Sensitivity	Category			
	Not specified	Accountancy	Marketing	Development
Unclassified	sO	s0:c0	s0:c1	s0:c2
Internal	s1	s1:c0	s1:c1	s1:c2
Restricted	s2	s2:c0	s2:c1	s2:c2
Highly Restricted	s3	s3:c0	s3:c1	s3:c2

Table 5-1 Matrix to illustrate data sensitivity and category application

In the example table, a highly privileged user in the accountancy department (c0) with a requirement to access highly restricted data (s3) might have the following security context defined:

user_u:user_r:user_t:s3:c0

MCS Requirements

Before configuring a system for MCS, fulfill the following requirements:

- SELinux must be configured in enforcing mode.
- SELinux must be configured to use either the targeted or mls policies.
- The policycoreutils-python-utils package must be installed so you can use the chcat and semanage commands.
- The setools-console package can be installed to use the seinfo command for verification.

 SELinux confined user mappings are typical when using MCS. For example, nonprivileged users are assigned to user_u, while privileged users are assigned to staff_u. It is helpful to have any user mappings defined before configuring MCS. See Administering SELinux Users.

Enabling MCS for Users

MCS is active by default in SELinux, but isn't configured for users. To configure MCS for users, you must create a policy module that adds a rule to assign the mcs constrained type attribute to the user domain.

1. Create a file that contains the rule, for example:

echo '(typeattributeset mcs_constrained_type (user_t))' > local_mcs_user.cil

2. Load the new policy module.

sudo semodule -i local mcs user.cil

3. Verify that the mcs constrained type is now applied to user t domain.

seinfo -xt user_t|grep mcs_constrained_type

You can add the mcs_constrained_type attribute to any other SELinux domain in the same way.

Applying MCS Categories to a User

You can control a user's access to resources by applying MCS categories to the user. You can define category ranges that are available to each SELinux user and you can specify subranges for each Oracle Linux user account that's mapped to an SELinux user. See Administering SELinux Users for more information on the different SELinux users and how to manage mappings between these users and standard Oracle Linux users.

1. To define the category ranges that are available to the SELinux user u user, run:

sudo semanage user -m -rs0:c0,c1-s0:c0.c9 user_u

Use category numbers c0 to c1023, or category aliases if you are using the mcstrans service. In the example, the category range of c0 to c9 is assigned to the $user_u$ user.

2. For each Oracle Linux user that's mapped to an SELinux user, for which you have defined a category range, you can specify the individual categories that apply. For example, to apply the c1 category to the *oracle* user you can run:

sudo semanage login -m -rs0:c1 oracle

The categories that you assign to users must be within the range that you defined for the mapped SELinux user.

You can equally use the chcat -1 command to modify which categories apply to a user. For example, you can add the c2 category to *oracle* and remove the c1 category:

sudo chcat -1 -- +c2,-c1 oracle

The command uses -- to indicate that the - character isn't to be interpreted as an option switch.

See the chcat (8) and semanage-user (8) manual pages for more information.

Applying MCS Categories to Files

Any user that has access rights to a file can apply an MCS category to the file if the category is assigned to that user. By applying a category to a file, a user can block access to that file for other users on the system that don't have the same category assigned to them. Note that as with all SELinux policies, standard Linux discretionary access controls are also in effect, so even if a user has category access to a file, the user may still be unable to access the file if the file permissions and mode prevent access for that user.

A user can set the categories that apply to a file if the categories that the user sets are also assigned to the user. File categories are set using the chcat command. For example, to add the c1 and c2 categories to a file, the user can run:

```
chcat -- +c1,+c2 /path/to/file
```

To remove the c1 category, the user can run:

```
chcat -- -c1 /path/to/file
```

The command uses -- to indicate that the - character isn't to be interpreted as an option switch. See the chcat (8) manual page for more information.

You can check which categories are assigned to a file by listing the file's security context:

```
ls -lZ /path/to/file
```

New files and directories, by default, inherit the SELinux type of their parent directories. You can check which categories are assigned to the parent directory of a file by running:

```
ls -dZ /path/to/file
```

Enabling the mcstrans Service

The mcstrans service automatically translates MCS category and MLS sensitivity values against a map of human-readable text labels that are defined as editable configuration entries. If you're using a targeted policy, the configuration file is in /etc/selinux/targeted/ setrans.conf. If you're using an mls policy, the configuration file is in /etc/selinux/mls/ setrans.conf or as individual configuration files within /etc/selinux/mls/setrans.d.

The mcstrans service can make it easier for users to make sense of category and sensitivity values returned by the system for different SELinux outputs and can make it easier to set appropriate values when defining security contexts. See the setrans.conf(8) and mcstransd(8) manual pages for more information.

To install and enable the mcstrans service, run:

```
sudo dnf install -y mcstrans
sudo enable --now mcstrans
```

If you update any of the setrans.conf files to create custom mappings, you must restart the mcstrans service:

sudo systemctl restart mcstrans

You can verify that translations are applied by running:

chcat -L

The command returns a list of the current mappings applied by the mcstrans service.

6 Troubleshooting Access-Denial Messages

This chapter provides information about how to troubleshoot access-denial messages.

The decisions that SELinux makes about allowing and denying access are stored in the Access Vector Cache (AVC). If the auditing service (auditd) isn't running, SELinux logs AVC denial messages to /var/log/messages. Otherwise, the messages are logged to the /var/log/audit/audit.log file. If the setroubleshootd daemon is running, easier-to-read versions of the denial messages are also written to /var/log/messages.

If you have installed the setroubleshoot and setroubleshoot-server packages, the auditd and setroubleshoot services are running. If you're using the X Window System, you can also use the sealert -b command to run the SELinux Alert Browser, which displays information about SELinux AVC denials. To view the details of the alert, click **Show**. To view a recommended solution, click **Troubleshoot**.

The following example shows how you would search the /var/log/audit/audit.log file for messages containing the string denied:

grep denied /var/log/audit/audit.log

```
type=AVC msg=audit(1364486257.632:26178): avc: denied { read } for
pid=5177 comm="httpd" name="index.html" dev=dm-0 ino=396075
scontext=unconfined_u:system_r:httpd_t:s0
tcontext=unconfined_u:object_r:acct_data_t:s0 tclass=file
```

The main causes of access-denial problems include the following:

Context labels for an application or file are incorrect.

A solution might be to change the default file type of the directory hierarchy. For example, change the default file type from /var/webcontent to httpd sys content t:

```
sudo /usr/sbin/semanage fcontext -a -t httpd_sys_content_t "/var/webcontent(/.*)?"
sudo /sbin/restorecon -R -v /var/webcontent
```

A Boolean that configures a security policy for a service is set incorrectly.

A solution might be to change the value of a Boolean. For example, you can open users' home directories to be browsable by turning on httpd enable homedirs:

sudo setsebool -P httpd enable homedirs on

A service is accessing a port to which a security policy prohibits access.

If the service's use of the port is valid, a solution is to use semanage to add the port to the policy configuration. For example, to set the Apache HTTP server to listen on port 8000:

sudo semanage port -a -t http_port_t -p tcp 8000

 An update to a package causes an application to behave in a way that breaks an existing security policy.

You can use the ${\tt audit2allow}$ $-{\tt w}$ $-{\tt a}$ command to view the reason why an access denial occurred.

If you then run the audit2allow -a -M module command, it creates a type enforcement (.te) file and a policy package (.pp) file. You can use the policy package file with the semodule -i module.pp command to stop the error from reoccurring. This procedure is typically intended to make package updates function until an updated policy is available. If used incorrectly, you can create potential security holes on the system.
