&jObj.AddJsonObject("Address", &jObj);
```

AddProperty

Syntax

AddProperty (*Name*, *Type*)

Description

Use this method to add a property to the Json object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the property that needs to be added as a string.
<i>Type</i>	Specifies the type of the property that needs to be added as a string.

Returns

None.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
&jObj.AddProperty("Id", "TYPE_INT");
```

GetAsString

Syntax

GetAsString (*Name*)

Description

Use this method to return the value of the input parameter object as a string.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the object as a string.

Returns

String.

Example

```
Local string &output = &jObj.GetAsString("Name");
```

GetBoolean

Syntax

```
GetBoolean (Name)
```

Description

Use this method to return the boolean value of the property mentioned by the input parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Boolean object as a string.

Returns

Boolean.

Example

```
Local JsonObject &jObj = CreateJsonObject();  
&jObj.AddProperty("Married", "TYPE_BOOLEAN");  
Local Boolean &jb = &jObj.GetBoolean("Married");
```

GetBooleanProperty

Syntax

```
GetBooleanProperty (Name)
```

Description

Use this method to return the Boolean property of the object as mentioned in the input parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Boolean property as a string.

Returns

Boolean.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Married", "TYPE_BOOLEAN");
Local boolean &bBoolProp = &jObj.GetBooleanProperty("Married");
```

GetChildCount

Syntax

```
GetChildCount()
```

Description

Use this method to return the child count of the Json object.

Parameters

None.

Returns

Integer.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
&jObj.AddProperty("Id", "TYPE_INT");
Local integer &childcount = &jObj.GetChildCount();
```

GetDate

Syntax

```
GetDate (Name)
```

Description

Use this method to return the date value of the property mentioned by the input parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the date object as a string.

Returns

Date.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("DOB", "TYPE_DATE");
Local date &jdt = &jObj.GetDate("DOB");
```

GetDateTime

Syntax

GetDateTime (*Name*)

Description

Use this method to return the datetime value of the property mentioned by the input parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the datetime object as a string.

Returns

DateTime.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("DT_TM", "TYPE_DATETIME");
Local datetime &jdtm = &jObj.GetDateTime("DT_TM");
```

GetFloat

Syntax

GetFloat (*Name*)

Description

Use this method to return the float value of the property mentioned by the input parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the float object as a string.

Returns

Float.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Expenses", "TYPE_FLOAT");
Local float &jf = &jObj.GetFloat("Expenses");
```

GetInteger

Syntax

GetInteger (*Name*)

Description

Use this method to return the integer value of the property mentioned by the input parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the integer object as a string.

Returns

Integer.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Id", "TYPE_INT");
Local integer &ji = &jObj.GetInteger("Id");
```

GetJSONArray

Syntax

GetJSONArray (*Name*)

Description

Use this method to return the Json array mentioned by the input parameter from the Json object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json array object as a string.

Returns

JSONArray.

Example

```
Local JsonObject &jObj = CreateJsonObject();
Local JSONArray &jArr = CreateJSONArray();
&jObj.AddJSONArray("MemberNames", &jArr);
Local JSONArray &ja = &jObj.GetJSONArray("MemberNames");
```

GetJsonNode

Syntax

GetJsonNode (*Name*)

Description

Use this method to return the Json node mentioned by the input parameter from the Json object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json node object as a string.

Returns

JsonNode.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
Local JsonNode &jn = &jObj.GetJsonNode("Name");
```

GetJsonObject

Syntax

GetJsonObject (*Name*)

Description

Use this method to return the Json object mentioned by the input parameter from the Json object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json object as a string.

Returns

JsonObject.

Example

```
Local JsonObject &jObj = CreateJsonObject();
Local JsonObject &jObj2 = CreateJsonObject();
&jObj.AddJsonObject("Address", &jObj2);
Local JsonObject &jo = &jObj.GetJsonObject("Address");
```

GetNumber

Syntax

GetNumber (*Name*)

Description

Use this method to return the number value of the property mentioned by the input parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the number object as a string.

Returns

Number.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Salary", "TYPE_NUMBER");
Local Number &jn = &jObj.GetNumber("Salary");
```

GetPropertyAt

Syntax

```
GetPropertyAt(index)
```

Description

Use this method to return the name of the properties at the specified index in the Json object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json object as an integer.

Returns

String.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
&jObj.AddProperty("Id", "TYPE_INT");
Local string &propName = &jObj.GetPropertyAt(1);
```

GetString

Syntax

```
GetString(Name)
```

Description

Use this method to return the string value of the property mentioned by the input parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the string object as a string.

Returns

String.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
Local String &js = &jObj.GetString("Name");
```

GetTime

Syntax

GetTime (*Name*)

Description

Use this method to return the time value of the property mentioned by the input parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the time object as a string.

Returns

Time.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("TOB", "TYPE_TIME");
Local time &jtm = &jObj.GetTime("TOB");
```

IsExist

Syntax

IsExist (*Name*)

Description

Use this method to check whether the property exists.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json object that needs to be checked as a string.

Returns

Boolean.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
Local boolean &bExist = &jObj.IsExist("Id");
```

IsJsonArray

Syntax

IsJsonArray (*Name*)

Description

Use this method to check whether the property is a Json array.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the property that needs to be checked as a string.

Returns

Boolean.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
Local boolean &bIsJsonArr = &jObj.IsJsonArray("Name");
```

IsJsonObject

Syntax

```
IsJsonObject (Name)
```

Description

Use this method to check whether the property is a Json object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the property that needs to be checked as a string.

Returns

Boolean.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
Local boolean &bIsJsonObj = &jObj.IsJsonObject("Name");
```

IsNullProperty

Syntax

```
IsNullProperty (Name)
```

Description

Use this method to check whether the property is null or not.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json object that needs to be checked as a string.

Returns

Boolean.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
&jObj.AddProperty("Id", "TYPE_INT");
Local boolean &bNull = &jObj.IsNullProperty("Id");
```

ToString

Syntax

```
Tostring()
```

Description

Use this method to serialize the Json object to string.

Parameters

None.

Returns

String.

Example

```
Local JsonObject &jObj = CreateJsonObject();
&jObj.AddProperty("Name", "TYPE_STRING");
&jObj.AddProperty("Id", "TYPE_INT");
Local string &output = &jObj.ToString();
```

JsonObject Class Properties

In this section, the JsonObject class property is discussed.

ChildCount

Description

Use this property to return the child count of the Json object.

Example

```
Local integer &pchildcount = &jObj.ChildCount;
```

JsonValue Class

This section provides an overview of the JsonValue class and discusses:

- JsonValue class methods.
- JsonValue class properties.

The JsonValue class provides the ability to set, retrieve and check for different types of field values.

JsonValue Class Methods

In this section, the JsonValue class methods are presented in alphabetical order.

GetBoolean

Syntax

```
GetBoolean()
```

Description

Use this method to return a Boolean value of the object.

Parameters

None.

Returns

Boolean.

Example

```
Local JsonValue &jVal = CreateJsonValue();  
&jVal.SetBoolean( True);  
Local Boolean &jValBool = &jVal.GetBoolean();
```

GetDate

Syntax

```
GetDate()
```

Description

Use this method to return date value of the object.

Parameters

None.

Returns

Date.

Example

```
Local date &dt = Date(20000101);  
&jVal.SetDate(&dt);  
Local date &jValDt = &jVal.GetDate();
```

GetDateTime

Syntax

```
GetDateTime()
```

Description

Use this method to return datetime value of the object.

Parameters

None.

Returns

DateTime.

Example

```
Local datetime &dttm = DateTime6(2000, 1, 1, 1, 5, 7);  
&jVal.SetDateTime(&dttm);  
Local datetime &jValDtTm = &jVal.GetDateTime();
```

GetInteger

Syntax

```
GetInteger()
```

Description

Use this method to return integer value of the object.

Parameters

None.

Returns

Integer.

Example

```
Local JsonValue &jVal = CreateJsonValue();  
&jVal.SetInteger(5);  
Local integer &jValInt = &jVal.GetInteger();
```

GetNumber

Syntax

```
GetNumber()
```

Description

Use this method to return number value of the object.

Parameters

None.

Returns

Number.

Example

```
Local JsonValue &jVal = CreateJsonValue();  
&jVal.SetNumber(5);  
Local Number &jValNum = &jVal.GetNumber();
```

GetString

Syntax

```
GetString()
```

Description

Use this method to return string value of the object.

Parameters

None.

Returns

String.

Example

```
Local JsonValue &jVal = CreateJsonValue();  
&jVal.SetString("Test String");  
Local string &jValStr = &jVal.GetString();
```

GetTime

Syntax

```
GetTime()
```

Description

Use this method to return time value of the object.

Parameters

None.

Returns

Time.

Example

```
Local time &tm = Time(10507);  
&jVal.SetTime(&tm);  
Local time &jValTime = &jVal.GetTime();
```

GetValue

Syntax

```
GetValue()
```

Description

Use this method to return the value of the object.

Parameters

None.

Returns

Any.

Example

```
Local datetime &dtm = DateTime6(2000, 1, 1, 1, 5, 7);  
&jVal.SetDateTime(&dtm);  
Local any &jValAny = &jVal.GetValue();
```

IsNull

Syntax

```
IsNull()
```

Description

Use this method to check whether the value of the object is null.

Parameters

None.

Returns

Boolean.

Example

```
Local JsonValue &jVal = CreateJsonValue();  
Local boolean &bIsNull = &jVal.IsNull();
```

SetBoolean

Syntax

```
SetBoolean(Value)
```

Description

Use this method to set the Boolean value of the object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Value</i>	Specifies a Boolean value.

Returns

None.

Example

```
Local JsonValue &jVal = CreateJsonValue();  
&jVal.SetBoolean(True);
```

SetDate

Syntax

```
SetDate(Date)
```

Description

Use this method to set the date value of the object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Date</i>	Specifies a date value.

Returns

None.

Example

```
Local JsonValue &jVal = CreateJsonValue();
Local date &dt = Date(20000101);
&jVal.SetDate(&dt);
```

SetDateTime

Syntax

```
SetDateTime(Date_time)
```

Description

Use this method to set the datetime value of the object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Date_time</i>	Specifies a datetime value.

Returns

None.

Example

```
Local JsonValue &jVal = CreateJsonValue();
Local datetime &dtm = DateTime6(2000, 1, 1, 1, 5, 7);
&jVal.SetDateTime(&dtm);
```

SetFalse

Syntax

```
SetFalse()
```

Description

Use this method to set the value of the object to false.

Parameters

None.

Returns

None.

Example

```
Local JsonValue &jVal = CreateJsonValue();
&jVal.SetFalse();
```

SetInteger

Syntax

```
SetInteger (Value)
```

Description

Use this method to set the integer value of the object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Value</i>	Specifies an integer value.

Returns

None.

Example

```
Local JsonValue &jVal = CreateJsonValue();
&jVal.SetInteger(5);
```

SetNull

Syntax

```
SetNull ()
```

Description

Use this method to set the value of the object to null.

Parameters

None.

Returns

None.

Example

```
Local JsonValue &jVal = CreateJsonValue();
&jVal.SetNull();
```

SetNumber

Syntax

```
SetNumber(Value)
```

Description

Use this method to set the number value of the object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Value</i>	Specifies a number value.

Returns

None.

Example

```
Local JsonValue &jVal = CreateJsonValue();
&jVal.SetNumber(5);
```

SetString

Syntax

```
SetString(Value)
```

Description

Use this method to set the string value of the object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Value</i>	Specifies a string value.

Returns

None.

Example

```
Local JsonValue &jVal = CreateJsonValue();
&jVal.SetString("Test String");
```

SetTrue

Syntax

```
SetTrue()
```

Description

Use this method to set the value of the object to true.

Parameters

None.

Returns

None.

Example

```
Local JsonValue &jVal = CreateJsonValue();
&jVal.SetTrue();
```

ToString

Syntax

```
ToString()
```

Description

Use this method to serialize the Json value object to a string.

Parameters

None.

Returns

String.

Example

```
Local JsonValue &jVal = CreateJsonValue();
Local datetime &dtm = DateTime6(2000, 1, 1, 1, 5, 7);
&jVal.SetDateTime(&dtm);
Local string &jValToString = &jVal.ToString();
```

JsonValue Class Properties

In this section, the JsonValue class property is discussed.

ValueType

Description

Use this property to return the type of the value.

Example

```
Local JsonValue &jVal = CreateJsonValue();
Local datetime &dtm = DateTime6(2000, 1, 1, 1, 5, 7);
&jVal.SetDateTime(&dtm);
Local integer &jValueType = &jVal.ValueType;
```

JsonArray Class

This section provides an overview of the JsonArray class and discusses:

- JsonArray class methods.
- JsonArray class properties.

The JsonArray class provides the ability to add or retrieve field values in the form of an array.

JsonArray Class Methods

In this section, the JsonArray class methods are presented in alphabetical order.

AddElement

Syntax

```
AddElement (Element)
```

Description

Use this method to add an element of any type to the Json array.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Element</i>	Specifies the element that needs to be added as any type.

Returns

None.

Example

```
Local jsonArray &jArray = CreateJsonArray();
&jArray.AddElement("Name");
```

AddJsonArrayElement

Syntax

```
AddJsonArrayElement(Name, Array)
```

Description

Use this method to add a Json array to the Json array.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json array as a string.
<i>Array</i>	Specifies the array as a jsonArray.

Returns

None.

Example

```
Local jsonArray &jArray = CreateJsonArray();
Local jsonArray &jArr1 = CreateJsonArray();
&jArray.AddJsonArrayElement("Member Names", &jArr1);
```

AddJsonObjectElement

Syntax

```
AddJsonObjectElement (Name, Obj)
```

Description

Use this method to add a Json object to the Json array.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json object as a string.
<i>Obj</i>	Specifies the object as a JsonObject.

Returns

None.

Example

```
Local JSONArray &jArray = CreateJsonArray();  
Local JsonObject &jArrObj = CreateJsonObject();  
&jArrObj.AddProperty("Name1", "TYPE_STRING");  
&jArrObj.AddProperty("Name2", "TYPE_STRING");  
&jArray.AddJsonObjectElement("Member Names", &jArrObj);
```

AddNullElement

Syntax

```
AddNullElement ()
```

Description

Use this method to add a null element to the Json array.

Parameters

None.

Returns

None.

Example

```
Local JSONArray &jArray = CreateJSONArray();
&jArray.AddNullElement();
```

GetAsString

Syntax

```
GetAsString(Index)
```

Description

Use this method to return the Json array element at the index location as a string.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

String.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local string &myJeStr = &jArray.GetAsString(2);
```

GetBoolean

Syntax

```
GetBoolean(Index)
```

Description

Use this method to return the Boolean value at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

Boolean.

Example

```
Local JSONArray &jArray = CreateJSONArray();  
Local Boolean &myBool = &jArray.GetBoolean(2);
```

GetDate

Syntax

```
GetDate (Index)
```

Description

Use this method to return the date at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

Date.

Example

```
Local JSONArray &jArray = CreateJSONArray();  
Local Date &myDt = &jArray.GetDate(2);
```

GetDateTime

Syntax

```
GetDateTime (Index)
```

Description

Use this method to return the date time at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

DateTime.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local DateTime &myDt = &jArray.GetDateTime(2);
```

GetFloat

Syntax

GetFloat (*Index*)

Description

Use this method to return the float value at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

Float.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local float &myFloat = &jArray.GetFloat(2);
```

GetInteger

Syntax

GetInteger (*Index*)

Description

Use this method to return the integer value at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

Integer.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local integer &myInt = &jArray.GetInteger(2);
```

GetJSONArray

Syntax

```
GetJSONArray(Index)
```

Description

Use this method to return the Json array at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

JSONArray.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local JSONArray &myJsonArr = &jArray.GetJSONArray(2);
```

GetJsonNode

Syntax

```
GetJsonNode (Index)
```

Description

Use this method to return the Json node at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

JsonNode.

Example

```
Local JSONArray &jArray = CreateJsonArray();  
Local JsonNode &myJsonNd = &jArray.GetJsonNode(2);
```

GetJsonObject

Syntax

```
GetJsonObject (Index)
```

Description

Use this method to return the Json object at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

JsonObject.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local JsonObject &myJsonObj = &jArray.GetJsonObject(2);
```

GetNumber

Syntax

```
GetNumber (Index)
```

Description

Use this method to return the number value at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

Number.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local number &myNum = &jArray.GetNumber(2);
```

GetString

Syntax

```
GetString (Index)
```

Description

Use this method to return the string value at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

String.

Example

```
Local JSONArray &jArray = CreateJSONArray();  
Local string &myStr = &jArray.GetString(2);
```

GetTime

Syntax

```
GetTime (Index)
```

Description

Use this method to return the time at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

Time.

Example

```
Local JSONArray &jArray = CreateJSONArray();  
Local Time &myTm = &jArray.GetTime(2);
```

GetType

Syntax

```
GetType (Index)
```

Description

Use this method to return the Json value type at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

Integer.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local integer &myJvTyp = &jArray.GetType(2);
```

IsNull

Syntax

IsNull (*Index*)

Description

Use this method to check whether the Json array element at the index location is null.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index in the Json array as an integer.

Returns

Boolean.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local Boolean &bIsNull = &jArray.IsNull(2);
```

Length

Syntax

Length ()

Description

Use this method to return the length of the Json array.

Parameters

None.

Returns

Integer.

Example

```
Local JSONArray &jArray = CreateJSONArray();  
Local integer &myJaLen = &jArray.Length();
```

Pop

Syntax

```
Pop()
```

Description

Use this method to remove the last element in the Json array.

Parameters

None.

Returns

None.

Example

```
Local JSONArray &jArray = CreateJSONArray();  
&jArray.Pop();
```

Remove

Syntax

```
Remove(Index)
```

Description

Use this method to remove the element at the index location.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specifies the index as an integer.

Returns

None.

Example

```
Local jsonArray &jArray = CreateJsonArray();  
&jArray.Remove(3);
```

ToString

Syntax

```
ToString()
```

Description

Use this method to serialize the Json array to a string.

Parameters

None.

Returns

String.

Example

```
Local jsonArray &jArray = CreateJsonArray();  
Local string &myJaStr = &jArray.ToString();
```

JsonArray Class Properties

In this section, the JsonArray class property is discussed.

Size

Description

Use this property to return the size of the Json array.

Example

```
Local JSONArray &jArray = CreateJSONArray();
Local integer &jArrSz = &jArray.Size;
```

JsonNode Class

This section provides an overview of the JsonNode class and discusses:

- JsonNode class methods.
- JsonNode class properties.

The JsonNode class provides the ability to identify a field or a Json object from the Json builder object.

JsonNode Class Methods

In this section, the JsonNode class methods are presented in alphabetical order.

GetBoolean

Syntax

```
GetBoolean()
```

Description

Use this method to return a Boolean value from the node.

Parameters

None.

Returns

Boolean.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local Boolean &myBoolean = &jNode.GetBoolean();
```

GetFloat

Syntax

```
GetFloat()
```

Description

Use this method to return the float value from the node.

Parameters

None.

Returns

Float.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local float &myFloat = &jNode.GetFloat();
```

GetInteger

Syntax

```
GetInteger()
```

Description

Use this method to return the integer value from the node.

Parameters

None.

Returns

Integer.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local integer &myInt = &jNode.GetInteger();
```

GetJSONArray

Syntax

```
GetJSONArray()
```

Description

Use this method to return the Json array from the node.

Parameters

None.

Returns

JSONArray.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local JSONArray &jArray = &jNode.GetJSONArray();
```

GetJsonObject

Syntax

```
GetJsonObject()
```

Description

Use this method to return the Json object from the node.

Parameters

None.

Returns

JsonObject.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local JsonObject &jObj = &jNode.GetJsonObject();
```

GetJsonValue

Syntax

```
GetJsonValue()
```

Description

Use this method to return the Json value from the node.

Parameters

None.

Returns

JsonValue.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local JsonValue &jValue = &jNode.GetJsonValue();
```

GetNodeType

Syntax

```
GetNodeType()
```

Description

Use this method to return the type of the node.

Parameters

None.

Returns

Integer.

List of numeric values and the corresponding node types:

<i>Numeric Value</i>	<i>Node Types</i>
0	JSON_NODE_NULL
1	JSON_NODE_OBJECT

<i>Numeric Value</i>	<i>Node Types</i>
2	JSON_NODE_ARRAY
3	JSON_NODE_VALUE

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local integer &nodeType = &jNode.GetNodeType();
```

GetNumber

Syntax

```
GetNumber()
```

Description

Use this method to return the number value from the node.

Parameters

None.

Returns

Number.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local Number &myNumber = &jNode.GetNumber();
```

GetParentNode

Syntax

```
GetParentNode()
```

Description

Use this method to return the parent node of the current node.

Parameters

None.

Returns

JsonNode.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local JsonNode &parentNode = &jNode.GetParentNode();
```

GetString

Syntax

```
GetString()
```

Description

Use this method to return the string value from the node.

Parameters

None.

Returns

String.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local String &myString = &jNode.GetString();
```

GetValueType

Syntax

```
GetValueType()
```

Description

Use this method to return the type of the value.

Parameters

None.

Returns

Integer.

List of numeric values and the corresponding value types.

<i>Numeric Value</i>	<i>Value Types</i>
0	JSON_VALUE_INVALID
1	JSON_VALUE_INT
2	JSON_VALUE_FLOAT
3	JSON_VALUE_DOUBLE
4	JSON_VALUE_NUMBER
5	JSON_VALUE_BOOLEAN
6	JSON_VALUE_STRING
7	JSON_VALUE_NULL
8	JSON_VALUE_DATE
9	JSON_VALUE_TIME
10	JSON_VALUE_DATETIME

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local integer &nodeValue = &jNode.GetValueType();
```

IsJsonArray

Syntax

```
IsJsonArray ()
```

Description

Use this method to check whether the type of the node is a JsonArray.

Parameters

None.

Returns

Boolean.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local Boolean &bIsJsonArr = &jNode.IsJsonArray();
```

IsJsonObject

Syntax

```
IsJsonObject()
```

Description

Use this method to check whether the type of the node is a JsonObject.

Parameters

None.

Returns

Boolean.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
Local Boolean &bIsJsonObj = &jNode.IsJsonObject();
```

IsJsonValue

Syntax

```
IsJsonValue()
```

Description

Use this method to check whether the type of the node is a JsonValue.

Parameters

None.

Returns

Boolean.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local Boolean &bIsJsonVal = &jNode.IsJsonValue();
```

IsNull

Syntax

```
IsNull()
```

Description

Use this method to check whether the value of the node is null.

Parameters

None.

Returns

Boolean.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local Boolean &bIsNull = &jNode.IsNull();
```

SetBoolean

Syntax

```
SetBoolean(boolean_value)
```

Description

Use this method to set the Boolean value of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>boolean_value</i>	Specifies the value of the node as a Boolean.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
&jNode.SetBoolean(True);
```

SetDate

Syntax

```
SetDate(date_value)
```

Description

Use this method to set the date value of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>date_value</i>	Specifies the date value of the node as date.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local date &dt = Date(20000101);
&jNode.SetDate(&dt);
```

SetDateTime

Syntax

```
SetDateTime(datetime_value)
```

Description

Use this method to set the datetime value of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>datetime_value</i>	Specifies the datetime value of the node as datetime.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local datetime &dtm = DateTime6(2000, 1, 1, 1, 5, 7);
&jNode.SetDateTime(&dtm);
```

SetFalse

Syntax

```
SetFalse()
```

Description

Use this method to set the value of the node to false.

Parameters

None.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
&jNode.SetFalse();
```

SetFloat

Syntax

```
SetFloat(float_value)
```

Description

Use this method to set the float value of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>float_value</i>	Specifies the float value of the node as a float.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
&jNode.SetFloat(1.2);
```

SetInteger

Syntax

```
SetInteger(integer_value)
```

Description

Use this method to set the integer value of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>integer_value</i>	Specifies the integer value of the node as an integer.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
&jNode.SetInteger(10);
```

SetJSONArray

Syntax

```
SetJSONArray(jArray)
```

Description

Use this method to set the Json array of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>jArray</i>	Specifies the Json array of the node as a JSONArray object.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local JSONArray &jArr = CreateJsonArray();
&jNode.SetJsonArray(&jArr);
```

SetJsonObject

Syntax

```
SetJsonObject(Object)
```

Description

Use this method to set the Json object of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Object</i>	Specifies the object as a JsonObject.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local JsonObject &jObj = CreateJsonObject();
&jNode.SetJsonObject(&jObj);
```

SetJsonValue

Syntax

```
SetJsonValue(jValue)
```

Description

Use this method to set the Json value of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>jValue</i>	Specifies the JsonValue of the node as a JsonValue object.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local JsonValue &jVal = CreateJsonValue();
&jNode.SetJsonValue (&jVal);
```

SetNodeName

Syntax

SetNodeName (*Name*)

Description

Use this method to set the name of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the node as a string.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
&jNode.SetNodeName ("Test Node");
```

SetNull

Syntax

```
SetNull()
```

Description

Use this method to set the value of the node to null.

Parameters

None.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
&jNode.SetNull();
```

SetNumber

Syntax

```
SetNumber(number_value)
```

Description

Use this method to set the number value of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>number_value</i>	Specifies the number value of the node as a number.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();  
&jNode.SetNumber(5);
```

SetString

Syntax

```
SetString(string_value)
```

Description

Use this method to set the string value of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>string_value</i>	Specifies the string value of the node as a string.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
&jNode.SetString("Test String");
```

SetTime

Syntax

```
SetTime(time_value)
```

Description

Use this method to set the time value of the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>time_value</i>	Specifies the time value of the node as time.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local time &tm = Time(10507);
&jNode.SetTime(&tm);
```

SetTrue

Syntax

```
SetTrue()
```

Description

Use this method to set the value of the node to true.

Parameters

None.

Returns

None.

Example

```
Local JsonNode &jNode = CreateJsonNode();
&jNode.SetTrue();
```

ToString

Syntax

```
ToString()
```

Description

Use this method to serialize the JsonNode object to string.

Parameters

None.

Returns

String.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local String &myJNodeStr = &jNode.ToString();
```

JsonNode Class Properties

In this section, the JsonNode class properties are presented in alphabetical order

NodeType

Description

Use this property to return the type of the JsonNode object.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local integer &nodetype = &jNode.NodeType;
```

ValueType

Description

Use this property to return the type of the JsonNode value.

Example

```
Local JsonNode &jNode = CreateJsonNode();
Local integer &valuetype = &jNode.ValueType;
```

JsonBuilder Class

This section provides an overview of the JsonBuilder class and discusses:

- JsonBuilder class methods.
- JsonBuilder class properties.

The JsonBuilder class provides the starting point to build an unstructured Json using its methods & properties. The outcome of the builder can be directly converted to a Json string.

JsonBuilder Class Methods

In this section, the JsonBuilder class methods are presented in alphabetical order.

AddElement

Syntax

```
AddElement(Element)
```

Description

Use this method to add an element.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Element</i>	Specifies the element that needs to be added as any type.

Returns

None.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();  
If &jBldr.StartArrayReturnsTrue("properties") Then  
    &jBldr.AddElement("content");  
    &jBldr.EndArray("properties");  
End-If;
```

AddNullElement

Syntax

```
AddNullElement()
```

Description

Use this method to add a null element at the end of an array.

Parameters

None.

Returns

None.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
```

```

If &jBldr.StartArrayReturnsTrue("properties") Then
    &jBldr.AddNullElement();
    &jBldr.EndArray("properties");
End-If;

```

AddNullProperty

Syntax

AddNullProperty (*Name*)

Description

Use this method to add the property with null as its value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the property as a string.

Returns

None.

Example

```

Local JsonBuilder &jBldr = CreateJsonBuilder();
&jBldr.AddNullProperty("Item_None");

```

AddProperty

Syntax

AddProperty (*Name*, *Type*)

Description

Use this method to add a property.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the property as a string.
<i>Type</i>	Specifies the type of the property as any.

Returns

None.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
&jBldr.AddProperty("store", "false");
&jBldr.AddProperty("description", "orcl_attachment_pipe");
&jBldr.AddProperty("ignore_above", "254");
&jBldr.AddProperty("tokenizer", "whitespace");
```

EndArray

Syntax

EndArray (*Name*)

Description

Use this method to end the Json array with a name that is optional.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json array as a string.

Returns

None.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
&jBldr.EndArray("filter");
```

EndObject

Syntax

EndObject (*Name*)

Description

Use this method to end the Json object with a name that is optional.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json object as a string.

Returns

None.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
&jBldr.EndObject("filter");
```

GetBuildMode

Syntax

```
GetBuildMode()
```

Description

Use this method to get the build mode such as array, object, and so on.

Parameters

None.

Returns

Integer.

List of numeric values and their corresponding build modes.

<i>Numeric Value</i>	<i>Build Modes</i>
0	JSON_BUILD_MODE_NONE
1	JSON_BUILD_MODE_OBJECT
2	JSON_BUILD_MODE_ARRAY
3	JSON_BUILD_MODE_MEMBER

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
Local integer &iBldMode = &jBldr.GetBuildMode();
```

GetRootNode

Syntax

```
GetRootNode()
```

Description

Use this method to get the root node.

Parameters

None.

Returns

JsonNode.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
Local JsonNode &jNode = &jBldr.GetRootNode();
```

StartArray

Syntax

```
StartArray (Name)
```

Description

Use this method to start building the Json array with a name that is optional.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json array as a string.

Returns

None.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
&jBldr.StartArray("");
```

StartArrayReturnsTrue

Syntax

```
StartArrayReturnsTrue (Name)
```

Description

Use this method to start building the Json array with a name that is optional.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json array as a string.

Returns

Boolean.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
Local Boolean &bStArr = &jBldr.StartArrayReturnsTrue("articles");
```

StartObject

Syntax

```
StartObject (Name)
```

Description

Use this method to start building the Json object with a name that is optional.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json object as a string.

Returns

None.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
&jBldr.StartObject("");
```

StartObjectReturnsTrue

Syntax

```
StartObjectReturnsTrue (Name)
```

Description

Use this method to start building the Json object with a name that is optional.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the Json object as a string.

Returns

Boolean.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
Local Boolean &bStObj = &jBldr.StartObjectReturnsTrue("index");
```

ToString

Syntax

```
Tostring()
```

Description

Use this method to serialize the Json builder object to a string.

Parameters

None.

Returns

String.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
Local String &jBldrStr = &jBldr.ToString();
```

JsonBuilder Class Properties

In this section, the JsonBuilder class property is discussed.

BuildMode

Description

Use this property to return the build mode.

Example

```
Local JsonBuilder &jBldr = CreateJsonBuilder();
Local integer &iBldrMode = &jBldr.BuildMode;
```

JsonParser Class

This section provides an overview of the JsonParser class and discusses JsonParser class methods.

The JsonParser class is used for parsing Json string to access and drill down to objects and field values.

JsonParser Class Methods

In this section, the JsonParser class methods are presented in alphabetical order.

GetRootObject

Syntax

```
GetRootObject()
```

Description

Use this method to return the root object.

Parameters

None.

Returns

JsonObject.

Example

```
Local JsonParser &jParser = CreateJsonParser();
Local JsonObject &jRootObj = &jParser.GetRootObject();
```

Parse

Syntax

```
Parse(json_string)
```

Description

Use this method to parse the Json for details.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>json_string</i>	Specifies Json as a string.

Returns

Boolean.

Example

```
Local JsonParser &jParser = CreateJsonParser();
Local JsonBuilder &jBldr = CreateJsonBuilder();
Local Boolean &bParseStatus = &jParser.Parse(&jBldr.ToString());
```

ToString

Syntax

```
ToString()
```

Description

Use this method to serialize the JsonParser object to string.

Parameters

None.

Returns

String.

Example

```
Local JsonParser &jParser = CreateJsonParser();  
Local String &jParserStr = &jParser.ToString();
```

Chapter 31

Mail Classes

Understanding PeopleSoft MultiChannel Framework Mail Classes

This section provides an overview of the PeopleSoft MultiChannel Framework Mail Classes and discusses their scope and data types.

PeopleSoft MultiChannel Framework Mail Classes

The PT_MCF_MAIL application package contains the following classes:

- MCFBodyPart
- MCFEmail
- MCFGetMail
- MCFHeaders
- MCFInboundEmail
- MCFMailStore
- MCFMultiPart
- MCFMailUtil
- MCFOutboundEmail
- MCFPart
- SMTPSession

Use the mail classes to develop applications to create and send emails, fetch and delete emails on the mail server, manage emails in your PeopleSoft database, and access attachments . By using the mail classes, you are not required to know the details of the GETMAILTARGET connector or the database schema.

Scope of the Mail Classes

The mail classes can be instantiated only from PeopleCode.

The mail classes can be called from a component, an internet script, or a Application Engine program.

Mail classes can be of local, global, or component scope.

Data Types of the Mail Classes

Every mail class is its own data type; that is, get mail objects are declared as data type `MCFGetMail`, store mail objects are declared as type `MCFMailStore`, and so on.

The following are the data types of the mail classes:

- `MCFBodyPart`
- `MCFEmail`
- `MCFGetMail`
- `MCFHeaders`
- `MCFInboundEmail`
- `MCFMailStore`
- `MCFMailUtil`
- `MCFMultiPart`
- `MCFOutboundEmail`
- `MCFPart`
- `SMTPSession`

Importing Mail Classes

The mail classes are *not* built-in classes, like `Rowset`, `Field`, `Record`, and so on. They are application classes. Before you can use these classes in your PeopleCode program, you must import them to your program.

An import statement names either all the classes in a package or a particular application class.

The application package `PT_MCF_MAIL` contains the following classes:

- `MCFBodyPart`
- `MCFEmail`
- `MCFGetMail`
- `MCFHeaders`
- `MCFInboundEmail`
- `MCFMailStore`
- `MCFMailUtil`
- `MCFMultiPart`

- MCFOutboundEmail
- MCFPart
- SMTPSession

To import all the mail classes, use the following import statement:

```
import PT_MCF_MAIL:*;
```

Using an asterisk after the package name makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are *not* made available. The PT_MCF_MAIL application package contains no subpackages.

[Understanding Application Classes](#)

Creating a Mail Object

After you've imported the mail classes, you instantiate an object of one of those classes using the constructor for the class and the Create function.

The following example creates a new instance of the MCFGetMail class, as the variable &gm, with local scope:

```
Local MCFGetMail &gm = create MCFGetMail();
```

Using the Mail Classes

This section provides overview of the life cycle of an outbound email and discusses how to use the mail classes.

Life Cycle of an Outbound Email

The following are the general steps used to create an outbound email:

1. Create an MCFOutboundEmail object
2. Set the usual properties for an email, such as the From, Subject, Recipients, and Text properties.
3. If necessary, set the parts of the email using MCFMultipart and MCFBodyPart classes.
4. Use the Send method to send the email.

The MCFPart and MCFEmail classes provide the common functionality for the MCFBodyPart and MCFOutboundEmail (and MCFInboundEmail) classes, respectively. In general, you never need to use the MCFPart or MCFEmail classes directly in your PeopleCode programs. However, in rare cases you may use these classes if you want to extend the application package.

The SMTPSession class encapsulates all the session parameters that can be set in a Simple Mail Transfer Protocol (SMTP) session. Each MCFOutboundEmail object points to one SMTPSession object. In most cases, the parameters for the SMTP session are set from values found in the application server configuration file (psappsrv.cfg). However, you can also set these parameters by creating an SMTPSession object, setting the desired parameters, then creating an MCFOutboundEmail object.

For convenience, all SMTP attributes are also directly accessible from the MCFOutboundEmail class, so you don't need to create an SMTPSession object when you're sending just one email.

When you want to send many emails in a single SMTP session, you don't have to set the SMTP session parameter in each and every email. For this case, you can create a single SMTPSession, using either the default settings or explicitly setting the desired parameters, then use the CreateOutboundEmail method of SMTPSession object to create all the MCFOutboundEmail objects. This way all the MCFOutboundEmail objects use the same SMTP session parameters. After specifying the value of all the parameters for all the MCFOutboundEmail objects, use the SendAll method of SMTPSession object to send all the emails in one SMTP session.

All the application classes mentioned above hold all the data until one of the Send methods is called. The Send methods connect to the mail server using a JavaMail API that sends the mail.

Since all communication to the mail server happens when a Send method is called, errors are only reported when the Send method returns. The return value indicates the success or the failure of the send process. In case of failure, you can query the MCFOutboundEmail application class for the details of the error. The error details are available in properties such as MessageSetNumber, MessageNumber, ErrorDescription, ErrorDetails, and so on.

Delivery Status Notification and Return Receipts

There is an SMTP extension that supports Delivery Status Notifications (DSN) defined in RFC 1891. This may or may not be supported by the user's Mail Transport Agent (MTA). The acknowledgements do not indicate whether the user reads the message, they only acknowledge receipt of the message by their mail server. It is possible that the mail server throws the message away as spam and the end user never actually receives the email. To get such notifications, set the StatusNotifyOptions and StatusNotifyReturn properties, as in the following example:

```
&email.StatusNotifyOptions = "SUCCESS,FAILURE";
&email.StatusNotifyReturn = "HDRS";
```

You can use the IsReturnReceiptReqd property to specify if a return receipt should be sent when the mail server receives and opens the email. This property only works if the underlying SMTP server supports this feature. The following is an example of using this property:

```
&email.IsReturnReceiptReqd = True;
```

Priority

There is no SMTP standard for message priority. Most email applications use an X-Priority value of 3 for messages with "normal" priority. More important messages have lower values and less important messages have higher values. In most cases, urgent messages have an X-Priority value of 1. The priority code used with the Mail classes, and set in the headers are as follows:

1. Highest Priority
2. High Priority

3. Normal
4. Low Priority
5. Lowest Priority

The default value is 3, that is, normal priority.

Different email programs render these different values in a variety of ways, usually using some kind of colored symbols or arrows.

Set the priority for an email using the Priority property. The following is an example:

```
&Email.Priority = 2;
```

MCFBodyPart and MCFEmail Considerations

Both MCFBodyPart and MCFEmail objects are used for both inbound and outbound email. The following sections specify which methods and properties are generally used for inbound, and which are used for outbound, for the different objects.

Inbound and Outbound MCFBodyPart Class Methods

All of the methods except the GetUnparsedHeaders method for the MCFBodyPart class are used with outbound email. The following methods are generally used with inbound email as well:

- GetHeader
- GetHeaderNames
- GetUnparsedHeaders

Inbound and Outbound MCFBodyPart Class Properties

The following properties are primarily used with inbound email. Note that some of these properties are also used with outbound email.

- AttachmentURL
- ContentType
- Filename
- IsAttachment
- Text

The following properties are primarily used with outbound email. Note that some of these properties are used with inbound email as well.

- ContentLanguage
- ContentType
- Description

- Disposition
- FileName
- FilePath
- FilePathType
- Multipart
- Text

Inbound and Outbound MCFEmail Class Properties

The following properties are used with inbound email. Note that most of these properties are also used with outbound email.

- From
- RefIDs
- ReplyIDs
- ReplyTo
- Sender
- Subject

The following properties are used with outbound email. Note that many of these properties are also used with inbound email.

- BCC
- BounceTo
- CC
- From
- Importance
- Priority
- Recipients
- RefIDs
- ReplyIDs
- ReplyTo
- Sender
- Sensitivity
- Subject

Retrieving Email From a Mail Server With the MCFGetMail Class

Use the MCFGetMail class to retrieve email from your mail server and load it in a rowset. After you have decided that an email needs to be saved to the PeopleSoft database, use MCFMailStore class.

Structure of Rowset Used for Email Information

The following list describes the different levels of the rowset that contains email information, and what each level contains.

<i>Field or Control</i>	<i>Description</i>
Level 0	The first row at level zero is empty except for the number of rows contained within level zero and return status. The first row contains the return status for the entire batch of emails. Apart from the return status of the whole batch, each individual row has its own EMAIL_RET_STATUS. When a fatal error occurs, such as a connector size overflow, an IB overflow, or an error accessing attachments, the return status is copied to the first row. Subtle errors like unsupported encoding for a part of a individual email appear in the return status of that email only. Each row after the first row contains information about an individual email, such as the header information, the time received, and so on.
Level 1	Level one is where the parts of an email reside. The level one child rowsets are linked to the parent rowset in level zero by the MCF_EMAIL_ID, a unique ID assigned by PeopleSoft.

Note: Multipurpose Internet Mail Extensions (MIME) is an Internet standard for representing multipart and multimedia data in email. It enables email to be exchanged between different email systems. The parts may be nested. PeopleSoft embeds the JavaMail API to implement support for the MIME standard. However, all parts of an email are represented in PeopleSoft as level one rowsets, regardless of the hierarchy that existed in the original email.

The following table describes the fields within the rowset at level zero.

<i>Field</i>	<i>Description</i>
MCF_ATTACH_LIST	Contains a list of all the file names that are attachments for a particular email. Multiple items are separated by a semicolon (;).

Field	Description
MCF_IS_ATT_URL	<p>This is a Boolean value indicating whether the email body is located in the MCF_EMAIL_TEXT or in the attachment directory.</p> <p>If this value is 1 (true), the email body is located in the attachment directory and can be accessed using the MCF_ATT_URL value.</p> <p>If this value is 0 (false), then the email body is located in MCF_EMAIL_TEXT.</p>
MCF_ATT_URL	<p>This URL enables you to view an attachment. This URL is viewable only if the corresponding email has been authorized for the current user.</p> <p>This value is a relative URL. The URL becomes fully qualified only after the rowset has been saved to the PeopleSoft database and then later retrieved using the MCFMailStore class.</p> <p>The following is a sample URL: <code>http://sundance.example.com/PSAttachServlet/ps/mcfdev1/39297_31030554591_1.gif?contentType=image/gif</code></p> <p><i>mcfdev1</i> is the mail user name.</p> <p><i>39297_31030554591_1.gif</i> is the file name in the attachment directory.</p> <p><i>contentType</i> is used by the browser to open a viewer associated with this type.</p> <p>The filename of the downloaded attachment is constructed by using the email's unique ID and the part number.</p> <hr/> <p>Warning! Downloading the same emails twice from the mail server overwrites the associated files in the directory. If the same email is stored twice in the PeopleSoft database, the system creates two separate rows. If you delete either one of these rows, the system deletes the associated files in the directory. To avoid this situation, delete emails from the mail server after you have retrieved them.</p> <hr/> <p>See AuthorizeEmailAttach.</p>
MCF_IBNODE_NAME	<p>Identifies the name of the Integration Broker node that received the email, such as MCF_GetMail.</p> <p>The system uses this value to construct the fully qualified URL required for viewing attachments.</p>

Field	Description
MCF_ATTACH_SIZES	<p>Indicates the size of the attachments associated with an email.</p> <p>Multiple values are separated by a semicolon (;).</p> <p>The attachment sizes appear in the same order as the file names in MCF_ATTACH_LIST.</p>
MCF_EMAIL_FROM	<p>Indicates the email account that sent the email, such as jsmith@example.com.</p>
MCF_DTTM_RECV	<p>Indicates the time that the mail server received the email.</p> <hr/> <p>Warning! If you are using a Post Office Protocol 3 (POP3) mail server, this field may not be populated.</p> <hr/>
MCF_OFFSET_RECV	<p>Indicates the time zone of the mail server that received this email.</p> <hr/> <p>Note: This field contains the time zone of the integration gateway used to fetch this email.</p> <hr/>
MCF_DTTM_SENT	<p>Indicates the time that the email was sent.</p>
MCF_OFFSET_SENT	<p>Indicates the time zone of the mail server that sent this email.</p> <hr/> <p>Note: Currently, this field contains the time zone of the integration gateway used to fetch this email.</p> <hr/>
MCF_DTTM_SAVED	<p>Records the date and time that the PeopleSoft system saved an email to the PeopleSoft database.</p> <p>If you use a POP3 mail server, PeopleSoft recommends using this value as the base, or starting point, for any time-sensitive transactions.</p>
MCF_EMAIL_SENDER	<p>This is the reply to address. This supports a mail feature in which users can send an email from one account, but when the receiver chooses to reply, the system addresses the email to a different account. For instance, sales representatives may send an email from their personal email account, as in tom_sawyer@example.com, but when customers reply, the email is addressed to sales@example.com.</p>

Field	Description
MCF_EMAIL_TEXT	<p>Represents the text that was delivered in the body of the email.</p> <p>Before the email is downloaded, this field contains the body of the email. After the email has been downloaded, this field is blank.</p> <p>Check the MCF_IS_ATT_URL value to determine whether your email text resides in this field or the attachment directory.</p> <p>PeopleSoft relies on the originating email client embedding encoding information to determine character set. For example, Content-type: text/plain; charset=Big5</p>
MCF_NOTIFY_CC	Indicates the parties who were copied (carbon copied) on the email. Multiple addresses are separated by a semicolon (;).
MCF_NOTIFY_TO	Indicates the parties who received the email. Multiple addresses are separated by a semicolon (;).
MCF_UID_LIST	<p>This contains a unique identifier created by POP3 or an IMAP4 mail server. It is guaranteed to be unique within a particular mail box.</p> <hr/> <p>Note: The DeleteEmail method also uses this value when deleting a list of emails. When deleting emails, this field can contain multiple values separated by a space.</p> <hr/>
MCF_WL_SUBJECT	<p>Contains the subject of the email. A maximum of 254 characters is allowed.</p> <p>PeopleSoft relies on the originating email client embedding encoding information to determine character set.</p> <p>For example:</p> <pre>Email Subject: Subject: =?Big5?B? uvuqwLBPqsy67qZYs/i+yS+kpLDqQXik6Ldztdg=> ? = =?Big5?B?uvS1SKTOpEilwbr0MzCk6bVvqu2q +KTloUGkaqRP?==?Big5?B?scCxUqa/v0G1wQ==?=> =</pre> <p>where ?Big5? is the prefixed encoding information.</p>
MCF_RET_STATUS	Represents where the system stores the return status of a particular mail class method.
MCF_EMAIL_STATUS	This field is not currently used.

Field	Description
MCF_NUMROWS	<p>Indicates the number of rows (level one child rowsets) that contain parts of a particular email. For example, if an email has two child rowsets associated with it at level one, this value would be 2.</p> <hr/> <p>Note: For row one of the level zero rowset, this field reflects the number of emails in this rowset. If you fetch 10 emails, the rowset contains 11 rows, but the MCF_NUMROWS value in row 1 equals 10. Row 1 of the level zero rowset never contains an email.</p>
MCF_EMAIL_MSG_ID	This is the globally unique identifier for this email. This ID is generated by the mail server that sent this email.
MCF_REPY_TO	This is the reply to field.
MCF_REF_IDS	Use this field for the reference header fields of the message.
MCF_REPLY_IDS	This value contains the email address that the email can reply to.
MCF_MSG_SIZE	Represents the total size of the entire email. This value includes the sizes of attachments.
MCF_EMAIL_LANG_CD	<p>This value reflects the language code of the Integration Broker node that received this email.</p> <hr/> <p>Note: PeopleSoft recommends setting up email accounts that are dedicated to one language such as, support_french@example.com and support_english@example.com. This enables you to anticipate the language of the email you read into your system. In turn, configure separate Integration Broker nodes to handle each of the languages you support. There are no language recognition procedures within the PeopleSoft system.</p>
MCF_USER	Represents the user account (mail box) on the mail server that received the email.
MCF_SERVER	Represents the mail server that received the email.
MCF_ERROR_COUNT	Used to return the number of messages that caused errors during processing on the target connector.
MCF_QUARANTINE_COUNT	Used to return the number of messages that caused errors during processing on the target connector and were successfully moved to the quarantine folder (This value is always 0 for POP3).

Field	Description
MCF_CONTENT_TYPE	This is the content type of the email itself. For example, a content type could be text/plain, text/html, or multipart/alternative.
MCF_EMAIL_HEADERS	This field is used to return the email message headers. It contains the raw headers in RFC 822 format. The MCFHeaders class can be used to parse the contents of this field.

The following table describes the fields within the rowset at level one. This rowset contains the parts of the email.

Field	Description
MCF_ATT_URL	<p>This is the URL of an associated attachment in the attachment directory.</p> <p>This URL is a relative value when this rowset is first received from the mail server and stored in the database. It only becomes a fully qualified URL once you retrieve the rowset using the MCFMailStore class.</p> <p>Keeping the URL a relative value enables you to make changes within the system without breaking the URL.</p>
MCF_IS_ATT_URL	<p>This is a Boolean value indicating whether the email part is located in the MCF_EMAIL_TEXT or on the attachment directory.</p> <p>If this value is 1 (true), the email part can be accessed using the MCF_ATT_URL value.</p> <p>If this value is 0 (false), then the email part is located in MCF_EMAIL_TEXT.</p>
MCF_FILENAME	<p>Represents the file name for an attachment, such as revenue.xls or resume.doc. The file name can be used as a read-only label on the page used by end users to view attachments. For example, the file name may appear next to the link that opens the attachment.</p> <hr/> <p>Note: Not all parts have file names.</p> <hr/>
MCF_FILE_DATA	This field is not currently used.
MCF_EMAIL_HEADERS	This field is used to return the email part headers. It contains the raw headers in RFC 822 format. The MCFHeaders class can be used to parse the contents of this field.

<i>Field</i>	<i>Description</i>
MCF_EMAIL_TEXT	Contains the text content of the email part.

Note: Although the same rowset structure is used for retrieving email from the mail server and for retrieving email from the PeopleSoft database, not all of the fields apply to each situation. For example, when you first retrieve email from the mail server, the rowset does not contain the fully qualified URL to any attachments.

Note: After an email is saved to the database, always use the methods in the MailStore application package class to access the email. Do not read directly from the mail tables.

Error Messages Returned by MCFGetMail Class Methods

The GetMail Integration Broker connector returns message codes denoting status. These return codes apply to all the methods within the MCFGetMail class. The following are returned in MCF_RET_STATUS field, and by the Status property.

<i>Field or Control</i>	<i>Description</i>
0	Success.
1	<p>Connector size overflow.</p> <p>The size of the email requested exceeds the value in MCF_EmSz_Conn.</p> <p>The system returns the header information for this email with the return status set to 1.</p> <p>See "Configuring GETMAILTARGET Connector Properties" (MultiChannel Framework).</p>
2	<p>Integration Broker threshold size overflow.</p> <p>The size of the email requested exceeds the value in MCF_EmSz_IB.</p> <p>This happens when the size of the XML message constructed to transfer emails from the mail server to the database exceeds the threshold value.</p> <p>If there are any more emails to be processed in the current batch, the system does not fetch them from the mail server. For example, suppose your program fetches 20 emails at a time from the mail server, and this error occurred on the tenth email. In this case, the system processes the tenth email, but emails 11–20 are still be on the mail server.</p> <p>See "Configuring GETMAILTARGET Connector Properties" (MultiChannel Framework).</p>

Field or Control	Description
3	Cannot delete all the messages from the mail server.
4	Connecting to the mail server failed.
5	The attachments to be deleted were not found.
6	At least one attachment cannot be deleted.
7	Unsupported encoding.
8	Cannot write to the attachment directory.
9	<p>Messages were downloaded to directory and deleted from mail server.</p> <p>This status code occurs when an exception occurs in Integration Broker while storing the emails to the database. The exception might occur due to invalid characters in the email. If the email is left on the mail server, the same exception will occur repeatedly, preventing you from fetching further emails. Because the header might contain these invalid characters also, only MCF_RET_STATUS, MCF_MSG_SIZE, MCF_UID_LIST, date time fields, MCF_IS_ATT_URL, MCF_ATT_URL are set. There is no way to determine which email caused the exception, so the system writes all the emails to the directory. All the emails in the batch are deleted from the mail server.</p>

Field or Control	Description
10	Email content error. One example of this is unsupported encoding.

Field or Control	Description
11	Returned if attempting to create a mail server folder while using the POP3 protocol.
12	Folder creation on mail server failed.
13	GetMail connector internal error.

See [Status](#).

Mail Classes Constructors

The following section provides examples of the mail class constructors.

MCFBodyPart

Example

```
Local PT_MCF_MAIL:MCFBodyPart &text = create PT_MCF_MAIL:MCFBodyPart();
```

MCFGetMail

Example

```
Local MCFGetMail &gm = create MCFGetMail();
```

MCFOutboundEmail

Example

```
Local PT_MCF_MAIL:MCFOutboundEmail &eMail =  
create PT_MCF_MAIL:MCFOutboundEmail();
```

MCFMailStore

Example

```
Local MCFGetMail &sm = create MCFMailStore();
```

SMTPSession

Example

```
Local PT_MCF_MAIL:SMTPSession &commonSession =  
create PT_MCF_MAIL:SMTPSession();
```

MCFBodyPart Class

Use the MCFBodyPart class to send email with attachments, HTML, or other non-standard text information.

MCFBodyPart Class Methods

In the following, we discuss the MCFBodyPart class methods. The methods are described in alphabetical order.

AddHeader

Syntax

```
AddHeader (HeaderName, HeaderValue)
```

Description

Use the AddHeader method to add a header to the body part. This method allows for email server customizations. Some commonly used headers are already exposed as properties, such as ContentType and ContentLanguage. Advanced applications can adapt this technique to meet their own requirements. These headers can be either standard SMTP headers or custom headers starting with "X-".

Parameters

<i>Parameter</i>	<i>Description</i>
<i>HeaderName</i>	Specify the name of the header that you want to add. This parameter takes a string value.
<i>HeaderValue</i>	Specify the actual text of the header, as a string.

Returns

None.

Example

```
Local PT_MCF_MAIL:MCFOutboundEmail &email = create PT_MCF_MAIL:MCFOutboundEmail(⇒
);
Local string &TestName = "Custom Header";

&email.From = &def.From;
&email.Recipients = &def.Recipients;
&email.SMTPServer = &def.SMTPServer;
&email.Subject = &TestName;
&email.Text = &TestName;

&email.AddHeader("X-Mailer", "CRM Sales Application 8.9 SP2");
&email.AddHeader("X-Mailer", "CRM Sales Application 8.9 SP3");
&email.AddHeader("X-Mailer", "CRM Sales Application 8.9 SP4");
&res = &email.Send();
```

GetHeader

Syntax

`GetHeader (HeaderName)`

Description

Use the `GetHeader` method to return the value of the specified header.

This method is primarily used with inbound email messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>HeaderName</i>	Specify the name of the header that you want to access the values for, as a string. The matching of header names is case insensitive.

Returns

An array of string containing the header values. If the header is not present, returns an array of length zero.

[GetHeaderNames](#)

[GetHeaderValues](#)

[GetUnparsedHeaders](#)

GetHeaderCount

Syntax

```
GetHeaderCount ()
```

Description

Use the GetHeaderCount method to return the number of headers.

Parameters

None.

Returns

An integer, representing the number of headers present.

Related Links

[GetHeaderNames](#)

[GetHeaderValues](#)

[GetUnparsedHeaders](#)

GetHeaderName

Syntax

```
GetHeaderName (Index)
```

Description

Use the GetHeaderName to return the name of the header that is located at *Index*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the numeric position of the header you want to access.

Returns

A string.

[GetHeaderValues](#)

[GetUnparsedHeaders](#)

GetHeaderNames

Syntax

```
GetHeaderNames ()
```

Description

Use the `GetHeaderNames` method to return an array containing the names of all the headers.

This method is primarily used with inbound email messages.

Parameters

None.

Returns

An array of string.

[GetHeaderName](#)

[GetHeaderValues](#)

[GetUnparsedHeaders](#)

GetHeaderValues

Syntax

```
GetHeaderValues (Index)
```

Description

Use the `GetHeaderValues` method to return the value for the header located at the position specified by *Index*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the numeric position of the header whose value you want to access.

Returns

An array of string.

[GetHeaderName](#)

[GetHeaderNames](#)

[GetUnparsedHeaders](#)

GetUnparsedHeaders

Syntax

```
GetUnparsedHeaders ()
```

Description

Use the `GetUnparsedHeaders` method to return all of the headers in the body part without any formatting occurring.

Parameters

None.

Returns

A string containing the headers.

SetAttachmentContent

Syntax

```
SetAttachmentContent ({FilePath | FileURL}, FilePathType, FileName, FileDescr, OverrideContentType, OverrideCharset)
```

Description

Use the `SetAttachmentContent` method to specify the body (content) of this body part from a file.

Use the `FilePathType` parameter to specify if the file path is relative or absolute. If it's an absolute path, the file path could be a file on the local machine, a network folder, or a fully-qualified URL.

Parameters

Parameter	Description
<i>FilePath</i> <i>FileURL</i>	<p>You can either specify the file path to the file, or a URL to the file.</p> <p>Depending on the <code>FilePathType</code> parameter, you may specify either a relative or absolute file path to the file.</p> <p>This parameter should include the file name and extension of the file.</p> <p>If you specify a URL address where the file is located, it must be an absolute URL. This URL should include the actual name of the file. If you specify a URL address, you must specify the <code>FilePathType</code> parameter as <code>%FilePath_Absolute</code>.</p>
<i>FilePathType</i>	<p>Specify the path type for the file, whether it is an absolute or relative path. The values are:</p> <ul style="list-style-type: none"> • <code>%FilePath_Absolute</code> — the file path is an absolute path. • <code>%FilePath_Relative</code> — the file path is a relative path.
<i>FileName</i>	<p>Specify the name of the file that you want to attach, as a string. You must include the file extension as well.</p>
<i>Description</i>	<p>Specify a description of the file.</p>
<i>OverrideContentType</i>	<p>The system detects the content type of the attachment using the file location and name. Specifying <code>OverrideContentType</code> overrides the system detected content type.</p> <p>The character set can also be included in the <code>ContentType</code>. For example, “text/plain; charset=US-ASCII”</p>

Parameter	Description
<i>OverrideCharset</i>	Specify a character set to be used to override the existing character set.

Returns

None.

Example

The following uses an absolute path to set the content:

```
&image.SetAttachmentContent ("///file:C:/User/Documentum/XML%20Applications/proddoc/⇒
peoplebook_upc/peoplebook_upc.dtd",
%FilePath_Absolute, "sample.jpg", "This is a sample image!", "", "");
```

The following uses a relative path to set the content:

```
&attach1.SetAttachmentContent ("Ocean Wave.jpg", %FilePath_Relative,
"Ocean Wave.jpg", "Ocean Wave", "", "");
```

The following uses a URL to set the content:

```
&attach1.SetAttachmentContent ("http://www.yahoo.com/members_agreement",
%FilePath_Absolute, "hotmail.htm", "Hotmail Home page", "", "");
```

[AddAttachment](#)

MCFBodyPart Class Properties

In this section we discuss the MCFBodyPart class properties. The properties are described in alphabetical order.

AttachmentURL

Description

Use this property to specify the URL for the attachment for this body part, as a string.

The URL must be an absolute URL.

This property is read/write.

Charset

Description

Use this property to specify the character set for the text or the attachment.

You can also specify this property using the `SetAttachmentContent` method, or the `ContentType` property.

This property is read/write.

Related Links

[ContentType](#)

[SetAttachmentContent](#)

ContentType

Description

Use this property to specify the content type of this body part.

You can specify the content type with the `SetAttachmentContent` method.

You can also use this property to specify the character set. For example, “text/plain; charset=US-ASCII”.

This property is read/write.

Related Links

[SetAttachmentContent](#)

[Charset](#)

Description

Description

Use this property to specify a description of the attachment. You should only use this property if the content is an attachment.

This property is read/write.

Disposition

Description

Use this property to specify how the body part is presented in the received mail.

Some email clients ignore the setting of this property and present body parts either inline or as file attachments.

Valid values for this property are:

Value	Description
Attachment	The body part is shown as a file attachment.
Inline	The body part is shown in the body itself.

This property is read/write.

Filename

Description

If you are adding an attachment to the email, use this property to specify the name of the file.

PeopleSoft recommends that you keep the file extension specified with this property the same as the original extension found in the file path, otherwise client applications may not be able to display it properly.

This property is read/write.

FilePath

Description

Specify the path for the file that contains the contents of this email.

Whether this is a relative or absolute path depends on the `FilePathType` property.

You can also specify a URL to the file using this property, if the `FilePathType` property is specified as `%FilePath_Absolute`.

If you specify a value for this property, the 'Text' content is ignored.

This property is read/write.

Related Links

[FilePathType](#)

FilePathType

Description

Use this property to specify whether the path specified with the `FilePath` property is a relative or absolute path. The values for this property are:

Value	Description
%FilePath_Relative	The file path specified with the FilePath property is a relative path.
%FilePath_Absolute	The file path specified with the FilePath property is either an absolute path to a file, or a URL to a file.

If you specify a relative path, the file must be available in the FILES folder of application server folder.

If you specify an absolute path, the file could be on the local machine, in any network folder, or a URL.

This property is read/write.

IsAttachment

Description

This property indicates if the body part is an attachment or not. This property returns a Boolean value: true if it is an attachment, false otherwise.

This property is read-only.

MultiPart

Description

A body part can contain simple text, one attachment, or a MultiPart object.

If you have assigned a MultiPart object using this property, the text and attachment related properties are ignored.

This property is read/write.

Example

```
Local PT_MCF_MAIL:MCFMultipart &mp = create PT_MCF_MAIL:MCFMultipart();
&mp.SubType = "alternative; differences=Content-type";

&mp.AddBodyPart (&text);
&mp.AddBodyPart (&html);

&email.MultiPart = &mp;
```

Text

Description

Use this property to specify the text for the email.

Use the `SetAttachmentContent` method to specify image or other types of attachments. For a more complex bodypart, build a multipart and set the `Multipart` property of `MCFBodyPart`.

This property is read/write.

Related Links

[SetAttachmentContent](#)

MCFEmail Class

This class inherits many properties from the `MCFPart` class, and is the superclass class for both the `MCFOutboundEmail` and `MCFInboundEmail` classes. Generally, you only use the `MCFOutboundEmail` and `MCFInboundEmail` classes. You should only use the `MCFEmail` class if you are extending the `PT_MCF_MAIL` application package.

MCFEmail Class Properties

In this section, we discuss the `MCFEmail` class properties. The properties are discussed in alphabetical order.

BCC

Description

Use this property to specify comma-separated list of addresses of all the blind carbon copy recipients of this email. (A blind carbon copy is a copy of the email that contains all of the text of the email, but does not show any of the other email addresses to which this email was sent.)

This property is read/write.

Related Links

[CC](#)

BounceTo

Description

Use this property to specify the email address the system should direct all bounced mail to.

This property is read/write.

CC

Description

Use this property to specify a comma-separated list of addresses that copies of this email are to be sent to (carbon copy.)

This property is read/write.

Related Links

[BCC](#)

From

Description

Use this property to specify the email address of the person sending the email.

You can specify more than one address as from in a comma-separated list.

This property is read/write.

Related Links

[Recipients](#)

[ReplyTo](#)

[Sender](#)

Importance

Description

Use this property to specify the value of the importance header field.

The importance can be set to the following:

- low
- normal
- high

If the Priority property is not set, the system automatically sets it to the corresponding values like 5, 3 and 1.

This property is read/write.

Priority

Description

Use this property to specify the priority of this email.

The values are:

1. Highest Priority
2. High Priority
3. Normal
4. Low Priority
5. Lowest Priority

The default value is 3, that is, normal priority.

This value set with this property is used to set to a header X-Priority field, as this is the most common but non-standard field to show priority. In addition, the corresponding values are set in two header fields: X-MSMail-Priority and Priority. The headers X-Priority or X-MSMail-Priority are set to the corresponding value only if the user does not specify a value.

This property is read/write.

Recipients

Description

Use this property to specify the email addresses of all the main recipients to whom the email is being sent. All the addresses are specified in a comma-separated string.

This property is read/write.

RefIDs

Description

Use this property to specify a value for the REFERENCES header field of the message.

This property is read/write.

ReplyIDs

Description

Use this property to specify a value for the IN-REPLY-TO header field of the message.

This property is read/write.

ReplyTo

Description

Use this property to specify the email address where the reply should be sent. You do not need to specify a value for this property if the value is the same as the From property.

This property is read/write.

Related Links

[From](#)

Sender

Description

Use this property to specify the address of the author of the message. You do not need to specify a value for this property if the value for the From property is the same.

This property is read/write.

Related Links

[From](#)

Sensitivity

Description

Use this property to specify the value of the sensitivity header field.

The values are:

- personal
- private
- company-confidential

This property is read/write.

Subject

Description

Use this property to specify the subject of the email. A subject can only contain 254 characters.

This property is read/write.

Text

Description

Use this property to specify the text of the email.

This property is read/write.

MCFGetMail Class Methods

This section discusses MCFGetMail class methods.

CreateQuarantineFolder

Syntax

```
CreateQuarantineFolder()
```

Description

Use the CreateQuarantineFolder method to create a quarantine folder on the server. Specify the name of the folder using the QuarantineFolder property

Parameters

None.

Returns

A Boolean value; true if the folder is created, or if it already exists on the server, false otherwise.

Related Links

[QuarantineFolder](#)

[QuarantineCount](#)

GetCount

Syntax

```
GetCount()
```

Description

Use the GetCount method to determine the total number of emails currently stored in a particular email account.

This method does not distinguish between read and unread emails.

This method uses the connection properties set by `SetMCFEmail`.

If you want to determine the number of emails for an account, and to set your own connection properties, use the `GetEmailCount` method instead.

Parameters

None.

Returns

Returns the total number of emails stored on the mail server for a particular email account. If the method returns `-4`, the system could not connect to the mail server using the user name and password passed in the parameter list.

Related Links

[GetEmailCount](#)

[SetMCFEmail](#)

GetEmailCount

Syntax

```
GetEmailCount(user, password, server, node)
```

Description

Use `GetEmailCount` to determine the number of emails currently stored in a particular email account. `GetEmailCount` does not distinguish between read and unread email. You can use this value to set limits on loops in your program.

If you want to determine the number of emails for an account using the connection properties set with `SetMCFEmail`, use the `GetCount` method instead.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>user</i>	The user name on the mail server, such as “support” or “john_doe”.
<i>password</i>	The password associated with the specified user name.
<i>server</i>	The name of the mail server handling the specified user account.
<i>node</i>	The Integration Broker node on which the request runs.

Note: If the value of any of these parameters is null, the method uses default values stored on the specified node. If the node is not specified, Integration Broker returns an error.

Returns

Returns the total number of emails stored on the mail server for a particular email account. If the method returns -4 , the system could not connect to the mail server using the user name and password passed in the parameter list.

Example

```
Local number &email_count;

&email_count = &gm.GetEmailCount(&username, &passwd, &mailserver,
&node);
```

Related Links

[GetCount](#)

[SetMCFEmail](#)

ReadAllEmailHeadersWithAttach

Syntax

```
ReadAllEmailHeadersWithAttach(user, password, server, node)
```

Description

Use `ReadAllEmailHeadersWithAttach` to read the headers of all of the emails and a list of associated attachments that are currently stored on the mail server for a particular email account. The details about the emails are returned in the level zero rowset. The actual emails and any associated attachments *are not* returned.

Use this method as a screening method to determine whether to store an email in your PeopleSoft system. For example, if you determine that an email is junk mail, you could delete it from your mail server. After you determine the allowable email through header information, you can retrieve the physical email and attachments of the allowable emails.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>user</i>	The user name on the mail server, such as “support” or “john_doe”.
<i>password</i>	The password associated with the specified user name.

Parameter	Description
<i>server</i>	The name of the mail server handling the specified user account.
<i>node</i>	The Integration Broker node on which the request runs.

Note: If the value of any of these parameters is null, the method uses default values stored on the specified node. If the node is not specified, Integration Broker returns an error.

Returns

This method returns rowsets containing email headers.

Example

```
import PT_MCF_MAIL:*;

Local MCFGetMail &gm;

Local Rowset &emails_rs;

&emails_rs = &gm.ReadAllEmailHeadersWithAttach(&username, &passwd, &mailserver
&node);
```

ReadEmails

Syntax

ReadEmails (*Count*)

Description

Use the ReadEmails method to read the specified number of emails for this mailbox.

This method uses the connection properties set by SetMCFEmail.

The overall status of the success of this method is available in the Status property.

Parameters

Parameter	Description
<i>Count</i>	Specify the number of emails you want to read.

Returns

An array of MCFInboundEmail.

Related Links

[MCFInboundEmail Class Methods](#)

[Status](#)

ReadEmailsWithAttach

Syntax

```
ReadEmailsWithAttach(User, password, server, node, count)
```

Description

The ReadEmailsWithAttach method reads the number of emails specified by *count* for a particular user account. If attachments are associated with an email, this method reads the attachments as well.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>User</i>	Specify the user account that contains the emails you want to access, such as "support" or "john_doe".
<i>password</i>	The password associated with the specified user name.
<i>server</i>	The name of the mail server handling the specified user account.
<i>node</i>	The Integration Broker node on which the request runs.
<i>count</i>	Specifies the number of emails to read. If <i>count</i> = 0, the method reads <i>all</i> the emails of the user account. If <i>count</i> > 0, the method reads the number specified. For example, if <i>count</i> = 10, the method reads 10 emails.

Note: If the value of any of these parameters is null, the method uses default values stored on the specified node. If the node is not specified, Integration Broker returns an error.

Returns

This method returns an email within a rowset. Level one of the rowset contains the email parts. Level zero row 1 only contains values for MCF_NUMROWS and MCF_RET_STATUS.

Example

```
import PT_MCF_MAIL:*;  
Local MCFGetMail &gm;
```

```
Local Rowset &emails_rs;

&emails_rs = &gm.ReadEmailsWithAttach(&username, &passwd, &mailserver
&node, &email_count);
```

Related Links

[ReadEmailWithAttach](#)

ReadEmailsWithUID

Syntax

```
ReadEmailsWithUID(UID)
```

Description

Use the ReadEmailsWithUID method to read and return an email based on a unique identifier *UID*. This method uses the connection properties set by SetMCFEmail. Emails that have an attachment are also read.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>UID_List</i>	The UID is the unique identifier of the email. This parameter is only unique within a particular user account. POP3 and IMAP 4 mail servers automatically create a unique identifier for an email when the server receives the email. The list can contain multiple values, each separated by a space.

Returns

A reference to an array of MCFInboundEmail.

Related Links

[MCFInboundEmail Class Methods](#)

ReadEmailWithAttach

Syntax

```
ReadEmailWithAttach(User, password, server, node, UID)
```

Description

Use the ReadEmailWithAttach method to read and return an email based on a unique identifier (*UID*) for the specific email to be read. If attachments are associated with this email, ReadEmailWithAttach fetches those as well.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>user</i>	The user name on the mail server, such as “support” or “john_doe”.
<i>password</i>	The password associated with the specified user name.
<i>server</i>	The name of the mail server handling the specified user account.
<i>node</i>	The Integration Broker node on which the request runs.
<i>UID</i>	<p>The unique identifier of the email. This parameter is only unique within a particular user account. POP3 and IMAP 4 mail servers automatically create a unique identifier for an email when the server receives the email.</p> <p>You may specify more than one UID, each separated by a space.</p>

Note: If the value of any of these parameters is null, the method uses default values stored on the specified node. If the node is not specified, Integration Broker returns an error.

Returns

This method returns an email within a rowset. Level one of the rowset contains the email parts. Level zero row 1 only contains values for MCF_NUMROWS and MCF_RET_STATUS.

Example

```
import PT_MCF_MAIL:*;
Local MCFGetMail &gm;
Local Rowset &emails_rs;
&emails_rs = &gm.ReadEmailWithAttach(&username, &passwd, &mailserver, &node, &UID);⇒
```

Related Links

[ReadEmailsWithAttach](#)

ReadHeaders

Syntax

```
ReadHeaders ()
```

Description

Use the ReadHeaders method to read the headers of all emails currently on the server. This method also returns the attachment information for all emails (names and sizes.)

This method uses the connection properties set by SetMCFEmail.

The overall success of the method is available using the Status property.

Parameters

None.

Returns

An array of MCFInboundEmail objects.

Related Links

[MCFInboundEmail Class Methods](#)

[SetMCFEmail](#)

RemoveEmail

Syntax

```
RemoveEmail(user, password, server, node, UID list)
```

Description

Based on values in the unique identifier list, RemoveEmail deletes emails from the user account on the mail server. It is important to delete emails from the mail server once they are read into PeopleSoft. If you do not delete emails from the mail server after they are read into PeopleSoft, the rowset contains the same collection of email the next time you retrieve email from the mail server.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>user</i>	The user name on the mail server, such as “support” or “john_doe”.
<i>password</i>	The password associated with the specified user name.
<i>server</i>	The name of the mail server handling the specified user account.
<i>node</i>	The Integration Broker node on which the request runs.

Parameter	Description
<i>UID list</i>	The UID list contains the unique identifier values for the emails that need to be deleted from the mail server. The list can contain multiple values separated by a space.

Note: If the value of any of these parameters is null, the method uses default values stored on the specified node. If the node is not specified, the Integration Broker returns an error.

Returns

A Boolean value, indicating the status of the deletion process. If the email has been successfully deleted, this method returns True. Otherwise the method returns False.

Example

```
Local MCFGetMail &GM;
Local boolean &del_status;
Local string &uid_list = "";
Local string &msg_str;

    If (&uid_list <> "") Then
        &del_status = &GM.RemoveEmail(&user, &password, &server, &ibnode, &uid_list);
        &msg_str = "Email(s) deleted from the Mail Server with UID = " | &uid_list;
        MessageBox(0, "", 0, 0, &msg_str);
    End-If;
```

Related Links

[RemoveEmails](#)

RemoveEmails

Syntax

```
RemoveEmails(UID_List)
```

Description

Use the RemoveEmails method to delete emails from an account on the mail server, based on the *UID_list*. It is important to delete emails from the mail server once they are read into PeopleSoft. If you do not delete emails from the mail server after they are read into PeopleSoft, the rowset contains the same collection of email the next time you retrieve email from the mail server.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>UID_List</i>	The UID list contains the unique identifier values for the emails that need to be deleted from the mail server. The list can contain multiple values separated by a space.

Returns

An array of string containing UIDs of the messages that were successfully removed, separated by semicolons.

Related Links

[RemoveEmail](#)

SetMCFEmail

Syntax

```
SetMCFEmail(user, password, server, node)
```

Description

Use the SetMCFEmail method to set the connection properties for subsequent method calls.

This method is a shortcut for setting the UserId, Password, MailServer, and IBNode properties.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>user</i>	The user name on the mail server, such as “support” or “john_doe”.
<i>password</i>	The password associated with the specified user name.
<i>server</i>	The name of the mail server handling the specified user account.
<i>node</i>	The Integration Broker node on which the request runs.

Note: If the value of any of these parameters is null, the method uses default values stored on the specified node. If the node is not specified, the integration broker returns an error.

Returns

None.

MCFGetMail Class Properties

In this section we discuss the MCFGetMail class properties. The properties are described in alphabetical order.

AttachmentRoot

Description

Use this property to specify the root directory where the attachments are stored. If not specified, the value from the node is used.

Valid metastrings that can be included in the value for this property are:

<i>Parameter</i>	<i>Description</i>
%CURRDATE%	Current date in YYYYMMDD format
%CURRHOUR%	Current hour in 24-hour format (00-23)
%DBNAME%	Current value of %DbName system variable.
%OPRID%	Current value of %UserId system variable.

This property is read/write.

Example

To have the attachment root directory change hourly, you could use the following code example:

```
&MyEmail.AttachmentRoot = "c:\temp\%CURRDATE%\%CURRHOUR\";
```

ContentTypes

Description

Use this property to specify content types that should be returned in the message or part text rather than stored in the directory that contains the attachments. Specify content types in a comma separated list. For example: "text/html, text/xml".

Note: "Text/plain" is always returned in the text field and does not need to be included.

If not specified, the value from the node is used.

This property is read/write.

ErrorCount

Description

This property returns the number of messages that caused errors during processing on the target connector.

You should use this property after you use the ReadHeaders, ReadEmails, ReadEmailsWithUID, or RemoveEmails methods.

This property is read-only.

Related Links

[ReadHeaders](#)

[ReadEmails](#)

[ReadEmailsWithUID](#)

[RemoveEmails](#)

IBNode

Description

This property returns the name of the Integration Broker node on which a request ran, such as MCF_GetMail.

This property is set by the SetMCFEmail method. It is used by ReadHeaders, ReadEmails, ReadEmailsWithUID, RemoveEmails, and CreateQuarantineFolder methods.

This property is read/write.

Related Links

[ReadHeaders](#)

[ReadEmails](#)

[ReadEmailsWithUID](#)

[RemoveEmails](#)
[CreateQuarantineFolder](#)

MailServer

Description

This property returns the name of the mail server that received the email.

This property is set by the SetMCFEmail method. It is used by ReadHeaders, ReadEmails, ReadEmailsWithUID, RemoveEmails, and CreateQuarantineFolder methods.

This property is read/write.

Related Links

[ReadHeaders](#)
[ReadEmails](#)
[ReadEmailsWithUID](#)
[RemoveEmails](#)
[CreateQuarantineFolder](#)

Password

Description

This property returns the password associated with the userID that was used to get the email.

This property is set by the SetMCFEmail method. It is used by ReadHeaders, ReadEmails, ReadEmailsWithUID, RemoveEmails, and CreateQuarantineFolder methods.

This property is read/write.

Related Links

[ReadHeaders](#)
[ReadEmails](#)
[ReadEmailsWithUID](#)
[RemoveEmails](#)
[CreateQuarantineFolder](#)

QuarantineCount

Description

This property returns the number of email messages that caused errors during processing on the target connector and were successfully moved to the quarantine folder.

This property is valid after calls to ReadHeaders, ReadEmails, ReadEmailsWithUID, and RemoveEmails.

This property is read-only.

Related Links

[QuarantineFolder](#)

[ReadHeaders](#)

[ReadEmails](#)

[ReadEmailsWithUID](#)

[RemoveEmails](#)

QuarantineFolder

Description

Use this property to specify the name of the quarantine folder. If not specified, the value from the node will be used.

The name must adhere to whatever naming restrictions are imposed by the mail server in use. There is no built-in validation of the folder name.

The following types of errors can cause an email to be moved to the quarantine folder:

- Connector size overflow.
- Unsupported encoding.
- Unknown Java exception.
- Javamail content error.
- No attachment directory.
- Mail parse exception.

This property is read/write.

Related Links

[QuarantineCount](#)

Status

Description

This property returns the status of the last mail server operation.

See [Error Messages Returned by MCFGetMail Class Methods](#).

This property is valid after calls to [ReadHeaders](#), [ReadEmails](#), [ReadEmailsWithUID](#), and [RemoveEmails](#).

This property is read-only.

UserID

Description

This property returns the user ID (mail box) on the mail server that received the email.

This property is set by SetMCFEmail. It is used by ReadHeaders, ReadEmails, ReadEmailsWithUID, RemoveEmails, and CreateQuarantineFolder methods.

This property is read/write.

MCFInboundEmail Class

This class inherits many properties from the MCFEmail class, which in turn inherits many properties from the MCFPart class. Generally, you use only the subclasses, MCFInboundEmail and MCFOutboundEmail, and not the superclasses.

MCFInboundEmail Class Methods

In this section, we discuss the MCFInboundEmail class methods. The methods are described in alphabetical order.

DumpToFile

Syntax

```
DumpToFile (&File)
```

Description

Use the DumpToFile method to write information from the email to an already instantiated file.

This method copies the information from the following email properties, placing each on a separate line:

- ContentType
- IsAttachment
- AttachmentURL
- Text

Whether the information is appended to the bottom of the file or if it overwrites the file depends on how you instantiated the file object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&File</i>	Specify an already instantiated file object that you want to write the email data to.

Returns

None.

Example

```
Local File &BI_FILE;
&BI_FILE = GetFile("mcfdata.out", "w", "UTF8");

Local PT_MCF_MAIL:MCFGetMail &gm;
Local number &ret_status, &nemails, &i;
&gm = create PT_MCF_MAIL:MCFGetMail();

Local array of PT_MCF_MAIL:MCFInboundEmail &emails;
&gm.SetMCFEmail(&user, &password, &server, &ibnode);

&emails = &gm.ReadEmails(0);
If (&gm.StatusCheck(&BI_FILE) = False) Then
    Return;
End-If;

&nemails = &emails.Len;
&ret_status = &gm.Status;
If &nemails > 0 Then
    For &i = 1 To &nemails
        &BI_FILE.WriteLine(MsgGetText(162, 1615, "Message Not Found", &i));
        &emails [&i].DumpToFile(&BI_FILE);
    End-For;
End-If;
```

Related Links

[Understanding File Layout](#)

"GetFile" (PeopleCode Language Reference)

GetAttachments

Syntax

```
GetAttachments ()
```

Description

Use the GetAttachments method to return the attachments with this email.

Parameters

None.

Returns

An array of MCFBodyPart objects. The methods returns an array of length 0 if there are no attachments

Related Links

[Understanding Arrays](#)

[MCFBodyPart Class Methods](#)

GetFrom

Syntax

```
GetFrom ()
```

Description

Use the GetFrom method to split the semicolon delimited list of addresses in the From property into an array of addresses.

Parameters

None.

Returns

An array of string. Each item in the array contains an email address.

Related Links

[From](#)

GetParts

Syntax

```
GetParts ()
```

Description

Use the GetParts method to return all of this email's parts.

Parameters

None.

Returns

An array of MCFBodyPart objects.

Related Links

[MCFBodyPart Class Methods](#)

GetSender

Syntax

```
GetSender ()
```

Description

Use the GetSender method to split the semicolon delimited list of addresses in the Sender property into an array of addresses.

Parameters

None.

Returns

An array of string.

Related Links

[Sender](#)

[GetFrom](#)

ReadFromDatabase

Syntax

```
ReadFromDatabase (Email_ID)
```

Description

Use the ReadFromDatabase method to load a saved email from the database into this instance of email.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Email_ID</i>	Specify the ID of the email, as a number.

Returns

A Boolean: true if the email is restored successfully, false otherwise.

Related Links

[SaveToDatabase](#)

SaveToDatabase

Syntax

```
SaveToDatabase ()
```

Description

Use the SaveToDatabase method to save this instance of email to the database.

Parameters

None.

Returns

A number, representing the email_ID of the saved email.

Related Links

[ReadFromDatabase](#)

MCFInboundEmail Class Properties

In this section, we discuss the MCFInboundEmail class properties. The properties are described in alphabetical order.

AttachList

Description

This property returns the list of all the file names that are attachments for a particular email.

Multiple items are separated by a semicolon (;).

This property is read/write.

Related Links

[AttachSizes](#)

AttachSizes

Description

This property returns the sizes of the attachments associated with an email.

This property takes a string value, *not* a numeric value. Multiple values are separated by a semicolon (;).

The attachment sizes appear in the same order as the file names in AttachList.

This property is read/write.

Related Links

[AttachList](#)

DttmReceived

Description

Use this property to return the date and time an email was received.

Warning! If you are using a Post Office Protocol 3 (POP3) mail server, this property may not be populated.

This property takes a DateTime value.

This property is read/write.

Related Links

[DttmSaved](#)

[DttmSent](#)

DttmSaved

Description

This property returns the date and time that the PeopleSoft system saved an email to the database.

If you use a POP3 mail server, PeopleSoft recommends using this value as the base, or starting point, for any time-sensitive transactions.

This property takes a DateTime value.

This property is read/write.

Related Links

[DttmReceived](#)

[DttmSent](#)

DttmSent

Description

This property returns the date time an email was sent.

This property takes a DateTime value.

This property is read/write.

Related Links

[DttmReceived](#)

[DttmSent](#)

IBNode

Description

This property returns the name of the Integration Broker node that received the email, such as MCF_GetMail.

The system uses this value to construct the fully qualified URL required for viewing attachments.

This property is read/write.

Language

Description

This value reflects the language code of the Integration Broker node that received this email.

Note: PeopleSoft recommends setting up email accounts that are dedicated to one language such as, support_french@example.com and support_english@example.com. This enables you to anticipate the language of the email you read into your system. In turn, configure separate Integration Broker nodes to handle each of the languages you support. There are no language recognition procedures within the PeopleSoft system.

This property is read/write.

MessageID

Description

Use this property to return the globally unique identifier for this email.

This ID is generated by the mail server that sent this email.

NotifyCC

Description

This property returns a list of the parties who were copied (carbon copied) on the email. Multiple addresses are separated by a semicolon (;).

This property is read/write.

NotifyTo

Description

This property returns a list of the parties who received the email. Multiple addresses are separated by a semicolon (;).

This property is read/write.

OffsetReceived

Description

This property returns time zone of the mail server that received this email, as a number.

Note: This property contains the time zone of the integration gateway used to fetch this email.

This property is read/write.

Related Links

[OffsetSent](#)

OffsetSent

Description

This property returns the time zone of the mail server that sent this email, as a string.

Note: Currently, this property contains the time zone of the integration gateway used to fetch this email.

This property is read/write.

Related Links

[OffsetReceived](#)

Server

Description

This property specifies the name of the mail server that received the email.

This property is read/write.

Size

Description

This property returns the total size of the entire email. This value includes the sizes of attachments.

This property is read/write.

Status

Description

This property returns the status of an individual email.

This property is read-only.

UID

Description

This property returns the unique identifier of the email.

This property is only unique within a particular user account. POP3 and IMAP 4 mail servers automatically create a unique identifier for an email when the server receives the email.

This property is read/write.

User

Description

This property returns the user account (mail box) on the mail server that received the email.

This property is read/write.

MCFMailStore Class

Use the MCFMailStore class to write emails to the PeopleSoft database and to retrieve emails from the PeopleSoft database.

Note: When writing emails to the PeopleSoft database, it is assumed that you have previously used the MCFGetMail class to retrieve email into memory. You use the MCFMailStore class immediately after to save the rowsets to the database.

MCFMailStore Import Statements

Here is the import statement:

```
import PT_MCF_MAIL:MCFMailStore;
```

MCFMailStore Methods

This section discusses MCFMailStore class methods.

AuthorizeEmailAttach

Syntax

```
AuthorizeEmailAttach(email ID, authentication name, authentication type, operation)⇒
```

Description

Use AuthorizeEmailAttach to authorize a user or a PeopleSoft role to view attachments associated with an email. By default, no user or role is authorized to view an email; you must explicitly grant authorization with this method. This method authorizes email and the associated attachments one at a time.

Note: If you specify ALL as the user, *any* user can view the attachments for an email.

Parameters

Parameter	Description
<i>email ID</i>	The unique email ID for the email. This is the PeopleSoft email ID, not the ID issued by the mail server.
<i>authentication name</i>	The name of the PeopleSoft user profile or role that needs to be authorized to view the attachments.
<i>authentication type</i>	Specify the type security definition entered as the authentication name. <ul style="list-style-type: none"> Specify 2 to indicate a user profile. Specify 3 to indicate a role.

Parameter	Description
<i>operation</i>	Specify the type of authorization operation. The following list contains the supported operations. You either add or delete user or role authorization. <ul style="list-style-type: none"> • 1 = ADD • 2 = DELETE

Returns

Returns a Boolean value: True for success, False otherwise.

Example

```
&ms = create MCFMailStore();
&status = &ms.AuthorizeEmailAttach(&emailid, "MCFUser", 2, 1);
```

DeleteEmail

Syntax

```
DeleteEmail(email ID, forced delete)
```

Description

Deletes the specified email from the PeopleSoft database and corresponding attachments from the directory where they are stored.

Parameters

Parameter	Description
<i>email ID</i>	The ID used to uniquely identify each email within the PeopleSoft database.
<i>forced delete</i>	This parameter is used to set the forced delete flag. It is a Boolean value. A forced delete ensures that the deletion process continues even in cases where the process encounters issues or errors related to an email. For example, with forced delete enabled, the deletion process continues even though the attachments of the email cannot be found or do not exist. True means “force delete” and False means “do not force delete if there is an error in deleting this email.”

Returns

Returns a Boolean value. True for success, False otherwise.

Example

```
Local MCFMailStore &ms;

&ms = create MCFMailStore();
&forcedel = True;
&status = &ms.DeleteEmail(&emailid, &forcedel);
```

RetrieveEmail

Syntax

```
RetrieveEmail(email ID)
```

Description

Use RetrieveEmail to read email from the PeopleSoft database.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>email ID</i>	The ID that uniquely identifies an email within the PeopleSoft database.

Returns

Returns a rowset.

Example

```
Local MCFMailStore &ms;
Local Rowset &EMAIL_ROWSET;

&ms = create MCFMailStore();
&EMAIL_ROWSET = &ms.RetrieveEmail(&emailid);
```

StoreEmail

Syntax

```
StoreEmail(&rowset, row)
```

Description

The StoreEmail method inserts an email retrieved from the mail server into the PeopleSoft database. PeopleSoft stores the contents or pieces of the email in rowsets and child rowsets.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&rowset</i>	<p>The rowset containing the contents of an email. The rowset should be the rowset used by the MCFGetMail class to retrieve emails from the mail server. The rowset should be an already instantiated rowset.</p> <hr/> <p>Note: The first row of the rowset is empty. The first email in the rowset has a row value of 2.</p>
<i>row</i>	<p>The row number in which the email data is stored.</p> <hr/> <p>Note: The first row is always empty. Row 2 always contains the first email of the rowset.</p>

Returns

Returns a PeopleSoft email ID to act as the unique key for a particular email within the PeopleSoft database.

Returns 0 if an error occurred.

Example

```

Local MCFGetMail &GM;
Local Rowset &rs;
Local number &nemails;
Local string &email_id;

&GM = create MCFGetMail();
&rs = &GM.ReadEmailsWithAttach(&user, &password, &server, &ibnode,
&count);

/* Get the number of emails in the recordset from MCF_NUMROWS field */
&nemails = &rs.GetRow(1).GetRecord(Record.MCFEM_RES_MAIN).GetField
(Field.MCF_NUMROWS).Value;

    If (&nemails > 0) Then

/* First row in the rowset is for header info only. Start writing from
second row */

    For &i = 1 To &nemails
        &email_id = &ms.StoreEmail(&rs, &i + 1);
        If (&email_id <> 0) Then
            /* Store was successful - email ID returned = &email_id */
        Else
            /* Error in storing email */
        End-If;
    
```

```
End-For;  
End-If;
```

MCFMailUtil Class

Use the MCFMailUtil class to perform utility operations including encoding and decoding text, validating the email address, validating the email domain name, and determining whether the SMTP email server is available.

MCFMailUtil Class Methods

In this section we discuss the MCFMailUtil class methods. The methods are described in alphabetical order.

DecodeText

Syntax

```
DecodeText (TextToDecode, &DecodedText)
```

Description

Use the DecodeText method to decode text. If you only want to decode a word, use the DecodeWord property.

The text is decoded based on the values used with the EncodeText method.

The decoded text is placed in the *&DecodedText* parameter.

This method returns true if successful. If the return value is false, the following MCFMailUtil properties are set accordingly:

- ErrorDescription
- ErrorDetails
- ErrorMsgParamsCount
- MessageNumber
- MessageSetNumber

In addition you can use the GetErrorMsgParam method to return each of the substitution strings used to format the error message.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TextToDecode</i>	Specify the text that is to be decoded, as a string.
<i>&DecodedText</i>	Specify a string variable, used to hold the decoded text.

Returns

A Boolean value: true if successful, false otherwise.

Related Links

[MessageSetNumber](#)

DecodeWord

Syntax

```
DecodeWord (WordToDecode, &DecodedWord)
```

Description

Use the DecodeWord method to decode a word. If you want to decode a string, use the DecodeText method instead.

The word is decoded based on the values used with the EncodeWord method.

The decoded word is placed in the *&DecodedWord* parameter.

This method returns true if successful. If the return value is false, the following MCFMailUtil properties are set accordingly:

- ErrorDescription
- ErrorDetails
- ErrorMsgParamsCount
- MessageNumber
- MessageSetNumber

In addition you can use the `GetErrorMsgParam` method to return each of the substitution strings used to format the error message.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>WordToDecode</i>	Specify the word that is to be decoded, as a string.
<i>&DecodedWord</i>	Specify a string variable, used to hold the decoded word.

Returns

A Boolean value: true if successful, false otherwise.

[ErrorDescription](#)

[ErrorDetails](#)

[MessageNumber](#)

[MessageSetNumber](#)

EncodeText

Syntax

```
EncodeText(TextToEncode, charset, EncodingStyle, &EncodedText)
```

Description

Use the `EncodeText` method to encode text. If you only want to encode a single word, use the `EncodeWord` method instead.

The encoded text is placed in the *&EncodedText* parameter.

This method returns true if successful. If the return value is false, the following `MCFMailUtil` properties are set accordingly:

- `ErrorDescription`
- `ErrorDetails`
- `ErrorMsgParamsCount`
- `MessageNumber`

- `MessageSetNumber`

In addition you can use the `GetErrorMsgParam` method to return each of the substitution strings used to format the error message.

Using Encoding Styles

You can specify either “B” or “Q” for the *EncodingStyle* parameter, indicating either Base64 or “Quoted-Printable” content-transfer-encoding, respectively.

Oracle recommends using the “Q” encoding when most of the characters to be encoded are in the ASCII character set; otherwise, you should use the “B” encoding. However, a mail reader that claims to recognize encoded text must be able to accept either encoding for any character set that it supports.

Both Base64 and “Quoted-Printable” content-transfer-encoding are defined by RCF 1521. See RCF 1521: [Base64 Content-Transfer-Encoding](#) and [Quoted-Printable Content-Transfer-Encoding](#).

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TextToEncode</i>	Specify the text that is to be encoded, as a string.
<i>charset</i>	Specify the character set to be used for encoding the text, as a string. See "Character Sets Across the Tiers of the PeopleSoft Architecture" (Global Technology).
<i>EncodingStyle</i>	Specify the encoding style. Valid values are: <ul style="list-style-type: none"> • B — for Base64 encoding. • Q — for "Quoted-Printable" content- transfer-encoding.
<i>&EncodedText</i>	Specify a string variable used to hold the encoded text.

Returns

A Boolean value: true if successful, false otherwise.

EncodeWord

Syntax

```
EncodeWord(WordToEncode, charset, EncodingStyle, &EncodedWord)
```

Description

Use the EncodeWord method to encode a word. If you want to encode more than a single word, use the EncodeText method.

The encoded word is placed in the *&EncodedWord* parameter.

This method returns true if successful. If the return value is false, the following MCFMailUtil properties are set accordingly:

- ErrorDescription
- ErrorDetails
- ErrorMsgParamsCount
- MessageNumber
- MessageSetNumber

In addition you can use the GetErrorMsgParam method to return each of the substitution strings used to format the error message.

Using Encoding Styles

You can specify either “B” or “Q” for the *EncodingStyle* parameter, indicating either Base64 or “Quoted-Printable” content-transfer-encoding, respectively.

PeopleSoft recommends using the “Q” encoding when most of the characters to be encoded are in the ASCII character set; otherwise, you should use the “B” encoding. However, a mail reader that claims to recognize encoded text must be able to accept either encoding for any character set that it supports.

Both Base64 and “Quoted-Printable” content-transfer-encoding are defined by RCF 1521. See RCF 1521: [Base64 Content-Transfer-Encoding](#) and [Quoted-Printable Content-Transfer-Encoding](#).

Parameters

<i>Parameter</i>	<i>Description</i>
<i>WordToEncode</i>	Specify the word that is to be encoded, as a string.
<i>charset</i>	Specify the character set to be used for encoding the word, as a string. See "Character Sets Across the Tiers of the PeopleSoft Architecture" (Global Technology).

Parameter	Description
<i>EncodingStyle</i>	Specify the encoding style. Valid values are: <ul style="list-style-type: none"> • B — for Base64 encoding. • Q — for "Quoted-Printable" content-transfer-encoding.
<i>&EncodedWord</i>	Specify a string variable, used to hold the encoded word.

Returns

A Boolean value: true if successful, false otherwise.

GetErrorMsgParam

Syntax

```
GetErrorMsgParam (&index)
```

Description

Use this method to return each of the substitution strings used in the error message.

Parameters

Parameter	Description
<i>&index</i>	Specifies which substitution string to return from the array of substitution parameters.

Returns

A string containing the substitution parameter.

Example

```
Local PT_MCF_MAIL:MCFMailUtil &emailutil = create PT_MCF_MAIL:MCFMailUtil();
For &index = 1 To &emailutil.ErrorMsgParamsCount
    Local String &trace = "Param" | &index | ": " | &emailutil.GetErrorMsgParam(&i⇒
ndex) | "'";
End-For;
```

Related Links

[ErrorMsgParamsCount](#)

IsDomainNameValid

Syntax

```
IsDomainNameValid(domainname)
```

Description

Use this method to check whether a domain name is valid. The `isDomainNameValid` method queries your DNS server to check whether the domain name is listed in an "MX", or mailbox exchange, record. Please note that not all domains are properly listed by DNS servers.

Note: The number of retries for domain validation is set by the `SMTDPDNSTimeoutRetries` parameter in `psappsrv.cfg`. The default number of retries is 1.

This method returns true if successful. If the return value is false, the following `MCFMailUtil` properties are set accordingly:

- `ErrorDescription`
- `ErrorDetails`
- `ErrorMsgParamsCount`
- `MessageNumber`
- `MessageSetNumber`

In addition you can use the `GetErrorMsgParam` method to return each of the substitution strings used to format the error message.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>domainname</i>	Specifies the domain name to be validated, as a string.

Returns

A Boolean value: true if the domain name is valid, false otherwise.

Example

```
Local PT_MCF_MAIL:MCFMailUtil &emailutil = create PT_MCF_MAIL:MCFMailUtil();
&result = &emailutil.IsDomainNameValid("oracle.com");
```

IsEmailServerAvailable

Syntax

```
IsEmailServerAvailable(server, port, user, password)
```

Description

Use the IsEmailServerAvailable method to check if the email server specified with the SMTP settings in the application server configuration file is available.

This method returns true if successful. If the return value is false, the following MCFMailUtil properties are set accordingly:

- ErrorDescription
- ErrorDetails
- ErrorMsgParamsCount
- MessageNumber
- MessageSetNumber

In addition you can use the GetErrorMsgParam method to return each of the substitution strings used to format the error message.

Parameters

Parameter	Description
<i>server</i>	Specify the name of the mail server handling the specified user account, as a string.

Parameter	Description
<i>port</i>	Specify the port of the mail server handling the specified user account, as an integer.
<i>user</i>	Specify the user name on the mail server, such as “support” or “john_doe”, as a string.
<i>password</i>	Specify the password associated with the specified user name, as a string.

Returns

A Boolean value: true if the server is available, false otherwise.

ParseRichTextHtml

Syntax

```
ParseRichTextHtml (richtext)
```

Description

Use this method to split rich text content with images into an array of MCFBodyPart objects. Typically, this method is used with rich text produced by the rich text editor on a long edit box.

The first element in the array is the text of the email message. The remaining elements in the array represent each image in the message. The images are added as inline parts of the email, rather than as attachments, preserving the original formatting of the HTML content.

Prior to sending the email, the images are stored in a temporary directory. The default directory is *PS_SERVDIR/images*. Use the MCFMailUtil class *imagesLocation* property to specify a different directory location. Images in this temporary directory must be deleted manually after sending the email; these image files are not deleted automatically.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>richtext</i>	Rich text with images that needs to be parsed.

Returns

An array of MCFBodyPart objects.

Example

See the example on creating an email from rich text editor output later in this topic.

Related Links

[imagesLocation](#)

[Creating an Email from Rich Text Editor Output](#)

ValidateAddress

Syntax

```
ValidateAddress (addresslist)
```

In which *addresslist* is a list of email addresses in the form:

```
email_address1 [{,|;} email_address2] ...
```

Description

Use the ValidateAddress method to validate a comma- or semicolon-separated list of email addresses. This method checks the syntax of the email address. It does not verify the domain name or the validity of the user name.

This method returns true if successful. If the return value is false, the following MCFMailUtil properties are set accordingly:

- badaddresses
- ErrorDescription
- ErrorDetails
- ErrorMessageParamsCount
- MessageNumber
- MessageSetNumber

In addition you can use the `GetErrorMsgParam` method to return each of the substitution strings used to format the error message.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>addresslist</i>	Specify the email address (or addresses) you want to verify as a comma- or semicolon-separated list.

Returns

A Boolean value: true if the specified email addresses are valid, false otherwise. When `ValidateAddress` returns false, the `badaddresses` property will contain an array of all invalid addresses.

Example

```
import PT_MCF_MAIL:*;

Local PT_MCF_MAIL:MCFMailUtil &emailutil = create PT_MCF_MAIL:MCFMailUtil();
Local boolean &result = &emailutil.ValidateAddress(&email.Recipients);
Local array of string &bAddresses = &emailutil.badaddresses;

If (&result = False) Then
  If (&bAddresses <> Null) Then
    &i = 0;
    While &bAddresses.Next(&i)
      Warning ("Bad email address in input = " | &bAddresses [&i]);
    End-While;
  End-If;
End-If;
```

MCFMailUtil Class Properties

In this section we discuss the `MCFMailUtil` class properties. The properties are described in alphabetical order.

badaddresses

Description

When the `ValidateAddress` method returns `false`, use the `badaddresses` property to get an array of invalid email addresses.

This property is effectively read-only.

Note: While this property is actually read/write, from `PeopleCode`, it is meant to be used in a read-only manner. If this property has a user-specified value, that value will be overwritten automatically when there is an error condition.

Related Links

[ValidateAddress](#)

ErrorDescription

Description

If an error occurs, use the `ErrorDescription` property to get the description of the error.

This property is effectively read-only.

Note: While this property is actually read/write, from `PeopleCode`, it is meant to be used in a read-only manner. If this property has a user-specified value, that value will be overwritten automatically when there is an error condition.

Related Links

[ErrorDetails](#)

ErrorDetails

Description

If an error occurs, use the `ErrorDetails` property to get the details for the error.

This property is effectively read-only.

Note: While this property is actually read/write, from `PeopleCode`, it is meant to be used in a read-only manner. If this property has a user-specified value, that value will be overwritten automatically when there is an error condition.

Related Links

[ErrorDescription](#)

ErrorMsgParamsCount

Description

Use this property to return the number of substitution parameters as an integer.

This property is read-only.

Related Links

[GetErrorMsgParam](#)

imagesLocation

Description

Use this property to specify a string representing a temporary directory for image storage to be used by the `ParseRichTextHtml` method. Images in this temporary directory must be deleted manually after sending the email; these image files are not deleted automatically.

If this property is not specified, the default image directory is `PS_SERVDIR/images`.

This property is read/write.

Related Links

[ParseRichTextHtml](#)

[Creating an Email from Rich Text Editor Output](#)

MessageNumber

Description

This property returns the message number of the error message associated with the failed mail utility method. The message number is associated with messages in the PeopleTools message catalog.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner. If this property has a user-specified value, that value will be overwritten automatically when there is an error condition.

Related Links

[MessageSetNumber](#)

MessageSetNumber

Description

This property returns the message set number of the error message associated with the failed mail utility method. The message set number is associated with messages in the PeopleTools message catalog.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner. If this property has a user-specified value, that value will be overwritten automatically when there is an error condition.

MCFMultiPart Class

Use the MCFMultiPart class to create complex emails with attachments, HTML content, and so on.

MCFMultiPart Class Methods

In this section, we discuss the MCFMultiPart class methods. The methods are described in alphabetical order.

AddBodyPart

Syntax

```
AddBodyPart(&bodyPart)
```

Description

Use the AddBodyPart method to add the specified body part to this multipart email.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&bodyPart</i>	Specify an already instantiated MCFBodyPart object.

Returns

None.

GetBodyPart

Syntax

```
GetBodyPart(Index)
```

Description

Use the GetBodyPart method to return a reference to the body part specified by *Index*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the numeric position of the body part you want to access.

Returns

A reference to an MCFBodyPart object.

Related Links

[MCFBodyPart Class Methods](#)

GetContentType

Syntax

```
GetContentType()
```

Description

Use the GetContentType method to determine the content type.

Parameters

None.

Returns

A string.

GetCount

Syntax

```
GetCount()
```

Description

Use the `GetCount` method to return the number of parts in the `MCFMultiPart` object.

Parameters

None.

Returns

A number.

MCFMultiPart Class Property

In this section we discuss the `MCFMultiPart` class property.

SubType

Description

Use this property to specify the subtype of the `MCFMultiPart` object. The values are:

- `alternative`
- `related`
- `mixed`

The default value is `mixed`.

This property is read/write.

MCFOutboundEmail Class

This class inherits many properties from the `MCFEmail` class, which in turn inherits many properties from the `MCFPart` class. Generally, you use only the subclasses, `MCFOutboundEmail` and `MCFInboundEmail`, and not the superclasses.

MCFOutboundEmail Class Methods

In this section, we discuss the `MCFOutboundEmail` class methods. The methods are discussed in alphabetical order.

AddAttachment

Syntax

```
AddAttachment ({FilePath | FileURL}, FilePathType, FileName, FileDescr,  
OverrideContentType, OverrideCharset)
```

Description

Use the AddAttachment method to add an attachment to this email.

Use the *FilePathType* parameter to specify if the file path is relative or absolute. If it's an absolute path, the file path could be a file on the local machine, a network folder, or a fully-qualified URL.

You can also add an attachment by creating a multipart object, adding the attachments as bodyparts to the multipart object, and then setting the MultiPart property of the MCFOutboundEmail object. The AddAttachment method is provided for convenience.

Parameters

Parameter	Description
<i>FilePath</i> <i>FileURL</i>	<p>You can either specify the file path to the file, or a URL to the file.</p> <p>Depending on the <i>FilePathType</i> parameter, you may specify either a relative or absolute file path to the file.</p> <p>This parameter should include the file name and extension of the file.</p> <p>If you specify a URL address where the file is located, it must be an absolute URL. This URL should include the actual name of the file. If you specify a URL address, you must specify the <i>FilePathType</i> parameter as %FilePath_Absolute.</p>
<i>FilePathType</i>	<p>Specify the path type for the file, whether it is an absolute or relative path. The values are:</p> <ul style="list-style-type: none"> • %FilePath_Absolute — the file path is an absolute path. • %FilePath_Relative — the file path is a relative path.
<i>FileName</i>	<p>Specify the name of the file that you want to attach, as a string. You must include the file extension as well.</p>
<i>Description</i>	<p>Specify a description of the file.</p>

Parameter	Description
<i>OverrideContentType</i>	The system detects the content type of the attachment using the file location and name. Specifying <i>OverrideContentType</i> overrides the system detected content type. The character set can also be included in the ContentType. For example, "text/plain; charset=US-ASCII"
<i>OverrideCharset</i>	Specify a character set to be used to override the existing character set.

Returns

None.

AddHeader

Syntax

```
AddHeader (HeaderName, HeaderValue)
```

Description

Use the AddHeader method to add a header to the email. This method allows for email server customizations. Some commonly used headers are already exposed as properties, such as From, To, Subject, ContentType and ContentLanguage. Advanced applications can adapt this technique to meet their own requirements. These headers can be either standard SMTP headers or custom headers starting with "X-".

Parameters

Parameter	Description
<i>HeaderName</i>	Specify the name of the header that you want to add. This parameter takes a string value.
<i>HeaderValue</i>	Specify the actual text of the header, as a string.

Returns

None.

Example

```
Local PT_MCF_MAIL:MCFOutboundEmail &email = create PT_MCF_MAIL:MCFOutboundEmail(⇒
);
```

```

Local string &TestName = "Custom Header";

&email.From = &def.From;
&email.Recipients = &def.Recipients;
&email.SMTPServer = &def.SMTPServer;
&email.Subject = &TestName;
&email.Text = &TestName;

&email.AddHeader("X-Mailer", "CRM Sales Application 8.9 SP2");
&email.AddHeader("X-Mailer", "CRM Sales Application 8.9 SP3");
&email.AddHeader("X-Mailer", "CRM Sales Application 8.9 SP4");

&res = &email.Send();

```

AddImportedAttachment

Syntax

```
AddImportedAttachment(&emailID, &emailPartID)
```

Description

Use the AddImportedAttachment method to add a new attachment email part to an email, from an existing email attachment that has already been imported into the system. The attachment is identified by the email ID and email part ID passed into the method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&emailID</i>	Specify the email ID to identify the attachment to be added to an email. This parameter takes an integer value.
<i>&emailPartID</i>	Specify the email part ID to identify the attachment to be added to an email. This parameter takes an integer value.

Returns

None.

Example

```
Local PT_MCF_MAIL:MCFOutboundEmail &email = create PT_MCF_MAIL:MCFOutboundEmail();
```

```

&email.From = &From;
&email.Recipients = &Recipients;
&email.Subject = &Subject;

Local PT_MCF_MAIL:MCFFBodyPart &text = create PT_MCF_MAIL:MCFFBodyPart();
&text.Text = "Hello";

Local PT_MCF_MAIL:MCFFMultipart &mp = create PT_MCF_MAIL:MCFFMultipart();
&mp.AddBodyPart(&text);
&email.MultiPart = &mp;

&email.AddImportedAttachment(&emailID, &emailPartNum);

&res = &email.Send();

```

GetErrorMsgParam

Syntax

```
GetErrorMsgParam (&index)
```

Description

Use this method to return each of the substitution strings used in the error message.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&index</i>	Specifies which substitution string to return from the array of substitution parameters.

Returns

A string containing the substitution parameter.

Example

```

Local PT_MCF_MAIL:MCFFOutboundEmail &email = create PT_MCF_MAIL:MCFFOutboundEmail();
For &index = 1 To &email.ErrorMsgParamsCount
    Local String &trace = "Param" | &index | ": " | &email.GetErrorMsgParam(&index⇒
) | " ";
End-For;

```

GetHeader

Syntax

`GetHeader` (*HeaderName*)

Description

Use the `GetHeader` method to return the value of the specified header.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>HeaderName</i>	Specify the name of the header that you want to access the values for, as a string. The matching of header names is case insensitive.

Returns

An array of string containing the header values. If the header is not present, returns an array of length zero.

GetHeaderNames**Send****Syntax****Send** ()**Description**

Use the Send method to send the email.

When you call the Send method, the following properties might be set based on the type of error:

- InvalidAddresses
- MessageNumber (from the PeopleTools Message Catalog)
- MessageSetNumber (from the PeopleTools Message Catalog)
- ValidSentAddresses
- ValidUnsentAddresses

In addition, a list of substitution strings for the error message can be accessed by the ErrorMessageParamsCount property and the GetErrorMessageParam method.

Parameters

None.

Returns

A number indicating the status of the send. Values are:

Numeric Value	Constant Value	Description
0	%ObEmail_ FailedBeforeSending	Email failed before being sent.
1	%ObEmail_Delivered	Email was delivered.
2	%ObEmail_NotDelivered	Email delivery not attempted.
3	%ObEmail_PartiallyDelivered	Email has only been partially delivered. Only some of the addresses in the list of addresses were delivered to.
-1	%ObEmail_SentButResultUnknown	Email was sent but whether it was successful or not is not known.

SetSMTPParam

Syntax

```
SetSMTPParam(ParamName, ParamValue)
```

Description

Use the SetSMTPParam method to set parameters for the SMTP session to be used for sending the email. If you are only sending out one email, use this method. If you are sending many emails, use the SMTPSession class and set the parameters once for all the emails you are sending out.

Note: You should use this method before you use the Send method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ParamName</i>	Specify the name of the parameter you want to overwrite.
<i>ParamValue</i>	Specify the value for the named parameter that you want used instead of the existing value.

Returns

None.

Example

```
&email.setSMTPParam("mail.mime.decodetext.strict", "false");
&email.setSMTPParam("mail.mime.address.strict", "false");
&email.setSMTPParam("mail.debug", "true");
```

MCFOutboundEmail Class Properties

In this section we discuss the MCFOutboundEmail class properties. The properties are described in alphabetical order.

BackupSMTPPort

Description

Use this property to specify the port number of the backup SMTP server. This is an optional property when creating an email. If you don't specify a value, the default value is 25.

This property is read/write.

BackupSMTPServer

Description

Use this property to specify the server name of the backup SMTP server. The system tries to connect to the backup server if the primary SMTPserver is not available.

This property is read/write.

BackupSMTPSSLClientCertAlias

Description

Use this property to specify the alias for the certificate for Secure Sockets Layer (SSL) client authentication on the backup SMTP server.

This property is read/write.

Related Links

[BackupSMTPSSLPort](#)

[BackupSMTPUseSSL](#)

BackupSMTPSSLPort

Description

Use this property to specify the SSL port number for the backup SMTP server. This is an optional property. If you don't specify a value for this property, the default value is 465.

This property is read/write.

Related Links

[BackupSMTPSSLClientCertAlias](#)

[BackupSMTPUseSSL](#)

BackupSMTPUserName**Description**

Use this property to specify the user name used to sign onto the backup SMTP server. This user name is used for authentication when sending mail using the backup mail server.

This property is read/write.

BackupSMTPUserPassword**Description**

Use this property to specify the user password used for signing onto the backup SMTP server. The BackupSMTPUserName and password are used for the authentication when sending mail using the backup mail server.

This property is read/write.

BackupSMTPUseSSL**Description**

Use this property to indicate whether the connection to the backup SMTP server will be attempted using SSL or not.

This property takes a Boolean value: true if an SSL connection is to be attempted, false if a non-SSL connection is to be attempted.

This property is read/write.

Related Links

[BackupSMTPSSLClientCertAlias](#)

[BackupSMTPSSLPort](#)

BCC**Description**

Use this property to specify a comma- or semicolon-separated list of addresses that are sent a copy of this email. These blind carbon copy recipients won't appear on the list of recipients.

This property is read/write.

Related Links

[CC](#)

BounceTo

Description

Use this property to specify the email address the system should direct all bounced mail to.

This property is read/write.

CC

Description

Use this property to specify a comma- or semicolon-separated list of addresses that are sent a copy (carbon copy) of this message.

This property is read/write.

Related Links

[BCC](#)

Charset

Description

Use this property to specify the character set for the text or the attachment.

You can also specify this property using the `SetAttachmentContent` method, or the `ContentType` property.

This property is read/write.

Related Links

[SetAttachmentContent](#)

[ContentType](#)

ContentLanguage

Description

Use this property to set the language of this email. More than one language can be set in a comma-separated list. Use the standard abbreviated language names, such as en, fr, de, da, and so on.

You can also include the country codes when you specify the language, such as en-us.

This property is read/write.

Related Links

[ISO 3166 Codes \(Countries\)](#)

[ISO 639 Language Codes \(Obsolete\)](#)

ContentType

Description

Use this property to specify the content type of this body part.

You can also specify the content type with the `SetAttachmentContent` method.

You can also use this property to specify the character set. For example, “text/plain; charset=US-ASCII”.

This property is read/write.

Related Links

[SetAttachmentContent](#)

[Charset](#)

DefaultCharSet

Description

Use this property to specify the character set to be applied to all the parts of the email.

This property is read/write.

Description

Description

Use this property to specify a description of the file attachment associated with this email. If there is no file attachment, this property is ignored.

This property is read/write.

Related Links

[AddAttachment](#)

Disposition

Description

Use this property to specify how the body part is presented in the received mail.

Some email clients ignore the setting of this property and present body parts either inline or as file attachments.

Values for this property are:

Value	Description
Attachment	The body part is shown as a file attachment.
Inline	The body part is shown in the body itself.

This property is read/write.

ErrorDescription

Description

If an error occurs, use the ErrorDescription property to get the description of the error.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner. If this property has a user-specified value, that value will be overwritten automatically when there is an error condition.

Related Links

[ErrorDetails](#)

ErrorDetails

Description

If an error occurs, use the ErrorDetails property to get the details of the error.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner. If this property has a user-specified value, that value will be overwritten automatically when there is an error condition.

Related Links

[ErrorDescription](#)

ErrorMsgParamsCount

Description

Use this property to the number of substitution parameters as an integer.

This property is read-only.

Related Links

[GetErrorMsgParam](#)

Filename

Description

If you are adding an attachment to the email, you can specify the name of the file using this property.

PeopleSoft recommends that you keep the file extension specified with this property the same as the original extension found in the file path, otherwise the client applications may not be able to display it properly.

This property is read/write.

FilePath

Description

Specify the path for the file that contains the contents of this email.

Whether this is a relative or absolute path depends on the `FilePathType` property.

You can also specify a URL to the file using this property, if the `FilePathType` property is specified as `%FilePath_Absolute`.

If you specify a value for this property, the 'Text' content is ignored (when used with the `ContentType` property.)

This property is read/write.

Related Links

[FilePathType](#)

FilePathType

Description

Use this property to specify whether the path specified with the `FilePath` property is a relative or absolute path. The values for this property are:

<i>Value</i>	<i>Description</i>
<code>%FilePath_Relative</code>	The file path specified with the <code>FilePath</code> property is a relative path.

Value	Description
%FilePath_Absolute	The file path specified with the FilePath property is either an absolute path to a file, or a URL to a file.

If you specify a relative path, the file must be available in the FILES folder of application server folder.

If you specify an absolute path, the file could be on the local machine, in any network folder, or a URL.

If you specify a value for this property, the Text property is ignored.

This property is read/write.

From

Description

Use this property to specify the email address of the person sending the email.

You can specify more than one address as from in a comma-separated list.

This property is read/write.

Related Links

[Recipients](#)

[ReplyTo](#)

[Sender](#)

Importance

Description

Use this property to specify the value of the importance header field.

The importance can be set to the following:

- low
- normal
- high

If the Priority property is not set, the system automatically sets it to the corresponding values like 5, 3 and 1.

This property is read/write.

InvalidAddresses

Description

Use this property to get a partial list of email addresses to which the email could not be sent. The email addresses are in a string, separated by commas.

This property is read-only.

Related Links

[ValidSentAddresses](#)

[ValidUnsentAddresses](#)

IsAuthenticationReqd

Description

Use this property to specify if authentication is required or not. If the SMTP server does not support authentication or authentication is not enabled, this property is ignored.

This property takes a Boolean value: true if authentication is required, false otherwise.

This property is read/write.

IsOkToSendPartial

Description

Use this property to specify if the email can be sent to only some of the specified recipients or if it must be sent to all. This property takes a Boolean value: true if a partial list of addresses is acceptable, false otherwise. If the email must go out to all those listed, or to none at all, specify false.

This property is read/write.

Considerations Using IsOkToSendPartial

If the syntax of the email address is wrong, no mail is sent, regardless of the value of this property. The error is reported.

If the syntax of the email addresses is correct but the email server is unable to send mail to some addresses, the value of this property is used to either send or not send to the partial list of email addresses.

If the syntax of all the email addresses are correct and the email server is able to dispatch mail to all the addresses, no error is reported immediately. Later, if some addresses are found invalid by the recipient email server or gateway, the mail is sent back. In this case the source email server has no way to find the invalidity of the email address in advance.

IsReturnReceiptReqd

Description

Use this property to specify if the receiver must send acknowledgement that the email was received when it's received. This property takes a Boolean value: true if the return receipt is required, false otherwise.

This property is read/write.

MessageNumber

Description

This property returns the message number of the error message associated with this email. The message number is associated with messages in the PeopleTools Message Catalog.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner. If this property has a user-specified value, that value will be overwritten automatically when there is an error condition.

Related Links

[MessageSetNumber](#)

MessageSetNumber

Description

This property returns the message set number of the error message associated with the email.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner. If this property has a user-specified value, that value will be overwritten automatically when there is an error condition.

[MessageNumber](#)

MultiPart

Description

The email can contain simple text, one attachment, or a MultiPart object.

If you have assigned a MultiPart object using this property, the text and attachment related properties are ignored.

This property is read/write.

Example

```
Local PT_MCF_MAIL:MCFMultipart &mp = create PT_MCF_MAIL:MCFMultipart();
&mp.SubType = "alternative; differences=Content-type";

&mp.AddBodyPart (&text);
&mp.AddBodyPart (&html);

&email.MultiPart = &mp;
```

Priority

Description

Use this property to specify the priority of this email.

The values are:

1. Highest Priority
2. High Priority
3. Normal
4. Low Priority
5. Lowest Priority

The default value is 3, that is, normal priority.

This value set with this property is used to set to a header X-Priority field, as this is the most common but non-standard field to show priority. In addition, the corresponding values are set in two header fields: X-MSMail-Priority and Priority. The headers X-Priority or X-MSMail-Priority are set to the corresponding value only if the user does not specify a value.

This property is read/write.

Recipients

Description

Use this property to specify the email addresses of all the main recipients to whom the email is being sent. All the addresses are specified in a comma- or semicolon-separated string.

This property is read/write.

RefIDs

Description

Use this property to specify a value for the REFERENCES header field of the message.

This property is read/write.

ReplyIDs

Description

Use this property to specify a value for the IN-REPLY-TO header field of the message.

This property is read/write.

ReplyTo

Description

Use this property to specify the email address where the reply should be sent. You do not need to specify a value for this property if the value is the same as the From property.

This property is read/write.

ResultOfSend

Description

This property returns the result of the Send method. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%ObEmail_FailedBeforeSending	Email failed before being sent.
1	%ObEmail_Delivered	Email was delivered.
2	%ObEmail_NotDelivered	Email delivery not attempted.
3	%ObEmail_PartiallyDelivered	Email has only been partially delivered. Only some of the addresses in the list of addresses were delivered to.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
-1	%ObEmail_ SentButResultUnknown	Email was sent but whether it was successful or not is not known.

This property is read-only.

Related Links

StatusNotifyOptions

Description

Use this property to specify when the system should notify the sender. The values are separated by commas in a string. The values are:

Value	Description
SUCCESS	Send notification if the email is delivered successfully.
FAILURE	Send notification if the email is not delivered successfully.
DELAY	Send notification if delivery of the email is delayed.

This property is read/write.

Related Links

[StatusNotifyReturn](#)

[TimeToWaitForResult](#)

StatusNotifyReturn

Description

Use this property to specify what should be returned as the status notification. You can return either the header or the full message. This option is meaningful only if StatusNotifyOptions property is set.

The values are:

Value	Description
HDRS	Return only the headers of the email.
FULL	Return the full email message.

This property is read/write.

Subject

Description

Use this property to specify the subject of the email. A subject can only contain 254 characters.

This property is read/write.

Text

Description

Use this property to specify the text for the email.

This property is read/write.

TimeToWaitForResult

Description

Use this property to specify the number of milliseconds to wait for the result of send email process. If the result comes back within this time, the returned value is a positive number. Otherwise, %ObEmail_SentButResultUnknown (or -1) is returned.

This property is read/write.

[StatusNotifyReturn](#)

UsedDefaultConfig

Description

Use this property to determine whether the default configuration as specified in application server configuration file was used or not.

This property returns a Boolean value: true if the default configuration was used, false if the value specified with the MCFOutboundEmail or the SMTPSession object was used.

This property is read-only.

UsedPrimaryServer

Description

Use this property to determine if the default SMTP server was used, or the backup server.

This property returns a Boolean value: true if the default SMTP server was used, false if the backup server was used.

This property is read-only.

ValidSentAddresses

Description

This property returns the list of addresses that were valid and that the email was sent to. The email addresses are in a string, separated by commas.

This property is read-only.

Related Links

[ValidSentAddresses](#)

SMTPSession Class

Use the SMTPSession class to when you want to send more than one email using the same SMTP session. If you are only sending a single email, use the MCFOutboundEmail class instead.

SMTPSession Class Methods

In this section we describe the SMTPSession class methods. The methods are described in alphabetical order.

Send

Syntax

```
Send (&Email)
```

Description

Use the Send method to send an MCFOutboundEmail object as email.

By default, the system sends the email to the SMTP server using the properties set in the application server configuration file. You can specify different setup parameters by supplying values for the SMTPSession object properties, such as Server, BackupServer, and so on.

Parameters

Parameter	Description
<i>&Email</i>	Specify an already instantiated MCFOutboundEMail object to be sent.

Returns

A constant indicating the status of the method. The values are:

Value	Description
%ObEmail_Delivered	The email was delivered.
%ObEmail_NotDelivered	Email delivery not attempted.
%ObEmail_PartiallyDelivered	The email was only partially delivered, that is, it was only delivered to some of the recipients.
%ObEmail_FailedBeforeSending	The email wasn't delivered.
%ObEmail_SentButResultUnknown	The email was sent but the result is unknown. The TimeToWaitForResult value was not sufficient to get the result of the send process.

Related Links

[SendAll](#)

SendAll

Syntax

```
SendAll (&Emails)
```

Description

Use the SendAll method to send a number of emails, all using the same SMTP session and session properties.

Parameters

Parameter	Description
<i>&Emails</i>	Specify an array of MCFOutboundEmail objects.

Returns

An array of number. Each item in the array indicates the status of an individual email object. Values are:

Value	Description
%ObEmail_Delivered	The email was delivered.
%ObEmail_NotDelivered	Email delivery not attempted.
%ObEmail_PartiallyDelivered	The email was only partially delivered, that is, it was only delivered to some of the recipients.
%ObEmail_FailedBeforeSending	The email wasn't delivered.
%ObEmail_SentButResultUnknown	The email was sent but the result is unknown. The TimeToWaitForResult value was not sufficient to get the result of the send process.

Related Links

[Send](#)

SetSMTPParam

Syntax

```
SetSMTPParam(ParamName, ParamValue)
```

Description

Use the SetSMTPParam method to set additional parameters for the SMTP session.

You must use this method before you use any Send method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ParamName</i>	Specify the name of the parameter you want to overwrite.
<i>ParamValue</i>	Specify the value for the named parameter that you want used instead of the existing value.

Returns

None.

SMTPSession Class Properties

In this section we describe the SMTPSession class properties. The properties are described in alphabetical order.

BackupPort

Description

Use this property to specify the port number of backup SMTP server. This is an optional property. If you don't specify a value for this property, the default value is 25.

This property is read/write.

BackupServer

Description

Use this property to specify the name of the backup SMTP server. The system tries connecting to the backup server if the primary SMTP server is not available.

This property is read/write.

BackupSSLClientCertAlias

Description

Use this property to specify the alias for the certificate for SSL client authentication on the backup SMTP server.

This property is read/write.

Related Links

[BackupSSLPort](#)

[BackupUseSSL](#)

BackupSSLPort**Description**

Use this property to specify the SSL port number for the backup SMTP server. This is an optional property. If you don't specify a value for this property, the default value is 465.

This property is read/write.

Related Links

Mail Classes Examples

This section provides examples for creating and authenticating email messages.

Creating a Text Email

The following code example creates and sends a very simple email, then tests the results.

```
import PT_MCF_MAIL:*;

/*-- Create an outbound email object --*/

Local PT_MCF_MAIL:MCFOutboundEmail &eMail =
create PT_MCF_MAIL:MCFOutboundEmail();

/*-- Initialize the usual fields of an email --*/

&eMail.From = &FromAddress;
&eMail.Recipients = &ToList;
&eMail.Subject = &Subject;
&eMail.Text = &MailBody;

/*-- The send method uses the default SMTP parameters as set in the app server conf=
iguration file.

This send method makes a connection to the SMTP server, sends the mail and then dis=
connects.

The result are returned as a number corresponding to the possible values.

The list of ValidSent, InvalidSent and Invalid addresses are returned in the email =>

object itself
----*/

Local integer &resp = &eMail.Send();
Local boolean &done;

Evaluate &resp
  When %ObEmail_Delivered
    /* every thing ok */
    &done = True;
    Break;

  When %ObEmail_NotDelivered
    &done = False;
    MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools=>
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
    Break;

  When %ObEmail_PartiallyDelivered
    &done = True;
    Break;

  When %ObEmail_FailedBeforeSending
    &done = False;
    MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools=>
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
    Break;
End-Evaluate;
```

Creating Email and Overriding SMTP Settings

The following code example creates a text email and overrides the SMTP settings as found in the application server configuration file.

```
import PT_MCF_MAIL:*;

/*-- Create an email object by setting individual parameters ---*/

Local PT_MCF_MAIL:MCFOutboundEmail &eMail =
create PT_MCF_MAIL:MCFOutboundEmail();

&eMail.Recipients = &ToList; /* comma separated list of email addresses */
&eMail.CC = &CCList; /* comma separated list of email addresses */
&eMail.BCC = &BCCList; /* comma separated list of email addresses */
&eMail.From = &FromAddress; /* from email address */
&eMail.ReplyTo = &ReplyToAddress; /* in case the reply is to be sent to a different⇒
    email address */
&eMail.Sender = &SenderAddress; /* If different from the "from" address */

&eMail.Subject = &Subject; /* email subject line */
&eMail.Text = &MailBody; /* email body text */

/*-- Override the default SMTP parameters specified in app server configuration fil⇒
e ----*/

&eMail.SMTPServer = "psp-smtpg-01";
&eMail.SMTPPort = 10266; /*-- Usually this is 25 by default */

Local integer &resp = &eMail.Send();

/* Now check the &resp for the result */

Local boolean &done;

Evaluate &resp
    When %ObEmail_Delivered
        /* every thing ok */
        &done = True;
        Break;

    When %ObEmail_NotDelivered
        &done = False;
        MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
        Break;

    When %ObEmail_PartiallyDelivered
        &done = True;
        Break;

    When %ObEmail_FailedBeforeSending
        &done = False;
        MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
        Break;
End-Evaluate;
```

Creating an HTML Email

The following example creates an HTML email.

```
import PT_MCF_MAIL:*;

/*-- Create an email object by setting individual parameters
---*/

Local PT_MCF_MAIL:MCFOutboundEmail &email =
create PT_MCF_MAIL:MCFOutboundEmail();

    &email.From = &FromAddress;
    &email.Recipients = &ToList;
    &email.Subject = &Subject;

&email.Text =
"<html><body><H1><b>Hi there!</b></H1><P>We are ready.</body></html>";

    &email.ContentType = "text/html";

Local integer &res = &email.Send();

Local boolean &done;

Evaluate &resp
    When %ObEmail_Delivered
        /* every thing ok */
        &done = True;
        Break;

    When %ObEmail_NotDelivered
        &done = False;
        MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
        Break;

    When %ObEmail_PartiallyDelivered
        &done = True;
        Break;

    When %ObEmail_FailedBeforeSending
        &done = False;
        MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
        Break;
End-Evaluate;
```

Creating a Multipart Email with Text and HTML Parts

The following code example creates an email with both HTML and text sections.

The email client on the target host must be able to detect the HTML and text parts in the email and display the part that the client is configured to display.

```
import PT_MCF_MAIL:*;

Local PT_MCF_MAIL:MCFOutboundEmail &email =
create PT_MCF_MAIL:MCFOutboundEmail();
Local string &TestName = "Text and its alternate html body";

&email.From = &FromAddress;
&email.Recipients = &ToList;
&email.Subject = &Subject;
```

```

Local PT_MCF_MAIL:MCFBodyPart &text = create PT_MCF_MAIL:MCFBodyPart();
&text.Text = "Hi There";

Local PT_MCF_MAIL:MCFBodyPart &html = create PT_MCF_MAIL:MCFBodyPart();
&html.Text =
"<html><BODY><H1>EMail test with HTML content</H1><b>Hi There</b>" |
"<A href='http://www.example.com'>Check this out!</A>" |
"<P></BODY></html>";
&html.ContentType = "text/html";

Local PT_MCF_MAIL:MCFMultipart &mp = create PT_MCF_MAIL:MCFMultipart();
&mp.SubType = "alternative; differences=Content-type";

&mp.AddBodyPart(&text);
&mp.AddBodyPart(&html);

&email.MultiPart = &mp;

Local integer &res = &email.Send();

Local boolean &done;

Evaluate &resp
  When %ObEmail_Delivered
    /* every thing ok */
    &done = True;
    Break;

  When %ObEmail_NotDelivered
    &done = False;
    MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
    Break;

  When %ObEmail_PartiallyDelivered
    &done = True;
    Break;

  When %ObEmail_FailedBeforeSending
    &done = False;
    MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
    Break;
End-Evaluate;

```

Creating an HTML Email with Images

The following code example creates an HTML email with embedded images. The content ID for an image can be a reference to a part in the email. In the following code example, the images become a part of the email and are transmitted as attachments to the email.

```

import PT_MCF_MAIL:*;

Local PT_MCF_MAIL:MCFOutboundEmail &email =
create PT_MCF_MAIL:MCFOutboundEmail();

  &email.From = &FromAddress;
  &email.Recipients = &ToList;
  &email.Subject = &Subject;

Local string &htmlText =
"<html>" |
" <head><title></title></head>" |
" <body>" |

```

```

"    <b>A sample jpg</b><br>" |
"    <IMG SRC=cid:23abc@pc27 width=566 height=424><br>" |
"    <b>End of jpg</b>" |
"  </body>" |
"</html>";

/* In this sample, the htmlText is assembled using | operator
only for the readability.
Specifying just one string can be more efficient
*/

Local PT_MCF_MAIL:MCFMultipart &mp = create PT_MCF_MAIL:MCFMultipart();
&mp.SubType = "related";

Local PT_MCF_MAIL:MCFBodyPart &html = create PT_MCF_MAIL:MCFBodyPart();
&html.Text = &htmlText;
&html.ContentType = "text/html";

Local PT_MCF_MAIL:MCFBodyPart &image = create PT_MCF_MAIL:MCFBodyPart();

&image.SetAttachmentContent("///file:C:/User/Documentum/XML%20Applications/proddoc/⇒
peoplebook_upc/peoplebook_upc.dtd",
  %FilePath_Absolute, "sample.jpg", "This is a sample image!", "", "");

  &image.AddHeader("Content-ID", "<23abc@pc27>");

  &mp.AddBodyPart(&html);
  &mp.AddBodyPart(&image);

  &email.MultiPart = &mp;

  Local integer &res = &email.Send();

Local boolean &done;

Evaluate &resp
  When %ObEmail_Delivered
    /* every thing ok */
    &done = True;
    Break;

  When %ObEmail_NotDelivered
    &done = False;
    MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
    Break;

  When %ObEmail_PartiallyDelivered
    &done = True;
    Break;

  When %ObEmail_FailedBeforeSending
    &done = False;
    MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
    Break;
End-Evaluate;

```

Creating an Email from Rich Text Editor Output

The following example creates an email message using output from a long edit box enabled with the rich text editor. Using the ParseRichTextHtml method, rich text output of the long edit box is split into an array of MCFBodyPart objects.

```
import PT_MCF_MAIL:*;
```

```

Local PT_MCF_MAIL:MCFOutboundEmail &email = create PT_MCF_MAIL:MCFOutboundEmail();
Local PT_MCF_MAIL:MCFMultipart &mp = create PT_MCF_MAIL:MCFMultipart();
Local PT_MCF_MAIL:MCFCMailUtil &mu = create PT_MCF_MAIL:MCFCMailUtil();

Local string &htmlText = RECORD_NAME.FIELD_NAME.Value;

&mp.SubType = "related";
&email.Recipients = &recipients;
&email.From = &from;
&email.Subject = "Your Order";

Local array of PT_MCF_MAIL:MCFCBodyPart &bp;
&mu.imagesLocation = "c:\temp\images";
&bp = &mu.ParseRichTextHtml(&htmlText);

If (&bp = Null) Then
    MessageBox(0, "", 0, 0, &mu.ErrorDescription);
    Return;
End-If;

&mp.AddBodyPart(&bp [1]);

For &i = 2 To &bp.Len
    &mp.AddBodyPart(&bp [&i]);
End-For;

&email.MultiPart = &mp;
Local integer &resp = &email.Send();

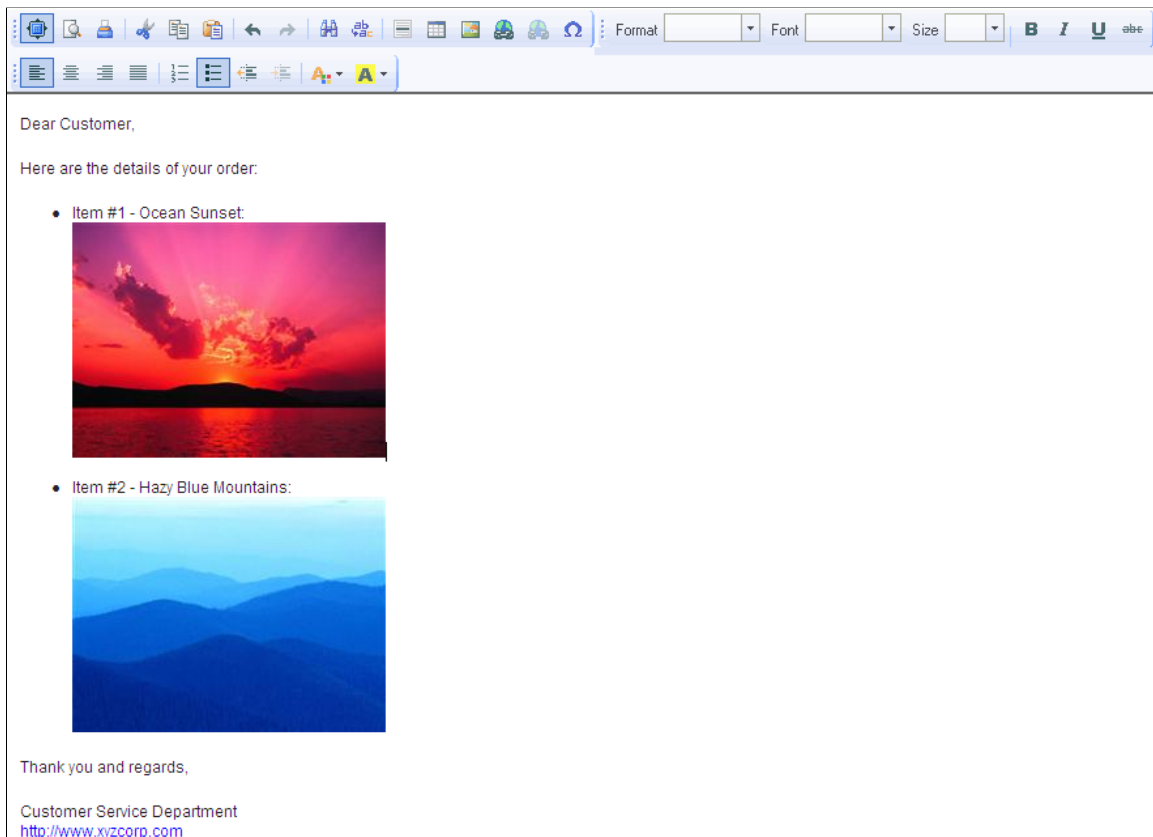

/* Exec code to check the &resp for the result */

/* Exec code to delete temporary image files from the imagesLocation directory */

```

For example, the rich text editor is used to create a message containing text and two images as shown in this example:

This example illustrates the fields and controls on the Rich text editor displaying an example email. You can find definitions for the fields and controls later on this page.

The HTML for this email is as follows:

```
<p>Dear Customer,</p>
<p>Here are the details of your order:</p>
<ul>
<li> Item #1 - Ocean Sunset:
<br /> <img height="180" id="PT_RTE_IMG_DB_LOC###20091111142435187Sunset_thumbnail.=>
jpg" src="/cs/QEDMO/cache/PTRTDB_JPG_GIYDAOJRGEYTCMJUGI1DGNJRHA2VG4LOON SXIX2UNB1W1Y=>
TOMFUWYLTKOBTQ=_GA==_GE==_2000000000.JPG" width="240" /><br /> &nbsp;</li>
<li> Item #2 - Hazy Blue Mountains:
<br /> <img height="180" id="PT_RTE_IMG_DB_LOC###20091111142508395Mountains_thumbna=>
il.jpg" src="/cs/QEDMO/cache/PTRTDB_JPG_GIYDAOJRGEYTCMJUGI1TAOBTHE1U122VNZ1GC1LOONP=>
XI1DVNVRG3YLJNQXGU3DH_GA==_GE==_2000000000.JPG" width="240" /></li>
</ul>
<p>Thank you and regards,</p>
<p>Customer Service Department
<br /><a href="http://www.xyzcorp.com">http://www.xyzcorp.com</a></p>
```

When this HTML is parsed by the ParseRichTextHtml method, an array with three MCFBodyPart elements is created. The first MCFBodyPart is array element `&bp [1]` with the following properties:

- `&bp [1].ContentType =`
`text/html`

- `&bp [1].Text =`

```
<p>Dear Customer,</p>
<p>Here are the details of your order:</p>
<ul>
<li> Item #1 - Ocean Sunset:
<br /> 
<br /> &nbsp;</li>
<li> Item #2 - Hazy Blue Mountains:
<br /> </li>
</ul>
<p>Thank you and regards,</p>
<p>Customer Service Department
<br /><a href="http://www.xyzcorp.com">http://www.xyzcorp.com</a></p>
```

The second MCFBodyPart is array element `&bp [2]` with the following properties:

- `&bp [2].ContentType =`

```
image/gif
```

- `&bp [2].Description =`

```
Image1
```

- `&bp [2].Disposition =`

```
inline
```

- `&bp [2].AttachmentURL =`

```
c:\temp\images/20091111142435187Sunset_thumbnail.jpg
```

The final MCFBodyPart is array element `&bp [3]` with the following properties:

- `&bp [3].ContentType =`

```
image/gif
```

- `&bp [3].Description =`

```
Image2
```

- `&bp [3].Disposition =`

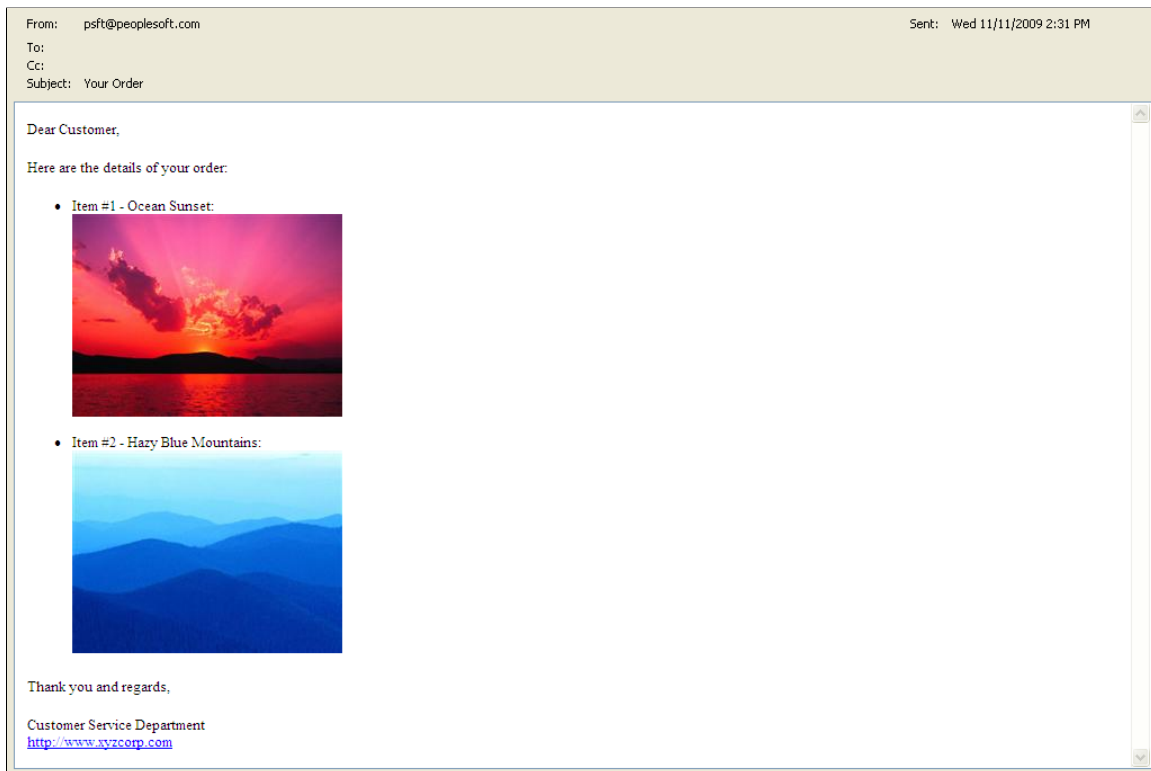

```
inline
```

- `&bp [3].AttachmentURL =`

```
c:\temp\images/20091111142508395Mountains_thumbnail.jpg
```

Observe that the email received by the recipient is formatted the way that it appeared in the rich text editor as shown in the following example:

This example illustrates the fields and controls on the Email as received in Microsoft Outlook. You can find definitions for the fields and controls later on this page.

Finally, the XML code that represents this email message is as follows:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>

Creating an Email with Attachments

The following code example creates an email with two attachments.

Oracle recommends that you always provide the proper extension in the file name, otherwise the receiving email client may not be able to associate it with the appropriate application.

Note: There is no automatic restriction of attachment size using the mail classes. To restrict an email based on attachment size, your application must check the size of an attachment before composing and sending the email.

```

import PT_MCF_MAIL:*;

Local PT_MCF_MAIL:MCFOutboundEmail &email =
create PT_MCF_MAIL:MCFOutboundEmail();

&email.From = &FromAddress;
&email.Recipients = &ToList;
&email.Subject = &Subject;

Local string &plain_text = "Hi there!";
Local PT_MCF_MAIL:MCFBodyPart &text = create PT_MCF_MAIL:MCFBodyPart();
&text.Text = &plain_text;

Local PT_MCF_MAIL:MCFBodyPart &attach1 = create PT_MCF_MAIL:MCFBodyPart();
&attach1.SetAttachmentContent("Ocean Wave.jpg", %FilePath_Relative,
"Ocean Wave.jpg", "Ocean Wave", "", "");
/* %FilePath_Relative indicates the file is available at Appserver's FILES director⇒
y */

Local PT_MCF_MAIL:MCFBodyPart &attach2 = create PT_MCF_MAIL:MCFBodyPart();
&attach2.SetAttachmentContent("///file:C:/User/Documentum/XML%20Applications/proddo⇒
c/peoplebook_upc/peoplebook_upc.dtd",
%FilePath_Absolute, "Sample.jpg", "Sample", "", "");
/* The Sample.jpg is available in the "public" folder of my-server machine*/

Local PT_MCF_MAIL:MCFMultipart &mp = create PT_MCF_MAIL:MCFMultipart();
&mp.AddBodyPart(&text);
&mp.AddBodyPart(&attach1);
&mp.AddBodyPart(&attach2);

&email.MultiPart = &mp;

Local integer &res = &email.Send();

Local boolean &done;

Evaluate &resp
When %ObEmail_Delivered
/* every thing ok */
&done = True;
Break;

When %ObEmail_NotDelivered
&done = False;
MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒

```

```

error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
    Break;

    When %ObEmail_PartiallyDelivered
        &done = True;
        Break;

    When %ObEmail_FailedBeforeSending
        &done = False;
        MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
        Break;
End-Evaluate;

```

Creating Email Attachments by Specifying URLs

The following code example creates two email attachments by specifying a URL for each file location instead of an absolute or relative path to the file.

```

import PT_MCF_MAIL:*;

Local PT_MCF_MAIL:MCFOutboundEmail &email = create PT_MCF_MAIL:MCFOutboundEmail();

&email.From = &FromAddress;
&email.Recipients = &ToList;
&email.Subject = &Subject;

Local string &plain_text = "Hi there!";
Local PT_MCF_MAIL:MCFFBodyPart &text = create PT_MCF_MAIL:MCFFBodyPart();

&text.Text = &plain_text;

Local PT_MCF_MAIL:MCFFBodyPart &attach1 = create PT_MCF_MAIL:MCFFBodyPart();
&attach1.SetAttachmentContent("http://example.com/index.htm", %FilePath_Absolute, "⇒
example.html", "An Example", "", "");

Local PT_MCF_MAIL:MCFFBodyPart &attach2 = create PT_MCF_MAIL:MCFFBodyPart();
&attach2.SetAttachmentContent("ftp://www.w3c/docs/somedoc.htm", %FilePath_Absolute,⇒
"somedoc.htm", "somedoc from w3c", "", "");

Local PT_MCF_MAIL:MCFFMultipart &mp = create PT_MCF_MAIL:MCFFMultipart();

&mp.AddBodyPart(&text);
&mp.AddBodyPart(&attach1);
&mp.AddBodyPart(&attach2);

&email.MultiPart = &mp;

Local integer &res = &email.Send();
Local boolean &done;

Evaluate &resp
    When %ObEmail_Delivered
        /* every thing ok */
        &done = True;
        Break;

    When %ObEmail_NotDelivered
        &done = False;
        MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
        Break;

    When %ObEmail_PartiallyDelivered

```

```

        &done = True;
        Break;

    When %ObEmail_FailedBeforeSending
        &done = False;
        MessageBox(0, "", &email.MessageSetNumber, &email.MessageNumber, "PeopleTools⇒
error not found", &email.GetErrorMsgParam(1), &email.GetErrorMsgParam(2));
        Break;
End-Evaluate;

```

Creating and Sending Multiple Email Messages

You can create several emails and send them all in a single connection to the SMTP server. However, your system administrator may also need to configure the SMTP server with longer connection time-outs if you are sending multiple emails.

```

import PT_MCF_MAIL:*;

/*-- Create an email object by setting individual parameters
---*/
Local array of PT_MCF_MAIL:MCFOutboundEmail &mails;
Local PT_MCF_MAIL:MCFOutboundEmail &email;

Local PT_MCF_MAIL:SMTPSession &commonSession =
create PT_MCF_MAIL:SMTPSession();

    &email = &commonSession.CreateOutboundEmail();
    &email.From = &FromAddress;
    &email.Recipients = &ToList1;
    &email.Subject = &Subject;
    &email.Text = &MailBody1;

    &mails = CreateArray(&email);

    &email = &commonSession.CreateOutboundEmail();
    &email.From = &FromAddress;
    &email.Recipients = &ToList2;
    &email.Subject = &Subject;
    &email.Text = &MailBody2;
    &mails [2] = &email;

    &email = &commonSession.CreateOutboundEmail();
    &email.From = &FromAddress;
    &email.Recipients = &ToList3;
    &email.Subject = &Subject;
    &email.Text = &MailBody3;
    &mails [3] = &email;

Local array of integer &allRes = &commonSession.SendAll(&mails);

```

Sending an Email With Authentication

The following code example includes a user name and password to be used by the SMTP server.

```

import PT_MCF_MAIL:*;

Local PT_MCF_MAIL:MCFOutboundEmail &email =
create PT_MCF_MAIL:MCFOutboundEmail();

    &email.From = &FromAddress;
    &email.Recipients = &ToList;
    &email.Subject = &Subject;
    &email.Text = &MailBody;

    &email.SMTPServer = "MySMTPServer";

```

```
&email.IsAuthenticationReqd = True;

&email.SMTPUserName = "SomeLoginName";
&email.SMTPUserPassword = "SomeLoginPassword";

Local integer &res = &email.Send();
```

Using an SSL Connection to Send Email

The following code example uses an SSL connection to send an email message:

```
import PT_MCF_MAIL:*;

Local PT_MCF_MAIL:MCFOutboundEmail &email = create PT_MCF_MAIL:MCFOutboundEmail();

&email.From = &FromAddress;
&email.Recipients = &ToList;
&email.Subject = &Subject;
&email.Text = &MailBody;

&email.SMTPServer = "MySMTPServer";
&email.IsAuthenticationReqd = True;

&email.SMTPUserName = "SomeLoginName";
&email.SMTPUserPassword = "SomeLoginPassword";
&email.SMTPUseSSL = "Y";
&email.SMTPSSLClientCertAlias = &cAlias;
&email.SMTPSSLPort = &SSLPort;

Local integer &res = &email.Send();
```

Managed Object Classes

Understanding the Managed Object Classes

PeopleSoft enables users and application developers to generate PeopleTools definitions for managed objects and database objects by providing PeopleCode classes, methods, and properties. Existing field and record definitions cannot be updated through PeopleCode. Therefore, users and application developers must differentiate between the field and record definitions created through the Application Designer and the definitions generated through PeopleCode. Broadly, we'll refer to the Application Designer definitions as design time definitions and the PeopleCode-generated definitions as runtime definitions.

Considerations When Using Definitions Created Through the Managed Object Classes

Important! The classes, methods, properties, and built-in functions are intended for use during configuration time only, before active runtime usage is initiated. Using these classes, methods, properties, and built-in functions during active runtime is not supported. Changes to managed object definitions are not recognized on currently loaded component. In general, changes aren't recognized until the component is reloaded.

Consider the following before you begin using the Managed Object classes, methods, properties, and built-in functions:

Field and Record Definitions

Managed Object classes are FieldDefn, RecordDefn, RecordFieldDefn where FieldDefn objects are the standalone field definitions, and RecordFieldDefn objects are the fields on the records. FieldDefn and RecordDefn objects can be used anywhere in PeopleCode, that is, in an application class, Application Engine PeopleCode, record field PeopleCode, and so on. If you invoke any of the Save methods, you should ensure that it is invoked from an event that allows database updates, such as:

- SavePreChange
- WorkFlow
- SavePostChange
- FieldChange
- Application Engine PeopleCode action

Objects of the Managed Object classes can be declared as component, global, or local variables.

Similar to Application Designer, the Managed Object field and record definition properties are validated when save is invoked to ensure that the properties are used correctly. If validation fails, the detailed error messages are available through the Messages property.

Runtime vs Design Time Definitions

You should not mix the runtime definitions (created through the Managed Object classes) with the design time (created in Application Designer) definitions. For example, you cannot add a runtime field definition to a design time record definition. In order to differentiate the definitions, a read-only property, `RuntimeDefn`, is added to both the field and record managed objects to indicate how the definition was created. *Runtime Definition* is displayed on the Field and Record editors in Application Designer.

The following Application Designer rules apply:

- You cannot add runtime definitions to any design time definition (for example, fields on records, records on components, and so on) with the exception of Projects.
- Runtime definitions are displayed as read-only.
- During an import, runtime definitions cannot overwrite design time definitions.

The following Managed Object classes rules apply:

- Design time definitions can be fetched using the Managed Object classes, but they cannot be saved using the Managed Object classes.
- Design time fields can be added to runtime records.

Consider using a naming convention to distinguish runtime definitions from design time definitions.

Related Languages

The following restrictions apply with regard to related languages when you use the `FieldDefn` and `RecordDefn` classes:

- Class methods for saving related language data of the definitions is not supported. That is, class methods only support saving base language data.
- If a user is signed on in a non-base language, the data entered for related language types of fields will be saved to both the base language table and the related language table. For example, if the base language is English and a user is signed on in Spanish, and they enter a record description in Spanish, that description will be saved to both the base language table and related language table.

Records

The `RecordDefn` class only supports creating SQL views. If a user attempts to save any other type of record, the record is rejected.

Note: Similar to Application Designer record definitions, all record names used with the `RecordDefn` class should not be prefixed with `PS_` although the view that is created is prefixed with `PS_`.

Consider the following ramifications, depending on the database platform, on SQL views:

- Existing views will be dropped before rebuilding them. Dependent views may be dropped or invalidated, but these are not rebuilt automatically. Users and application developers should manage the views and rebuild the dependent views.

- A separate method is provided to build views, that is, views are not built during the save method. It enables users to save their record definitions as frequently as they require and build a view when required.
- The SQL for the view is validated when the view is saved or built. If the SQL is invalid, the view is not built. The RecordDefn class follows the conventions on creating and building views similar to Application Designer.

Message Catalog

The delivered component interface, MESSAGE_CATALOG_CI, can be used to create and delete message catalog entries, but the message catalog entries that can be manipulated are restricted to non-PeopleTools message sets.

Consider the following when you use MESSAGE_CATALOG_CI:

- The structure of the Message Catalog component is such that the message catalog entries are a collection within a given message set.
- Message sets cannot be deleted; only message catalog entries can be deleted.
- The Message Catalog component interface supports the Component Interface Class methods: Cancel, Create, Find, Get, Save.
- The Message Catalog component interface can manipulate non-PeopleTools message sets. PeopleTools message sets (1–999) are *not* allowed to be modified. If you attempt to save one of these, an error is displayed.
- When creating a new message set, the underlying component automatically generates the first message catalog entry, which must be populated before the new message set can be saved.
- When adding or updating a message catalog and the user is signed on in a non-base language, the base language tables and the related language tables are updated with the same text.

FieldDefn Class

This section provides an overview of the FieldDefn class and discusses:

- FieldDefn class methods.
- FieldDefn class properties.

FieldDefn Class Methods

In this section, the FieldDefn class methods are presented in alphabetical order.

Save

Syntax

Save ()

Description

Use the Save method to validate and save a field definition to the database.

Parameters

None.

Returns

An integer representing the following statuses.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Descriptoin</i>
0	%MDA_Success	The field definition is saved successfully.
1	%MDA_Failed	The field definition is not saved.
2	%MDA_UseAppDesigner	The specified field is not created using the PeopleCode FieldDefn class.
4	%MDA_Unsupported	The specified field type is not supported in PeopleCode.
12	%MDA_InvalidDefn	This value is returned when the validation fails. The detailed validation error messages are available through the Messages property.
14	%MDA_NoWriteAccess	The user doesn't have write permissions to the field.

Example

```

Local FieldDefn &newField = CreateFieldDefn();
If All(&newField) Then
    &newField.Name = "MYNEWFIELD";
    &newField.Type = %FieldType_Char;
    &newField.Description = "My new field";
    &retVal = &newField.SetLabel("MYNEWFIELD", "My field", "My New Field", True);
    /* do error checking ... */
    Local date &myDate = Date3(1900, 1, 1);
    &retVal = &newField.SetTranslateValue("A", True, &myDate, "My New XLAT", "My XLA⇒
T");
    /* do error checking ... */
    &retVal = &newField.Save();
    /* do error checking ... */
End-If;

```

[SaveAs](#)

SaveAs

Syntax

SaveAs (*New_FieldName*)

Description

Use this method to set the RuntimeDefn flag, validate, and save the field definition to the database.

Labels are copied from the source field to the target field. The translate values are copied if the field type is character (CHAR) and the field length is less than or equal to 4.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>New_FieldName</i>	Specifies the new name of the field.

Returns

An integer representing the following statuses.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%MDA_Success	The field definition is saved successfully.
1	%MDA_Failed	The field definition is not saved.

Numeric Value	Constant Value	Description
4	%MDA_Unsupported	The field type is not supported in PeopleCode.
5	%MDA_Duplicate	The given field already exists.
12	%MDA_InvalidDefn	This value is returned when the validation fails. The detailed validation error messages are available through the Messages property.
14	%MDA_NoWriteAccess	The user does not have write permissions to the field.

Example

```

Local FieldDefn &mktField = GetFieldDefn("MARKET");
If All(&mktField) Then
    &mktField.Description = "My new Market field";
    &retVal = &mktField.SetLabel("MYMARKET", "My Market", "My New Market", True);
    /* do error checking ... */
    Local date &myDate = Date3(1900, 1, 1);
    &retVal = &mktField.SetTranslateValue("A", True, &myDate, "My New Market", "My M⇒
arket");
    /* do error checking ... */
    &retVal = &mktField.SaveAs("MYMARKET");
    /* do error checking ... */
End-If;

```

Related Links

[Save](#)

SetLabel

Syntax

```
SetLabel (Label_ID, Long_name, Short_name, Default_label)
```

Description

Use this method to add a new label or modify an existing label. At least one label is required for the field definition to be saved. Also, one label is required to be set as the default label for the field definition to be saved.

Parameters

Parameter	Description
<i>Label_ID</i>	Specifies the label as string.
<i>Long_name</i>	Specifies the long name of the field as string.
<i>Short_name</i>	Specifies the short name of the field as string.
<i>Default_label</i>	Specify a Boolean value whether the label entered in the Label_ID parameter is the default label or not.

Returns

An integer representing the following statuses.

Numeric Value	Constant Value	Description
0	%MDA_Success	The label for the field is updated successfully.
1	%MDA_Failed	The label for the field is not updated.

Example

```
Local FieldDefn &newField = CreateFieldDefn();
If All(&newField) Then
    &newField.Name = "MYNEWFIELD";
    &newField.Type = %FieldType_Char;
    &newField.Description = "My new field";
    &retVal = &newField.SetLabel("MYNEWFIELD", "My field", "My New Field", True);
    /* do error checking ... */
    &retVal = &newField.Save();
    /* do error checking ... */
End-If;
```

SetTranslateValue

Syntax

```
SetTranslateValue (Translate_value, Active, EffDate, Long_name, Short_name)
```

Description

Use this method to add a new translate value or modify an existing value.

Parameters

Parameter	Description
<i>Translate_value</i>	Specifies the translate value as string.
<i>Active</i>	Specify a Boolean value whether the translate value is active or not.
<i>EffDate</i>	Specifies the effective date.
<i>Long_name</i>	Specifies the long name of the translate value as string
<i>Short_name</i>	Specifies the short name of the translate value as string

Returns

An integer representing the following statuses.

Numeric Value	Constant Value	Description
0	%MDA_Success	The translate values are updated.
1	%MDA_Failed	The translate values are not updated.

Example

```

Local FieldDefn &newField = CreateFieldDefn();
If All(&newField) Then
    &newField.Name = "MYNEWFIELD";
    &newField.Type = %FieldType_Char;
    &newField.Description = "My new field";
    &retVal = &newField.SetLabel("MYNEWFIELD", "My field", "My New Field", True);
    /* do error checking ... */
    Local date &myDate = Date3(1900, 1, 1);
    &retVal = &newField.SetTranslateValue("A", True, &myDate, "My New XLAT", "My XLA⇒
T");
    /* do error checking ... */
    &retVal = &newField.Save();
    /* do error checking ... */
End-If;

```

Validate

Syntax

```
validate ()
```

Description

Use this method to validate a field definition.

Parameters

None.

Returns

A Boolean value. True if the field definition is successfully validated; false otherwise. If it returns false, the detailed error messages are available through the Messages property.

Example

```

Local FieldDefn &newField = CreateFieldDefn();
If All(&newField) Then
    &newField.Name = "MYNEWFIELD";
    &newField.Type = %FieldType_Char;
    &newField.Description = "My new field";
    &retVal = &newField.SetLabel("MYNEWFIELD", "My field", "My New Field", True);
    /* do error checking ... */
    Local date &myDate = Date3(1900, 1, 1);
    &retVal = &newField.SetTranslateValue("A", True, &myDate, "My New XLAT", "My XLA⇒
T");
    /* do error checking ... */
    &retVal = &newField.Validate();
End-If;

```

FieldDefn Class Properties

In this section, the FieldDefn class properties are described in alphabetical order.

DecimalPositions

Description

Use this property to specify the number of digits after the decimal point to be displayed for a field defined as number or signed number. The valid values are 0 to 31.

This property is read/write.

Related Links

[Type](#)

DefaultCentury

Description

Use this property to specify the display of century in a field defined as date or date and time.

This property is read/write.

Related Links

[Type](#)

Description

Description

Use this property to specify a description for a field.

This property is read/write.

Example

```
&myField.Description = "My new field";
```

Related Links

[Name](#)

FormatType

Description

Use this property to specify the formatting of a field. It is valid for character (CHAR) field type.

You can use a value from the pre-defined format types. Value 5 with its associated constant value is deprecated, so it is not included in the list.

<i>Numeric Value</i>	<i>Constant Value</i>
0	%FormatFamilyType_Upper
1	%FormatFamilyType_Name
2	%FormatFamilyType_Phone
3	%FormatFamilyType_Zip
4	%FormatFamilyType_SSN
6	%FormatFamilyType_MixedCase
7	%FormatFamilyType_RawBinary

<i>Numeric Value</i>	<i>Constant Value</i>
8	%FormatFamilyType_NumOnly
9	%FormatFamilyType_SIN
10	%FormatFamilyType_PhoneIntl
11	%FormatFamilyType_ZipIntl

Note: Custom format type is not supported.

This property is read/write.

Related Links

[Type](#)

IntegerPositions

Description

Use this property to specify the number of digits to be displayed for a field defined as number or signed number. The valid values are 0 to 31.

This property is read/write.

Related Links

[Type](#)

Length

Description

Use this property to specify the length of the field of type character (CHAR). The valid values are 1 to 254.

This property is read/write.

Related Links

[Type](#)

MaxLength

Description

Use this property to specify the maximum length of a field. It is valid for long character (LONGCHAR) field type. Valid values are 0 to 32767.

This property is read/write.

Related Links

[Type](#)

Messages

Description

This property returns a multi-dimensional array of Any that contains the messages that occurred during execution of the Validate or Save methods. This array is only populated after the Validate or Save method has been executed.

The first dimension contains the message set number. The second dimension contains the message number. The third dimension contains the number of parameters in that message. The subsequent dimensions contain the values for the parameters. The maximum number of possible dimensions is 8.

This property is read-only.

Example

```

If Not &fieldDefn.Validate() Then
  Local array of array of any &msgs = &fieldDefn.Messages;
  &default_msg_txt = "";
  &message_set = &msgs [1][1];
  &message_nbr = &msgs [1][2];
  &numParams = &msgs [1][3];
  Evaluate &numParams
  When 0
    &errString = MsgGetText(&message_set, &message_nbr, &default_msg_txt);
  When 1
    &errString = MsgGetText(&message_set, &message_nbr, &default_msg_txt, &msgs [⇒
&index][4]);
  When 2
    &errString = MsgGetText(&message_set, &message_nbr, &default_msg_txt, &msgs [⇒
&index][4], &msgs [&index][5]);
  When 3
    &errString = MsgGetText(&message_set, &message_nbr, &default_msg_txt, &msgs [⇒
&index][4], &msgs [&index][5], &msgs [&index][6]);
  When 4
    &errString = MsgGetText(&message_set, &message_nbr, &default_msg_txt, &msgs [⇒
&index][4], &msgs [&index][5], &msgs [&index][6], &msgs [&index][7]);
  When 5
    &errString = MsgGetText(&message_set, &message_nbr, &default_msg_txt, &msgs [⇒
&index][4], &msgs [&index][5], &msgs [&index][6], &msgs [&index][7], &msgs [&index]⇒

```

```
[8]);  
    When-Other  
        &errString = "Too many parameters - not supported"  
    End-Evaluate;  
    /* do something with &errString */  
End-If;
```

Related Links

[Save](#)

[Validate](#)

Name

Description

Use this property to specify the name of a field as a string value. Changing the name of a field and then saving it is equivalent to the rename operation. All references to the field by other managed objects will be updated as well.

This property is read/write.

Example

```
&myField.Name = "MYFIELD";
```

Related Links

[Description](#)

ObjectOwnerId

Description

Use this property to specify a translate value from the OBJECTOWNERID field as a string value.

This property is read/write.

RawBinary

Description

Use this property to set or return a Boolean value representing true (on) or false (off). It is valid for long character (LONGCHAR) field type.

This property is read/write.

Related Links

[Type](#)

RuntimeDefn

Description

Use this property to determine whether this field definition was created using the FieldDefn class or not.

This property is read-only.

TimeFormat

Description

Use this property to specify the format in which time should be displayed in a field defined as time or date and time.

You can use the following values:

<i>Numeric Value</i>	<i>Constant Value</i>
0	%TimeFormat_HHMI
1	%TimeFormat_HHMISS
2	%TimeFormat_HHMISS999999

This property is read/write.

Example

```
&myField.TimeFormat = %TimeFormat_HHMI;
```

Type

Description

Use this property to set the type for a field. The values can be one of the following:

<i>Numeric Value</i>	<i>Constant Value</i>
0	%FieldType_Char
1	%FieldType_LongChar
2	%FieldType_Number

<i>Numeric Value</i>	<i>Constant Value</i>
3	%FieldType_SignedNumber
4	%FieldType_Date
5	%FieldType_Time
6	%FieldType_DateTime

The following field types are not supported:

- Attachment
- Image
- Image Reference

This property is read/write.

Example

```
&myField.Type = %FieldType_Char;
```

RecordDefn Class

This section provides an overview of the RecordDefn class and discusses:

- RecordDefn class methods.
- RecordDefn class properties.

RecordDefn Class Methods

In this section, the RecordDefn class methods are presented in alphabetical order.

AddField

Syntax

```
AddField(existing_fieldname)
```

Description

Use this method to create a new record field definition for a given field populated with default record field definition values. The new record field is appended to the list of record fields.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>existing_fieldname</i>	Specifies an existing field in the record definition.

Returns

If the field is already on the record, the record field definition for that record field is returned.

Returns a null value if the field definition does not exist in the database.

Example

```
Local RecordDefn &myNewRecord = CreateRecordDefn();
&myNewRecord.Name = "MYRECORD_VW";
&myNewRecord.Description = "My new record";
&myNewRecord.SQL = "SELECT DISTINCT(PROCESS_INSTANCE) FROM PS_MESSAGE_LOG WHERE MES⇒
SAGE_NBR = 1018";
Local RecordFieldDefn &recField = &myNewRecord.AddField("MYFIELD");
If All(&recField) Then
    &recField.Key = True;
End-If;
```

Related Links

[GetField](#)

[RemoveField](#)

Build

Syntax

```
Build()
```

Description

This method validates and saves a record definition, drops the view if it exists, and then runs the DDL to create or recreate the view in the database.

Parameters

None.

Returns

A Boolean value representing the following statuses.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%MDA_Success	The record definition is built successfully.
1	%MDA_Failed	The record definition is not built.
4	%MDA_Unsupported	
12	*%MDA_InvalidDefn	The SQL text is invalid.
14	*%MDA_NoWriteAccess	The user does not have write permissions for the record.

Example

```
Local RecordDefn &myNewRecord = CreateRecordDefn();
&myNewRecord.Name = "MYRECORD_VW";
&myNewRecord.Description = "My new record";
&myNewRecord.SQL = "SELECT DISTINCT(PROCESS_INSTANCE) FROM PS_MESSAGE_LOG WHERE MES⇒
SAGE_NBR = 1018";
Local RecordFieldDefn &recField = &myNewRecord.AddField("MYNEWFIELD");
If All(&recField) Then
    &recField.Key = True;
End-If;
&retVal = &myNewRecord.Save();
/* do error checking ... */
&retVal = &myNewRecord.Build();
/* do error checking ... */
```

Related Links

[Save](#)

[Validate](#)

GetField

Syntax

```
GetField({n | field_name})
```

Description

Use this method to obtain the record field definition of the specified field.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n</i> <i>field_name</i>	Specifies the field to be retrieved. This method takes the type as Any. The PeopleCode program is terminated if the specified field number does not exist on the record.

Returns

A record field definition object for the specified field.

Returns a null value if the specified field does not exist on the record.

Example

```
Local RecordFieldDefn &recField = &myNewRecord.GetField("MYNEWFIELD");
```

Related Links

[AddField](#)

[RemoveField](#)

RemoveField

Syntax

```
RemoveField({n | field_name})
```

Description

Use this method to remove a field from a record.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n</i> <i>field_name</i>	Specifies the field to be removed. This method takes the type as Any.

Returns

An integer representing the following statuses.

<i>Numeric Value</i>	<i>Constant</i>	<i>Description</i>
0	%MDA_Success	The field is removed successfully.
1	%MDA_Failed	The field is not removed.

Example

```
&returnValue = &myNewRecord.RemoveField("MYNEWFIELD");
```

Related Links

[AddField](#)

[GetField](#)

Save

Syntax

```
Save ()
```

Description

Use this method to validate and save a record definition to the database.

Parameters

None.

Returns

A Boolean value representing the following statuses.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%MDA_Success	The record definition is saved successfully.
1	%MDA_Failed	The record definition is not saved.
2	%MDA_UseAppDesigner	The record was not created using the PeopleCode RecordDefn class.

Numeric Value	Constant Value	Description
4	%MDA_Unsupported	The record type is not a SQL view.
5	%MDA_Duplicate	The specified record definition already exists.
12	%MDA_InvalidDefn	This value is returned when the validation fails. The detailed validation error messages are available through the Messages property.
14	%MDA_NoWriteAccess	The user does not have write permissions to the record.
15	%MDA_SQLNotSaved	The record is saved, but the SQL is not saved.

Example

```

Local RecordDefn &myRecord = GetRecordDefn("MYRECORD_VW");
If All(&myRecord) Then
    &myRecord.Description = "My new record description";
    &retVal = &myRecord.Save();
    /* do error checking ... */
    &retVal = &myNewRecord.Build();
    /* do error checking ... */
End-If;

```

Related Links

[Validate](#)

SaveAsView

Syntax

```
SaveAsView(record_name)
```

Description

This method sets the RuntimeDefn flag, changes the record type to View, validates, and saves the record definition to the database.

Parameters

Parameter	Description
<i>record_name</i>	Specifies the new record, which is saved as a view.

Returns

A Boolean value representing the following statuses.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%MDA_Success	The record definition is successfully saved as a view.
1	%MDA_Failed	The record definition is not saved as a view.
5	%MDA_Duplicate	The specified record already exists.
12	%MDA_InvalidDefn	This value is returned when the validation fails. The detailed validation error messages are available through the Messages property.
15	%MDA_SQLNotSaved	The record is saved, but the SQL is not saved.

Example

```
&retVal = &srcRecord.SaveAsView("RT_VIEW");
```

Validate

Syntax

```
validate()
```

Description

Use this method to validate a record definition.

Parameters

None.

Returns

A Boolean value. True if the record definition is successfully validated; false otherwise. If it returns false, the detailed error messages are available through the Messages property.

Example

```
&retVal = &srcRecord.Validate();
```

RecordDefn Class Properties

In this section, the RecordDefn class properties are described in alphabetical order.

BuildSequenceNumber

Description

DataMover and SQR scripts use this property to order the build sequence of dependent views. This property is *not* used by the Build method when building a view.

The default value is 1.

This property is read/write.

Description

Description

Use this property to specify a short description for a record.

This property is read/write.

Example

```
&myNewRecord.Description = "My new record";
```

Related Links

[Name](#)

FieldCount

Description

This property returns the total number of fields contained in the record. This value is a number.

This property is read-only.

Example

```
WinMessage("This record has this many fields : " | &REC.FieldCount);
```

Messages

Description

This property returns a multi-dimensional array of Any that contains the messages that occurred during execution of the Validate or Save methods. This array is only populated after the Validate or Save method has been executed.

The first dimension contains the message set number. The second dimension contains the message number. The third dimension contains the number of parameters in that message. The subsequent dimensions contain the values for the parameters. The maximum number of possible dimensions is 8.

This property is read-only.

Related Links

Example

```
&myNewRecord.Name = "MYRECORD_VW";
```

Related Links

[Description](#)

ObjectOwnerId

Description

Use this property to specify a translate value from the OBJECTOWNERID field as a string value.

This property is read/write.

QuerySecurityRecord

Description

Use this property to set or return a query security record if you want secure access to a record using a security view.

This property is read/write.

Related Links

"Setting Record Properties" (Application Designer Developer's Guide)

RelatedLanguageRecord

Description

This property sets or returns the related language record as a string. The value will be a null string (""), if there is no related language record.

This property is read/write.

Related Links

"Setting Record Properties" (Application Designer Developer's Guide)

RuntimeDefn

Description

Use this property to determine whether this record definition was created using the RecordDefn class or not.

This property is read-only.

SetControlField

Description

Use this property to specify the set control field on the record definition.

This property is read/write.

SQL

Description

Use this property to specify the SQL for a view.

This property is read/write.

Example

```
&myNewRecord.SQL = "SELECT DISTINCT(PROCESS_INSTANCE) FROM PS_MESSAGE_LOG WHERE MES→
SAGE_NBR = 1018";
```

Type

Description

Use this property to set the type for a record. The values can be one of the following. Value 4 with its associated constant value is deprecated, so it is not included in the list.

<i>Numeric Value</i>	<i>Constant Value</i>
0	%RecordType_SQLTable
1	%RecordType_SQLView
2	%RecordType_Derived
3	%RecordType_SubRecord
5	%RecordType_DynamicView
6	%RecordType_QueryView
7	%RecordType_TempTable

The default type is %RecordType_SQLView.

Example

```
&myNewRecord.Type = %RecordType_SQLTable;
```

RecordFieldDefn Class

This section provides an overview of the RecordFieldDefn class and discusses:

- RecordFieldDefn class methods.
- RecordFieldDefn class properties.

RecordFieldDefn Class Methods

Note: The RecordFieldDefn class does not provide a Save method. Save must be issued against the RecordDefn object with which the RecordFieldDefn object is associated.

Related Links

[Save](#)

RecordFieldDefn Class Properties

In this section, the RecordFieldDefn class properties are described in alphabetical order.

AllowSearchEventsForPromptDialogs

Description

If the AllowSearchEventsForPromptDialogs property is set to True, it enables the SearchSave and SearchInit PeopleCode events on a prompt dialog for a field. The default value is False.

This property is read/write.

Related Links

"Setting Record Field Properties" (Application Designer Developer's Guide)

AlternateSearchKey

Description

This property is True if this record field is defined as an alternate search key in the associated record definition. The default value is False.

This property is read/write.

Example

```
&recField.AlternateSearchKey = True;
```

DescendingKey

Description

This property is True if this record field is defined as a descending key in the associated record definition. The default value is False.

This property is read/write.

Example

```
&recField.DescendingKey = True;
```

DuplicateOrderKey**Description**

This property is True if this record field is defined as a duplicate key in the associated record definition. The default value is False.

This property is read/write.

Example

```
&recField.DuplicateOrderKey = True;
```

Key**Description**

This property is True if this record field is defined as a primary key of the associated record definition. The default value is False.

This property is read/write.

Example

```
Local RecordFieldDefn &recField = &myNewRecord.AddField("MYNEWFIELD");
If All(&recField) Then
    &recField.Key = True;
End-If;
```

ListBoxItem**Description**

This property is True if this record field is defined as a List Box item of the associated record definition.

The default value is False.

This property is read/write.

Example

```
&recField.ListBoxItem = True;
```

Name

Description

This property returns the name of the record field definition that the field object is based on as a string value.

This property is read-only.

Number

Description

This property returns the number of a record field definition as an integer value.

This property is read-only.

RecordFieldLabelID

Description

Use this property to set the label text (long name or short name) for the record field when it's displayed on a page.

This property is read/write.

Required

Description

This property is True if this field is defined as Required in the associated record definition. The default value is False.

This property is read/write.

Example

```
&recField.Required = True;
```

SearchEdit

Description

If this property is set to True, SearchEdit enables system edits (edits specified in the record field definition) for the field, for the life of the search dialog box. Setting SearchEdit to False disables system edits. In the Add mode search dialog box, the following edits are performed when the end-user selects the Add button. In any other mode, the following edits are performed when the end-user selects the Search button:

- Formatting
- Required Field
- Yes/No Table
- 1/0 Table
- Translate Table
- Prompt Table

SearchEdit does not cause the FieldEdit, FieldChange, or SaveEdit PeopleCode events to fire during the search dialog.

You may use SearchEdit to control access to the system. For example, you can apply this property to the SETID field of a dialog box and require the user to enter a valid SETID before they are able to click OK on the search dialog box.

The default value is False.

This property is read/write.

Example

```
&recField.SearchEdit = True;
```

SearchKey

Description

This property is True if this field is defined as a search key in the associated record definition. The default value is False.

This property is read/write.

Example

```
&recField.SearchKey = True;
```

TableEditPromptTable

Description

Use this property to set or return the name of the existing prompt table (if any) associated with this record field definition. This property returns a string value. This property returns null if no prompt table is associated with the record field definition.

This property is read/write.

TableEditSetControlField

Description

Use this property to specify or return a set control field that overrides the set control field of the record definition specified in the prompt table. If you do not specify a set control field, the default is the set control field of the record definition in the prompt table.

This property is read/write.

Related Links

"Setting Record Field Properties" (Application Designer Developer's Guide)

TableEditType

Description

Use this property to set or return the table edit type of a record field definition. The values can be one of the following:

<i>Numeric Value</i>	<i>Constant Value</i>
0	%EditTableType_NoEdit
1	%EditTableType_Prompt
2	%EditTableType_YesNo
3	%EditTableType_Translate
4	%EditTableType_OneZero

The default value is %EditTableType_NoEdit.

Note: You use %EditTableType_NoEdit when there is no table edit and also when there is a table edit and its type is PromptTable with No Edit.

Example

```
&recField.TableEditType = %EditTableType_Prompt;
```

Type

Description

This property returns the type of field. The values can be one of the following predefined values:

- %FieldType_Char
- %FieldType_Date
- %FieldType_DateTime
- %FieldType_LongChar
- %FieldType_Number
- %FieldType_SignedNumber
- %FieldType_Time

This property is read-only.

Example

```
&recField.Type = %FieldType_Date;
```

Message Catalog Component Interface

This section provides an overview of the delivered component interface, MESSAGE_CATALOG_CI, and discusses:

- Message Catalog Methods
- Message Catalog Properties.

The delivered component interface, MESSAGE_CATALOG_CI, can be used to create, modify, and delete message catalog entries.

Message Catalog Methods

In this section, the Message Catalog methods are described in alphabetical order.

In addition to the methods listed in this topic, the following Component Interface Class methods can be used — Cancel, Create, Find, Get, Save.

Related Links

[Component Interface Class Methods](#)

AddMessage

Syntax

```
AddMessage(message_text,message_desc,message_severity)
```

Description

Use the `AddMessage` method to populate a message set with text, description, and message type. All parameters can be blank strings to create an empty message. However, it must be populated before you can save it.

The `Save` method must be run after `AddMessage` to save the message.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>message_text</i>	Specifies the text of a message as a string value. The message length can be 100 characters or less.
<i>message_desc</i>	Specifies the description of a message as a string value. No limit on the length of the description.
<i>message_severity</i>	Specifies the type of a message as a string value. The following message types are available — Cancel, Error, Message, and Warning. The default message type is Message. If an unrecognized message type is passed in, then the <code>message_severity</code> parameter is set to Message.

Returns

A number value; 0 if the specified message text is longer than 100 characters, otherwise it returns the new message number.

Example

```
Function AddNewMessage()
    Local ApiObject &MYSESSION;
    Local ApiObject &MSG_CTLG;

    &MYSESSION = %Session;
    &MSG_CTLG = &MYSESSION.GetCompIntfc(CompIntfc.MESSAGE_CATALOG_CI);
    &MSG_CTLG.MESSAGE_SET_NBR = 31600;
    &MSG_CTLG.Get();
    &MYLEVEL1 = &MSG_CTLG.PSMSGCATDEFN;

    Local string &msgText = "Attempted to insert duplicate rows.";
    Local number &msgNumber = &MSG_CTLG.AddMessage(&msgText, "", "Error");
    If &msgNumber = 0 Then
        MessageBox(0, "", 0, 0, "Failed to create new message");
        Return;
    End-If;
End-Function;
```

DeleteMessage

Syntax

DeleteMessage (*message_num*)

Description

Use the DeleteMessage method to delete a message catalog entry.

Note: You cannot delete a message sets; only message catalog entries can be deleted.

The Save method must be run after DeleteMessage to save the changes.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>message_num</i>	Specifies the number of a message catalog entry to be deleted as a number value.

Returns

A Boolean value; False if the message for the given message number does not exist, True otherwise.

Example

```
Function Delete()
    Local ApiObject &MYSESSION;
    Local ApiObject &MSG_CTLG;

    &MYSESSION = %Session;
    &MSG_CTLG = &MYSESSION.GetCompIntfc(CompIntfc.MESSAGE_CATALOG_CI);
    &MSG_CTLG.MESSAGE_SET_NBR = 31600;
    &MSG_CTLG.Get();
    &MYLEVEL1 = &MSG_CTLG.PSMMSGCATDEFN;

    If Not &MSG_CTLG.DeleteMessage(2) Then
        MessageBox(0, "", 0, 0, "Invalid message number");
        Return;
    End-If;
End-Function;
```

Message Catalog Properties

In this section, we discuss the message catalog properties. The properties occur in two groups: Message Set and Message Catalog Entry. In each group, the properties are described in alphabetical order.

DESCR (Message Set)

Description

Use this property to set or return a long description of a Message Set. This property takes a string value; ensure that the description is 30 characters or less.

This property is not required when you create a message set.

This property is read/write.

DESCRSHORT (Message Set)

Description

Use this property to set or return the short description of a Message Set. This property takes a string value; ensure that the description is 10 characters or less.

This property is not required when you create a message set.

This property is read/write.

MESSAGE_SET_NBR (Message Set)

Description

Use this property to set or return the number of a Message Set. This property takes a number value.

This property is required when you create a message set.

This property is read/write.

DESCRLONG (Message Catalog Entry)

Description

Use this property to set or return a long description of a Message Catalog entry. This property takes a string value; no limit on length of the message.

This property is not required when you create a message catalog entry.

This property is read/write.

MESSAGE_NBR (Message Catalog Entry)

Description

Use this property to set or return the message catalog entry number. This value is automatically generated at Save time for new entries.

This property is not required when you create a message catalog entry.

This property is read/write.

MESSAGE_SET_NBR (Message Catalog Entry)

Description

Use this property to set or return the number of a Message Set. This property takes a number value. This number is the same as the message set number on the Message Set.

This property is not required when you create a message catalog entry.

This property is read/write.

MESSAGE_TEXT (Message Catalog Entry)

Description

Use this property to set or return the text of the message. This property takes a string value; ensure that the message is 100 characters or less. This message will be a shorter version of the long description of the message catalog entry.

This property is required when you create a message catalog entry.

This property is read/write.

MSG_SEVERITY (Message Catalog Entry)

Description

Use this property to set or return the severity indicator for a message. This property takes a character value. The default value for new message catalog entry is *M* (Message). The values can be one of the following:

Value	Description
W	Warning
M	Message
C	Cancel
E	Error

This property is not required when you create a message catalog entry.

This property is read/write.

MCF IM Classes

MCFIMInfo Class Methods

Note: All methods of the MCFIMInfo class have been deprecated and exist for backward compatibility only.

In this section, the MCFIMInfo class methods are presented in alphabetical order.

AddUser

Message Classes

Understanding Message Classes

You can create the following types of messages using PeopleSoft Pure Internet Architecture::

- *Rowset-based* messages, which use record definitions to create a hierarchical structure for the data. These are generally used for data from applications, pages, components, and so on.
- *Nonrowset-based* messages, which do not use record definitions. These messages can have virtually any content or structure.
- *Container* messages, which are messages made up of one or more part messages.

Use the PeopleCode message classes to instantiate message objects based on existing message definitions, as well as to populate the objects with data and manipulate the data. You can also use PeopleCode to publish a message.

Rowset-based messages are built on top of the rowset, row, record, and field classes, so the PeopleCode written to populate or access those types of messages looks similar to PeopleCode written to populate or access the component buffer.

Nonrowset-based messages contain XML data, and can be accessed using the XmlDocument class methods and properties.

Container messages contain parts. Each part is a separate message. A container message can contain either all rowset-based messages, *or* all nonrowset-based messages.

"Creating Message Definitions" (Integration Broker)

"Understanding Data Buffer Access" (PeopleCode Developer's Guide)

"Introduction to PeopleSoft Integration Broker" (Integration Broker)

Messages, Service Operations and Handlers

Message definitions only define the shape of the data contained in a message. A message definition doesn't contain any other type of information, such as if the message is being used synchronously or if it's a response message.

After you create a message definition, you can use it in or more service operations. The service operation contains all the information about how the message is to be used, the routing, the queue if appropriate, and so on.

At least one handler is defined with every service operation. Handlers define additional programming to be used with processing the message associated with the service operation. The handlers can be thought of as corresponding to pre PeopleSoft 8.48 message events.

The PeopleCode for the various handlers is contained in the Integration Broker application classes.

Integration Broker Application Classes

The Integration Broker application classes house the processing logic for asynchronous and synchronous messages. By implementing the Integration Broker application classes, you can reuse code more easily and access the other benefits of using application classes.

The following application classes are defined for Integration Broker. To access these application classes, in PeopleTools Application Designer, open the PS_PT application package, then open the Integration subpackage.

All of the Integration Broker application classes are defined as interfaces. This means that there is no native implementation of them: you must import them to your program and implement them if you want to use them.

<i>Application Class</i>	<i>Methods Contained in Application Class</i>	<i>Comments</i>
INotificationHandler	OnNotify OnError	This interface is the equivalent of the Subscription event in releases prior to PeopleTools 8.48.
IPrePostNotification	OnPreNotify OnPostNotify OnError	This interface provides pre-processing and post-processing of segmented messages.
IReceiver	OnAckReceive OnError	This interface is the equivalent of the OnAckReceive Message event in releases prior to PeopleTools 8.48.
IRequestHandler	OnRequest OnError	This interface is the equivalent of the OnRequest Message event in releases prior to PeopleTools 8.48.
IRouter	OnRouteSend OnRouteReceive OnError	This interface is the equivalent of the OnRouteSend and OnRouteReceive Message events in releases prior to PeopleTools 8.48.
ISend	OnRequestSend OnError	This interface is the equivalent of the OnSend Message event in releases prior to PeopleTools 8.48.

Data Types of Message Objects

Every message class is its own data type, that is, messages are declared as data type `Message`, `IntBroker` objects are declared as type `IntBroker`, and so on.

The following are the data types of the message classes:

- `Message`
- `IntBroker`
- `IBInfo`
- `IBConnectorInfo`

Scope of Message Objects

The message objects can only be instantiated from `PeopleCode`. These objects can be used anywhere you have `PeopleCode`, that is, in Component Interface `PeopleCode`, notification `PeopleCode`, record field `PeopleCode`, application engine `PeopleCode`, and so on.

Message Object Population

After you've declared and instantiated your message object, you want to populate it with data. If your data is coming from the component buffers, populating your message is easy.

A message definition can contain a hierarchy of records. A component buffer contains a hierarchy of records. If you want to copy data from a component buffer rowset to a message, the *structure* of the message and the component must be the same. That is, if you have a record at level two in your message and you want that data, you must have the same level zero and level one records in your message as in your component.

For example, suppose your component had the following structure (that is, that `PO_INFO` and `PO_LINE` are at the same level, and `PO_DETAIL` is the child of `PO_INFO`):

```
PO_HEADER
  PO_LINE
  PO_INFO
    PO_DETAIL
```

To include the information in the `PO_DETAIL` record, you must have *at least* the following record structure in your message:

```
PO_HEADER
  PO_INFO
    PO_DETAIL
```

Any records that are in the page that aren't in the message (and vice-versa) are ignored.

After you get your message object, you can create a rowset from it. This rowset has the same structure as the message. If the message is empty, the rowset has no data. If the message has data, the rowset is automatically populated.

The following example is the simplest way of populating a message with data. This assumes that the structure of the message is the same as the structure of the page.

```

        /* this gets all the data in the Component buffer */
&RS = GetLevel0(); /* this instantiates a message object */

&MSG = CreateMessage(OPERATION.MY_MESSAGE); /* creates a rowset with the same struct→
ure as the message */

&MSG_RS = &MSG.GetRowset(); /* this copies all the data from the page to the message→
*/

&RS.CopyTo(&MSG_RS); /* this publishes the message */

%IntBroker.Publish(&MSG_RS);

```

A message rowset is the same as a Component buffer rowset, or any other rowset. It is composed of rows, records, and fields. Suppose you didn't want to get all the data from the Component buffer, but instead wanted to populate just a particular record in your message.

To access a record in a message rowset is the same as accessing a record in a component buffer rowset. You must instantiate the rowset, then specify the row before you can access the record.

The following selects values into a record, then uses the record method CopyFieldTo to copy from the Component buffer record to the message record.

```

Local SQL &LN_SQL;
Local Message &MSG;
Local Rowset &HDR_RS, &LN_RS;
Local Record &LN_REC, &ln_rec_msg;

&MSG = CreateMessage(OPERATION.STOCK_REQUEST);
&HDR_RS = &MSG.GetRowset();
&LN_REC = CreateRecord(Record.DEMAND_INF_INV);

&LN_SQL = CreateSQL("Select * from PS_DEMAND_INF_INV where BUSINESS_UNIT= :1 and O→
RDER_NO = :2", &BUSINESS_UNIT, &ORDER_NO);

&J = 1;
While &LN_SQL.Fetch(&LN_REC)

    /* copy data into the Level 1 of &MSG object */
    &LN_RS = &HDR_RS(&I).GetRowset(1);

    If &J > 1 Then
        &LN_RS.InsertRow(&J - 1);
    End-If;

    &ln_rec_msg = &LN_RS.GetRow(&J).GetRecord(Record.DEMAND_INF_INV);
    &LN_REC.CopyFieldsTo(&ln_rec_msg);
    &J = &J + 1;
End-While;

```

This section also discusses items to keep in mind when:

- Populating a rowset from a message.

- Publishing and subscribing to partial records.
- Subscribing to character fields.

Considerations When Populating a Rowset From a Message

Suppose your message had two rowsets, one at level zero, a second at level one. In the message, only the level zero rowset contains any data. When you use `GetRowset` to create a rowset for the entire message, the rowset at level one will contain an empty row, even if there isn't any data in it. (This is standard behavior for *all* rowsets.) However, you can use the `IsChanged` property on the record object to determine the status of the data.

The following notification PeopleCode example traverse the rowset. (Notice the use of `ChildCount`, `ActiveRowCount`, and `IsChanged` properties).

'...' is where application specific code would go.

```
&MSG_ROWSET = &MSG.GetRowset();
For &A0 = 1 To &MSG_ROWSET.ActiveRowCount

/*****/
/* Process Level 1 Records */
/*****/

  If &MSG_ROWSET(&A0).ChildCount > 0 Then
    For &B1 = 1 To &MSG_ROWSET(&A0).ChildCount

      &LEVEL1_ROWSET = &MSG_ROWSET(&A0).GetRowset(&B1);
      For &A1 = 1 To &LEVEL1_ROWSET.ActiveRowCount
        If &LEVEL1_ROWSET(&A1).GetRecord(1).IsChanged Then
          . . .

/*****/
/* Process Level 2 Records */
/*****/

          If &LEVEL1_ROWSET(&A1).ChildCount > 0 Then
            For &B2 = 1 To &LEVEL1_ROWSET(&A1).ChildCount
              &LEVEL2_ROWSET = &LEVEL1_ROWSET(&A1).GetRowset(&B2);
              For &A2 = 1 To &LEVEL2_ROWSET.ActiveRowCount
                If &LEVEL2_ROWSET(&A2).GetRecord(1).IsChanged Then
                  . . .

/*****/
/* Process Level 3 Records */
/*****/

                  If &LEVEL2_ROWSET(&A2).ChildCount > 0 Then
                    For &B3 = 1 To &LEVEL1_ROWSET(&A2).ChildCount
                      &LEVEL3_ROWSET = &LEVEL2_ROWSET(&A2).GetRowset(&B3);
                      For &A3 = 1 To &LEVEL3_ROWSET.ActiveRowCount
                        If &LEVEL3_ROWSET(&A3).GetRecord(1).IsChanged Then
                          . . .

                          End-If; /* A3 - IsChanged */
                        End-For; /* A3 - Loop */
                      End-For; /* B3 - Loop */
                    End-If; /* A2 - ChildCount > 0 */

/*****/
/* End of Process Level 3 Records */
/*****/

                    End-If; /* A2 - IsChanged */
                  End-For; /* A2 - Loop */
                End-For; /* A1 - Loop */
              End-For; /* B2 - Loop */
            End-If; /* A1 - ChildCount > 0 */
          End-For; /* B1 - Loop */
        End-If; /* A0 - ChildCount > 0 */
      End-For; /* A0 - Loop */
    End-For; /* MSG_ROWSET - Loop */
  End-For; /* MSG - Loop */
End-For; /* MSG - Loop */
```

```

        End-For; /* B2 - Loop */
    End-If; /* A1 - ChildCount > 0 */

/*-----*/
/* End of Process Level 2 Records */
/*****/

        End-If; /* A1 - IsChanged */
    End-For; /* A1 - Loop */
    End-For; /* B1 - Loop */
    End-If; /* A0 - ChildCount > 0 */

/*-----*/
/* End of Process Level 1 Records */
/*****/

End-For; /* A0 - Loop */

```

Considerations for Publishing and Subscribing to Partial Records

If you've selected to not publish all the fields in the message, you must be careful when inserting that data into a record.

Deselecting the **Include** check box in the message definition means that the field is *excluded* from the message definition.

- The field won't be included when generating an XML document (when publishing a message.)
- If the field is present in the XML (that is, it wasn't excluded from the published message) it is ignored by the subscribing system.

When you insert the data from the message into the database, you *must* set the values for the fields that aren't in the message. You can use the `SetDefault` record class method to do this. You could also use a Component Interface based on the component the message was created from to leverage the component defaults.

[SetDefault](#)

"Understanding Creating Component Interface-Based Services" (Integration Broker)

Considerations When Subscribing to Character Fields

If a message definition has character fields that are defined as uppercase, when the message is subscribed to, character data for those fields is automatically converted to uppercase.

Message Segments

To make processing more efficient, you can divide a large message into pieces using message segments. Generally, you only divide asynchronous messages into segments.

Message nodes can be specified as “segment aware”. If a node is not segment aware and you send an asynchronous message that is segmented to it, you received an error message when viewing the error message log in message details on the message monitor. No publication contracts are created. If you send a synchronous message that is segmented to a node that is not segment aware, you receive an error.

There are several methods for creating, updating, and deleting segments. There are also two properties that you need to take into consideration when working with segments.

If you specify the `SegmentsByDatabase` property as `false`, you can only have the configured number defined in PSADMIN (Message Segment From DB). If you specify this property as `true`, you can have as many segments as you need.

The `SegmentsByDatabase` property also specifies whether the segments are kept in memory or written to the database when they are received. If you specify `true`, the segments are automatically written to the database. If you specify `false`, the segments are held in memory. If you specify `true`, then cancel out of the program processing the segments, the changes are not committed to the database.

The `SegmentUnOrder` property is only applicable for asynchronous messages. If you specify the `SegmentUnOrder` property as `true`, the receiving node processes the segments in parallel.

Note: You should use `DeleteSegment` and `UpdateSegment` only when writing to memory, or when `SegmentsByDatabase` is set to `False`. These methods do not work when writing to the database, or when `SegmentsByDatabase` is set to `True`.

The following is an example of how to use the segment properties and methods to send a segmented message. Note that there are only two `CreateNextSegment` calls. By default the first segment is automatically created. The first time you use `CreateNextSegment`, the message is split into two segments. The next time, you add a third segment. You don't need to call `CreateNextSegment` to access the third segment, it's automatically generated.

```
Local Message &MSG;
Local Rowset &FLIGHT_PROFILE, &RS;
Local boolean &Bo, &Stuff;
Local string &lip;

&nodes = CreateArray("");
&nodes[1] = "QE_YO";
&nodes[2] = "QE_STUFF";

QE_FLIGHTDATA.QE_ACNUMBER.Value = QE_FLIGHTDATA.QE_ACNUMBER + 1;

&FLIGHT_PROFILE = GetLevel0();

&MSG = CreateMessage(OPERATION.QE_FLIGHTPLAN);

/* the next lines copy the rowset into the first segment */

&MSG.CopyRowset(&FLIGHT_PROFILE);
&MSG.CreateNextSegment();

/* This copies the next portion of the rowset into the next segment */

&MSG.CopyRowset(&FLIGHT_PROFILE);
&MSG.CreateNextSegment();

/* This copies the last portion of the rowset into the third segment */

&MSG.CopyRowset(&FLIGHT_PROFILE);

/* This specifies that the message segments can be processed separately */

&MSG.IBInfo.SegmentsUnOrder = True;

%IntBroker.publish(&MSG);
```

The following is an example of receiving a segmented message. This would be found in a notification PeopleCode program:

```

Local Message &MSG;
Local Rowset &rs, &rs1;
Local Record &FLIGHTDATA, &REC;

Local string &acnumber_value, &msi_sensor_value, &ofp_value, &actype_value, &callsi⇒
gn_value, &squadron_value, &comm1_value, &comm2_value, &ecm_value;

Local XmlDoc &xmldoc;
Local string &yo;
Local boolean &bo;

&CRLF = Char(13) | Char(10);

&MSG = %IntBroker.GetMessage();

/* It is very important to set the rowset to null for every iteration */

/* Also, you may want to verify if the segment count is
greater than 10, and if it is, set the SegmentsByDatabase property to True */

For &i = 1 To &MSG.SegmentCount
    &rs = Null;
    &MSG.GetSegment(&i);

    &rs = &MSG.GetRowset();
    &REC = &rs(1).QE_FLIGHTDATA;

    &FLIGHTDATA = CreateRecord(Record.QE_FLIGHTDATA);
    &REC.CopyFieldsTo(&FLIGHTDATA);

    /* Parse out Message Data */
    &acnumber_value = &FLIGHTDATA.QE_ACNUMBER.Value;
    &msi_sensor_value = &FLIGHTDATA.QE_MSI_SENSOR.Value;
    &ofp_value = &FLIGHTDATA.QE_OFP.Value;
    &actype_value = &FLIGHTDATA.QE_ACTYPE.Value;
    &callsign_value = &FLIGHTDATA.QE_CALLSIGN.Value;
    &squadron_value = &FLIGHTDATA.QE_SQUADRON.Value;
    &comm1_value = &FLIGHTDATA.QE_COMM1.Value;
    &comm2_value = &FLIGHTDATA.QE_COMM2.Value;
    &ecm_value = &FLIGHTDATA.QE_ECM.Value;

    &outstring = "Send Async FLight test";

    /* Construct Output String */
    &outstring = &outstring | &acnumber_value | &CRLF | &msi_sensor_value | &CRLF | ⇒
&ofp_value | &CRLF | &actype_value | &CRLF | &callsign_value | &CRLF | &squadron_va⇒
lue | &CRLF | &comm1_value | &CRLF | &comm2_value | &CRLF | &ecm_value;

    /* Log Output String into page record */
    &FLIGHTDATA.GetField(Field.DESCRLONG).Value = &outstring;

    SQLExec("DELETE FROM PS_QE_FLIGHTDATA");
    &FLIGHTDATA.Insert();

End-For;

```

"Understanding Nodes" (Integration Broker Administration)

Content-Based Routing

With PeopleSoft Integration Broker, you typically define the routing information separately from the message itself. This allows you to apply multiple routings to a message and change the routings independent of the message definition.

With content-based routing, attributes of the message are used to make routing decisions. The attributes are set before the message is published. Then, within your implementation of the `IRouter.OnRouteSend` method, these attributes can be examined and evaluated—for example, to send the message to a defined list of nodes instead of to all nodes. Because the attributes are separate from the message data, the Message object itself does not have to be parsed and loaded into a rowset and then searched to get the routing information. This separation of routing attributes from the message data provides a performance improvement over having those routing attributes within the message content.

In the following example, the routing attributes are set with calls to the `AddAttribute` method of the `IBInfo` class:

```
Local Message &MSG;
Local Rowset &FLIGHT_PROFILE;
Local string &AC_Type, &Pilot;
Local boolean &bRet;

&FLIGHT_PROFILE = GetLevel0();

&MSG = CreateMessage(Operation.QE_FLIGHTPLAN);

&AC_Type = GetLevel0().GetRow(1).GetRecord(Record.QE_FLIGHTDATA).AC_TYPE.Value;
&Pilot = GetLevel0().GetRow(1).GetRecord(Record.QE_FLIGHTDATA).PILOT.Value;

&bRet = &MSG.IBInfo.AddAttribute("ACType", &AC_Type);
&bRet = &MSG.IBInfo.AddAttribute("Pilot", &Pilot);

&MSG.CopyRowset(&FLIGHT_PROFILE);

%IntBroker.Publish(&MSG);
```

Then, in the implementation-specific `IRouter.OnRouteSend` method, the message attributes are evaluated to make routing decisions. The `OnRouteSend` method does not load and examine the Message object itself, only the attributes:

```
import PS_PT:Integration:IRouter;

class RoutingHandler implements PS_PT:Integration:IRouter;
  method RoutingHandler();
  property array of any destinationNodes;
  method OnRouteSend(&MSG As Message) Returns integer;
  method GetDestinationList(&AC_Type As string, &Pilot As string) Returns any;
end-class;

/* constructor */
method RoutingHandler
end-method;

method OnRouteSend
  /+ &MSG as Message +/
  /+ Returns Integer +/
  /+ Extends/implements PS_PT:Integration:IRouter.OnRouteSend +/
```

```

/* Variable Declaration */
Local string &AC_Type;
Local string &Pilot;
Local any &aNodeList;
Local integer &i;

If &MSG.IBInfo.GetNumberOfAttributes() = 0 Then
    Return (%IntBroker_ROUTE_NONE);
End-If;

For &i = 1 To &MSG.IBInfo.GetNumberOfAttributes()

    If &MSG.IBInfo.GetAttributeName(&i) = "ACType" Then
        &AC_Type = &MSG.IBInfo.GetAttributeValue(&i);
    End-If;

    If &MSG.IBInfo.GetAttributeName(&i) = "Pilot" Then
        &Pilot = &MSG.IBInfo.GetAttributeValue(&i);
    End-If;

End-For;
/* method evaluates these strings and return NodeList */
&aNodeList = %This.GetDestinationList(&AC_Type, &Pilot);

Evaluate &aNodeList
When "True"
    Return (%IntBroker_ROUTE_ALL);
    Break;
When "False"
    Return (%IntBroker_ROUTE_NONE);
    Break;
When-Other
    &destinationNodes = &aNodeList.Clone();
    Break;
End-Evaluate;

end-method;

method GetDestinationList
    /* &AC_Type as String, */
    /* &Pilot as String */
    /* Returns Any */

    /* determine node list based on input data */

    Return Null;
end-method;

```

Error Handling

In your notification PeopleCode, you may want to validate the information received in the message. If you find that the data isn't valid, use `Exit(1)` to end your PeopleCode program. This sets the status of the message to `ERROR`, logs any error messages to the Application Message Queues, and automatically rolls back any database changes you may have made.

There are many ways to validate the data and capture the error messages:

- Use ExecuteEdits on the message object
- Use ExecuteEdits on the record object
- Use a Component Interface

Write your own validation PeopleCode in the notification program:

The following example validates the Business Unit of a message against an array of valid BU's:

```
For &I = 1 To &ROWSET.RowCount;

    &POSITION = &BUArray.Find(&ROWSET(&I).GetRecord(1).BUSINESS_UNIT.Value);
    If &POSITION = 0 Then
        &Status = "ERROR: BU not Found or not Active";
        &ROWSET(&I).BCT_ADJS_MSG_VW.BUSINESS_UNIT.IsEditError = True;
        &ROWSET(&I).BCT_ADJS_MSG_VW.BUSINESS_UNIT.MessageSetNumber = 11100;
        &ROWSET(&I).BCT_ADJS_MSG_VW.BUSINESS_UNIT.MessageNumber = 1230;
    /* The error message 11100-1230 reads: This Business Unit is */
    /* not a valid, open, Inventory Business Unit */

    End-If;
End-For;
```

In the calling PeopleCode, the program calls Exit(1) based on the value of &Status.

Note: All errors for notification PeopleCode get logged to the application message error table, *not* to the PSMessages collection (on the session object.)

"CreateMessage" (PeopleCode Language Reference)

"DeleteSystemPauseTimes" (PeopleCode Language Reference)

"PingNode" (PeopleCode Language Reference)

"ReValidateNRXmlDoc" (PeopleCode Language Reference)

Message Class Methods

In this section, we discuss the Message class methods. The methods are discussed in alphabetical order.

Clone

Syntax

```
Clone ()
```

Description

The Clone method creates an identical copy of the message, copying the data tree of the message executing the method. The Clone function sets the following properties for the resulting message object, based on the values set for the message definition created in Pure PeopleSoft Internet Architecture:

- Name
- QueueName
- IsOperationActive

Other properties are set when the message is published or subscribed to (TransactionID, PubNodeName, and so on), or are dynamically generated at other times (Size, IsEditError, and so on.)

Clone creates a unique version of the message. If the original message changes, it is not reflected in the cloned object.

Parameters

None.

Returns

A message object.

Example

Clone could be used in a Hub and Spoke messaging environment. The Hub node uses this method during notification processing to publish a copy of the messages it receives from the Spokes.

```
&Msg = %IntBroker.GetMessage();  
&Rowset = &Msg.GetRowset();
```

```
&Clone = &Msg.Clone();
%IntBroker.Publish(&Clone);
```

The hub's publication routing rules are then used to determine which spokes receive the message.

[CopyRowset](#)

"CreateMessage" (PeopleCode Language Reference)

"Assigning Objects" (PeopleCode Developer's Guide)

CopyPartRowset

Syntax

```
CopyPartRowset (PartIndex, &Rowset)
```

Description

Use the CopyPartRowset to copy the rowset specified by *&Rowset* to the part of the message specified by *PartIndex*.

Note: This method only works with rowset-based container messages.

The primary record of the level zero rowset for both the specified message part and the specified rowset must be the same.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PartIndex</i>	Specify the number of the part you want to copy the rowset data to.
<i>&Rowset</i>	Specify an already instantiated rowset object that contains the data that you want to copy to the message part.

Returns

None.

Related Links

[GetPartRowset](#)

[GetPartXMLDoc](#)

CopyRowset

Syntax

```
CopyRowset(source_rowset [, record_list]);
```

Where *record_list* is a list of record names in the form:

```
RECORD.source_recname1, RECORD.target_recname1  
[, RECORD.source_recname2, RECORD.target_recname2]. . .
```

Description

The CopyRowset method copies data from the source rowset to the like-named fields in the message object executing the method. This is an easy way to populate a message with data from a component.

Note: If a Related Language record is defined on a record that is effective dated, then the result of the CopyRowset method will not populate the Effective Date or Effective Sequence fields due to possible ambiguity when processed on the receiving system. If these fields are desired to include this information, then the Message Rowset can be updated accordingly after the CopyRowset call is invoked.

Note: CopyRowset copies the data, including rows that haven't been modified. If you want to copy only data that has changed in some way, use the CopyRowsetDelta method.

See [CopyRowsetDelta](#).

When the record names in the message and component do not match exactly, use the optional *record_list* to specify the records to be copied from the component into the message.

When you use the CopyRowset method to copy the contents from the source rowset to the message object, you are creating a *unique* copy of the object. If you change the original rowset, the message object is not changed.

Note: You can execute CopyRowset against a message only once. After a message is populated, any other CopyRowsets are ignored. If you have to populate different levels of a message rowset separately, you can use the CreateRowset method to create a rowset that has the same structure as your message, populate the created rowset, then use CopyRowset to populate your message. You can also use the Rowset CopyTo method to populate a message rowset, then populate the PSCAMA record by hand.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>source_rowset</i>	Specifies the name of the rowset to be copied into the message object.
<i>record_list</i>	Specifies specific source and target records to be copied into the message object.

Returns

None.

Example

The following example copies an entire component into a message object.

```
&Msg = %IntBroker.GetMessage();
&Rowset = &Msg.GetRowset();
&Component_Rowset = GetLevel0();
&Msg.CopyRowset(&Component_Rowset);
```

The following example copies a header/line page rowset into a header/line message object, using the *record_list* because the record names don't match:

```
&Msg = %IntBroker.GetMessage();
&Rowset= &Msg.GetRowset();
&Component_Rowset = GetLevel0();
&Msg.CopyRowset(&Component_Rowset, RECORD.PO_HDR_VW, RECORD.PO_HDR, RECORD.PO_LINE_⇒
VW, RECORD.PO_LINE);
```

Related Links

[CopyRowsetDelta](#)

"GetRowset" (PeopleCode Language Reference)

[Understanding Rowset Class](#)

[Fill](#)

CopyRowsetDelta

Syntax

```
CopyRowsetDelta(source_rowset [, record_list]);
```

Where *record_list* is a list of record names in the form:

```
[RECORD.source_recname1, RECORD.target_recname1
[, RECORD.source_recname2, RECORD.target_recname2]]. . .
```

Description

The CopyRowsetDelta method copies rows of data that have changed from the source rowset to the like-named records and like-named fields in the message object executing the method.

Note: CopyRowsetDelta copies all the like-named fields from the changed *row* into the message. It is *not* copying just the changed like-named fields.

When the record names in the message and component do not match exactly, use the optional *record_list* to specify the records to be copied from the component into the message. The specified target records must be records in your message, while the specified source records must be records in a rowset that exists in the data buffer and is populated.

This is an easy way to populate a message when the records in the message match the records in the component that the message is published from.

In addition, the `CopyRowsetDelta` method sets the `AUDIT_ACTN` field in the `PSCAMA` table for every row in the message. The notification process can then use `PSCAMA.AUDIT_ACTN` to determine how to process every row that was published.

The set values match those used in audit trail processing, that is:

- A - Row inserted.
- D - Row deleted.
- C - Row changed (updated), but no key fields changed. The system copies the new value to the Message rowset.
- K - Row changed (updated), and at least one key field changed. The system copies the old value to the Message rowset and the new value (see "N").
- N - Row changed (updated), and at least one key field changed. The system copies the old value to the Message rowset and the new value (see "K").
- "" – blank value means that nothing on that row has changed. This is the default value, and is the value used to tag the parent rows of children that have changed.

Note: If a child row is inserted (or changed or deleted) `CopyRowsetDelta` also copies the parent row (and the parent row of that row, and so on, up to the top row) so the subscriber has a full picture of the transaction. A blank value is set in the `AUDIT_ACTN` field for these rows to let the subscriber know they don't have to take action; the parent rows are there for reference only.

The `Audit_Action` values "A", "C", "D" are set when a record is added, changed, or deleted, respectively. In some cases such as effective-dated records, the user may change a key field value, such as `Effective Date`. In response to such an user action, two records are created, one with an `Audit_Action` value of "N", and the other with `Audit_Action` value "K". The "N" record has all the new values, while the "K" record retains the old values.

When you use the `CopyRowsetDelta` method to copy the contents from the source rowset to the message object, you are creating a *unique* copy of the object. If you change the original rowset, the message object is not be changed.

Note: You can execute `CopyRowsetDelta` against a message only once. After a message is populated, any other `CopyRowsetDeltas` are ignored. If you have to populate different levels of a message rowset separately, you can use the `CreateRowset` method to create a rowset that has the same structure as your message, populate the created rowset, then use `CopyRowsetDelta` to populate your message. You can also use the `Rowset CopyTo` method to populate a message rowset, then populate the `PSCAMA` record by hand.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>source_rowset</i>	Specifies the name of the rowset to be copied into the message object.
<i>record_list</i>	Specifies source and target records to be copied into the message object. The target records must be records in your message, while the source records must be records in a rowset that exists in the data buffer and is populated.

Returns

None.

Example

The following example copies all the changed rows of data from a component into a message object.

```
&Component_Rowset = GetLevel0();
&Msg.CopyRowsetDelta(&Component_Rowset);
```

CopyRowsetDeltaOriginal

Syntax

```
CopyRowsetDeltaOriginal(source_rowset [, record_list]);
```

Where *record_list* is a list of record names in the form:

```
[RECORD.source_recname1, RECORD.target_recname1
[, RECORD.source_recname2, RECORD.target_recname2]].
. .
```

Description

The CopyRowsetDeltaOriginal method copies rows of data that have changed from the source rowset to the like-named records and like-named fields in the message. It also copies the original value of the changed rows.

Note: CopyRowsetDeltaOriginal copies all the like-named fields from the changed and original *rows* into the message. It is not copying just the changed like-named fields.

When the record names in the message and component do not match exactly, use the optional *record_list* to specify the records to be copied from the component into the message. The specified target records must be records in your message, while the specified source records must be records in a rowset that exists in the data buffer and is populated.

The CopyRowsetDeltaOriginal method sets the AUDIT_ACTN field in the PSCAMA table for every row in the message. The notification process can then use PSCAMA.AUDIT_ACTN to determine how to process every row that was published.

The set values match those used in audit trail processing, that is:

- A - Row inserted.
- D - Row deleted.
- C - Row changed (updated), but no key fields changed. The system copies the new value to the Message rowset and the original value (see "O" below).
- O - Prior value of changed row. The system copies the new value to the Message rowset and the original value (see "C").
- K - Row changed (updated), and at least one key field changed. The system copies the original value to the Message rowset and the new value (see "N").
- N - Row changed (updated), and at least one key field changed. The system copies the original value to the Message rowset and the new value (see "K").
- "" – blank value means that nothing on that row has changed. This is the default value, and is the value used to tag the parent rows of children that have changed.

Note: If a child row is inserted (or changed or deleted) CopyRowsetDeltaOriginal also copies the parent row (and the parent row of that row, and so on, up to the top row) so the subscriber has a full picture of the transaction. A blank value is set in the AUDIT_ACTN field for these rows to let the subscriber know they don't have to take action; the parent rows are there for reference only.

The Audit_Action values "A", "C", "D" are set when a record is added, changed or deleted, respectively. When a row is changed, two records are created, one with an Audit_Action of "C", the other with Audit_Action value of "O". The "C" record has all the new values, while the "O" record retains the original values. In some cases such as effective-dated records, a user may change a key field value, such as Effective Date. In response to such a user action, two records are created, one with an Audit_Action value of "N", and the other with Audit_Action value "K". The "N" record has all the new values, while the "K" record retains the original values. The "N"/"K" combination is also created if both a key change and a non-key change is made on the same row of data.

The following table details the output from CopyRowsetDeltaOriginal:

User Action	CopyRowsetDeltaOriginal Output	Comments
Change a key.	"N" and "K" rows created.	The "K" row contains the original Key value, the "N" row, the new.
Change a Key + change a Non-Key.	"N" and "K" rows created only (that is: no "C"/"O" rows in that case).	The Key and Non-Key Original Values are both contained in the "K" row.
Change a Non-Key.	"C" and "O" rows created.	Original Value stored in "O" row.
Add non-effective dated row.	"A" row created.	No additional rows created.
Add effective-dated row and only 1 original effective-dated row exists.	"A" and "O" rows created.	"O" row contains the original effective dated row.
Add effective-dated row and more than 1 original effected dated rows exist.	"A" and "O" rows created.	<p>"O" row contains data from row that cursor was on when the new row was added.</p> <p>For example: If a rowset contains two rows (01/01/1980 and 02/02/2000), the current row is the 01/01/1980 row and the user adds a new row with today's date. The original values contain the data from the 01/01/1980.</p> <p>Likewise, if a rowset contains two rows (01/01/1980 and 02/02/2000), the current row is the 02/02/2000 row and the user adds a new row with today's date. Then the original values contain the data from the 02/02/2000.</p>
Delete a row	"D" row created.	No additional rows created.

When you use the CopyRowsetDeltaOriginal method to copy the contents from the source rowset to the message object, you are creating a unique copy of the object. If you change the original rowset, the message object is not changed.

Note: You can execute CopyRowsetDeltaOriginal against a message only once. After a message is populated, any other CopyRowsetDeltaOriginal PeopleCode statements are ignored. If you have to populate different levels of a message rowset separately, you can use the CreateRowset method to create a rowset that has the same structure as your message, populate the created rowset, then use CopyRowsetDeltaOriginal to populate your message. You can also use the Rowset CopyTo method to populate a message rowset, then populate the PSCAMA record manually.

Parameters

Parameter	Description
<i>source_rowset</i>	Specifies the name of the rowset to be copied into the message object.
<i>record_list</i>	Specifies source and target records to be copied into the message object. The target records must be records in your message, while the source records must be records in a rowset that exists in the data buffer and is populated.

Returns

None.

Example

```
Function Update_Dir(&MSGName As string)

    &MSGName = "OPERATION." | &MSGName;
    &MSG = CreateMessage(@(&MSGName));

    &PnlRowset = GetLevel0();
    &MSG.CopyRowsetDeltaOriginal(&PnlRowset);
    %IntBroker.Publish(&MSG);

End-Function;
```

CreateNextSegment

Syntax

```
CreateNextSegment()
```

Description

Use the CreateNextSegment method to divide a message into segments. You generally only divide asynchronous messages that contain a large amount of data. This method is used only when creating a message for publication, not after a message has been published.

Parameters

None.

Returns

None.

Example

See [Message Segments](#).

Related Links

[CreateNextSegment](#)

[DeleteSegment](#)

[SegmentRestart](#)

[UpdateSegment](#)

[CurrentSegment](#)

[SegmentCount](#)

DeleteSegment

Syntax

```
DeleteSegment(SegmentNumber)
```

Description

Use the DeleteSegment method to delete the specified segment. This method is used only when creating a message for publication, not after a message has been published.

Note: You should use DeleteSegment and UpdateSegment only when writing to memory, or when SegmentsByDatabase is set to False. These methods do not work when writing to the database, or when SegmentsByDatabase is set to True.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SegmentNumber</i>	Specify a number indicating which segment you want to delete from the unpublished message.

Returns

None.

Related Links

[CreateNextSegment](#)

[GetSegment](#)

[UpdateSegment](#)

[CurrentSegment](#)

[SegmentCount](#)

ExecuteEdits

Syntax

```
ExecuteEdits([editlevels]);
```

where *editlevels* is a list of values in the form:

```
editlevel1 [+ editlevel2] . . .];
```

and where *editleveln* is one of the following system constants:

%Edit_DateRange

%Edit_OneZero

%Edit_PromptTable

%Edit_Required

%Edit_TranslateTable

%Edit_YesNo

Description

The ExecuteEdits method executes the standard system edits on every field for every record in the message executing the method. All edits are based on the record edits defined for the record that the message is based on. The types of edits performed depends on the *editlevel*. If no *editlevel* is specified, all system edits defined for the record definition are executed, that is:

- Reasonable Date Range (Is the date contained within plus or minus 30 days from the current date?)
- 1/0 (Do all 1/0 fields only contain 1 or 0?)
- Prompt Table (Is field data contained in the specified prompt table?)
- Required Field (Do all required fields contain data? For numeric or signed fields, it checks that they do not contain NULL or 0 values.)
- Translate Table (Is field data contained in the translate table?)
- Yes/No (Do all yes/no fields only contain only yes or no data?)

Note: ExecuteEdits does not perform any validation on DateTime fields.

If any of the edits fail, the status of the property `IsEditError` is set to `True` for the Message Object executing the method, and any Rowset, Row, Record, or Field Objects that could be instantiated from the same data as the Message Object. In addition, the Field class properties `MessageNumber` and `MessageSetNumber` are set to the number of the returned message and message set number of the returned message, for the field generating the error.

If you want to check the field values only for a particular record, you can use the `ExecuteEdits` method with a record object.

In addition, if you want to dynamically set the prompt tables used for a field (with the `%EditTable` function) you must use the `SetEditTable` method.

Considerations for ExecuteEdits and SetEditTable

If an effective date is a key on the prompt table, and the record being edited doesn't contain an effective-dated field, the current date/time is used as the key value.

If a setID is a key on the prompt table, and the record being edited doesn't contain a setID field, the system looks for the setID on the other records in the current row first, then search parent rows.

Considerations for ExecuteEdits and Numeric Fields

A zero (0) might or might not be a valid value for a numeric field. `ExecuteEdits` processes numeric fields in different ways, depending on whether the field is required:

- If the numeric field is required: 0 is considered invalid.
- If the numeric field is not required: 0 is considered valid.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>editlevel</i>	<p>Specifies the standard system edits to be performed against every field on every record. If <i>editlevel</i> isn't specified, all system edits are performed. <i>editlevel</i> can be any of the following system constants:</p> <ul style="list-style-type: none"> • <code>%Edit_DateRange</code> • <code>%Edit_OneZero</code> • <code>%Edit_PromptTable</code> • <code>%Edit_Required</code> • <code>%Edit_TranslateTable</code> • <code>%Edit_YesNo</code>

Returns

None.

Example

The following is an example of a call to execute Required Field and Prompt Table edits:

```
&MSG.ExecuteEdits(%Edit_Required + %Edit_PromptTable);
```

The following is an example showing how ExecuteEdits() could be used:

```
&MSG.ExecuteEdits();  
If &MSG.IsEditError Then  
    Exit(1);  
End-If;
```

"Processing Inbound Errors" (Integration Broker)

FirstCorrelation

Syntax

```
FirstCorrelation()
```

Description

Use this method within an Integration Broker OnPreNotify event on the subscribing node to determine if this is the first message with this correlation ID.

Parameters

None.

Returns

A Boolean value: True if this is the first message with this correlation ID, False if a previous message with the same correlation ID has already run the OnPreNotify event.

Example

To improve the performance of correlated messages with multiple segments, use the FirstCorrelation method to run the OnPreNotify event for the first correlated message only. On the first message to be published, set the InitializeConversationId property to True. After the message is published, retrieve the transaction ID from the message. This transaction ID should be used to set the conversation ID (that is, the correlation ID) for all subsequent messages to be published.

```
/* On the first message to be published */
```

```

&MSG.InitializeConversationId = True;
%IntBroker.Publish(&MSG);
&strCorrelationID = &MSG.TransactionId;

/* For all subsequent correlated messages */

&MSG.IBInfo.ConversationID = &strCorrelationID;
%IntBroker.Publish(&MSG);

```

Then, on the subscribing node, use the `FirstCorrelation` method to run the `OnPreNotify` event one time only:

```

If &MSG.FirstCorrelation() = True Then
    /* process the OnPreNotify event logic */
End-If;

```

[ConversationID](#)

"Using the `OnPreNotify` and `OnPostNotify` PeopleCode Events" (Integration Broker Administration)

GenXMLPartString

Syntax

```
GenXMLPartString(PartIndex)
```

Description

Use the `GenXMLPartString` to create an XML string based on the message part specified by *PartIndex*.

Note: This method only works with rowset-based container messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PartIndex</i>	Specify the number of the part that you want to generate an XML string for.

Returns

An XML string.

Related Links

[GenXMLString](#)

[GetPartRowset](#)

LoadXMLPartString

GenXMLString

Syntax

```
GenXMLString()
```

Description

The GenXMLString method creates an XML string based on the message after it's loaded from the message buffer.

Note: This method does not support nonrowset-based messages.

Parameters

None.

Returns

An XML string.

Example

In the following example, the first three lines of code creates the message object and copies the data from a Component buffer into the message object. The last line creates an XML string based on that message object.

```
&MSG = CreateMessage (OPERATION.PO_INSERT);  
&RS = GetLevel0 ();  
&MSG.CopyRowset (&RS);  
&XML_STRING = &MSG.GenXMLString();
```

Related Links

LoadXMLString

GetContentString

Syntax

```
GetContentString ([SegmentIndex])
```

Description

Use the GetContentString to return a string populated with the content from the specified message segment. If you don't specify a segment, the data from the first segment is used.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SegmentIndex</i>	Specify the message segment that you want to access.

Returns

A string populated with the content of the specified segment if successful, null otherwise.

Related Links

[CreateNextSegment](#)

[SetContentString](#)

GetDocument

Syntax

```
GetDocument([segmented_message])
```

Description

Use these method to get a Document object associated with this message.

Note: If a fault occurs, continue to use GetContentString to read the fault message, and not GetDocument.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>segmented_message</i>	Specify a Boolean value indicating whether the message is segmented.

Returns

A Document object.

Example

```
Local Message &Msg;
Local Document &Doc;

&Msg = CreateMessage(Operation.QEFLIGHTPLAN_DOC);

&Doc = &Msg.GetDocument( True);

/* populate the document */
...
```

```

&Msg.CreateNextSegment();

&Doc = Null;
&Doc = &Msg.GetDocument( True);

/* populate the document */

...

```

Related Links

[GetContentString](#)

[Document Class](#)

GetPartAliasName

Syntax

```
GetPartAliasName (PartIndex)
```

Description

Use the GetPartAliasName to access the alias of the specified message part.

Note: This method works only with container messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PartIndex</i>	Specify the message part that you want to access the alias.

Returns

A string containing the message part alias.

GetPartName

Syntax

```
GetPartName (PartIndex)
```

Description

Use the GetPartName method to return the message name of the message specified by *PartIndex*.

Note: This method works only with container messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PartIndex</i>	Specify the number of the message part that you want to get the name for.

Returns

A string.

[CopyPartRowset](#)

[GenXMLPartString](#)

GetPartRowset

Syntax

`GetPartRowset(PartIndex)`

Description

Use the `GetPartRowset` to instantiate and populate a rowset object based on the specified message part in a container message.

Note: This method only works with rowset-based container messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PartIndex</i>	Specify the number of the message part that you want to instantiate and populate a rowset from.

Returns

A reference to a rowset object if successful, Null otherwise.

GetPartVersion

Syntax

```
GetPartVersion(PartIndex)
```

Description

Use the GetPartVersion method to return the version number of the message part specified by *PartIndex*.

Note: This method only works with container messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PartIndex</i>	Specify the number of the message part that you want to access the version of.

Returns

A string containing the version number.

[PartCount](#)

GetPartXMLDoc

Syntax

```
GetPartXMLDoc(PartIndex)
```

Description

Use the GetPartXMLDoc to retrieve the message part data as an XmlDocument object.

Note: This method can only be used for a nonrowset-based message parts.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PartIndex</i>	Specify the message part that you want to access the data for as an XmlDocument object.

Returns

An XmlDocument object populated with the message part data.

GetQueryString

Syntax

```
GetQueryString(Parameter_Name)
```

Description

Use the GetQueryString method to obtain the parameter values of a query string.

Note: This method has been deprecated and remains for backward compatibility only. Use the IBCConnectorInfo collection GetQueryStringArg method instead.

Related Links

[GetQueryStringArgName](#)

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Parameter_Name</i>	Specify the parameter name you want to obtain.

Returns

A string containing the value of the parameter.

Example

```
Local Message &request;
Local Rowset &Rowset;
Local String &emplid;

&request = %IntBroker.GetMessage();
&Rowset = &request.GetRowset();
&emplid = &request.GetQueryString("EMPLID");
```

[GetQueryStringArgName](#)

[GetQueryStringArgValue](#)

[SetQueryString](#)

GetRowset

Syntax

`GetRowset([version])`

Description

The GetRowset method returns a standard PeopleCode level zero rowset object for the specified message version. It creates an empty rowset for the specified message version if it doesn't already exist. If no message version is specified, the default message version is used.

When you use the GetRowset method, you are not creating a unique copy of the object. You are making only a copy of the reference. If you change the rowset, the original message is changed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>version</i>	An optional parameter, specifying an existing message version as a string. If <i>version</i> isn't specified, the default message version is used.

Returns

A Rowset object if successful.

Example

The following gets all the SET_CNTRL_REC rows related to the row on the page, then updates the field SETID with the value from the page. GetRowset is used to create a rowset based on the message structure, that is, an unpopulated rowset. Because the rowset is unpopulated, you can use the Fill method to populate with data from the page.

```

Local Message &MSG;
Local Rowset &MSG_ROWSET;

If FieldChanged(SETID) Then
    &MSG = CreateMessage(OPERATION.SET_CNTRL_REC);
    &MSG_ROWSET = &MSG.GetRowset();
    &MSG_ROWSET.Fill("where SETCNTRLVALUE =:1 and REC_GROUP_ID =:2", SETCNTRLVALUE, R⇒
EC_GROUP_ID);

    For &I = 1 To &MSG_ROWSET.ActiveRowCount
        &MSG_ROWSET.GetRow(&I).SET_CNTRL_REC.SETID.Value = SETID;
        &MSG_ROWSET.GetRow(&I).PSCAMA.AUDIT_ACTN.Value = "C";
    End-For;

    %IntBroker.Publish(&MSG);

End-If;
    
```

GetURIDocument

Syntax

GetURIDocument ()

Description

Use this method to retrieve the document template as defined on the service operation.

Parameters

None.

Returns

A Document object.

Example

```
&MSG = CreateMessage(Message.WEATHERSTATION_GET);
&DOC = &MSG.GetURIDocument();
&COM = &DOC.DocumentElement;

&COM.GetPropertyByName("state").Value = "Washington";
&COM.GetPropertyByName("city").Value = "Redmond";
&COM.GetPropertyByName("day").Value = "today";
&COM.GetPropertyByName("week").Value = "first";
&COM.GetPropertyByName("year").Value = "2010";
&COM.GetPropertyByName("country").Value = "USA";
&MSG.URIResourceIndex = 1;
&bRet = &MSG.IBInfo.LoadRESTHeaders();
&return_message = %IntBroker.SyncRequest(&MSG);
```

Related Links

"REST Resource Definitions" (Integration Broker)

GetURIResource

Syntax

```
GetURIResource([index])
```

Description

Use this method to retrieve the URI for the representational state transfer (REST) resource based on the specified index.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>index</i>	Corresponds to the row number in the URI grid of the REST Resource Definition section of the service operation definition.

Returns

A string.

Example

```
&MSG = CreateMessage(Message.WEATHERSTATION_GET);
&DOC = &MSG.GetURIDocument();

&STR = &MSG.GetURIResource(2);
```

[ConversationID](#)

"REST Resource Definitions" (Integration Broker)

GetXmlDoc

Syntax

```
GetXmlDoc ()
```

Description

Use the GetXmlDoc method to retrieve the message data as an XmlDocument object.

Note: This method can only be used for a nonrowset-based message. If you use this method with a rowset-based message an error message is returned.

Parameters

None.

Returns

A XmlDocument object.

InBoundPublish

Syntax

```
InBoundPublish (PubNodeName)
```

Description

Use the InBoundPublish method to send an asynchronous message based on a message rowset to simulate an inbound asynchronous request from an external node.

Note: This method has been deprecated and remains for backward compatibility only. Use the IntBroker class InBoundPublish method instead.

Though you are sending a message to yourself, it goes through all the inbound message processing on *PubNodeName*.

Related Links

[InBoundPublish](#)

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PubNodeName</i>	Specify the name of the node for which you want to test inbound message publishing.

Returns

None.

"Understanding Filtering, Transformation, and Translation" (Integration Broker)

LoadXMLPartString

Syntax

```
LoadXMLPartString(PartIndex, XmlString)
```

Description

Use the LoadXMLPartString method to populate the part of the container message specified by *PartIndex* with the XML string *XmlString*.

Note: This method works only with container messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PartIndex</i>	Specify the number of the part of the container message that you want to populate with XML data.
<i>XmlString</i>	Specify the XML string to be loaded into the message part.

Returns

None.

Related Links[GenXMLPartString](#)[GenXMLString](#)**LoadXMLString****Syntax**`LoadXMLString(XMLstring)`**Description**

The LoadXMLString method loads the message object executing the method with the XML string *XMLstring*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>XMLString</i>	Specify the XML string to be loaded into the message object.

Returns

None.

Example

```
&MSG = CreateMessage(OPERATION.PO_HEADER);
&MSG.LoadXMLString(&XML_STRING);
```

Related Links[GenXMLString](#)**OverrideURIResource****Syntax**`OverrideURIResource(string)`**Description**

Use this method on the subscribing node (the consumer) to override the URI template portion of the generated URL for a REST-based transaction.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>string</i>	Specifies the full URL to the REST-based resource.

Returns

None.

Example

```
&MSG = CreateMessage(Operation.QE_WEATHERSTATION_CONSUME_GET);
&MSG.OverrideURIResource("http://example.com/PSIGW/RESTListeningConnector/AKTT/Weat→
herStation.v1/weather/Washington");
```

Publish

Syntax

```
Publish([NodeName] [, Deferred_Mode] )
```

Description

The Publish method publishes a message to the application message queue for the default message version.

Note: This method has been deprecated and remains for backward compatibility only. Use the IntBroker class Publish method instead.

This method does not publish the message if the IsActive property is False.

This method publishes a message asynchronously, that is, a reply message is not automatically generated. To publish a message synchronously, use the SyncRequest method.

Note: This method supports nonrowset-based messages only if the data is populated using the SetXmlDoc method.

If the Publish method is called and the message isn't populated (either using SetXmlDoc or one of the rowset methods,) an empty message is published.

The Publish method can be called from any PeopleCode event, but is generally called from an Application Engine PeopleCode step or from a component.

When publishing from a component, you should publish messages only from the SavePostChange event, either from record field or component PeopleCode. This way, if there's an error in your publish code, the data isn't committed to the database. Also, since SavePostChange is the last Save event fired, you avoid locking the database while the other save processing is happening.

However, until the message is published, the tables involved with the component are locked and are not saved. To avoid problems with this, specify the *Deferred_Mode* property as true, so the message is published after the table data has been committed to the database.

Generally, if the message is successfully published, the PubID, and PubNodeName properties are set to the publication ID and publishing system node name, respectively. The only exception is when the Publish is performed as part of your notification PeopleCode. The notification process is always executed in deferred mode, due to performance considerations, and so the PubID is not populated.

Note: If you're publishing a message from within an Application Engine program, the message won't actually be published until the calling program performs a Commit.

Related Links

[Publish](#)

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the node to which the message should be published.
<i>Deferred_Mode</i>	Specify whether the message should be published immediately or at the end of the transaction. This parameter takes a Boolean value: False, publish the message immediately, or True, defer the publication. The default value is False.

Returns

None.

Example

The following copies all the data from a page into a message and publishes it.

```
Local Message &MSG;
Local Rowset &ROWSET;

&MSG = CreateMessage (OPERATION.MESSAGE_PO) :
&ROWSET = GetLevel0 ();
&MSG.CopyRowset (&ROWSET);
&MSG.Publish;
```

The following is an example of putting the Incremental Publish PeopleCode on a Record at Level 1 (or 2, 3). If you just do the normal publishing PeopleCode, you get as many messages as there are records at that level (because the code fires for each record).

To make sure the code fires only once, use the following code.

```
/*NAMES.EMPLID.WORKFLOW */
Local Message &MSG;
Local Rowset &RS;

&LEVEL = CurrentLevelNumber ();
```

```

&CURRENT_ROW = CurrentRowNumber(&LEVEL);
&TOT_ROW = ActiveRowCount(EMPLID);
/* Only Publish the message once for all records on */
/* this level */
If &CURRENT_ROW = &TOT_ROW Then
    &MSG = CreateMessage(OPERATION.NAMES);
    &RS = GetRowset();
    &MSG.CopyRowsetDelta(&RS);
    &MSG.Publish();
End-If;
    
```

SegmentRestart

Syntax

```

SegmentRestart(TransactionID, Segment_index, segmentByDB)
    
```

Description

Use the SegmentRestart method to restart a message segment. This is used only in a Application Engine program, and only if check point logic is used.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Transaction_ID</i>	Specify the transaction ID of the message you want to restart.
<i>Segment_Index</i>	Specify the number of the segment that you want to restart.
<i>SegmentByDB</i>	Specify the segments by database.

Returns

None.

Related Links

[DeleteOrphanedSegments](#)

"Understanding Message Segments" (Integration Broker)

SetContentString

Syntax

```
SetContentString(string)
```

Description

Use this method to set the content for the message segment for a non-rowset-based message only.

Note: An error will occur if SetContentString is used with other message types, such as rowset-based messages, document-based messages, and so on.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>string</i>	Specifies the content of the message segment.

Returns

A Boolean value: True if the message segment was updated, False otherwise.

Example

```
Local Message &MSG;
Local Document &DOC;
Local Compound &COM, &COM1;

&MSG = CreateMessage(Message.QE_WEATHERSTATION_POST);

&DOC = &MSG.GetURIDocument();

&COM = &DOC.DocumentElement;

&COM.GetPropertyByName("state").Value = "Washington";
&COM.GetPropertyByName("city").Value = "Redmond";
&COM.GetPropertyByName("day").Value = "today";
&COM1.GetPropertyByName("week").Value = "first";
&COM.GetPropertyByName("year").Value = "2010";
&COM.GetPropertyByName("country").Value = "USA";

&MSG.URIResourceIndex = QE_FLIGHTDATA.QE_ACNUMBER;

&DOC = CreateDocument("Weather", "WeatherData", "v1");
&COM1 = &DOC.DocumentElement;
&COM1.GetPropertyByName("city").Value = "Troutlake";
&STR1 = %IntBroker.GetURL("WEATHERSTATION_DATA", 2, &DOC);

&strHTML = GetHTMLText(HTML.WEATHER_CITIES, &STR1);
&bRet = &MSG.SetContentString(&strHTML);
```

Related Links

[GetContentString](#)

SetEditTable

Syntax

```
SetEditTable(%PromptField, RECORD.recordname)
```

Description

The SetEditTable method works with the ExecuteEdits method. It is used to set the value of a field on a record that has its prompt table defined as %PromptField value. %PromptField values are used to dynamically change the prompt record for a field.

There are several steps to setting up a field so that you can dynamically change its prompt table.

To set up a field with a dynamic prompt table:

1. Define a field in the DERIVED record called *fieldname*.
2. In the record definition for the field that you want to have a dynamic prompt table, define the prompt table for the field as %PromptField, where PromptField is the name of the field that you created in the DERIVED record.
3. Use SetEditTable to dynamically set the prompt table.

%PromptField is the name of the field on the DERIVED work record. RECORD.recordname is the name of the record to be used as the prompt table.

```
&MSG.SetEditTable("%EDITTABLE1", Record.DEPARTMENT);
&MSG.SetEditTable("%EDITTABLE2", Record.JOB_ID);
&MSG.SetEditTable("%EDITTABLE3", Record.EMPL_DATA);
&MSG.ExecuteEdits();
```

Every field on a record that has the prompt table field %EDITTABLE1 will have the same prompt table, such as, DEPARTMENT.

Parameters

Parameter	Description
%PromptField	Specifies the name of the field in the DERIVED record that has been defined as the prompt table for a field in a record definition.
RECORD.recordname	Specifies the name of the record definition that contains the correct standard system edits to be performed for that field in the message.

Returns

None.

Related Links[ExecuteEdits](#)[EditError](#)[MessageNumber](#)[MessageSetNumber](#)[IsEditError](#)[SetEditTable](#)["Creating New Record Definitions" \(Application Designer Developer's Guide\)](#)**SetQueryString****Syntax**

```
SetQueryString(Parameter_Name, Value)
```

Description

Use the SetQueryString method to add a parameter value to the query string.

Note: This method has been deprecated and remains for backward compatibility only. Use the IBCConnectorInfo class AddQueryStringArg method instead.

Related Links[AddQueryStringArg](#)**Parameters**

<i>Parameter</i>	<i>Description</i>
<i>Parameter_Name</i>	Specify the name of the parameter that you want to add to the query string, as a string.
<i>Value</i>	Specify the value of the parameter you are adding to the query string.

Returns

None.

Example

```
Local Message &request;
&request = CreateMessage(OPERATION.QE_SALES_ORDER);
. . .

. . .

&request.SetQueryString("BUYER", "12345");
```

Related Links

[AddQueryStringArg](#)

[GetQueryString](#)

SetREStCache

Syntax

```
SetREStCache (&futureDT)
```

Description

Use the SetREStCache method to set server-side caching for provider REST GET service operations the OnRequest PeopleCode event. When you set server-side caching, the system caches the entire transactional data for the *specific URI resource*. Subsequent requests from a client with an identical resource will result in the data being pulled from the cache. The cache expires on the date and time specified by the *&futureDT* parameter.

You can delete the cache at any time by calling the DeleteREStCache method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&futureDT</i>	Specifies a future date and time as a DateTime variable.

Returns

None.

Example

```
Local Message &MSG;
Local datetime &dt;
Local string &op, &ver;

&MSG.SetREStCache (&dt);

&b_ret = %IntBroker.DeleteREStCache (&op, &ver);
```

Related Links

[DeleteREStCache](#)

SetStatus

Syntax

```
SetStatus (Status)
```

Description

Use the `SetStatus` method to set the status of a publication or subscription contract, much the same way you do in the message monitor.

Note: This method has been deprecated and remains for backward compatibility only. Use the `IntBroker` class `SetStatus` method instead.

You may want to use this method after an end-user has finished fixing any errors in the message data.

You can set the status of a contract to one of the following statuses:

- Cancel
- Done
- Error
- New

The method is available only when the message instance has one of the following statuses:

- Cancel
- Done
- Error
- New

Related Links

[SetStatus](#)

Parameters

Parameter	Description
<i>Status</i>	Specify the status that you want to set the message to. Value are: <ul style="list-style-type: none"> • %Message_Error • %Message_New • %Message_Done • %Message_Started • %Message_Working • %Message_Retry • %Message_Timeout • %Message_Edited • %Message_Canceled

Returns

None.

Related Links

"Creating Message Definitions" (Integration Broker)

SetXmlDoc

Syntax

```
SetXmlDoc (&XmlDoc)
```

Description

Use the SetXmlDoc method to load a nonrowset-based message with data from an XmlDocument object.

Note: This method can only be used for nonrowset-based message. If you use this method with a rowset-based message an error message is returned.

Considerations Using SetXmlDoc

In order to wrap non-XML data in cdata wraps as part of a message that would be automatically removed when posted to the gateway, the following cdata wraps are supported:

- <?xml version="1.0"?> <data PsNonXml="Yes"><![CDATA..
- <?xml version="1.0"?> <data psnonxml="Yes"><![CDATA..

- `<?xml version="1.0"?><add_some_root_tag> <data PsNonXml="Yes"><![CDATA...]`
- `<?xml version="1.0"?><add_some_root_tag> <data psnonxml="Yes"><![CDATA...]`

Parameters

<i>Parameter</i>	<i>Description</i>
<code>&XmlDoc</code>	Specify an already instantiated, populated XmlDocument object.

Returns

None.

Related Links

[GetXmlDoc](#)

[Understanding XmlDocument Classes](#)

SyncRequest

Syntax

`SyncRequest ([NodeName])`

Description

Use the SyncRequest method to send a synchronous message for the default message version.

Note: This method has been deprecated and remains for backward compatibility only. Use the IntBroker class SyncRequest method instead.

Use the IsActive property to determine if a message is active or not before using this method.

This method sends a single message synchronously, that is a reply message is returned as a result of this method.

If you want to publish a message asynchronously, use the Publish method.

If you want to publish more than one message at a time synchronously, use the IntBroker SyncRequest method.

Note: This method supports nonrowset-based messages only if the SetXmlDoc method is used to populate the message prior to using the SyncRequest method.

The SyncRequest method can be called from any PeopleCode event, but is generally called from an Application Engine PeopleCode step or from a component.

When sending a synchronous request from a component, you should send messages only from the SavePostChange event, either from record field or component PeopleCode. This way, if there's an error in your SyncRequest code, the data isn't committed to the database. Also, since SavePostChange is the last Save event fired, you avoid locking the database while the other save processing is happening.

If the message is successfully sent, a response message is returned. In addition, the GUID property is updated with a unique identifier.

Related Links

[SyncRequest](#)

Parameters

<i>Parameter</i>	<i>Description</i>
<i>nodeName</i>	Specify the name of the node that you want to send this message to.

Returns

A response message.

Example

```
Local Message &request, &response;
Local Rowset &sales_order;

&sales_order = GetLevel0();
&request = CreateMessage(OPERATION.QE_SALES_ORDER);
&request.CopyRowsetDelta(&sales_order);
&response = &request.SyncRequest();
If (&response.ResponseStatus = 0) Then
    /* do processing */
End-If;
```

Related Links

[Publish](#)

[SyncRequest](#)

Update

Syntax

```
Update ([versionlist])
```

where *versionlist* is an arbitrary list of message versions in the following format:

```
version1 [, version2] . . .
```

Description

The Update method updates a message in the message queue with the specified message versions.

Note: This method has been deprecated and remains for backward compatibility only. Use the IntBroker class Update method instead.

If *versionlist* isn't specified, the default message version is used. This method is commonly used in the OnRouteSend and OnRouteReceive PeopleCode events.

Note: This method does not support nonrowset-based messages. The Update method can't be called from notification PeopleCode.

Related Links

[Update](#)

Parameters

<i>Parameter</i>	<i>Description</i>
<i>versionlist</i>	Specify an optional comma-separated list of message versions. If <i>versionlist</i> isn't specified, the default message version is used.

Returns

None.

Message Class Properties

In this section, we discuss the Message class properties. The properties are discussed in alphabetical order.

ActionName

Description

This property returns the name of the action associated with the message, as a string.

This property is read-only.

AliasName

Description

This property returns the name of the alias associated with the message part executing the property.

This property is read-only.

Related Links

[GetPartAliasName](#)

"Specifying Record Aliases" (Integration Broker)

ChannelName

Description

This property references the name of the channel associated with the message definition.

Note: This property has been deprecated and remains for backward compatibility only. Use the Message class QueueName property instead.

See [QueueName](#).

This property is set when the message is created. The message instance keys are a subset of the publication and subscription contract keys. This property is one of the message instance keys: the others are PubID and PubNodeName for asynchronous messages, GUID and PubNodeName for synchronous messages.

This property is valid for both synchronous and asynchronous messages.

This property is read-only.

Example

```
&CHANNEL = &MSG.ChannelName
```

Related Links

"Creating Message Definitions" (Integration Broker)

Cookies

Description

This property returns or sets the cookies associated with a message.

Note: This property has been deprecated and remains for backward compatibility only. Use the IBInfo class Cookies property instead.

See [Cookies](#).

You can accept a synchronous response message containing cookies, save those cookies in a global variable, and later return them to the target node in an outbound synchronous or asynchronous request message.

You can access this property only in an inbound synchronous response message or an outbound request message.

This property is read/write.

Example

The following is an example of receiving cookies:

```
Local Message &SalesRequest, &SalesResponse;
Local Rowset &SALES_ORDER;
Global string &SalesCookies;

&SALES_ORDER = GetLevel0();
&SalesRequest = CreateMessage(OPERATION.SALES_ORDER_SYNC);
&SalesRequest.CopyRowsetDelta(&SALES_ORDER);

/* send the synchronous request; the return value is */
```

```

/* the response message object */
&SalesResponse = &SalesRequest.SyncRequest();

/* Retrieve cookies from the response message */
&SalesCookies = &SalesResponse.Cookies;

```

The following is an example of returning cookies:

```

Local Message &SalesRequest, &SalesResponse;
Local Rowset &SALES_ORDER;
Global string &SalesCookies;

&SALES_ORDER = GetLevel0();
&SalesRequest = CreateMessage(OPERATION.SALES_ORDER_SYNC);
&SalesRequest.CopyRowsetDelta(&SALES_ORDER);

/* Insert the cookies in the request message */
&SalesRequest.Cookies = &SalesCookies;

/* Send the asynchronous request */
&SalesRequest.Publish();

```

CurrentSegment

Description

This property returns a number, indicating which segment is the current segment.

This property is read-only.

DefaultMessageVersion

Description

This property returns the default version of the message as a string.

Note: This property has been deprecated and remains for backward compatibility only. Use the Message class `OperationVersion` property instead.

See [OperationVersion](#).

This is the message version from the pub/sub contract, not the default message version of the message defined in the current system.

This property is valid for both synchronous and asynchronous messages.

This property is read-only.

Example

```

Local Message &MSG;
Local String &VER;

&MSG = %IntBroker.GetMessage();
&VER = &MSG.DefaultMessageVersion;

```

DoNotPubToNodeName

Description

Use this property to set the node name of a node that you do not want to publish this message to. For example, a single node may publish and subscribe to the same message. You can use this property to prevent the system from subscribing to the same message it publishes. This can help prevent circular processing where the original publisher eventually receives the same message.

This property is only valid for asynchronous messages.

This property is read/write.

Example

```
&MSG.DoNotPubToNodeName = &MSG.PubNodeName;  
&MSG.Publish();
```

GUID

Description

This property returns a string representing a global unique identifier generated when the message was sent.

Note: This property has been deprecated and remains for backward compatibility only. Use the Message class `TransactionId` property instead.

See [OperationVersion](#).

This property returns the unique identifier used with the message.

This property is valid only for synchronous messages.

This property is read-only.

Example

```
Local Message &request;  
Local String &guid;  
  
&request = %IntBroker.GetMessage();  
  
&guid = &request.GUID;
```

HTTPMethod

Description

Use this property to return an integer constant representing the HTTP request method that was specified by the subscribing node (the consumer) in REST-based service operations. The request method determines the proper response message to send.

Value	Description
%IntBroker_HTTP_GET	HTTP GET method – Requests a representation of a resource.
%IntBroker_HTTP_POST	HTTP POST method – Submits data to be processed to the specified resource. This might result in the creation of a new resource or updates to an existing resource or both.
%IntBroker_HTTP_DELETE	HTTP DELETE method – Deletes the specified resource.
%IntBroker_HTTP_PUT	HTTP PUT method – Uploads a representation of the specified resource. This might result in the creation of a new resource or updates to an existing resource or both.
%IntBroker_HTTP_HEAD	HTTP HEAD method – Requests a representation of a resource without the response body that would be returned in a GET request.

This property is read-only.

Example

```

If &MSG.HTTPMethod = %IntBroker_HTTP_POST Then
    /* populate the POST response data */
End-If;

If &MSG.HTTPMethod = %IntBroker_HTTP_GET Then
    /* populate the GET response data */
End-If;

```

HTTPResponseCode

Description

Use this property to return the HTTP response code for the transaction as an integer.

This property is read-only.

Example

```

&return_msg = %IntBroker.SyncRequest (&MSG);
If &return_msg.ResponseStatus = %IB_Status_Success Then
    &nRET = &return_msg.HTTPResponseCode;
End-If;

```

IBException

Description

Use the IBException property to return a reference to an exception object. The object is populated with information about the integration broker error.

This property is read-only.

Related Links

[Understanding Exception Class](#)

IBInfo

Description

Use this property to return a reference to an IBInfo object.

This property is read-only.

InitializeConversationId

Description

Use this property to set or return a Boolean value indicating whether this is the first of a set of correlated messages. On the first message to be published, set the InitializeConversationId property to True. After the message is published, retrieve the transaction ID from the message. This transaction ID should be used to set the conversation ID (that is, the correlation ID) for all subsequent messages to be published.

This property is read/write.

Related Links

[FirstCorrelation](#)

[TransactionId](#)

[ConversationID](#)

"Using the OnPreNotify and OnPostNotify PeopleCode Events" (Integration Broker Administration)

IsActive

Description

Indicates whether the message definition has been set to inactive.

Note: This property has been deprecated and remains for backward compatibility only. Use the Message class IsOperationActive property instead.

See [IsOperationActive](#).

This property is True if the message definition is active, False if it's been inactivated. If you have a lot of PeopleCode associated with publishing a message, you might use this property to check if the message is active before you publish it.

This property is valid for both asynchronous and synchronous messages.

This property is read-only.

Example

```
&MSG = CreateMessage(OPERATION.MY_MESSAGE)
If &MSG.IsActive Then
    /* do PeopleCode processing */
    &MSG.Publish();
Else
    /* do other processing */
End-if;
```

Related Links

"Creating Message Definitions" (Integration Broker)

"IsMessageActive" (PeopleCode Language Reference)

IsBulkLoadTruncation

Description

Use this property to return a Boolean value indicating whether the table truncation option has been selected on the bulk loader handler.

This property is read-only.

Example

```
If &MSG.IsBulkLoadTruncation = False Then
    /* then any truncation of tables would have to be performed here */
End-If;
```

Related Links

"Implementing Handlers Using Bulk Load Processing" (Integration Broker)

IsDelta

Description

This property indicates if any fields in a message populated from page data have been changed since they were first loaded into the component buffer.

This is generally used in the following scenario:

You want to publish a message only if the end-user has changed a value on a page. The problem is that if the end-user makes a change to a field in the level three rowset, the `IsChanged` property for the top level row remains `False`. If the rowset is large, and you don't want to iterate through it to find a single `IsChanged`, you can use this property to quickly determine if something has changed at a lower level and the message should be published.

Note: This property should be used only when the message and the component do not have the same structure (that is, the same records at the same levels). If the message and the component have the same structure use the `CopyRowsetDelta` method instead.

This property takes a Boolean value: `True` if there are changed fields in the message, `False` otherwise.

This property is valid for both asynchronous and synchronous messages.

This property is read-only.

Example

```
&Msg = CreateMessage(OPERATION.MY_MESSAGE);
&Msg_Rowset = &Msg.GetRowset(); /* get first level in Msg RS */
&Msg_Detail = &Msg_Rowset(1).GetRowset(); /* get detail in Msg */
&Page_Rowset = GetRowset(); /* get page */
For &I = &Page_Rowset.RowCount
    &Page_Detail = &Page_Rowset.GetRow(&I).GetRowset();
    &Msg_Detail.CopyRowset(&Page_Detail);
End-For;
/* Find if any data changed and should publish message */
If &Msg.IsDelta Then
    &Msg.Publish();
Else
    /* don't publish message and do other processing */
End-If;
```

Related Links

[CopyRowsetDelta](#)

IsEditError

Description

This property is `True` if an error has been found on any field in any record of the current message after executing the `ExecuteEdits` method on either a message object or a record object. This property can be used with the Field Class properties `MessageSetNumber` and `MessageNumber` to find the error message set number and error message number.

You can use this property in notification `PeopleCode` with the `Exit` function with a value of 1. This automatically rolls back any changes that were made to the database, saves the message errors to the message queue, and marks the message status as `ERROR`.

This property is valid for both asynchronous and synchronous messages.

This property is read-only.

Example

```
&MSG = %IntBroker.GetMessage();
&Rowset = &MSG.GetRowset();
&MSG.ExecuteEdits();
If &MSG.IsEditError Then
    Exit(1);
End-If;
```

Related Links

[ExecuteEdits](#)

[MessageNumber](#)

[MessageSetNumber](#)

"Exit" (PeopleCode Language Reference)

"Processing Inbound Errors" (Integration Broker)

IsLocal

Description

This property is True if the message object that was just instantiated was published locally. This property takes a Boolean value.

This property is valid for both asynchronous and synchronous messages.

This property is read-only.

Example

```
&MSG = %IntBroker.GetMessage();
If &MSG.IsLocal Then /* LOCAL NODE */
    /* do processing specific to local node */
Else
    /* do processing specific to remote nodes */
End-If;
```

IsOperationActive

Description

Use the IsOperationActive property to determine if an operation is active or not.

This property returns a Boolean value: true if the operation is still active, false otherwise.

This property is read-only.

Related Links

"Creating Message Definitions" (Integration Broker)

IsParts

Description

Use the IsParts property to determine if the message is a container message, that is, composed of parts.

This property only determines if a message is a container message. If you'd like to know if the message is a rowset-based message with parts, use the IsPartsStructured property instead.

This property returns a Boolean value: true if the message executing the property is a container message, false otherwise.

This property is read-only.

Related Links

[IsPartsStructured](#)

IsPartsStructured

Description

Use the IsPartsStructured property to determine if the message is a container message, that is, composed of parts, as well as a rowset-based message.

This property determines if a message is a container message as well as rowset-based. If you only want to know if the message is a container message, use the IsParts property instead.

This property returns a Boolean value: true if the message executing the property is a container message that is rowset-based, false otherwise.

This property is read-only.

Related Links

[IsParts](#)

IsRequest

Description

Use the IsRequest property to determine whether a message is a request message (as opposed to a response message.)

This property returns a Boolean value: true if the message object executing the property is a request message, false otherwise.

This property is read-only.

IsSourceNodeExternal

Description

Use the IsSourceNodeExternal property to determine whether the message came from an internal system or a third-party system.

This property returns a Boolean value: true if the message originated from a third-party system, false otherwise.

This property is read-only.

IsStructure

Description

This property indicates whether the message is rowset-based, that is, based on a rowset, or nonrowset-based that is, based on an XmlDocument. This property returns a Boolean value, true if the message is rowset-based, false otherwise.

This property is read-only.

MessageDetail

Description

This property specifies the message detail, as a string. The message detail can be used to further identify a message.

Note: This property has been deprecated. It is no longer supported.

Name

Description

This property returns the name of the message as a string.

This property is valid with both asynchronous and synchronous messages.

This property is read-only.

NRId

Description

This property returns the non-repudiation ID as a string. This property is populated with a unique string when the message is published.

This property is only valid with messages that use non-repudiation.

This property is read-only.

Related Links

"Implementing Nonrepudiation" (Integration Broker Administration)

OperationName

Description

Use the OperationName property to return the name of the operation associated with the message object executing the property, as a string.

This property is read-only.

OperationVersion

Description

Use the OperationVersion property to determine version for the operation associated with the message object executing the property, as a string.

This property is read-only.

ParentTransactionId

Description

Use the ParentTransactionId property to return the parent transaction ID, that is, the ID that is generated with the original request message from a third-party system.

This property is read-only.

Related Links

[TransactionId](#)

PartCount

Syntax

Use the PartCount property to determine the number of parts in a container message. This property is only valid with container messages. You will receive an error if you try to use it on a message that isn't a container message.

This property is read-only.

PubID

Description

This property refers to the publication identifier, which is a number.

Note: This property has been deprecated and remains for backward compatibility only. Use the Message class `QueueSeqId` property instead.

See [QueueSeqId](#).

It's generated for asynchronous messages when the message is published, and is sequential, based on the number of messages published for that channel. The message instance keys are a subset of the publication and subscription contract keys. This property is one of the message instance keys: the others are `ChannelName` and `PubNodeName`.

Note: The `PubID` property is not populated when the message is published from a notification.

This property is valid only with asynchronous messages.

This property is read-only.

Example

```
&MSG.Publish();  
&PUBID = &MSG.PubID;
```

PubNodeName

Description

This property refers to a string that contains the name of the publishing node. It is generated by the system when the message is published. The message instance keys are a subset of the publication and subscription contract keys.

This property is valid for both asynchronous and synchronous messages.

For a synchronous message, this property returns the name of the requesting node.

This property is read-only.

Example

```
&MSG = %IntBroker.GetMessage();  
&PUBNODE = &MSG.PubNodeName;
```

QueueName

Description

Use the `QueueName` property to return the name of the queue associated with the message.

This property is read-only.

Related Links

"Understanding Service Operation Queues" (Integration Broker)

QueueSeqId

Description

Use the QueueSeqId property to return the sequence number of the message in the message queue.

This property is read-only.

ResponseStatus

Description

This property is valid only for the returned response message from a synchronous request message.

This property indicates whether a response was successful or not.

Note: This is not the same as SetStatus, which is used only with the message monitor.

This property returns a numeric value: 0, the response was successful, any other number indicates an error.

This property is read-only.

SegmentContentTransfer

Description

Use this property to set or return a string constant indicating whether the message segment is binary or text data:

<i>Value</i>	<i>Description</i>
%ContentTransfer_Binary	Transfer this segment as binary data. <hr/> Note: Any binary data must be encoded as text, which increases its size by up to 33%. <hr/>
%ContentTransfer_Default	Transfer this segment as text data.

The HTTP target connector has a property called MTOM. When this property is set to Y, the transaction uses the Message Transmission Optimization Mechanism (MTOM) protocol for message transmission, which is more efficient for binary attachments.

This property is read/write.

Example

```
Local Message &MSG;

&MSG = CreateMessage(Message.FLIGHTDATA);

&MSG.SetXmlDoc(&xmldoc);

&MSG.CreateNextSegment();
&bRet = &MSG.SetContentString("your encoded image data here");
&MSG.SegmentContentType = "image/gif";
&MSG.SegmentContentTransfer = %ContentTransfer_Binary;

&MSG.CreateNextSegment();
&bRet = &MSG.SetContentString("your encoded video here");
&MSG.SegmentContentType = "video/mp4";
&MSG.SegmentContentTransfer = %ContentTransfer_Binary;

%IntBroker.Publish(&MSG);
```

Related Links

[SetContentString](#)

[SegmentContentType](#)

"Sending and Receiving Binary Data" (Integration Broker)

SegmentContentType

Description

Use this property to set or return a string representing the content (or MIME) type for the message segment—for example, application/pdf. This property is read/write.

Example

```
&MSG.SegmentContentType = "video/mp4";
```

Related Links

[SetContentString](#)

[SegmentContentTransfer](#)

"Sending and Receiving Binary Data" (Integration Broker)

SegmentCount

Description

This property returns the total number of segments for the message.

This property is read-only.

SegmentsByDatabase

Description

Use this property to specify whether segments are stored in memory while being processed.

If you specify SegmentsByDatabase as false, you can only have the number of segments as specified in PSADMIN (Message Segment From DB). If you specify this property as true, you can have as many segments as you need.

The SegmentsByDatabase property also specifies whether the segments are kept in memory or written to the database when they are received. If you specify true, the segments are automatically written to the database. If you specify false, the segments are held in memory. If you specify true, then cancel out of the program processing the segments, the changes are not committed to the database.

This property is automatically set to true for message segments being processed using a Application Engine program.

This property is read/write.

Related Links

[Message Segments](#)

[SegmentsUnOrder](#)

Size

Description

The Size property is the approximate size of the uncompressed XML data generated when the message is published. The availability and meaning of the Size property depends on the message type as follows:

- For rowset-based message parts, the Size property is available and based on the estimated XML size.
- For non-rowset-based messages, the Size property is available and based on the XML data size.
- For container-based messages, the Size property is available on received messages only—that is for OnRequest or OnNotify PeopleCode events.
- For container-based message parts, the Size property is available and based on the estimated XML size.
- For document-based messages, the Size property is available and based on the XML data size.

The size is approximate for the following reasons:

- The maximum size of fields is used except for the case of long text and image fields.
- The active row count is used, without regard to whether the rows have been changed. In a CopyRowsetDelta, rows that are not changed, are not published.
- It doesn't include the size of the XML tags.

This property can be used with the system property `%MaxMessageSize` in a batch Application Engine program to prevent the application from publishing a message that is too large.

This property is valid for both asynchronous and synchronous messages.

This property is read-only.

Example

```
If &MSG.Size > %MaxMessageSize Then
    &MSG.Publish();
Else
    /*Move more data into the message object */
End-If;
```

Related Links

"`%MaxMessageSize`" (PeopleCode Language Reference)

"Understanding Sending and Receiving Messages" (Integration Broker)

SubName

Description

This property refers to a string that contains the name of the notification process currently processing the message.

Note: This property has been deprecated and remains for backward compatibility only. Use the Message class `ActionName` property instead.

See [ActionName](#).

It is available only when `GetMessage` is used in a notification PeopleCode program.

This property is only valid for asynchronous messages.

This property is read-only.

Example

```
&MSG = %IntBroker.GetMessage();
&SUBNAME = &MSG.SubName
```

SubQueueName

Description

Use the `SubQueueName` to return or specify the name of the sub-queue associated with the message, as a string.

This property is read/write.

Related Links

"Understanding Service Operation Queues" (Integration Broker)

SubscriptionProcessId

Description

This property returns a string containing the subscription process identifier. This is a unique sequential number.

Note: This property has been deprecated and remains for backward compatibility only. Use the Message class `TransactionId` property instead.

See [TransactionId](#).

This property is populated only if the “Generate Subscription Process Instance” option is turned on in the Subscription Process definition.

The subscription process identifier corresponds to the subscription process instance, not the message instance. If there are multiple subscription processes for the same message each subscription process will have a different, unique ID.

If the subscription process terminated abnormally, its process instance is lost, and a new one is generated on the next retry (that is, there will be a gap in the sequence.)

This property is valid only for asynchronous messages.

This property is read-only.

Considerations for Using SubscriptionProcessId

Consider the following when using `SubscriptionProcessId`:

- Using the **Run PeopleCode** option from Message Subscription does not generate the number. It is generated only if the Application Server is running the PeopleCode.
- If for some reason you have to rerun the subscription, a new number is assigned.
- Because generating the number is optional, your program must contain code to support the option being turned off. Here is a code example from `ITEM_SYNC`:

```
If All(&MSG.SubscriptionProcessId) Then
    &EIP_CTL_ID = Generate_EIP_CTL_ID(4, &MSG.SubscriptionProcessId);
Else
    &EIP_CTL_ID = Generate_EIP_CTL_ID(1, "Random");
End-If;
```

- If the flag is off, this property is blank. In this case, you may want to adopt a standard for generating a random number, as shown in the previous example.

Related Links

"Understanding Sending and Receiving Messages" (Integration Broker)

TransactionId

Description

Use the TransactionId property to return the transaction ID for an already published message, as a string. This is a unique transaction identifier for the message.

This property is read-only.

URIResourceIndex

Description

Use this property to set or return the index for the URI as an integer. This index corresponds to the row number in the URI grid of the REST Resource Definition section of the service operation definition.

This property is read/write.

Example

```
&MSG = CreateMessage(Message.WEATHERSTATION_GET);
&DOC = &MSG.GetURIDocument();
&COM = &DOC.DocumentElement;

&COM.GetPropertyByName("state").Value = "Washington";
&COM.GetPropertyByName("city").Value = "Redmond";
&COM.GetPropertyByName("day").Value = "today";
&COM.GetPropertyByName("week").Value = "first";
&COM.GetPropertyByName("year").Value = "2010";
&COM.GetPropertyByName("country").Value = "USA";
&MSG.URIResourceIndex = 1;
```

Related Links

[SegmentContentType](#)

"REST Resource Definitions" (Integration Broker)

Version

Description

Use the Version property to determine the version of the message executing the property, as a string.

This property is read-only.

IntBroker Class

An IntBroker object is returned from the system variable %IntBroker.

IntBroker Class Methods

In the following section, we discuss the IntBroker class methods. The methods are described in alphabetical order.

Cancel

Syntax

```
Cancel(TransactionId, QueueName, DataType, SegmentIndex | TransactionIdArray, QueueNameArray, DataTypeArray, SegmentIndexArray)
```

Description

Use the Cancel method to programmatically cancel either a message, or a list of messages, from the message queue, much the same as you can do in the message monitor.

This method is only available when the message has one of the following statuses:

- Edited
- Error
- New
- Retry
- Timeout

If you are specifying an array of messages to be canceled, and any message in the array fails for any reason (for example, you specify a message that doesn't have the correct status) no messages are canceled and the method return value is false.

Parameters

Parameter	Description
<i>TransactionId</i> <i>TransactionIdArray</i>	Specify either a single transaction ID as a string, or specify an array of string containing the transaction IDs of the messages you want to cancel.
<i>QueueName</i> <i>QueueNameArray</i>	Specify either a single queue name as a string, or specify an array of string containing the queue names that contain the messages you want to cancel.
<i>DataType</i> <i>DataTypeArray</i>	Specify either a single data type, or an array of integer containing the data types. See below for valid data types.

Parameter	Description
<i>SegmentIndex</i> <i>SegmentIndexArray</i>	Specify either a specific segment, or an array of integer containing the segment numbers you want to cancel.

For the *DataType* or *DataTypeArray* parameters, the valid data types are:

Constant Value	Description
%IntBroker_BRK	Cancel the message for the web services gateway.
%IntBroker_PUB	Cancel the message for the publication contract.
%IntBroker_SUB	Cancel the message for the subscription contract.

Returns

A Boolean value: true if the message or messages are canceled successfully, false otherwise.

Related Links

[Resubmit](#)

ConnectorRequest

Syntax

```
ConnectorRequest (&Message[, process_exceptions])
```

Description

Use the ConnectorRequest method to return a response message from the connector based on the message passed in.

You would only use this method after you had set the connector information.

Parameters

Parameter	Description
<i>&Message</i>	Specify an already instantiated message object to return a response message from the connector.

Parameter	Description
<i>process_exceptions</i>	<p>Specifies a Boolean value indicating whether the PeopleCode program will process exceptions.</p> <hr/> <p>Important! When this parameter is set to True, your program must read the response status property of the response message to determine if the call was successful. If there is an exception, then interrogate the IBException object within the Message object to get the details of the exception.</p> <hr/>

Returns

A Message object.

Example

```

Local string &nonXmlData = "<?xml version=""1.0""?><data psnonxml=""yes""><![CDA=>
TA[" | &encoded | "]"></data>";
&soapMsg = CreateXmlDoc(&nonXmlData);

&reqMsg.SetXmlDoc(&soapMsg);

Local Message &respMsg;

%This.SetConnectorProperties(&reqMsg, &url);

&respMsg = %IntBroker.ConnectorRequest(&reqMsg);

If &respMsg = Null Then /* Throw exception */
%This.HandleNullSoapResponse(&soapMsg, &url);
End-If;

```

This second example demonstrates how to evaluate the response message status when *process_exceptions* is True:

```

Local Message &MSG, &resp_MSG;

&resp_MSG = %IntBroker.ConnectorRequest(&MSG, True);

If &resp_MSG.ResponseStatus = %IB_Status_Success Then
/* Perform processing of a successful response message */
Else
/* Read the IBException object for exception specifics */
&error = &resp_MSG.IBException.ToString();

End-If;

```

Related Links

[ConnectorRequestUrl](#)

[IBException](#)

ConnectorRequestUrl

Syntax

`ConnectorRequestUrl (URL)`

Description

Use the ConnectorRequestUrl method to return the URL for a connector.

You must have already set the connector parameters before executing this command.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>URL</i>	Specify an absolute URL as a string.

Returns

A string.

Example

```

/**
 * Get XML Doc from URL
 *
 * @param String - Location
 * @return XmlDoc - retrieved XmlDoc
 **/

method getXmlDocumentFromURL
    /+ &location as String +/
    /+ Returns XmlDoc +/
    Local XmlDoc &xmldoc;
    Local string &xmlstr;

    If Substring(LTrim(RTrim(Upper(&location))), 1, 4) = "HTTP" Then
        &xmlstr = %IntBroker.ConnectorRequestUrl(&location);
    Else
        &xmlstr = %This.getXmlContentFromFile(&location);
    End-If;

    &xmldoc = CreateXmlDoc("");

    If &xmldoc.ParseXmlString(&xmlstr) Then
        Return &xmldoc;
    End-If;

end-method;

```

Related Links

[ConnectorRequest](#)

DefaultLocalNode

Syntax

```
DefaultLocalNode ()
```

Description

Use the DefaultLocalNode method to return the name of the default local node on this system.

Parameters

None.

Returns

String.

Example

In a Mobile Application Platform (MAP) application, use this method when generating a link to a classic component or to a fluid component. For example, the following PeopleCode generates a link to a fluid homepage.

```
&URL = GenerateComponentPortalURL(%IntBroker.DefaultPortalName(), %IntBroker.DefaultLocalNode(), MenuName.NUI_FRAMEWORK, %MAP_Market, Component.PT_LANDINGPAGE, Page.PT_LANDINGPAGE, "U");
```

Related Links

[DefaultPortalName](#)

"GenerateComponentPortalURL" (PeopleCode Language Reference)

DefaultPortalName

Syntax

```
DefaultPortalName ()
```

Description

Use the DefaultPortalName method to return the name of the default portal on this system.

Parameters

None.

Returns

None.

Example

In a MAP application, use this method when generating a link to a classic component or to a fluid component. For example, the following PeopleCode generates a link to a fluid homepage.

```
&URL = GenerateComponentPortalURL(%IntBroker.DefaultPortalName(), %IntBroker.DefaultLocalNode(), MenuName.NUI_FRAMEWORK, %MAP_Market, Component.PT_LANDINGPAGE, Page.PT_LANDINGPAGE, "U");
```

Related Links

[DefaultLocalNode](#)

"GenerateComponentPortalURL" (PeopleCode Language Reference)

DeleteLayoutCache

Syntax

```
DeleteLayoutCache (MAP_layout)
```

Description

Use this method to delete all cached copies of this Mobile Application Platform (MAP) application.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>MAP_layout</i>	Specifies the name of the MAP application (layout) as a String.

Returns

A Boolean value: True if the method completes successfully, False otherwise.

Example

Use the DeleteLayoutCache method in the OnInitEvent to clear any cached copies of this MAP application:

```
&b = %IntBroker.DeleteLayoutCache("MAP_APP_2");
```

DeleteOrphanedSegments

Syntax

```
DeleteOrphanedSegments(TransactionId)
```

Description

Use the DeleteOrphanedSegments method to delete segments that might have been orphaned if you were processing message segments using an Application Engine program that had to be restarted. Since each segment is committed to the database, if the application engine program is aborted, these segments need to be deleted from the database.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TransactionId</i>	Specify the transaction ID that identifies the message which contains the segments you want to delete.

Returns

A Boolean value: true if the method completes successfully, false otherwise.

Related Links

[SegmentRestart](#)

"Understanding Message Segments" (Integration Broker)

DeleteREStCache

Syntax

```
DeleteREStCache(service_op, service_op_ver)
```

Description

Use the DeleteREStCache method to delete a server-side REST cache created by the SetREStCache method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>service_op</i>	Specifies the Integration Broker service operation as a string.

<i>Parameter</i>	<i>Description</i>
<i>service_op_ver</i>	Specify the version of the specified operation as a string.

Returns

A Boolean value: True if the cache was deleted successfully, False otherwise.

Example

```
Local Message &MSG;
Local datetime &dt;
Local string &op, &ver;

&MSG.SetREStCache (&dt);

&b_ret = %IntBroker.DeleteREStCache (&op, &ver);
```

Related Links

[SetREStCache](#)

EscapeControlCodes

Syntax

```
EscapeControlCodes (string)
```

Description

Use the EscapeControlCodes method to perform the necessary checks and escapes prior to populating the rowset. You can use this method only for the field that could possibly have these control codes.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>string</i>	Specify a string for which you want to add control codes.

Returns

A string with escape control codes.

Example

```
return string = %IntBroker.EscapeControlCodes (string);

local string &myString = "this is a string";
&string = %IntBroker.EscapeControlCodes (&myString);
```

GenLayoutDoc

Syntax

```
GenLayoutDoc(layout_name, URI_index, &URI_doc [, use_custom_doc])
```

Description

Use the GenLayoutDoc method to return a new Document object from the one that was used to invoke the MAP layout. This allows you to run the MAP application and return just the data generated instead of the resulting HTML so that you can then generate a physical format (JSON or XML) from the Document.

Parameters

Parameter	Description
<i>layout_name</i>	Specifies the name of the MAP application (layout) as a String value.
<i>URI_index</i>	Specifies the URI index as an Integer.
<i>&URI_doc</i>	Specifies the document for the MAP application to be invoked as a Document object.
<i>use_custom_doc</i>	Specifies an optional boolean value indicating whether to return the Document object based on the custom document instead of the parent document.

Returns

A Document object.

Example

In the following example, the returned Document object is used to generate a JSON (JavaScript Object Notation) structure:

```
local Document &Doc1 = CreateDocument("MAP_LAYOUT", "QE_FLIGHTTEST1_MAP", "v1");
&COM2 = &Doc1.DocumentElement;
&COM2.GetPropertyByName("PAGE_ID").Value = "INIT";
&COM2.GetPropertyByName("LAYOUT_ID").Value = - 1;
&COM2.GetPropertyByName("Pilot").Value = "Major Tom";

local Document &Doc2 = %IntBroker.GenLayoutDoc("QE_FLIGHTTEST", 1, &Doc1);
local string &data = &Doc2.GenJsonString();
```

Related Links

[GenJsonString](#)

[GenXmlString](#)

GenLayoutHTML

Syntax

```
GenLayoutHTML(MAP_layout, URI_index, &doc [, element_ID] [, gen_JSON])
```

Description

Use this method to generate all or a portion of the HTML for a specified Mobile Application Platform (MAP) application. Use this method when you want to invoke another MAP application as an external page from the calling MAP application

Parameters

<i>Parameter</i>	<i>Description</i>
<i>MAP_layout</i>	Specifies the name of the MAP application (layout) as a String.
<i>URI_index</i>	Specifies the URI index as an Integer.
<i>&doc</i>	Specifies the document for the MAP application to be invoked as a Document object.
<i>element_ID</i>	Specifies the ID for a specific element as a String, if only the HTML for that element is to be generated. Valid element types include containers, sidebars, headers, and footers. You can use either the system-generated ID or the developer-defined alternate ID for the element.
<i>gen_JSON</i>	Specifies a Boolean value indicating whether to also return the document data as a JSON string.

Returns

The return data type depends on the *gen_JSON* parameter:

- When *gen_JSON* is False or is omitted, the method returns a String that is the HTML.
- When *gen_JSON* is True, the method returns a two-dimensional Array of String:
 - The first element is the HTML.
 - The second element is the document data as a JSON string of attribute-value pairs.

Example

In the following example, the external MAP application is to be called from page 4 of the invoking MAP application. A Document object is created and populated with data from the current MAP application.

Then, the GenLayoutHTML method is executed to return the portion of HTML corresponding to a specific container in the invoked MAP application. Finally, this returned HTML is assigned to a primitive that has been associated with an HTML area element in the invoking MAP application.

```

If &URICOM.GetPropertyByName("PAGE_ID").Value = 4 Then
    &Doc1 = CreateDocument("MAP_LAYOUT", "FLIGHTCARD1_MAP", "v1");
    &COM2 = &Doc1.DocumentElement;
    &COM2.GetPropertyByName("PAGE_ID").Value = "INIT";
    &COM2.GetPropertyByName("LAYOUT_ID").Value = - 1;
    &COM2.GetPropertyByName("Pilot").Value = &URICOM.GetPropertyByName("Pilot").Value;
e;
    &COM2.GetPropertyByName("CardNbr").Value = &URICOM.GetPropertyByName("CardNbr").Value;
Value;
    &temp = %IntBroker.GenLayoutHTML("FLIGHTCARD", 2, &Doc1, "mapcont_start_1");
    &COM.GetPropertyByName("prim_text").Value = &temp;
end-if;

```

GetArchData

Syntax

GetArchData(*TransactionId*, *SegmentIndex*)

Description

Use the GetArchData method to retrieve an archived message from the message queue.

Note: This method shouldn't be used in standard message processing. It should only be used when accessing archived messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TransactionId</i>	Specify the transaction ID of the archived message you want to retrieve.
<i>SegmentIndex</i>	Specify the number of the segment of the archived message that you want to retrieve.

Returns

An XML string containing the archived data.

Related Links

[GetArchIBInfoData](#)

GetArchIBInfoData

Syntax

```
GetArchIBInfoData(TransactionId, ParentTransactionId)
```

Description

Use the GetArchIBInfoData method to retrieve return archived IBInfo data.

Note: This method shouldn't be used in standard message processing. It should only be used when accessing archived messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TransactionId</i>	Specify the transaction ID of the archived message you want to retrieve.
<i>ParentTransactionId</i>	Specify the parent transaction ID, for the message.

Returns

An XML string containing the archived data.

Related Links

[GetArchData](#)

GetContentURI

Syntax

```
GetContentURI ()
```

Description

Use the GetContentURI method to return the value of the content URI text defined for this system. For example:

```
http://myserver.example.com:8010/psc/MY_SITE/
```

Parameters

None.

Returns

A String value.

Related Links

[GetPortalURI](#)

"Setting Portal Node Characteristics" (Portal Technology)

GetDocSchema

Syntax

```
GetDocSchema(DocumentKey &Key, Type[optional])
```

Description

Use the GetDocSchema method to access the saved schema for the specified document.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>DocumentKey</i>	Specify the document by populating the Document Key object with package name, document name, and version name.
<i>Type</i>	By default, XML schema is returned if no value is passed. You can use the following values to specify the schema type: <ul style="list-style-type: none"> • %IB_XML - Returns XML schema. • %IB_JSON - Returns JSON schema.

Returns

A string containing the specified document schema.

Example

```
Local DocumentKey &Key;

&Key = CreateDocumentKey("package", "document", "version");
&str_json = %IntBroker.GetDocSchema(&Key, %IB_JSON);
```

GetIBInfoData

Syntax

```
GetIBInfoData(TransactionId, DataType)
```

Description

Use the GetIBInfoData to return the specified IBInfo data.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TransactionID</i>	Specify the transaction ID of the message that you want to access.
<i>Data Type</i>	Specify the data type of the message you want to access. The valid values are:

<i>Constant Value</i>	<i>Description</i>
%IntBroker_BRK	Get the message for the web services gateway.
%IntBroker_PUB	Get the message for the publication contract.
%IntBroker_SUB	Get the message for the subscription contract.

Returns

An XML string containing the message data.

Related Links

[GetArchIBInfoData](#)

GetIBTransactionIDforAE

Syntax

`GetIBTransactionIDforAE(OperID, RunCtlID)`

Description

Use this method to get the Integration Broker transaction ID from within an Application Engine program. You can use this transaction ID to instantiate a message object and thereby retrieve the message content data.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>OperID</i>	Specifies the operator ID for the Application Engine program as a string.
<i>RunCtlID</i>	Specifies the run control ID for the Application Engine program as a string.

Returns

A string representing the transaction ID.

Example

```
&TransID = %IntBroker.GetIBTransactionIDforAE(&opid, &runid);
&Msg = %IntBroker.GetMessage(&TransID, %IntBroker.SUB);
```

GetImageURL

Syntax

```
GetImageURL(image_name)
```

Description

Use this method to get the URL to an image that has been uploaded using the Layout Image Upload page.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>image_name</i>	Specifies the name of the image as a String.

Returns

A String value.

Example

Use the GetImageURL method in a Mobile Application Platform (MAP) application to return the image's URL to be assigned to the designated dynamic image's primitive.

```
&COM_NAV.GetPropertyByName("Altitude").Value = %IntBroker.GetImageURL("MAP_ACTIONS" =>
);
```

GetMessage

Syntax

```
GetMessage([TransactionId, DataType])
```

Description

Use the GetMessage method to return a message object.

If you specify a transaction ID and data type, the GetMessage method populates the message object with the data from that message.

If you do not specify any parameters, the GetMessage method doesn't populate the message with data. Instead, it creates a new instance of a message object. In this case, you must use another method, such as GetRowset, to populate the message object. You must always populate the message object with data before running any methods on it.

Parameters

Parameter	Description
<i>TransactionId</i>	Specify the transaction ID for the message that you want returned.
<i>DataType</i>	Specify the type of message that you want returned. The valid values are:

Constant Value	Description
%IntBroker_BRK	Get the message for the web services gateway.
%IntBroker_PUB	Get the message for the publication contract.
%IntBroker_SUB	Get the message for the subscription contract.

Returns

A reference to a message object if successful, Null if not successful.

Example

The following example returns a populated message object:

```
Local Message &MSG;
Local string &TransactionId;

&TransactionId = "0f3617d1-c6f4-11d9-a4bd-c12c8a1bc2f9"
&MSG = %IntBroker.GetMessage(&TransactionId, %IntBroker_BRK);
```

Related Links

[TransactionId](#)

GetMessageErrors

Syntax

```
GetMessageErrors (TransactionId)
```

Description

Use the GetMessageErrors method to return an array that contains the errors that an application has set for the message, and have been written to the error queue. This method is generally only used with asynchronous messages.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TransactionId</i>	Specify the transaction ID for the message, as a string.

Returns

An array of string. If there are no error messages, the Len property of the array is 0.

Example

The following is an example of using the method for returning web services gateway error messages:

```
&MyErrors = %IntBroker.GetMessageErrors(&TransactionId);
```

GetMsgSchema

Syntax

```
GetMsgSchema (MsgName, MsgVersion)
```

Description

Use the GetMsgSchema method to access the saved schema for the specified message.

If you specify a message that does not have a saved schema, you receive a null value.

Parameters

Parameter	Description
<i>MsgName</i>	Specify the name of the message for which you want to access a schema. You can either specify the name of the message as a string, or preface the message name with the keyword Message .
<i>MsgVersion</i>	Specify the message version.

Returns

A string containing the message schema. If you try to get a schema for a message that does not have a saved schema, returns null.

GetPortalURI

Syntax

```
GetPortalURI()
```

Description

Use the GetPortalURI method to return the value of the portal URI text defined for this system. For example:

```
http://myserver.example.com:8010/psp/MY_SITE/
```

Parameters

None.

Returns

A String value.

[GetContentURI](#)

"Setting Portal Node Characteristics" (Portal Technology)

GetSyncIBInfoData

Syntax

```
GetSyncIBInfoData(TransactionId, %LogType [, Archive])
```

Description

Use the GetSyncIBInfoData method to return a log containing information about synchronous transactions.

Parameters

Parameter	Description
<i>TransactionId</i>	Specify the transaction ID of the published message.
<i>LogType</i>	Specify the type of log you want returned, based on the type of message. See below for the valid values.
<i>Archive</i>	Specify whether to retrieve any archived logs as well. This parameter takes a Boolean value: true to return archived logs, false otherwise. The default value is false.

For the *LogType* parameter, the valid values are:

Constant Value	Description
%Sync_RequestOrig	Gets the log for a sync request original data message.
%Sync_RequestTrans	Gets the log for a sync request transformed data message.
%Sync_ResponseOrig	Gets the log for a sync response original data message.
%Sync_ResponseTrans	Gets the log for a sync response transformed data message.

Returns

An XML string containing the log data.

Related Links

"Service Operations Monitor Features" (Integration Broker Service Operations Monitor)

GetSyncLogData

Syntax

```
GetSyncLogData (TransactionId, %LogType [, Archive])
```

Description

Use the GetSyncLogData method to return a log containing information about the specified synchronous message.

You can use this information for debugging. Using this method, you can obtain the request and response data in a synchronous request, both pre- and post-transformation.

This function is used in the PeopleCode for the Message Monitor.

Parameters

Parameter	Description
<i>TransactionId</i>	Specify the transaction ID of the published message.
<i>LogType</i>	Specify the type of log you want returned, based on the type of message. See below for the valid values.
<i>Archive</i>	Specify whether to retrieve any archived logs as well. This parameter takes a Boolean value: true to return archived logs, false otherwise. The default value is false.

For the *LogType* parameter, the valid values are:

Constant Value	Description
%Sync_RequestOrig	Gets the log for a sync request original data message.
%Sync_RequestTrans	Gets the log for a sync request transformed data message.
%Sync_ResponseOrig	Gets the log for a sync response original data message.
%Sync_ResponseTrans	Gets the log for a sync response transformed data message.

Returns

An XML string containing the log data.

"Service Operations Monitor Features" (Integration Broker Service Operations Monitor)

GetURL

Syntax

```
GetURL(service_op_name, service_op_index, &doc_object, [secure_target],
[encode_unsafe])
```

Description

Use this method to generate a fully qualified URL for any REST-based service operation resource.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>service_op_name</i>	Specifies the Integration Broker service operation as a string.
<i>service_op_index</i>	Specifies the index for the URI as an integer. This index corresponds to the row number in the URI grid of the REST Resource Definition section of the service operation definition.
<i>&doc_object</i>	Specifies the document template for the service operation as a Document object.
<i>secure_target</i>	Specifies whether the REST location is a secure target location. The default value is the non-secure target location.
<i>encode_unsafe</i>	Specifies whether to encode unsafe characters as a Boolean value. The default is False (no encoding).

Returns

A string populated with the fully qualified URL.

Example

HTML is generated within the OnRequest event of a REST-based provider service using links defined from other REST-based service operations. Note that the REST-based service operation resources on either the publishing node (the provider) or the subscribing node (the consumer) can be used to generate the fully qualified links.

```
import PS_PT:Integration:IRequestHandler;

class RESThandler implements PS_PT:Integration:IRequestHandler
  method OnRequest(&message As Message) Returns Message;
  method OnError(&request As Message) Returns string;
```

```

end-class;

method OnRequest
  /+ &message as Message +/
  /+ Returns Message +/
  /+ Extends/implements PS_PT:Integration:IRequestHandler.OnRequest +/

  Local Document &Doc_Tmpl, &DOC;
  Local Compound &COM_Tmpl, &COM;
  Local Message &response;
  Local string &STR, &STR1, &STR2, &STR3, &STR4, &strHTML;
  Local boolean &bRet;

  &response = CreateMessage(Operation.WEATHERSTATION_GET, %IntBroker_Response);

  /* read URI Document to get parms out from the request*/
  &Doc_Tmpl = &message.GetURIDocument();
  &COM_Tmpl = &Doc_Tmpl.DocumentElement;

  /* Instantiate a Document object based on the REST-based service operations      d⇒
document template that you want to create a link for */

  &DOC = CreateDocument("Weather", "WeatherTemplate", "v1");
  &COM = &DOC.DocumentElement;

  /* based off the data from the request populate the Document object */
  If &COM_Tmpl.GetPropertyByName("state").Value = "Washington" Then
    &COM.GetPropertyByName("state").Value = "Washington";

  /* call new method to create fully qualified URL(s) */

  &COM.GetPropertyByName("city").Value = "WhiteSalmon";
  &STR = %IntBroker.GetURL("WEATHERSTATION_GET", 2, &DOC, true, true);

  &COM.GetPropertyByName("city").Value = "Troutlake";
  &STR1 = %IntBroker.GetURL("WEATHERSTATION_GET", 2, &DOC);

  &COM.GetPropertyByName("city").Value = "Yakima";
  &STR2 = %IntBroker.GetURL("WEATHERSTATION_GET", 2, &DOC);

  &COM.GetPropertyByName("city").Value = "Lyle";
  &STR3 = %IntBroker.GetURL("WEATHERSTATION_GET", 2, &DOC);

  /* use these URLs as bind variables for the HTML definition */
  &strHTML = GetHTMLText(HTML.WEATHER_CITIES, &STR, &STR1, &STR2, &STR3);

  /* set the data in the response message */
  &bRet = &response.SetContentString(&strHTML);

  End-If;

  Return &response;

end-method;

```

InBoundPublish

Syntax

InBoundPublish (&Message)

Description

Use the `InBoundPublish` method to send an asynchronous message based on the specified message to simulate an inbound asynchronous request from an external node. Although you are sending a message to yourself, it goes through all the inbound message processing that the specified message would.

Prior to call the `InBoundPublish` method, the `Message` object needs to populated with the requesting node and external operation name.

See "Simulating Receiving Messages from External Nodes" (Integration Broker).

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Message</i>	Specify an already instantiated message object that you want to use for the message simulation.

Returns

A Boolean value, true if the message is published successfully, false otherwise.

Related Links

[Publish](#)

[SyncRequest](#)

IsOperationActive

Syntax

```
IsOperationActive (OperationName [, OperationVersion])
```

Description

Use the `IsOperationActive` method to determine if an operation is active or not.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>OperationName</i>	Specify the name of the operation that you want to check the status of.
<i>OperationVersion</i>	Specify the version of the specified operation that you want to check the status of, as a string.

Returns

A Boolean value: true if the operation is active, false otherwise.

MAPLogout

Syntax

```
MAPLogout (MAP_layout)
```

Description

Use this method to generate the logout URL for this Mobile Application Platform (MAP) application. This URL can be assigned to a button, link, or some other page element. When the user clicks this element, the user is signed out of the application.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>MAP_layout</i>	Specifies the name of the MAP application (layout) as a String.

Returns

A String value.

Example

Use this method to return the URL that can be assigned to a button, which when clicked will sign the user out of the application.

```
&URL_str = %IntBroker.MAPLogout (&MAP.LayoutName);
```

MAPSessionTimeout

Syntax

```
MAPSessionTimeout ()
```

Description

Use the MAPSessionTimeout method to return an Integer value representing the session timeout value (in minutes) as defined on the Map Security - General page.

Parameters

None.

Returns

A Integer value.

MAPTimeout

Syntax

```
MAPTimeout (layout_name)
```

Description

Use the MAPTimeout method to return the timeout URL for the specified MAP layout. The following provides an example of a timeout URL:

```
http://myserver.example.com:8010/PSIGW/RESTListeningConnector/MY_SITE/SUB1_MAP.v1/?⇒
cmd=maptimeout
```

Parameters

<i>Parameter</i>	<i>Description</i>
<i>layout_name</i>	Specifies the MAP application (layout) as a String value.

Returns

A String value.

MsgSchemaExists

Syntax

```
MsgSchemaExists (MsgName, MsgVersion)
```

Description

Use the MsgSchemaExists method to determine if a schema has been created and saved for the specified message.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>MsgName</i>	Specify the name of the message for which you want to access a schema. You can either specify the name of the message as a string, or preface the message name with the keyword Message .

<i>Parameter</i>	<i>Description</i>
<i>MsgVersion</i>	Specify the message version.

Returns

A Boolean value: true if the message schema exists, false otherwise.

Related Links

[GetMsgSchema](#)

"Understanding the Message Schema Builder" (Integration Broker)

Publish

Syntax

```
Publish(&Message [, &ArrayOfNodeNames] [, IsEnqueued])
```

Description

The Publish method publishes a message to the message queue for the default message version.

This method does not publish the message if the IsOperationActive property for the message is False.

This method publishes a message asynchronously, that is, a reply message is not automatically generated. To publish a message synchronously, use the SyncRequest method.

Note: This method supports nonrowset-based messages only if the data is populated using the SetXmlDoc method.

If the Publish method is called and the message isn't populated (either using SetXmlDoc or one of the rowset methods,) an empty message is published.

The Publish method can be called from any PeopleCode event, but is generally called from an Application Engine PeopleCode step or from a component.

When publishing from a component, you should publish messages only from the SavePostChange event, either from record field or component PeopleCode. This way, if there's an error in your publish code, the data isn't committed to the database. Also, since SavePostChange is the last Save event fired, you avoid locking the database while the other save processing is happening.

However, until the message is published, the tables involved with the component are locked and are not saved. To avoid problems with this, specify the *Deferred_Mode* property as true, so the message is published after the table data has been committed to the database.

Note: If you're publishing a message from within an Application Engine program, the message won't actually be published until the calling program performs a Commit.

Parameters

Parameter	Description
<i>&Message</i>	Specify an already instantiated message object to be published.
<i>&ArrayOfNodeNames</i>	Specify an already instantiated array of string containing the names of the nodes that you want to publish to.
<i>IsEnqueued</i>	Specify whether the message is to be enqueued or not. This parameter takes a Boolean value: true if the message is to be enqueued, false otherwise. The default value is false.

Returns

None.

Example

```
Local Message &Msg;
Local Rowset &rs;
Local IntBroker &Ib;

&Flight_profile = GetLevel0();

&Msg = CreateMessage(Operation.ASYNC, %IntBroker_Request);

&Msg.CopyRowset(&FlightProfile);

&Ib = %IntBroker;

&Ib.Publish(&Msg);
```

Related Links

[SyncRequest](#)

Resubmit

Syntax

```
Resubmit({TransactionId, QueueName, DataType, SegmentIndex} | {TransactionIdArray, ⇒  
QueueNameArray, DataTypeArray, SegmentIndexArray})
```

Description

Use the Resubmit method to programmatically resubmit either a message, or a list of messages, from the message queue, much the same as you can do in the message monitor.

You may want to use this method after an end-user has finished fixing any errors in the message data, and you want to resubmit the message, rerunning the PeopleCode.

This method is only available when the message has one of the following statuses:

- Canceled
- Edited
- Error
- Timeout

If you are specifying an array of messages to be resubmitted, and any message in the array fails for any reason (for example, you specify a message that doesn't have the correct status) no messages are resubmitted and the method return value is false.

Parameters

Parameter	Description
<i>TransactionId</i> <i>TransactionIdArray</i>	Specify either a single transaction ID as a string, or specify an array of string containing the transaction IDs of the messages you want to resubmit.
<i>QueueName</i> <i>QueueNameArray</i>	Specify either a single queue name as a string, or specify an array of string containing the queue names that contain the messages you want to resubmit.
<i>DataType</i> <i>DataTypeArray</i>	Specify either a single data type, or an array of string containing the data types. See below for the valid data type values.
<i>SegmentIndex</i> <i>SegmentIndexArray</i>	Specify either a specific segment, or an array of integer containing the segment numbers you want to resubmit.

For the *DataType* or *DataTypeArray* parameters, the valid data types are:

Constant Value	Description
%IntBroker_BRK	Resubmit the message for the web services gateway.
%IntBroker_PUB	Resubmit the message for the publication contract.
%IntBroker_SUB	Resubmit the message for the subscription contract.

Returns

A Boolean value: true if the message or messages are resubmitted successfully, false otherwise.

Related Links

[Cancel](#)

SetMessageError

Syntax

```
SetMessageError(TransactionID, MsgSet, MsgNumber, Error_Location, ParamListCounter,⇒
[Param] ...)
```

Description

Use the SetMessageError method to write messages to the error queue. This method is used with asynchronous messages only.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TransactionID</i>	Specify the transaction ID for the message as a string.
<i>MsgSet</i>	Specify the number of the message set that the message associated with the error is associated with.
<i>MsgNumber</i>	Specify the message number that you want to associate with this error.
<i>Error_Location</i>	Specify where the error occurred, or any additional information you want to give about the error. This is a string, and allows 254 characters.
<i>ParamListCounter</i>	An integer value from 0 to 4 specifying the number of <i>Param</i> substitution strings to be passed.
<i>Param</i>	Specify up to four <i>Param</i> values to be used as substitution strings in the message text. The first <i>Param</i> value is used in the first substitution (that is, for %1,) the second is used in the second (that is, for %2), and so on.

Returns

A Boolean value, true if the error message was associated correctly, false otherwise.

Example

The following is an example of setting an error message for the web services gateway:

```
&Rslt = %IntBroker.SetMessageError(&TransactionId, &msgset, &msgnum, "error locatio⇒
```

```
n", 4, &parm1, &parm2, &parm3, &parm4);
```

If you are passing just two parameters, then the call would be similar to this:

```
&Rslt = %IntBroker.SetMessageError(&TransactionId, &msgset, &msgnum, "error locatio→
n", 2, &parm1, &parm2);
```

Related Links

"Processing Inbound Errors" (Integration Broker)

[GetMessageErrors](#)

SetStatus

Syntax

```
SetStatus(&Message, Status)
```

Description

Use the SetStatus method to set the status of a publication or subscription contract, much the same way you do it in the message monitor.

You may want to use this method after an end-user has finished fixing any errors in the message data.

You can set the status of a contract to one of the following statuses:

- Canceled
- Done
- Error
- New

The method is available only when the message instance has one of the following statuses:

- Canceled
- Done
- Error
- New

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Message</i>	Specify an already instantiated message object that you want to set the status for.

Parameter	Description
<i>Status</i>	Specify the status that you want to set the message to. Valid status are:

Constant Value	Description
%Operation_Canceled	Cancel the message.
%Operation_Done	Set the message to done.
%Operation_Error	Set the message to be in error.
%Operation_New	Specify the message as new.

Returns

None.

SwitchAsyncEventUserContext

Syntax

```
SwitchAsyncEventUserContext (UserID, LanguageCode)
```

Description

Use the SwitchAsyncEventUserContext method to switch the user context within an Integration Broker asynchronous event.

Parameters

Parameter	Description
<i>UserID</i>	Specify the user ID, as a string, to which you want to switch the context.
<i>LanguageCode</i>	Specify the language code, as a string, for the user ID.

Returns

A Boolean value: true if the switch user was successful, false otherwise.

Example

```
&returnValue = %IntBroker.SwitchAsyncEventUserContext("VP1", "ENG");
```

SyncRequest

Syntax

```
SyncRequest ([&MsgArray, &NodeNames])
```

Description

Use the SyncRequest method to send multiple messages at the same time. You should only use this message with synchronous messages. You can also use this method to send a single synchronous message at a time, or you can use the SyncRequest Message class method.

If you want to publish messages asynchronously, use the Publish method.

Note: This method supports nonrowset-based messages only if the SetXmlDoc method is used to populate the message prior to using the SyncRequest method.

You must set the thread pool size of the application server on the receiving system to a value greater than 1 (the default) in order to process more than one message at a time.

How many threads you specify determines how many messages are worked on simultaneously. For example, if you have 10 messages in &MsgArray, and your thread pool size is 5, then only 5 messages are processed at a time.

The maximum number you can specify for your thread pool size is 10.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&MsgArray</i>	Specify an already instantiated array of messages that contains the messages you want to publish.
<i>&NodeNames</i>	Specify an already instantiated array of string containing the names of the nodes that you want to publish to. The first message in the array of messages is published to the first node, the second message is published to the second node, and so on.

Returns

An array of messages. These are the corresponding messages returned for the published messages. The first message in the returned array corresponds to the first message in the published array, the second message with the second, and so on.

Example

The following is an example of how creating and receiving a series of messages:

```
Local Rowset &FLIGHTPLAN, &FLIGHTPLAN_RETURN;
Local Message &MSG;
Local File &BI_FILE;
Declare Function out_BI_results PeopleCode QE_FLIGHTDATA.QE_ACNUMBER FieldFormula;

Local array of Message &messages;
Local array of Message &return_mesages;

&messages = CreateArrayRept(&MSG, 0);
&return_mesages = CreateArrayRept(&MSG, 0);

&FLIGHT_PROFILE = GetLevel0();
&messages [1] = CreateMessage(OPERATION.QE_FLIGHTPLAN_SYNC);
&messages [1].CopyRowset(&FLIGHT_PROFILE);

&messages [2] = CreateMessage(OPERATION.QE_FLIGHTPLAN_SYNC);
&messages [2].CopyRowsetDelta(&FLIGHT_PROFILE);

&return_mesages = %IntBroker.SyncRequest(&messages);

&FLIGHTPLAN_RETURN = &return_mesages [1].GetRowset();
&temp = &return_mesages [1].GenXMLString();

out_BI_results(&temp);

&FLIGHTPLAN_RETURN = &return_mesages [2].GetRowset();
&temp = &return_mesages [2].GenXMLString();

out_BI_results(&temp);
```

[SyncRequest](#)

Update

Syntax

```
Update (&Message)
```

Description

Use the Update method to update a message in the message queue with the specified message object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Message</i>	Specify an already instantiated and populated message object to be used to update an existing message in the message queue.

Returns

A Boolean value, true if the message is updated successfully, false otherwise.

Related Links

[UpdateXmlDoc](#)

UpdateCSSMetadata

Syntax

`UpdateCSSMetadata (CSS)`

Description

Use the UpdateCSSMetadata method to return the input style sheet after substituting an actual image for the %MAP_IMAGE meta-HTML variable.

Parameters

<i>Parameter</i>	<i>Description</i>
CSS	Specifies the free form style sheet data as a String value.

Returns

A String value.

UpdateDocument

Syntax

`UpdateDocument (&doc, update_type)`

Description

Use this method to update the database based on the data in the specified Document object. The method can be used in a Mobile Application Platform (MAP) event only.

Important! To use this method, the document must be defined as a physical relational document.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&doc</i>	Specifies the document as a Document object.
<i>update_type</i>	Specifies the type of update to perform as an Integer. The constant values are:

Constant Value	Description
%Document_Update	Update the database by adding the keys and data from the specified document.
%Document_Replace	Update the database by first deleting data associated with any keys specified in the document, and then replacing them with the keys and data from the specified document.
%Document_Delete	Update the database by deleting data associated with any keys from the specified document.

Returns

A Boolean value: True if the update occurred successfully, False otherwise.

UpdateJSMetadata

Syntax

`UpdateJSMetadata (JS)`

Description

Use the UpdateJSMetadata method to return the input JavaScript after substituting the system's default local node name for the %MAP_NODE meta-HTML variable.

Parameters

Parameter	Description
JS	Specifies the JavaScript data as a String value.

Returns

A String value.

UpdateXmlDoc

Syntax

`UpdateXmlDoc (&XmlDoc, TransactionId, DataType)`

Description

Use the UpdateXmlDoc method to update a message in the message queue with the specified message data.

Note: This method shouldn't be used in a subscription program.

Parameters

Parameter	Description
<i>&XmlDoc</i>	Specify an already instantiated and populated XmlDocument object.
<i>TransactionId</i>	Specify the transaction ID of the message you want to update.
<i>Data Type</i>	Specify the data type of the message that you want to update. Valid values are:

Constant Value	Description
%IntBroker_BRK	Update the message for the web services gateway.
%IntBroker_PUB	Update the message for the publication contract.
%IntBroker_SUB	Update the message for the subscription contract.

Returns

A Boolean value, true if the message was updated successfully, false otherwise.

[Update](#)

IBInfo Class

An IBInfo object is returned from the IBInfo message class property.

Related Links

[IBInfo](#)

IBInfo Class Methods

In this section, we discuss the IBInfo class methods. The methods are discussed in alphabetical order.

All methods work with both asynchronous as well as synchronous messages unless specified

AddAEAttribute

Syntax

AddAEAttribute (*Name*, *value*)

Description

Use this method to add an attribute as a name-value pair to the Message object to be passed back to the response application class defined on the Application Engine handler.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the attribute name as a string.
<i>value</i>	Specifies the attribute value as a string.

Returns

A Boolean value: True if the attribute was added successfully, False otherwise.

Example

```

/* Add the name value pair data you want to pass to the response app class */
/* in the AE program */

&b = &MSG.IBInfo.AddAEAttribute("sail name", "NorthWave");
If &b <> True Then
    MessageBox(0, "", 0, 0, "error adding ae attribute");
End-If;

&b = &MSG.IBInfo.AddAEAttribute("size", "4.2");
If &b <> True Then
    MessageBox(0, "", 0, 0, "error adding ae attribute");
End-If;

&b = &MSG.IBInfo.AddAEAttribute("type", "Surflite");
If &b <> True Then
    MessageBox(0, "", 0, 0, "error adding ae attribute");
End-If;

/* Need to call this method for the attributes to be saved and transferred */
/* correctly */
&b = &MSG.IBInfo.InsertAEResponseAttributes();
If &b <> True Then
    MessageBox(0, "", 0, 0, "error inserting AE response attributes");
End-If;

/* ***** */
/* In the response application class to retrieve the name-value pairs */

For &i = 1 To &MSG.IBInfo.GetNumberOfAEAttributes()

    &name = &MSG.IBInfo.GetAEAttributeName(&i);
    &value = &MSG.IBInfo.GetAEAttributeValue(&i);

```

End-For;

AddAttachment

Syntax

AddAttachment (*Path*)

Description

Use the AddAttachment method to add an attachment to a message.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Path</i>	Specify an absolute path, including the file name and type, as a string, of the file you want to attach to the message.

Returns

A string containing a content ID, which can be used for accessing the attachment with other methods, such as DeleteAttachment or SetAttachmentProperty.

Example

The following example shows sending an attachment with an asynchronous message:

```

Local Message &MSG;
Local Rowset &FLIGHT_PROFILE;
Local String &Attachment_Id;
Local Boolean &Test;
Local IntBroker &IntBroker;

QE_FLIGHTDATA.QE_ACNUMBER.Value = QE_FLIGHTDATA.QE_ACNUMBER + 1;

&FLIGHT_PROFILE = GetLevel0();

&MSG = CreateMessage(Operation.ASYNC_RR);

&Attachment_Id = &MSG.IBInfo.AddAttachment("C:\\temp\\MyFile.txt");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Encoding, "UT⇒
    
```

```

F-8");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Base, "Standa
rd");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Disposition, =>
"Pending");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Language, "En=>
glish");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Description, =>
"Parts data");

&MSG.CopyRowset (&FLIGHT_PROFILE);

&IntBroker = %IntBroker
&IntBroker.Publish (&MSG);

```

AddAttribute

Syntax

AddAttribute(*name*, *value*)

Description

Use this method to add an attribute to an IBInfo object.

Note: This method can be used for content-based routing only, typically in your implementation of the `IRouter.OnRouteSend` or `IRouter.OnRouteReceive` methods.

The maximum length of the attribute name is 30 characters. The maximum length of the attribute value is 254 characters.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>name</i>	Specifies the attribute name as a string.
<i>value</i>	Specifies the attribute value as a string.

Returns

A Boolean value: true if the addition of the attribute was successful, false otherwise.

Example

```
&bRet = &MSG.IBInfo.AddAttribute("employeeID", "123456");
```

Related Links

[Content-Based Routing](#)

AddContainerAttribute

Syntax

```
AddContainerAttribute(Name, Value)
```

Description

Use this method to add a container attribute by specifying an attribute name-value pair.

You can add attributes to container messages that contain rowset-based message parts to provide integration partners with data and information, without adding the information to the message definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the container attribute name as a string.
<i>Value</i>	Specifies the container attribute value as a string.

Returns

A Boolean value: True if the container attribute was added successfully, False otherwise..

Example

```
Local Message &MSG;
Local Rowset &RS;
Local boolean &Bo;

&RS = GetLevel0();
&MSG = CreateMessage(Operation.QE_CONT_ATTRB);

&Bo = &MSG.IBInfo.AddContainerAttribute("Test1", "1");
&Bo = &MSG.IBInfo.AddContainerAttribute("Test2", "10");
&Bo = &MSG.IBInfo.AddContainerAttribute("Test3", "100");

&MSG.CopyPartRowset(1, &RS);
```

```
%IntBroker.Publish (&MSG);
```

ClearAEAttributes

Syntax

```
ClearAEAttributes ()
```

Description

Use this method to delete all Application Engine handler attributes from the Message object.

Parameters

None.

Returns

None.

Related Links

[AddAEAttribute](#)

[DeleteAEAttribute](#)

ClearAttachments

Syntax

```
ClearAttachments ()
```

Description

Use the ClearAttachments method to clear all attachments. If you want to delete a particular attachment, use DeleteAttachment instead.

Parameters

None.

Returns

None.

Related Links

[AddAttachment](#)

[DeleteAttachment](#)

ClearAttributes

Syntax

```
ClearAttributes ()
```

Description

Use this method to delete all attributes from an IBInfo object.

Note: This method can be used for content-based routing only, typically in your implementation of the `IRouter.OnRouteSend` or `IRouter.OnRouteReceive` methods.

Parameters

None.

Returns

None.

Example

```
&MSG.IBInfo.ClearAttributes ();
```

DeleteAEAtribute

Syntax

```
DeleteAEAtribute(Name)
```

Description

Use this method to delete the Application Engine handler attribute specified by attribute name from the Message object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the attribute as a string.

Returns

A Boolean value: True if the deletion was successful, False otherwise.

Related Links

[AddAEAtribute](#)

[ClearAEAtributes](#)

[GetAEAtributeName](#)

DeleteAttachment

Syntax

```
DeleteAttachment(Index | Content_ID)
```

Description

Use the DeleteAttachment method to remove the specified attachment from the message. You can either specify the number of the attachment, or the content ID associated with the attachment (generated when the attachment was added to the message with AddAttachment.)

If you want to clear all attachments, instead of a particular one, use the ClearAttachments methods instead.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i> <i>Content_ID</i>	Specify either the number of the attachment, or the content ID associated with the attachment, for the attachment you want to delete.

Returns

A Boolean value: true if the attachment was deleted successfully, false otherwise.

Related Links

[AddAttachment](#)

[ClearAttachments](#)

DeleteAttribute

Syntax

```
DeleteAttribute(name)
```

Description

Use this method to delete an attribute from an IBInfo object by specifying the attribute's name as a string.

Note: This method can be used for content-based routing only, typically in your implementation of the IRouter.OnRouteSend or IRouter.OnRouteReceive methods.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>name</i>	Specifies the attribute by name as a string.

Returns

A Boolean value: true if the deletion of the attribute was successful, false otherwise.

Example

```
&bRet = &MSG.IBInfo.DeleteAttribute("employeeID");
```

Related Links

[Content-Based Routing](#)

[GetAttributeName](#)

DeleteContainerAttribute

Syntax

```
DeleteContainerAttribute(Name)
```

Description

Use this method to delete a container attribute based on the attribute name.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the container attribute name as a string.

Returns

A Boolean value: True if the deletion was successful, False otherwise.

Example

```
&Ret = &MSG.IBInfo.DeleteContainerAttribute("MyAttribute");
```

GetAttachmentContentID

Syntax

```
GetAttachmentContentID(Index)
```

Description

Use the GetAttachmentContentID to return the content ID for the specified attachment. The content ID is associated with an attachment when it is added to a message using AddAttachment.

You can use the content ID with other methods, such as AddAttachmentProperty and DeleteAttachment.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the number of the attachment that you want to access the content ID for.

Returns

A string containing the content ID.

Related Links

[AddAttachment](#)

[GetAttachmentProperty](#)

GetAttachmentProperty

Syntax

```
GetAttachmentProperty(Content_ID, Property_Type)
```

Description

Use the GetAttachmentProperty method to return the value of an attachment property.

Parameters

Parameter	Description
<i>Content_ID</i>	Specify the content ID of the attachment that you want to access, as a string.
<i>Property_Type</i>	Specify the type of property that you want to access. Valid values are:

Constant Value	Description
%Attachment_Base	Specifies the base name of the attachment, that is, if the actual document name you want is different, such as if it is zipped or otherwise compressed as part of other documents.
%Attachment_Description	Specifies the description of the attachment.
%Attachment_Disposition	Specifies the disposition of the attachment, whether it's displayed inline or as an attachment.
%Attachment_Encoding	Specify the encoding of the attachment. For example, Content-type: text/plain or charset=Big5.
%Attachment_Language	Specify the language used in the attachment, as a string.
%Attachment_Location	Specify an additional location for the attachment.
%Attachment_Type	Specify the attachment type.
%Attachment_URL	Specifies the URL for the attachment. The URL must be an absolute URL.

Returns

A string containing the value of the specified property.

Example

The following example processes an attachment from a notification PeopleCode program:

```

import PS_PT:Integration:INotificationHandler;

class FLIGHTPROFILE implements PS_PT:Integration:INotificationHandler
    method FLIGHTPROFILE ();
    method OnNotify(&MSG As Message);
end-class;
    
```

```

/* Constructor */
method FLIGHTPROFILE
  %Super = create PS_PT:Integration:INotificationHandler();
end-method;

method OnNotify
  /+ &MSG as Message +/
  /+ Extends/implements PS_PT:Integration:INotificationHandler.OnNotify +/

Local rowset &RS;
Local integer &Count;
Local string &Attachment_Id;
Local array of array of string &Result;

&RS = &MSG.GetRowset();

&Count = &MSG.IBInfo.NumberOfAttachments;
If &Count > 0 Then

  For &I = 1 to &Count
    &Attachment_ID = &MSG.IBInfo.GetAttachmentContentID(&I);
    &Result[&I][1] = &MSG.IBInfo.GetAttachmentProperty(&Attachment_Id, %Attachmen=>
t_Encoding);
    &Result[&I][2] = &MSG.IBInfo.GetAttachmentProperty(&Attachment_Id, %Attachmen=>
t_Type);
    &Result[&I][3] = &MSG.IBInfo.GetAttachmentProperty(&Attachment_Id, %Attachmen=>
t_URL);
    &Result[&I][4] = &MSG.IBInfo.GetAttachmentProperty(&Attachment_Id, %Attachmen=>
t_Base);
    &Result[&I][5] = &MSG.IBInfo.GetAttachmentProperty(&Attachment_Id, %Attachmen=>
t_Location);
    &Result[&I][6] = &MSG.IBInfo.GetAttachmentProperty(&Attachment_Id, %Attachmen=>
t_Disposition);
    &Result[&I][7] = &MSG.IBInfo.GetAttachmentProperty(&Attachment_Id, %Attachmen=>
t_Description);

    End-For;
  End-if;

/* process data from message */
end-method;

```

GetAttributeName

Syntax

GetAttributeName (*nIndex*)

Description

Use this method to return the attribute name for the *n*th attribute of the IBInfo object as a string.

Note: This method can be used for content-based routing only, typically in your implementation of the `IRouter.OnRouteSend` or `IRouter.OnRouteReceive` methods.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>nIndex</i>	An integer specifying which attribute in the <code>IBInfo</code> object.

Returns

A string populated with the attribute name.

Example

```
&AttrName = &MSG.IBInfo.GetAttributeName(&i);
```

GetNumberOfAttributes

Syntax

```
GetNumberOfAttributes ()
```

Description

Use this method to get the number of attributes for the `IBInfo` object as an integer.

Note: This method can be used for content-based routing only, typically in your implementation of the `IRouter.OnRouteSend` or `IRouter.OnRouteReceive` methods.

Parameters

None.

Returns

An integer representing the number of attributes for the `IBInfo` object.

Example

```
For &i = 1 To &MSG.IBInfo.GetNumberOfAttributes()  
    &AttrName = &MSG.IBInfo.GetAttributeName(&i);  
    &AttrValue = &MSG.IBInfo.GetAttributeValue(&i);  
End-For;

[GetAttributeValue](#)

GetNumberOfContainerAttributes

Syntax

```
GetNumberOfContainerAttributes()
```

Description

Use this method to return the number of container attributes in the `IBInfo` object.

Parameters

None

Returns

An integer representing the number of container attributes.

Example

```
&MSG = CreateMessage(Operation.FLIGHTPLAN);  
&ret = &MSG.IBInfo.AddContainerAttribute("MESSAGE_STATUS", "good");
```

```

&ret = &MSG.IBInfo.AddContainerAttribute("MyAttribute", "abcd");

/* When attempting to read these attributes within an IB event (OnNotify, */
/* OnRequest etc.) one must first get a part rowset, this will load up the */
/* attributes into the message object from the xml. Here is an example of */
/* how to read the attributes from a message. */

&RS = &MSG.GetPartRowset(1);
&index = &MSG.IBInfo.GetNumberOfContainerAttributes();

For &i = 1 To &index

    &attrName = &MSG.IBInfo.GetContainerAttributeName(&i);
    &attrValue = &MSG.IBInfo.GetContainerAttributeValue(&i);

End-For;

```

GetTransactionIDforAE

Syntax

```
GetTransactionIDforAE()
```

Description

Use this method to get the transaction ID from within Application Engine program.

Parameters

None.

Returns

A number representing the transaction ID from within Application Engine program.

Related Links

[AddAEAtribute](#)

InsertAEResponseAttributes

Syntax

```
InsertAEResponseAttributes()
```

Description

Use this method to save and transfer the Application Engine handler attributes to be read by the response application class.

Parameters

None.

Returns

A Boolean value: True if the save and insertion were successful, False otherwise.

Related Links

[AddAEAtribute](#)

LoadConnectorProp

Syntax

```
LoadConnectorProp (ConnectorName)
```

Description

Use the LoadConnectorProp method to load connector properties to the specified connector. The properties are contained in the message executing the method.

Note: Use this method in the message OnSend event.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ConnectorName</i>	Specify the name of the connector that you want to load properties for from the message.

Returns

A Boolean value: true if properties are loaded successfully, false otherwise.

Example

```
LOCAL MESSAGE &MSG;
&MSG = %IntBroker.GetMessage();
&Rowset = &MSG.GetRowset();
&MSG.IBInfo.LoadConnectorProp("HTTP TargetConnector");
/* add connector properties */
&MSG.IBInfo.ConnectorOverride= true;
ReturnToServer (&MSG);
```

Related Links

[ConnectorOverride](#)

"ReturnToServer" (PeopleCode Language Reference)

LoadConnectorPropFromNode

Syntax

`LoadConnectorPropFromNode (NodeName)`

Description

Use the LoadConnectorPropFromNode method to load connector properties into the message executing the method. Then you can use the LoadConnectorProp method to load the specified connector with the properties.

Note: Use this method in the message OnSend event.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the node that contains the connector properties you want to use. You can either specify the node name as a string, or prefix the node name with the reserved word Node .

Returns

A Boolean value: true if the properties are loaded successfully, false otherwise.

Related Links

[ConnectorOverride](#)

"ReturnToServer" (PeopleCode Language Reference)

LoadConnectorPropFromRouting

Syntax

`LoadConnectorPropFromRouting (RoutingDefnName)`

Description

Use the LoadConnectorPropFromRouting method to load connector properties into the message executing the method. Then you can use the LoadConnectorProp method to load the specified connector with the properties.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RoutingDefnName</i>	Specify the routing definition name that contains the connector properties you want to use, as a string.

Returns

A Boolean value: true if the method completes successfully, false otherwise.

Related Links

[LoadConnectorProp](#)

[LoadConnectorPropFromNode](#)

LoadConnectorPropFromTrx

Syntax

```
LoadConnectorPropFromTrx(NodeName, TransactionType, MsgName, MsgVersion)
```

Description

Note: This method is no longer supported.

LoadRESTHeaders

Syntax

```
LoadRESTHeaders ()
```

Description

Use this method to load the headers defined on the appropriate routing for a REST-based service operation. Once loaded, the headers can be modified without specifying the connector override property.

The LoadRESTHeaders method is simply a way to pre-load the headers that you have defined on the Service Operation via the Routing Header Properties tab. Any response or request headers from a third party simply need to read those off the IBCConnectorInfo object.

Parameters

None.

Returns

A Boolean value: True if the method executed successfully, False otherwise.

Note: The connector override property does not need to be set when using LoadRESTHeaders.

Example

The following example demonstrates how you can modify HTTP headers through PeopleCode. In this example, the request on the subscribing node (the consumer) is modified.

Note: No HTTP properties are currently applicable for REST and will be removed by Integration Broker.

```
&request = CreateMessage(Operation.MAPS_GET);

&bRet = &request.IBInfo.LoadRESTHeaders();

/* Add any additional headers not defined on the routing */
&bRet = &request.IBInfo.IBConnectorInfo.AddConnectorProperties("Content-Language", =>
"eng", %HTTPHeader);
```

The following example demonstrates how you can add HTTP headers to a REST-based service operation response within an OnRequest event:

```
&response = CreateMessage(Operation.WEATHERSTATION_GET, %IntBroker_Response);

&bRet = &response.IBInfo.LoadRESTHeaders();

/* Add or modify additional headers not defined on the routing */
&bRet = &response.IBInfo.IBConnectorInfo.AddConnectorProperties("Content-Language", =>
"eng", %HTTPHeader);

Return &response;
```

Related Links

[ConnectorOverride](#)

SetAttachmentProperty

Syntax

```
SetAttachmentProperty(Content_ID, Property_Type, Value)
```

Description

Use the SetAttachmentProperty to specify the value and type of a property associated with an attachment.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Content_ID</i>	Specify the content ID associated with the attachment.
<i>Property_Type</i>	Specify the type of property. See below for the valid values.

Parameter	Description
<i>Value</i>	Specify the value associated with this property.

For the *Property_Type* parameter, the valid values are:

Constant Value	Description
%Attachment_Encoding	Specify the encoding type.
%Attachment_Type	Specify the attachment type.
%Attachment_URL	Specifies the URL for the attachment. The URL must be an absolute URL.
%Attachment_Base	Specify the attachment base.
%Attachment_Location	Specify an additional location for the attachment.
%Attachment_Disposition	Specifies the disposition of the attachment, whether it's displayed inline or as an attachment.
%Attachment_Description	Specifies the description of the attachment.

Returns

A Boolean value: true if the property is set successfully, false otherwise.

Example

The following example shows sending an attachment with an asynchronous message:

```
Local Message &MSG;
Local Rowset &FLIGHT_PROFILE;
Local String &Attachment_Id;
Local Boolean &Test;
Local IntBroker &IntBroker;

QE_FLIGHTDATA.QE_ACNUMBER.Value = QE_FLIGHTDATA.QE_ACNUMBER + 1;

&FLIGHT_PROFILE = GetLevel0();

&MSG = CreateMessage(Operation.ASYNC_RR);

&Attachment_Id = &MSG.IBInfo.AddAttachment("C:\\temp\\MyFile.txt");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Encoding, "UT⇒
F-8");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Base, "Standa⇒
rd");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Disposition, ⇒
```

```

"Pending");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Language, "English");
&Test = &MSG.IBInfo.SetAttachmentProperty(&Attachment_Id, %Attachment_Description, =>
"Parts data");

&MSG.CopyRowset (&FLIGHT_PROFILE);

&IntBroker = %IntBroker
&IntBroker.Publish (&MSG);
    
```

[GetAttachmentProperty](#)

IBInfo Class Properties

In this section, we discuss the IBInfo class properties. The properties are discussed in alphabetical order.

Important! Depending on the type of transaction and how it is executed by Integration Broker, certain properties may or may not be set on the IBInfo object. To determine which properties are available on the IBInfo object, check the Service Monitor first. If the information is not available there, it will not be available in the IBInfo object.

AppServerDomain

Description

This property can be used to set the application server domain for the connector, as a string.

This property is read/write.

CompressionOverride

Description

This property can be used to set a compression override for the transaction. This property takes three system constants to set the compression override:

<i>Constant Value</i>	<i>Description</i>
%IntBroker_Compress	Turns compression on for this transaction.
%IntBroker_UnCompress	Turns compression off for this transaction.

Constant Value	Description
%IntBroker_Compress_Reset	Resets compression to use the threshold specified by PSADMIN.

The integration engine compresses and base64-encodes messages destined for the PeopleSoft listening connector on its local integration gateway.

Asynchronous messages are always compressed and base64 encoded when sent to the integration gateway.

For synchronous messages, in PSADMIN you can set a threshold message size above which messages are compressed. With the CompressionOverride property, you can override the message compression setting specified in PSADMIN at the transaction level.

Warning! Turning compression off can negatively impact system performance when transporting synchronous messages greater than 1 MB. As a result, you should turn off compression only during integration development and testing.

Note: This property does not affect the compression of messages that the integration gateway sends using its target connectors.

This property is read/write.

Example

```
&MSG.IBInfo.CompressionOverride = %IntBroker_UnCompress;
```

ConnectorOverride

Description

This property specifies whether the connector override is specified for the transaction. This property takes a Boolean value: true, override the connector properties, false otherwise.

For REST-based service operations, the LoadRESTHeaders method can be used without the need to explicitly set this property.

This property is read/write.

Related Links

[LoadRESTHeaders](#)

ConversationID

Description

This property returns the conversation ID associated with the request/response message transaction.

This property is read/write.

DeliveryMode

Description

This property sets or returns the delivery mode override for the connector as an integer. This property takes one of three system constants to set the delivery mode override:

<i>Constant Value</i>	<i>Description</i>
%IB_DM_BestEffort	Sets the delivery mode to best effort. If the delivery mode is set to best effort, then only one attempt is made to send the message to the destination; there is no attempt to retry the message.
%IB_DM_Guarantee	Sets the delivery mode to guaranteed. This mode automatically invokes retry logic to ensure that the message is successfully sent to a destination. This is the default delivery mode.
%IB_DM_Reset	Resets the delivery mode to the value defined outside the PeopleCode program.

This property is read/write.

Example

```
&int = &MSG.IBInfo.DeliveryMode = %IB_DM_BestEffort;
```

DestinationNode

Description

This property returns the name of the destination node that the request was sent to, as a string.

This property is read-only.

ExternalMessageID

Description

This property returns the external ID of the message. This property is used in testing, and to resolve duplicate message issues from third-party systems.

This property is read-only.

Example

```
&str = &MSG.IBInfo.ExternalMessageID;
```

ExternalOperationName

Description

This property returns the external operation name of the message. This property is used in testing, and to resolve duplicate message issues from third-party systems.

This property is read/write.

ExternalUserName

Description

This property returns the external user name associated with the message. This property is used in testing, and to resolve duplicate message issues from third-party systems.

This property is read/write.

ExternalUserPassword

Description

This property returns the external user password associated with the message. This property is used in testing, and to resolve duplicate message issues from third-party systems.

This property is read/write.

FinalDestinationNode

Description

When the message is passed across several nodes, this property specifies the ultimate target of the message, as a string.

This property is read-only.

FuturePublicationDateTime

Description

Use this property to specify when, as a DateTime value, an actual publish of the transaction is to occur.

This property is for use with asynchronous transactions. If a null value or an invalid future date and time is specified, the publish will occur immediately.

This property is read/write.

HTTPSessionId

Description

Use the HTTPSessionId property to specify the HTTP session ID, as a string.

This property is read/write.

IBConnectorInfo

Description

This property returns a reference to a IBConnectorInfo collection object.

This property is read-only.

InReplyToID

Description

Use the InReplyToID property to specify the reply to ID contained in the message.

This property is read/write.

MessageChannel

Description

This property references the name of the channel associated with the message definition, as a string.

Note: This property has been deprecated and remains for backward compatibility only. Use the IBInfo class MessageQueue property instead.

This property is set in when the message is created.

This property is read-only.

Related Links

[ChannelName](#)

[MessageQueue](#)

MessageName

Description

This property returns the name of the message, as a string.

This property is read-only.

Related Links

[Name](#)

MessageQueue

Description

This property returns the name of the queue associated with the message, as a string.

This property is read-only.

MessageType

Description

This property returns the type of the message, as a string.

Note: This property has been deprecated and remains for backward compatibility only. Use the `IBInfo` class `OperationType` property instead.

See [OperationType](#).

Valid types are:

<i>Value</i>	<i>Description</i>
Sync	Indicates that the message is synchronous.
Async	Indicates that the message is asynchronous.
Ping	Indicates that the message is used to test the application server to make sure it is available and accepting requests.

This property is read-only.

MessageVersion

Description

This property returns the message version as a number.

This property is read-only.

NodeDN

Description

For incoming requests, this property gives the distinguished name (DN) extracted from the certificate authentication process, as a string.

This property is read/write.

NonRepudiationID

Description

This property returns the non-repudiation ID as a string. This property is populated with a unique string when the message is published.

This property is only valid with messages that use non-repudiation.

This property is read-only.

Related Links

"Implementing Nonrepudiation" (Integration Broker Administration)

NumberOfAttachments

Description

This property returns the number of attachments associated with a message.

This property is read-only.

Related Links

[AddAttachment](#)

OperationType

Description

This property returns the type of the operation, as a string.

This property is read-only.

OperationVersion

Description

This property returns the version of the operation, as a string.

This property is read-only.

OrigNode

Description

For requests that cross multiple nodes, this property identifies the node that initiated the request as a string.

The OrigNode property returns the originating node of the message. If the message is not going across nodes, the OrigNode and SourceNode properties return the same value. However, if the message is going across nodes, the source node is the node that most recently published the message.

For example, if A publishes to B, then B publishes the message to C, from C's perspective, A is the original node and B is the source node.

This property is read-only.

Related Links

[SourceNode](#)

OrigProcess

Description

This property returns the name of the process where the publish originated, as a string. For example, a message published from the Inventory definitions page would have a process name of INVENTORY DEFIN.

This property is read-only.

OrigTimeStamp

Description

This property returns the time stamp that corresponds to the time that the request was created, as a string. For requests that cross nodes, this is the time that the first request was created.

This property is read-only.

OrigUser

Description

This property returns the user ID login where the message was initially generated, as a string.

This property is read-only.

PublicationID

Description

This property returns the unique identifier for the message, as a string.

Note: This property has been deprecated. It is no longer supported.

RequestingNodeName

Description

This property returns the name of the node making the request, as a string.

This property is read/write.

RequestingNodeDescription

Description

This property returns the description of the node making the request, as a string.

This property is read/write.

ResponseAsAttachment

Description

Use the ResponseAsAttachment property to specify whether the response should be returned as an attachment or inline.

This property is read/write.

SegmentsUnOrder

Description

The SegmentUnOrder property is only applicable for asynchronous messages. If you specify the SegmentUnOrder property as true, the receiving node processes the segments in parallel.

This property is read/write.

Related Links

[SegmentsByDatabase](#)

[Message Segments](#)

SourceNode

Description

This property returns the name of the publishing node as a string.

The OrigNode property returns the originating node of the message. If the message is not going across nodes, the OrigNode and SourceNode properties return the same value. However, if the message is going across nodes, the source node is the node that most recently published the message.

For example, if A publishes to B, then B publishes the message to C, from C's perspective, A is the original node and B is the source node.

This property is read-only.

Related Links

[OrigNode](#)

SyncServiceTimeout

Description

This property takes a time (in seconds). This time overrides the default HTTP timeout that is used for all requests. If you set this property, you can use this to read back the time, that is, set the time before the SyncRequest is executed, then see when it is changed in an implementation of the OnSend method.

Note: This property is only for synchronous requests.

Generally, you use SyncServiceTimeout to dynamically set the timeout value for a specific transaction. The http header file is modified to take this new parameter. In addition this value is sent to the gateway to be used for the http timeout. Use this so that a long running transaction will not timeout. In addition, you don't have to wait through the default period for a specific transaction to timeout.

The following is a typical example of using this property:

```
&MSG.SetXmlDoc (&xmlReq) ;
&MSG.IBInfo.LoadConnectorPropFromNode (Node.EAI)
&MSG.IBInfo.SyncServiceTimeout = 360000;
&MSG.IBInfo.ConnectorOverride = true;
&MSG.Resp = SyncRequest (&MSG, Node.EAI);
&xmlResponseDoc = &MSG.GetXmlDoc ();
```

Setting the XML directly is not valid. You need to use the message object to set the value. In order for this to work you must override the connector properties, which means you must set up the connector

properties for this transaction, using one of the load methods (such as `LoadConnectorPropFromNode`, `LoadConnectorPropFromTrx`, and so on.)

This property is read/write.

TransactionID

Description

This property returns the transaction ID as a string. This is used to uniquely identify a request.

This property is read-only.

UserName

Description

This property returns the user name associated with the message, as a string.

This property is read-only.

VisitedNodes

Description

This property returns an array of string containing the names of all the nodes visited by the message. This is useful when a message is being propagated across multiple nodes.

This property is read-only.

WSA_Action

Description

Use this property to specify the Web Services Addressing (WS-Addressing) action for the message. The WS-Addressing action is defined as a string.

This property is read/write.

WSA_FaultTo

Description

Use this property to specify the WS-Addressing fault end point for the message. The WS-Addressing fault end point is defined as a string.

If this property is not null, a message ID (the `WSA_MessageID` property) must also be defined.

This property is read/write.

WSA_MessageID

Description

Use this property to specify the WS-Addressing message ID for the message. The WS-Addressing message ID is defined as a string.

This property is read/write.

WSA_ReplyTo

Description

Use this property to specify the WS-Addressing reply-to address for the message. The WS-Addressing reply-to address is defined as a string.

This property is read/write.

WSA_To

Description

Use this property to specify the WS-Addressing destination for the message. The WS-Addressing destination is defined as a string.

This property is read/write.

IBConnectorInfo Collection

A IBConnectorInfo collection object is returned from the IBConnectorInfo IBInfo class property.

IBConnectorInfo Collection Methods

In this section, we discuss the IBConnectorInfo collection methods. The methods are discussed in alphabetical order.

AddConnectorProperties

Syntax

`AddConnectorProperties` (*Name*, *Value*, *Type*)

Description

Use the AddConnectorProperties method to add a set of connector properties to a connector.

Parameters

Parameter	Description
<i>Name</i>	Specify the name of the property as a string.
<i>Value</i>	Specify the value of the property as a string.
<i>Type</i>	Specify the type of the property as a string. The valid values are:

Constant Value	Description
%Property	Add a property type property.
%Header	Add a header type property.

Returns

A Boolean value: true if the connector properties are added successfully, false otherwise.

Example

The following are examples of typical name/value pairs.

```
&b1 = &MSG.IBInfo.IBConnectorInfo.AddConnectorProperties("URL", "http://finance.yahoo.com/d/quotes.txt/?symbols=PSFT&format=llcldl1", %Property);
```

```
&b2 = &MSG.IBInfo.IBConnectorInfo.AddConnectorProperties("sendUncompressed", "Y", %Header);
```

```
&b3 = &MSG.IBInfo.IBConnectorInfo.AddConnectorProperties("FilePath", "C:\Temp", %Property);
```

The following example demonstrates setting a passive connection for the FTP target connector:

```
&b4 = &MSG.IBInfo.IBConnectorInfo.AddConnectorProperties ("FTPMODE", "PASSIVE", %Property);
```

```
operty);
```

AddQueryStringArg

Syntax

```
AddQueryStringArg (Name, Value)
```

Description

Use the AddQueryStringArg method to add query string arguments to the outbound request. The query string arguments are used by the HTTP connector to step parameters in the URL.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the query string argument as a string.
<i>Value</i>	Specify the value for the query string argument as a string.

Returns

A Boolean value: true if the query string argument is added successfully, false otherwise.

[AddConnectorProperties](#)

[DeleteConnectorProperties](#)

ClearQueryStringArgs

Syntax

```
ClearQueryStringArgs ()
```

Description

Use the ClearQueryStringArgs method to clear all of the existing query string arguments.

Use the DeleteQueryStringArg method if you want to remove a specific query string argument.

Parameters

None.

Returns

None.

Related Links

[DeleteQueryStringArg](#)

DeleteConnectorProperties

Syntax

```
DeleteConectorProperties (Name)
```

Description

Use the DeleteConnectorProperties to delete a specific connector property.

Use the ClearConnectorProperties method to remove all the properties.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the connector property you want to delete.

Returns

A Boolean value: true if the property is deleted successfully, false otherwise.

Related Links

[ClearConnectorProperties](#)

DeleteQueryStringArg

Syntax

`DeleteQueryStringArg` (*Name*)

Description

Use the `DeleteQueryStringArg` method to delete a specific query string argument.

Use the `ClearQueryStringArg` method to delete all of the query string arguments.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the query string argument that you want to delete.

Returns

A Boolean value: true if the query string argument is deleted successfully, false otherwise.

Related Links

[ClearQueryStringArgs](#)

GetConnectorPropertiesName

Syntax

`GetConnectorPropertiesName` (*Index*)

Description

Use the `GetConnectorPropertiesName` to return the name of the connector property in the numeric position specified by *Index*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the numeric position of the connector property name that you want to access.

Returns

A string containing the name of a connector property.

Example

```
For &I = 1 to &Msg.IBInfo.IBConnectorInfo.GetNumberOfConnectorProperties();
    &PropName = &Msg.IBInfo.IBConnectorInfo.GetConnectorPropertiesName(&I)
    /* do processing */
End-For;
```

GetConnectorPropertiesType

Syntax

```
GetConnectorPropertiesType (Index)
```

Description

Use the `GetConnectorPropertiesType` method to return the type of the connector property specified by its numeric position by *Index*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the numeric position of the connector property type that you want to access.

Returns

A string containing the type of the specified connector.

GetConnectorPropertiesValue

Syntax

```
GetConnectorPropertiesValue (Index)
```

Description

Use the GetConnectorPropertiesValue method to return the value of the connector property specified by its numeric position by *Index*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the numeric position of the connector property type that you want to access.

Returns

A string containing the value of the specified connector.

GetNumberOfConnectorProperties

Syntax

```
GetNumberOfConnectorProperties ()
```

Description

Use the GetNumberOfConnectorProperties method to determine the number of connector properties.

Parameters

None.

Returns

A number.

GetNumberOfQueryStringArgs

Syntax

```
GetNumberOfQueryStringArgs ()
```

Description

Use the `GetNumberOfQueryStringArgs` method to determine the number of query string arguments.

Parameters

None.

Returns

A number.

GetQueryStringArgName

Syntax

```
GetQueryStringArgName (Index)
```

Description

Use the `GetQueryStringArgName` method to access the name of the query string argument by its numeric position as specified by *Index*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the numeric position of the query string argument name that you want to access.

Returns

A string containing the name of a query string argument.

GetQueryStringArgValue

Syntax

```
GetQueryStringArgValue (Index)
```

Description

Use the `GetQueryStringArgValue` method to access the value of the query string argument by its numeric position as specified by *Index*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the numeric position of the query string argument value that you want to access.

Returns

A string containing the value of a query string argument.

IBConnectorInfo Collection Properties

In this section, we discuss the IBConnectorInfo collection properties. The properties are discussed in alphabetical order.

ConnectorClassName

Description

Use this property to identify the name of the target connector to invoke as a string.

This property is read/write.

ConnectorName

Description

Use this property to identify the target connector to invoke to send to the message, as a string.

This property is read/write.

Cookies

Description

Use this property to access the cookies associated with a message.

You can accept a synchronous response message containing cookies, save those cookies in a global variable, and later return them to the target node in an outbound synchronous or asynchronous request message.

You can access this property only in an inbound synchronous response message or an outbound request message.

This property is read/write.

Example

The following example retains the cookies from a response message to a global variable:

```
Local Message &SalesRequest, &SalesResponse;
Local Rowset &SALES_ORDER;
Global string &SalesCookies;

&SALES_ORDER = GetLevel0();
&SalesRequest = CreateMessage(OPERATION.SALES_ORDER_SYNC);
&SalesRequest.CopyRowsetDelta(&SALES_ORDER);

/* Send the synchronous request; the return value is the response
message object */
&SalesResponse = &SalesRequest.SyncRequest();

/* Retrieve cookies from the response message */
&SalesCookies = &SalesResponse.IBInfo.IBConnectorInfo.Cookies;
```

The following example retrieves the previously retained cookies from the global variable and inserts them into a new request message:

```
Local Message &SalesRequest, &SalesResponse;
Local Rowset &SALES_ORDER;
Global string &SalesCookies;

&SALES_ORDER = GetLevel0();
&SalesRequest = CreateMessage(Message.SALES_ORDER_SYNC);
&SalesRequest.CopyRowsetDelta(&SALES_ORDER);

/* Insert the cookies in the request message */
&SalesRequest.IBInfo.IBConnectorInfo.Cookies = &SalesCookies;

/* Send the asynchronous request */
%IntBroker.Publish(&SalesRequest);
```

PathInfo

Description

This property is specific to incoming HTTP requests. This is the path information extracted from the request, represented as a string.

This property is read/write.

RemoteFrameworkURL

Description

Use this property to identify the URL to which to send a message, as a string. This value overrides the server URL specified in the Project Definitions section.

This property is read/write.

Optimization PeopleCode

Using Optimization PeopleCode on the Application Server

While running optimization PeopleCode on the application server, ensure that changed data is committed to the database before calling the CreateOptEngine optimization function and the following OptEngine class methods:

- RunSynch
- RunAsynch
- CheckOptEngineStatus
- ShutDown
- SetTraceLevel
- GetTraceLevel
- InsertOptProbInst
- DeleteOptProbInst

Note: The PeopleCode functions CommitWork and DoSaveNow can be called within a step to save uncommitted data to the database before calling the listed functions and methods. Keep in mind that forcing a commit on pending database updates is a serious step; it prevents roll-back on error. CreateOptEngine, ShutDown, InsertOptProbInst, and DeleteOptProbInst calls modify the database, so take care when terminating the Application Engine program without committing the changes made by those calls.

Using Optimization PeopleCode in an Application Engine Program

When you write an optimization PeopleCode program in an Application Engine program and you schedule it in PeopleSoft Process Scheduler, you must set the process definition with a process type of *Optimization Engine*. Other process types do not allow optimization PeopleCode in Application Engine programs.

While using optimization PeopleCode in Application Engine programs, make sure data is committed before calling the CreateOptEngine optimization function and the following OptEngine class methods:

- RunSynch
- RunAsynch
- CheckOptEngineStatus

- ShutDown
- SetTraceLevel
- GetTraceLevel
- InsertOptProbInst
- DeleteOptProbInst

Note: You can call the PeopleCode functions CommitWork and DoSaveNow within a step to save uncommitted data to the database before calling the listed functions and class methods. Keep in mind that forcing a commit on pending database updates is a serious step; it prevents roll-back on error. CreateOptEngine, ShutDown, InsertOptProbInst, and DeleteOptProbInst calls modify the database, so take care when terminating the Application Engine program without committing the changes made by those calls.

Performing Optimization in PeopleCode

This section discusses how to perform optimization in PeopleCode using analytic instances.

Important! The optimization PeopleCode classes are not supported on IBM z/OS and Linux for IBM System z platforms.

Creating New Analytic Instances

To create a new analytic instance for an analytic type:

1. Call the function InsertOptProbInst with the analytic type and analytic instance as parameters to create an analytic instance ID.
2. Use Application Engine or a similar mechanism to load the optimization application tables with data.

Use the analytic instance ID as the key value in scenario-managed optimization application tables.

The analytic instance is now ready to be loaded into an analytic server.

Note: You can load multiple copies of the same analytic instance into multiple instances of an analytic server, provided that each instance of the analytic server resides in a different application server domain. Each analytic instance loaded into a given domain must be unique. Within a given domain, you cannot have the same analytic instance in more than one analytic server. The analytic server maintains data integrity by checking to see if the data has been altered by another user (refer to the steps in the optimization system architecture description). Try to maintain data consistency when the same analytic instance uses the same database in different domains.

Related Links

"PeopleSoft Optimization Framework System Architecture" (Optimization Framework)

[InsertOptProbInst](#)

Loading Analytic Instances Into an Analytic Server

Use the `CreateOptEngine` function to load an analytic server with an analytic instance. It takes analytic instance ID and a mode parameter with `%Synch` and `%Asynch` as possible values and returns a PeopleCode object of type `OptEngine`.

You can run the PeopleCode on the application server or from Application Engine.

Loading Analytic Instances by Running PeopleCode on the Application Server

To block PeopleCode from running on the application server until the load is done (synchronous mode), use the `%Synch` value for the mode parameter. An error is generated if the load isn't successful. The application server imposes a timeout beyond which the PeopleCode and optimization engine load are terminated. Here is a code example:

```
Local OptEngine &myopt;
&myopt = CreateOptEngine("PATSMITH", %Synch);
```

To load the analytic server without blocking the PeopleCode from running (asynchronous mode) on the application server, use the `%Asynch` value for the mode parameter. The analytic server performs a preliminary check of the load request and returns the `OptEngine` object if it is successful or an error if it is unsuccessful. A successful return does not mean that the load was successful. You must then use repeated `CheckOptEngineStatus` methods on the returned `OptEngine` object to determine whether the analytic engine is done with the load and whether it was successful. Here is a code example:

```
Local OptEngine &myopt;
&myopt = CreateOptEngine("PATSMITH", %Asynch);
```

Loading Analytic Instances by Running PeopleCode in Application Engine

Both synchronous (`%Synch`) and asynchronous (`%Asynch`) modes block the PeopleCode from running on Application Engine until the load is done. Use only `%Asynch` while loading an optimization engine.

The absolute number of optimization engine instances that may be loaded in a given domain is governed by a configuration file loaded by Tuxedo during its domain startup.

Related Links

[CheckOptEngineStatus](#)

Running Optimization Transactions

You send an optimization transaction to the optimization engine using the `RunSynch` and `RunAsynch` methods. Both are methods on an `OptEngine` object. The `OptEngine` object can be created either by calling `CreateOptEngine` (if the optimization engine is not loaded already) or by calling `GetOptEngine` (if the optimization engine is already loaded). Both `RunSynch` and `RunAsynch` have the same signature, except that `RunSynch` runs the optimization transaction in synchronous mode and `RunAsynch` runs it in asynchronous mode. Both return an integer status code. You can run transactions either on the application server or with Application Engine.

To invoke an optimization transaction:

1. Use the `GetOptEngine` function to get the `OptEngine` object as a handle for the optimization engine that has loaded an analytic instance ID.

Use the `CreateOptEngine` function to create the `OptEngine` object for a new optimization engine if the analytic instance has not been loaded.

2. Call `RunSynch` or `RunAsynch` to send an optimization transaction to the optimization engine to be run in synchronous or asynchronous mode.
3. If the transaction is run in synchronous mode (`RunSynch`), use the `OptEngine` methods `GetString`, `GetNumber`, and so on, to retrieve the output result from the optimization transaction.

The transaction names, parameter names, and data types are viewable in the analytic type in Application Designer.

4. If the transaction is run in asynchronous mode, use the `OptEngine` method `CheckOptEngineStatus` to check the status of the optimization transaction in the optimization engine.

After the transaction is done, result data is available in the database for retrieval using standard PeopleCode mechanisms.

Running Optimization Transactions from the Application Server

To block the PeopleCode from running on the application server until the optimization transaction is done (synchronous mode) and receives the results, use `RunSynch` to send an optimization transaction. An error status code is returned if the transaction isn't successful. If successful, you can use other methods to retrieve the results from the transaction call. The application server imposes a timeout beyond which the PeopleCode and optimization engine transaction are terminated.

To run a transaction without blocking PeopleCode from running (asynchronous mode) on the application server, use `RunAsynch` to send an optimization transaction. In this mode, the optimization engine performs a preliminary check of the transaction request and returns a success or failure status code. A successful return does not mean that the transaction is successful; it means only that the syntax is correct. You must then use repeated calls to the `CheckOptEngineStatus` method on the `OptEngine` object to determine whether the optimization engine is done with the transaction and whether it is successful.

`RunAsynch` does not allow transaction output results to be returned. Use this method for long-running transactions that return results entirely through the database.

Running Optimization Transactions from Application Engine

Both synchronous (`RunSynch`) and asynchronous (`RunAsynch`) methods block the PeopleCode from running on Application Engine until the optimization transaction is done. `RunSynch` allows output results to be returned, but it should be used for transactions that are fast (less than 10 seconds). `RunAsynch` does not have a time limit, but it does not return output results.

Related Links

[RunAsynch](#)

Invoking the Optimization PeopleCode Plug-In

If you're developing an optimization application that uses the Optimization PeopleCode plug-in, you must do the following to invoke the plug-in:

- Develop a PeopleCode application class that extends the `PT_OPT_BASE:OptBase` class.

- Define methods in your application class that use the PeopleCode OptInterface class to perform your optimization functions.
- Define an analytic type that specifies the Optimization PeopleCode plug-in, by selecting the **PeopleCode Plugin** check box in the analytic type properties.
- In the analytic type properties, specify the application package and application class that you developed.
- Define transactions in your analytic type definition that correspond to the methods you developed in your application class, with corresponding parameters.

"Creating Analytic Type Definitions" (Optimization Framework)

[CreateOptInterface](#)

[OptBase Application Class](#)

[OptInterface Class Methods](#)

Shutting Down Optimization Engines

Use the GetOptEngine function to get the OptEngine object as a handle for the optimization engine that loaded an analytic instance ID.

Use the OptEngine method named ShutDown to shut down the optimization engine. This ends the optimization engine process with the current analytic instance ID. Based on application server settings, the system restarts a new, unloaded optimization engine process that can be loaded with any other analytic instance.

Related Links

[ShutDown](#)

Deleting Existing Analytic Instances

To delete an existing analytic instance for an analytic type:

1. Shut down any optimization engines that have this analytic instance currently loaded.
2. Using Application Engine or a similar mechanism, delete the data in the optimization application tables pertaining to that analytic instance.

Use the analytic instance ID as the key value to find and delete analytic instance rows from scenario-managed optimization application tables.

3. Use the function DeleteOptProbInst with the analytic type and analytic instance as arguments to delete the analytic instance ID from PeopleTools metadata.

Note: If you try to delete an existing analytic instance that is loaded in a running optimization engine, DeleteOptProbInst returns *%OptEng_Fail*, and the optional status reference parameter is set to *%OptEng_Exists*.

Related Links

[DeleteOptProbInst](#)

Programming for Database Updates

You must plan for uncommitted database changes in your optimization PeopleCode. The PeopleSoft Optimization Framework detects pending database updates, and generates a failure status if data is not committed to the database before certain optimization methods are called.

This checking for database updates happens in runtime for the CreateOptEngine function and the following methods: RunSync, RunAsync, Shutdown, GetTraceLevel, and SetTraceLevel. Ensure that your PeopleCode performs proper database updates and commits before you execute these methods. If you use the optional parameter for detailed status that is available for these functions, or the DetailedStatus property that is available for the methods, you can check for the status of %OptEng_DB_Updates_Pending to see if there is a pending database update.

Note: The pending database update may have happened considerably earlier in the code. Forcing a commit within your PeopleCode to avoid this problem prevents roll-back on database error. Forcing a commit should be used with care.

The InsertOptProbInst and DeleteOptProbInst functions can be called only inside FieldChange, PreSaveChange and PostSaveChange PeopleCode events, and in Workflow.

This database update checking happens in compile time for the following functions: InsertOptProbInst and DeleteOptProbInst. Make sure that there are no pending database updates before you execute these methods.

Using Lights-Out Mode with Optimization

This section provides an overview of lights-out mode, and discusses how to create and edit messages.

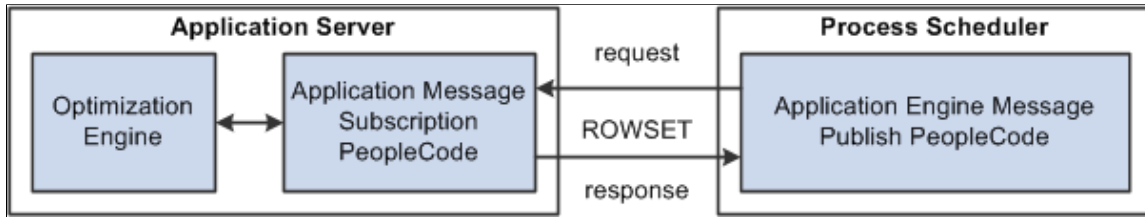

Understanding Lights-out Mode

Some optimization applications can take several hours to run. These are typically run as overnight batch jobs every night when the work load is small to regenerate the optimization solution and have it ready for end users to use in the morning hence the term *lights-out mode*.

In the current release, application messages communicate between the Application Engine batch job and the online optimization engine. After the Application Engine job completes and the optimization solution has been written to the database, an application message initiates the download of the data from the database batch job to the online optimization engine.

Lights-out mode uses an Application Engine PeopleCode program within PeopleSoft Process Scheduler to send requests to an application server and receive responses from it. Within the application server, the OnRequest PeopleCode runs an optimization engine process.

This diagram illustrates the lights-out process:

This request and response is in the form of a rowset as shown by the example supplied with optimization, the `OPT_CALL` message. Also supplied as an example is an Application Engine message publish PeopleCode program called `PT_OPTCALL`.

Important! Application Engine includes an action of type *Log Message*, which PeopleSoft Process Scheduler uses to record its activity in the `PS_MESSAGE_LOG` table. The PeopleCode `MessageBox` and `WinMessage` built-in functions also record their activity in the `PS_MESSAGE_LOG` table. During lights-out optimization, these processes can conflict with each other or with the optimization engine when one process locks a row of the table, and another process tries to access the same row. To prevent this conflict, pay close attention to where the `MessageBox` or `WinMessage` built-in functions are used in your Application Engine PeopleCode. In general, there can't be any outstanding database updates pending when communicating with the optimization engine using application messages.

The `OPT_CALL` Message

The `OPT_CALL` message is an example of what the lights-out process uses as the message for optimization. The `OPT_CALL` message has a structure using a record, `PT_OPTPARMS`, having the fields `PARMKEY` and `VALUE` which represent a name/value pair. These send requests and responses from the Application Engine PeopleCode in PeopleSoft Process Scheduler to and from the message `OnRequest` PeopleCode in the application server.

The `OPT_CALL` message also uses a record, `PT_OPTDETMSGS`, which contains the information needed for processing a detailed message.

This is an example of the Message Definition page (select **PeopleTools** > **Integration Broker** > **Integration Setup** > **Message Definitions**) showing the `OPT_CALL` message definition:

This example illustrates the fields and controls on the Message Definition page – OPT_CALL message definition. You can find definitions for the fields and controls later on this page.

The OPT_CALL message is associated with the OPT_CALL service operation. The OPT_CALL service operation defines the OPT_CALL application package as a handler. This application package implements the Integration Broker methods needed to handle any messaging PeopleCode.

Creating a Request Message

This section provides an overview of the request message and describes how to create messages that:

- Create an optimization engine.
- Check optimization engine status.
- Run an optimization engine transaction.
- Set the trace level.
- Get the trace level.
- Shutdown an optimization engine.

Understanding the Request Message

For optimization, the Application Engine PeopleCode in PeopleSoft Process Scheduler sends a request `OPT_CALL` message. The message uses rowsets built from `PT_OPTPARMS` records as the request. You can use the following rowset structures as an example of how to perform certain optimization actions, by sending them as requests from the application engine program in the process scheduler to the message notification PeopleCode in the application server.

Creating an Optimization Engine

To create an optimization engine, structure the rowset as follows, using the `PT_OPTPARMS` record. You set key values using the `PARMKEY` field, and then set a value for that key field in the `VALUE` field.

<i>PARMKEY Field</i>	<i>VALUE Field</i>
OPTCMD	<p>CREATE</p> <p>Causes the PeopleCode program implementing the Integration Broker OnRequest method to load an optimization engine. The <code>OPT_CALL</code> example executes the <code>CreateOptEngine</code> function.</p>
PROBINST	The name of the analytic instance.
PROCINSTANCE	The name of the process instance for this process scheduler job.
SYNCH	<i>Y</i> if this optimization engine load is to occur synchronously, <i>N</i> if asynchronously.

Checking Optimization Engine Status

To check optimization engine status (for example, to see when it finishes loading), structure the rowset as follows, using the `PT_OPTPARMS` record.

<i>PARMKEY Field</i>	<i>VALUE Field</i>
OPTCMD	<p>CHECK_STATUS</p> <p>Causes the PeopleCode program implementing the Integration Broker OnRequest method to check the status of an optimization engine. The <code>OPT_CALL</code> example executes the <code>CheckOptEngineStatus</code> function.</p>
PROBINST	The name of the analytic instance.

<i>PARAMKEY Field</i>	<i>VALUE Field</i>
PROCINSTANCE	The name of the process instance for this process scheduler job.

Running a Transaction

To run a transaction, structure the rowset as follows, using the PT_OPTPARMS record.

<i>PARAMKEY Field</i>	<i>VALUE Field</i>
OPTCMD	RUN Causes the PeopleCode program implementing the Integration Broker OnRequest method to run an optimization transaction. The OPT_CALL example executes the GetOptEngine method and either the RunSynch or RunAsynch method.
PROBINST	The name of the analytic instance.
PROCINSTANCE	The name of the process instance for this process scheduler job.
SYNCH	Y for a synchronous transaction, N for asynchronous.
TRANSACTION	The name of the transaction to run.
The names of one or more transaction parameters.	The value of each named transaction parameter.

Setting the Trace Level

To set a trace level, structure the rowset as follows, using the PT_OPTPARMS record.

<i>PARAMKEY Field</i>	<i>VALUE Field</i>
OPTCMD	SET_TRACE_LEVEL Causes the PeopleCode program implementing the OnRequest Integration Broker method to set the severity level at which events will be logged for an optimization engine. The OPT_CALL example executes the SetTraceLevel method.
PROBINST	The name of the analytic instance.

<i>PARAMKEY Field</i>	<i>VALUE Field</i>
PROCINSTANCE	The name of the process instance for this process scheduler job.
COMPONENT	<p>One of the following values:</p> <ul style="list-style-type: none"> • %Opt_Engine server activity of the running optimization engine. • %Opt_Utility low level elements that support the running optimization engine. • %Opt_Datacache the in-memory database cache. • %Opt_Plugin the plug-in being used for the running optimization engine.
SEVERITY_LEVEL	<p>The severity level to log.</p> <p>The following list starts with the most severe level; the level you specify includes all higher levels. For example, if you specify %Severity_Error, it logs %Severity_Fatal, %Severity_Status, and %Severity_Error messages and filters out the others.</p> <ul style="list-style-type: none"> • %Severity_Fatal • %Severity_Status • %Severity_Error • %Severity_Warn • %Severity_Info • %Severity_Trace1 • %Severity_Trace2

Getting the Trace Level

To get a trace level, structure the rowset as follows, using the PT_OPTPARMS record.

<i>PARAMKEY Field</i>	<i>VALUE Field</i>
OPTCMD	<p>GET_TRACE_LEVEL</p> <p>Causes the PeopleCode program implementing the OnRequest Integration Broker method to get the severity level at which events will be logged for an optimization engine. The OPT_CALL example executes the GetTraceLevel method.</p>
PROBINST	Set to the name of the analytic instance.
PROCINSTANCE	Set to the name of the process instance for this process scheduler job.
COMPONENT	<p>One of the following values:</p> <ul style="list-style-type: none"> • %Opt_Engine server activity of the running optimization engine. • %Opt_Utility low level elements that support the running optimization engine. • %Opt_Datacache the in-memory database cache. • %Opt_Plugin the plugin being used for the current opt engine.

Shutting Down an Optimization Engine

To shut down an optimization engine, structure the rowset as follows, using the PT_OPTPARMS record.

<i>PARAMKEY Field</i>	<i>VALUE Field</i>
OPTCMD	<p>SHUTDOWN</p> <p>Causes the PeopleCode program implementing the OnRequest Integration Broker method to shut down an optimization engine. The OPT_CALL example executes the Shutdown method.</p>
PROBINST	The name of the analytic instance.
PROCINSTANCE	The name of the process instance for this process scheduler job.

Creating a Response Message

This section provides an overview of the response message and describes how to create messages that:

- Send optimization status.
- Send a detailed message.

Understanding the Response Message

For optimization, the message PeopleCode in application server receives the request messages, performs an optimization actions, and sends response OPT_CALL messages. One message uses rowsets built from PT_OPTPARMS records, the other uses rowsets from PT_DETMSGGS records. You can use the rowset structures in the next section (Sending Optimization Status) as an example of how to send responses from the message notification PeopleCode in the application server to the application engine program in the process scheduler.

Sending Optimization Status

To send the status of the optimization functions and methods called within the PeopleCode program implementing the OnRequest Integration Broker method, structure the rowset as follows using the PT_OPTPARMS record. The optimization functions and messages are called in response to the request input message. You set key values using the PARMKEY field, and then set a value for that key field in the VALUE field.

<i>PARMKEY Field</i>	<i>VALUE Field</i>
STATUS	The return status of the optimization function or method that is called in the message PeopleCode.
DETAILED_STATUS	The optional detailed status returned by many of the optimization functions and methods.

Sending a Detailed Message

To send a detailed message, structure the rowset as follows, using the PT_DETMSGGS record. You set key values using the PARMKEY field, and then set a value for that key field in the VALUE field.

<i>PARMKEY Field</i>	<i>VALUE Field</i>
MSGSET	The message set number. In the case of optimization, the message set number is 148.
MSGNUM	The name of the detailed message.
PARMCOUNT	The number of message parameters for the detailed message. There can be up to five parameters.

<i>PARAMKEY Field</i>	<i>VALUE Field</i>
MSGPARAM1	The first parameter value.
MSGPARAM2	The second parameter value.
MSGPARAM3	The third parameter value.
MSGPARAM4	The fourth parameter value.
MSGPARAM5	The fifth parameter value.

Editing the Request PeopleCode

The PT_OPTCALL Application Engine program serves as a template. It is delivered with all the sections marked as inactive. You can edit the program to suit your needs, then mark the appropriate sections active before running it. You can also use the program as a guide to creating your own Application Engine program.

The program uses these steps to send request messages to perform the following tasks:

1. Load the optimization engine.
2. Wait for the optimization engine load to finish.
3. Run an optimization transaction against the loaded optimization engine.
4. Wait for the optimization transaction to finish running.
5. Set the trace level.
6. Get the trace level.
7. Shut down the optimization engine.

You can edit steps 1 and 3 to run an optimization transaction. You can also use the entire program as a template to create your own Application Engine program.

Loading an Optimization Engine

In step 1, enter the name of your analytic instance. In this example, the name of the analytic instance is *FEMALE1*.

If you have multiple domains, enter the local node name and the machine name and port number for your application server. In this case, the local node name is *%LocalNode* and the machine name and port number are *foo111111:9000*.

```
Local Message &MSG;
Local Message &response;

Component string &probid;
```

```

Component string &isSync;
Component string &procinSt;
Local integer &nInst;
Local string &url;

Local Rowset &rs;
Local Row &row;
Local Record &rec;

Local string &stName;
Local integer &stVal;

&MSG = CreateMessage (OPERATION.OPT_CALL);
&rs = &MSG.GetRowset ();

&row = &rs.GetRow (1);
&rec = &row.GetRecord (Record.PT_OPTPARMS);
&rec.PARMKEY.Value = "OPTCMD";
&rec.VALUE.Value = "CREATE";

&rs.InsertRow (1);
&rec = &rs.GetRow (2).PT_OPTPARMS;
&rec.PARMKEY.Value = "PROBINST";
&rec.VALUE.Value = "FEMALE1";
&probid = "FEMALE1";

&rs.InsertRow (2);
&rec = &rs.GetRow (3).PT_OPTPARMS;
&rec.PARMKEY.Value = "PROCINSTANCE";
&nInst = Record.PT_OPT_AET.PROCESS_INSTANCE.Value;
&rec.VALUE.Value = String (&nInst);
&procinSt = String (&nInst);

&rs.InsertRow (3);
&rec = &rs.GetRow (4).PT_OPTPARMS;
&rec.PARMKEY.Value = "SYNCH";
&rec.VALUE.Value = "N";
&isSync = "N";

/* Specify the Application Server domain URL (foo111111:9000 in this example)
*/
&response = %IntBroker.SyncRequest (%LocalNode, "://foo111111:9000 e");

If &response.ResponseStatus = 0 Then
    &stName = &response.GetRowset ().GetRow (1).GetRecord (Record.PT_OPTPARMS).Get
Field (Field.PARMKEY).Value;
    &stVal = Value (&response.GetRowset ().GetRow (1).GetRecord (Record.PT_
OPTPARMS).GetField (Field.VALUE).Value);
    If &stName = "STATUS" And
        &stVal = %OptEng_Fail Then
        /* Check detailed message here */
        throw CreateException (148, 2, "Can not send to OptEngine");
    End-If;
End-If;

```

Running An Optimization Transaction

In step 3, enter the name of your optimization transaction and its parameter name/value pairs. In this example, the transaction name is *TEST_LONG_TRANS*, the first parameter name/value pair is *Delay_in_Secs* and *30*, and the second parameter name/value pair is *Sleep0_Work1* and *0*.

The parameter values are stored as strings. You may need to convert them in the OnRequest PeopleCode.

```

Local Message &MSG;
Local Message &response;

Local Rowset &rs, &respRS;

```

```

Local Row &row;
Local Record &rec, &msgRec;

Component string &probid;
Component string &procinst;
Component string &isSync;
Local string &url = "";
Local integer &parmCount, &msgSet, &msgNum;

&MSG = CreateMessage(OPERATION.OPT_CALL);
&rs = &MSG.GetRowset();

&row = &rs.GetRow(1);
&rec = &row.GetRecord(Record.PT_OPTPARMS);
&rec.PARMKEY.Value = "OPTCMD";
&rec.VALUE.Value = "RUN";

&rs.InsertRow(1);
&rec = &rs.GetRow(2).PT_OPTPARMS;
&rec.PARMKEY.Value = "PROBINST";
&rec.VALUE.Value = &probid;

&rs.InsertRow(2);
&rec = &rs.GetRow(3).PT_OPTPARMS;
&rec.PARMKEY.Value = "PROCINSTANCE";
&rec.VALUE.Value = &procinst;

&rs.InsertRow(3);
&rec = &rs.GetRow(4).PT_OPTPARMS;
&rec.PARMKEY.Value = "SYNCH";
&rec.VALUE.Value = &isSync;

&rs.InsertRow(4);
&rec = &rs.GetRow(5).PT_OPTPARMS;
&rec.PARMKEY.Value = "TRANSACTION";
&rec.VALUE.Value = "TEST_LONG_TRANS";

&rs.InsertRow(5);
&rec = &rs.GetRow(6).PT_OPTPARMS;
&rec.PARMKEY.Value = "Delay_in_Secs";
&rec.VALUE.Value = "30";

&rs.InsertRow(6);
&rec = &rs.GetRow(7).PT_OPTPARMS;
&rec.PARMKEY.Value = "Sleep0_Work1";
&rec.VALUE.Value = "0";

/* SyncRequest will carry a url */
SQLExec("select URL from PSOPTSTATUS where PROBINST=:1 AND URL NOT LIKE '%:0';",
&probid, &url);
If &url = "" Then
    throw CreateException(148, 2, "Can not send to OptEngine");
End-If;

/* Specify the Application Server domain URL.
(This was specified in Step 1 in this example.)
*/
&response = %IntBroker.SyncRequest(%LocalNode, &url);

If &response.ResponseStatus = 0 Then
    &stName = &response.GetRowset().GetRow(1).GetRecord(Record.PT_OPTPARMS).Get
Field(Field.PARMKEY).Value;
    &stVal = Value(&response.GetRowset().GetRow(1).GetRecord(Record.PT_
OPTPARMS).GetField(Field.VALUE).Value);

    If &stName = "STATUS" And
        &stVal = %OptEng_Fail Then
        throw CreateException(148, 2, "Can not send to OptEngine");
    End-If;

    /* Check Detailed msg here */

```

```

If &isSync = "Y" And
    &stVal = %OptEng_Success Then

    &respRS = &response.GetRowset();
    &rowNum = &respRS.ActiveRowCount;
    For &iloop = 1 To &rowNum
        &msgRec = &respRS.GetRow(&iloop).GetRecord(Record.PT_OPTDETMGS);
        If (&msgRec.GetField(Field.MSGSET).Value <> 0) Then
            &msgSet = Value(&msgRec.GetField(Field.MSGSET).Value);
            &msgNum = Value(&msgRec.GetField(Field.MSGNUM).Value);
            &parm1 = &msgRec.GetField(Field.MSGPARAM1).Value;
            &parm2 = &msgRec.GetField(Field.MSGPARAM2).Value;
            &parm3 = &msgRec.GetField(Field.MSGPARAM3).Value;
            &parm4 = &msgRec.GetField(Field.MSGPARAM4).Value;
            &parm5 = &msgRec.GetField(Field.MSGPARAM5).Value;
            &string = MsgGetText(&msgSet, &msgNum, "Message Not Found", &parm1,
                &parm2, &parm3, &parm4, &parm5);

            End-If;
        End-For;

    End-If;

End-If;

```

Editing the Response PeopleCode

The OPT_CALL message definition serves as a template. It is delivered to work with the PT_OPTCALL Application Engine program. You can edit the program to suit your needs, or use it as a guide when creating your own response message program.

OPT_CALL Message Program

The OPT_CALL application package implements the Integration Broker method OnRequest. The PeopleCode in this method shows application messages for lights-out mode.

Depending upon the request message, the OnRequest method PeopleCode calls appropriate optimization functions and methods to perform these tasks, and sends a response message containing the returned status and detailed messages from the optimization functions and methods.

You can use the OnRequest method PeopleCode as a template to create your own response message PeopleCode program. For example, you can edit it to run an optimization transaction, which is shown below as an example. This example is edited to match the examples for step 1 and step 3 in the PT_OPTCALL program.

Processing the Transaction Parameters

Edit the OPT_CALL application program OnRequest method to enter the name of your optimization transaction and the name/value pairs for its parameters. In this example, the transaction name is *TEST_LONG_TRANS*, the first parameter name/value pair is *&delayParm* and *&delay* (maps to *Delay_in_Secs* from the request message), and the second parameter name/value pair is *&sleepParm* and *&isSleep* (maps to *Sleep0_Work1* from the request message).

The parameter values are stored as strings in step 3 of the Application Engine program. You may need to convert them here to your desired format. Here is a section of the application program showing the places to edit.

```

If &trans = "TEST_LONG_TRANS" Then
    &REC = &rs.GetRow(6).PT_OPTPARMS; &delayParm = &REC.PARMKEY.Value; &delay = Value(⇒

```

```

&REC.VALUE.Value);

    &REC = &rs.GetRow(7).PT_OPTPARMS;&sleepParm = &REC.PARMKEY.Value;&isSleep = Valu⇒
e(&REC.VALUE.Value);

    &myopt = GetOptEngine(&inst, &detStatus);
    If (&myopt = Null) Then
        &optstatus = %OptEng_Fail;
    End-If;

    If &myopt <> Null And &isSync = "Y" Then
        &optstatus = &myopt.RunSynch(&trans, &delayParm, &delay, &sleepParm, &isSleep⇒
);

        &detStatus = &myopt.DetailedStatus;
    End-If;

    If &myopt <> Null And &isSync = "N" Then
        &myopt.ProcessInstance = &procInst;
        &optstatus = &myopt.RunASynch(&trans, &delayParm, &delay, &sleepParm, &is
Sleep);
        &detStatus = &myopt.DetailedStatus;
    End-If; /* iif myopt=null */
End-If;

```

Building a Status Response Message

This section shows the a response message to send a status message for the OPT_CALL message in the application server.

```

/* Insert detailed status and detailed msgs into Response msg rowset */
&respRS = &response.GetRowset();
&respRS.GetRow(1).GetRecord(Record.PT_OPTPARMS).GetField(Field.PARMKEY).Value =
"STATUS";
&respRS.GetRow(1).GetRecord(Record.PT_OPTPARMS).GetField(Field.VALUE).Value =
String(&optstatus);

&respRS.InsertRow(1);
&respRS.GetRow(2).GetRecord(Record.PT_OPTPARMS).GetField(Field.PARMKEY).Value =
"DETAILED_STATUS";
&respRS.GetRow(2).GetRecord(Record.PT_OPTPARMS).GetField(Field.VALUE).Value =
String(&detStatus);

```

Building a Detailed Response Message

This section shows a response message to send a detailed message for the OPT_CALL message on the application server.

```

/*Either optcmd or inst is not passed in correctly, or optengine is not loaded
/created correctly */
If &myopt = Null Then
    &msgRec = &respRS.GetRow(1).GetRecord(Record.PT_OPTDETMSGS);
    If &isParmBad = True Then
        &msgRec.GetField(Field.MSGSET).Value = 148;
        &msgRec.GetField(Field.MSGNUM).Value = 505;
    End-If;
End-If;

/* If it is sync transaction, insert DetailMsg to response msg */
If &myopt <> Null And
    &isSync = "Y" And
    &optcmd = "RUN" And
    &optstatus = %OptEng_Success Then
    &arrArray = &myopt.DetailMsgs;
    For &iLoop = 1 To &arrArray.Len

```

```

    /* First two rows have been inserted because of PT_OPTPARMS for two status
codes */
    If &iLoop > 2 Then
        &respRS.InsertRow(&iLoop - 1);
    End-If;

    &msgRec = &respRS.GetRow(&iLoop).GetRecord(Record.PT_OPTDETMSG);
    &msgRec.GetField(Field.MSGSET).Value = String(&arrArray [&iLoop][1]);
    &msgRec.GetField(Field.MSGNUM).Value = String(&arrArray [&iLoop][2]);
    &msgRec.GetField(Field.PARMCOUNT).Value = String(&arrArray [&iLoop][3]);
    &msgRec.GetField(Field.MSGPARAM1).Value = String(&arrArray [&iLoop][4]);
    &msgRec.GetField(Field.MSGPARAM2).Value = String(&arrArray [&iLoop][5]);
    &msgRec.GetField(Field.MSGPARAM3).Value = String(&arrArray [&iLoop][6]);
    &msgRec.GetField(Field.MSGPARAM4).Value = String(&arrArray [&iLoop][7]);
    &msgRec.GetField(Field.MSGPARAM5).Value = String(&arrArray [&iLoop][8]);
    End-For;
End-If;

```

Optimization Built-in Functions

This section discusses the optimization functions. The functions are discussed in alphabetical order.

CreateOptEngine

Syntax

```

CreateOptEngine (analytic_inst, {%Synch | %ASynch}[, &detailedstatus] [, processinst⇒
ance])

```

Description

The CreateOptEngine function instantiates an OptEngine object, loads an optimization engine with an analytic instance and returns a reference to it.

Parameters

Parameter	Description
<i>Analytic_inst</i>	Specify the analytic instance ID, which is a unique ID for this analytic instance in this optimization engine. This is supplied by users when they request that an optimization be run.
%Synch %ASynch	Specify whether the optimization engine is synchronous or asynchronous. The values are: <ul style="list-style-type: none"> • %Synch: run the optimization engine synchronously. • %ASynch: run the optimization engine asynchronously.

Parameter	Description
<i>&detailedstatus</i>	<p>Specify a variable that the engine uses to give further information about the evaluation of this function. The value returned is one of the following:</p> <ul style="list-style-type: none"> • %OptEng_Success: The function completed successfully. • %OptEng_Fail: The function failed. • %OptEng_Invalid_Aiid: The analytic instance ID passed to the function is invalid. • %OptEng_Exists: An optimization engine instance already exists and is loaded. • %OptEng_Method_Disabled: A method is disabled or not valid. • %OptEng_DB_Updates_Pending: indicates that database updates are pending.
<i>processinstance</i>	<p>Enter the process instance ID. You use this parameter only with lights-out processing, most likely with the subscription PeopleCode for application message.</p> <hr/> <p>Note: This optional parameter is positional. If you use it, you must also use the <i>&detailedstatus</i> parameter.</p> <hr/> <p>The state record that you use with Application Engine contains the process instance ID.</p> <p>See Using Lights-Out Mode with Optimization.</p> <p>See "Using State Records" (Application Engine).</p>

Returns

If successful, CreateOptEngine returns an OptEngine PeopleCode object. If the function fails, it returns a null value. Examine the optional status reference parameter in case of a Null return for additional information regarding the failure.

Example

An OptEngine object variable can be scoped as Local, Component, or Global.

You declare OptEngine objects as type OptEngine. For example:

```
Local OptEngine &MyOptEngine;
Component OptEngine &MyOpt;
Global OptEngine &MyOptEng;
```

The following example loads an optimization engine with the analytic instance:

```
Local OptEngine &myopt;
Local string &probinst;
Local string &transaction;
```

```

Local integer &detailedstatus;

&probinst = GetRecord(Record.PSOPTPRBINST).GetField(Field.PROBINST).Value;
&myopt = CreateOptEngine(&probinst, %Synch);

```

The following example shows the use of the optional status parameter:

```

&myopt = CreateOptEngine(&probinst, %Synch, &detailedstatus);
if &myopt = Null then
    if &detailedstatus = %OptEng_Invalid_Piid then
        /*perform some action */
    end_if;
end_if;

```

CreateOptInterface

Syntax

```

CreateOptInterface()

```

Description

The CreateOptInterface function instantiates an OptInterface object.

Note: You can use this function and the OptInterface methods only within an application class that you extend from the OptBase application class, or within PeopleCode that you call from that application class. This ensures that the OptInterface PeopleCode runs only on the optimization engine.

Parameters

None.

Returns

If successful, CreateOptInterface returns an OptInterface PeopleCode object. If the function fails, it returns a null value.

Example

You declare OptInterface objects as type OptInterface. For example:

```

Local OptInterface &MyOptInterface;
Component OptInterface &MyOptInt;
Global OptInterface &MyOptInt;

```

The following example instantiates an OptInterface object:

```

Local OptInterface &myInterface;
Int &status;

&myInterface = CreateOptInterface(&additionalStatus);
if (&myInterface != NULL) then
    &status = &myInterface.ActivateModel("RMO_TEST");
    if (&status = %OptInter_Fail) then
        /* examine &myInterface.DetailedStatus for reason */
        ...
    end-if;

```

```

else
    /* CreateOptInterface has returned NULL */
    /* take some corrective action here */
    ...
end_if;

```

DeleteOptProbInst

Syntax

```

DeleteOptProbInst(probinst[, &detailedstatus])

```

Description

The DeleteOptProbInst function deletes the analytic instance ID from PeopleTools metadata. This function can be called only inside FieldChange, PreSaveChange and PostSaveChange PeopleCode events, and in Workflow.

Note: Use this function to delete the analytic instance ID after deleting data in optimization application tables for this analytic instance.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>probinst</i>	Enter the analytic instance ID to delete.
<i>&detailedstatus</i>	(Optional) This status reference parameter returns an integer value giving further information about the evaluation of this function. The value returned is one of the following: <ul style="list-style-type: none"> • %OptEng_Success: The function completed successfully. • %OptEng_Fail: The function failed. • %OptEng_Invalid_Piid: The analytic instance ID passed to the function is invalid. • %OptEng_Sql_Exception: A SQLException is encountered when access database. • %OptEng_Exists: An analytic server loaded with this analytic instance still exists.

Returns

Returns %OptEng_Success if successful; otherwise returns %OptEng_Fail.

Example

The following example deletes the instance for an analytic type:

Note: Whenever you add records to an analytic type, you must call `DeleteOptProbInst` to delete the old analytic type instances and then call `InsertOptProbInst` to recreate them.

```

Local string &probinst;
Local string &probtype;
Local integer &ret;
&probinst = "PATSMITH";
&probtype = "QEOPT";
&ret = DeleteOptProbInst(&probinst, &probtype);
If &ret <> %OptEng_Success Then
    QEOPT_WRK.MESSAGE_TEXT = "Delete of analytic instance " | &probinst | "
    failed.";
Else
    QEOPT_WRK.MESSAGE_TEXT = "Analytic Instance " | &probinst | " deleted.";
End-If;

```

The following example shows the use of the optional status parameter:

```

Local integer &detailedstatus;
&ret = DeleteOptProbInst(&probinst, &probtype, &detailedstatus);
If &ret <> %OptEng_Success AND &detailedstatus=%OptEng_Invalid_Piid then
    QEOPT_WRK.MESSAGE_TEXT = "Delete of analytic instance " | &probinst | " failed
    for bad piid.";
Else
    QEOPT_WRK.MESSAGE_TEXT = "Analytic Instance " | &probinst | deleted.";
End-If;

```

GetOptEngine

Syntax

GetOptEngine(*probinst* [, &*detailedstatus*])

Description

The `GetOptEngine` function returns a handle to an optimization engine that is already loaded with the analytic instance.

Note: You cannot call `GetOptEngine` from a domain other than the application server.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>probinst</i>	Enter the analytic instance ID, which is unique ID for this analytic instance in this optimization engine.

Parameter	Description
<i>&detailedstatus</i>	(Optional) This status reference parameter returns an integer value giving further information about the evaluation of this function. The value returned is one of the following: <ul style="list-style-type: none"> • %OptEng_Success: The function completed successfully. • %OptEng_Fail: The function failed. • %OptEng_Invalid_Piid: The analytic instance ID passed to the function is invalid.

Returns

Returns an OptEngine PeopleCode object if successful, a null value otherwise.

Example

The following example causes an optimization engine to shut down its analytic instance:

```
Global string &probinst;
Local OptEngine &myopt;
Local integer &status;

&myopt = GetOptEngine(&probinst);
If &myopt <> NULL then
&status = &myopt.ShutDown();
QEOPT WRK.MESSAGE TEXT = "Analytic Instance ID " | &probinst
| " has been shutdown successfully.";
End-if;
```

Or, you can use the optional status parameter:

```
&myopt = GetOptEngine(&probinst, &detailedstatus);
if &myopt=NULL and &detailedstatus=%OptEng_Invalid_Piid then
/* perform some action */
End-if;
```

GetOptProbInstList

Syntax

```
GetOptProbInstList(ProblemType , OutputErrorCode [, Prefix] [, &detailedstatus])
```

Description

The GetOptProbInstList function gets the list of all analytic instance IDs in an analytic type.

Parameters

Parameter	Description
<i>ProblemType</i>	Enter the name of the analytic type that you created in Application Designer.
<i>OutputErrorCode</i>	Future use. Always returns zero.
<i>Prefix</i>	(Optional) Enter a string. If used, this prefix causes the returned list to include only the analytic instance IDs that start with this prefix. If not used, all the analytic instance IDs in the analytic type are returned.
<i>&detailedstatus</i>	(Optional) This status reference parameter returns an integer value giving further information about the evaluation of this function. The value returned is one of the following: <ul style="list-style-type: none"> • %OptEng_Success: The function completed successfully. • %OptEng_Fail: The function failed. • %OptEng_Invalid_Piid: The analytic type name passed to the function is invalid.

Returns

Returns an array of strings containing the optimization analytic instance list.

Example

The following example shows the usage of GetOptProbInstList to fill the display field on a page:

```
Global string &probinst;
Local integer &detailedstatus;
Local integer &iloop;
Local array of string &instarray;

QEOPT.OPERATOR = %UserId;

&instarray = GetOptProbInstList(QEOPT.PROBTYPE, &ret, &detailedstatus);

If &ret <> %OptEng_Success Then
    QEOPT_WRK.MESSAGE_TEXT = "Could not get analytic instances
for analytic type " | QEOPT.PROBTYPE ;
Else
    For &iloop = 1 To &instarray.Len
        QEOPT_WRK.MESSAGE_TEXT = QEOPT_WRK.MESSAGE_TEXT | &instarray[&iloop] | " ";
    End-For;
End-If;
```

The following example shows the use of the optional status parameter:

```
&instarray = GetOptProbInstList(QEOPT.PROBTYPE, &ret, &detailedstatus);
If &ret <> %OptEng_Success and &detailedstatus=%OptEng_Invalid_Piid Then
    QEOPT_WRK.MESSAGE_TEXT = "Could not get analytic instances for analytic type "
| QEOPT.PROBTYPE | "because bad piid" ;
End-If;
```

InsertOptProbInst

Syntax

```
InsertOptProbInst(probinst, ProblemType [, &detailedstatus] [, Description])
```

Description

The InsertOptProbInst function inserts a new analytic instance ID into the PeopleTools metadata.

The InsertOptProbInst function can be called only inside FieldChange, PreSave and PostSave PeopleCode events, and in Workflow.

Note: You must use this function to create the analytic instance ID before inserting data into optimization application tables for this analytic instance.

Parameters

Parameter	Description
<i>probinst</i>	Enter the analytic instance ID to be inserted into the analytic type.
<i>ProblemType</i>	Enter the name of the analytic type that you created in Application Designer.
<i>&detailedstatus</i>	(Optional) This status reference parameter returns an integer value giving further information about the evaluation of this function. The value returned is one of the following: <ul style="list-style-type: none"> • %OptEng_Success: The function completed successfully. • %OptEng_Fail: The function failed. • %OptEng_Invalid_Piid: The analytic instance ID passed to the function is invalid.
<i>Description</i>	(Optional) Specify a description for the analytic instance. This parameter takes a string value.

Returns

This method returns a constant. Valid values are:

Value	Description
%OptEng_Success	Returned if method succeeds.

Value	Description
%OptEng_Fail	Returned if the method fails.

Example

```

Local string &probinst;
Local string &probtype;
Local integer &ret;
Local integer &detailedstatus;

&probinst = "PATSMITH";
&probtype = "QEOPT";
&probDescr = "New QEOPT instance";
&ret = InsertOptProbInst(&probinst, &probtype, &probDescr);
If &ret <> %OptEng_Success Then
    QEOPT_WRK.MESSAGE_TEXT = "Insert of analytic instance "
    | &probinst | " failed.";
Else
    QEOPT_WRK.MESSAGE_TEXT = "Analytic Instance " | &probinst | " created.";
End-If;

```

The following example shows the use of the optional status parameter:

```

&ret = InsertOptProbInst(&probinst, &probtype, &detailedstatus);
If &ret <> %OptEng_Success and &detailedstatus=%OptEng_Invalid_Piid Then
    QEOPT_WRK.MESSAGE_TEXT = "Insert of analytic instance "
    | &probinst | " failed for bad piid.";
End-if;

```

IsValidOptProbInst

Syntax

```
IsValidOptProbInst(probinst [, &detailedstatus])
```

Description

IsValidOptProbInst determines if a given analytic instance exists in the optimization metadata.

Parameters

Parameter	Description
<i>probinst</i>	Enter the analytic instance ID to be validated.
<i>&detailedstatus</i>	<p>(Optional) This status reference parameter returns an integer value giving further information about the evaluation of this function. The value returned is one of the following:</p> <ul style="list-style-type: none"> %OptEng_Success: The function completed successfully. %OptEng_Invalid_Piid: The analytic type name passed to the function is invalid.

Returns

This method returns a constant. Valid values are:

Value	Description
%OptEng_Success	Returned if method succeeds.
%OptEng_Fail	Returned if the method fails.

Example

```
Local string &probinst;
Local integer &detailedstatus;
Local integer &ret;

&probinst = "PATSMITH";
&ret = IsValidOptProbInst(&probinst, &detailedstatus);
If &ret <> %OptEng_Success and &detailedstatus=%OptEng_Invalid_Piid Then
    <perform some action>
End-if;
```

OptEngine Class Methods

This section discusses the optimization methods for the OptEngine PeopleCode class. The methods are listed in alphabetical order.

CheckOptEngineStatus

Syntax

```
CheckOptEngineStatus ()
```

Description

The CheckOptEngineStatus method returns the status of the optimization engine, using a combination of its return value and the DetailedStatus OptEngine class property. Keep the following in mind:

- The value returned by CheckOptEngineStatus is the operational status of the optimization engine.
- The DetailedStatus property indicates the completion status of the OptEngine method call CheckOptEngineStatus.

For example, CheckOptEngineStatus can return %OptEng_Idle and DetailedStatus is %OptEng_Success. For CheckOptEngineStatus, DetailedStatus can have the value:

- %OptEng_Success
- %OptEng_Fail

- %OptEng_Not_Available

Note: Before this method is called, the CreateOptEngine or GetOptEngine must be called.

Returns

Returns an integer for the status of the optimization engine. These numbers are message IDs belonging to message set 148 in the message catalog.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
21	%OptEng_Not_Loaded	The optimization engine process is running, but is not currently loaded with an application problem.
22	%OptEng_Busy>Loading	The optimization engine is busy loading an application problem. It will not accept transaction requests until loading completes.
23	%OptEng_Idle	The optimization engine is loaded with an application problem and waiting for a transaction request.
24	%OptEng_Busy	The optimization engine is busy processing a transaction request for the loaded application problem. It will not accept additional transaction requests until the current one completes.
26	%OptEng_Unknown	An error has occurred. The optimization engine status cannot be determined.

Example

This PeopleCode example shows optimization engine status being checked:

```
Local OptEngine &myopt;
Local string &probinst;
Local integer &status;
&myopt = GetOptEngine("PATSMITH");
/* Initialize the DESCRLONG field in the QE_FUNCLIB_OPT record to null. */
GetLevel0().GetRow(1).GetRecord(Record.QE_FUNCLIB_OPT).DESCRLONG.Value = "";
&status = &myopt.CheckOptEngineStatus();
GetLevel0().GetRow(1).GetRecord(Record.QE_FUNCLIB_OPT).DESCRLONG.Value = "Opt
Engine status = " | MsgGet(148, &status, "Could not send to the OptEngine.");
```

You can also retrieve the detailed status:

```
Local integer &detailedstatus
&status = &myopt.CheckOptEngineStatus();
&detailedstatus = &myopt.DetailedStatus;
```

FillRowset

Syntax

```
FillRowset(PARAM_NAME, &Rowset[, &functionstatus])
```

Description

This method gets the value of a transaction output parameter that is a rowset. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

When using the OptEngine DetailedStatus property, keep the following in mind:

- The value returned by FillRowset is the operational status of the optimization engine.
- The OptEngine DetailedStatus property indicates the completion status of the OptEngine method call FillRowset.

For example, FillRowset returns %OptEng_Fail, and DetailedStatus is %OptEng_Method_Disabled.

For FillRowset, the DetailedStatus property can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled.

This indicates that the method is disabled or not valid.

- %OptEng_Wrong_Parm_Type

Parameters

Parameter	Description
<i>PARAM_NAME</i>	Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition. See "Configuring Analytic Type Transactions" (Optimization Framework).
<i>&Rowset</i>	Enter the rowset containing the values. This rowset must be a single record rowset, and the record must match the record name associated with the transaction parameter in the analytic type definition.

Parameter	Description
<i>&functionstatus</i>	<p>(Optional) This status reference parameter returns an integer value giving further information about the evaluation of this function. The value returned is one of the following:</p> <ul style="list-style-type: none"> • OptEng_Success: The function completed successfully. • OptEng_Fail: The function failed. • OptEng_Method_Disabled: A method is disabled or not valid.

Returns

This method returns a constant. Valid values are:

Value	Description
%OptEng_Success	Returned if method succeeds.
%OptEng_Fail	Returned if the method fails.

Example

The following PeopleCode example runs a synchronous optimization transaction named RETURN_MACHINE_UNAVAILABLE. It has these parameters:

- Input: MACHINE_NAME to specify the machine for which we need unavailable times.
- Output: RETURN_TIMES to specify a rowset and MACHINE_WRK record containing the BEGIN_DATE and END_DATE fields.

This PeopleCode example sets input parameter values and gets an output parameter value:

```

Local OptEngine &myopt;
Local integer &status;
Local string &machname;
Local Rowset &rs;
&myopt = GetOptEngine("PATSMITH");
&machname = QEOPT_WRK.MACHINE_NAME.Value;
/* Run the RETURN_MACHINE_UNAVAILABLE transaction synchronously with input values.
*/
&status = &myopt.RunSynch("RETURN_MACHINE_UNAVAILABLE", "MACHINE_NAME", &machname);
If Not &status Then
    QEOPT_WRK.MESSAGE_TEXT = " RETURN_MACHINE_UNAVAILABLE transaction failed.";
    Return;
End-If;
/* Get output value from the RETURN_MACHINE_UNAVAILABLE transaction. */
&rs = CreateRowset(Record.MACHINE_WRK);
&status = &myopt.FillRowset("RETURN_TIMES", &rs);

```

You can also use the [new->] DetailedStatus property as follows:

```

&status = &myopt.FillRowset("RETURN_TIMES", &rs);
if &status=%OptEng_Fail and &myopt.DetailedStatus=%OptEng_Method_Disabled then

```

```

        /* perform some action */
    End-if;

```

GetDate

Syntax

```
GetDate(PARAM_NAME [, &status])
```

Description

This method gets the value of a transaction output parameter with a data type of Date. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The OptEngine DetailedStatus property indicates the completion status of the OptEngine method call GetDate. For GetDate, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.

Parameters

Parameter	Description
<i>PARAM_NAME</i>	Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition. See "Configuring Analytic Type Transactions" (Optimization Framework).

Returns

Returns a Date object; use this method when that is the data type of the transaction output parameter value.

Example

See [GetNumber](#).

GetDateArray

Syntax

```
GetDateArray(PARAM_NAME)
```

Description

This method gets the value of a transaction output parameter with a data type Array of Date. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The OptEngine DetailedStatus property indicates the completion status of the OptEngine method call GetDateArray. For GetDateArray, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PARAM_NAME</i>	Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition. See "Configuring Analytic Type Transactions" (Optimization Framework).

Returns

Returns an Array of Date object; use this method when that is the data type of the transaction output parameter value.

Example

See [GetStringArray](#).

GetDateTime

Syntax

GetDateTime (*PARAM_NAME*)

Description

This method gets the value of a transaction output parameter with a data type of DateTime. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call GetDateTime. For GetDateTime, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PARAM_NAME</i>	<p>Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition.</p> <p>See "Configuring Analytic Type Transactions" (Optimization Framework).</p>

Returns

Returns a DateTime object; use this method when that is the data type of the transaction output parameter value.

Example

See [GetNumber](#).

GetDateTimeArray

Syntax

GetDateTimeArray (*PARAM_NAME*)

Description

This method gets the value of a transaction output parameter with a data type Array of DateTime. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call GetDateTimeArray. For GetDateTimeArray, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.

Parameters

Parameter	Description
<i>PARAM_NAME</i>	<p>Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition.</p> <p>See "Configuring Analytic Type Transactions" (Optimization Framework).</p>

Returns

Returns an Array of DateTime object; use this method when that is the data type of the transaction output parameter value.

Example

See [GetStringArray](#).

GetNumber

Syntax

GetNumber (*PARAM_NAME*)

Description

This method gets the value of a transaction output parameter with a data type of Number. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call GetNumber. For GetNumber, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.

Parameters

Parameter	Description
<i>PARAM_NAME</i>	<p>Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition.</p> <p>See "Configuring Analytic Type Transactions" (Optimization Framework).</p>

Returns

Returns a Number object; use this method when that is the data type of the transaction output parameter value.

Example

The following PeopleCode example runs a synchronous optimization transaction named `IS_MACHINE_AVAILABLE`. It has these parameters:

- Input `MACHINE_NAME` to specify the machine.
- Inputs `BEGIN_DATE` and `END_DATE` to specify the time slot.
- Output `AVAILABLE_FLAG` to specify whether the machine is available in that time slot.

This PeopleCode example sets input parameter values and gets an output parameter value:

```

Local OptEngine &myopt;
Local integer &status;
Local string &machname;
Local datetime &begindate;
Local datetime &enddate;
&myopt = GetOptEngine("PATSMITH");
&machname = QEOPT_WRK.MACHINE_NAME.Value;
&begindate = QEOPT_WRK.BEGIN_DATE.Value;
&enddate = QEOPT_WRK.END_DATE.Value;
/* Run the IS_MACHINE_AVAILABLE transaction synchronously with input values. */
&status = &myopt.RunSynch("IS_MACHINE_AVAILABLE", "MACHINE_NAME",
    &machname, "BEGIN_DATE", &begindate, "END_DATE", &enddate);
If Not &status Then
    QEOPT_WRK.MESSAGE_TEXT = "IS_MACHINE_AVAILABLE transaction failed.";
    Return;
End-If;
/* Get output value from the IS_MACHINE_AVAILABLE transaction. */
QEOPT_WRK.AVAILABLE_FLAG = &myopt.GetNumber("AVAILABLE_FLAG");

```

You can use the `DetailedStatus` property as follows:

```

QEOPT_WRK.AVAILABLE_FLAG = &myopt.GetNumber("AVAILABLE_FLAG");
if &myopt.DetailedStatus=%OptEng_Fail then
    /* perform some action */
End-if;

```

GetNumberArray

Syntax

GetNumberArray (*PARAM_NAME*)

Description

This method gets the value of a transaction output parameter with a data type Array of Number. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call GetNumberArray. For GetNumberArray, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: this indicates that the method is disabled or not valid.

Note: Do not pass an array of type Integer as a transaction parameter. Use an array of type Number instead.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PARAM_NAME</i>	Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition. See "Configuring Analytic Type Transactions" (Optimization Framework).

Returns

Returns an Array of Number object; use this method when that is the data type of the transaction output parameter value.

Example

See [GetStringArray](#).

GetString

Syntax

GetString (*PARAM_NAME*)

Description

This method gets the value of a transaction output parameter with a data type of String. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call GetString. For GetString, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PARAM_NAME</i>	Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition. See "Configuring Analytic Type Transactions" (Optimization Framework).

Returns

Returns a String object; use this method when that is the data type of the transaction output parameter value.

Example

See [GetNumber](#).

GetStringArray

Syntax

GetStringArray (*PARAM_NAME*)

Description

This method gets the value of a transaction output parameter with a data type Array of String. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call GetStringArray. For GetStringArray, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PARAM_NAME</i>	<p>Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition.</p> <p>See "Configuring Analytic Type Transactions" (Optimization Framework).</p>

Returns

Returns an Array of String object; use this method when that is the data type of the transaction output parameter value.

Example

The following PeopleCode example runs a synchronous optimization transaction named ARE_MACHINES_AVAILABLE. It has these parameters:

- Inputs BEGIN_DATE and END_DATE to specify the time slot.
- Output MACHINE_NAMES to specify the machines available in that time slot.

This PeopleCode example sets input parameter values and gets an output parameter value:

```

Local OptEngine &myopt;
Local integer &status;
Local array of string &machnames;
Local datetime &begindate;
Local datetime &enddate;
&myopt = GetOptEngine("PATSMITH");
&begindate = QEOPT_WRK.BEGIN_DATE.Value;
&enddate = QEOPT_WRK.END_DATE.Value;
/* Run the ARE_MACHINES_AVAILABLE transaction synchronously with input values. */
&status = &myopt.RunSynch("ARE_MACHINES_AVAILABLE",
    "BEGIN_DATE", &begindate, "END_DATE", &enddate);
If &status=%OptEng_Fail Then
    QEOPT_WRK.MESSAGE_TEXT = "ARE_MACHINES_AVAILABLE transaction failed.";
    Return;
End-If;
/* Get output value from the ARE_MACHINES_AVAILABLE transaction. */
&machnames = &myopt.GetStringArray("MACHINE_NAMES");

```

The following example shows the use of the DetailedStatus property:

```

Local array of string &machnames;
&machnames = &myopt.GetStringArray("MACHINE_NAMES");
if &myopt.DetailedStatus=%OptEng_Fail then
    /* perform some action */

```

```
End-if;
```

GetTime

Syntax

```
GetTime (PARAM_NAME)
```

Description

This method gets the value of a transaction output parameter with a data type of Time. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call GetTime. For GetTime, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PARAM_NAME</i>	Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition. See "Configuring Analytic Type Transactions" (Optimization Framework).

Returns

Returns a Time object; use this method when that is the data type of the transaction output parameter value.

Example

See [GetNumber](#).

GetTimeArray

Syntax

```
GetTimeArray (PARAM_NAME)
```

Description

This method gets the value of a transaction output parameter with a data type Array of Time. This cannot be used with the RunAsynch method; RunSynch is needed to make the transaction output parameter values immediately available.

The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call GetTimeArray. For GetTimeArray, DetailedStatus can have the value:

- %OptEng_Success.
- %OptEng_Fail.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PARAM_NAME</i>	Enter a string for the name of the output parameter to get from the transaction that was just performed with RunSynch. This parameter must be defined as an output or both (input and output) in the analytic type definition. See "Configuring Analytic Type Transactions" (Optimization Framework).

Returns

Returns an Array of Time object; use this method when that is the data type of the transaction output parameter value.

Example

See [GetStringArray](#).

GetTraceLevel

Syntax

GetTraceLevel (*component*)

Description

GetTraceLevel gets the severity level at which events are logged for a given component.

The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call GetTraceLevel. For GetTraceLevel, DetailedStatus can have the value:

- %OptEng_Success.

This indicates that the function completed successfully.

- %OptEng_Fail.

This indicates that the function failed.

- %OptEng_Method_Disabled.

This indicates that the method is disabled or not valid.

- %OptEng_DB_Updates_Pending.

This indicates that database updates are pending.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>component</i>	Enter one of the following PeopleCode constants: Opt_Engine, Opt_Utility, Opt_Datacache, or Opt_Plugin.

Returns

Returns one of the following.

- %Severity_Fatal
- %Severity_Status
- %Severity_Error
- %Severity_Warn
- %Severity_Info
- %Severity_Trace1
- %Severity_Trace2

Example

```
Local OptEngine &myopt;
Local integer &tracelevel;

&myopt = GetOptEngine("PATSMITH");

&tracelevel = &myopt.GetTraceLevel(%Opt_Engine);
if &myopt.DetailedStatus = %OptEng_Success then
    if (&tracelevel = %Severity_Info_ then
        winmessage("Severity level for the OptEngine is 'Info'");
    End-if;
End-if;
```

RunAsynch

Syntax

RunAsynch (*TRANSACTION*, *PARAM_PAIRS*)

Description

The RunAsynch method requests the optimization engine to run the transaction in asynchronous mode.

When using the DetailedStatus OptEngine property, keep the following in mind:

- The value returned by RunASynch is the operational status of the optimization engine.
- The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call RunASynch.

For example, RunASynch can return %OptEng_Fail and DetailedStatus is %OptEng_DB_Updates_Pending. For RunASynch, DetailedStatus can have the value:

- %OptEng_Success: indicates that the function completed successfully.
- %OptEng_Fail: indicates that the function failed.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.
- %OptEng_DB_Updates_Pending: indicates that database updates are pending.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TRANSACTION</i>	Enter a string for the name of the transaction to run.
<i>PARAM_PAIRS</i>	Enter the name and value pairs (string name and value) for this transaction. Not used if the transaction has no parameters. Parameters are defined in the analytic type definition. See "Configuring Analytic Type Transactions" (Optimization Framework).

Returns

This method returns a constant. Valid values are:

<i>Value</i>	<i>Description</i>
%OptEng_Success	Returned if method succeeds.
%OptEng_Fail	Returned if the method fails.

Example

This PeopleCode example runs an asynchronous optimization transaction named SOLVE. It has no input or output parameters. The SOLVE transaction solves the exercise scheduling problem and puts the results into the QE_RWSM_EXERSCH table.

```
Local OptEngine &myopt;
Local integer &status;
&myopt = GetOptEngine("PATSMITH");
/* Run the SOLVE transaction asynchronously with input values. */
&status = &myopt.RunAsynch("SOLVE");
If &status=%OptEng_Fail Then
    QEOPT_WRK.MESSAGE_TEXT = "SOLVE transaction failed.";
    Return;
End-If;
```

The following example shows the use of the DetailedStatus property.

```
Local integer &status;
&status = myopt.RunAsynch("SOLVE");
if &status=%OptEng_Fail and &myopt.DetailedStatus=%OptEng_Method_Disabled then
    <perform some action>
End-if;
```

RunSynch

Syntax

RunSynch (*TRANSACTION*, *PARAM_PAIRS*)

Description

The RunSynch method requests the optimization engine to run the transaction in synchronous mode.

When using the DetailedStatus OptEngine property, keep the following in mind:

- The value returned by RunSynch is the operational status of the optimization engine.
- The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call RunSynch.

For example, RunSynch can return %OptEng_Fail and DetailedStatus is %OptEng_DB_Updates_Pending. For RunSynch, DetailedStatus can have the value:

- %OptEng_Success: indicates that the function completed successfully.
- %OptEng_Fail: indicates that the function failed.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.
- %OptEng_DB_Updates_Pending: indicates that database updates are pending.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TRANSACTION</i>	Enter a string for the name of the transaction to run.
<i>PARAM_PAIRS</i>	Enter the name and value pairs (string name and value) for this transaction. Not used if the transaction has no parameters. Parameters are defined in the analytic type definition. See "Configuring Analytic Type Transactions" (Optimization Framework).

Returns

This method returns a constant. Valid values are:

<i>Value</i>	<i>Description</i>
%OptEng_Success	Returned if method succeeds.
%OptEng_Fail	Returned if the method fails.

Example

The following PeopleCode example runs a synchronous optimization transaction named `IS_MACHINE_AVAILABLE`. It has these parameters:

- Input `MACHINE_NAME` to specify the machine.
- Inputs `BEGIN_DATE` and `END_DATE` to specify the time slot.
- Output `AVAILABLE_FLAG` to specify whether the machine is available in that time slot.

This PeopleCode example sets input parameter values and gets an output parameter value:

```
Local OptEngine &myopt;
Local integer &status;
Local string &machname;
Local datetime &begindate;
Local datetime &enddate;
&myopt = GetOptEngine("PATSMITH");
&machname = QEOPT_WRK.MACHINE_NAME.Value;
&begindate = QEOPT_WRK.BEGIN_DATE.Value;
&enddate = QEOPT_WRK.END_DATE.Value;
/* Run the IS_MACHINE_AVAILABLE transaction synchronously with input values. */
&status = &myopt.RunSynch("IS_MACHINE_AVAILABLE",
    "MACHINE_NAME", &machname, "BEGIN_DATE", &begindate, "END_DATE", &enddate);
If &status=%OptEng_Fail Then
    QEOPT_WRK.MESSAGE_TEXT = "IS_MACHINE_AVAILABLE transaction failed.";
    Return;
End-If;
/* Get output value from the IS_MACHINE_AVAILABLE transaction. */
QEOPT_WRK.AVAILABLE_FLAG = &myopt.GetNumber("AVAILABLE_FLAG");
```

Or, the following example shows the use of the DetailedStatus property.

```
Local integer &status;
&status = myopt.RunSynch("SOLVE");
if &status=%OptEng_Fail and &myopt.DetailedStatus=%OptEng_Method_Disabled then
    <perform some action>
End-if;
```

SetTraceLevel

Syntax

```
SetTraceLevel(component, severity )
```

Description

SetTraceLevel sets the severity level at which events are logged for a given component.

When using the DetailedStatus OptEngine property, keep the following in mind:

- The value returned by SetTraceLevel is the operational status of the optimization engine.
- The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call SetTraceLevel.

For example, SetTraceLevel can return %OptEng_Fail and DetailedStatus is %OptEng_DB_Updates_Pending. For SetTraceLevel, DetailedStatus can have the value:

- %OptEng_Success: indicates that the function completed successfully.
- %OptEng_Fail: indicates that the function failed.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.
- %OptEng_DB_Updates_Pending: indicates that database updates are pending.

Parameters

Parameter	Description
<i>component</i>	Use one of the following PeopleCode constants: Opt_Engine, Opt_Utility, Opt_Datacache, or Opt_Plugin.

Parameter	Description
<i>severity</i>	<p>Use one of the following PeopleCode constants. These options set the degree to which errors are logged. You can set the tracing levels differently for various parts of your program. This enables you to control the amount of trace information that your program generates.</p> <p>The following list shows the order of the severity, starting with the highest level. For example, %Severity_Error logs %Severity_Fatal, %Severity_Status, and %Severity_Error messages, while the system filters out other messages. Keep in mind that the higher the severity, the greater the performance overhead.</p> <ul style="list-style-type: none"> • %Severity_Fatal • %Severity_Status • %Severity_Error • %Severity_Warn • %Severity_Info • %Severity_Trace1 • %Severity_Trace2

Returns

This method returns a constant. Valid values are:

Value	Description
%OptEng_Success	Returned if method succeeds.
%OptEng_Fail	Returned if the method fails.

Example

```

Local OptEngine &myopt;
Local integer &status;
Local string &machname;
Local datetime &begindate;
Local datetime &enddate;

&myopt = GetOptEngine("PATSMITH");

&status = &myopt.SetTraceLevel(%Opt_Engine, %Severity_Warn);
if &status = %OptEng_Fail then
    <example: notify user that set trace action has failed>
End-if;

```

ShutDown

Syntax

ShutDown ()

Description

The ShutDown method requests the optimization engine to shut down.

If the optimization engine cannot be contacted for shutdown, the return status is %OptEng_Fail and the DetailedStatus property is OptEng_Not_Available.

When using the DetailedStatus OptEngine property, keep the following in mind:

- The value returned by Shutdown is the operational status of the optimization engine.
- The DetailedStatus OptEngine property indicates the completion status of the OptEngine method call Shutdown.

For example, Shutdown can return %OptEng_Fail and DetailedStatus is %OptEng_DB_Updates_Pending. For Shutdown, DetailedStatus can have the value:

- %OptEng_Success: indicates that the function completed successfully.
- %OptEng_Fail: indicates that the function failed.
- %OptEng_Method_Disabled: indicates that the method is disabled or not valid.
- %OptEng_DB_Updates_Pending: indicates that database updates are pending.

Note: Before this method is called, CreateOptEngine or GetOptEngine must be called. Call ShutDown to shut down optimization engines even when running in Application Engine.

Parameters

None.

Returns

This method returns a constant. Valid values are:

Value	Description
%OptEng_Success	Returned if method succeeds.
%OptEng_Fail	Returned if the method fails.

Example

This PeopleCode example shows an optimization engine being shut down:

```
Local OptEngine &myopt;
Local integer &status;
&myopt = GetOptEngine("PATSMITH");
/* Shut down the optimization engine */
&status = &myopt.ShutDown();
If &status=%OptEng_Fail Then
    QEOPT_WRK.MESSAGE_TEXT = "PATSMITH optimization engine shutdown failed.";
    Return;
Else
    QEOPT_WRK.MESSAGE_TEXT = "PATSMITH optimization engine shutdown successful.";
    Return;
End-If;
```

The following example shows the use of the DetailedStatus property:

```
Local integer &status;
&status = myopt.ShutDown();
if &status=%OptEng_Fail and &myopt.DetailedStatus=%OptEng_Method_Disabled then
    <perform some action>
End-if;
```

OptEngine Class Properties

This section lists the optimization properties for the OptEngine PeopleCode class. The properties are listed in alphabetical order.

DetailMsgs

Description

The DetailMsgs property returns a list of messages generated by an optimization engine. Use DetailMsgs after you use the RunAsynch and RunSynch methods to check the status messages for an optimization transaction.

If the transaction fails, detailed messages are automatically shown to the user. If the transaction succeeds, warnings and informational messages may be generated by the transaction. Use this property to retrieve those messages and make them available to the user.

DetailMsgs provides a two-dimensional array containing the message set ID, the message number in the message catalog, and any arguments. Each row in the two-dimensional array has the following structure:

1. Message set ID.
2. Message number.
3. Number of message arguments.
4. Argument1.
5. Argument2.
6. Argument3.

7. Argument4.

8. Argument5.

A maximum of five arguments is supported for each message.

Note: To hold the property value returned, you need to declare an array of array of type *Any*.

Note: Before this method is called, you must call `CreateOptEngine` or `GetOptEngine`.

Example

```
Local OptEngine &myopt;
Local integer &status;
Local string &piid;

Local string &string;
Local array of array of any &arrArray;

&NEWLINE = Char(10);
&string = "";

&piid = GetRecord(Record.PSOPTPRBINST).GetField(Field.PROBINST).Value;
&myopt = GetOptEngine(&piid);

&status = &myopt.RunSynch("TEST_TRANSACTION");

If (&status = %OptEng_Success) then

&arrArray = &myopt.DetailMsgs;
For &iLoop = 1 To &arrArray.Len

    &string = &string | &NEWLINE | MsgGetText(&arrArray [&iLoop][1] /*message set*/
/,
    &arrArray [&iLoop][2] /*message id*/, "Message Not Found",&arrArray [&iLoop][4],
    &arrArray [&iLoop][5],&arrArray [&iLoop][6],
    &arrArray [&iLoop][7],&arrArray [&iLoop][8]);

End-For;

GetLevel0().GetRow(1).GetRecord(Record.QE_FUNCLIB_OPT).DESCRLONG.Value = &string;
End-If;
```

DetailedStatus

Description

The `DetailedStatus` property contains the detailed execution status of an `OptEngine` method after the method is executed.

Example

```
Local integer &status;
&status = myopt.ShutDown();
if &status=%OptEng_Fail and &myopt.DetailedStatus=%OptEng_Method_Disabled then
    <perform some action>
End-if;
```

OptBase Application Class

This PeopleCode application class is part of the PT_OPT_BASE application package. It establishes the basic framework for developing PeopleCode that invokes the Optimization PeopleCode plug-in. To use the plug-in, you develop a application class that extends the OptBase application class. OptBase contains the following types of methods:

- A set of base methods that you can extend for the purpose of handling input and output parameters.

You can use them within any method you develop that corresponds by name to a transaction in an analytic type definition. These methods apply to the parameters that are defined for the transaction in the analytic type.

- A set of abstract placeholder methods that you can use to implement callback capability.

You must extend these if you designate one or more records as callback records in your analytic type definition, even if you don't add any functionality to the methods.

- An abstract placeholder method, Init, that you can extend if you want to do any preprocessing before your first Optimization PeopleCode plug-in transaction runs.

Note: The analytic type definition to which these methods apply is the one that specifies this derived application class.

The CreateOptInterface function is the only optimization built-in function that you can use within an application class that you extend from the OptBase application class, or within PeopleCode that you call from that application class.

Optbase Callback Methods

PeopleSoft Optimization Framework has a built-in callback functionality when the OptInterface PeopleCode calls an Optimization PeopleCode plug-in transaction, it first determines whether you designated one or more records in your analytic type definition as callback records. For each callback record, the framework determines if any the record's database rows have been inserted, deleted, or updated since the optimization datacache was populated. If any changes have occurred, the framework propagates those changes to the datacache before invoking the transaction.

PeopleSoft provides methods that the framework uses to apply its callback functionality. In combination with the framework's callback changes, you might want to perform additional processing for your own purposes, including updating any derived data structures that are used by your optimization application. You can accomplish this by extending the callback methods and adding your own PeopleCode. Each callback method launches under different circumstances.

Note: Don't call any of these methods in your own PeopleCode. They're called automatically at the appropriate moment by PeopleSoft Optimization Framework, which enables your added functionality to run within each method.

Following is a list of the abstract callback placeholder methods documented as part of the PT_OPT_BASE:OptBase application class:

- OptInsertCallback

This method launches when the framework propagates to the datacache any database insertions encountered for a callback record.

- `OptDeleteCallback`

This method launches when the framework propagates to the datacache any database deletions encountered for a callback record.

- `OptPreUpdateCallback`

This method launches before the framework propagates each database update encountered for a callback record.

- `OptPostUpdateCallback`

This method launches after the framework propagates each database update encountered for a callback record.

- `OptRefreshCallback`

This method launches after the framework propagates all database deletions, insertions, and updates encountered for all callback records.

Important! If any record in your analytic type definition is designated a callback record, you must ensure that you extend all of the callback methods in your extended class, even if each extended method contains only a Return statement. Otherwise your Optimization PeopleCode plug-in will fail.

See "Configuring Analytic Type Records" (Optimization Framework).

OptBase Class Methods

This section discusses the abstract base class placeholder methods for the `PT_OPT_BASE:OptBase` application class. The methods are listed in alphabetical order.

GetParmDate

Syntax

```
GetParmDate (parmName, &parmVal)
```

Description

The `GetParmDate` method retrieves a Date parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the `OptBase` application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a Date variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmDateArray

Syntax

```
GetParmDateArray(parmName, &parmVal)
```

Description

The GetParmDateArray method retrieves a Date array parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a Date array variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmDateTime

Syntax

```
GetParmDateTime(parmName, &parmVal)
```

Description

The `GetParmDateTime` method retrieves a `DateTime` parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the `OptBase` application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a <code>DateTime</code> variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmDateTimeArray

Syntax

```
GetParmDateTimeArray(parmName, &parmVal)
```

Description

The `GetParmDateTimeArray` method retrieves a `DateTime` array parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the `OptBase` application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a <code>DateTime</code> array variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmNumber

Syntax

GetParmNumber (*parmName*, *&parmVal*)

Description

The GetParmNumber method retrieves a Number parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a Number variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmNumberArray

Syntax

GetParmNumberArray (*parmName*, *&parmVal*)

Description

The GetParmNumberArray method retrieves a Number array parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.

Parameter	Description
<i>&parmVal</i>	Specify a Number array variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmInt

Syntax

```
GetParmInt(parmName, &parmVal)
```

Description

The GetParmInt method retrieves an Integer parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify an Integer variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmIntArray

Syntax

```
GetParmIntArray(parmName, &parmVal)
```

Description

The GetParmIntArray method retrieves a Number array parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a Number array variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmString

Syntax

```
GetParmString(parmName, &parmVal)
```

Description

The GetParmString method retrieves a String parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a String variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmStringArray

Syntax

```
GetParmStringArray(parmName, &parmVal)
```

Description

The `GetParmStringArray` method retrieves a `String` array parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the `OptBase` application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a <code>String</code> array variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmTime

Syntax

```
GetParmTime(parmName, &parmVal)
```

Description

The `GetParmTime` method retrieves a `Time` parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the `OptBase` application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a <code>Time</code> variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

GetParmTimeArray

Syntax

```
GetParmTimeArray(parmName, &parmVal)
```

Description

The GetParmTimeArray method retrieves a Time array parameter value that passed as input by any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a Time array variable to contain the value passed as input by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

Init

Syntax

```
Init()
```

Description

The Init method launches when the CreateOptEngine built-in function loads an analytic instance that uses the Optimization PeopleCode plug-in.

Use this method to perform additional processing for your own purposes, including checking table data, or any functionality you want to apply before any plug-in transactions run. You accomplish this by adding your own PeopleCode to the extended method.

Don't call this method in your own PeopleCode. It's called automatically at the appropriate moment by PeopleSoft Optimization Framework, which enables your added functionality to run before any other code in your extended class.

Note: If you don't extend this method, PeopleSoft Optimization Framework calls its base version from the OptBase application class.

Parameters

None.

Returns

A Boolean value: True if the method is successful, False otherwise.

OptDeleteCallback

Syntax

```
OptDeleteCallback (&Record)
```

Description

The OptDeleteCallback method launches when PeopleSoft Optimization Framework propagates to the datacache any database deletions that it encounters for a callback record.

Use this method to perform additional processing for your own purposes, including modifying any derived data structures that might be affected by the deletion. You accomplish this by adding your own PeopleCode to the extended method.

Don't call this method in your own PeopleCode. It's called automatically at the appropriate moment by PeopleSoft Optimization Framework, which enables your added functionality to run.

Important! If you designate any record in the analytic type definition as a callback record, you must ensure that you extend this callback method in your derived class, even if the extended method contains only a Return statement. Otherwise the Optimization PeopleCode plug-in will fail.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Record</i>	Specifies a record variable that contains the keys of the data row to be deleted.

Returns

A Boolean value: True if the method is successful, False otherwise.

OptInsertCallback

Syntax

```
OptInsertCallback (&Record)
```

Description

The `OptInsertCallback` method launches when PeopleSoft Optimization Framework propagates to the datacache any database insertion that it encounters for a callback record.

Use this method to perform additional processing for your own purposes, including modifying any derived data structures that might be affected by the insertion. You accomplish this by adding your own PeopleCode to the extended method.

Don't call this method in your own PeopleCode. It's called automatically at the appropriate moment by PeopleSoft Optimization Framework, which enables your added functionality to run.

Important! If you designate any record in the analytic type definition as a callback record, you must ensure that you extend this callback method in your derived class, even if the extended method contains only a Return statement. Otherwise the Optimization PeopleCode plug-in will fail.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Record</i>	Specifies a record variable that contains the new data row to be inserted.

Returns

A Boolean value: True if the method is successful, False otherwise.

OptPostUpdateCallback

Syntax

```
OptPostUpdateCallback(&OldRecord, &NewRecord)
```

Description

The `OptPostUpdateCallback` method launches after PeopleSoft Optimization Framework propagates to the datacache any database update that it encounters for a callback record.

Use this method to perform additional processing for your own purposes, including modifying any derived data structures that might have been affected by the update. You accomplish this by adding your own PeopleCode to the extended method. The parameters provide the previous and current content of the row.

Don't call this method in your own PeopleCode. It's called automatically at the appropriate moment by PeopleSoft Optimization Framework, which enables your added functionality to run.

Important! If you designate any record in the analytic type definition as a callback record, you must ensure that you extend this callback method in your derived class, even if the extended method contains only a Return statement. Otherwise the Optimization PeopleCode plug-in will fail.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&OldRecord</i>	Specifies a record variable that contains the pre-update content of the data row that was updated.
<i>&NewRecord</i>	Specifies a record variable that contains the post-update content of the data row that was updated.

Returns

A Boolean value: True if the method is successful, False otherwise.

OptPreUpdateCallback

Syntax

`OptPreUpdateCallback (&OldRecord, &NewRecord)`

Description

The OptPreUpdateCallback method launches before PeopleSoft Optimization Framework propagates to the datacache any database update that it encounters for a callback record.

Use this method to perform additional processing for your own purposes, including modifying any derived data structures that might be affected by the update. You accomplish this by adding your own PeopleCode to the extended method. The parameters provide the current and future content of the row.

Don't call this method in your own PeopleCode. It's called automatically at the appropriate moment by PeopleSoft Optimization Framework, which enables your added functionality to run.

Important! If you designate any record in the analytic type definition as a callback record, you must ensure that you extend this callback method in your derived class, even if the extended method contains only a Return statement. Otherwise the Optimization PeopleCode plug-in will fail.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&OldRecord</i>	Specifies a record variable that contains the pre-update content of the data row to be updated.
<i>&NewRecord</i>	Specifies a record variable that contains the post-update content of the data row to be updated.

Returns

A Boolean value: True if the method is successful, False otherwise.

OptRefreshCallback

Syntax

```
OptRefreshCallback ()
```

Description

The OptRefreshCallback method launches after PeopleSoft Optimization Framework propagates to the datacache all database insertions, deletions, and updates that it encounters for all callback records.

Use this method to perform additional processing for your own purposes, including modifying any derived data structures that might be affected by the modifications. You accomplish this by adding your own PeopleCode to the extended method.

Don't call this method in your own PeopleCode. It's called automatically at the appropriate moment by PeopleSoft Optimization Framework, which enables your added functionality to run.

Important! If you designate any record in the analytic type definition as a callback record, you must ensure that you extend this callback method in your derived class, even if the extended method contains only a Return statement. Otherwise the Optimization PeopleCode plug-in will fail.

Parameters

None.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmDate

Syntax

```
SetOutputParmDate (parmName, &parmVal)
```

Description

Use the SetOutputParmDate method to pass a Date parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a Date variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmDateArray

Syntax

```
SetOutputParmDateArray(parmName, &parmVal)
```

Description

Use the SetOutputParmDateArray method to pass a Date array parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a Date array variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmDateTime

Syntax

```
SetOutputParmDateTime(parmName, &parmVal)
```

Description

Use the `SetOutputParmDateTime` method to pass a `DateTime` parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the `OptBase` application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a <code>DateTime</code> variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmDateTimeArray

Syntax

```
SetOutputParmDateTimeArray (parmName, &parmVal)
```

Description

Use the `SetOutputParmDateTimeArray` method to pass a `DateTime` array parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the `OptBase` application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a <code>DateTime</code> array variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmNumber

Syntax

```
SetOutputParmNumber(parmName, &parmVal)
```

Description

Use the SetOutputParmNumber method to pass a Number parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
& <i>parmVal</i>	Specify a Number variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmNumberArray

Syntax

```
SetOutputParmNumberArray(parmName, &parmVal)
```

Description

Use the SetOutputParmNumberArray method to pass a Number array parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.

Parameter	Description
<i>&parmVal</i>	Specify a Number array variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmInt

Syntax

SetOutputParmInt (*parmName*, *&parmVal*)

Description

Use the SetOutputParmInt method to pass an Integer parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify an Integer variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmIntArray

Syntax

SetOutputParmIntArray (*parmName*, *&parmVal*)

Description

Use the SetOutputParmIntArray method to pass a Number array parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a Number array variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmString

Syntax

```
SetOutputParmString(parmName, &parmVal)
```

Description

Use the SetOutputParmString method to pass a String parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

Parameter	Description
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a String variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmStringArray

Syntax

```
SetOutputParmStringArray(parmName, &parmVal)
```

Description

Use the `SetOutputParmStringArray` method to pass a `String` array parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the `OptBase` application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a <code>String</code> array variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmTime

Syntax

```
SetOutputParmTime(parmName, &parmVal)
```

Description

Use the `SetOutputParmTime` method to pass a `Time` parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the `OptBase` application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
<i>&parmVal</i>	Specify a <code>Time</code> variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

SetOutputParmTimeArray

Syntax

```
SetOutputParmTimeArray(parmName, &parmVal)
```

Description

Use the SetOutputParmTimeArray method to pass a Time array parameter value as output from any method you develop that corresponds to an Optimization PeopleCode plug-in transaction. You develop the transaction method in an application class that you derive from the OptBase application class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parmName</i>	Specify the name of the parameter as it's defined for the Optimization PeopleCode plug-in transaction.
& <i>parmVal</i>	Specify a Time array variable that contains a value to be passed as output by the parameter.

Returns

A Boolean value: True if the method is successful, False otherwise.

OptInterface Class Methods

This section discusses the optimization methods for the OptInterface PeopleCode class. The methods are listed in alphabetical order.

Note: You can use the OptInterface class methods only within an application class that you extend from the OptBase application class, or within PeopleCode that you call from that application class. This ensures that the OptInterface PeopleCode runs only on the optimization engine.

ActivateModel

Syntax

```
ActivateModel(ModelID, SolverSettingID)
```

Description

The ActivateModel method designates the specified model and solver setting as active. The model and the solver are initialized and populated with data from the current analytic instance.

Note: This method fails if the specified model (and by extension, one of its solver settings) is already active. If you want to activate a different solver setting for the same model, you must first deactivate the model.

See [DeactivateModel](#).

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ModelID</i>	Specify the name of the optimization model you want to activate. This must be the name of one of the models associated with the analytic type definition.
<i>SolverSettingID</i>	Specify the name of the solver setting you want to activate. This is the name you specified for the solver setting in the analytic type definition.

Returns

This method returns a constant value. Valid values are:

<i>Value</i>	<i>Description</i>
%OptInter_Success	Returned if method succeeds.
%OptInter_Fail	Returned if the solver fails to solve the problem.

Example

```
Local integer &result;
Local OptInterface &oi = CreateOptInterface();

&result = &oi.ActivateModel("QE_PSA_MODEL", "abc");
```

ActivateObjective

Syntax

ActivateObjective (*Model_Name*, *Objective_Name*)

Description

Use the ActivateObjective method to activate the specified objective for an optimization model.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Model_Name</i>	Specify the name of the model.
<i>Objective_Name</i>	Specify the name of the objective.

Returns

This method returns a constant value. Valid values are:

<i>Value</i>	<i>Description</i>
%OptInter_Success	Returned if method succeeds.
%OptInter_Fail	Returned if the solver fails to solve the problem.

DeactivateModel

Syntax

DeactivateModel (*ModelID*)

Description

The DeactivateModel method detaches the solver from the specified model.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ModelID</i>	Specify the name of the optimization model you want to deactivate. This must be the name of one of the models associated with the analytic type definition.

Returns

This method returns a constant value. Valid values are:

<i>Value</i>	<i>Description</i>
%OptInter_Success	Returned if method succeeds.

Value	Description
%OptInter_Fail	Returned if the solver fails to solve the problem.

Example

```
Local integer &result;
Local OptInterface &oi = CreateOptInterface();

&result = &oi.DeactivateModel("QE_PSA_MODEL");
```

DumpMsgToLog

Syntax

```
DumpMsgToLog(LogSeverity, Message)
```

Description

The DumpMsgToLog method writes the specified status message to the optimization engine log file, with the specified severity.

Parameters

Parameter	Description
<i>LogSeverity</i>	Specify the severity level of the message, as one of the following system constants: <ul style="list-style-type: none"> • %Severity_Fatal • %Severity_Status • %Severity_Error • %Severity_Warn • %Severity_Info • %Severity_Trace1 • %Severity_Trace2
<i>Message</i>	Specify as a string the text of the log message.

Returns

None.

FindRowNum

Syntax

```
FindRowNum(&Record [, startrow [, endrow [, field_list]])
```

Where *field_list* is a list of field names in the form:

```
[fieldname1 [, fieldname2]]...
```

Description

The FindRowNum method determines the row number of a row in the datacache rowset. You provide a record with key values, and this method finds the row with the same key values and returns its row number.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Record</i>	Specify a record with the same structure as the records that comprise the rowset, with its key fields populated.
<i>startrow</i>	Specify as an integer the starting row number of the search. Specify 0 to search from the first row in the rowset.
<i>endrow</i>	Specify as an integer the ending row number of the search. Specify 0 to search through the last row in the rowset.
<i>fieldname</i>	Specify the name of a field in the input record which contains a value to be matched. You can specify one or more field names, in any order. Note: If you use this parameter, the fields specified here are used to search, instead of the record's key fields. Any value that doesn't correspond to a field name is ignored.

Returns

The row number of the row containing the specified key values, or 0 if no row is found.

Example

The following example searches the whole scroll to find the partial key OPT_SITE:

```
Local Record &rec = CreateRecord(Scroll.OPT_TRANSCOST);
Local Optineterface &oi;

&rec.OPT_SITE.value = "New York";
int nRowNum = &oi.FindRowNum(&rec, 0, 0, "OPT_SITE");
```

The following example searches from row 5 to row 15 with the full key values New York and San Jose:

```
Local Record &rec = CreateRecord(Scroll.OPT_TRANSCOST);
Local Optineterface &oi;

&rec.OPT_SITE.value = "New York";
&rec.OPT_STORE.value = "San Jose";
int numRows = &oi.FindRowNum(&rec, 5, 15);
```

GetSolution

Syntax

```
GetSolution(ModelID, varArrayID, skipZero [, KeyFieldNames, KeyFieldValues [, &Solution]])
```

Description

The GetSolution method retrieves the model solution values generated by the Solve method.

Parameters

Parameter	Description
<i>ModelID</i>	Specify as a string the name of the optimization model for which you want the solution. This is the name used for the model definition in Application Designer.
<i>varArrayID</i>	Specify as a string the name of the variable array being optimized. Your application documentation should provide this name.
<i>skipZero</i>	Indicate whether solutions with a value of zero should be fetched. This parameter takes a Boolean value: <ul style="list-style-type: none"> • True: Don't fetch solutions with a zero value. This can increase the performance of the GetSolution method if zero values aren't meaningful. • False: Do fetch solutions with a zero value.
<i>KeyFieldNames</i> and <i>KeyFieldValues</i>	Specify a set of key field names as an array of string and a set of key field values as an equal length array of ANY, with one key field value corresponding to each key field name. You use these arrays to restrict the set of returned solutions. Solutions are returned only for model variables with the specified key field values. <p>Note: If you provide either of these arrays, you must provide both. You can include each parameter from the variable array at most only once.</p>

Parameter	Description
<i>&Solution</i>	Specify a rowset to contain the solutions.

Returns

This method returns a constant value. Valid values are:

Value	Description
%OptInter_Success	Returned if method succeeds.
%OptInter_Fail	Returned if the solver fails to solve the problem.

Example

```

Local array of string &strArray;
Local array of any &valArray;
Local integer &index;
Local Rowset &rowSet;
Local integer &result;
Local string &modelId = "QE_PSA_MODEL";
Local string &varArrayName = "X";
Local boolean &bSkipZero = True;

Local OptInterface &oi = CreateOptInterface();

&strArray = CreateArrayRept("", 0);
&valArray = CreateArrayAny();
&rowSet = CreateRowset(Record.QEOPT_VAL_X_WRK);

&strArray [1] = "EMPLID";
&valArray [1] = 1;
&strArray [2] = "ORDER_ID";
&valArray [2] = 23;

/* fetch only the part of the solution where EMPLID = 1 and ORDER_ID = 23 */
&result = &oi.GetSolution(&modelId, &varArrayName,
    &bSkipZero, &strArray, &valArray, &rowSet);

```

GetSolutionDetail

Syntax

```
GetSolutionDetail(ModelID, SolutionType, Name, &Solution)
```

Description

The GetSolutionDetail method retrieves the model solution detail of the specified type generated by the Solve method. You can retrieve dual value, slack value, or reduced cost information.

Parameters

Parameter	Description
<i>ModelID</i>	Specify as a string the name of the optimization model for which you want the solution detail. This is the name used for the model definition in Application Designer.
<i>SolutionType</i>	Specify a system constant indicating the type of solution detail you want to retrieve. The value you specify here determines the content of the <i>Name</i> and <i>&Solution</i> parameters. <ul style="list-style-type: none"> <code>%OPT_DUAL</code>: Retrieve the dual value attributes of the specified constraint block. <code>%OPT_SLACK</code>: Retrieve the slack value attributes of the specified constraint block. <code>%OPT_RCOST</code>: Retrieve the reduced cost attributes of the specified variable array.
<i>Name</i>	If you specified a <i>SolutionType</i> of <code>%OPT_DUAL</code> or <code>%OPT_SLACK</code> , specify here the name of a constraint block from the active model. If you specified a <i>SolutionType</i> of <code>%OPT_RCOST</code> , specify here the name of a variable array from the active model.
<i>&Solution</i>	Specify a rowset to contain the solution details. The rowset should have the same key fields as the constraint block or the variable array you specified with the <i>Name</i> parameter.

Returns

This method returns a constant value. Valid values are:

Value	Description
<code>%OptInter_Success</code>	Returned if method succeeds.
<code>%OptInter_Fail</code>	Returned if solver fails to solve the problem.

Example

```
Local Rowset &dual_rowset;
Local integer &result;
Local OptInterface &oi = CreateOptInterface();
Local string &modelId = "QE_PSA_MODEL";
Local string &varArrayName = "X";
Local string &constrName = "Constraint_1";

/* fetch dual values for Constraint "Constraint_1"
in a rowset based on the QEOPT_C1_WRK record */
```

```
&dual_rowset = CreateRowset(Record.QEOPT_C1_WRK);
&result = &oi.GetSolutionDetail(&modelID, %Opt_Dual, &constrName, &dual_rowset);
```

IsModelActive

Syntax

```
IsModelActive(ModelID)
```

Description

Use the IsModelActive method to determine if the model specified by *ModelID* is active before it is used.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ModelID</i>	Specify the model ID as a string. This is the name used for the model definition in Application Designer.

Returns

A Boolean value: true if the model is active, false otherwise.

RestoreBounds

Syntax

```
RestoreBounds(modelID [, varArrayID])
```

Description

The RestoreBounds method returns the bounding values of the specified variable array or arrays to the current settings in the specified model.

If you previously called the SetVariableBounds method with the *changeModelBounds* parameter set to true for any variable or variable array, those bounding values still apply.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>modelID</i>	Specify as a string the name of the optimization model for which you want to restore the bounding values. This is the name used for the model definition in Application Designer.

Parameter	Description
<i>varArrayID</i>	Specify as a string the name of a variable array for which you want to restore the bounding values. Your application documentation should provide this name. If you don't specify a variable array name, the bounding values are restored for all variable arrays in the specified model.

Returns

%OptInter_Success if the method succeeds, %OptInter_Fail otherwise.

SetVariableBounds

Syntax

```
SetVariableBounds(modelID, varArrayID, boundType, lowerBound, upperBound, &keyRecord [, changeModelBounds])
```

Description

The SetVariableBounds method overrides the bounding values specified for a model variable array, or for a variable within the array.

Parameters

Parameter	Description
<i>modelID</i>	Specify as a string the name of the optimization model for which you want to override the bounding values. This is the name used for the model definition in Application Designer.
<i>varArrayID</i>	Specify as a string the name of the variable array being optimized. Your application documentation should provide this name.

Parameter	Description
<i>boundType</i>	<p>Specify a system constant indicating which bounding values to override. The value you specify here determines how the <i>lowerBound</i> and <i>upperBound</i> parameters are applied to the specified model.</p> <ul style="list-style-type: none"> • <code>%OPT_LOWER_BOUND</code>: Override only the lower bound as specified by the <i>lowerBound</i> parameter. The <i>upperBound</i> parameter is ignored. • <code>%OPT_UPPER_BOUND</code>: Override only the upper bound as specified by the <i>upperBound</i> parameter. The <i>lowerBound</i> parameter is ignored. • <code>%OPT_BOUND_BOTH</code>: Override both the lower bound and the upper bound as specified by the <i>lowerBound</i> and <i>upperBound</i> parameters, respectively.
<i>lowerBound</i>	<p>Specify as a number the lower bound that should be applied to a variable or a variable array if the <i>boundType</i> parameter permits the override. You can also set this parameter to one of the following system constants:</p>
<i>upperBound</i>	<p>Specify as a number the upper bound that should be applied to a variable or a variable array if the <i>boundType</i> parameter permits the override. You can also set this parameter to one of the following system constants:</p>
<i>&keyRecord</i>	<p>Specify a record with the same key fields as the variable array being optimized. To override the bounding values specified for a single variable within the array, populate the record's key fields to specify the variable. To override the bounding values specified for the entire variable array, set all of the record's fields to a null value.</p> <hr/> <p>Note: You must either provide values for all keys, or set them all to null values.</p> <hr/>
<i>changeModelBounds</i>	<p>Specify a Boolean value:</p> <ul style="list-style-type: none"> • <code>true</code>: Indicates that the specified model should be updated in memory to reflect the specified variable bounds. Any analytic instance that invokes this model from the active optimization engine is affected by these settings, which are propagated to the solver in memory. This is the default value if you omit this parameter. • <code>false</code>: Indicates that the specified model should not be updated in memory, and that the specified variable bounds apply only to the next time the Solve method is called.

Returns

`%OptInter_Success` if the method succeeds, `%OptInter_Fail` otherwise.

Example

```

Local Record &rec;
Local integer &result;
Local OptInterface &oi = CreateOptInterface();
Local float &objval = 0.0;
Local string &modelId = "QE_PSA MODEL";
Local string &varArrayName = "X";
Local float &lb = 0.0;
Local float &ub = 0.0;

&rec = CreateRecord(Record.QEOPT_VAL_X_WRK);
&rec.QEOPT_RESINDEX.Value = 1;
&rec.QEOPT_SOLINDEX.Value = 2;
&rec.QEOPT_TIMEINDEX.Value = 3;

&result = &oi.SetVariableBounds(&modelId, &varArrayName,
    %Opt_Upper_Bound, &lb, &ub, &rec, False);

```

SetVariableType

Syntax

```
SetVariableType (modelID, varArrayID, varType)
```

Description

Use the SetVariableType method to change the data type of a model variable array.

Parameters

Parameter	Description
<i>ModelID</i>	Specify as a string the name of the optimization model for which you want to change the variable type. This must be the name of one of the models associated with the analytic type definition.
<i>varArrayID</i>	Specify as a string the name of the variable array for which you want to change the variable type. Your application documentation should provide this name.
<i>varType</i>	Specify one of the following system constants representing the new variable type: <ul style="list-style-type: none"> <code>%Opt_Var_Cont</code>: Represents a continuous variable type, which can be any floating point value. <code>%Opt_Var_Bin</code>: Represents a binary variable type, for which the value can be only 0 or 1. <code>%Opt_Var_Int</code>: Represents an integer variable type, which can be any integer.

Returns

%OptInter_Success if the method succeeds, %OptInter_Fail otherwise.

Example

```
Local OptInterface &oi = CreateOptInterface();
Local string &varArrayName = "X";
Local integer &result;

&result = &oi.SetVariableType("QE_PSA_MODEL", &varArrayName, %Opt_Var_Bin);

If (&result <> %OptInter_Success) Then
    &oi.DumpMsgToLog(%Severity_Status, "Failed to change variable type ");
End-If;
```

Solve

Syntax

Solve(*modelID*, *SolutionType* [, &*objValue* [, *name-value_pairs*]])

Where *name-value_pairs* is a list of solver setting parameter values in the form:

[*parmname1*, *parmvalue1* [, *parmname2*, *parmvalue2*]]...

Description

The Solve method solves the specified model using the currently active solver settings, and provides an objective value as the solution output. You can override the solver setting parameters. The returned solution status is a predefined system constant.

Parameters

Parameter	Description
<i>ModelID</i>	Specify as a string the name of the optimization model you want to solve. This is the name used for the model definition in Application Designer.
<i>SolutionType</i>	Specify a system constant indicating the type of solution detail you want the model to be solved for. <ul style="list-style-type: none"> • %OPT_DUAL: Generate dual value attributes. • %OPT_SLACK: Generate slack value attributes. • %OPT_RCOST: Generate reduced cost attributes. You can also combine any or all of these system constants, by connecting them with a plus sign (+), for example: %OPT_DUAL + %OPT_RCOST.

Parameter	Description
<i>&objValue</i>	Specify a reference to a variable of type float. This variable contains the output objective value produced by the solver upon successfully solving the specified optimization model.
<i>parmname</i> and <i>parmvalue</i>	Specify a solver setting parameter ID and value to override the original value you specified for the solver setting in the analytic type definition. You can override any or all of the solver setting parameter values. See "Configuring Models for Optimization" (Optimization Framework).

Returns

One of the following system constants:

`%OptInter_Fail`: The solver fails to solve the problem.

`%Opt_Optimal`: The solution is optimal.

`%Opt_Infeasible`: The solution is infeasible.

`%Opt_Unbounded`: The solution is unbounded.

`%Opt_Timeup`: The solver reached the time limit specified in the solver setting.

`%Opt_Iterlimit`: The solver reached the limit on the number of iterations specified in the solver setting.

`%Opt_LP_Max_Sols`: The solver generated maximum number of solutions without improvement.

`%Opt_Idle`: The solution shows no improvement in a specified time limit.

`%Opt_Unknown`: The solver status is unknown.

`%Opt_MIP_NumSolutions`: The specified number of solutions corresponding to an MIP solver reached.

`%Opt_MIP_NumNodes`: The specified number of nodes corresponding to an MIP solver reached.

`%Opt_Aborted`: The solver aborted.

`%Opt_User_Exit`: A user exit was encountered.

`%Opt_First_LP_NoOpt`: While solving an MIP, the first LP solution obtained was not optimal.

Example

Following is an example of the basic use of the Solve method:

```
Local OptInterface &oi = CreateOptInterface();

Local float &objval = 0.0;
Local integer &result;
Local string &modelId = "QE_PSA_MODEL";
Local string &varArrayName = "X";
```

```
Local integer &solType;

&solType = %Opt_RCost + %Opt_Dual + %Opt_Slack;

/* Solve the problem */
&result = &oi.Solve("QE_PSA_MODEL", &solType, &objval);

If & result = %Opt_Optimal Then
    &oi.DumpMsgToLog(%Severity_Warn, " Solution Status = " Optimal !!!");
Else
    &oi.DumpMsgToLog(%Severity_Warn, " Solution Status = " | &result );
End-If;
```

Following is an example of a solver setting parameter override:

```
Local OptInterface &oi = CreateOptInterface();
Local float &objval = 0.0;
Local integer &result;

/* This overrides the solver setting for MPS_Filename and generates
an MPS file called myfile.mps instead of the name specified
in the current solver setting parameter. */

&result = &oi.Solve("QE_PSA_MODEL", %Opt_Primal, &objval, "MPS_FileName",
"myfile");
```

Chapter 36

Page Class

Understanding Page Class

Use the page class to manipulate a page in a component. The most common use of this class is to hide or display a page in a component, either based on field values or the level of security of the user.

Generally, the PeopleCode used to manipulate a page object is associated with PeopleCode in the Activate event.

Note: The page object should not be used until after the page processor has loaded the page: do not instantiate this object in RowInit PeopleCode, use it in PreBuild, PostBuild or Activate instead. In addition, if you need to hide the current page, PeopleSoft recommends using the PreBuild event for your program.

"Component Build Processing in Update Modes" (PeopleCode Developer's Guide)

Shortcut Considerations

An expression of the form

`PAGE.pagename.property`

is equivalent to `GetPage(PAGE.name).property`. For example, the following two lines of code are equivalent:

```
PAGE.MANAGER_APPROV.DisplayOnly = False;  
GetPage(PAGE.MANAGER_APPROV).DisplayOnly = False;
```

Data Type of a Page Object

Use the Page data type to declare Page objects. For example,

```
Local Page &MYPAGE;
```

Scope of a Page Object

A page object can be instantiated from PeopleCode only.

Use this object only in PeopleCode programs that are associated with an online process, not in an Application Engine program, a message subscription, a Component Interface, and so on.

In addition, the page object should not be used until after the page processor has loaded the page: do not instantiate this object in RowInit PeopleCode. Use it in PostBuild or Activate instead.

Page Class Built-in Function

"GetPage" (PeopleCode Language Reference)

Page Class Properties

In this section, we discuss each Page class properties.

CopyURLLink

Description

Use this property to enable the **http** link for a component. Clicking this link copies the address (URL) of the page to the clipboard. This is a Pagebar property.

Note: If you select the **Disable Pagebar** check box for the component in Application Designer, you cannot set any of the Pagebar properties using PeopleCode. If you deselect the **Copy URL Link** check box for the component in Application Designer, you can still set this option using this property.

This property is read/write.

Related Links

"Setting Use Properties" (Application Designer Developer's Guide)

CustomizePageLink

Description

Use this property to enable **Customize Page** link for a component. Clicking this link enables the user to control the initial display of the component. This property takes a Boolean value, true, the user can control the display, false otherwise. This is a Pagebar property.

Note: If you select the **Disable Pagebar** check box for the component in the Application Designer, you cannot set any of the Pagebar properties using PeopleCode. If you deselect the **Customize Page Link** check box for the component in Application Designer, you can still set this option using this property.

This property is read/write.

Related Links

"Setting Use Properties" (Application Designer Developer's Guide)

DisplayOnly

Description

Use this property to make a page display-only, or to enable a page so the fields can be edited. This property takes a Boolean value: True if the page is display-only, False otherwise.

Note: You cannot enable or disable the current page.

The value of DisplayOnly for a page is restored to the value set in Application Designer when the user goes to another component. This means you must set DisplayOnly for the page each time a component is accessed.

This property is read/write.

Example

```
If &MYPAGE.DisplayOnly Then
    &MYPAGE.Visible = True;
Else
    &MYPAGE.Visible = False;
End-If;
```

HelpLink

Description

Use this property to enable the **Help** link for a component. Clicking this link accesses the online help PeopleBook entry for the current page. This is a Pagebar property.

Note: If you select the **Disable Pagebar** check box for the component in the Application Designer, you cannot set any of the Pagebar properties using PeopleCode. If you deselect the **Help Link** check box for the component in Application Designer, you can still set this option using this property.

This property is read/write.

Related Links

"Setting Use Properties" (Application Designer Developer's Guide)

Name

Description

This property returns a reference to the page name definition (a string value.)

This property is read-only.

Example

```
&MYPAGENAME = &MYPAGE.Name;
```

NewWindowLink

Description

Use this property to enable **New Window** link for a component. Clicking this link opens a new browser window with the search page for the current component. Users can view or enter data in the new window. This is a Pagebar property.

Note: If you select the **Disable Pagebar** check box for the component in the Application Designer, you cannot set any of the Pagebar properties using PeopleCode. If you deselect the **New Window Link** check box for the component in Application Designer, you can still set this option using this property.

This property is read/write.

Related Links

"Setting Use Properties" (Application Designer Developer's Guide)

Visible

Description

Use this property to set the visibility of a page. If this property is set to True, the page is visible. If this property is set to False, the page is not visible. When the visibility is changed, the component tabs and menus are also automatically changed to reflect the new settings. Menus and tabs return to their original values when the user navigates to another component. In addition, if a page is set to be hidden in the component definition, you can change the value of the page to be visible at runtime.

Oracle recommends using the PreBuild event if you need to hide the current page.

Important! If the visibility of the current page is set to False in a PeopleCode program, then you must invoke the TransferPage function to transfer control to a visible page.

Note: Page visibility alone (as set by the Visible property) does not determine whether a user can see a page. Visibility plus the permissions to access the page together determine whether a specific page is displayed to a particular user.

Example

In the following example, a page is hidden based on the value of the current field.

```
If PAYROLE TYPE = "Global" Then
    PAGE.JOB_EARNINGS.Visible = False;
End-If;
```

PeopleSoft Search Framework Classes

Understanding the PeopleSoft Search Framework Classes

In previous PeopleTools releases, search functionality was provided in a non-declarative fashion in which search engine indexes were built using custom PeopleCode and Application Engine programs. Each PeopleSoft application used a unique method for creating and maintaining search artifacts like collections and indexes—all of which required search engine-specific calls, commands, syntax, and so on.

The PeopleSoft Search Framework enables application developers and implementation teams to create search artifacts in a declarative manner and to deploy and maintain search indexes using one standard interface, regardless of PeopleSoft application.

The PeopleSoft Search Framework consists of PeopleSoft components (pages and records provided by PeopleTools), which provide a centralized interface for configuring PeopleSoft integration with the search engine, creating search artifacts such as search definitions and search categories, and building and maintaining search indexes. The PeopleSoft Search Framework was developed to provide an interaction layer that is independent of any specific search engine. In particular, the PeopleSoft Search Framework classes documented in this chapter are general purpose classes not associated with any particular search engine.

In addition to the user interface, the PeopleSoft Search Framework is supported by several PeopleCode application classes including PT_SEARCH and several PTSF application packages. The PT_SEARCH application package provides the administration and query service interfaces for integration with web service based free-text search engines. The root package comprises a factory class, interfaces, superclasses, and implementations for classes that are not dependent on a specific search engine.

[Search Technology](#)

Instantiating a SearchQuery Object

With the PeopleSoft Search Framework, a SearchQuery object is instantiated by instantiating a SearchFactory object, which is used to create a SearchQueryService object. The SearchQuery object is then instantiated from the SearchQueryService.

The high-level program flow is as follows:

```
import PT_SEARCH:SearchFactory;
import PT_SEARCH:SearchQueryService;
import PT_SEARCH:SearchQuery;

Local PT_SEARCH:SearchFactory &factory = create PT_SEARCH:SearchFactory();
Local PT_SEARCH:SearchQueryService &svc = &factory.CreateQueryService("default");
Local PT_SEARCH:SearchQuery &srchQuery = &svc.CreateQuery();
```

Importing PeopleSoft Search Framework Classes

The PeopleSoft Search Framework classes are application classes, not built-in classes, like Rowset, Field, Record, and so on. Before you can use these classes in your PeopleCode program, you must import them into your program.

An import statement either names a particular application class or imports all the classes in a package.

Using the asterisks after the package name makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are not made available.

Performing a Simple Search

The following example code demonstrates how to retrieve properties of the SearchResultCollection and how to iterate over the results in the collection:

1. Import the application package.

```
import PT_SEARCH:*;
```

2. Create an instance of SearchQueryService and SearchFactory.

```
Local PT_SEARCH:SearchFactory &factory = create PT_SEARCH:SearchFactory();
Local PT_SEARCH:SearchQueryService &svc = &factory.CreateQueryService("default⇒
");
```

3. Instantiate the SearchQuery object.

```
Local PT_SEARCH:SearchQuery &srchQuery = &svc.CreateQuery();
```

4. Initialize the search query by setting properties.

```
&srchQuery.QueryText = "some text";
&srchQuery.Language = &lang_cd;
&srchQuery.MarkDuplicates = False;
&srchQuery.RemoveDuplicates = False;
```

5. Execute the search query.

Use the Execute method and specify two integer parameters: *start* determines the index of the first document, *size* determines the number of search documents to return "page" of results.

```
Local number &start = 1;
Local number &size = 10;

Local PT_SEARCH:SearchResultCollection &results;
&results = &srchQuery.Execute(&start, &size);
```

6. Process the search query results

The search query returns a SearchResultCollection. To process this collection: The SearchResultCollection contains SearchResult objects. Each SearchResult has its own methods to access its attributes such as Title, Summary, URL Link, and so on. Each SearchResult also optionally has custom attributes that can be accessed through the SearchFieldCollection object.

```
Local number &i, &j;
```

```

Local number &score;
Local string &title;
Local string &summary;
Local datetime &lastMod;
Local string &url;
Local string &name;
Local string &value;

Rem - Get a couple return properties;

Local number &docCount = &results.GetDocumentCount();
Local number &hitCount = &results.GetEstimatedHitCount();

Rem - Iterate through the search results;

Local PT_SEARCH:SearchResult &curResult;
Local PT_SEARCH:SearchFieldCollection &customs;
For &i = 1 To &results.GetDocumentCount()
    &curResult = &results.Item(&i);
    &score = &curResult.GetScore();
    &title = &curResult.GetTitle();
    &summary = &curResult.GetSummary();
    &lastMod = &curResult.GetLastModified();
    &url = &curResult.GetUrlLink();

    /* Do something with these result attributes */

Rem - Get the custom fields of the result if any;

&customs = &curResult.GetCustomAttributes();
If (&customs <> Null) Then

    Rem - Iterate through custom fields of the result;
    For &j = 1 To &customs.Count()
        &name = &customs.Item(&j).Name;
        &value = &customs.Item(&j).Value;

        /* do something with the custom field */

    End-For;
End-If;
End-For;

Rem - Calculate the number of additional pages in the results;
Local integer &pages;

&pages = Idiv(&hitCount, &size);
If Mod(&hitCount, &size) > 0 Then
    &pages = &pages + 1;
End-If;

Rem - Render the additional pages as links;

```

7. Get the page number for the next request.

Re-execute the search query to retrieve the next page. Increment *start* to the next page; then invoke the `Execute` method.

```

Rem - Get the requested page from the link clicked by the user;
Rem - Store the value in the &req_page variable;
Local integer &req_page;

Rem - Calculate the new start value and re-execute the query;
&start = (&req_page - 1) * &size + 1;
&results = &srchQuery.Execute(&start, &size);

```

The preceding example returns the results in chunks, or pages, which provides better query performance than returning all results at once. However, you could elect to return all results in a single search query. In that case, you will need to consider the maximum number of results returned by the search engine. For

example, when Elasticsearch is the search engine, 200 is the default value for the maximum number of results. In this case, the Execute method would be invoked as follows to return all results at once:

```
Local number &start = 1;
Local number &size = 200;

Local PT_SEARCH:SearchResultCollection &results;
&results = &srchQuery.Execute(&start, &size);
```

[Exception Handling](#)

[Additional Search Examples](#)

[Search Filter Generator Examples](#)

Exception Handling

The PeopleSoft Search Framework uses the try/catch exception construct to handle special conditions that interrupt normal program execution. When special runtime conditions are encountered, the PeopleSoft Search Framework will construct and throw objects of the Exception class or some class derived from the Exception class. There are two main categories of PeopleSoft Search Framework exceptions:

- Those thrown when the PeopleSoft Search Framework detects a special condition.
- Those thrown when the search provider responds with anything other than what was expected for the given request.

The second category of exceptions is necessarily search engine specific since these are coming from the search provider. For example, there are three exception classes defined in the PT_SEARCH:SESIMPL:EXCEPTION subpackage: SESQueryServiceException, SESAdminServiceException, and SESSearchAttributeException. These exception classes may expose SOAPFaultCode and SOAPFaultString properties that are returned by the search engine. The implementation of Elasticsearch as a search provider relies on this PT_SEARCH:SESIMPL:EXCEPTION subpackage.

Virtually all methods of all classes in the PeopleSoft Search Framework can throw an exception; therefore, Oracle recommends that you put all calls to the PeopleSoft Search Framework classes within try-catch blocks.

The following example builds on the previous example that processed search results. In this example, the results processing is augmented by try-catch exception handling:

```
import PT_SEARCH:*;
import PT_SEARCH:SESIMPL:EXCEPTION:*;

/* instantiate and initialize the query object */
/* ... */
/* execute the query */
Local PT_SEARCH:SearchResultCollection &results;

try
    &results = &qry.Execute(&start, &size);
catch PT_SEARCH:SESIMPL:EXCEPTION:SESQueryServiceException &sesEx
    MessageBox(0, "", 0, 0, "The search could not be performed.");
    MessageBox(0, "", 0, 0, "The Search Provider returned an error.");
    MessageBox(0, "", 0, 0, "SOAP fault: ", &sesEx.SoapFaultString);
    WriteToLog(0, &sesEx.SoapFaultCode);
```

```

        WriteToLog(0, &sesEx.S SoapFaultString);
        Exit;
    catch Exception &psEx
        MessageBox(0, "", 0, 0, "The search could not be performed.");
        MessageBox(0, "", 0, 0, "Exception: ", &psEx.DefaultText);
        WriteToLog(0, &psEx.DefaultText);
        Exit;
    end-try;

    /* process the results */
    try
        Local number &docCount = &results.GetDocumentCount();
        Local number &hitCount = &results.GetEstimatedHitCount();

        Local PT_SEARCH:SearchResult &curResult;
        Local PT_SEARCH:SearchFieldCollection &customs;
        For &i = 1 To &results.GetDocumentCount()
            &curResult = &results.Item(&i);

            &score = &curResult.GetScore();
            &title = &curResult.GetTitle();
            &summary = &curResult.GetSummary();
            &lastMod = &curResult.GetLastModified();
            &url = &curResult.GetUrlLink();
            /* do something with the values */
            &customs = &curResult.GetCustomAttributes();
            If (&customs <> Null) Then
                /* iterate over custom fields of the result */
                For &j = 1 To &customs.Count()
                    &name = &customs.Item(&j).Name;
                    &value = &customs.Item(&j).Value;
                    /* do something with the name/value pair */
                End-For;
            End-If;
        End-For;
    catch Exception &ex
        /* encountered an exception while processing results */
        /* inspect the exception to determine appropriate action */
    end-try;

```

PeopleSoft Search Framework Classes Reference

This reference section documents the following classes from the PT_SEARCH application package:

- AssociatedFacet class
- FacetFilter class
- FacetNode class
- SearchAttribute class
- SearchCategory class
- SearchFactory class
- SearchField class
- SearchFieldCollection class

- SearchFilter class
- SearchFilterGenerator class
- SearchQuery class
- SearchQueryCollection class
- SearchQueryService class
- SearchResult class
- SearchResultCollection class

This reference section also documents the following classes from the PTSF_SECURITY application package: SearchAuthnQueryFilter class.

PeopleSoft Search Framework Classes Built-in Functions

"EncodeSearchCode" (PeopleCode Language Reference)

AddConfiguration Class

This section provides an overview of the AddConfiguration class and discusses its methods.

The AddConfiguration class is used to retrieve add a new value configuration properties of a content reference when the content reference is configured on the Manage Configurable Search page.

AddConfiguration Class Methods

In this section, the AddConfiguration class methods are presented in alphabetical order.

AddConfiguration

Syntax

```
AddConfiguration()
```

Description

Use the AddConfiguration method to instantiate an object of the AddConfiguration class.

Parameters

None.

Returns

None.

Example

```
Local PTS_CFGSRCH_CRITERIA:AddConfiguration &addObj = create PTS_CFGSRCH_CRITERIA:A→  
ddConfiguration();
```

GetAddPageInstructionsInfo

Syntax

```
GetAddPageInstructionsInfo ()
```

Description

Use the GetAddPageInstructionsInfo method to retrieve instructions to display on the add a new value page.

Parameters

None.

Returns

A string value containing the instructions to display on the add a new value page.

Example

```
&addObj.GetAddPageInstructionsInfo ();
```

GetAddPageTitleInfo

Syntax

```
GetAddPageTitleInfo ()
```

Description

Use the GetAddPageTitleInfo method to retrieve the specified title for an add a new value page.

Parameters

None.

Returns

A string value containing the page title.

Example

```
&addObj.GetAddPageTitleInfo();
```

GetAddSearchRecord

Syntax

```
GetAddSearchRecord()
```

Description

Use the GetAddSearchRecord method to retrieve the search record specified on the add a new value page for a content reference.

Parameters

None.

Returns

A string value containing the search record for the add a new value page.

Example

```
&addObj.GetAddSearchRecord();
```

GetConfiguredAppClass

Syntax

```
GetConfiguredAppClass()
```

Description

Use the GetConfiguredAppClass method to retrieve the configured application class for the Add button override.

Parameters

None.

Returns

A string value containing the application class.

Example

```
&addObj.GetConfiguredAppClass();
```

GetConfiguredAppClassMethod

Syntax

```
GetConfiguredAppClassMethod()
```

Description

Use the `GetConfiguredAppClassMethod` method to retrieve the configured method of the application class for the Continue button override.

Parameters

None.

Returns

A string value containing the method of the application class.

Example

```
&addObj.GetConfiguredAppClassMethod();
```

GetConfiguredApppackage

Syntax

```
GetConfiguredApppackage()
```

Description

Use the `GetConfiguredApppackage` method to retrieve the configured application package for the Continue button override.

Parameters

None.

Returns

A string value containing the configured application package.

Example

```
&addObj.GetConfiguredApppackage();
```

GetConfiguredClassPath

Syntax

```
GetConfiguredClassPath()
```

Description

Use the GetConfiguredClassPath method to retrieve the configured application class path for the Continue button override.

Parameters

None.

Returns

A string value containing the application class path.

Example

```
&addObj.GetConfiguredClassPath();
```

GetCriteriaFields

Syntax

```
GetCriteriaFields()
```

Description

Use the GetCriteriaFields method to retrieve the criteria fields selected for the add a new value page.

Parameters

None.

Returns

An array of PTS_CFGSRCH_CRITERIA:AddField.

Example

```
&addObj.GetCriteriaFields();
```

GetPageLinksList

Syntax

```
GetPageLinksList ()
```

Description

Use the GetPageLinksList method to retrieve the page links specified on the add a new value page.

Parameters

None.

Returns

An array of PTS_CFGSRCH_CRITERIA:PageLink.

Example

```
&addObj.GetPageLinksList ();
```

AssociatedFacet Class

This section provides an overview of the AssociatedFacet class and discusses AssociatedFacet class methods.

The AssociatedFacet class is used to extend the PeopleTools-delivered PeopleSoft Search Framework by allowing the use of application-specific association keys. This class must be implemented to return the value of the AssociationValue property of the FacetFilter class.

Related Links

[AssociationValue](#)

AssociatedFacet Class Methods

In this section, the AssociatedFacet class methods are presented in alphabetical order.

getAssociatedFacetValue

Syntax

```
getAssociatedFacetValue (category, facet, user)
```

Description

Use this method to return an application-specific association key for the specified user.

An application that requires an associated facet value must implement and extend the `getAssociatedFacetValue` abstract method.

Note: This is an abstract method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>category</i>	Specifies the search category name as a string.
<i>facet</i>	Specifies the facet name as a string.
<i>user</i>	Specifies the search user name as a string.

Returns

A String value.

DashboardFilters Class

This section provides an overview of the `DashboardFilters` class and discusses its methods.

Create an application class extending the `DashboardFilters` class to return created filters for Kibana.

DashboardFilters Class Methods

In this section, the `DashboardFilters` class methods are presented in alphabetical order.

Related Links

[FilterValues Class Methods](#)

GetDashboardFilter

Syntax

```
GetDashboardFilter (&sCrefReferer, &sDashboardName, &nMode)
```

Description

Use the `GetDashboardFilter` method to use filters on dashboards to display the desired visualization.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&sCrefReferer</i>	Specifies the content reference in which the dashboard is displayed in the panel on the right.
<i>&sDashboardName</i>	Specifies the dashboard for which the current filter is applicable.
<i>&nMode</i>	Specifies the mode in which the dashboard is presented as an integer. Valid values are: <ul style="list-style-type: none"> • 1 - Full view • 2 - Right frame • 3 - Tile view.

Returns

A `FilterValues` object.

Example

The following example extends the `DashboardFilters` class and uses the `NotEquals` filter.

```
import PTSF_KIBANA:DashboardFilters;
import PTSF_KIBANA:FilterValues;

class FVAPPCLS1 extends PTSF_KIBANA:DashboardFilters
  method GetDashboardFilter(&sCrefReferer As string, &sDashboardName As string, &n⇒
Mode As integer) Returns array of PTSF_KIBANA:FilterValues
end-class;

method GetDashboardFilter
  /+ &sCrefReferer as String, +/
  /+ &sDashboardName as String, +/
  /+ &nMode as Integer +/
  /+ Returns Array of PTSF_KIBANA:FilterValues +/
  /+ Extends/implements PTSF_KIBANA:DashboardFilters.GetDashboardFilter +/

  Local array of PTSF_KIBANA:FilterValues &filter;

  Local PTSF_KIBANA:FilterValues &NotContNum;
  &NotContNum.NotEquals().Key("INV_ITEM_ID_ORCL_ES_ENG", "", True).Value("15041");
  &filter.Push(&NotContNum);
  Return &filter;
end-method;
```

FacetFilter Class

This section provides an overview of the FacetFilter class and discusses:

- FacetFilter class methods.
- FacetFilter class properties.

The FacetFilter class is used to filter the search results on one or more facet values. Facets are aspects, properties, or characteristics of a piece of data. In a PeopleSoft application, this could be PeopleSoft metadata (for example, SETID or business unit), or it could be any other attribute of the data. For example, job openings could be classified (faceted) by location, department or job family, working hours, pay scale, posting date, business unit, SETID, and so on. Facets allow for “filtered search” or “filtered navigation” of search results.

FacetFilter Class Methods

In this section, the FacetFilter class methods are presented in alphabetical order.

clearFacetSorting

Syntax

```
clearFacetSorting()
```

Description

Use this method to reset facet sorting on all levels to default sorting values.

Parameters

None.

Returns

None.

FacetFilter

Syntax

```
FacetFilter(FacetName, Path)
```

Description

Use this constructor to instantiate a FacetFilter object for a specific facet to indicate the facet and path.

Parameters

Parameter	Description
<i>FacetName</i>	Specifies the name of the facet as a string.
<i>Path</i>	Specifies the value of the facet as a string.

Returns

A FacetFilter object.

Example

The following examples demonstrate four ways to create a facet filter:

- Use the SearchCategory class to return the initial list of facet filters with empty paths as an array of FacetFilter objects:

```
Local PT_SEARCH:SearchCategory &srchCat = create PT_SEARCH:SearchCategory("MY_>
SRCH_CAT");
&qry.Categories = CreateArray(&srchCat);
&qry.FacetFilters = &srchCat.GetFacetFilters();
```

- When requesting a specific facet for the first time, specify an empty string for the path:

```
Local PT_SEARCH:FacetFilter &facetFilter = create PT_SEARCH:FacetFilter("LOCAT=>
ION", "")
```

- When the facet is hierarchical, specify the hierarchy in the path. For example, the LOCATION facet could have a hierarchy of country/state/city. To filter by country, use the following filter:

```
Local PT_SEARCH:FacetFilter &facetFilter = create PT_SEARCH:FacetFilter("LOCAT=>
ION", "USA")
```

- To filter by state, use the following filter:

```
Local PT_SEARCH:FacetFilter &facetFilter = create PT_SEARCH:FacetFilter("LOCAT=>
```

```
ION", "USA/CA")
```

Related Links

[GetFacetFilters](#)

getFacetSortings

Syntax

```
getFacetSortings ()
```

Description

Use this method to return a map of facet sortings as a StringMap object. If no facet sorting is defined, the map will be of size 0.

Parameters

None.

Returns

A StringMap Object.

getFacetValuesSortType

Syntax

```
getFacetValuesSortType (level)
```

Description

Use this method to return the sort type for the specified level.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>level</i>	Specifies the level in the facet path hierarchy as an integer. For facets without a path hierarchy, specify <i>1</i> .

Returns

A string value.

hasCustomFacetSorting

Syntax

```
hasCustomFacetSorting(level)
```

Description

Use this method to verify whether the default facet sorting has been overridden for the specified level.

Parameters

Parameter	Description
<i>level</i>	Specifies the level in the facet path hierarchy as an integer. For facets without a path hierarchy, specify <i>1</i> .

Returns

A Boolean value. True if facet sorting has been overridden for the specified level, False otherwise.

sortFacetValuesAlphabetically

Syntax

```
sortFacetValuesAlphabetically(level, sort_ascending)
```

Description

Use this method to sort facet values for the specified level alphabetically.

Parameters

Parameter	Description
<i>level</i>	Specifies the level in the facet path hierarchy as an integer. For facets without a path hierarchy, specify <i>1</i> .
<i>sort_ascending</i>	Specifies the sorting order: True for ascending order and False for descending order sorting.

Returns

None.

sortFacetValuesByDocumentCount

Syntax

```
sortFacetValuesByDocumentCount(level, sort_ascending)
```

Description

Use this method to sort facet values for the specified level by the document count.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>level</i>	Specifies the level in the facet patch hierarchy as an integer. For facets without a path hierarchy, specify <i>l</i> .
<i>sort_ascending</i>	Specifies the sorting order: True for ascending order and False for descending order sorting.

Returns

None.

sortFacetValuesByType

Syntax

```
sortFacetValuesByType(level, sort_type)
```

Description

Use this method to define the sort type by specifying a string value. This method can be used instead of `sortFacetValuesByDocumentCount`, `sortFacetValuesAlphabetically`, and `sortFacetValuesNumerically` methods.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>level</i>	Specify the level in the facet path hierarchy. For facets without a path hierarchy, specify <i>l</i> .

Parameter	Description
<i>sort_type</i>	<p>Specifies the sort type as one of the following string values:</p> <ul style="list-style-type: none"> • <i>ALPHA_DES</i> – Sort alphabetically descending. • <i>ALPHA_ASC</i> – Sort alphabetically ascending. • <i>COUNT_DES</i> – Sort by document count descending. • <i>COUNT_ASC</i> – Sort by document count ascending. • <i>NUMBER_ASC</i> – Sort numerically ascending. • <i>NUMBER_DES</i> – Sort numerically descending.

Returns

None.

sortFacetValuesNumerically

Syntax

```
sortFacetValuesNumerically(level, sort_ascending)
```

Description

Use this method to sort facet values numerically for the specified level. If the facet values are not numbers, this method will cause an error when it is executed at run time.

Parameters

Parameter	Description
<i>level</i>	Specifies the level in the facet path hierarchy as an integer. For facets without a path hierarchy, specify <i>1</i> .
<i>sort_ascending</i>	Specifies the sorting order as a Boolean value: True for ascending order and False for descending order sorting.

Returns

None.

FacetFilter Class Properties

In this section, the FacetFilter class properties are presented in alphabetical order.

AssociationValue

Description

Use this property to set or return the association value for this facet as a string. The association value is used to select the first level of associated facets.

This property is read/write.

FacetLabel

Description

Use this property to set or return the long description for the facet as a string. This description appears as the label for the facet in the user interface.

This property is read/write.

FacetName

Description

Use this property to set or return the name of the facet as a string.

This property is read/write.

Path

Description

Use this property to set or return the value for facet as a path string.

This property is read/write.

Example

The Path property is implicitly set to the value of the *Path* parameter supplied in the constructor for the FacetFilter class. In this example, the Path property is set to USA/CA:

```
&facetFilter = create PT_SEARCH:FacetFilter("LOCATION", "USA/CA")
```

However, the Path property can also be explicitly set as in the following example:

```
&facetFilter.Path = "USA/CO/Denver";
```

FacetNode Class

This section provides an overview of the FacetNode class and discusses:

- FacetNode class methods.
- FacetNode class properties.

The FacetNode class extends the FacetFilter class and is used to return the list of facet node values along with other information about the facet nodes.

Facet nodes are used to render the list of facet values of a particular facet for a given search. This list of facet nodes is retrieved using GetFacetNodes method of the SearchResultCollection. Since a facet node is constructed with a facet path, this information can be used to create a facet filter indicating that the user has chosen to filter the results further based on the facet node.

FacetNode Class Methods

In this section, the FacetNode class methods are presented in alphabetical order.

addChild

Syntax

```
addChild(&node)
```

Description

Use this method to add a child facet node to the current facet node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&node</i>	Specifies the child facet node as a FacetNode object.

Returns

None.

FacetNode

Syntax

```
FacetNode(FacetName, NodeName, Path, DisplayValue, DocCount)
```

Description

Use this constructor to instantiate a FacetNode object for a specific facet.

Parameters

Parameter	Description
<i>FacetName</i>	Specifies the name of the facet as a string and is used to refer to that member of the superclass.
<i>NodeName</i>	Specifies the name of this facet node as a string.
<i>Path</i>	Specifies the value of the facet as a string and is used to refer to that member of the superclass.
<i>DisplayValue</i>	Specifies the display value for this facet node as a string.
<i>DocCount</i>	Specifies an integer representing the number of documents that would be returned if this facet node were selected as a search filter.

Returns

A FacetNode object.

getChildNodes

Syntax

```
getChildNodes()
```

Description

Use this method to return an array of child nodes.

Parameters

None.

Returns

An array of FacetNode objects.

Related Links

[addChild](#)

FacetNode Class Properties

In this section, the FacetNode class properties are presented in alphabetical order.

DisplayValue

Description

Use this property to set or return the display value for this facet node as a string.

This property is read/write.

DocumentCount

Description

Use this property to set or return an integer representing the number of documents that would be returned if this facet node were selected as a search filter.

This property is read/write.

FacetValue

Description

Use this property to set or return the value of this facet node as a string.

This property is read/write.

The FacetName, FacetValue, and DisplayValue are all closely related. For example, consider the following facet filter: `FacetFilter("LOCATION","USA")`. These properties would have the following values:

- FacetName: LOCATION
- FacetValue: USA
- DisplayValue: United States

Related Links

[DisplayValue](#)

FacetName

HasChildren

Description

Use this property to set or return a Boolean value indicating whether this facet node has children.

This property is read/write.

FilterValues Class

This section provides an overview of the FilterValues class and discusses its methods.

Use the FilterValues class to create filters to display visualization data based on a context.

FilterValues Class Methods

In this section, the FilterValues class methods are presented in alphabetical order.

Equals

Syntax

```
Equals ()
```

Description

Use the Equals method to set the equal filter of Kibana.

Parameters

None.

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;
```

```
Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
&filt.Equals().Key("INV_ITEM_ID_ORCL_ES_ENG", "", True).Value("15041");
```

Related Links

[NotEquals](#)

[Key](#)

EqualsDateTime

Syntax

```
EqualsDateTime (&DtTm)
```

Description

Use the EqualsDateTime method to set the date and time filter of Kibana.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&DtTm</i>	Specifies date and time (as a datetime).

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
&filt.Key("ORCL_ES_LAST_MODIFIED_DATE", "", True).EqualsDateTime(%Datetime);
```

Related Links

[NotEqualsDateTime](#)

Exists

Syntax

```
Exists ()
```

Description

Use the Exists method to set a filter to check for the specified key. It returns all documents that contain the specified key.

Parameters

None.

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
&filt = &filt.Exists().Key("INV_ITEM_ID_ORCL_ES_ENG", "", True);
```

FilterValues

Syntax

```
FilterValues()
```

Description

Use the FilterValues method to create a filter.

Parameters

None.

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
```

InBetweenDateTime

Syntax

```
InBetweenDateTime (&FromDtTm, &ToDtTm)
```

Description

Use the `InBetweenDateTime` method to set the date and time range filter of Kibana.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&FromDtTm</i>	Specifies the from date and time part of a date range in the form of datetime.
<i>&ToDtTm</i>	Specifies the to date and time part of a date range in the form of datetime.

Returns

A `FilterValues` object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
Local datetime &FromDtTm = DateTimeValue("2000-01-01 19:20:30.000");
&filt.Key("ORCL_ES_LAST_MODIFIED_DATE", "", True).InBetweenDateTime(&FromDtTm, %DateTime);
```

Related Links

[NotInBetweenDateTime](#)

Key

Syntax

```
Key (&sKey, &sKeyLabel, &isRLR)
```

Description

Use the `Key` method to set the key or field, which is used with other methods that take the key value to filter data, such as `Equals`, `NotEquals`, and so on.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&sKey</i>	Specifies the key as a String.

Parameter	Description
<i>&sKeyLabel</i>	Specifies the label of a key as a String.
<i>&isRLR</i>	Specifies whether the value should be translated in the related language table. If you enter True, the value is translated; False, otherwise.

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
/*Create a string sArrVals with array of strings */
&filt.Equals().Key("INV_ITEM_ID_ORCL_ES_ENG", "", True).Values(&sArrVals);
```

[Equals](#)

[NotEquals](#)

[Exists](#)

[NotExists](#)

NotEquals

Syntax

```
NotEquals()
```

Description

Use the NotEquals method to filter data by checking whether a specified key does not match the specified value.

Parameters

None.

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;
```

```
Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
&filt.NotEquals().Key("INV_ITEM_ID_ORCL_ES_ENG", "", True).Value("15041");
```

Related Links

[Equals](#)

[Key](#)

NotEqualsDateTime

Syntax

```
NotEqualsDateTime (&DtTm)
```

Description

Use the NotEqualsDateTime method to set the not equal to date and time filter of Kibana.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&DtTm</i>	Specifies date and time (as a Datetime).

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
&filt.Key("ORCL_ES_LAST_MODIFIED_DATE", "", True).NotEqualsDateTime(%Datetime);
```

Related Links

[EqualsDateTime](#)

NotExists

Syntax

```
NotExists ()
```

Description

Use the NotExists method to determine whether the specified key does not exist.

Parameters

None.

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
&filt = &filt.NotExists().Key("INV_ITEM_ID_ORCL_ES_ENG", "", True);
```

Related Links

[Exists](#)

[Key](#)

NotInBetweenDateTime

Syntax

```
NotInBetweenDateTime (&FromDtTm, &ToDtTm)
```

Description

Use the NotInBetweenDateTime method to set the date and time filter of Kibana that excludes the specified date and time range.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&FromDtTm</i>	Specifies the from date and time part of a date range in the form of datetime.
<i>&ToDtTm</i>	Specifies the to date and time part of a date range in the form of datetime.

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
```

```
Local datetime &FromDtTm = DateTimeValue("2000-01-01 19:20:30.000");
&filt.Key("ORCL_ES_LAST_MODIFIED_DATE", "", True).NotInBetweenDateTime(&FromDtTm, %⇒
Datetime);
```

Related Links

[InBetweenDateTime](#)

Value

Syntax

```
Value (&sVal)
```

Description

Use the Value method to set a single value for a filter of Kibana.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&sVal</i>	Specifies the value as a String.

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
&filt.Equals().Key("INV_ITEM_ID_ORCL_ES_ENG", "", True).Value("15041");
```

Related Links

[Values](#)

Values

Syntax

```
Values (&sArrVals)
```

Description

Use the Values method to set multiple values for a filter of Kibana.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&sArrVals</i>	Specifies the value as an array of String.

Returns

A FilterValues object.

Example

```
import PTSF_KIBANA:FilterValues;

Local PTSF_KIBANA:FilterValues &filt = create PTSF_KIBANA:FilterValues();
/*Create a string sArrVals with array of strings */
&filt.Equals().Key("INV_ITEM_ID_ORCL_ES_ENG", "", True).Values(&sArrVals);
```

PTRTI Class

This section provides an overview of the PTRTI class and discusses its methods.

Search Framework enables you to index data in near real time using the real time indexing process. In the real time indexing process, the preprocessing and post processing of a search definition is achieved through a delivered application class- PRTIPKG:PTRTI.

Related Links

"Configuring Real Time Indexing" (Search Technology)

PTRTI Class Methods

In this section, the PTRTIR class methods are presented in alphabetical order.

PostProcess

Syntax

```
PostProcess(&triggerrec, &searchdefn, &keys, &keyvalueset)
```

Description

Use this method to perform post processing activities of a search definition in real time indexing.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&triggerrec</i>	Specifies the name of the trigger record as a String.
<i>&searchdefn</i>	Specifies the name of the search definition as a String.
<i>&keys</i>	Specifies the key names as in a staging row as an array of String.
<i>&keyvalueset</i>	Specifies the key values of the keys as in a staging row as an array of array of String.

Returns

A number; 0 indicates success and 1 indicates failure.

Note: However, the real time indexing process does not use the return value of the PostProcess method for any processing.

Example

```
import PTRTIIPKG:PTRTI;

class RTI extends PTRTIIPKG:PTRTI
    method PostProcess(&triggerrec As string, &searchdefn As string, &keys As array =>
of string, &keyvalueset As array of array of string) Returns number;
end-class;

method PostProcess
    /+ &triggerrec as String, +/
    /+ &searchdefn as String, +/
    /+ &keys as Array of String, +/
    /+ &keyvalueset as Array2 of String +/
    /+ Returns Number +/
    /+ Extends/implements PTRTIIPKG:PTRTI.PostProcess +/

    Local number &result;
    &result = 0;
    /* Perform some processing */
    Return &result;

end-method;
```

Related Links

[Process](#)

Process

Syntax

```
Process(&triggerrec, &searchdefn, &keys, &keyvalueset)
```

Description

Use the Process method to perform the following activities:

- Preprocessing: Performs the preprocessing task that was performed by an Application Engine program in a search definition.
- Defer processing of current entries.
- Discard processing of current entries.

Parameters

Parameter	Description
<i>&triggerrec</i>	Specifies the name of the trigger record as a String.
<i>&searchdefn</i>	Specifies the name of the search definition as a String.
<i>&keys</i>	Specifies the key names as in a staging row as an array of String.
<i>&keyvalueset</i>	Specifies the key values of the keys as in a staging row as an array of array of String.

Returns

An array of number with exactly one of the following values.

Value	Description
0	Defers the entry.
1	Processes the entry.
-1	Discards the entry.

If the method returns an array of numbers consisting of only *one* array element, the same value is applied to all the entries.

For example, if the keyvalueset has five rows and the return value is 1 (processes the entry), the return value 1 is applied to all the five rows, that is, processing the five rows.

Example

```
import PTRTI PKG:PTRTI;

class RTI extends PTRTI PKG:PTRTI
  method Process(&triggerrec As string, &searchdefn As string, &keys As array of s⇒
tring, &keyvalueset As array of array of string) Returns array of number;
end-class;

method Process
  /+ &triggerrec as String, +/
  /+ &searchdefn as String, +/
  /+ &keys as Array of String, +/
  /+ &keyvalueset as Array2 of String +/
  /+ Returns Array of Number +/
  /+ Extends/implements PTRTI PKG:PTRTI.Process +/

  Local array of number &result;
  &result = CreateArrayRept(0, 1);
  &result.Push(1);
  /* Perform some processing */
  Return &result;

end-method;
```

SearchAttribute Class

This section provides an overview of the SearchAttribute class and discusses:

- SearchAttribute class methods.
- SearchAttribute class properties.

The SearchAttribute class represents a search attribute, which is an alias to a search query field. Search attributes enable you to hide the attribute name and query field name from the end user, who will see the search attribute display name.

An array of search attributes are returned using the GetAllAttributes, GetConfiguredFilterAttributes, GetNonConfiguredFilterAttributes, and GetRequestedAttributes methods of the SearchCategory class.

SearchAttribute Class Methods

In this section, the SearchAttribute class methods are presented in alphabetical order.

SearchAttribute

Syntax

```
SearchAttribute (Name, Type)
```

Description

Use this constructor to instantiate a SearchAttribute object for a specific attribute.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specifies the name of the attribute as a string .
<i>Type</i>	Specifies the type for this attribute as a one-character string. The values for <i>Type</i> can be as follows: <ul style="list-style-type: none">• D – Date• N – Number• S – String

Returns

A SearchAttribute object.

SearchAttribute Class Properties

In this section, the SearchAttribute class properties are presented in alphabetical order.

Display

Description

Use this property to set or return a string to be used as the display name for this attribute within the user interface.

This property is read/write.

Name

Description

Use this property to set or return a string representing the name of this search attribute.

This property is read/write.

Type

Description

Use this property to set or return a one-character sting indicating the type for this attribute. The values for this property can be as follows:

- D – Date
- N – Number
- S – String

This property is read/write.

SearchbarContext Class

This section provides an overview of the SearchbarContext class and discusses its methods.

PeopleTools enables you to embed the search tool on an application page. To embed the search tool, you should add the New Search UI subpage to the component page, and call the SearchbarContext() method from the page activate event.

SearchbarContext Class Methods

In this section, the SearchbarContext class methods are presented in alphabetical order.

Related Links

[SearchbarContext Class Properties](#)

SearchbarContext

Syntax

```
SearchbarContext ()
```

Description

Use the SearchbarContext method to customize a search bar and specify which search index to use.

Returns

None.

Example

```
import PTSF_SEARCHUI:SearchbarContext;

&sc = create PTSF_SEARCHUI:SearchbarContext ();

&sc.Placeholder = "custom placeholder text";
&sc.CustomSearchCategory = "PTPORTALREGISTRY"; /* default search category */
&sc.IsIncludeHiddenCref = True; /* only valid for PTPORTALREGISTRY search category =>
*/
&sc.IsComponentOrGenericURL = True; /* only valid for PTPORTALREGISTRY search categ=>
ory */
&sc.ShowGridIcons = False;
&sc.ShowCategoryDropDown = False;
&sc.ShowGlobalSearchButton = False;

&sc.SetSearchbarContext ();
```

SearchbarContext Class Properties

In this section, the SearchbarContext class properties are presented in alphabetical order.

CustomSearchCategory

Description

Use this property to specify the default search category as a String value.

This property is read/write.

IsComponentOrGenericURL

Description

Use this property to determine whether to show or hide PeopleSoft components or generic content references as a Boolean value.

This property is valid only for the PTPORTALREGISTRY search category.

This property is read/write.

IsIncludeHiddenCref

Description

Use this property to determine whether to show or hide hidden content references as a Boolean value.

This property is valid only for the PTPORTALREGISTRY search category.

This property is read/write.

Placeholder

Description

Use this property to specify the default placeholder text in the keyword field as a String value.

This property is read/write.

ShowCategoryDropDown

Description

Use this property to determine whether to show or hide the category drop-down list as a Boolean value.

The default value is True, that is, the page displays the category drop-down list.

This property is read/write.

ShowGlobalSearchButton

Description

Use this property to determine whether to show or hide the global search button in the search bar as a Boolean value.

The default value is True, that is, the page displays the global search button.

This property is read/write.

ShowGridIcons

Description

Use this property to determine whether to show or hide the grid icons that differentiate between items that are recently accessed and items that are suggestions.

The default value is True, that is, the grid icons are displayed.

This property is read/write.

SearchCategory Class

This section provides an overview of the SearchCategory class and discusses:

- SearchCategory class methods.
- SearchCategory class properties.

SearchCategory is the PeopleCode representation of a search category definition, which groups search data source definitions. A search category is a searchable collection of indexes. SearchCategory objects can only be constructed by giving the name of a search category definition that has already been saved to the database. In general SearchCategory objects are instantiated either to be assigned to the Categories property of a SearchQuery object or to be passed to methods of the SearchAdminService.

SearchCategory Class Methods

In this section, the SearchCategory class methods are presented in alphabetical order.

GetAllAttributes

Syntax

```
GetAllAttributes ()
```

Description

Use this method to return the union of all the attributes available across all the search definitions assigned to this search category.

Parameters

None.

Returns

An array of SearchAttribute objects.

Related Links

[SearchAttribute Class](#)

GetConfiguredFilterAttributes

Syntax

```
GetConfiguredFilterAttributes ()
```

Description

Use this method to return a list of advanced search filter attributes defined *and* configured for the advanced search for this search category. These are the attributes that have been configured on the Advanced Search Fields page.

Parameters

None.

Returns

An array of SearchAttribute objects.

Related Links

[SearchAttribute Class](#)

GetFacetFilters

Syntax

```
GetFacetFilters ()
```

Description

Use this method to return an array of facet filters for a specific search category. Dynamically building this array based on system metadata avoids the hard-coding of facet names in your PeopleCode programs. However, this means that this method can only be used for search categories defined on the local system (therefore, it cannot be used for universal search).

Parameters

None.

Returns

An array of FacetFilter objects.

Related Links

[FacetFilter Class](#)

GetLastIndexedDateTime

Syntax

```
GetLastIndexedDateTime ()
```

Description

Use this method to return a `DateTime` value representing the oldest index that is current from all the indexed search definitions in this category. If no search definition in this category has ever been indexed, this method returns `Null`.

Parameters

None.

Returns

A `DateTime` value.

GetNonConfiguredFilterAttributes

Syntax

```
GetNonConfiguredFilterAttributes ()
```

Description

Use this method to return a list of advanced search filter attributes defined *but not* configured for the advanced search for this search category. These are the attributes that have been defined for the search category but not configured on the Advanced Search Fields page.

Parameters

None.

Returns

An array of `SearchAttribute` objects.

Related Links

[SearchAttribute Class](#)

GetRequestedAttributes

Syntax

```
GetRequestedAttributes ()
```

Description

Use this method to return the list of search attributes that have been configured as display-only attributes on the Display Fields page. Since this method returns the display label for these search attributes, you must also use the `GetRequestedFields` method to return the list of search fields to pass to the query API.

Parameters

None.

Returns

An array of `SearchAttribute` objects.

Related Links

[SearchAttribute Class](#)

[GetRequestedFields](#)

GetRequestedFields

Syntax

```
GetRequestedFields ()
```

Description

Use this method to return the list of search fields that have been configured as display-only attributes on the Display Fields page. This array can then be passed to the `RequestedFields` method of the `SearchQuery` class. Since this method returns the query field names for the search attributes, you must also use the `GetRequestedAttributes` method to return the display labels to display in the user interface.

Parameters

None.

Returns

An array of `SearchField` objects.

Example

```
PT_SEARCH:SearchCategory &cat = create PT_SEARCH:SearchCategory("MY_SRCH_CAT");  
&qry.Categories = CreateArray(&cat);
```

```
&qry.RequestedFields = &cat.GetRequestedFields ();
```

Related Links

[GetRequestedAttributes](#)

[SearchField Class](#)

RequestedFields**SearchCategory****Syntax****SearchCategory** (*Name*)**Description**

Use this constructor to instantiate a SearchCategory object populated with the data from the specified saved definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	The name of the search category to instantiate as a string.

Returns

A SearchCategory object.

Example

```
import PT_SEARCH:SearchCategory;
Local PT_SEARCH:SearchCategory &SrchCat = create PT_SEARCH:SearchCategory("MySrchCa⇒
t");
```

Related Links[Categories](#)[Constructors](#)[Import Declarations](#)**SearchCategory Class Properties**

In this section, the SearchCategory class properties are presented in alphabetical order.

DataSourceNames**Description**

Use this property to return an array of string containing the names of the search definitions that have been assigned to this search category.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner.

Displayname

Description

Use this property to return the long description (display) for the search category as a string.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner.

Duplicates

Description

Use this property to return a string indicating whether duplicates have been set for this search category.

This property is effectively read-only.

Related Links

"Specifying General Search Category Settings" (Search Technology)

IsDeployed

Description

Use this property to return a Boolean value indicating whether this search category has been deployed to a search provider.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner.

Name

Description

Use this property to return the name of this SearchCategory object as a string.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner.

ServiceName

Description

Use this property to return a string representing the name of the search engine instance to which this search category has been deployed.

This property is effectively read-only.

Note: While this property is actually read/write, from PeopleCode, it is meant to be used in a read-only manner.

SearchConfiguration Class

This section provides an overview of the SearchConfiguration class and discusses its methods.

The SearchConfiguration class is used to retrieve search configuration properties of a content reference when the content reference is configured on the Manage Configurable Search page.

Related Links

"Working with Configurable Search" (Search Technology)

SearchConfiguration Class Methods

In this section, the SearchConfiguration class methods are presented in alphabetical order.

CollapseSearchCriteriaAfterSrch

Syntax

```
CollapseSearchCriteriaAfterSrch()
```

Description

Use the CollapseSearchCriteriaAfterSrch method to retrieve the Boolean value, which indicates whether to collapse search criteria or not after displaying the search results.

Parameters

None.

Returns

A Boolean value.

Example

```
&criteriaObj.CollapseSearchCriteriaAfterSrch();
```

GetConfigSrchId

Syntax

```
GetConfigSrchId()
```

Description

Use the GetConfigSrchId method to retrieve the configured search ID. The search ID is auto assigned in the PTS_SRCH_ASGN table.

The search ID is in this format: <PortalName>_<PortalObjName>.

Parameters

None.

Returns

A string value containing the search ID.

Example

```
&criteriaObj.GetConfigSrchId();
```

GetConfiguredImageRecord

Syntax

```
GetConfiguredImageRecord()
```

Description

Use the GetConfiguredImageRecord method to retrieve the image record.

Parameters

None.

Returns

A string value containing the image record.

Example

```
&criteriaObj.GetConfiguredImageRecord();
```

Related Links

[GetConfiguredImageRecordField](#)

GetConfiguredImageRecordField

Syntax

```
GetConfiguredImageRecordField()
```

Description

Use the GetConfiguredImageRecordField to retrieve the field for an image.

Parameters

None.

Returns

A string value containing the corresponding field for the image.

Example

```
&criteriaObj.GetConfiguredImageRecordField();
```

Related Links

[GetConfiguredImageRecord](#)

GetConfiguredSearchType

Syntax

```
GetConfiguredSearchType()
```

Description

Use the GetConfiguredSearchType method to retrieve the configured search type (standard or keyword).

Parameters

None.

Returns

A string value containing the search type.

Example

```
&criteriaObj.GetConfiguredSearchType();
```

GetCriteriaFields

Syntax

```
GetCriteriaFields (&display_option)
```

Description

Use the GetCriteriaFields method to retrieve the criteria fields selected for the search page (basic and advanced mode).

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&display_option</i>	Specifies the search presentation mode. Valid values are: <ul style="list-style-type: none"> • "A" - represents advanced mode. • "B" - represents basic mode.

Returns

An array of PTS_CFGSRCH_CRITERIA:SearchField.

Example

The following code samples describe the use of the GetCriteriaFields method for basic and advanced modes.

```
/*Basic mode*/
import PTS_CFGSRCH_CRITERIA:SearchField;

Local array of PTS_CFGSRCH_CRITERIA:SearchField &CriteriaFieldsList = &criteriaObj.⇒
GetCriteriaFields("B");

If &CriteriaFieldsList <> Null Then
  For &i = 1 To &CriteriaFieldsList.Len
    &sField = &CriteriaFieldsList [&i];
```

```
        MessageBox(0, "", 0, 0, &sField.FieldName | "," | &sField.FieldLable | "," | =>
&sField.FieldOrder | "," | &sField.RequiredFlag);
    End-For;

End-If;
/* Advanced mode */
import PTS_CFGSRCH_CRITERIA:SearchField;

Local array of PTS_CFGSRCH_CRITERIA:SearchField &CriteriaFieldsList = &criteriaObj.>
GetCriteriaFields("A");

If &CriteriaFieldsList <> Null Then

    For &i = 1 To &CriteriaFieldsList.Len
        &sField = &CriteriaFieldsList [&i];
        MessageBox(0, "", 0, 0, &sField.FieldName | "," | &sField.FieldLable | "," | =>
&sField.FieldOrder | "," | &sField.RequiredFlag);
    End-For;

End-If;
```

GetDefaultSrchLookup

Syntax

```
GetDefaultSrchLookup()
```

Description

Use the GetDefaultSrchLookup method to retrieve the default search lookup type (basic or advanced) specified for a content reference.

Parameters

None.

Returns

A string value containing the default search lookup type.

Example

```
&criteriaObj.GetDefaultSrchLookup();
```

GetDefaultSrchLookupForSFF

Syntax

```
GetDefaultSrchLookupForSFF()
```

Description

Use the `GetDefaultSrchLookupForSFF` method to retrieve the default search lookup type (basic or advanced) specified for a content reference in small form factor devices.

Parameters

None.

Returns

A string value containing the default search lookup type.

Example

```
&criteriaObj.GetDefaultSrchLookupForSFF();
```

GetESCriteriaFields

Syntax

```
GetESCriteriaFields()
```

Description

Use the `GetESCriteriaFields` method to retrieve the criteria fields selected for the keyword search page (advanced mode).

Parameters

None.

Returns

An array of `PTS_CFGSRCH_CRITERIA:SearchField`.

Example

```
&criteriaObj.GetESCriteriaFields();
```

GetMaxSrchResults

Syntax

```
GetMaxSrchResults()
```

Description

Use the `GetMaxSrchResults` method to retrieve the maximum search results specified for a content reference.

Parameters

None.

Returns

An Integer value indicating the maximum search results.

Example

```
&criteriaObj.GetMaxSrchResults();
```

GetPageLinksList

Syntax

```
GetPageLinksList ()
```

Description

Use the `GetPageLinksList` method to retrieve the page links specified on the search page.

Parameters

None.

Returns

An array of `PTS_CFGSRCH_CRITERIA:PageLink`.

Example

```
&criteriaObj.GetPageLinksList();
```

GetRecentSearchesCount

Syntax

```
GetRecentSearchesCount ()
```

Description

Use the `GetRecentSearchesCount` method to retrieve the number of recent searches stored in the system.

Parameters

None.

Returns

An Integer value.

Example

```
&criteriaObj.GetRecentSearchesCount ();
```

GetRecentSearchesNamingFormat

Syntax

```
GetRecentSearchesNamingFormat ()
```

Description

Use the GetRecentSearchesNamingFormat method to retrieve the naming format used for recent searches.

Parameters

None.

Returns

A string value containing the naming format for recent searches.

Example

```
&criteriaObj.GetRecentSearchesNamingFormat ();
```

GetResultFields

Syntax

```
GetResultFields ()
```

Description

Use the GetResultFields method to retrieve the fields selected to display on the search results page.

Parameters

None.

Returns

An array of `PTS_CFGSRCH_CRITERIA:ResultField`.

Example

```
&criteriaObj.GetResultFields();
```

GetSavedSearchesCount

Syntax

```
GetSavedSearchesCount()
```

Description

Use the `GetSavedSearchesCount` method to retrieve the number of searches saved for a content reference.

Parameters

None.

Returns

An Integer value indicating the count of saved searches.

Example

```
&criteriaObj.GetSavedSearchesCount();
```

GetSavedSearchesNamingFormat

Syntax

```
GetSavedSearchesNamingFormat()
```

Description

Use the `GetSavedSearchesNamingFormat` method to retrieve the naming format used for saved searches.

Parameters

None.

Returns

A string value containing the naming format for saved searches.

Example

```
&criteriaObj.GetSavedSearchesNamingFormat();
```

GetSearchCriteriaDisplayPattern

Syntax

```
GetSearchCriteriaDisplayPattern()
```

Description

Use the GetSearchCriteriaDisplayPattern method to retrieve the display pattern of search criteria.

Parameters

None.

Returns

A string value containing the display pattern.

Example

```
&criteriaObj.GetSearchCriteriaDisplayPattern();
```

GetSearchDefinition

Syntax

```
GetSearchDefinition()
```

Description

Use the GetSearchDefinition method to retrieve the search definition specified for keyword search for a content reference.

Parameters

None.

Returns

A string value containing the search definition specified for keyword search.

Example

```
&criteriaObj.GetSearchDefinition();
```

GetSearchPageInstructionsInfo

Syntax

```
GetSearchPageInstructionsInfo()
```

Description

Use the GetSearchPageInstructionsInfo method to retrieve instructions to display on the search page.

Parameters

None.

Returns

A string value containing instructions to display on the search page.

Example

```
&criteriaObj.GetSearchPageInstructionsInfo();
```

GetSearchPageTitleInfo

Syntax

```
GetSearchPageTitleInfo()
```

Description

Use the GetSearchPageTitleInfo method to retrieve the specified title for a search page.

Parameters

None.

Returns

A string value containing the search page title.

Example

```
&criteriaObj.GetSearchPageTitleInfo();
```

GetSearchRecord

Syntax

```
GetSearchRecord()
```

Description

Use the `GetSearchRecord` method to retrieve the search record specified for standard search on a content reference.

Parameters

None.

Returns

A string value containing the search record for a content reference.

Example

```
&criteriaObj.GetSearchRecord();
```

GetSrchLookupType

Syntax

```
GetSrchLookupType()
```

Description

Use the `GetSrchLookupType` method to retrieve the search lookup type (basic or advanced) specified for a content reference.

Parameters

None.

Returns

A string value containing the specified search lookup type.

Example

```
&criteriaObj.GetSrchLookupType();
```

IsAutoSearchEnabled

Syntax

```
IsAutoSearchEnabled()
```

Description

Use the `IsAutoSearchEnabled` method to determine whether auto search is enabled for the content reference.

Parameters

None.

Returns

A Boolean value.

Example

```
&criteriaObj.IsAutoSearchEnabled();
```

IsSearchPrimaryAction

Syntax

```
IsSearchPrimaryAction()
```

Description

Use the `IsSearchPrimaryAction` method to determine whether search is set as the primary action for the content reference.

Parameters

None.

Returns

A Boolean value.

Example

```
&criteriaObj.IsSearchPrimaryAction();
```

SearchConfiguration

Syntax

```
SearchConfiguration()
```

Description

Use the `SearchConfiguration` method to instantiate an object of the `SearchConfiguration` class.

Parameters

None.

Returns

None.

Example

```
Local PTS_CFGSRCH_CRITERIA:SearchConfiguration &criteriaObj = create PTS_CFGSRCH_CR→  
ITERIA:SearchConfiguration();
```

ShowRelatedActions

Syntax

```
ShowRelatedActions()
```

Description

Use the ShowRelatedActions method to determine whether to show related actions on the search results page.

Parameters

None.

Returns

A Boolean value.

Example

```
&criteriaObj.ShowRelatedActions();
```

SearchFactory Class

This section provides an overview of the SearchFactory class and discusses:

- SearchFactory class methods.
- SearchFactory class properties.

The SearchFactory class is a concrete factory class used to instantiate search engine-specific implementations of the SearchQueryService and other services.

SearchFactory Class Methods

In this section, the SearchFactory class methods are presented in alphabetical order.

CreateQueryService

Syntax

```
CreateQueryService (name)
```

Description

Use this method to instantiate a search engine-specific SearchQueryService object. This search engine-specific search query service enables accessing search engine-specific attributes of a SearchQuery object

Parameters

<i>Parameter</i>	<i>Description</i>
<i>name</i>	Specifies the name of the search query service as a string.

Returns

A SearchQueryService object.

Example

```
import PT_SEARCH:SearchFactory;
import PT_SEARCH:SearchQueryService;

Local PT_SEARCH:SearchFactory &MySearchFactory = create PT_SEARCH:SearchFactory();
Local PT_SEARCH:SearchQueryService &MySrchQrySvc = &MySearchFactory.CreateQueryService("default");
```

Related Links

[SearchQueryService Class](#)

SearchFactory

Syntax

```
SearchFactory()
```

Description

Use this constructor to instantiate a SearchFactory object, which allows you to instantiate a search-provider specific search query service.

Parameters

None.

Returns

A SearchFactory object.

Example

```
import PT_SEARCH:SearchFactory;
Local PT_SEARCH:SearchFactory &MySearchFactory = create PT_SEARCH:SearchFactory();
```

SearchFactory Class Properties

In this section, the SearchFactory class properties are presented in alphabetical order.

DEFAULTSERVICE

Description

This property returns the name of the default search engine service as a string.

This property is read-only.

SearchField Class

This section provides an overview of the SearchField class and discusses: .

- SearchField class methods.
- SearchField class properties.

The SearchField class is a superclass that requires implementation of a search engine-specific subclass. A SearchField is returned by the First, Item, ItemByName, and Next methods of the SearchFieldCollection class.

Related Links

[SearchFieldCollection Class](#)

SearchField Class Methods

In this section, the SearchField class methods are presented in alphabetical order.

getAsDate

Syntax

```
getAsDate ()
```

Description

Use this method to return the Value property as a Date value.

Note: This is an abstract method.

Parameters

None.

Returns

A Date value.

Related Links

[Value](#)

getAsDateTime

Syntax

```
getAsDateTime ()
```

Description

Use this method to return the Value property as a DateTime value.

Note: This is an abstract method.

Parameters

None.

Returns

A DateTime value.

Related Links

[Value](#)

getAsInteger

Syntax

```
getAsInteger ()
```

Description

Use this method to return the Value property as a Integer value.

Note: This is an abstract method.

Parameters

None.

Returns

An Integer value.

Related Links

[Value](#)

getAsNumber

Syntax

```
getAsNumber ()
```

Description

Use this method to return the Value property as a Number value.

Note: This is an abstract method.

Parameters

None.

Returns

A Number value.

Related Links

[Value](#)

SearchField Class Properties

In this section, the SearchField class properties are presented in alphabetical order.

Name

Description

This property returns the name of the search field as a string.

This property is read-only.

Related Links

[ItemByName](#)

Type

Description

This property returns the data type of the search field as a one-character string as follows:

- D – Date
- N – Number
- S – String

This property is read-only.

Value

Description

This property returns the value of the search field as a string. The Value property can be transformed from a String value to a Date, DateTime, Integer, or Number value using the methods of the SearchField class.

This property is read-only.

Related Links

[getAsDate](#)

[getAsDateTime](#)

SearchFieldCollection Class

This section provides an overview of the SearchFieldCollection class and discusses: SearchFieldCollection class methods.

The SearchFieldCollection class provides a collection of SearchField objects. Because the SearchFieldCollection class is a generic interface class, a search engine-specific subclass is required. A SearchFieldCollection is returned by the GetCustomAttributes method of the SearchResult class.

Related Links

[SearchField Class](#)

[GetCustomAttributes](#)

SearchFieldCollection Class Methods

In this section, the SearchFieldCollection class methods are presented in alphabetical order.

Count

Syntax

```
Count ()
```

Description

Use this method to return the number of SearchField objects in the SearchField collection as an integer.

Parameters

None.

Returns

An integer.

First

Syntax

```
First ()
```

Description

Use this method to return the first SearchField object in the SearchField collection. If the SearchField collection is empty, this method returns Null.

Parameters

None.

Returns

A SearchField object if successful, Null otherwise.

Related Links

[SearchField Class](#)

Item

Syntax

`Item(index)`

Description

Use this method to return the SearchField object at the position in the SearchField collection specified by the *index* parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>index</i>	Specifies the position of the SearchField object in the SearchField collection as an integer.

Returns

A SearchField object if successful, Null otherwise.

Related Links

[SearchField Class](#)

ItemByName

Syntax

`ItemByName(name)`

Description

Use this method to return the SearchField object specified by the *name* parameter.

Note: The ItemByName method does not set the index for the SearchField object returned. Therefore, the Next method cannot be used after a call to ItemByName.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>name</i>	Specifies the name of the SearchField object as a string.

Returns

A SearchField object if successful, Null otherwise.

Related Links

[SearchField Class](#)

Next

Syntax

Next ()

Description

Use this method to return the next SearchField object in the SearchField collection. This method can only be invoked after a successful invocation of the First, Item, or Next methods.

Note: The ItemByName method does not set the index for the SearchField object returned. Therefore, the Next method cannot be used after a call to ItemByName.

Parameters

None.

Returns

A SearchField object if successful, Null otherwise.

Related Links

[SearchField Class](#)

SearchFilter Class

This section provides an overview of the SearchFilter class and discusses:

- SearchFilter class properties.
- SearchFilter class methods.

The SearchFilter class creates a filter for search results (similar to building a WHERE clause in a SQL statement) that is passed to the SearchQuery class.

SearchFilter Class Methods

In this section, the SearchFilter class methods are presented in alphabetical order.

setDateFilter

Syntax

```
setDateFilter(date)
```

Description

Use this method to set a Date value as the search filter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>date</i>	Specifies the search filter value as a Date value.

Returns

None.

Example

```
import PT_SEARCH:SearchFilter;  
  
Local PT_SEARCH:SearchFilter &Srchfilter;  
Local date &Date = DateValue("10/09/11");  
  
&Srchfilter.setDateFilter(&Date);
```

Related Links

[Value](#)

[FormatDateFilter](#)

setDateTimeFilter

Syntax

```
setDateTimeFilter(datetime)
```

Description

Use this method to set a DateTime value as the search filter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>datetime</i>	Specifies the search filter value as a DateTime value.

Returns

None.

Example

```
import PT_SEARCH:SearchFilter;

Local PT_SEARCH:SearchFilter &Srchfilter;
Local datetime &Date_TIME = DateTimeValue("10/13/97 10:34:25 PM");

&Srchfilter.setDateTimeFilter(&Date_TIME);
```

SearchFilter Class Properties

In this section, the SearchFilter class properties are presented in alphabetical order.

Field

Description

Use this property to set or return a SearchField object.

This property is read/write.

Related Links

[SearchField Class](#)

FilterConnector

Description

Use this property to return the filter connector (& or |) that is in effect when this search filter is a composite search filter. This property is set by the SearchFilterGenerator class.

This property is effectively read-only.

Related Links

[Filters](#)

[SearchFilterGenerator Class](#)

Filters

Description

Use this property to return an array of SearchFilter objects that define this search filter as a composite search filter. This property is set by the SearchFilterGenerator class

This property is effectively read-only.

Related Links

[FilterConnector](#)

[SearchFilterGenerator Class](#)

Operator

Description

Use this property to set or return the operator for the filter as a string. Depending on the type of the search attribute, the following operators can be used:

Operator	String	Number	Date
equals	X	X	X
notequals*	X	X	X
contains	X		
greaterthan		X	X

Operator	String	Number	Date
greaterthanequals		X	X
lessthan		X	X
lessthanequals		X	X

* The notequals operator can be used when EnableExtendedFilterOperators property is set to true.

This property is read/write.

Related Links

[Type](#)

[EnableExtendedFilterOperators](#)

Value

Description

Use this property to set or return the value for the filter as a string.

This property is read/write.

Use this property only when setting a string or a number (represented as a string) as a filter. If you wish to set a Date or a DateTime value as a filter, use the setDateFilter and setDateFilter methods, respectively

Related Links

[setDateFilter](#)

[SearchFilter Class Methods](#)

SearchFilterGenerator Class

This section provides an overview of the SearchFilterGenerator class and discusses SearchFilterGenerator class methods.

The SearchFilterGenerator class is used to create composite search filters from different data types and operators. The SearchFilterGenerator class provides the flexibility to create a composite search filter by associating different filters using connectors such as **&** and **|**.

Note: The **&** is the default connector; therefore, for composite filters, MatchAll is implied and does not have to be explicitly specified.

AddQueryFilter

Syntax

```
AddQueryFilter(&srch_qry)
```

Description

Use this method to push the composite query filter onto the array of filters in the SearchQuery object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&srch_gry</i>	Specifies the query as a SearchQuery object.

Returns

None.

Related Links

[SetQueryFilter](#)

[SearchQuery Class](#)

[Filters](#)

AfterDate

Syntax

```
AfterDate(srch_field, datetime)
```

Description

Use this method to generate a datetime filter on the specified search field for dates after the specified value.

Note: The AfterDate method is equivalent to the AfterDateTime method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

AfterDateTime

Syntax

```
AfterDateTime(srch_field, datetime)
```

Description

Use the AfterDateTime method to generate a datetime filter on the specified search field for dates after the specified value.

Note: The AfterDateTime method is equivalent to the AfterDate method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

AfterDateValue

Syntax

```
AfterDateValue(srch_field, date)
```

Description

Use the AfterDateValue method to generate a date filter on the specified search field for dates after the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.

Parameter	Description
<i>date</i>	Specifies the date as a date value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

AppendFilter

Syntax

```
AppendFilter (&SearchFilter)
```

Description

Use the AppendFilter method to append the filter from one SearchFilterGenerator object to another SearchFilterGenerator object.

Parameters

Parameter	Description
<i>&SearchFilter</i>	Specifies the filter as a SearchFilter object.

Returns

None.

Example

```
import PT_SEARCH:SearchFilter;
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &SFG1 = create PT_SEARCH:SearchFilterGenerato⇒
r ();
Local PT_SEARCH:SearchFilterGenerator &SFG2 = create PT_SEARCH:SearchFilterGenerato⇒
r ();
Local PT_SEARCH:SearchFilter &Flt = create PT_SEARCH:SearchFilter ();

&Flt = &SFG2.GetFilter ();
&SFG1.AppendFilter (&Flt);
```

Related Links

[GetFilter](#)

BeforeDate

Syntax

```
BeforeDate(srch_field, datetime)
```

Description

Use this method to generate a datetime filter on the specified search field for dates before the specified value.

Note: The BeforeDate method is equivalent to the BeforeDateTime method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

BeforeDateTime

Syntax

```
BeforeDateTime(srch_field, datetime)
```

Description

Use the BeforeDateTime method to generate a datetime filter on the specified search field for dates before the specified value.

Note: The BeforeDateTime method is equivalent to the BeforeDate method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

BeforeDateValue

Syntax

`BeforeDateValue(srch_field, date)`

Description

Use the BeforeDateValue method to generate a date filter on the specified search field for dates before the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>date</i>	Specifies the date as a date value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

BoostCompositeFilterScore

Syntax

`BoostCompositeFilterScore (boost)`

Description

Use the `BoostCompositeFilterScore` method to boost the score of a combination of filters together. Using this method in the formation of a search filter indicates that the score of the search results is boosted from the default scoring used by the search engine. When two or more score boosts have been applied to individual search filters, then specify the boost mode. Otherwise, the default boost mode is MIN, which is equivalent to executing the `setBoostModeMinimum` method.

Note: The PeopleSoft Search Framework scores results from 0-100, meaning the maximum score for a search result row is 100.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>boost</i>	Specifies the score boost as number value from 0.00 to 1.00 (that is, as a percentage). For example, if a boost of 2 points is desired, set <i>boost</i> to 0.02.

Returns

None.

Example

In the following example, the score returned by the search engine is boosted by 2 points if either (or both) of the filters returns a result:

```
If &fg.MatchAnyReturnTrue() Then
  &fg.ContainsWord("QE_YEAR_H", "07");
  &fg.ContainsWord("QE_STATÜS", "Draft");
  &fg.BoostCompositeFilterScore(0.02);
  &fg.EndMatchAny();
End-If;
```

Related Links

[Related SearchFilterGenerator Methods](#)

[Score Boosting Examples](#)

BoostFilterScore

Syntax

BoostFilterScore (*boost*)

Description

Use the BoostFilterScore method to boost the score of specific filter match. Using this method in the formation of a search filter indicates that the score of the search results is boosted from the default scoring used by the search engine. When two or more score boosts have been applied to individual search filters, then specify the boost mode. Otherwise, the default boost mode is MIN, which is equivalent to executing the setBoostModeMinimum method.

Note: The PeopleSoft Search Framework scores results from 0-100, meaning the maximum score for a search result row is 100.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>boost</i>	Specifies the score boost as number value from 0.00 to 1.00 (that is, as a percentage). For example, if a boost of 2 points is desired, set <i>boost</i> to 0.02.

Returns

None.

Example

In the following example, the score returned by the search engine is boosted by 2 points:

```
If &fg.MatchAllReturnTrue() Then
    &fg.ContainsWord("DEPTNAME", "support");
    &fg.BoostFilterScore(0.02);
    &fg.EndMatchAll();
End-If;
```

Related Links

[Related SearchFilterGenerator Methods](#)

[Score Boosting Examples](#)

ContainsKeywords

Syntax

ContainsKeywords (*srch_field*, *words*)

Description

Use the `ContainsKeyWords` method to generate a string filter that matches strings. Unlike the `ContainsWord` method, this method allows to supply logical operator (& or |) to separate words within the `words` parameter. If no operator is specified, then the default & operator is used.

Important! This method cannot be used in conjunction with any of the score boosting methods.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>words</i>	Specifies the keywords as a string.

Returns

None.

Example

In the following example, the search filter returns results that match either apples or oranges:

```
&SFG.ContainsKeyWords(&sAttrName, " apples | oranges");
```

In the following example, the search filter returns results that match both apples and oranges:

```
&SFG.ContainsKeyWords(&sAttrName, " apples & oranges");
```

Related Links

[Related SearchFilterGenerator Methods](#)

ContainsPartialWord

Syntax

```
ContainsPartialWord(srch_field, fragment)
```

Description

Use this method to generate a string filter that matches strings containing a word that begins with the specified partial word.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>fragment</i>	Specifies the word fragment as a string.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

ContainsPhrase

Syntax

```
ContainsPhrase(srch_field, phrase)
```

Description

Use this method to generate a string filter that matches strings containing the exact phrase.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>phrase</i>	Specifies the exact phrase as a string.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

ContainsWord

Syntax

```
ContainsWord(srch_field, word)
```

Description

Use the ContainsWord method to generate a string filter that matches strings containing the exact word or words. Words are separated by spaces and the logical *and* operator is implied; explicit logical operators are not supported between the words. This method forms the filter to find a match on all the words in the *word* parameter.

Note: While the *word* parameter can include one or more words, this method differs from the ContainsPhrase method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>word</i>	Specifies the exact word or words as a string.

Returns

None.

Example

Consider a document that includes the following sentence:

```
Apples are tastier than oranges.
```

The following use of ContainsWord will return a match.

```
&fg.ContainsWord("LONG_TEXT", "apples oranges");
```

However, the following use of ContainsPhrase will not return a match.

```
&fg.ContainsPhrase("LONG_TEXT", "apples oranges");
```

Related Links

[Related SearchFilterGenerator Methods](#)

DateToDatetime

Syntax

`DateToDatetime (date)`

Description

Use this method to convert a date value to datetime value. The time portion of the value is set to 12:00:00.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>date</i>	Specifies the date value to be converted.

Returns

A datetime value.

Related Links

[StringDateToDatetime](#)

EndMatchAll

Syntax

`EndMatchAll ()`

Description

Use this method to mark the end of a temporary composite search filter initiated by MatchAll or MatchAllReturnTrue. This temporary composite search filter is then pushed onto the array of filters for the preceding search filter.

Parameters

None.

Returns

None.

Related Links

[MatchAll](#)

[MatchAllReturnTrue](#)

EndMatchAny

Syntax

```
EndMatchAny()
```

Description

Use this method to mark the end of a temporary composite search filter initiated by MatchAny or MatchAnyReturnTrue. This temporary composite search filter is then pushed onto the array of filters for the preceding search filter.

Parameters

None.

Returns

None.

Related Links

[MatchAny](#)

[MatchAnyReturnTrue](#)

EqualsDate

Syntax

```
EqualsDate(srch_field, datetime)
```

Description

Use this method to generate a datetime filter on the specified search field for dates equal to the specified value.

Note: The EqualsDate method is equivalent to the EqualsDateTime method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

EqualsDateTime

Syntax

```
EqualsDateTime(srch_field, datetime)
```

Description

Use the EqualsDateTime method to generate a datetime filter on the specified search field for dates equal to the specified value.

Note: The EqualsDateTime method is equivalent to the EqualsDate method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

EqualsDateValue

Syntax

```
EqualsDateValue(srch_field, date)
```

Description

Use the EqualsDateValue method to generate a date filter on the specified search field for dates equal to the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>date</i>	Specifies the date as a date value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

EqualsNumber

Syntax

```
EqualsNumber(srch_field, number)
```

Description

Use this method to generate a numeric filter on the specified search field for numbers equal to the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>number</i>	Specifies the search value as a Number value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

EqualsString

Syntax

```
EqualsString(srch_field, string)
```

Description

Use this method to generate a string filter on the specified search field for strings equal to the specified value.

Important! This method cannot be used in conjunction with any of the score boosting methods.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>string</i>	Specifies the search string as a String value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

GetFilter

Syntax

```
GetFilter()
```

Description

Use the GetFilter method to return the root filter (the first element of the filter array) for the specified SearchFilterGenerator object.

Parameters

None.

Returns

A SearchFilter object.

Example

```
&Flt = &SFG2.GetFilter();
```

Related Links

[SearchFilter Class](#)

GreaterThanEqualsNumber

Syntax

```
GreaterThanEqualsNumber(srch_field, number)
```

Description

Use this method to generate a numeric filter on the specified search field for numbers greater than or equal to the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>number</i>	Specifies the search value as a Number value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

GreaterThanNumber

Syntax

```
GreaterThanNumber(srch_field, number)
```

Description

Use this method to generate a numeric filter on the specified search field for numbers greater than the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>number</i>	Specifies the search value as a Number value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

LessThanEqualsNumber

Syntax

```
LessThanEqualsNumber(srch_field, number)
```

Description

Use this method to generate a numeric filter on the specified search field for numbers less than or equal to the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>number</i>	Specifies the search value as a Number value.

Returns

None.

[Related SearchFilterGenerator Methods](#)

LessThanNumber

Syntax

```
LessThanNumber(srch_field, number)
```

Description

Use this method to generate a numeric filter on the specified search field for numbers less than the specified value.

Parameters

Parameter	Description
<i>srch_field</i>	Specifies the search field name as a string.
<i>number</i>	Specifies the search value as a Number value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

MatchAll

Syntax

```
MatchAll ()
```

Description

Use this method to initiate a temporary composite search filter using the **&** filter connector between filters.

Parameters

None.

Returns

None.

Example

In the following example, the composite filter consists of two filters joined by the **&** filter connector:

```
&fg.MatchAll();  
&fg.NotEqualsString("a", "x");  
&fg.NotEqualsString("b", "y");  
&fg.EndMatchAll();
```

Related Links

[EndMatchAll](#)

[MatchAllReturnTrue](#)

MatchAllReturnTrue

Syntax

```
MatchAllReturnTrue()
```

Description

Use this method to initiate a temporary composite search filter using the **&** filter connector between filters. Since successful execution of this method returns True, you can use this method in logical expressions.

Parameters

None.

Returns

A Boolean value.

Example

In the following example, the composite filter consists of two filters joined by the **&** filter connector:

```
If &fg.MatchAllReturnTrue() Then  
    &fg.NotEqualsString("a", "x");  
    &fg.NotEqualsString("b", "y");  
    &fg.EndMatchAll();  
End-If;
```

Related Links

[EndMatchAll](#)

[MatchAll](#)

MatchAny

Syntax

```
MatchAny ( )
```

Description

Use this method to initiate a temporary composite search filter using the | filter connector between filters.

Parameters

None.

Returns

None.

Related Links

[EndMatchAny](#)

[MatchAnyReturnTrue](#)

MatchAnyReturnTrue

Syntax

```
MatchAnyReturnTrue ( )
```

Description

Use this method to initiate a temporary composite search filter using the | filter connector between filters. Since successful execution of this method returns True, you can use this method in logical expressions.

Parameters

None.

Returns

A Boolean value.

Example

In the following example, the final composite filter consists of two composite filters each consisting of two filters. The individual filters and the composite filters are all joined by the | filter connector:

```
If &fg.MatchAnyReturnTrue() Then
    If &fg.MatchAnyReturnTrue() Then
        &fg.LessThanNumber("c", 4);
```

```

    &fg.GreaterThanNumber("c", 5);
    &fg.EndMatchAny();
End-If;

If &fg.MatchAnyReturnTrue() Then
    &fg.ContainsWord("d", "x");
    &fg.EqualsString("e", "z");
    &fg.EndMatchAny();
End-If;

&fg.EndMatchAny();

```

Related Links

[EndMatchAny](#)

[MatchAny](#)

NotContainsWord

Syntax

```
NotContainsWord(srch_field, word)
```

Description

Use the NotContainsWord method to generate a string filter that does not match strings containing the exact word or words. Words are separated by spaces and the logical *and* operator is implied; explicit logical operators are not supported between the words. This method forms the filter to find a match on all the words in the *word* parameter.

Note: While the *word* parameter can include one or more words, this parameter is not equivalent to a phrase.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>word</i>	Specifies the exact word or words as a string.

Returns

None.

Example

Consider a document that includes the following sentence:

```
Apples are tastier than oranges.
```

The following use of `NotContainsWord` will exclude this document.

```
&fg.NotContainsWord("LONG_TEXT", "apples oranges");
```

NotEqualsDate

Syntax

```
NotEqualsDate(srch_field, datetime)
```

Description

Use this method to generate a datetime filter on the specified search field for dates not equal to the specified value.

Note: The `NotEqualsDate` method is equivalent to the `NotEqualsDateTime` method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

NotEqualsDateTime

Syntax

```
NotEqualsDateTime(srch_field, datetime)
```

Description

Use the `NotEqualsDateTime` method to generate a datetime filter on the specified search field for dates not equal to the specified value.

Note: The `NotEqualsDateTime` method is equivalent to the `NotEqualsDate` method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

[Related SearchFilterGenerator Methods](#)

NotEqualsDateValue

Syntax

```
NotEqualsDateValue(srch_field, date)
```

Description

Use the `NotEqualsDateValue` method to generate a date filter on the specified search field for dates not equal to the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>date</i>	Specifies the date as a date value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

NotEqualsNumber

Syntax

```
NotEqualsNumber(srch_field, number)
```

Description

Use this method to generate a numeric filter on the specified search field for numbers not equal to the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>number</i>	Specifies the search value as a Number value.

Returns

None.

[Related SearchFilterGenerator Methods](#)

NotEqualsString

Syntax

```
NotEqualsString(srch_field, string)
```

Description

Use this method to generate a string filter on the specified search field for strings not equal to the specified value.

Important! This method cannot be used in conjunction with any of the score boosting methods.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.

Parameter	Description
<i>string</i>	Specifies the search string as a String value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

OnOrAfterDate

Syntax

```
OnOrAfterDate(srch_field, datetime)
```

Description

Use this method to generate a datetime filter on the specified search field for dates on or after the specified value.

Note: The OnOrAfterDate method is equivalent to the OnOrAfterDateTime method.

Parameters

Parameter	Description
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

OnOrAfterDateTime

Syntax

```
OnOrAfterDateTime(srch_field, datetime)
```

Description

Use the `OnOrAfterDateTime` method to generate a datetime filter on the specified search field for dates on or after the specified value.

Note: The `OnOrAfterDateTime` method is equivalent to the `OnOrAfterDate` method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

OnOrAfterDateValue

Syntax

```
OnOrAfterDateValue(srch_field, date)
```

Description

Use the `OnOrAfterDateValue` method to generate a date filter on the specified search field for dates on or after the specified value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>date</i>	Specifies the date as a date value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

OnOrBeforeDate

Syntax

```
OnOrBeforeDate(srch_field, datetime)
```

Description

Use this method to generate a datetime filter on the specified search field for dates on or before the specified value.

Note: The OnOrBeforeDate method is equivalent to the OnOrBeforeDateTime method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

OnOrBeforeDateTime

Syntax

```
OnOrBeforeDateTime(srch_field, datetime)
```

Description

Use the OnOrBeforeDateTime method to generate a datetime filter on the specified search field for dates on or before the specified value.

Note: The OnOrBeforeDateTime method is equivalent to the OnOrBeforeDate method.

Parameters

Parameter	Description
<i>srch_field</i>	Specifies the search field name as a string.
<i>datetime</i>	Specifies the date as a datetime value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

OnOrBeforeDateValue

Syntax

```
OnOrBeforeDateValue(srch_field, date)
```

Description

Use the OnOrBeforeDateValue method to generate a date filter on the specified search field for dates on or before the specified value.

Parameters

Parameter	Description
<i>srch_field</i>	Specifies the search field name as a string.
<i>date</i>	Specifies the date as a date value.

Returns

None.

Related Links

[Related SearchFilterGenerator Methods](#)

SearchFilterGenerator

Syntax

```
SearchFilterGenerator()
```

Description

Use this constructor to instantiate a SearchFilterGenerator object. Similar to the MatchAll method, the composite filter is initialized with the & filter connector.

Parameters

None.

Returns

None.

Example

Instantiate the SearchFilterGenerator class as follows:

```
Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒  
);
```

setBoostMode

Syntax

```
setBoostMode(mode)
```

Description

Use the setBoostMode method to specify the computation to be performed to determine the final boost score when two or more score boosts have been applied to individual search filters.

Parameters

Parameter	Description
<i>mode</i>	<p>Specifies the boost mode as a string value:</p> <ul style="list-style-type: none"> • “ADD” – To set the computed boost to the sum of all the matches. Equivalent to setBoostModeSum. • “AVG” – To set the computed boost to the average of all of the matches. Equivalent to setBoostModeAverage. • “MAX” – To set the computed boost to the maximum score from all of the matches. Equivalent to setBoostModeMaximum. • “MIN” – To set the computed boost to the minimum score from all of the matches. Equivalent to setBoostModeMinimum. <hr/> <p>Note: MIN is the default boost mode.</p> <hr/>

Returns

None.

Example

In the following example, if there is a match for both filters, then the score would be boosted by 5 points, which is the sum of the score boosts; otherwise, if just one filter is matched, then the score is boosted by that match alone:

```

If &fg.MatchAnyReturnTrue() Then
    &fg.ContainsWord("DEPTNAME", "support");
    &fg.BoostFilterScore(0.02);
    &fg.ContainsWord("QE_STATUS", "open");
    &fg.BoostFilterScore(0.03);
    &fg.EndMatchAny();
    &fg.setBoostMode("ADD");
    Rem &fg.setBoostModeSum(); /* Equivalent mode */
End-If;

```

[Score Boosting Examples](#)

setBoostModeSum

Syntax

```
setBoostModeSum ()
```

Description

Use the `setBoostModeSum` method to set the computed boost to the sum of all of the matches.

Parameters

None.

Returns

None.

Example

In the following example, if there is a match for both filters, then the score would be boosted by 5 points, which is the sum of the score boosts; otherwise, if just one filter is matched, then the score is boosted by that match alone:

```
If &fg.MatchAnyReturnTrue() Then
    &fg.ContainsWord("DEPTNAME", "support");
    &fg.BoostFilterScore(0.02);
    &fg.ContainsWord("QE_STATUS", "open");
    &fg.BoostFilterScore(0.03);
    &fg.EndMatchAny();
    &fg.setBoostModeSum();
    Rem &fg.setBoostMode("ADD"); /* Equivalent mode */
```

```
End-If;
```

StringDateToDatetime

Syntax

```
StringDateToDatetime (str_date)
```

Description

Use this method to convert a string value representing a date to datetime value. The time portion of the value is set to 12:00:00.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>str_date</i>	Specifies the string value representing a date to be converted.

Returns

A datetime value.

Search Filter Generator Examples

This section provides additional code examples for generating search filters using the SearchFilterGenerator class:

- Creating complex search filters.
- Boosting the score of filter matches.

Note: The & is the default connector; therefore, for composite filters, MatchAll is implied and does not have to be explicitly specified.

Creating Complex Filters

Example 1 — Using an Explicit Or

The following example generates a composite search filter with Field1 equal to string X or Field2 containing string Y:

```
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);
&fg.MatchAny();
&fg.EqualsString("Field1", &str_X);
&fg.ContainsWord("Field2", &str_Y);
&fg.EndMatchAny();
&fg.SetQueryFilter(&qry);
```

See [MatchAny](#) for more information.

Example 2 — Using an Implicit And

The following example generates a composite search filter with Field1 equal to string X and Field2 containing string Y:

```
import PT_SEARCH:SearchFilterGenerator;
```

```

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);
/* The & is the default connector; therefore, MatchAll is implied and does not */
/* have to be explicitly specified. */
&fg.EqualsString("Field1", &str_X);
&fg.ContainsWord("Field2", &str_Y);
&fg.SetQueryFilter(&qry);

```

See [MatchAll](#) for more information.

Example 3 — Specifying a Complex, Composite Filter

To generate the following composite search filter ((Field1 = string X & Field2 > number N1) & ((Field3 >= number N2 & Field3 <= number N3) | (Field4 = string A | Field4 = string B | Field4 = string C)))

```

import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);
If &fg.MatchAllReturnTrue() Then
    &fg.EqualsString("Field1", &str_X);
    &fg.GreaterThanNumber("Field2", &N1);
    &fg.EndMatchAll();
End-If;

If &fg.MatchAnyReturnTrue() Then

    If &fg.MatchAllReturnTrue() Then
        &fg.GreaterThanEqualsNumber("Field3", &N2);
        &fg.LessThanEqualsNumber("Field3", &N3);
        &fg.EndMatchAll();
    End-If;

    If &fg.MatchAnyReturnTrue() Then
        &fg.EqualsString("Field4", &str_A);
        &fg.EqualsString("Field4", &str_B);
        &fg.EqualsString("Field4", &str_C);
        &fg.EndMatchAny();
    End-If;

    &fg.EndMatchAny();
End-If;

&fg.SetQueryFilter(&qry);

```

Example 4 — Specifying a Numeric Filter Between Two Values

The following example generates a composite search filter with BU equal to 001 and price between 10 and 200:

```

import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

&fg.EqualsString("BU", "001");
If &fg.MatchAllReturnTrue() Then
    &fg.GreaterThanEqualsNumber("PRICE", 10);
    &fg.LessThanEqualsNumber("PRICE", 200);
    &fg.EndMatchAll();
End-If;
&fg.SetQueryFilter(&qry);

```

See [GreaterThanOrEqualsNumber](#) and [LessThanOrEqualsNumber](#) for more information.

Example 5 — Specifying a String Filter Within a Set of Values

The following example generates a composite search filter with BU equal to 001 and status in (Open, Pending, Approved):

```
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

&fg.EqualsString("BU", "001");
If &fg.MatchAnyReturnTrue() Then
    &fg.EqualsString("STATUS", "Open");
    &fg.EqualsString("STATUS", "Pending");
    &fg.EqualsString("STATUS", "Approved");
&fg.EndMatchAny();
End-If;

&fg.SetQueryFilter(&qry);
```

See [EqualsString](#) for more information.

Example 6 — Specifying a String Filter Not in a Set of Values

The following example generates a composite search filter with BU equal to 001 and status not in (Open, Pending, Approved):

```
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

&fg.EqualsString("BU", "001");
If &fg.MatchAllReturnTrue() Then
    &fg.NotEqualsString("STATUS", "Open");
    &fg.NotEqualsString("STATUS", "Pending");
    &fg.NotEqualsString("STATUS", "Approved");
&fg.EndMatchAll();
End-If;

&fg.SetQueryFilter(&qry);
```

See [NotEqualsString](#) for more information.

Score Boosting Examples

Note: When two or more score boosts have been applied to individual search filters, then specify the boost mode. Otherwise, the default boost mode is MIN, which is equivalent to executing the `setBoostModeMinimum` method.

Example 1 — Specifying a Single Score Boost

In the following example, the score returned by the search engine is boosted by 2 points if there is a match:

```
import PT_SEARCH:SearchFilterGenerator;
```

```

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAllReturnTrue() Then
  &fg.ContainsWord("DEPTNAME", "support");
  &fg.BoostFilterScore(0.02);
  &fg.EndMatchAll();
End-If;

```

Example 2 — Using the Default Score Boost Mode (with MatchAll)

In the following example, the score returned by the search engine is boosted by 2 points when all filters match because the default boost mode of minimum is applied when no boost mode is explicitly defined:

```

import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAllReturnTrue() Then
  &fg.ContainsWord("DEPTNAME", "support");
  &fg.BoostFilterScore(0.02);
  &fg.ContainsWord("QE_STATUS", "open");
  &fg.BoostFilterScore(0.03);
  &fg.EndMatchAll();
End-If;

```

Example 2 — Using the Default Score Boost Mode (with MatchAny)

Similarly, in the following example, the score returned by the search engine is also boosted by 2 points when both filter matches because the default boost mode of minimum is applied when no boost mode is explicitly defined; however if only one filter matches, then the score is boosted by that match alone:

```

import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAnyReturnTrue() Then
  &fg.ContainsWord("DEPTNAME", "support");
  &fg.BoostFilterScore(0.02);
  &fg.ContainsWord("QE_STATUS", "open");
  &fg.BoostFilterScore(0.03);
  &fg.EndMatchAny();
End-If;

```

Example 3 — Specifying Sum as the Score Boost Mode

In the following example, if there is a match for both filters, then the score would be boosted by 5 points, which is the sum of the score boosts; otherwise, if just one filter is matched, then the score is boosted by that match alone:

```

import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAnyReturnTrue() Then
  &fg.ContainsWord("DEPTNAME", "support");
  &fg.BoostFilterScore(0.02);

```

```

    &fg.ContainsWord("QE_STATUS", "open");
    &fg.BoostFilterScore(0.03);
    &fg.EndMatchAny();
    &fg.setBoostModeSum();
    Rem &fg.setBoostMode("ADD"); /* Equivalent mode */
End-If;

```

See [setBoostMode](#) and [setBoostModeSum](#) for more information.

Example 4 — Adding a Filter That Does Not Include a Score Boost

The score returned by the search engine is boosted by 5 points, which is the sum of the score boosts; otherwise, if just one filter is matched, then the score is boosted by that match alone. While this example includes a third filter (city = Sydney), it does not contribute to the score boosting.

```

import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAnyReturnTrue() Then
    &fg.ContainsWord("DEPTNAME", "systems");
    &fg.BoostFilterScore(0.02);
    &fg.ContainsWord("QE_STATUS", "draft");
    &fg.BoostFilterScore(0.03);
    &fg.ContainsWord("CITY", "Sydney");
    &fg.EndMatchAny();
    &fg.setBoostModeSum();
End-If;

```

Example 5 — Using the BoostCompositeFilterScore Method

While the `BoostCompositeFilterScore` method provides a boost of 2 points for the inner block of filters (match any), the entire score boost would be 6 points if all filters match:

```

import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAllReturnTrue() Then
    &fg.ContainsWord("DEPTNAME", "Support");
    &fg.BoostFilterScore(0.02);
    Local date &date = Date("2009/05/07");
    &fg.AfterDateValue("OPEN_DT", &date);
    &fg.BoostFilterScore(0.02);
    &fg.ContainsWord("QE_YEAR_H", "2009");
    If &fg.MatchAnyReturnTrue() Then
        &fg.ContainsWord("QE_YEAR_H", "07");
        &fg.ContainsWord("QE_STATUS", "Draft");
        &fg.BoostCompositeFilterScore(0.02);
        &fg.EndMatchAny();
    End-If;
    &fg.EndMatchAll();
    &fg.setBoostModeSum();
End-If;

```

See [BoostCompositeFilterScore](#) for more information.

Example 7 — Using the ContainsPhrase Method

In the following example, the score returned by the search engine is boosted by 2 points when the phrase is matched exactly:

```
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAnyReturnTrue() Then
    &fg.ContainsPhrase("MESSAGE_TEXT", "some long days");
    &fg.BoostFilterScore(0.02);
    &fg.EndMatchAny();
End-If;
```

See [ContainsPhrase](#) for more information.

Example 8 — Performing a Search Using Wildcard Characters

Use the * wildcard to search and match on one or more characters; use the ? wildcard to search and match on a single character.

In the following example, the score returned by the search engine is boosted by 1 point when all filters match because the default boost mode of minimum is applied when no boost mode is explicitly defined:

```
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAllReturnTrue() Then
    &fg.ContainsWord("MESSAGE_TEXT", "l*g");
    &fg.BoostFilterScore(0.01);
    &fg.ContainsWord("MESSAGE_TEXT", "b??ght");
    &fg.BoostFilterScore(0.02);
    &fg.EndMatchAll();
End-If;
```

Example 9 — Performing Stemming in a Search

Use the \$ character to indicate that stemming is to be performed.

In the following example, the score returned by the search engine is boosted by 3 points if there is a match:

```
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAllReturnTrue() Then
    &fg.ContainsWord("MESSAGE_TEXT", "$wanted");
    &fg.BoostFilterScore(0.03);
    &fg.EndMatchAll();
End-If;
```

Example 10 — Performing a Phonetic Search

Use the ! character to indicate that a phonetic search is to be performed.

In the following example, the score returned by the search engine is boosted by 3 points if there is a match:

```
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAllReturnTrue() Then
    &fg.ContainsWord("MESSAGE_TEXT", "!smithee");
    &fg.BoostFilterScore(0.03);
    &fg.EndMatchAll();
End-If;
```

Example 11 — Performing a Fuzzy Search

Use the ~ character to indicate that a fuzzy search is to be performed.

In the following example, the score returned by the search engine is boosted by 2 points if there is a match:

```
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAnyReturnTrue() Then
    &fg.ContainsWord("MESSAGE_TEXT", "speaks~");
    &fg.BoostFilterScore(0.02);
    &fg.EndMatchAny();
End-If;
```

Example 12 — Specifying Custom Scoring with a Keyword-Like Search

Typically, a keyword-like search (similar to a keyword search performed on the Global Search field in the browser) would be constructed programmatically by using the QueryText property of the SearchQuery class. To specify custom scoring for a keyword-like search, you would use either the ContainsWord or ContainsPhrase methods without specifying the search field name value (that is, it is an empty string indicating that the search is against all search fields) as show in the following example.

```
import PT_SEARCH:SearchFilterGenerator;

Local PT_SEARCH:SearchFilterGenerator &fg = create PT_SEARCH:SearchFilterGenerator(⇒
);

If &fg.MatchAnyReturnTrue() Then
    &fg.ContainsWord("", "long");
    &fg.BoostFilterScore(0.02);
    &fg.EndMatchAny();
End-If;
```

See [QueryText](#) for more information for the typical approach to performing a keyword-like search.

SearchQuery Class

This section provides an overview of the SearchQuery class and discusses:

- SearchQuery class methods.
- SearchQuery class properties.

The SearchQuery object is used to define the attributes of a search query—such as its category or categories (index or indexes), facet filters, query text, and so on—and then execute that query on a search engine instance. The required properties of a SearchQuery must be initialized before invoking the Execute method. However, which properties are required depend on the specific search engine. Moreover, all properties are not necessarily used for every execution of a search query. For example, if no filters are to be applied to the search then it is not necessary to initialize the Filter property.

A SearchQuery object is returned by the CreateQuery method of the SearchQueryService class.

Related Links

[CreateQuery](#)

SearchQuery Class Methods

In this section, the SearchQuery class methods are presented in alphabetical order.

BrowseFacetNodes

Syntax

```
BrowseFacetNodes ()
```

Description

Use this method to return an array of facet nodes with out actually executing a search. Because this method does not execute the search query, it is lot faster than the Execute method. This method relies on the Language property only and ignores other SearchQuery class properties and settings, such as facet filters.

Note: This is an abstract method.

Parameters

None.

Returns

An array of FacetNode objects.

Related Links

[FacetNode Class](#)

Execute

Syntax

```
Execute(start, size)
```

Description

Use this method to execute the search query on the search engine. The Execute method returns search results beginning at the document number specified by *start*, and returns a maximum number of results specified by *size*.

The Execute method uses the following SearchQuery class properties:

- Categories

Note: If this property is undefined, the query will be executed against *all* search categories.

- Language

Note: If no value is specified, the query will be executed against *all* languages.

- QueryText

Note: If no value is specified, then *all* documents in the index are returned.

Note: This is an abstract method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>start</i>	Specifies an integer representing the first document of the returned results. This parameter must be greater than or equal to 1. If <i>start</i> exceeds the total number of documents in the index or the search engine-specified maximum number of results, then zero results are returned.
<i>size</i>	Specifies the maximum size of the result set as an integer. This parameter should be greater than or equal to 1. If <i>size</i> is set to 0, then 10 documents are returned.

Returns

A SearchResultCollection object.

Example

```
import PT_SEARCH:SearchFactory;
import PT_SEARCH:SearchQueryService;
import PT_SEARCH:SearchQuery;
import PT_SEARCH:SearchResultCollection;

/* Instantiate the SearchQuery object */

Local PT_SEARCH:SearchFactory &factory = create PT_SEARCH:SearchFactory();
Local PT_SEARCH:SearchQueryService &svc = &factory.CreateQueryService("default");
Local PT_SEARCH:SearchQuery &srchQuery = &svc.CreateQuery();

/* Initialize the search query */

&srchQuery.QueryText = "some text";
&srchQuery.Language = &lang_cd;
&srchQuery.MarkDuplicates = False;
&srchQuery.RemoveDuplicates = False;

/* Execute the search query */

Local number &start = 1;
Local number &size = 10;
Local PT_SEARCH:SearchResultCollection &results = &srchQuery.Execute(&start, &size)⇒

;

/* Re-execute the search query to return the next 10 results */

&start = &start + &size;
&results = &srchQuery.Execute(&start, &size);
```

FormatDateFilter

Syntax

```
FormatDateFilter(datefilter)
```

Description

Use this method to convert dates from the internal PeopleSoft date format into a search engine-specific format. You must use this method when the query string is programmatically created.

Note: This is an abstract method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>datefilter</i>	Specifies the search filter as a Date value.

Returns

A String value.

Related Links

[setDateFilter](#)

FormatDateTimeFilter

Syntax

`FormatDateTimeFilter` (*datetmfilter*)

Description

Use this method to convert dates from the internal PeopleSoft date/time format into a search engine-specific format. You must use this method when the query string is programmatically created.

Note: This is an abstract method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>datetmfilter</i>	Specifies the search filter as a DateTime value.

Returns

A String value.

Related Links

[setDateTimeFilter](#)

SearchQuery Class Properties

In this section, the SearchQuery class properties are presented in alphabetical order.

Categories

Description

Use this property to set or return the list of search categories (search indexes) you want to search as an array of SearchCategory objects. If this property is defined, the Execute method will run the query on all the search categories specified in this property.

Important! If this property is undefined, the query will be executed against *all* search categories in the search engine instance.

This property is read/write.

Example

The following example uses two search categories called cat1 and cat2.

```
import PT_SEARCH:SearchCategory;

Local array of PT_SEARCH:SearchCategory &cats;

&cats = CreateArray(create PT_SEARCH:SearchCategory("cat1"));
&cats.Push(create PT_SEARCH:SearchCategory("cat2"));

&searchQuery.Categories = &cats;
```

Related Links

[SearchCategory Class](#)

ContainsAnyWords

Description

Use this property to set a search string that contains one or more words. The search results include those documents that contain *any* of these words and whatever is defined by other search text properties (for example, ContainsExactPhrase, QueryText, or WithoutWords).

This property is not required.

This property is read/write.

ContainsExactPhrase

Description

Use this property to set a search string that contains one or more words. The search results include those documents that this *exact phrase* and whatever is defined by other search text properties (for example, ContainsAnyWords, QueryText, or WithoutWords).

This property is not required.

This property is read/write.

ClusteringSpecs

Description

This property is reserved for future use.

DocsRequested

Description

Use this property to set or return the size of the result set as an integer. After invoking the Execute method, use this property to return the value of the *size* parameter passed to Execute. Alternatively, if the search query is to be executed by the ExecuteQuery method of the QueryService class, then use this property to specify the size of the result set.

Example

For example, one could compare DocsRequested to the GetDocumentCount method of the ResultCollection class to determine if there are possibly more documents to be retrieved.

The StartIndex and DocsRequested properties (that is, the *start* and *size* parameters to the Execute method) allow for “chunking” of search results. The idea is to repeatedly call Execute while increasing the *start* parameter by the increment specified by *size*. For example, the following psuedo-code will return the first 100 results the first time through the loop. The second time through the loop, it will return documents 101 through 200, and so on.

```
int start=1, size=100

, // return results in chunks of 100 documents
while not done
  results = query.execute(start, size)
  if (results.GetDocumentCount() < query.DocsRequested)
    done = true
    // we got fewer documents than we asked for so we're done executing this    =>

  // query
  if (results.GetDocumentCount() = 0)
    done = true
    // no more documents being returned so we're done executing this query

  // do something with the results

  start = start + size
end-while
```

Related Links

[GetDocumentCount](#)

EnableExtendedFilterOperators

Description

Use this property to set or return a Boolean value indicating whether to enable the set of extended filter operators (specifically, the notequals operator). In addition, when this property is set to True, all search filters are added to the QueryText property and sent to the search engine in this manner. Otherwise, when this property is set to False, the search filters are handled by the Filters property as an array of SearchFilter objects. The default value is False.

This property is not required.

This property is read/write.

Related Links

[Operator](#)

FacetFilters

Description

Use this property to set or return an array of FacetFilter objects on which the search results are currently filtered.

Note: The SearchCategory class GetFacetFilters method can be used to get the initial list of facet filters.

This property is not required.

This property is read/write.

Related Links

GroupingSpec

Description

This property is reserved for future use.

IncludelImages

Description

Use this property to set or return a Boolean value indicating whether to return images in the search results.

This property is read/write.

Example

```
Local PT_SEARCH:SearchQuery &qry;  
...  
If PTSF_QRY_CLIENT.PTSF_SHOW_IMAGE = "Y" Then  
    &qry.IncludeImages = True;  
End-If;
```

Related Links

[GetImageUrl](#)

Language

Description

Use this property to set or return a three-character string representing the language code to which the search query results should be restricted. This property must be a PeopleSoft language code—for example, ENG for English, FRA for French, and so on.

Note: If no value is specified, the query will be executed against *all* languages.

This property is read/write.

Example

```
&SearchQuery.Language = "ENG";
```

"Selecting Database Character Sets" (Global Technology)

MarkDuplicates

Description

Use this property to set or return a Boolean value indicating whether duplicates in the result set should be marked as such. A search result can be identified by running the `isDuplicate` method.

This property is not required. However, it defaults to `False` if no value is specified.

This property is read/write.

Related Links

[RemoveDuplicates](#)

[IsDuplicate](#)

MaximumNumberOfFacetValues

Description

Use this property to set or return an Integer value representing the maximum number of child facet nodes. For example, if there are 100 facet values, setting this property to 10 will return the first ten facet values as determined by the sorting order. If this property is not set, the default value is -1, which indicates to return all child nodes.

This property is not required.

This property is read/write.

Related Links

[FacetNode Class](#)

MinimumDocumentsPerFacetValue

Description

Use this property to set or return an Integer value representing the minimum number of documents required for the child facet node to be returned. Child facet nodes with less than this document count are

not returned. If this property is not set, the default value is 1, which indicates that a facet node must have at least one document to be returned.

This property is not required.

This property is read/write.

Related Links

[DocumentCount](#)

ProgrammaticSearchString

Description

Use this property to set or return the programmatically generated search string as a string. This search string is not displayed to the end user.

This property is not required.

This property is read/write.

QueryText

Description

Use this property to set or return a string representing the text to use in the search query. The search results include those documents that contain this text and whatever is defined by other search text properties (for example, `ContainsAnyWords`, `ContainsExactPhrase`, or `WithoutWords`).

Note: If no value is specified and none of the other search text properties are defined, then *all* documents in the index are returned.

This property is read/write.

RemoveDuplicates

Description

Use this property to set or return a Boolean value indicating whether duplicates should be removed from the result set.

This property is not required. However, it defaults to `False` if no value is specified.

This property is read/write.

Related Links

[MarkDuplicates](#)

RequestedFields

Description

Use this property to set or return the list of custom attributes to be included for each search result. The list is an array of SearchField objects.

This property is not required.

This property is read/write.

[GetRequestedFields](#)

[SearchField Class](#)

ReturnFacetValueCounts

Description

Use this property to set or return a Boolean value indicating whether to compute and return document counts per facet node.

This property is not required. However, it defaults to True if no value is specified.

This property is read/write.

Related Links

[DocumentCount](#)

SearchWithin

Description

Use this property to set or return a string of search terms as a string. This is used to search within the current results.

This property is not required.

This property is read/write.

SortFacetValuesBy

Description

Use this property to set or return a String value indicating the sort order by which facet nodes are sorted:

Value	Description
ALPHA_ASC	Sort by node name alphabetically ascending.
ALPHA_DES	Sort by node name alphabetically descending.
COUNT_ASC	Sort by document count numerically ascending.
COUNT_DES	Sort by document count numerically descending. COUNT_DES is the default value, which means that facet nodes with highest document count are displayed first in the list.

This property is not required.

This property is read/write.

Related Links

[DocumentCount](#)

SortSpecs

Description

This property is reserved for future use.

StartIndex

Description

Use this property to set or return an integer representing the first document of the result set. After invoking the Execute method, use this property to return the value of the *start* parameter passed to Execute. Alternatively, if the search query is to be executed by the ExecuteQuery method of the QueryService class, then use this property to specify the first document of the result set.

TopN

Description

This is reserved for future use.

WithoutWords

Description

Use this property to set a search string that contains one or more words. The search results include those documents that *do not include* any of these words and whatever is defined by other search text properties (for example, ContainsAnyWords, ContainsExactPhrase, or QueryText).

This property is not required.

This property is read/write.

SearchQueryCollection Class

This section provides an overview of the SearchQueryCollection class and discusses SearchQueryCollection class methods.

The SearchQueryCollection class provides a collection of SearchQuery objects. Because the SearchQueryCollection class is a generic interface class, a search engine-specific subclass is required.

Related Links

[SearchQuery Class](#)

SearchQueryCollection Class Methods

In this section, the SearchQueryCollection class methods are presented in alphabetical order.

addQuery

Syntax

```
addQuery (&srch_qry)
```

Description

Use this method to add a search query to the search query collection. The addQuery method can be called repeatedly to add multiple search queries to the collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&srch_qry</i>	Specifies the query as a SearchQuery object.

Returns

None.

Related Links

[SearchQuery Class](#)

Count

Syntax

`Count ()`

Description

Use this method to return the number of SearchQuery objects in the search query collection as an integer.

Parameters

None.

Returns

An Integer value.

ExecuteQuerys

Syntax

`ExecuteQuerys ()`

Description

Use this method to run multiple search queries in parallel. The ExecuteQuerys method returns an array of SearchResultCollection objects, one for each search query executed. If any of the search queries fails, ExecuteQuerys throws an exception.

Note: The number of parallel requests is determined by the thread pool size that is defined in the application server configuration file (psappsrv.cfg).

Parameters

None.

Returns

An array of SearchResultCollection objects.

Related Links

[SearchResultCollection Class](#)

First

Syntax

```
First()
```

Description

Use this method to return the first SearchQuery object in the search query collection. If the search query collection is empty, this method returns Null.

Parameters

None.

Returns

A SearchQuery object if successful, Null otherwise.

Related Links

[SearchQuery Class](#)

Item

Syntax

```
Item(index)
```

Description

Use this method to return the SearchQuery object at the position in the search query collection specified by the *index* parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&index</i>	Specifies the position of the SearchQuery object in the search query collection as an integer.

Returns

A SearchQuery object if successful, Null otherwise.

Related Links

[SearchQuery Class](#)

Next

Syntax

`Next ()`

Description

Use this method to return the next SearchQuery object in the search query collection. This method can only be invoked after a successful invocation of the First, Item, or Next methods.

Parameters

None.

Returns

A SearchQuery object if successful, Null otherwise.

[SearchQuery Class](#)

SearchQueryService Class

This section provides an overview of the SearchQueryService class and discusses: SearchQueryService class methods.

The SearchQueryService provides the ability to instantiate a SearchQuery object along with other interfaces. Because the SearchQueryService class is an interface class, it requires a search engine-specific search query service and search query class to instantiate a search engine-specific SearchQuery object.

A SearchQueryService object is created by the CreateQueryService method of the SearchFactory class.

Related Links

[CreateQueryService](#)

SearchQueryService Class Methods

In this section, the SearchQueryService class methods are presented in alphabetical order.

CreateQuery

Syntax

```
CreateQuery()
```

Description

Use this method to instantiate a SearchQuery object.

Note: This is an abstract method.

Parameters

None.

Returns

A SearchQuery object.

Related Links

[SearchQuery Class](#)

CreateQueryCollection

Syntax

```
CreateQueryCollection()
```

Description

Use this method to instantiate a search query collection.

Note: This is an abstract method.

Parameters

None.

Returns

A SearchQueryCollection object.

Related Links

[SearchQueryCollection Class](#)

ExecuteQuery

Syntax

ExecuteQuery (*&query*)

Description

Use this method to execute the specified search query on the search provider and return the collection of search results. This method is equivalent to invoking the Execute method of the SearchQuery class.

Note: This is an abstract method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&query</i>	Specifies the search query as a SearchQuery object.

Returns

A SearchResultCollection object.

Related Links

[SearchQuery Class](#)

[Execute](#)

[SearchResultCollection Class](#)

ExecuteQuerys

Syntax

ExecuteQuerys (*&srch_qry_coll*)

Description

Use this method to run multiple search requests in parallel. The number of parallel request is determined by the Thread Pool Size that is defined in the application server configuration file (psappsrv.cfg).

Use this method to run multiple search queries in parallel. The ExecuteQuerys method returns an array of SearchResultCollection objects, one for each search query executed. If any of the search queries fails, ExecuteQuerys throws an exception.

Note: The number of parallel requests is determined by the thread pool size that is defined in the application server configuration file (psappsrv.cfg).

Note: This is an abstract method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&srch_gry_coll</i>	Specifies the search queries as a SearchQueryCollection object.

Returns

An array of SearchResultCollection objects.

Related Links

[SearchQueryCollection Class](#)

[SearchResultCollection Class](#)

SearchResult Class

This section provides an overview of the SearchResult class and discusses: SearchResult class methods

The SearchResult object represents a specific search result (that is, a document) in a SearchResultCollection object. Because the SearchResult class is a generic interface class, a search engine-specific subclass is required. The SearchResult object is defined to comprise 10 standard attributes (or “properties”)—for example, title, URL, summary, and so on. These private, read-only “properties” can be accessed only through the methods of the SearchResult class.

A SearchResult object is instantiated by the First, Item or Next methods of the SearchResultCollection.

Related Links

[SearchResultCollection Class](#)

SearchResult Class Methods

In this section, the SearchResult class methods are presented in alphabetical order.

GetCategoryNames

Syntax

```
GetCategoryNames ()
```

Description

Use this method to return the list of search categories to which this search result belongs as an array of string.

Parameters

None.

Returns

An array of string.

Related Links

[SearchCategory Class](#)

GetContentLength

Syntax

```
GetContentLength ()
```

Description

Use this method to return the content length for this search result as an integer. If the content length cannot be determined, this method returns -1.

The content length, signature, title, and other attributes are used to determine whether a search result is a duplicate.

Parameters

None.

Returns

An integer.

Related Links

[IsDuplicate](#)

GetCustomAttributes

Syntax

```
GetCustomAttributes ()
```

Description

Use this method to return a SearchFieldCollection representing the custom attributes for this search result. A SearchFieldCollection is a collection of SearchField objects.

Parameters

None.

Returns

A SearchFieldCollection object.

Related Links

[SearchFieldCollection Class](#)

[SearchField Class](#)

GetImageUrl

Syntax

```
GetImageUrl()
```

Description

Use the GetImageUrl method to return the image URL for this search result.

Parameters

None.

Returns

A String value.

Example

```
Local PT_SEARCH:SearchResult &cur;

...

If PTSF_QRY_CLIENT.PTSF_SHOW_IMAGE = "Y" Then
  &rs(&i).PTSF_SRCHRESULT.PTSF_DISPIMAGEURL.Visible = True;
  &rs(&i).PTSF_SRCHRESULT.HTMLAREA.Visible = True;
  &imageUrl = &cur.GetImageUrl();
  &imageUrlHtml = GetHTMLText(HTML.HTML_IMAGE, &imageUrl);
  &rs(&i).PTSF_SRCHRESULT.PTSF_DISPIMAGEURL.Value = &imageUrl;
  &rs(&i).PTSF_SRCHRESULT.HTMLAREA.Value = &imageUrlHtml;
Else
  &rs(&i).PTSF_SRCHRESULT.PTSF_DISPIMAGEURL.Visible = False;
  &rs(&i).PTSF_SRCHRESULT.HTMLAREA.Visible = False;
End-If;
```

Related Links

[IncludeImages](#)

GetLanguage

Syntax

```
GetLanguage ()
```

Description

Use this method to return a string representing the three-character PeopleSoft language code for this search result.

Parameters

None.

Returns

A string.

Related Links

[Language](#)

GetLastModified

Syntax

```
GetLastModified ()
```

Description

Use this method to return the last modified date and time for this search result.

Parameters

None.

Returns

A DateTime value.

GetScore

Syntax

```
GetScore ()
```

Description

Use this method to return the search engine-specific score for this search result as an integer.

Parameters

None.

Returns

An integer.

GetSignature

Syntax

```
GetSignature ()
```

Description

Use this method to return the search engine-computed signature for this search result as an integer. If the signature cannot be determined, this method returns -1.

The signature, content length, title, and other attributes are used to determine whether a search result is a duplicate.

Parameters

None.

Returns

An integer.

Related Links

[IsDuplicate](#)

GetSummary

Syntax

```
GetSummary ()
```

Description

Use this method to return the summary for this search result as a string.

Parameters

None.

Returns

A string.

GetTitle**Syntax**

```
GetTitle()
```

Description

Use this method to return the title for this search result as a string.

Parameters

None.

Returns

A string.

GetUrlLink**Syntax**

```
GetUrlLink()
```

Description

Use this method to return the URL for this search result as a string.

Parameters

None.

Returns

A string.

HasDuplicate

Syntax

```
HasDuplicate()
```

Description

Use this method to return a Boolean value indicating whether this search result has duplicates.

Parameters

None.

Returns

A Boolean value: True if the search result has duplicates, False otherwise.

Related Links

[IsDuplicate](#)

[MarkDuplicates](#)

IsDuplicate

Syntax

```
IsDuplicate()
```

Description

Use this method to return a Boolean value indicating whether this search result is a duplicate. *Exact duplicates* and *near duplicates* are both marked as duplicates by the PeopleSoft Search Framework.

An exact duplicate is a document that satisfies *all* of the following conditions exactly:

- Same signature
- Same content length
- Same title

A near duplicate (a similar document) is a document that satisfies *any* of the following conditions:

- Same signature and documents are not empty.
- Same (non-null) title and same 4K checksum.
- Same (non-null) title and URLs differ by not more than one element (an element is a folder name and doesn't include the HTML/JSP page name of the HTTP GET parameters).

Parameters

None.

Returns

A Boolean value: True if this search result is a duplicate, False otherwise.

[Execute](#)

SearchResultCollection Class Methods

In this section, the SearchResultCollection class methods are presented in alphabetical order.

First

Syntax

```
First ()
```

Description

Use this method to return the first SearchResult object in the SearchResult collection. If the SearchResult collection is empty, it returns Null.

Parameters

None.

Returns

A SearchResult object if successful, Null otherwise.

Related Links

[SearchResult Class](#)

GetDocumentCount

Syntax

```
GetDocumentCount ()
```

Description

Use this method to return the actual number of SearchResult objects (documents) in the SearchResult collection.

Note: This is an abstract method.

Parameters

None.

Returns

An integer.

Related Links

[DocsRequested](#)

GetDuplicatesMarked

Syntax

```
GetDuplicatesMarked ()
```

Description

Use this method to return a Boolean value indicating whether duplicate items in the collection are marked as duplicates—that is, whether the search query was executed with MarkDuplicates set to true.

Note: This is an abstract method.

Parameters

None.

Returns

A Boolean value: True if duplicates were marked, False otherwise.

Related Links

[IsDuplicate](#)

GetEstimatedHitCount

Syntax

```
GetEstimatedHitCount()
```

Description

Use this method to return the estimated hit count for the search query as an integer. The estimated hit count can be used as a device for fetching search results on demand rather than retrieving all of the search results initially.

Note: This is an abstract method.

Parameters

None.

Returns

An integer.

GetFacetNodes

Syntax

```
GetFacetNodes ()
```

Description

Use this method to return an array of facet nodes available for this search result collection.

Parameters

None.

Returns

An array of FacetNode objects if successful, Null otherwise.

Related Links

[FacetNode Class](#)

GetQueryObject

Syntax

```
GetQueryObject ()
```

Description

Use this method to return the SearchQuery object that was used for the search.

Parameters

None.

Returns

A SearchQuery object.

Related Links

[SearchQuery Class](#)

GetQueryText

Syntax

```
GetQueryText ()
```

Description

Use this method to return the search text that was used for the search query as a string.

Note: This is an abstract method.

Parameters

None.

Returns

A string.

Related Links

[QueryText](#)

GetStartIndex

Syntax

```
GetStartIndex ()
```

Description

Use this method to return the value of the *&start* parameter that was used to execute this search query.

Note: This is an abstract method.

Parameters

None.

Returns

An integer.

Related Links

[Execute](#)

[StartIndex](#)

Item

Syntax

`Item(index)`

Description

Use this method to return the SearchResult object at the position in the SearchResult collection specified by the *index* parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>index</i>	Specifies the position of the SearchResult object in the SearchResult collection as an integer.

Returns

A SearchResult object if successful, Null otherwise.

Related Links

[SearchResult Class](#)

Next

Syntax

`Next()`

Description

Use this method to return the next SearchResult object in the SearchResult collection. This method can only be invoked after a successful invocation of the First, Item, or Next methods.

Parameters

None.

Returns

A SearchResult object if successful, Null otherwise.

SearchAuthnQueryFilter Class

This section provides an overview of the SearchAuthnQueryFilter class and discusses: SearchAuthnQueryFilter class methods.

The SearchAuthnQueryFilter class provides an abstract method to evaluate a list of values for a security attribute for a given search user. An application that requires document-level security in a searchable object must implement and extend the evaluateAttrValues abstract method.

SearchAuthnQueryFilter Class Methods

In this section, the SearchAuthnQueryFilter class methods are presented in alphabetical order.

evaluateAttrValues

Syntax

```
evaluateAttrValues (SBO_name, attr, user_ID)
```

Description

Use this method to return a list of values for a security attribute for a search user.

Note: This is an abstract method.

Parameters

Parameter	Description
<i>SBO_name</i>	Specifies a string representing a searchable object upon which the security attribute value needs to be evaluated
<i>attr</i>	Specifies a string representing the security attribute value as a document-level filtering attribute.
<i>user_ID</i>	Specifies user ID that executed the search query as a string.

Returns

An array of string.

Example

```
import PTSF_SECURITY:*;

class UserPermission implements PTSF_SECURITY:SearchAuthnQueryFilter
  method UserPermissionList();
  method evaluateAttrValues(&sboName As string, &secAttr As string, &searchUser As⇒
    string) Returns array of string;
end-class;

method UserPermissionList
end-method;

method evaluateAttrValues
  /+ &sboName as String, +/
  /+ &secAttr as String, +/
  /+ &searchUser as String +/
  /+ Returns Array of String +/
  /+ Extends/implements PTSF_SECURITY:SearchAuthnQueryFilter.evaluateAttrValues +/

  Local SQL &userPermissions_SQL;
  Local array of string &retvalues;
  Local string &isAdmin;
  &retvalues = CreateArrayRept("", 0);

  SQLExec("SELECT 'X' FROM PSROLEUSER WHERE ROLEUSER=:1 AND (ROLENAME=:2 OR ROLENA⇒
ME=:3)", &searchUser, "Portal Administrator", "PeopleSoft Administrator", &isAdmin)⇒
;

  If All(&isAdmin) Then
    &retvalues = CreateArray("R:Admin");
  Else
    &retvalues.Push("0"); /* Public */
    &retvalues.Push("1:" | &searchUser); /* Author */
    &userPermissions_SQL = CreateSQL("SELECT DISTINCT A.CLASSID FROM PSROLECLASS ⇒
A, PSROLEUSER B, PSOPRDEFN C WHERE A.ROLENAME = B.ROLENAME AND C.OPRID = B.ROLEUSER⇒
AND C.OPRID = :1", &searchUser);
    Local string &classids;
    While &userPermissions_SQL.Fetch(&classids)
      &retvalues.Push(&classids);
    End While
  End If
End Method
```

```

        End-While;
    End-If;
    Return &retvalues;

end-method;

```

Additional Search Examples

This section provides additional code examples for the PeopleSoft Search Framework: Searching using facets.

Searching Using Facets

The following provides an example of searching using facets.

```

import PT_SEARCH:*;

/* The following 3 lines are same for any implementation */
Local PT_SEARCH:SearchFactory &factory = create PT_SEARCH:SearchFactory();
Local PT_SEARCH:SearchQueryService &svc = &factory.CreateQueryService("default");
Local PT_SEARCH:SearchQuery &qry = &svc.CreateQuery();

/* This is the keywords user is searching for; */
&qry.QueryText = "a";

/*
&qry.StartIndex , For the first request this is always 1
When using pagination to get the next set of results this can be changed to DocsReq→
uested + StartIndex ex: here 51 on next request is 101..
The maximum number of results that can come back is 200 which is configurable the m→
ax results for this query can be fetched from SearchResultCollection hit count
*/
&qry.StartIndex = 1;

/*
&qry.DocsRequested , Number of results to be returned by the search , It is recomme→
nded to keep this default to 50 for performance reasons and show 10 results per pag→
e and if the end user is requesting for 6th page request with start index to 51;
*/
&qry.DocsRequested = 50;

/*
&qry.RemoveDuplicates ,&qry.MarkDuplicates Currently these two should always be set→
to false as our we generate unique id for every search document.
&qry.RemoveDuplicates = False;
*/
&qry.MarkDuplicates = False;

/*
This should be set to empty value to search in documents from all languages .
&qry.Language This can be provided a value to search in language specific documents
Currently the frame work does not allow searching in selected languages , its eithe→

```

```

r all or one language
*/
&qry.Language = %Language_User;

/*
&qry.Categories , Array of categories on which the search can be performed on
If not specified we will search in all categories
*/
Local PT_SEARCH:SearchCategory &srchCat = create PT_SEARCH:SearchCategory("MY_SRCH_⇒
CAT");
&qry.Categories = CreateArray(&srchCat);

/*
&qry.RequestedFields , Array of custom attribute values in the search result
Optional , if not specified all the standard information like URL , body , title ar⇒
e still returned
*/
&qry.RequestedFields = &srchCat.GetRequestedFields();

/*
&qry.FacetFilters , Array of facets filter the search result by
Optional , If not specified No facets will be returned
Limitation : Only documents having this facet and path (If included) will be return⇒
ed in the search result.
FacetFilter constructor will take two arguments 1.Facet name , 2.Facet Path
FacetFilter is required when dealing with hierarchy facets Ex: Attribute LOCATION h⇒
as COUNTRY/STATE/CITY
To filter results for country USA the request will be FacetName: LOCATION , Facet F⇒
ilter: USA
To filter results for country USA and State CA the request will be FacetName: LOCAT⇒
ION , FacetFilter: USA/CA

&qry.FacetFilters = CreateArray(create PT_SEARCH:FacetFilter("SETID", ""));
&qry.FacetFilters.Push(create PT_SEARCH:FacetFilter("STATE", ""));
*/

&qry.FacetFilters = &srchCat.GetFacetFilters();

/*
The other optional facet request related query parameters that can be set when sea⇒
rching for facets
ReturnFacetValueCounts -- returns the counts only if this is set to true , default⇒
t is true , set this to false if we do not want to display counts.
MinmumDocumentsPerFacetValue -- only return facet value whose document hit count ⇒
is more that this , ex: only facets values which have hit count more than 5 or 1;
MaximumNumberOfFacetValues -- the children facets can be huge list , this can lim⇒
it the return list
SortFacetValuesBy -- ALPHA_DES , ALPHA_ASC , COUNT_DES , COUNT_ASC
the max fetch returns the only top few children this can be used to provide which⇒
top children to return
*/

/*
Execute the query and get back the results
*/
Local PT_SEARCH:SearchResultCollection &res = &qry.Execute(&qry.StartIndex, &qry.Do⇒
csRequested);

```

```

/*
Find the number of results returned by the search , this will always be less than o⇒
r equal to "&qry.DocsRequested"
*/
Local integer &resultSize = &res.GetDocumentCount();

/*
Find the number of potential results that can be returned;
This can be used to determine if we get the next set of results and how many pages ⇒
that can be shown to the user
*/
Local integer &estimatedResultCount = &res.GetEstimatedHitCount();

Local string &outHtml;

/*
FacetNode will have the facet values and the hit count for the results
GetFacetNodes will return array of the facet nodes in the result
*/
Local array of PT_SEARCH:FacetNode &facetNodes = &res.GetFacetNodes();

/*
Facet Node has various information which can be retrieved.
&facetNodes [&i].DocumentCount will return hit count
&facetNodes [&j].FacetValue , is the facet value before translation
&facetNodes [&i].DisplayValue , translated facet value
&facetNodes [&i].Path , to which the facet value belongs to
&facetNodes [&i].getChildNodes() will return child facet nodes and will have all ab⇒
ove properties
*/

/*
loop through facet nodes and there children and render it in the UI
*/
If &facetNodes <> Null And
    &facetNodes.Len <> 0 Then

            &outHtml = &outHtml | "<br>" | &customs.Item(&j).Name | "=" | &customs.Ite
m(&j).Value;
        End-For;
    End-If;
    &outHtml = &outHtml | "</font>";
End-For;
&outHtml = &outHtml | "</BODY></HTML>";

```

Portal Registry Classes

Understanding the Portal Registry

The portal registry is a tree structure in which content for a portal is organized, classified, and registered. The portal registry classes (API) are used to update the portal registry. The Portal Administration pages provide a GUI access to the portal registry API. You can also access them using a PeopleCode program you write yourself. How you access the portal registry depends on the type of updates required. Your organization will likely use both methods of updating the portal registry. This topic focuses on accessing the portal registry classes using PeopleCode.

A portal is a website that helps you navigate to other web-based applications and content. The PeopleSoft Portal is a *business portal*. It is similar to general purpose portals, except that its main purpose is to help end-users be more effective in accessing information to perform their jobs.

Each PeopleSoft Portal is defined by one PeopleSoft portal registry. The PeopleSoft portal registry consists of a number of system tables and associated data in a PeopleSoft database. The portal registry must reside within one PeopleSoft database. There can be more than one portal registry in a PeopleSoft database, but only one portal registry is associated with a PeopleSoft Portal.

The portal registry consists of the following primary parts:

- Folders
- Content references
- Nodes

Folders and content references make up the majority of the portal registry, and provide a hierarchical tree structure to describe various content that is *registered* as part of a PeopleSoft portal.

Nodes provide a logical name to a specific webserver and database, so content can be registered independent of specific webserver. It is used when the portal servlet attempts to retrieve content—both internal PeopleSoft content as well as external content—and to assemble pages.

The primary function of the portal is to take a target URL (generally a URL for a PeopleSoft component) that comes in from a user's browser, and assemble a page with that content and any other content. The layout and what content to assemble on the page is defined by the *node template*, which is composed of HTML. The portal attempts to find the content reference associated (that is, registered) with the target URL to get the template, or uses a series of default templates if it cannot get the template from a content reference.

Folders

Folders are how a hierarchical structure is created within a portal registry. Each folder has a parent, except the root folder, which is the top-level folder in a portal registry. Each folder can also contain child folders and content references. Folders are roughly analogous to directories within a file system. A folder can be

further defined by a number of attributes (description, security, when it expires, and so on) that are useful within the portal environment.

Related Links

[Adding a Folder](#)

Content References

A content reference is simply a reference to a URL. After you create an entry for a content reference in the portal registry, it's considered registered. A content reference can be further defined by a number of attributes (description, security, when it expires, and so on) that are useful within the portal environment.

There are a number of distinct types of content references that can be broken down into the following broad categories:

- Target
- Template
- Component

A *target* type of content reference describes a registered URL that a user might reference. Typically, these would be a PeopleSoft Pure Internet Architecture component, such as a page in a transaction. When a user references a URL, the URL is looked up in the registry to find the target content reference.

A *template* type of content reference describes what, if any, other content to put on the page, and where to place that content. The portal attempts to find a template for every URL that is requested.

A *component* type of content reference describes a component that is typically placed on a target page or homepage.

Related Links

[ContentReference Links](#)

Nodes

When a content reference is created to register some content (that is, a URL) the specific URI (that is, the scheme, Web server, and so on) can be specified in the content reference. However, this has the drawback that every time the URI for a content reference changes (the Web server name changes, and so on), the content reference must be changed. Nodes are a way to create a logical name for a specific Web server, scheme, and so on. When the content reference is created you can specify a node name.

For example, suppose the name of a Web server changed. If you don't use nodes, you must check all your content references and change them accordingly. If you use nodes, you have to change only the Web server name in one place, and all the content references that use that node now automatically reference the correct Web server.

Nodes can be optional for content where the specified URL is already a complete URL, such as for external content. Nodes can be categorized as:

- default local

- local
- non-local (remote)

[Using Attributes](#)

Security

The same security mechanism is used for folders, content references, content reference links, tab definitions, pagelets, and user homepages. All of these items can be marked as public, owner accessible, or can have explicit PeopleSoft permission values set, including cascading the permissions to its child objects (that is, the child objects have the same permissions as the parent objects, when applicable.)

When marked as public, the item is accessible by any user. Public access cannot be cascaded, that is, passed down, to child objects.

When marked as owner accessible, an item is accessible only by the same user that created that item. Owner accessible cannot be cascaded, that is, passed down, to child objects.

Items can be marked as accessible by PeopleSoft permissions. This means that if a user is a member of a role, and the role contains the permission list that the item is also associated with, the user has access to that item. Additionally, when applied to folder permissions the permission can be cascaded. This means that any child of that folder, including a content reference, automatically has that permission added to its permission list.

Role-based security can be applied to the portal objects (folders, content references and content reference links) using the RolePermissions collection.

Note: You can only use role-based security for content references, folders, and content reference links that are not components or iScripts.

You can specify which roles are allowed to access the objects. This works similarly to permission lists. If a user has a specified role, authorization is granted.

A role collection is the same as the PermissionValue collection, though there are additional properties on PermissionValue.

Attributes

Folders, content references, content reference links, PageletCategory objects, and Pagelets can have any number of attributes added to them. Attributes are simply name/value pairs. These name/value pairs are defined and used by many portal-aware applications, such as the search engine, navigational display, and so on.

See [Using Attributes](#).

Additional Portal Objects

Using the PortalRegistry, you can also add and customize other items in your portal, such as tabs, homepages, and favorites.

The `TabDefinition` is a homepage tab that has been defined to the portal. It is what an administrator creates when they want to define a new homepage tab. The `TabDefinition` is based on content references.

The `User Homepage` is a personalized homepage for a user. It contains all the tabs and pagelets the user has selected for their homepage. The `User Homepage` is based on folders.

A `Favorite` represents a content reference that the user wants to keep a shortcut to. It contains the name of the content reference, and the label the user wants displayed for this favorite.

A `Pagelets` is an area on a page that contains content, and the template used to specify the style for that content. `Pagelets` are a type of content reference.

Using the Portal Registry API

The portal registry API provides the entry point to a specific portal registry. Common administrative tasks include adding, deleting, and renaming the registry objects (that is, folders, content references, tabs, and so on.) Additionally, there are many properties associated with every registry object, and all of these properties can be accessed and modified.

You can use the portal registry API in batch mode to make many changes to a portal at once. For example, suppose something changed in your security system. You could write your own `PeopleCode` program, using the portal registry classes, in an `Application Engine` program and change the access for all your users at once.

You can also use the portal registry API to exchange data with an external system. For example, suppose an external merchant had an area on your company's portal, and the information there must be updated. One way to do this is for the merchant to use an `Application Message` to send the data to your system, then a subscription program would update the portal using the portal registry API.

Each `PortalRegistry` object represents one specific `PortalRegistry` in a system. An empty `PortalRegistry` object is initially gotten from the `PeopleSoft Session` object. You can then open an existing `PortalRegistry` to view or change existing content, create a new `PortalRegistry`, or delete an existing `PortalRegistry`.

Using Security

The `PermissionValue` collection associated with a folder, content reference, and so on, as well as specific properties on the object, work together to form the security for an object. This section discusses how these attributes work together to determine access to a portal registry object.

Portal Registry Object Properties

Together with the `PermissionValue` collection, the following two properties determine access to a portal registry object:

- `AuthorAccess`
- `PublicAccess`

The `AuthorAccess` property determines whether the author of the object has access to the object.

The `PublicAccess` property determines whether the object is generally accessible or not. If this property is set to `True`, all users have access to the object.

These properties apply only to an object. They *cannot* be cascaded, that is, passed down to child objects.

The other object property used with security, the `Authorized` property, indicates whether a user is authorized to access an object. The value of this property depends on whether the user has access.

Accessing Portal Registry Objects

When you get a folder, content reference, content reference link, `PageletCategory` or `Pagelet` collection, only the items that the end-user is authorized to access are in the collection. Whether an object is contained in a collection is based on the following algorithm:

- If the object is marked as `PublicAccess` it is automatically accessible.
- If the object is marked as `AuthorAccess` and the current `UserId` is the `Author` it is accessible.
- If the current user is in a permission list (class) that is in the `Permissions` collection for that object.
- If the current user is in a permission list (class) that is in the `CascadedPermissions` collection for that object.
- If the current user has the `Portal Administrator` role.

When you access a content reference or folder using a valid name and one of the `Find` methods (`FindCRefByURL`, `FindCRefByName`, `FindCRefForURL`, or `FindFolderByName`) a content reference or folder is returned whether the user is authorized to it. When you use these methods, always check the `Authorized` property. This is the only property you can view from an object that an end-user isn't authorized to.

In addition, if you know the specific URL for a tab, you could specify that in the `FindCRefByURL`. The tab is returned whether the user is authorized to it, so you should always check the `Authorized` property.

Using `PermissionValue`, `RolePermissionValue`, `Cascading Permissions` and `CascadingRolePermissions`

To set non role-based permissions for a folder, content reference, content reference link, `PageletCategory` object, or `Pagelet`, you must access the `PermissionValue` collection for that object using the `Permissions` property. The `PermissionValue` objects refer to permission list values that already exist on the system, such as `ALLPANLS`, `CUSTOMER`, `EMPLOYEE`, and so on.

To set role-based permissions for a folder, content reference, or a content reference link that are not component or `iScript`, you must access the `RolePermissionValue` collection for that object using the `RolePermissions` property. The `PermissionValue` objects refer to role-based permission values that already exist on the system.

Note: The `PORTAL_PAGELETS` folder is the parent folder for all `PageletCategories`. Its security is set to public. PeopleSoft does not recommend cascading any permissions from this folder object. Cascade permissions only from the pagelet category (folder).

Both the `PermissionValue` collection and the `RolePermissionValue` collection return `PermissionValue` objects. Use the `PermType` property to determine whether a particular `PermissionValue` is role-based or not.

For every `PermissionValue` object, you can chose whether all the child folders and content references of this folder have the same permissions. This is called *cascading*. You cascade permissions by setting the `Cascade` property to `True`.

There are two types of `PermissionList` collections you can access. One is returned by the `Permissions` and `RolePermissions` properties, the other by the `CascadedPermissions` and `CascadedRolePermissions` properties.

Permissions and RolePermissions

The `Permissions` and `RolePermissions` properties return a collection containing the permissions set at the current level, that is, set with that folder or content reference. You can add `PermissionValues` to this list. Use the `Cascade` property to cascade the permission you add to child folders and content references.

Note: Folders can contain other folders, but the other objects that use the `Permissions` property can't contain themselves, that is, content references can't contain other content references, and so on. Therefore, the `Cascade` property is applicable only to folders, not to any other object.

CascadedPermissions and CascadedRolePermissions

The `CascadedPermissions` and `CascadedRolePermissions` properties return the a collection for *all* the permissions for an object. It contains any permission list values set in any parent folder.

Note: You *cannot* add any `PermissionValues` to a collection returned by the `CascadedPermissions` or `CascadedRolePermissions` property. You can add values only to the collection returned by the `Permissions` or `RolePermissions` property.

You can add `PermissionValues` for a child folder, but you *cannot* delete any of the existing ones that are cascaded. Permissions are augmented, not overwritten, that is, the permissions are the sum of both the parent permissions and whatever is set at the current level.

Therefore, keep the following in mind when working with `PermissionValues`:

- Set permissions only at the level where they're needed.
- Cascade permissions only when necessary.
- Generally, don't set cascaded `PermissionValues` for the root folder.
- Only the values in a `PermissionValue` object cascade. Properties on the folder itself (such as `PublicAccess` or `AuthorAccess`) do *not* cascade.

For example, suppose your `PortalRegistry` had the following hierarchy:

The following diagram illustrates PortalRegistry hierarchy example:

The following permission list values are assigned to the PermissionValue objects for the Employees folder, and both of them are cascaded:

- EMPLOYEE
- MANAGER

The Homepages and Benefits folders have the exact same permissions as the Employees folder, that is, all users associated with these two permission lists have access to these folders.

Suppose you decide that you don't want the permission list EMPLOYEE to access the Benefits folder. If you delete the EMPLOYEE PermissionValue from the Benefits PermissionValue collection, you have *not* altered the permissions. The permissions set at the parent folder, that is, at the Employees folder, can't be deleted, they can only be added to.

To make this change, you must:

- Change the Cascaded property for the EMPLOYEEES PermissionValue in the Employees folder to False
- Add EMPLOYEEES as a PermissionValue object to the Homepages folder.

Setting Permissions Using the PermissionValue Object

"Understanding Permission Lists" (Security Administration)

Working With ValidFrom and ValidTo

Folders, content references, content reference links, and tab definitions have both ValidFrom and ValidTo dates. What's the difference and how are they used in the portal registry API?

- A ValidFrom date is when something begins.
- A ValidTo date is when something ends.

For example, suppose your HR department has a page describing the benefits for your employees, and that page changed every calendar year. This means the page for the year 2000 has a ValidFrom date of 01/01/2000 and a ValidTo date of 12/31/2000. The benefits page for the year 2001 has a ValidFrom date of 01/01/2001 and a ValidTo date of 12/31/2001.

Folders, content references, content reference links and tab definitions are returned in their collections regardless of the ValidTo and ValidFrom dates. You must take these dates into account and only display to the end-user those values that should be seen.

In addition, a ValidFrom should always come *before* a ValidTo date. If they are set incorrectly, you receive a runtime error.

For all newly created folders, content references, content reference links and tab definitions, the default value for both these properties is Null (""), that is, they begin immediately and do not expire.

In addition, you can also check the IsVisible property to see if a portal object is viewable. IsVisible verifies if an object is Hidden, as well as if the ValidTo and ValidFrom dates are within the specified dates.

Doing Error Handling

All errors for the portal registry classes, like the other APIs, are logged in the PSMessages collection, instantiated from a session object.

The portal registry classes log errors that occur with methods immediately, and errors that occur with properties only after a method is executed.

For example, suppose you specified an invalid name when you were trying to delete a folder. The method (DeleteItem) returns False, and the error is logged in the PSMessages collection immediately.

Now suppose you created a new folder, and specified an invalid ValidTo date. The error won't be logged in the PSMessages collection until you tried to save your changes.

When you want to check for errors depends on your application. When users are entering data dynamically, and your program is registering their data in the portal, you may want to check for errors often. If you're using a batch program, you may want to check for errors only after the Open, Save, Insert, and Delete methods.

Most methods return a Boolean value indicating success or failure. After the failure of a method, you may want to check the `PSMessages` collection to determine the exact error.

```

Local ApiObject &MySession;
Local ApiObject &ErrorCol;
Local ApiObject &FolderCol, &Folder, &Registry;
Local Boolean &Open; /* Access the current session */

&MySession = %Session;
If &MySession Then
    /* connection is good */

    &Registry = &MySession.GetRegistry();

    &Open = &Registry.Open("CUSTOMER");

    If &Open Then
        /* Registry opened successfully */
        /* do processing */
    Else
        /* Do error checking */

        &ErrorCol = &MySession.PSMessages;
        For &I = 1 to &ErrorCol.Count
            /* do processing */
        End-For;

        End-If;
    Else
        /* do processing for no connection */
    End-If;

```

Understanding the Life Cycle of a PortalRegistry Object

At runtime, there are certain things you want to do with a `PortalRegistry` object, like getting an instance of it, adding tabs, editing content references, and so on. The following is an overview of this process. These steps are expanded in other sections.

1. Perform one of these steps.
 - a. Execute the `GetPortalRegistry` method on the PeopleSoft session object to get a `PortalRegistry` object, or
 - b. Use the `FindPortalRegistries` method on a session object to get a collection of all `PortalRegistries`. Select a `PortalRegistry` from the collection.
2. Open the `PortalRegistry`, using the portal name.
3. After you have an open `PortalRegistry` object, you can do various actions such as:
 - Add content references to the existing folders.
 - Add folders and the content references for them.
 - Add or change Nodes.

- Modify the PortalRegistry properties.
 - Modify the existing content references, folders, tabs, homepages, and so on.
4. After you make your changes, you must save your work. The Save method must be executed at the appropriate level, such as at the folder level for changes to a folder, at the PortalRegistry level for changes to the default template, and so on.

A property value change isn't committed to the database until the parent object is saved.

Some methods commit data to the database only when the parent object is saved. However, other methods cause data to be committed to the database as soon as they are executed, like DeleteItem on a folder. Methods that automatically make database changes are noted as such in their description.

See [Saving Content Considerations](#).

5. When you finish all operations for a PortalRegistry, close the object.

Note: PeopleSoft recommends that you open and close every PortalRegistry in a single PeopleCode event. You shouldn't open a PortalRegistry object and keep it open across multiple events. You should also keep only one PortalRegistry object open at a time.

The following diagram provides an understanding of the Life Cycle of a PortalRegistry Object.

Examples of using the PortalRegistry objects are provided at the end of this topic.

Using Content References

Content references have a number of properties, but several properties work together to define the type of Content reference. The values of these properties are interdependent, that is, the value of one indicates the values of others.

UsageType

This is the primary specifier for the type of content reference. There are a number of different types of content references, but all content references can be categorized into the following major types:

- Target
- Template
- Portal Component

Target

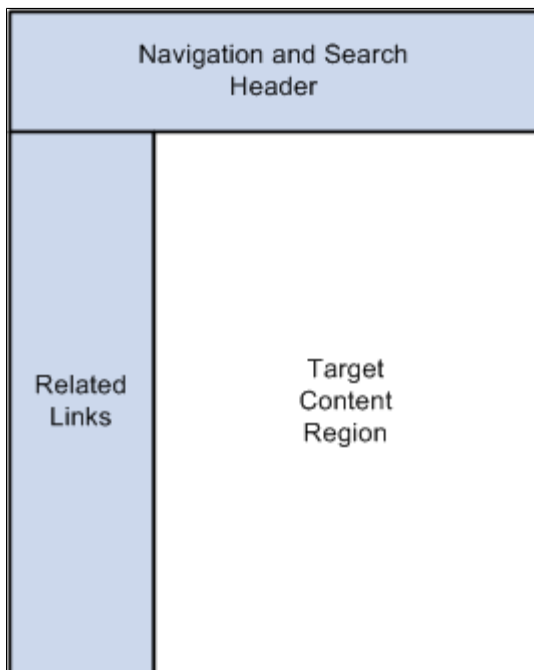

The *target* is the page referenced by a URL in the user's browser. This is the main transaction or page that the user wants, and the portal may place other content around this target page based on the template. The template describes any other content, and where to place it, on the page. The template is either gotten from the content reference or a set of default templates.

Content reference links can only be created for content references that have a type of target.

Template

A portal *template* defines how the portal creates a user's page. It's an HTML document that describes the content and where the content is placed. The template specifies one target and zero or more portal components.

The portal template in the following example is comprised of four separate template components: one for the navigation and search header, one for related links, one for the target content region, and one for the overall template which specifies where the other components should be placed. At runtime, the target content region would be filled by the HTML returned by the target page, as would the other template component regions.

See "Portal Templates and Template Pagelets" (Portal Technology).

Portal Component

A *portal component* is an HTML document, or something that produces an HTML document. The portal component must be defined within a template.

A portal component could be one of a Homepage tab, component reference, or Homepage Pagelet.

UsageType Values

The following table matches the general types of target, template, and portal component to the actual values of the UsageType property.

General Type	UsageType Value
Target	Target (TARG)
Template	Frame template (FRMT) or HTML template (HTMT)
Pagelet	Pagelet (HPGC)
Homepage Tab	Homepage Tab (HPGT)

More specifically:

- A UsageType value of TARG specifies a content reference that is a target.
- A UsageType value of FRMT specifies a content reference that is an HTML frame template.
- A UsageType value of HTMP specifies a content reference that is an HTML template.
- A UsageType value of HPGC specifies a content reference that is a PeopleSoft homepage component (pagelet).
- A UsageType value of HPGT specifies a Homepage tab.
- A UsageType value of LINK specifies a content reference link.

TemplateType

This property is valid only when the UsageType property is a target. For target type content references (TARG) this controls whether the portal looks for and uses a template to wrap the target.

TemplateType	Meaning
NONE	There is no template for this target
HTML	There is some kind of HTML template for this target

URLType

This property gives information about what format the URL is in.

<i>URLType Value</i>	<i>Meaning</i>
UEXT	URL points to a non-PeopleSoft (external) URL
UMPG	URL points to a PeopleSoft mobile page
UPGE	URL points to a component
UPHP	URL points to a homepage tab
UPTM	URL points to a template
USCR	URL points to an iScript
UGEN	URL points to a generic PeopleSoft URL.

The URL property is always required (it's one of the parameters for the InsertItem method.) The format of this parameter (or property) depends on the other properties.

Related Links

"Portal Technology Overview" (Portal Technology)

Nodes and URL

Nodes and the URL property work together and are interrelated. The node is how to 'register' a logical name for a Web server (the Web server name, on the servlet, and so on) not the actual details. This way, content references don't change when a Web server changes.

For example, suppose you had content that you referenced on the HRMS Web server. However, the machine name for that server changed. You can change the URI of the Node, instead of changing every content reference that referred to that content.

At least one node must be specified as the default local node. Nodes are also required for PeopleSoft components and iScripts.

Considerations When Using Nodes and the URL Property

When a content reference is created it is 'registered' with its URL (the portal, and others, typically find a content reference by its URL). The node is used to create a logical name for the Web server, servlet, and so on, so these details are not included in a content reference's URL. When details of a Web server change, such as at installation time, only the URI for the content provider must change. You don't have to change the URL for any content references.

When the node is specified, the content provider's URI is concatenated with the URL property.

The format of the URL property depends on the content it's pointing to.

Summary

The following table summarizes the interrelations between the different content reference properties.

UsageType	TemplateType	StorageType	URLType
Target (TARG)	HTML	Remote (RMTE)	Component (UPGE)
Target (TARG)	HTML	Remote (RMTE)	Internet Script (USCR)
Target (TARG)	HTML	Remote (RMTE)	External (UEXT)
Target (TARG)	NONE	Remote (RMTE)	Component (UPGE)
Target (TARG)	NONE	Remote (RMTE)	Internet Script (USCR)
Target (TARG)	NONE	Remote (RMTE)	External (UEXT)
Frame template (FRMT), HTMP template	NONE	Remote (RMTE)	Internet Script (USCR)
Frame template (FRMT), HTMP template	NONE	Local (LOCL)	N/A
Homepage (HPGT)	NONE	Local (LOCL)	N/A
Template component (TMPC), Homepage component (HPGC)	N/A	Remote (RMTE)	Component (UPGE)
Template component (TMPC), Homepage component (HPGC)	N/A	Remote (RMTE)	Internet Script (USCR)
Template component (TMPC), Homepage component (HPGC)	N/A	Remote (RMTE)	External (UEXT)
Template component (TMPC), Homepage component (HPGC)	N/A	Local (LOCL)	N/A

Naming Conventions

If you create two content references or with the exact same URL, the second one fails.

For example, suppose you create an external content reference with a URL of `www.example.com`. Then you create a second content reference that has a node of PeopleSoft, whose URI is `www.example.com`. The creation of the second content reference fails because the URL already exists.

If you have multiple nodes with the same URI, `FindCRefByURL` looks for the specified content reference with all those nodes.

If you have multiple nodes with the same URI, but no registered content references, the system uses the template from the alphabetically first node it finds.

Pagelet, node, and portal registry names can consist of any combination of letters, digits and underscores, but they must not contain any spaces or begin with a digit.

Content reference link names cannot have start with numbers, and can not have special characters and spaces.

Deleting Content Considerations

Be extremely careful when you delete any content. There may be more than one object relying on the content you delete.

- If you try to delete a template currently used by a content reference, the node template is set as the default template for the portal, you receive an error when you try to save the item.
- If you delete a homepage template for a user, the system tries to use the default user's template first, before resorting to the portal default template.
- If you try to delete a content provider that is currently used by a content reference, you receive an error and cannot save the `PortalRegistry` object.

Warning! If you delete a folder, you delete *all* content in the folder. If you delete a folder that contains other folders, that is, a parent folder, all the child folders, and all the content references are deleted. If you delete a `PortalRegistry`, you delete *everything*. Your entire `PortalRegistry` is gone, all the folders, content references, templates, and so on. Do not delete a `PortalRegistry` object unless you are absolutely certain you want to.

Saving Content Considerations

The following portal registry classes have `Save` methods:

- `PortalRegistry`
- `Folder`
- `Content reference`

- Content reference links
- TabDefinition
- PageletCategory
- Pagelet
- Homepage
- Favorites collection

This means if you change a folder, you must save the folder. If you change a folder and only save at the PortalRegistry level, your changes are *not* saved.

Some classes do *not* have a Save method. For these classes, you must save the parent object.

- If you change a node, node template, or remote portal, you must use the PortalRegistry Save method.
- If you change an AttributeValue you must use the Save method with the item that contains the AttributeValue (folder, content reference, PageletCategory, or Pagelet).
- If you change a PermissionValue, you must use the Save method with the item that contains the PermissionValue (folder, content reference, PageletCategory or Pagelet).
- If you change a UserTab or a SelectedPagelet, you must use the Homepage Save method.

Data Type of a PortalRegistry Object

PortalRegistry objects, and all objects instantiated from a PortalRegistry object, are declared as data type ApiObject. For example,

```
Local ApiObject &MyRegistry;
Local ApiObject &MyFolder, &MyAttributeValue;
```

Note: PortalRegistry objects can only be declared as Local.

Considerations Using Local Variables

When a local variable has a reference to an object and the end-user clicks the Back button on a browser, the local variable is set to NULL. This is always logged in the trace file.

Considerations Using Global Variables

Global variables are not available to a portal or applications on separate databases. They are available only on applications and Portals in the *same* database.

Scope of a PortalRegistry Object

A PortalRegistry object can be instantiated from the following language environments:

- [PeopleCode](#)
- [C/C++](#)
- [Java](#)

["%Session" \(PeopleCode Language Reference\)](#)

FindPortalRegistries

Syntax

```
FindPortalRegistries (Name)
```

Description

The FindPortalRegistries method returns a reference to a PortalRegistry Collection filled with zero or more PortalRegistry objects matching the *Name* parameter. The *Name* parameter takes a string value.

You can use a partial key to get a smaller subset of the PortalRegistry collection. For example, to get a collection of all the PortalRegistry objects whose names start with the letter "B", specify just the letter B for *Name*:

```
&MyColl = &MySession.FindPortalRegistries("B");
```

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the PortalRegistry object to find. This parameter takes a string value.

Returns

A PortalRegistry Collection object.

Example

The following example returns a collection with references to all PortalRegistry objects.

```
Local ApiObject &MySession;
Local ApiObject &MyColl;

&MySession = %Session;
&MyColl = &MySession.FindPortalRegistries("");
```

GetActualRemoteNodes

Syntax

```
GetActualRemoteNodes ()
```

Description

Use the GetActualRemoteNodes method to return a collection of remote nodes for the session.

Note: This method will only return remote nodes.

Parameters

None.

Returns

A reference to a collection of remote nodes if successful, null otherwise.

Example

```
&remoteNodeColl = %Session.GetActualRemoteNodes ();
```

Related Links

[RemoteNode Collection](#)

GetLocalNode

Syntax

```
GetLocalNode()
```

Description

Use the GetLocalNode method to return a reference to the node defined as the local node for this session.

Parameters

None.

Returns

A reference to a node object if successful, Null otherwise.

Example

```
&Node = %Session.GetLocalNode();
```

Related Links

[Node Class](#)

GetNodes

Syntax

```
GetNodes()
```

Description

Use the GetNodes method to return a collection of both local and remote nodes for the session.

Parameters

None.

Returns

A reference to a collection of nodes if successful, Null otherwise.

Example

```
&NodeColl = %Session.GetNodes();
```

Related Links

[Node Collection](#)

GetPortalRegistry

Syntax

```
GetPortalRegistry()
```

Description

The `GetPortalRegistry` method returns an empty `PortalRegistry` object. You can then open or delete an existing `PortalRegistry`, or create a new one.

Parameters

None.

Returns

An empty `PortalRegistry` object.

Example

```
Local ApiObject &MyPortal;  
  
&MyPortal = %Session.GetPortalRegistry();  
&PORTAL_NAME = %Request.GetParameter("PORTAL_NAME");  
&Portal.Open(PORTAL_NAME);
```

GetRemoteNodes

Syntax

```
GetRemoteNodes()
```

Description

Use the `GetRemoteNodes` method to return a collection of nodes for the session.

Note: This method returns both local and remote nodes.

Parameters

None.

Returns

A reference to a collection of nodes if successful, Null otherwise.

Example

```
&NodeColl = %Session.GetNodes();
```

Related Links

[RemoteNode Collection](#)

PortalRegistry Class

A PortalRegistry object is returned from:

- The GetPortalRegistry session method.
- The PortalRegistry Collection Methods First, ItemByName, or Next.

Note: In addition to the following methods, the PortalRegistry class has methods used with the search API.

[PortalRegistry Collection Methods](#)

[Changing PortalRegistry Properties](#)

PortalRegistry Class Methods

In this section, we discuss the PortalRegistry class methods. The methods are discussed in alphabetical order.

Close

Syntax

```
Close ()
```

Description

The Close method closes the PortalRegistry object, that is, this method sets the object to the state it was in immediately after the GetPortalRegistry was done on the PeopleSoft Session object. Any unsaved changes are discarded. The Close method can be used only on an open PortalRegistry, not a closed one. This means you must have opened the PortalRegistry with the Open method before you can close it.

Parameters

None.

Returns

A Boolean value: True if the PortalRegistry object is successfully closed, False otherwise.

Example

```
&Rslt = &MyRegistry.Close();

If Not &Rslt Then
    /* registry not closed - do error processing */
End-if;
```

Related Links

[Open](#)

[Save](#)

CopyObject

Syntax

```
CopyObject(sourcePortalName, sourceRefType, sourceObjName, targetPortalName,
targetPrntFldrName, copyChildren)
```

Description

Use the CopyObject method to copy folders and content references between portal registries.

If the object being copied has related HTML, the HTML is also copied and named according to the current portal naming convention for HTML objects, which is:

```
PR_<portalname>_<objectname>
```

where <portalname> is up to the first 8 characters of the portal name and <objectname> is up to the first 17 characters of the object name.

Considerations Using CopyObject

The source portal name and the target portal name cannot be the same name.

The *targetPrntFldrName* must be a folder that exists in the portal identified by the target portal name. It cannot be null (or empty). If you need to copy an entire portal, the portal must first be "created" using the Create method, before copying over all the folders and content references.

The *copyChildren* parameter is ignored for content references. However, it still must be set to "Yes" or "No".

Parameters

Parameter	Description
<i>sourcePortalName</i>	Specify the name of the portal from which the object is to be copied.
<i>sourceRefType</i>	Specify the type of object to be copied. Values are: <ul style="list-style-type: none"> • "C" for content references • "F" for folders This parameter is case-sensitive.
<i>sourceObjName</i>	Specify the name of the object to be copied.
<i>targetPortalName</i>	Specify the name of the portal to which the object will be copied.
<i>targetPrntFldrName</i>	Specify the name of the folder that will be the parent folder for the source object.
<i>copyChildren</i>	Specify whether to also copy the children of the source object. This parameter is valid only with folder objects. Values are: <ul style="list-style-type: none"> • "Yes" copy child objects • "No" do not copy child objects This parameter is case-sensitive.

Returns

A Boolean value: True if object copied successfully, False otherwise.

Example

```
&Success = &Portal.CopyObject("PORTAL", "F", "PEOPLETOOLS_QUALITY", "BOGUS", "PORTA⇒
L_ROOT_OBJECT", "Yes");
If (&Success = False) Then
    WinMessage("portal copy failed");
    Exit;
End-If;
```

Create

Syntax

```
Create (RegistryName)
```

Description

The Create method creates a new PortalRegistry in the PortalRegistry object called *RegistryName*. The specified registry must be a new registry. The Create method returns False if the registry already exists.

The new PortalRegistry is immediately committed to the database. If you change any property of a PortalRegistry after you create the object, use the Save method to commit your changes to the database.

When a registry is created, a folder called *Root* is automatically created. This is the root folder for the registry.

Note: If you're using Visual Basic, you must check that the PortalRegistry is actually created. If you use a duplicate name, a zero is returned, but no error results.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RegistryName</i>	The name of the registry to create. This parameter takes a string value. If you specify a registry that already exists, this method returns a False value.

Returns

A Boolean value: True if the PortalRegistry object is successfully created, False otherwise.

Example

```
&PORTAL_NAME = MY_PORTAL_RECORD.PORTALNAME;
&MyPortal = %Session.GetPortalRegistry();

If NOT &MyPortal.Create(&PORTAL_NAME) Then;
  /* portal not created - do error processing */
End-If;
```

[Save](#)

[Close](#)

[Delete](#)

CreateContentRefLink

Syntax

```
CreateContentRefLink (LinkName, LinkLabel, LinkParent, CRefPortalName, CRefObjectName⇒  
e)
```

Description

Use the `CreateContentRefLink` method to create a link to any content reference in any portal in a local database.

For example, using this method, you can create a link to a content reference in the EMPLOYEE portal, to a content reference in the CUSTOMER portal, or to a content reference in the current portal.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>LinkName</i>	Specify the name of the link as a string. This is the ID of the link. The name is validated as that of the content reference name. It cannot start with a number, and can not have special characters and spaces. This property is not translated.
<i>LinkLabel</i>	Specify the label of the link as a string. This property can be translated. This is the label that appears on the left hand navigation menu. If this value is blank, a linked content reference label is displayed instead.
<i>LinkParent</i>	Specify the parent folder of the link, as a string.
<i>CRefPortalName</i>	Specify the portal name of the content reference, to which the link is pointing, as a string.
<i>CRefObjectName</i>	Specify the ID of the content reference to which the link is pointing, as a string.

Returns

A reference to a newly created `ContentReference` link object.

Example

```
Local ApiObject &Portal, &CRef, &CRefLink;
&Portal = PortalOpen();
&CRefLink = &Portal.CreateContentRefLink(<Unique Link Name> , <LinkLabel>, "<Link's=>
    Parent folder >", "<Cref Portal Name>", <Cref Object Name>);
/*... Use the link object */
&Portal.Close();
```

CreateRemote

Syntax

```
CreateRemote(PortalName, RemoteNodeName)
```

Description

Use the CreateRemote method to create a remote portal. Although you can have more than one portal on a node, they must all be uniquely named.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PortalName</i>	Specify the name of the new portal to create on the remote node.
<i>RemoteNodeName</i>	Specify the name of the remote node to create the new portal on.

Returns

A Boolean value: True if the PortalRegistry object is successfully created, False otherwise.

Related Links

[Create](#)

[Portals](#)

Delete

Syntax

```
Delete (RegistryName)
```

Description

The Delete method deletes the PortalRegistry *from the database*, including any data and tables.

Warning! If you delete a PortalRegistry, you delete *everything*. Your entire PortalRegistry is gone, all the folders, content references, templates, and so on. Do not delete a PortalRegistry object unless you are absolutely certain that you want to.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for deletion, then actually deleted later. The item is deleted from the database *as soon as* the method is executed.

The Delete method can only be used with a *closed* registry, it cannot be used on an open registry. Before you use the Delete method, you must explicitly close the PortalRegistry object (with the Close method.) The Delete method returns False if you try to delete an open PortalRegistry object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RegistryName</i>	The name of the registry to delete. This parameter takes a string value. If you specify a registry that doesn't exist, this method returns a False value.

Returns

A Boolean value: True if the PortalRegistry object is successfully deleted, False otherwise.

Example

The following example deletes all PortalRegistry objects that start with HRMS_99.

```
Local ApiObject &MySession;
Local ApiObject &MyPortal;

&MySession = %Session;

&MyPortal = &MySession.GetPortalRegistry();

&MyPortal.Delete("HRMS_99");
```

Related Links

[Close](#)

[Open](#)

DeleteHomepage

Syntax

```
DeleteHomepage ()
```

Description

The DeleteHomepage method deletes the current user's homepage. This method is valid only after a user has opened a PortalRegistry object.

Parameters

None.

Returns

A Boolean value: True if the homepage is successfully deleted, False otherwise.

Related Links

[UserHomepage Class](#)

FindCRefByName

Syntax

FindCRefByName (*Name*)

Description

The FindCRefByName method returns the content reference object corresponding to *Name*. The name is a unique identifier for each content reference.

Considerations on Returned Content References

This method returns content reference objects that aren't yet valid as well as ones that are no longer valid. When you create your program, you must check for these invalid values if you don't want to use them. You can check using ValidTo, ValidFrom, or IsVisible.

This method returns content reference objects that you aren't authorized to. When you create your program, you should always check the Authorized property. This is the only property you can view from an object that you're not authorized to view.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	A unique name within the registry that identifies the content reference. This parameter takes a string value. This parameter uses the name, not the label, of a content reference.

Returns

What this method returns depends on the condition of the content reference:

- If the content reference name is valid and the end-user has access to the content reference, a content reference object is returned.
- If the content reference is valid but the end-user doesn't have access to it a content reference object is returned, however, the only property you can access is the Authorized property.
- If you specified an invalid name this method returns NULL.

Example

The following example returns a GLOBAL_PAYROLL content reference object:

```
&CRef = &Portal.FindCRefByName("GLOBAL_PAYROLL");
```

Related Links

[Content Reference Class](#)

FindCRefByURL

Syntax

FindCRefByURL (*URL*)

Description

The FindCRefByURL method returns the content reference object corresponding to *URL*. The URL specified by *URL* must be an absolute URL.

Note: The portal registry API needs the current URI of the local node to work. During runtime, it gets this information from the current Web server. For Application Engine programs, there isn't a current Web server, so it has to get this information from the database.

If you have multiple content providers with the same URI, FindCRefByURL looks for the specified content reference with all those content providers.

To access pagelet categories and their associated pagelets, use the PageletCategories collection from the PortalRegistry object, not FindCRefByURL.

Considerations on Returned Content References

This method returns content reference objects that aren't yet valid as well as ones that are no longer valid. When you create your program, check for these properties (ValidTo and ValidFrom) if you don't want to use them.

This method returns content reference objects that the end-user isn't authorized to. When you create your program, always check the Authorized property. This is the only property you can view from an object that the end-user isn't authorized to view.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>URL</i>	A URL that represents the content. This parameter takes a string value. This URL must be an absolute URL. This parameter is case-insensitive.

Returns

What this method returns depends on the condition of the content reference:

- If the end-user has access to the URL, a content reference object is returned.
- If the content reference is registered, but the end-user doesn't have access to it, a content reference is returned, but the only property you can access is the Authorized property.
- If a URL isn't registered or is invalid, this method returns NULL.

Example

The following example finds a content reference from a URL:

```
&UserCRef = &Portal.FindCRefByURL("http://www.example.com");
```

Related Links

[GetQualifiedURL](#)

[QualifiedURL](#)

[Content Reference Class](#)

FindCRefForURL

Syntax

```
FindCRefForURL (URL)
```

Description

The FindCRefForURL method returns the content reference object corresponding to *URL*. The URL specified by *URL* must be an absolute URL.

If the exact content reference is not found, this method tries to look for the content reference again, after stripping off the query portion of the URL.

If you don't want the system searched without the query string, use the FindCRefByURL method.

Note: The portal registry API needs the current URI of the local node to work. During runtime, it gets this information from the current Web server. For Application Engine programs, there isn't a current Web server, so it has to get this information from the database.

If you have multiple content providers with the same URI, FindCRefForURL looks for the specified content reference with all those content providers.

To access pagelet categories and their associated pagelets, use the PageletCategories collection from the PortalRegistry object, not FindCRefForURL.

Considerations on Returned Content References

This method returns content reference objects that aren't yet valid as well as ones that are no longer valid. When you create your program, check for these properties (ValidTo and ValidFrom) if you don't want to use them.

This method returns content reference objects that the end-user isn't authorized to. When you create your program, always check the Authorized property. This is the only property you can view from an object that the end-user isn't authorized to view.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>URL</i>	A URL that represents the content. This parameter takes a string value. This URL must be an absolute URL. This parameter is case-insensitive.

Returns

What this method returns depends on the condition of the content reference:

- If the end-user has access to the URL, a content reference object is returned.
- If the content reference is registered, but the end-user doesn't have access to it, a content reference is returned, but the only property you can access is the Authorized property.
- If a URL isn't registered or is invalid, this method returns NULL.

Example

The following example finds a content reference from a URL. If the content reference isn't found from the full URL, the query string is stripped and the system searches again:

```
&UserCRef = &Portal.FindCRefForURL("http://www.example.com/crefs/psportal/technolog⇒
ies/?url=http%3a%2f%2faugust2004%2fipass.html");
```

Related Links

[GetQualifiedURL](#)

[QualifiedURL](#)

[FindCRefByURL](#)

[Content Reference Class](#)

FindCRefLinkByName

Syntax

```
FindCRefLinkByName (LinkName)
```

Description

Use the FindCRefLinkByName method to find the existing link in the current portal. If the link is found a reference to ContentReference link object is returned. A Null value is returned if the link is not found in the database, and the error message is added to message collection

Considerations on Returned Links

This method returns links that aren't yet valid as well as ones that are no longer valid. When you create your program, you must check for these properties (ValidTo and ValidFrom) if you don't want to use

them. This method may also return objects that you aren't authorized to. When you create your program, you should always check the Authorized property. This is the only property you can view from an object that you're not authorized to view.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>LinkName</i>	Specify the name of the link as a string. This is the ID of the link.

Returns

A reference to an existing ContentReference link object or a Null value if the link is not found.

FindFolderByName

Syntax

FindFolderByName (*Name*)

Description

The FindFolderByName method returns the Folder object corresponding to *Name*. The name is a unique identifier for each folder.

Considerations on Returned Folders

This method returns Folder objects that aren't yet valid as well as ones that are no longer valid. When you create your program, check for these properties (ValidTo and ValidFrom) if you don't want to use them.

This method returns folder objects that you aren't authorized to. When you create your program, always check the Authorized property. This is the only property you can view from an object that you're not authorized to view.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	A unique name within the registry that identifies the folder. This parameter takes a string value. This parameter takes the name of a folder, not the label.

Returns

What this method returns depends on the condition of the folder:

- If the folder name is valid and the end-user has access to the folder, a folder object is returned.

- If the folder is valid but the end-user doesn't have access to it a folder object is returned, however, the only property you can access is the Authorized property.
- If you specified an invalid name this method returns NULL.

Example

The following example returns a folder named ROOT:

```
&MyFolder = &MyPortal.FindFolderByName("ROOT");
```

The following example returns the folder object for an already instantiated content reference:

```
&Folder = &Portal.FindFolderByName(&CRef.ParentName);
```

Related Links

[Folder Class](#)

FindPgltByName

Syntax

```
FindPgltByName (PageletName)
```

Description

The FindPgltByName method returns the pagelet object corresponding to *PageletName*. The name is a unique identifier for each pagelet.

Considerations on Returned Pagelets

This method returns pagelet objects that aren't yet valid as well as ones that are no longer valid. When you create your program, check for these properties (ValidTo and ValidFrom) if you don't want to use them.

This method returns pagelet objects that you aren't authorized to. When you use create your program, always check the Authorized property. This is the only property you can view from an object that you're not authorized to view.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PageletName</i>	A unique name within the registry that identifies the Pagelet. This parameter takes a string value. This parameter takes the name of a Pagelet, not the label.

Returns

What this method returns depends on the condition of the Pagelet:

- If the Pagelet name is valid and the end-user has access to the Pagelet, a Pagelet object is returned.
- If the Pagelet is valid but the end-user doesn't have access to it a Pagelet object is returned, however, the only property you can access is the Authorized property.
- If you specified an invalid name this method returns NULL.

Example

The following example returns a pagelet named HomePg_Dictionary:

```
&MyPglt = &MyPortal.FindPgltByName("HomePg_Dictionary");
```

[Pagelet Class](#)

GetAbsoluteContentURL

Syntax

```
GetAbsoluteContentURL(NodeName, URL)
```

Description

The GetAbsoluteContentURL method returns the absolute unwrapped simple URL of the content, in the context of the current portal. For example, if the PortalRegistry object accessed a portal called Employees, and the method were called like this:

```
&Registry.getAbsoluteContentURL(Node.CRM, "/c/SERVICES.ORDERES.GBL");
```

It would return the following string:

```
http://crmserver/servlets/psc/crmHome/Employees/CRM/c/SERVICES.ORDERES.GBL
```

In the returned string, the portion of the string from server name through *portal_home* (crmHome in the example) are the ones associated with the content node (CRM in the example). The portal is the current portal, and the rest of the URL is the URL string passed in.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of the node that contains the content. You can also use a string, such as %Node, for this value.
<i>URL</i>	Specify the relative URL pointing to the content that you want the absolute URL generated for.

Returns

A string containing the absolute URL.

GetDefaultHPTabOID

Syntax

```
GetDefaultHPTabOID ()
```

Description

Use the GetDefaultHPTabOID method to return the name of the first homepage tab that is found and authorized for the current user ID.

The search order of the tabs depends on Sequence number of the tab name and is sorted alphabetically.

Parameters

None.

Returns

A string

GetQualifiedURL

Syntax

```
GetQualifiedURL (ContentProvider, RelativeURL)
```

Description

Note: This method is maintained only for backward compatibility. If your existing code uses this method, it actually returns the value from GetAbsoluteContentURL method. New applications should use the GetAbsoluteContentURL method.

[GetAbsoluteContentURL](#)

GrantPermissionForComponent

Syntax

```
GrantPermissionForComponent (MenuName, ComponentName, Market, PermListName, NodeName⇒  
)
```

Description

Use the `GrantPermissionForComponent` method to grant the specified permission and cascaded upwards on parent folders to the specified component. In addition, the specified permission is granted to any component references that point to the specified component, and any parent folders.

Components that have query strings are also searched and permissions are applied on them.

If you use the string "LOCAL_NODE" as *NodeName*, the system uses the node name currently defined as local.

All component entries in the portal registry are affected for all the portals. Not just the current portal.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>MenuName</i>	Specify the menu name, as a string, that the component you want to grant permissions for is associated with.
<i>ComponentName</i>	Specify the component name, as a string, that you want to grant permissions for.
<i>Market</i>	Specify the market, as a string, associated with the component that you want to grant permissions for.
<i>PermListName</i>	Specify the name of the permission list, as a string, that you want to use.
<i>NodeName</i>	Specify the node of the component reference, as a string, that points to the component reference that you want to grant permissions for. If you use the string "LOCAL_NODE", the system uses the node name currently defined as local.

Returns

A Boolean value: True if method completed successfully, False otherwise.

Example

The My Profile Component Reference points to the USERMAINT_SELF component. Using the following example, "ALLPANLS" permission is granted to the MY_PROFILE component reference, as well as "MY INFO", the parent folder.

```
&Portal.GrantPermissionForComponent("MAINTAIN_SECURITY", "USERMAINT_SELF", "GBL", "=>
ALLPANLS", "LOCAL_NODE");
```

"Understanding Permission Lists" (Security Administration)

GrantPermissionForScript

Syntax

```
GrantPermissionForScript (RecordName, FieldName, EventName, FuncName, PermListName, =>
NodeName)
```

Description

Use the GrantPermissionForScript method to grant the specified permission to the specified iScript. In addition, the specified permission is granted to any component references that point to the specified iScript, and any parent folders.

If you use the string "LOCAL_NODE" as *NodeName*, the system uses the node name currently defined as local.

All iScript entries in the portal registry are affected for all the portals. Not just the current portal.

Parameters

Parameter	Description
<i>RecordName</i>	Specify the record name, as a string, of the record containing the iScript. All iScripts are contained on records whose names start with "WEBLIB".
<i>FieldName</i>	Specify the name of the field, as a string, containing the iScript.
<i>EventName</i>	Specify the name of the event, as a string, containing the iScript. Generally iScripts are contained in the FieldFormula event.
<i>FuncName</i>	Specify the name of the function, as a string, containing the iScript.
<i>PermListName</i>	Specify the name of the permission list, as a string, that you want to use.
<i>NodeName</i>	Specify the node of the component reference, as a string, that points to the component reference that you want to grant permissions for. If you use the string "LOCAL_NODE", the system uses the node name currently defined as local.

Returns

A Boolean value: True if method completed successfully, False otherwise.

Example

```
&Portal.GrantPermissionForScript("WEBLIB_ALERT", "ALERTCOUNT", "FieldFormula", "Connect_Alert", "ALLPGS", "Local_Node");
```

Open

Syntax

```
Open (RegistryName)
```

Description

The Open method opens the PortalRegistry specified by the parameters. The registry must already exist. The Open method can be used only with a *closed* PortalRegistry, it cannot be used on an open registry.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RegistryName</i>	The name of the registry to open. This parameter takes a string value. If you specify a registry that doesn't exist, this method returns a False value.

Returns

A Boolean value: True if the PortalRegistry object is successfully opened, False otherwise.

Example

In the following example, the name of the portal is stored as the value of a field in a record.

```
&PORTAL_NAME = EO_PE_REG_AET.PORTAL_NAME;
&Portal = %Session.GetPortalRegistry();

&Portal.Open (&PORTAL_NAME);
```

Related Links

[Open](#)

[Save](#)

[Close](#)[Delete](#)

PermissionListDelete

Syntax

```
PermissionListDelete (PermListName)
```

Description

Use the PermissionListDelete method to delete the specified permission list from the PortalRegistry.

If you try to delete a permission list that is still in use, you receive an error when you try to save the object.

The permission list is deleted from all the portal objects for all the portal.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PermListName</i>	Specify the permission list to delete from the PortalRegistry.

Returns

A Boolean value: True if the permission list is successfully deleted, False otherwise.

PermissionListSaveAs

Syntax

```
PermissionListSaveAs (PermListSourceName, PermListTargetName)
```

Description

Use the PermissionListSaveAs method to copy the specified permission list in the PortalRegistry.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PermListSourceName</i>	Specify the name of the PermissionList to copy.
<i>PermListTargetName</i>	Specify the name that you want to give the new PermissionList.

Returns

A Boolean value: True if the permission list is successfully copied, False otherwise.

RevokePermissionForComponent

Syntax

```
RevokePermissionForComponent(MenuName, ComponentName, Market, PermListName, NodeName→  
e)
```

Description

Use the `RevokePermissionForComponent` method to revoke the specified permission to the specified component. In addition, the specified permission is revoked for any component references that point to the specified component.

If you use the string "LOCAL_NODE" as *NodeName*, the system uses the node name currently defined as local.

All component entries in the portal registry are affected for all the portals. Not just the current portal.

Parameters

Parameter	Description
<i>MenuName</i>	Specify the menu name, as a string, that the component that you want to revoke permissions for is associated with.
<i>ComponentName</i>	Specify the component name, as a string, that you want to revoke permissions for.
<i>Market</i>	Specify the market, as a string, associated with the component that you want to revoke permissions for.
<i>PermListName</i>	Specify the name of the permission list, as a string, that you want to use.
<i>NodeName</i>	Specify the node of the component reference, as a string, that points to the component reference that you want to revoke permissions for. If you use the string "LOCAL_NODE", the system uses the node name currently defined as local.

Returns

A Boolean value: True if method completed successfully, False otherwise.

Example

The My Profile Component Reference points to the USERMAINT_SELF component. Using the following example, "ALLPANLS" permission is revoked to the MY_PROFILE component reference.

```
&Portal.RevokePermissionForComponent("MAINTAIN_SECURITY", "USERMAINT_SELF", "GBL", =>
"ALLPANLS", "LOCAL_NODE");
```

"Understanding Permission Lists" (Security Administration)

RevokePermissionForScript

Syntax

```
RevokePermissionForScript(RecordName, FieldName, EventName, FuncName, PermListName, =>
NodeName)
```

Description

Use the RevokePermissionForScript method to revoke the specified permission to the specified iScript. In addition, the specified permission is revoked for any component references that point to the specified iScript.

If you use the string "LOCAL_NODE" as *NodeName*, the system uses the node name currently defined as local.

All component entries in the portal registry are affected for all the portals. Not just the current portal.

Parameters

Parameter	Description
<i>RecordName</i>	Specify the record name, as a string, of the record containing the iScript. All iScripts are contained on records whose names start with "WEBLIB".
<i>FieldName</i>	Specify the name of the field, as a string, containing the iScript.
<i>EventName</i>	Specify the name of the event, as a string, containing the iScript.
<i>FuncName</i>	Specify the name of the function, as a string, containing the iScript. Generally iScripts are contained in the FieldFormula event.

Parameter	Description
<i>PermListName</i>	Specify the name of the permission list, as a string, that you want to use.
<i>NodeName</i>	Specify the node of the component reference, as a string, that points to the component reference that you want to revoke permissions for. If you use the string "LOCAL_NODE", the system uses the node name currently defined as local.

Returns

A Boolean value: True if method completed successfully, False otherwise.

Example

```
&Portal.RevokePermissionForScript("WEBLIB_ALERT", "ALERTCOUNT", "FieldFormula", "Connect_Alert", "ALLPGS", "Local_Node");
```

[GrantPermissionForScript](#)

"Understanding Permission Lists" (Security Administration)

Save

Syntax

```
Save ()
```

Description

The Save method saves changes that you made to the PortalRegistry or to a node template. It does *not* save any changes that you made to a folder, content reference, and so on.

Note: To save changes for a folder or content reference use the save method associated with that object.

Parameters

None.

Returns

A Boolean value: True if the PortalRegistry object is successfully saved, False otherwise.

Example

```
If Not (&MyPortal.Save ()) Then
```

```
    /* do error checking */  
End-if;
```

PortalRegistry Class Properties

In this section, we discuss the PortalRegistry class properties. The properties are discussed in alphabetical order.

DefaultTemplate

Description

This property returns or sets the name of the default template for this PortalRegistry object as a string.

If you delete a template for a content reference, and none of the other content references on a page have a template, the default template specified with the Node is used. If there's no template for the Node, the template specified with this property is used.

To return a reference to the content reference that contains the template specified by this property, use the TemplateObject property.

Note: If you change the Default Template for a portal, the template won't take effect until you close all the existing browser windows with the session and open a new browser window.

This property takes only the first 30 characters of a value. If you specify a value longer than 30 characters, the remaining characters are ignored.

This property is read/write.

Related Links

[TemplateObject](#)

Description

Description

This property returns or sets the description of this PortalRegistry object as a string

The length of this property is 256 characters.

This property is read/write.

Favorites

Description

This property returns a reference to the Favorites Collection for the current end-user.

This property is read-only.

Related Links

[Favorite Collection](#)

FolderNavObject

Description

This property specifies the content reference name to be used for the folder navigation object. When the folder navigation is turned on, this content reference is displayed as the folder navigation homepage. This property takes a string value.

This property is read/write.

Related Links

[IsFolderNavigation](#)

Homepage

Description

This property returns a reference to the Homepage for the current end-user.

This property is read-only.

IsFolderNavigation

Description

This property specifies if there is folder navigation. When the folder navigation is turned on, the user can see a folder homepage when clicked on the folder in the left-hand navigation menu. This property takes a Boolean value: true if folder navigation is on, false otherwise.

This property is read/write.

Related Links

[FolderNavObject](#)

LandingPage

Description

Use the LandingPage property to return a reference to a UserHomepage object representing the current fluid homepage for the current user.

This property is read-only.

Important! Use this property within fluid applications only.

Related Links

[UserHomepage Class](#)

LandingTabDefinitions

Description

Use the LandingTabDefinitions property to return a reference to a TabDefinitions collection that contains all the fluid homepage definitions for the current user for the current portal.

This property is read-only.

Important! Use this property within fluid applications only.

Related Links

[TabDefinition Collection](#)

Name

Description

This property returns the name of the PortalRegistry object as a string.

The length of this property is 30 characters.

This property is read-only.

NodeTemplates

Description

This property returns a reference to a NodeTemplate Collection. This property can be used with a *closed* portal registry, that is, before you open it with the Open method.

This property is read-only.

Related Links

[NodeTemplate Collection](#)

OwnerId

Description

This property returns or sets the owner ID of the PortalRegistry object as a string.

This property is read/write.

PageletCategories

Description

This property returns a reference to a PageletCategories Collection that contains all the PageletCategories for a portal.

This property is read-only.

Related Links

[PageletCategory Collection](#)

Portals

Description

This property returns a reference to a Portal collection that contains references to all the portals in the database.

This property is read-only.

Related Links

[Portal Collection](#)

RootFolder

Description

This property returns the root folder object for this PortalRegistry object.

This property is read-only.

TabDefinitions

Description

This property returns reference to a TabDefinitions Collection that contains all the TabDefinitions for a portal.

This property is read-only.

Related Links

[TabDefinition Collection](#)

TemplateObject

Description

This property returns a reference to a content reference object that contains the template specified by the `DefaultTemplate` property. If no template is specified with `DefaultTemplate`, this property returns `Null`.

This property is read-only.

Related Links

[DefaultTemplate](#)

PortalRegistry Collection

A `PortalRegistry Collection` is returned by the `FindPortalRegistries` session class method.

See [FindPortalRegistries](#).

PortalRegistry Collection Methods

In this section, we discuss the `PortalRegistry` collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The `First` method returns the first `PortalRegistry` object in the `PortalRegistry` collection.

Example

```
&MyRegistry = &MyCollection.First();
```

Item

Syntax

```
Item(number)
```

Description

The `Item` method returns the `PortalRegistry` object with the position in the `PortalRegistry` collection specified by *number*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>number</i>	Specify the position number in the collection of the <code>PortalRegistry</code> object that you want returned.

Returns

A `PortalRegistry` object if successful, `NULL` otherwise.

Example

```
For &I = 1 to &MyCollection.Count
    &MyRegistry = &MyCollection.Item(&I);
    /* Do processing */
End-For;
```

Next

Syntax

```
Next ()
```

Description

The `Next` method returns the next `PortalRegistry` object in the `PortalRegistry` collection. You can use this method only after you have used the `First` method: otherwise the system doesn't know where to start.

Example

```
&MyRegistry = &MyCollection.Next();
```

PortalRegistry Collection Property

This section discusses the `Count` property.

Count

Description

This property returns the number of `PortalRegistry` objects in the `PortalRegistry` collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

Node Class

The node indicates the URI of the content server. If the node is a PeopleSoft content server, it has a PeopleSoft server URI. If the node has external content, the URI indicates the external content.

Use the `IsLocal` or `IsDefault` to determine if a node from a `RemoteNode` collection is remote or local.

Node objects are instantiated from the following:

- From a `Session` object with the `GetLocalNode` method.
- From a `Node Collection` with the `First`, `InsertItem`, `ItemByName`, and `Next` methods.
- From a `RemoteNode Collection` with the `First`, `InsertItem`, `ItemByName`, and `Next` methods.

See [GetLocalNode](#), [Node Collection](#), [RemoteNode Collection](#).

Node Class Properties

In this section, we discuss the Node class properties. The properties are discussed in alphabetical order.

ActiveNode

Description

This property indicates whether the node has been specified as an active node. This property returns a Boolean value: `True`, the node is active, `False` otherwise.

This property is read-only.

AppsRelease

Description

This property returns the release of the PeopleSoft Applications hosted on this node as a string. This property is valid only when the `NodeType` property is set to `PeopleSoft (PIA)`.

This property is read-only.

Related Links

[NodeType](#)

ContentURI

Description

This property returns the URI for the content Web server of this node as a string.

This property is read-only.

DefaultPortalName

Description

This property returns the name of the portal associated with the node as the default portal for the node.

This property is read-only.

Description

Description

This property returns the description for this node as a string.

The length of this property depends on your system database limit for LONG fields.

This property is read-only.

IsDefault

Description

This property indicates whether the node has been specified as the default local node. This property takes a Boolean value: True, this node has been specified as the default local node, False otherwise.

This property is valid only when the NodeType property is set to PeopleSoft (PIA).

This property is read-only.

Related Links

[NodeType](#)

IsLocal

Description

This property indicates whether this node has been specified as the local PeopleSoft node. This property takes a Boolean value: True, this node has been specified as a local node, False otherwise.

This property is valid only when the NodeType property is set to PeopleSoft (PIA).

This property is read-only.

Related Links

[NodeType](#)

Name

Description

This property returns the name for this node object as a string. The name is a unique identifier for each node object.

Every node name must be unique in the database.

This property is read-only.

NodePassword

Description

This property returns the password for this node object as a string.

This property is read-only.

NodeType

Description

This property indicates what the node is used for. Nodes can either define PeopleSoft or external systems. PeopleSoft nodes have more capabilities than external nodes, therefore several other properties depend on this property.

Values are:

Value	Description
PIA	PIA (PeopleSoft 8.4 simple URL format)
EX	External Node
ICT	ICType (used for 8.1x content)

PIA is the default value on a new Node.

This property is read-only.

PortalURI

Description

This property returns the URI for the portal Web server of this node as a string. This property is valid only when the NodeType property is set to PeopleSoft (PIA).

This property is read-only.

Related Links

[NodeType](#)

ToolsRelease

Description

This property returns the release of PeopleTools running on this node as a string. This property is valid only when the NodeType property is set to PeopleSoft (PIA).

This property is read-only.

Related Links

[NodeType](#)

Node Collection

A node collection contains a set of references to all nodes defined in the database.

Node Collection Methods

In this section, we discuss the Node collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The First method returns the first Node object in the Node collection.

Parameters

None.

Returns

A Node object.

Example

```
&MyNode = &MyCollection.First();
```

ItemByName

Syntax

```
ItemByName (NodeName)
```

Description

The ItemByName method returns the Node object with the name specified by *NodeName*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of an existing node in the Node collection. If you specify an invalid name, the object returned is NULL.

Returns

A Node object if successful, NULL otherwise.

Example

```
&MyOldNode = &MyPortal.Nodes.ItemByName("HRMS");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next Node object in the Node collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A Node object.

Example

```
&MyNode = &MyCollection.Next();
```

Node Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of Node objects in the Node Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

RemoteNode Collection

A remote node collection contains a set of references to all the nodes defined in the database, both local and remote.

Use the IsLocal property of the returned node object to determine if the node is remote or local.

RemoteNode Collection Methods

In this section, we discuss the RemoteNode collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The First method returns the first Node object in the RemoteNode collection.

Parameters

None.

Returns

A Node object.

Example

```
&MyNode = &MyCollection.First();
```

ItemByName

Syntax

```
ItemByName (NodeName)
```

Description

The ItemByName method returns the Node object with the name specified by *NodeName*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of an existing node in the RemoteNode collection. If you specify an invalid name, the object returned is NULL.

Returns

A Node object if successful, NULL otherwise.

Example

```
&MyOldNode = &MyPortal.RemoteNodes.ItemByName ("HRMS");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next Node object in the RemoteNode collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A Node object.

Example

```
&MyNode = &MyCollection.Next();
```

RemoteNode Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of Node objects in the RemoteNode Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

Portal Class

The portal class provides access to portals declared in the session.

A portal object is instantiated by the First, InsertItem, ItemByName, and Next Portal Collection methods

See [Portal Collection](#).

Portal Class Method

In this section, we discuss the Portal class methods. The methods are discussed in alphabetical order.

Save

Syntax

```
Save ()
```

Description

Use the Save method to save changes you made to the portal object.

Parameters

None.

Returns

A Boolean value: True if the portal object is successfully saved, False otherwise.

Portal Class Properties

In this section, we discuss the Portal class properties. The properties are discussed in alphabetical order.

HostNameName

Description

This property sets or returns the name of the node hosting the portal as a string.

This property is read/write.

IsLocal

Description

This property indicates whether the portal is defined as local or remote. This property returns a Boolean value: True, the portal is defined as local, False otherwise.

This property is read-only.

Name

Description

This property returns the name of this portal as a string. This name exactly matches the portal name of the portal registry defined in the database.

This property is read-only.

Portal Collection

The portal collection contains a set of references to each portal defined in the database.

A portal collection is instantiated by the Portals PortalRegistry property.

See [Portals](#).

Portal Collection Methods

In this section, we discuss the Portal collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The First method returns the first Portal object in the Portal collection.

Parameters

None.

Returns

A Portal object.

Example

```
&MyPortal = &MyCollection.First();
```

ItemByName

Syntax

```
ItemByName(PortalName)
```

Description

The ItemByName method returns the Portal object with the name *PortalName*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PortalName</i>	Specify the name of an existing portal within the collection. If you specify an invalid name, the object returns NULL.

Returns

A Portal object if successful, NULL otherwise.

Example

```
&MyPortal = &MyPortal.Portals.ItemByName("HRMS");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next Portal object in the Portal collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A Portal object.

Example

```
&MyPortal = &MyCollection.Next();
```

Portal Collection Properties

In this section, we discuss the Count property.

Count

Description

This property returns the number of Portal objects in the Portal Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

NodeTemplate Class

The NodeTemplate class provides access to the default template assigned to a node in this portal.

A NodeTemplate object is instantiated by the First, InsertItem, ItemByName, and Next NodeTemplate Collection methods.

See [NodeTemplate Collection](#).

NodeTemplate Class Properties

In this section, we discuss the NodeTemplate class properties. The properties are discussed in alphabetical order.

DefaultTemplate

Description

This property specifies the name of the template to be applied to the node.

This property is read/write.

Name

Description

This property specifies the name of node that the template is to be applied to.

This property is read/write.

TemplateObject

Description

This property returns a reference to the template object associated with this node as a content reference.

This property is read-only.

Related Links

[Content Reference Class](#)

NodeTemplate Collection

The NodeTemplate collection contains a set of references to each node template object in a portal.

A NodeTemplate collection is instantiated by the NodeTemplates PortalRegistry property.

See [NodeTemplates](#).

NodeTemplate Collection Methods

In this section, we discuss the NodeTemplate collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(NodeName)
```

Description

The DeleteItem method deletes the NodeTemplate object identified by *NodeName* from the NodeTemplate Collection.

This method is not executed automatically. It is executed only when the PortalRegistry is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of a NodeTemplate to delete.

Returns

A Boolean value: True if the NodeTemplate was deleted, False otherwise.

Example

```
If Not &MyNodeTemplates.DeleteItem("HRMS") Then
    /* Do error processing */
End-if
```

First

Syntax

```
First()
```

Description

The First method returns the first NodeTemplate object in the NodeTemplate collection.

Parameters

None.

Returns

A NodeTemplate object.

Example

```
&MyNodeTemplate = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(NodeName)
```

Description

The InsertItem method inserts the NodeTemplate object identified by *NodeName* into the NodeTemplate Collection.

This method is not executed automatically. It is executed only when the PortalRegistry is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of the node template to insert.

Returns

A reference to the new NodeTemplate object if the method executed successfully, NULL otherwise.

Example

```
&NewNodeTemplate = &MyPortal.NodeTemplates.InsertItem("CRM");
```

ItemByName

Syntax

```
ItemByName(NodeName)
```

Description

The ItemByName method returns the NodeTemplate object with the name *NodeName*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of an existing NodeTemplate object in the collection. If you specify an invalid name, the object is NULL.

Returns

A NodeTemplate object if successful, NULL otherwise.

Example

```
&MyNodeTemplate = &MyPortal.NodeTemplates.ItemByName("HRMS");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next NodeTemplate object in the NodeTemplate collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A NodeTemplate object.

Example

```
&MyNodeTemplate = &MyCollection.Next();
```

NodeTemplate Collection Properties

In this section, we discuss the Count property.

Count

Description

This property returns the number of NodeTemplate objects in the NodeTemplate Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

Folder Class

Folder objects are instantiated from other classes as follows:

- From a PortalRegistry object with the RootFolder property or the FindFolderByName method.
- From a Folder Collection with the First, ItemByName, or Next methods

See [RootFolder](#), [FindFolderByName](#), [Folder Collection](#).

See [Adding a Folder](#).

Folder Class Method

In this section, we discuss the Folder class methods. The methods are discussed in alphabetical order.

Save

Syntax

```
Save ()
```

Description

The Save method saves any changes you made to the folder, for example, a changed description or ValidFrom date.

Using this method also saves any changes you made to PermissionValue (both role-based and non role-based) and AttributeValue objects associated with this folder. Security permissions added are cascade upward until the root folder or first public folder. Removed security permissions are removed from all the parent folders until root or public folder in folder hierarchy.

Parameters

None.

Returns

A Boolean value: True if the Folder object is successfully saved, False otherwise.

Example

```
If Not(&MyFolder.Save()) Then
    /* do error checking */
End-If;
```

Folder Class Properties

In this section, we discuss the Folder class properties. The properties are discussed in alphabetical order.

AbnContentProvider

Description

Note: SmartNavigation has been deprecated. This property remains for backward compatibility only.

Use this property to set or return a string representing the node on which the SmartNavigation content resides.

This property is read/write.

AbnDataSource

Description

Note: SmartNavigation has been deprecated. This property remains for backward compatibility only.

Use this property to set or return a string indicating whether the SmartNavigation data source is a tree ("T") or a rowset ("R").

This property is read/write.

AbnPeopleCode

Description

Note: SmartNavigation has been deprecated. This property remains for backward compatibility only.

Use this property to set or return a string representing the path and PeopleCode object to execute when processing this SmartNavigation folder.

For example, if the PeopleCode program to execute is a method, then AbnPeopleCode property would be constructed from these elements:

```
APP_PACKAGE_NAME.Class_Path.Method
```

For example, if the PeopleCode program to execute is an iScript, then AbnPeopleCode property would be constructed from these elements:

```
RECORD_NAME.FIELD_NAME.PC_Event.Function
```

This property is read/write.

Attributes

Description

This property returns an Attribute Collection containing the AttributeValue objects for this folder.

This property is read-only.

Related Links

[Attribute Collection](#)

Author

Description

This property returns the author (PeopleSoft user ID) for this folder as a string.

This property is read-only.

AuthorAccess

Description

This property specifies whether the author of the folder has access to the folder. This property takes a Boolean value. The default value for this property for a newly created object is True. This property is not cascaded.

This property is read/write.

Authorized

Description

This property specifies whether the user is authorized to view this Folder.

This property is used when you access a particular Folder using FindFolderByName. If you've specified a valid Folder with this method, a Folder is always returned, whether you are authorized to view it or not. This is the only property you can view from an object that you are not authorized to.

The initial value of this property depends on the other permission properties (PublicAccess and AuthorAccess) and the permission list values in the PermissionValue object associated with this folder.

This property is read-only.

Related Links

[FindFolderByName](#)

CascadedPermissions

Description

This property returns a PermissionValue Collection. This collection contains the value of the non role-based permissions for all the child and parent objects (up to the root folder). To determine only the permissions of the object use the Permission property instead. To determine the role-based permissions of the object use the CascadedRolePermissions property instead.

Note: You *cannot* add any PermissionValue objects to a collection returned by the CascadedPermissions property. You can add values only to the collection returned by the Permissions or RolePermissions property.

This property is read-only.

Related Links

[CascadedRolePermissions](#)

[PermissionValue Collection](#)

[Permissions](#)

CascadedRolePermissions

Description

This property returns a RolePermissionValue Collection. This collection contains the value of the role-based permissions for all the child and parent objects (up to the root folder). To determine only the role-based permissions of the object use the RolePermission property instead. To determine the non role-based permissions of the object use the CascadedPermissions property.

Note: You *cannot* add any PermissionValue objects to a collection returned by the CascadedRolePermissions property. You can add values only to the collection returned by the Permissions or RolePermissions property.

This property is read-only.

Related Links

[CascadedPermissions](#)

[RolePermissions](#)

[RolePermissionValue Collection](#)

ContentRefs

Description

This property returns the ContentReference Collection for this folder.

This property is read-only.

Related Links

[Content Reference Collection](#)

CreationDate

Description

This property returns the creation date for this folder as a string.

This property is read-only.

DefaultChartNavigation

Description

Note: SmartNavigation has been deprecated. This property remains for backward compatibility only.

Use this property to set or return a Boolean value indicating whether the default PeopleTools chart navigation page (PT_ABN_ORGCHART) is to be used for this folder: True, use the default PeopleTools chart navigation page; False, use the folder specified by the value Folder Navigation Object Name field (from the Folder Administration page) as the navigation object.

This property is read/write.

Description

Description

This property returns or sets the description for this folder as a string.

The length of this property is 256 characters. This property is translatable.

This property is read/write.

Folders

Description

This property returns a reference to the Folder Collection for this folder.

This property is read-only.

Related Links

[Folder Collection](#)

IsMobile

Description

Note: PeopleSoft Mobile Agent is a deprecated product. This mobile property currently exists for backward compatibility only.

This property returns True if the folder is used with mobile applications, False otherwise.

This property is read/write.

IsVisible

Description

This property returns True if the Hide from Portal Navigation check box is *not* selected when the folder is created. If the folder is hidden from portal navigation, this property returns False.

Considerations Using IsVisible

If you do not specifically set this property on a new or copied folder, the IsVisible property is set as follows:

- If the ValidFrom date is less than or equal to that day's date, the IsVisible property is set to True.
- If there is no ValidTo date the IsVisible property is set to True.
- If the ValidTo date is greater than or equal to that day's date, the IsVisible property is set to True.

This property is read-only.

Related Links

[ValidFrom](#)

[ValidTo](#)

Label

Description

This property returns or sets the label for this folder as a string.

The length of this property is 30 characters.

This property is translatable.

This property is read/write.

Name

Description

This property returns the name for this folder as a sting. The name is a unique identifier for each folder.

Every folder name must be unique across the portal, not just in the parent folder.

This property is *not* translatable. However, the values for the Label and Description properties are translatable.

This property is read-only.

Related Links

[Description](#)

[Label](#)

OwnerId

Description

This property returns the name of the owner for this folder as a string.

This property is read/write.

ParentName

Description

This property returns the parent folder name for this folder as a string. This property is valid only if the folder is contained within another folder. If the folder using this property is the root folder, this property returns an empty string.

This property is read-only.

Path

Description

The Path property returns a path to this folder, with each element of the path separated by a period. The path has the following syntax:

```
FolderLabel{Name}.[ChildFolderLabel{Name}]. . . .
```

This property is read-only.

Example

```
Departments{PORTA_ROOT_OBJECT}.HR{EastCoast}.AdministerWorkforce{Global}
```

Permissions

Description

This property returns a `PermissionValue` Collection. This collection contains the value of the non role-based permissions for this folder. To determine the permissions for all the parent objects (up to the root folder) use the `CascadedPermissions` property. To access the role-based permissions, use the `RolePermissions` property.

This property is read-only.

Related Links

[PermissionValue Collection](#)

[CascadedPermissions](#)

[RolePermissionValue Collection](#)

Product

Description

This property returns or sets the PeopleSoft product for this folder as a string.

The length of this property is 4 characters.

This property is read/write.

PublicAccess

Description

This property indicates whether a folder is generally accessible, that is, if this property is set to `True`, any user can access the folder. This property is not cascaded.

This property takes a Boolean value.

The default value for this property for a newly created object is `False`.

This property is read/write.

RolePermissions

Description

This property returns a `RolePermissionValue` Collection. This collection contains the value of the role-based permissions for this folder. To determine the role-based permissions for all the parent objects (up to

the root folder) use the `CascadedRolePermissions` property. To access the non role-based permissions, use the `Permissions` property.

This property is read-only.

Related Links

[CascadedRolePermissions](#)

[Permissions](#)

[RolePermissionValue Collection](#)

SequenceNumber

Description

The sequence number is used when returning a collection. The default order of the returned folders is based on the sequence number. Use this property to reorder folders.

If there are duplicates in the sequence number, the folders are returned alphabetically.

The length of this property is 4 characters.

This property is read/write.

TreeEffectiveDate

Description

Note: SmartNavigation has been deprecated. This property remains for backward compatibility only.

Use this property to set or return the effective date for the tree to be used as the SmartNavigation data source as a string.

Note: If the SmartNavigation data source is a rowset, this property is set to the Null string.

This property is read/write.

TreeName

Description

Note: SmartNavigation has been deprecated. This property remains for backward compatibility only.

Use this property to set or return the name for the tree to be used as the SmartNavigation data source as a string.

Note: If the SmartNavigation data source is a rowset, this property is set to the Null string.

SmartNavigation passes the values of several tree-specific fields to the application via URL. Certain characters are inappropriate for use in a URL and must be avoided. When using a tree as a SmartNavigation data source, do not use any of the following characters in the tree name, setID, user key value, and tree branch values:

pound (#)	percent (%)	dollar (\$)
ampersand (&)	plus (+)	comma (,)
forward slash/virgule (/)	colon (:)	semi-colon (;)
equals (=)	question mark (?)	at symbol (@)
space ()	quotation marks(")	less than symbol (<)
greater than symbol (>)	left curly brace ({)	right curly brace (})
vertical bar/pipe ()	backslash (\)	caret (^)
tilde (~)	left square bracket ([)	right square bracket (])
grave accent (`)		

This property is read/write.

TreeSetId

Description

Note: SmartNavigation has been deprecated. This property remains for backward compatibility only.

Use this property to set or return the setID for the tree to be used as the SmartNavigation data source as a string.

Note: If the SmartNavigation data source is a rowset, this property is set to the Null string.

SmartNavigation passes the values of several tree-specific fields to the application via URL. Certain characters are inappropriate for use in a URL and must be avoided. When using a tree as a SmartNavigation data source, do not use any of the following characters in the tree name, setID, user key value, and tree branch values:

pound (#)	percent (%)	dollar (\$)
ampersand (&)	plus (+)	comma (,)

forward slash/virgule (/)	colon (:)	semi-colon (;)
equals (=)	question mark (?)	at symbol (@)
space ()	quotation marks(")	less than symbol (<)
greater than symbol (>)	left curly brace ({)	right curly brace (})
vertical bar/pipe ()	backslash (\)	caret (^)
tilde (~)	left square bracket ([)	right square bracket (])
grave accent (`)		

This property is read/write.

TreeStructureName

Description

Note: SmartNavigation has been deprecated. This property remains for backward compatibility only.

Use this property to set or return the branch for the tree to be used as the SmartNavigation data source as a string.

Note: If the SmartNavigation data source is a rowset, this property is set to the Null string.

SmartNavigation passes the values of several tree-specific fields to the application via URL. Certain characters are inappropriate for use in a URL and must be avoided. When using a tree as a SmartNavigation data source, do not use any of the following characters in the tree name, setID, user key value, and tree branch values:

pound (#)	percent (%)	dollar (\$)
ampersand (&)	plus (+)	comma (,)
forward slash/virgule (/)	colon (:)	semi-colon (;)
equals (=)	question mark (?)	at symbol (@)
space ()	quotation marks(")	less than symbol (<)
greater than symbol (>)	left curly brace ({)	right curly brace (})

vertical bar/pipe ()	backslash (\)	caret (^)
tilde (~)	left square bracket ([)	right square bracket (])
grave accent (`)		

This property is read/write.

TreeUserKeyValue

Description

Note: SmartNavigation has been deprecated. This property remains for backward compatibility only.

Use this property to set or return the user key value (also known as the set control value) for the tree to be used as the SmartNavigation data source as a string.

Note: If the SmartNavigation data source is a rowset, this property is set to the Null string.

SmartNavigation passes the values of several tree-specific fields to the application via URL. Certain characters are inappropriate for use in a URL and must be avoided. When using a tree as a SmartNavigation data source, do not use any of the following characters in the tree name, setID, user key value, and tree branch values:

pound (#)	percent (%)	dollar (\$)
ampersand (&)	plus (+)	comma (,)
forward slash/virgule (/)	colon (:)	semi-colon (;)
equals (=)	question mark (?)	at symbol (@)
space ()	quotation marks(")	less than symbol (<)
greater than symbol (>)	left curly brace ({)	right curly brace (})
vertical bar/pipe ()	backslash (\)	caret (^)
tilde (~)	left square bracket ([)	right square bracket (])
grave accent (`)		

This property is read/write.

ValidFrom

Description

This property returns or sets the date this folder is valid from as a string.

This property is read/write.

ValidTo

Description

This property returns or sets the date this folder is valid until as a string.

This property is read/write.

Note: The portal registry API never uses the ValidTo and ValidFrom fields to determine what to return in a collection. You must check for these values in your application.

Folder Collection

The Folder Collection provides access to a collection of folders in a Folder object.

The Folder Collection is instantiated from the Folders Folder Class property.

See [Folders](#).

Folder Collection Methods

In this section, we discuss the Folder collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(FolderName)
```

Description

The DeleteItem method deletes the folder object identified by *FolderName* from the database. If the folder contains other folders, all child folders and their contents are also deleted.

Warning! If you delete a folder, you delete *all* content in the folder. If you delete a folder that contains other folders, that is, a parent folder, all the child folders, and all the content references are deleted.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for deletion, then actually deleted later. The item is deleted from the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>FolderName</i>	Specify the name of a folder existing in the folder collection.

Returns

A Boolean value: True if the folder was deleted, False otherwise.

Example

```
If Not &MyFolderColl.DeleteItem("MYFOLDER") Then
    /* Folder not deleted. Do error checking */
End-If;
```

First

Syntax

```
First()
```

Description

The First method returns the first Folder object in the folder collection.

Parameters

None.

Returns

Folder object.

Example

```
&MyFolder = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(FolderName, Label)
```

Description

The `InsertItem` method inserts the folder object identified by *FolderName* from the Folder Collection. You must specify both a name and a label for all folders. This method returns a reference to the new folder object. You must specify a unique *FolderName*, or you receive an error.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for insertion, then actually inserted later. The item is inserted into the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>FolderName</i>	Specify the name of a folder existing in the folder collection. This parameter takes a string value.
<i>Label</i>	Specify a label for the new folder. This parameter takes a string value.

Returns

A reference to the new Folder object if the method executed successfully, null otherwise.

Example

```
&DeptHPFldr = &MyPortal.Folders.InsertItem("PORT0145", "HR Folder for Department 01→
45");
```

ItemByName

Syntax

`ItemByName` (*Name*)

Description

The `ItemByName` method returns the Folder object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing folder within the folder collection. If you specify an invalid name, the object is NULL. You must specify a name, not a label.

Returns

A folder object if successful, NULL otherwise.

Example

```
&DeptFldr = &MyPortal.RootFolder.Folders.ItemByName (&Dept_Name);
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next Folder object in the Folder collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A folder object.

Example

```
Local ApiObject &MySession, &Root, &Folders, &MyFolder;  
  
&MySession = %Session;  
&MyPortal = &MySession.GetPortalRegistry("ADMIN");  
  
&Root = &MyPortal.GetRoot();  
&Folders = &Root.Folders;  
  
&MyFolder = &Folders.First();  
  
For &I = 1 to &Folders.Count  
    /* Do processing on folders */  
    If &I <> &Folders.Count  
        &MyFolder = &Folders.Next();  
    End-If;  
End-For;
```

Folder Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of Folder objects in the Folder Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

Content Reference Class

The content reference class provides access to some kind of content. The type of content depends on the content reference.

The content reference objects are instantiated from other classes:

- From a PortalRegistry object with the FindCRefByURL, FindCRefForURL, or FindCRefByName properties.
- From a Content Reference Collection (instantiated from a folder) with the First, ItemByName or Next methods

See [FindCRefByURL](#), [FindCRefByName](#), [FindCRefForURL](#), [Content Reference Collection](#).

See [Adding a Content Reference](#).

Content Reference Class Methods

In this section, we discuss the Content Reference class methods. The methods are discussed in alphabetical order.

CreateLink

Syntax

```
CreateLink(LinkName, Label)
```

Description

Use the CreateLink method to create a link quickly to the same content reference executing the method. The link by defaults assumes the parent folder is the same as the content reference's parent.

A CRefLink object is returned if there is no error.

After you create a link you must use the Save method to save it to the database.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>LinkName</i>	Specify the name of the link as a string. This parameter takes 30 characters. This is considered as ID of the link. It cannot start with number, and can not have special characters and spaces.
<i>Label</i>	Specify the label of the link as a string. This parameter takes 30 characters.

Returns

A reference to a ContentReference link object.

Example

```
&CRef = &Portal.FindCRefByName("MyCRef");
&Link = &CRef.CreateLink("Link Object");
&Link.Save();
```

Related Links

[Link Class](#)

[Save](#)

Save

Syntax

```
Save ()
```

Description

The Save method saves any changes you made to the content reference, for example, a changed description. It also performs some validation.

Using this method also saves any changes you made to PermissionValue or AttributeValue objects associated with this content reference.

Parameters

None.

Returns

A Boolean value: True if the content reference and its associated objects saved successfully, False otherwise.

Example

```
If NOT(&MyCRef.Save()) Then
  /* save failed, do error processing */
End-If;
```

Content Reference Class Properties

In this section, we discuss the Content Reference class properties. The properties are discussed in alphabetical order.

AbsoluteContentURL**Description**

This property returns the complete URL to the content from the content servlet (psc).

Use the URL property to return a partial URL beginning with the content type—that is, minus the portal URI text, portal name, and node name.

This property is read-only.

Example

The following is an example absolute content URL:

```
http://myserver.example.com:8000/psc/t56dp812x/EMPLOYEE/CRM/c/PTGP_MENU.PTGP_USERPR⇒
EF_FL.GBL
```

[URL](#)

AbsolutePortalURL**Description**

This property returns the complete URL to the content from the portal servlet (psp).

This property is read-only.

Example

```
http://myserver.example.com:8000/psp/t56dp812x/EMPLOYEE/CRM/c/PTGP_MENU.PTGP_USERPR⇒
```

EF_FL.GBL

AssignedPagelets

Description

This property returns an AssignedPagelet collection.

This property is read-only.

Related Links

[AssignedPagelet Collection](#)

Attributes

Description

This property returns an Attribute Collection containing the AttributeValues for this content reference object.

This property is read-only.

Related Links

[Attribute Collection](#)

Author

Description

This property returns the author (PeopleSoft user ID) for this content reference object as a string.

This property is read-only.

AuthorAccess

Description

This property specifies whether the author of the content reference has access to the content reference. This property takes a Boolean value. The default value for this property is True.

This property is read/write.

Authorized

Description

This property specifies whether the user is authorized to view this content reference.

This property is used when you access a particular content reference using `FindCRefByURL`, `FindCRefForURL`, or `FindCRefByName`. If you specified a valid content reference with either of these methods, a content reference is always returned, whether you are authorized to view it or not. This is the only property you can view from an object for which you are not authorized.

The initial value of this property depends on the other permission properties (`PublicAccess` and `AuthorAccess`) and the permission list values in the `PermissionValue` object associated with this content reference.

This property is read-only.

Related Links

[FindCRefByURL](#)

[FindCRefForURL](#)

CascadedPermissions

Description

This property returns a `PermissionValue` Collection. This collection contains the value of the non role-based permissions for all the parent objects (up to the root folder). To determine only the permissions of the object use the `Permissions` property instead. To access the role-based permissions, use the `CascadedRolePermissions` property.

Note: You *cannot* add any `PermissionValue` objects to a collection returned by the `CascadedPermissions` property. You can add values only to the collection returned by the `Permissions` property.

This property is read-only.

CascadedRolePermissions

Description

This property returns a `RolePermissionValue` Collection. This collection contains the value of the role-based permissions for all the parent objects (up to the root folder). To determine only the permissions of

the object use the RolePermissions property instead. To determine non role-based permissions, use the CascadedPermissions property.

Note: You *cannot* add any RolePermissionValue objects to a collection returned by the CascadedRolePermissions property. You can add values only to the collection returned by the RolePermissions property.

This property is read-only.

Related Links

[CascadedRolePermissions](#)

[RolePermissions](#)

[RolePermissionValue Collection](#)

ContentProvider

Description

This property returns or sets the name of the node for the content reference as a string.

This property takes the following values:

<i>Value</i>	<i>Description</i>
Node name	Specify the exact name of the node.
LOCAL_NODE	Specify the node for the content reference as the node defined as the default local node.

This property is read/write.

CreationDate

Description

This property returns the creation date for this content reference object as a string.

This property is read-only.

Data

Description

This property returns the data for this content reference. This property is valid only when the StorageType property is LOCL.

The length of this property depends on your system database limit for LONG fields.

This property is read/write.

Example

```
&MyData = &MyCRef.Data;
```

Related Links

[StorageType](#)

Description

Description

This property returns or sets the description for this content reference object as a string.

The length of this property is 256 characters.

This property is translatable.

This property is read/write.

DisplayIn

Description

Use the DisplayIn property to set or return a number value representing how the target transaction or content appears once a user taps the tile.

Use the following integer constants (integer values are provided for reference only):

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%GroupletActionInCurrentWindow	Display the content in the current browser window.
1	%GroupletActionInNewWindow	Display in a new browser window.
2	%GroupletActionInModal	Display in a modal window.
3	%GroupletActionNavBarGrouplet	Display in the NavBar (used by NavBar tiles only).
4	%GroupletActionNavrBarUrlInCurrentWindow	Display in the current browser window (used by NavBar tiles only).
6	%GroupletActionAGTargetFluid	Display the fluid component within the activity guide.
7	%GroupletActionMDTargetFluid	Display the fluid component within the master/detail target area.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
8	%GroupletActionMDTargetClassic	Display the classic component within the master/detail target area.
9	%GroupletActionAGTargetClassic	Display the classic component within the activity guide.

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

[SetGroupletDisplayIn](#)

DisplayModalParams

Description

Use the DisplayModalParams property to set or return a string value representing the custom modal options.

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

"Modal Options" (Fluid User Interface Developer's Guide)

[SetGroupletMOptions](#)

EventName

Description

Use the EventName property to set or return a string value representing the name of a push notification event used to dynamically update the tile's content.

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

"Understanding the Push Notification Framework" (Fluid User Interface Developer's Guide)

"Defining Events" (Fluid User Interface Developer's Guide)

[SetGroupletEventMsg](#)

GroupletAltHeight

Description

Use the GroupletAltHeight property to set or return a number value representing the alternate height for a resizable tile.

Note: If either GroupletAltHeight or GroupletAltWidth is a non-zero value, then the tile is assumed to be resizable. There is no specific property to set the tile as resizable.

This property is read/write.

Important! Use this property within fluid applications only.

GroupletAltWidth

Description

Use the GroupletAltWidth property to set or return a number value representing the alternate width for a resizable tile.

Note: If either GroupletAltHeight or GroupletAltWidth is a non-zero value, then the tile is assumed to be resizable. There is no specific property to set the tile as resizable.

This property is read/write.

Important! Use this property within fluid applications only.

GroupletAutoSize

Description

Use the GroupletAutoSize property to set or return a Y/N string value indicating whether to allow the fluid content to dynamically resize itself based on the size of the content. Note the following conditions and limitations with respect to the autosize option:

- The autosize option pertains to tiles and related information, but not to embedded related content.
- The autosize option is best used on dashboards with few tiles. Be aware that layout changes can occur from the autosized content.
- Autosize automatically accounts for resizing of the browser and rotation of the device.
- The autosize and resizable options are mutually exclusive; both cannot be selected simultaneously.
- The tile will not resize itself to larger than the dimensions of the device.
- If the content is larger than the size of the tile, the tile will display scroll bars.

- Due to the same-origin policy implemented by web browsers, for the autosize option to work with external content, the external content and the PeopleSoft application must either reside within the same domain or they must both set the document.domain property to the same value. Otherwise, the autosize option is ignored. For more information on how the domain and same-origin is determined, see [Same-origin policy](#).

This property is read/write.

Important! Use this property within fluid applications only.

Example

```
If &CRef.GroupletAutoSize = "Y" Then
    &CRef.GroupletAltHeight = 0;
    &CRef.GroupletAltWidth = 0;
End-If;
```

GroupletContentProvider

Description

Use the GroupletContentProvider property to set or return a string value representing the local or remote node name for the dynamic tile content.

This property is read/write.

Important! Use this property within fluid applications only.

GroupletContentURL

Description

Use the GroupletContentURL property to set or return a string value representing the full URL to the dynamic tile content. Use the GroupletURL property to return a partial URL beginning with the content type—that is, minus the portal URI text, portal name, and node name.

Note: When the dynamic tile content type is none (that is, GroupletURLType is NONE), this property returns an empty string.

This property is read/write.

Important! Use this property within fluid applications only.

Example

For example:

```
http://myserver.example.com:8000/psc/t56dp812x/EMPLOYEE/QEDMO/s/WEBLIB_PTNUI.FUNCLI⇒
B.FieldFormula.IScript_GroupletDiag
```

[GroupletURLType](#)

[SetGroupletUrl](#)

GroupletDisableHotspot

Description

Use the GroupletDisableHotspot property to set or return a Y/N string value indicating whether to disable displaying the target content defined for the tile when the tile is tapped. However, any links displayed dynamically within the tile are not disabled.

This property is read/write.

Important! Use this property within fluid applications only.

GroupletHeight

Description

Use the GroupletHeight property to set or return a number value representing the height of the tile.

The default dimensions of a tile are 1 tile unit by 1 tile unit. Tiles up to 8x8 are supported. Note the following conditions and limitations with respect to the height and width of a tile:

- A tile can never be larger than the width of the device. For example, if the width of a device is 2 in portrait mode, and 3 in landscape; the tile can only be maximum of width 2 on this device.
- The valid size is checked only when the tile is initially loaded. If the device is rotated, or if the browser is resized, the tile is not resized.
- Any tile sized larger than 2x2 is not guaranteed to display at the specified size depending on the device used to access the PeopleSoft system. For example, a 4x4 tile on a small form factor device in portrait mode would only show as a 2x3 tile.
- Therefore, tiles larger than 2x2 need to implement variable sizing to accommodate different device sizes. Use large size tiles sparingly.

This property is read/write.

Important! Use this property within fluid applications only.

GroupletId

Description

If applicable, use the GroupletId property to set or return an optional string value representing the ID of the specific group box from which the content is rendered. Use the page field name as defined on the General tab of the group box definition.

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

[SetGroupletID](#)

GroupletImageName

Description

Use the GroupletImageName property to set or return a string value specifying an image (in SVG format only) from the database to display a custom static image as the fluid content. Otherwise the default image is displayed.

Note: When dynamic content is also configured for a tile, this static image is displayed only until the dynamic content is loaded.

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

[SetGroupletImage](#)

GroupletPageName

Description

Use the GroupletPageName property to set or return a string value representing the fluid page name. This property is valid only when the dynamic tile content is specified as PeopleSoft Component.

Note: Because multi-page components are not recommended as dynamic content, the page name is not required.

This property is read/write.

Important! Use this property within fluid applications only.

GroupletTimer

Description

Use the GroupletTimer property to set or return a number value representing the refresh timer for this tile.

Enter the time in seconds to set an automatic refresh period for dynamic content on a tile. When the timer limit has been reached, the system re-draws the tile so that it displays the current data, such as in the case with chart.

The default value of 0 disables any automatic refresh.

Note: The system enforces a 10 second minimum limit. Any value entered less than 10 seconds is ignored and is treated as 10 seconds. When setting this value, be sure to monitor performance of the page refreshes and adjust accordingly.

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

[SetGroupletTimer](#)

GroupletType

Description

Use the GroupletType property to set or return a number value representing the type of grouplet.

A grouplet is the encapsulation of content from one source (for example, a component, an iScript, or external content) that is presented within the context of another fluid application page. Tiles, embedded related content, and related information are all examples of grouplets. In each of these scenarios, the grouplets are created by the system at runtime based solely on configuration details. However, you can use this and other methods and properties of the Field class to generate grouplets from group box fields programmatically.

Use the following integer constants (integer values are provided for reference only):

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%GroupletNone	Not a grouplet (also referred to as a tile). This is a regular group box with its content coming from the same page records.

Numeric Value	Constant Value	Description
1	%GroupletWithStyle	<p>Grouplet with style. This producer tile includes its own style sheets, JavaScript, or both.</p> <hr/> <p>Important! Be aware that this setting can inject style settings or JavaScript code that conflicts with those defined for the page.</p> <hr/>
2	%GroupletNoStyle	<p>Grouplet without style. This producer tile does not include style sheets or JavaScript.</p> <hr/> <p>Note: This is the recommended setting.</p> <hr/>
3	%GroupletIframe	Interactive grouplet.
4	%GroupletIframeExt	Interactive grouplet for external content.
5	%GroupletIframeAutoSize	<p>Interactive grouplet with autosizing.</p> <hr/> <p>Note: Use this setting for homepage and dashboard tiles only.</p> <hr/>
6	%GroupletIframeExtAutoSize	<p>Interactive grouplet for external content with autosizing.</p> <hr/> <p>Note: Use this setting for homepage and dashboard tiles only.</p> <hr/>
7	%GroupletIframeVAutoSize	<p>Interactive grouplet with vertical autosizing. The system will autosize the grouplet height based on the content at initial load. The grouplet will be automatically resized by the system when:</p> <ul style="list-style-type: none"> • The window is resized. • Any field change or server trip is invoked within the grouplet. • Any group boxes within the grouplet are expanded or collapsed. • When either side panel is opened or closed.

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

[SetGroupletType](#)

GroupletURL

Description

Use the GroupletURL property to set or return a string value representing a partial URL to the dynamic tile content. This partial URL begins with the content type—that is, it does not include the portal URI text, portal name, and node name. Use the GroupletContentURL property to return the full URL.

Note: When the dynamic tile content type is none (that is, GroupletURLType is NONE), this property returns an empty string.

This property is read/write.

Important! Use this property within fluid applications only.

Example

For example:

```
s/WEBLIB_PTUI.FUNCLIB.FieldFormula.iScript_GroupletDiag
```

Related Links

[GroupletContentURL](#)

[GroupletURLType](#)

GroupletURLType

Description

Use the GroupletURLType property to set or return a string value representing the URL type for the dynamic tile content.

<i>String Value</i>	<i>Description</i>
NONE	No dynamic tile content.
UEXT	Non-PeopleSoft URL.
UGEN	PeopleSoft Generic URL.
UPGE	PeopleSoft Component.
USCR	PeopleSoft iScript.

This property is read/write.

Important! Use this property within fluid applications only.

GroupletWidth

Description

Use the GroupletWidth property to set or return a number value representing the width of the tile

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

[GroupletHeight](#)

HasGrouplet

Description

Use the HasGrouplet property to set or return a boolean value indicating whether any of the properties have been set on the Fluid Attributes page of the content reference definition.

This property is read/write.

Important! Use this property within fluid applications only.

HtmlText

Description

This property returns the HTML text associated with this content reference as a string.

This property is read-only.

IsFluid

Description

Use the IsFluid property to set or return a boolean value indicating whether fluid mode is enabled for this content reference. For *local* component-based fluid content, this setting is maintained on the component definition in Application Designer; do not reset the property in PeopleCode.

Otherwise, programmatically specify fluid mode only for:

- iScript based URLs.
- Generic PeopleSoft URLs.

- *Remote* component-based fluid content.

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

"IsFluidMode" (PeopleCode Language Reference)

IsMobile

Description

Note: PeopleSoft Mobile Agent is a deprecated product. This mobile property currently exists for backward compatibility only.

This property returns True if this content reference is used with mobile applications, False otherwise.

This property is read/write.

IsSmallFFOptimized

Description

Use the IsSmallFFOptimized property to set or return a boolean value indicating whether the tile for this content reference definition has been designated to display on small form factor devices such as smart phones. If this property is False, this tile will not be available when the user is signed in on small form factor devices.

For *local* component-based fluid content, this setting is maintained on the component definition in Application Designer; do not reset the property in PeopleCode.

This property is read/write.

Important! Use this property within fluid applications only.

Related Links

"IsSmallFFOptimized" (PeopleCode Language Reference)

IsVisible

Description

This property returns True if the Hide from Portal Navigation check box is not selected when the content reference is created. If the content reference is hidden from portal navigation, this property returns False.

Considerations Using isVisible

If you do not specifically set this property on a new or copied content reference object, the isVisible property is set as follows:

- If the ValidFrom date is less than or equal to that day's date, the isVisible property is set to True.
- If there is no ValidTo date the isVisible property is set to True.
- If the ValidTo date is greater than or equal to that day's date, the isVisible property is set to True.

This property is read-only.

Related Links

[ValidFrom](#)

[ValidTo](#)

Label

Description

This property returns or sets the label for this content reference object as a string.

The length of this property is 30 characters.

This property is translatable.

This property is read/write.

Links

Description

This property returns a reference to a Link collection. This collection contains all the links that are associated with this content reference.

This property is read-only. However, a link collection is updated in real time when a new link is created on the object.

Related Links

[Link Collection](#)

Name

Description

This property returns the name for this content reference object as a string. The name is a unique identifier for each content reference object.

Every content reference name must be unique in the portal, not just in the parent folder.

This property is read-only.

OwnerId

Description

This property returns or sets the owner ID of the content reference object as a string.

This property is read/write.

ParentName

Description

This property returns the parent folder name for this content reference object as a string.

This property is read-only.

Example

The following example uses the ParentName to return a folder object for the content reference.

```
&Folder = &Portal.FindFolderByName(&CRef.ParentName);
```

Path

Description

The Path property returns a path to this content reference, with each element of the path separated by a period. The path has the following syntax:

```
ContentReferenceLabel{Name}.[ChildContentReferenceLabel{Name}]. . . .
```

This property is read-only.

Permissions

Description

This property returns a PermissionValue Collection. This collection contains the value of the non role-based permissions for this content reference. To determine the permissions for all the parent objects (up to the root folder) use the CascadedPermissions property.

If you want to find role-based permissions for the content reference, use the RolePermission property.

This property is read-only.

Related Links

[PermissionValue Collection](#)

CascadedPermissions

CascadedPermissions

Product

Description

This property returns or sets the PeopleSoft product for this content reference object as a string.

The length of this property is 4 characters.

This property is read/write.

PublicAccess

Description

This property indicates whether a content reference is generally accessible, that is, if it will always be included in the general content reference collection. This property takes a Boolean value.

The default value for this property is False.

This property is read/write.

QualifiedURL

Description

Note: This property is being kept for backward compatibility only. If your code uses this property, the value returned is actually from the `AbsoluteContentURL` property. New applications should use the `AbsoluteContentURL` property instead.

Related Links

[AbsoluteContentURL](#)

RelativeURL

Description

This property returns the relative URL in the following format:

```
../../../../PORTAL/NODE/content_type/CONTENT
```

The following is an example of a full URL:

```
http://myserver.example.com:8000/psc/t56dp812x/EMPLOYEE/CRM/c/PTGP_MENU.PTGP_USERPR⇒  
EF_FL.GBL
```

The `RelativeURL` property returns the following:

```
../../../../EMPLOYEE/CRM/c/PTGP_MENU.PTGP_USERPREF_FL.GBL
```

This property is read-only.

Related Links

[AbsoluteContentURL](#)

RolePermissions

Description

This property returns a `RolePermissionValue` Collection. This collection contains the value of the role-based permissions for this content reference. To determine the permissions for all the parent objects (up to the root folder) use the `CascadedRolePermissions` property.

If you want to find non role-based permissions for the content reference, use the `Permission` property.

This property is read-only.

Related Links

[CascadedRolePermissions](#)

[Permissions](#)

[RolePermissionValue Collection](#)

SequenceNumber

Description

The sequence number is used when returning a collection. The default order of the returned content references is based on the sequence number. Use this property to reorder content references. This property takes a number value.

If there are duplicates in the sequence number, the content references are returned alphabetically.

The length of this property is 4 characters.

This property is read/write.

StorageType

Description

In general, content references contain information about where to get the content, and do not store the content. However, content references that are template or portal component types can have their content accessible directly from the content reference. In these cases, the `Data` property is valid and can be read or written, and the data is stored locally in the portal database.

StorageType	Meaning
LOCL	Local: Data property on content reference is valid.
RMTE	Remote: Data property is not valid.

When UsageType is a target this property must be set to RMTE and the URLType property should specify what format the Node and URL are in.

When UsageType is either a template or a portal component this property can be set to either LOCL or RMTE.

Note that when StorageType is LOCL, it specifies a static template or portal component. But, when StorageType is RMTE it can specify either:

- a dynamically generated template or portal component
- a static template or portal component

In both cases, the Node and URL properties specifies how to get the template or portal component.

Only templates and homepage tab content references can have StorageType LOCL. The StorageType is always LOCL for homepage tabs. For templates LOCL means that corresponding URL is stored in database, not retrieved by URL.

The following table indicates the usage type, and what type of storage is available.

UsageType	RMTE	LOCL
FRMT (Frame template)	X	X
HTMT (HTML template)	X	X
HPGT (Homepage tab)		X
HPGC (Pagelet)	X	
TARG (Target)	X	

RMTE is the default value for a new content reference.

The length of this property is 4 characters.

This property is read/write.

Related Links

[Data](#)

Template

Description

This property returns or sets the name of the template used with this content reference as a string. You must specify the name of an existing template.

This property uses the name *not* the label of a content reference.

This property is used only when the UsageType property is specified as Target (TARG) and the TemplateType property is specified as HTML.

To return a reference to the content reference that contains the template specified by this property, use the TemplateObject property.

The length of this property is 30 characters.

This property is read/write.

Related Links

[UsageType](#)

[TemplateType](#)

[TemplateObject](#)

TemplateObject

Description

This property returns a reference to a content reference object that contains the template specified by the Template property as a content reference. If no template is specified with Template, this property returns NULL.

This property is read-only.

Related Links

[Template](#)

TemplateType

Description

This property indicates whether a template should be used to wrap the content. This property takes a string value.

Values are:

Value	Description
HTML	An HTML template should wrap the data (URL) in the content reference.
NONE	No template should be used. The text should not be wrapped.

HTML is the default value on a new content reference.

Use the NONE value if the URL should not appear in the portal. An example is when the content reference is a template itself.

If the homepage template for the user is un-retrievable, the system tries to use the default user's template first, before resorting to the portal default template.

When the content reference describes content, this property should be set to HTML.

This property is read/write.

Related Links

[Using Content References](#)

URL

Description

Use this property to set or return the partial URL to the content. This partial URL begins with the content type—that is, it does not include the portal URI text, portal name, and node name.

Use the AbsoluteContentURL property to return the full URL.

This property is read/write.

Example

The following is an example the URL property:

```
c/PTGP_MENU.PTGP_USERPREF_FL.GBL
```

Related Links

[AbsoluteContentURL](#)

URLType

Description

This property indicates what kind of URL is used to retrieve the content. This property takes a string value.

Note: This property is used only for content that has the `StorageType` property set as `Remote`.

Values are:

<i>URLType Value</i>	<i>Meaning</i>
UEXT	URL points to a non-PeopleSoft (external) URL
UMPG	URL points to a PeopleSoft mobile page
UPGE	URL points to a component.
UPHP	URL points to a homepage tab
UPTM	URL points to a template
USCR	URL points to an iScript
UGEN	URL points to a generic PeopleSoft URL
WRKL	URL points to a Worklist URL

UPGE is the default value on a new content reference.

This property is read/write.

Related Links

[StorageType](#)

UsageType

Description

This property indicates what the content reference is used for. Several other properties depend on this property.

This property takes a string value.

The length of this property is 4 characters.

<i>Value</i>	<i>Description</i>
FRMT	Frame template: the content reference is a frame-based template.

Value	Description
HTMT	HTML template: the content reference is an HTML template.
HPGT	Homepage tab: the content reference is a homepage tab.
HPGC	Pagelet: the content reference is a pagelet used in the homepage.
TARG	Target: the content reference is the target content its template determines what else must be loaded and how it will look.
LINK	Link: the content reference is a link.

TARG is the default value on a new content reference.

This property is read/write.

Related Links

[Using Content References](#)

ValidFrom

Description

This property returns or sets the date this content reference is valid from as a string.

This property is read/write.

ValidTo

Description

This property returns or sets the date this content reference is valid until as a string.

This property is read/write.

Note: The portal registry API never uses the ValidTo and ValidFrom fields to determine what to return in a collection. You must check for these values in your application.

Content Reference Collection

The Content Reference Collection provides access to the collection of content references in a Folder object.

The Content Reference Collection is instantiated from the ContentRefs Folder property.

See [ContentRefs](#).

Content Reference Collection Methods

In this section, we discuss the Content Reference collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(ContentReferenceName)
```

Description

The DeleteItem method deletes the content reference object identified by *ContentReferenceName* from the content reference Collection.

If you delete a template for a content reference, and none of the other content references on a page have a template, the default template specified with the ContentProvider is used. If there's no template for the ContentProvider, the template for the PortalRegistry is used. However, if you delete the template for the content reference, the ContentProvider, and the PortalRegistry, you receive a runtime error.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for deletion, then actually deleted later. The item is deleted from the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ContentReferenceName</i>	Specify the name of a content reference existing in the content reference collection.

Returns

A Boolean value: True if the content reference was deleted, False otherwise.

Example

```
If Not &MyCRef.DeleteItem("Test_CRef") Then
    /* can't delete test data. Do error processing */
End-if;
```

First

Syntax

```
First()
```

Description

The First method returns the first content reference object in the content reference collection.

Parameters

None.

Returns

A content reference object.

Example

```
&MyCRef = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(ContentReferenceName, ContentReferenceLabel, Node, URL)
```

Description

The InsertItem method inserts the content reference object identified by *ContentReferenceName* into the content reference Collection.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for insertion, then actually inserted later. The item is inserted into the database as soon as the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ContentReferenceName</i>	Specify the name of a new content reference. This parameter takes a string value. If you specify a name that already exists in the collection, you get an error.
<i>ContentReferenceLabel</i>	Specify a description of the new content reference. This is the translated value. This parameter takes a string value.

Parameter	Description
<i>Node</i>	Specify a node. This parameter takes a string value. If you specify a fully qualified value for <i>URL</i> , you can specify a NULL (that is, two quotation marks with no space between them ("")).
<i>URL</i>	Specify a URL that contains the content. The format of this parameter depends on other properties, such as the type of content reference, where the data is stored, and so on.

Returns

A reference to the new content reference object if the method executed successfully, NULL otherwise.

Example

The following example inserts an external content reference that is a template:

```
&URL = "t/" | &ITEMNAME;
&MyCRef = &CRefColl.InsertItem(&ITEMNAME, &ITEMLABEL, "", &URL);
```

The following example inserts a content reference where URLType is iScript (USCR):

```
&URL = "s/WEBLIB_PORTAL.FieldFormula.Portal_Trans_Dyn"
&MyCRef = &CRefColl.InsertItem(&ITEMNAME, &ITEMLABEL, "HRMS", &URL);
```

Related Links

[Using Content References](#)

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the content reference object with the name *Name*.

Parameters

Parameter	Description
<i>Name</i>	Specify the name of an existing content reference within the content reference collection. If you specify an invalid name, the object is NULL.

Returns

A content reference object if successful, NULL otherwise.

Example

```
&MyCRef = &CRefColl.ItemByName("PORTAL_ADMIN");
```

Next

Syntax

```
Next()
```

Description

The Next method returns the next content reference object in the content reference collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

content reference object.

Example

```
&MyCRef = &MyCollection.Next();
```

Content Reference Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of content reference objects in the content reference Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

AttributeValue Class

The AttributeValue class provides access to attributes associated with either folders or content references.

AttributeValue objects are instantiated from an Attribute Collection Methods with the First, InsertItem, ItemByName, or Next methods.

See [Attribute Collection Methods](#).

See [Using Attributes](#).

AttributeValue Class Properties

In this section, we discuss the AttributeValue class properties. The properties are discussed in alphabetical order.

Label

Description

This property returns the label of the AttributeValue as a string. This property works with the Translatable property. If Translatable is set to True, the value of Label can be translated.

The length of this property is 30 characters.

This property is read/write.

Related Links

[Translatable](#)

Name

Description

This property returns the name of the AttributeValue as a string.

The length of this property is 30 characters.

This property is read-only.

Example

```
&AttrColl = &Folder.Attributes;  
&Attr = &AttrColl.First();  
  
    &Scroll = GetLevel0().GetRow(1).GetRowset(Scroll.PORTAL_FLDR_ATR);  
  
    &I = 1;  
    While All(&Attr)  
        &Record = &Scroll.GetRow(&I).GetRecord(Record.PORTAL_FLDR_ATR);
```

```

&Record.PORTAL_ATTR_NAM.Value = &Attr.Name;
&Record.PORTAL_ATTR_VAL.Value = &Attr.Value;
&Attr = &AttrColl.Next();
/* need this check so we don't insert extra blank row */
If All(&Attr) Then
    &Scroll.InsertRow(&I);
    &I = &I + 1;
End-If;
End-While;

```

Translatable

Description

This property specifies if the AttributeValue is translatable. This property takes a Boolean value: True if the AttributeValue can be translated, False otherwise.

If this property is set to True, the value of the Label property can be translated.

Note: Regardless of the order in which attributes were entered, they are ordered according to their translatable property, that is, attributes that have this property set as True come first, followed by attributes that have this property set as False.

This property is read/write.

Related Links

[Label](#)

Value

Description

This property returns the value of the AttributeValue as a string.

The length of this property depends on your system database limit for LONG fields.

This property is read/write.

Example

To specify more than a single value for an AttributeValue, you can specify several values separated by a semicolon. For example:

```
&MyAtt.value = "401k;benefits;dependants;HR";
```

Attribute Collection

The Attribute Collection provides access to the collection of Attribute in a Folder or a content reference object.

An Attribute Collection is instantiated from other classes as follows:

- From a content reference object with the Attributes property.
See [Attributes](#).
- From a Folder object with the Attributes property.
See [Attributes](#).
- From a PageletCategory object with the Attributes property.
See [Attributes](#).
- From a Pagelet object with the Attributes property.
See [Attributes](#).

Attribute Collection Methods

In this section, we discuss the Attribute collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(AttributeValueName)
```

Description

The DeleteItem method deletes the AttributeValue object identified by *AttributeValueName* from the Attribute Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>AttributeValueName</i>	Specify the name of an AttributeValue existing in the Attribute Collection.

Returns

A Boolean value: True if the AttributeValue was deleted, False otherwise.

First

Syntax

```
First()
```

Description

The First method returns the first AttributeValue object in the Attribute Collection.

Parameters

None.

Returns

An AttributeValue object.

Example

```
&MyAttributeValue = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(AttributeValueName)
```

Description

The InsertItem method inserts the AttributeValue object identified by *AttributeValueName* from the Attribute Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>AttributeValueName</i>	Specify the name of an AttributeValue existing in the Attribute Collection.

Returns

A reference to the new AttributeValue object if the method executed successfully, NULL otherwise.

Example

```

For &I = 1 To &Rowset.ActiveRowCount
  If &CompName = "PORTAL_CREF_ADM" Then
    &Record = &Rowset.GetRow(&I).GetRecord(Record.PORTAL_CATR_DV);
  Else
    &Record = &Rowset.GetRow(&I).GetRecord(Record.PORTAL_FATR_DV);
  End-If;

  If &Record.PORTAL_ATTR_NAM.Value <> "" Then
    &Attr = &AttrColl.InsertItem(&Record.PORTAL_ATTR_NAM.Value);
    &Attr.Value = &Record.PORTAL_ATTR_VAL.Value;
  End-If;
End-For;

```

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the AttributeValue object with the name *Name*.

Parameters

Parameter	Description
<i>Name</i>	Specify the name of an existing AttributeValue within the Attribute Collection. If you specify an invalid name, the object is NULL.

Returns

An AttributeValue object if successful, NULL otherwise.

Example

```
&Attr = &AttrColl.ItembyName("RELLINK");
```

Next

Syntax

Next ()

Description

The Next method returns the next AttributeValue object in the Attribute Collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

AttributeValue object.

Example

```
&MyAttributeValue = &MyCollection.Next();
```

Attribute Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of AttributeValue objects in the Attribute Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

PermissionValue Class

The PermissionValue provides access to permission lists associated with folders, content references, PageletCategory objects, or Pagelets.

Note: You *cannot* add any PermissionValue objects to a collection returned by the CascadedPermissions or CascadedRolePermissions property. You can add values only to the collection returned by the Permissions or RolePermissions property.

PermissionValue objects are instantiated from the following:

- A PermissionValue Collection with the First, InsertItem, ItemByName, or Next methods.
- A RolePermissionValue Collection with the First, InsertItem, ItemByName, or Next methods.

See [PermissionValue Collection](#).

See [Using Security](#).

See [Setting Permissions Using the PermissionValue Object](#).

PermissionValue Class Properties

In this section we discuss the Cascade and Name properties.

Cascade

Description

This property indicates whether the current permission should be granted to all child folders.

This property is valid only with folders, not with content references.

This property takes a Boolean value. The default value for a new PermissionValue object is False.

This property is read/write.

Name

Description

Specify the name of a permission list as the name of this object. You must specify a permission list that has already been created. This property takes a string value.

The length of this property is 30 characters.

This property is read/write.

PermType

Description

Specify the type of the permission. Values are:

<i>Value</i>	<i>Description</i>
P	Specify a non role-based permission.
R	Specify a role-based permission.

This property is read/write.

[RolePermissionValue Collection](#)

[PermissionValue Collection](#)

PermissionValue Collection

A PermissionValue collection is returned by the following:

- CascadedPermissions and Permissions folder property
- CascadedPermissions and Permissions content reference property
- CascadedPermissions and Permissions PageletCategory object property
- CascadedPermissions and Permissions Pagelet property

What is contained in the PermissionValue collection depends on the property that created it.

See [CascadedPermissions](#), [Permissions](#).

See [CascadedPermissions](#), [Permissions](#).

See [CascadedPermissions](#), [Permissions](#).

See [CascadedPermissions](#), [Permissions](#).

See [Using Security](#).

PermissionValue Collection Methods

In this section, we discuss the PermissionValue collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(PermissionValueName)
```

Description

The DeleteItem method deletes the PermissionValue object identified by *PermissionValueName* from the PermissionValue Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PermissionValueName</i>	Specify the name of a PermissionValue existing in the PermissionValue collection.

Returns

A Boolean value: True if the `PermissionValue` was deleted, False otherwise.

Example

```
If Not &MyPValColl.DeleteItem("ALLPNLS") Then
    /* do error processing */
End-If;
```

First

Syntax

```
First()
```

Description

The `First` method returns the first `PermissionValue` object in the `PermissionValue` collection.

Parameters

None.

Returns

A `PermissionValue` object.

Example

```
&MyPermissionValue = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(PermissionValueName)
```

Description

The `InsertItem` method inserts the `PermissionValue` object identified by *PermissionValueName* into the `PermissionValue` Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Note: You *cannot* add any `PermissionValue` objects to a collection returned by the `CascadedPermissions` property. You can only add values to the collection returned by the `Permissions` property.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PermissionValueName</i>	Specify the name of an existing permission list.

Returns

A reference to the new `PermissionValue` object if the method executed successfully, `NULL` otherwise.

Example

```
&MyPermV = &MyPermVColl.InsertItem("ALLPNLS");

If Not &MyPermV Then
    /* do error processing */
End-If;
```

ItemByName

Syntax

ItemByName (*Name*)

Description

The `ItemByName` method returns the `PermissionValue` object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing <code>PermissionValue</code> within the <code>PermissionValue</code> collection. If you specify an invalid name, the object is <code>NULL</code> .

Returns

A `PermissionValue` object if successful, `NULL` otherwise.

Example

```
&MyPVal = &MyPValColl.ItemByName("CUSTOMER");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next PermissionValue object in the PermissionValue collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

PermissionValue object.

Example

```
&MyPermissionValue = &MyCollection.Next();
```

PermissionValue Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of PermissionValue objects in the PermissionValue Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

RolePermissionValue Collection

A RolePermissionValue collection is returned by the following:

- CascadedRolePermissions and RolePermissions folder property

See [CascadedRolePermissions](#).

See [RolePermissions](#).

- CascadedRolePermissions and RolePermissions content reference property

See [CascadedRolePermissions](#).

See [RolePermissions](#).

- CascadedRolePermissions and RolePermissions content reference link property

See [CascadedRolePermissions](#).

See [RolePermissions](#).

What is contained in the RolePermissionValue collection depends on the property that created it.

RolePermissionValue Collection Methods

In this section, we discuss the RolePermissionValue collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(RolePermissionValueName)
```

Description

The DeleteItem method deletes the RolePermissionValue object identified by *RolePermissionValueName* from the RolePermissionValue Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RolePermissionValueName</i>	Specify the name of a RolePermissionValue existing in the RolePermissionValue collection.

Returns

A Boolean value: True if the RolePermissionValue was deleted, False otherwise.

Example

```
If Not &MyPValColl.DeleteItem("ALLPNLS") Then
```

```

    /* do error processing */
End-If;

```

First

Syntax

```
First()
```

Description

The First method returns the first RolePermissionValue object in the RolePermissionValue collection.

Parameters

None.

Returns

A RolePermissionValue object.

Example

```
&MyRolePermissionValue = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(RolePermissionValueName)
```

Description

The InsertItem method inserts the RolePermissionValue object identified by *RolePermissionValueName* into the RolePermissionValue Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Note: You *cannot* add any RolePermissionValue objects to a collection returned by the CascadedRolePermissions property. You can only add values to the collection returned by the RolePermissions property.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RolePermissionValueName</i>	Specify the name of an existing role permission list.

Returns

A reference to the new RolePermissionValue object if the method executed successfully, NULL otherwise.

Example

```
&MyPermV = &MyPermVColl.InsertItem("ALLPNLS");

If Not &MyPermV Then
    /* do error processing */
End-If;
```

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the RolePermissionValue object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing RolePermissionValue within the RolePermissionValue collection. If you specify an invalid name, the object is NULL.

Returns

A RolePermissionValue object if successful, NULL otherwise.

Example

```
&MyPVal = &MyPValColl.ItemByName("CUSTOMER");
```

Next

Syntax

Next ()

Description

The Next method returns the next RolePermissionValue object in the RolePermissionValue collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

RolePermissionValue object.

Example

```
&MyRolePermissionValue = &MyCollection.Next();
```

RolePermissionValue Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of RolePermissionValue objects in the RolePermissionValue Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

ContentReference Links

A content reference link is a ContentReference object that delegates most of its properties to another content reference. It has its own separate properties, as well as a reference to the linked cref.

A content reference link is instantiated from the following:

- CreateLink content reference method
- CreateContentRefLink PortalRegistry method

Note: The `CreateLink` method creates a new link. To instantiate an existing link use the `FindLinkByName` method.

Related Links

[CreateContentRefLink](#)

[FindCRefLinkByName](#)

[CreateLink](#)

ContentReference Links Methods

In this section, we discuss the ContentReference link methods. The methods are discussed in alphabetical order.

Delete

Syntax

```
Delete ()
```

Description

Use the delete method to delete the link from the database.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The link is not marked for deletion, then actually deleted later. The link is deleted from the database as soon as the method is executed.

Parameters

None.

Returns

A Boolean value: True if the content reference link and its associated objects are deleted successfully, False otherwise.

Save

Syntax

```
Save ()
```

Description

The Save method saves any changes you made to the content reference link, for example, a changed description or ValidFrom date.

After you create a link using either the `CreateLink` or `CreateContentRefLink` methods you must use the `Save` method to save the link to the database.

Using this method also saves any changes you made to `PermissionValue` or `AttributeValue` objects associated with this content reference link.

Parameters

None.

Returns

A Boolean value: True if the content reference link and its associated objects saved successfully, False otherwise. If False is returned, a message is also written to the `PSMessage` collection.

Example

```
If NOT(&MyCRefLink.Save()) Then
    /* save failed, do error processing */
End-If;
```

ContentReference Links Properties

In this section, we discuss the `ContentReference` link properties. The properties are discussed in alphabetical order.

AbsoluteContentURL

Description

This property returns the absolute content URL, that is, the content from the content servlet (`psc`). The content is displayed without any portal template.

This property is read-only.

Example

The following is an example absolute content URL:

```
http://serverx/psc/PS84/EMPLOYEEPORTAL/CRM/c/SFA.CUSTOMERINFO.GBL?page=CUST_DATA1&&→
Action=U&emplid=00001
```

AbsolutePortalURL

Description

This property returns the absolute content reference link portal URL. This URL also contains the content in the portal template.

This property is read-only.

Example

```
http://serverx/psp/PS84/EMPLOYEEPORTAL/CRM/c/SFA.CUSTOMERINFO.GBL?page=CUST_DATA1&&=>
Action=U&emplid=00001
```

Attributes

Description

This property returns an Attribute Collection containing the AttributeValues for this content reference link object.

This property is read/write.

Related Links

[Attribute Collection](#)

Author

Description

This property returns the author (PeopleSoft user ID) for this content reference link as a string.

This property is read-only.

AuthorAccess

Description

This property specifies whether the author of the content reference link has access to the content reference link. This property takes a Boolean value. The default value for this property is true.

This property is read/write.

Authorized

Description

This property specifies whether the user is authorized to view this content reference link.

This property is used when you access a particular content reference link using FindCRefLinkByURL. If you specified a valid content reference link, a content reference link is always returned, whether you are authorized to view it or not. This is the only property you can view from an object that you are not authorized to and the content reference is empty.

The initial value of this property depends on the other permission properties (PublicAccess and AuthorAccess) and the permission list values in the PermissionValue object associated with this content reference link.

This property is read-only.

Related Links

[FindCRefLinkByName](#)

CascadedPermissions

Description

This property returns a PermissionValue Collection. This collection contains the value of the permissions for all the parent objects (up to the root folder). To determine only the permissions of the object use the Permissions property instead.

Note: You cannot add any PermissionValue objects to a collection returned by the CascadedPermissions property. You can add values only to the collection returned by the Permissions property.

This property is read-only.

Related Links

[PermissionValue Collection](#)

[Permissions](#)

CascadedRolePermissions

Description

This property returns a RolePermissionValue Collection. This collection contains the value of the role-based permissions for all the parent objects (up to the root folder). To determine only the permissions of the object use the RolePermissions property instead. To determine the non role-based permissions of the object use the Permissions property instead.

Note: You cannot add any PermissionValue objects to a collection returned by the CascadedRolePermissions property. You can add values only to the collection returned by the RolePermissions property.

This property is read-only.

Related Links

[CascadedRolePermissions](#)

[RolePermissions](#)

[RolePermissionValue Collection](#)

ContentProvider

Description

This property returns the name of the node for the content reference link as a string.

This property is read-only.

CreationDate

Description

This property returns the creation date for this content reference link object as a string.

This property is read-only.

Data

Description

This property returns the data for this content reference link. This property is valid only when the `StorageType` property is `LOCL`.

The length of this property depends on your system database limit for `LONG` fields.

This property is read/write.

Example

```
&MyData = &MyCReflink.Data;
```

Related Links

[StorageType](#)

Description

Description

This property returns or sets the description for this content reference link object as a string.

The length of this property is 256 characters.

This property is translatable.

This property is read/write.

IsMobile

Description

Note: PeopleSoft Mobile Agent is a deprecated product. This mobile property currently exists for backward compatibility only.

This property returns True if this content reference link is used with mobile applications, False otherwise.

This property is read/write.

IsVisible

Description

This property returns True if the Hide from Portal Navigation check box is not selected when the content reference link is created. If the content reference link is hidden from portal navigation, this property returns False. Also, if the date associated with the link is not valid (is not within the valid to and valid from dates,) this property returns False.

Considerations Using IsVisible

If you do not specifically set this property on a new or copied content reference link, the IsVisible property is set as follows:

- If the ValidFrom date is less than or equal to that day's date, the IsVisible property is set to True.
- If there is no ValidTo date the IsVisible property is set to True.
- If the ValidTo date is greater than or equal to that day's date, the IsVisible property is set to True.

This property is read-only.

Related Links

[ValidFrom](#)

[ValidTo](#)

Label

Description

This property returns or sets the label for this content reference link object as a string.

The length of this property is 30 characters.

This property is translatable.

This property is read/write.

Name

Description

This property returns the name for this content reference link object as a string. The name is a unique identifier for each content reference link object. The name cannot start with a number, and it cannot have spaces and special characters.

Every content reference link name must be unique in the portal, not just in the parent folder.

This property is read/write.

OwnerId

Description

This property returns or sets the owner ID of the content reference link object as a string.

This property is read/write.

ParentName

Description

This property returns the parent folder name for this content reference link object as a string.

You can use this property to move the content reference link to another folder.

This property is read/write.

Example

The following example uses the ParentName to return a folder object for the content reference link.

```
&Folder = &Portal.FindFolderByName(&Creflink.ParentName);
```

Path

Description

The Path property returns a path to this content reference link, with each element of the path separated by a period. The path has the following syntax:

```
Root{PORTAL_ROOT_OBJECT}.LinkFolder {<Id of links folder>}.CrefLink {<Id of the cre=>
f link> }
```

This property is read-only.

Permissions

Description

This property returns a `PermissionValue` Collection. This collection contains the value of the non role-based permissions for this content reference link. To access the role-based permissions, use the `RolePermissions` property.

This property is read-only.

Related Links

[PermissionValue Collection](#)

[CascadedPermissions](#)

[RolePermissions](#)

Product

Description

This property returns or sets the PeopleSoft product for this content reference link object as a string.

The length of this property is 4 characters.

This property is read/write.

PublicAccess

Description

This property specifies whether the link is public or private. This property takes a Boolean value: true if the content reference link is public and there are no permission lists associated with it. If it is false, the link uses permission list control.

For links, this values is same as that of the linked content reference. If the content reference is public, the link is public and can be viewed by anyone logged on to the system.

This property is read-only.

RelativeURL

Description

This property returns the relative URL in the following format:

```
../../../../Portal/Node/Content_Type/ContentID
```

For example, from the following URL:

```
http://mlee2038/servlets/psp/PS84/e_procurement/fdm/c/E_PRO.CheckOut.GBL?page=view&⇒
```

```
Setid=110&Custid=99
```

The RelativeURL returns the following:

```
e_procurement/fdm/c/E_PRO.CheckOut.GBL?page=view&Setid=110&Custid=99
```

This property is read-only.

RolePermissions

Description

This property returns a RolePermissionValue Collection. This collection contains the value of the role-based permissions for this content reference link. To access the non role-based permissions, use the Permissions property.

This property is read-only.

Related Links

[CascadedRolePermissions](#)

[Permissions](#)

[RolePermissionValue Collection](#)

SequenceNumber

Description

The sequence number is used when returning a collection. The default order of the returned content reference links is based on the sequence number. Use this property to reorder content reference links. This property takes a number value.

If there are duplicates in the sequence number, the content reference links are returned alphabetically.

The length of this property is 4 characters.

This property is read/write.

Template

Description

This property returns or sets the name of the template used with this content reference link as a string. You must specify the name of an existing template.

This property uses the name, not the label, of a content reference link.

This property is used only when the UsageType property is specified as Target (TARG) and the TemplateType property is specified as HTML.

To return a reference to the content reference link that contains the template specified by this property, use the TemplateObject property.

The length of this property is 30 characters.

This property is read/write.

Related Links

[UsageType](#)

[TemplateType](#)

[TemplateObject](#)

TemplateObject

Description

This property returns a reference to a content reference link object that contains the template specified by the Template property as a content reference link. If no template is specified with Template, this property returns a null value.

This property is read-only.

Related Links

[Template](#)

TemplateType

Description

This property indicates whether a template should be used to wrap the content. This property takes a string value.

Values are:

<i>Value</i>	<i>Description</i>
HTML	An HTML template should wrap the data (URL) in the content reference.
NONE	No template should be used. The text should not be wrapped.

HTML is the default value on a new content reference.

Use the NONE value if the URL should not appear in the portal. An example is when the content reference link is a template itself.

If the homepage template for the user is un-retrievable, the system tries to use the default user's template first, before resorting to the portal default template.

When the content reference link describes content, this property should be set to HTML.

This property is read/write.

Related Links

[Using Content References](#)

URL

Description

This property returns the URL for this content reference link object as a string. The content reference link derives the URL from the content reference it is linked to. The URL of the link is same as that of the linked content reference.

A query string value is added on the content reference URL to make the link unique. If the URL of the linked content reference changes, this URL is changed.

This property is read-only.

Related Links

[AbsoluteContentURL](#)

[Using Content References](#)

URLType

Description

This property returns what kind of URL is used to retrieve the content.

This property is read-only.

Related Links

[StorageType](#)

UsageType

Description

This property returns what the content reference link is used for.

The value for this property is same as that of the content reference when the link is viewed as a content reference.

The usage type of the link is LINK in the database.

A content reference link can be created only for content references that have a type of TARG.

This property is read-only.

Related Links

[Using Content References](#)

ValidFrom

Description

This property returns or sets the date this content reference link is valid from as a string.

This property is read/write.

ValidTo

Description

This property returns or sets the date this content reference link is valid until as a string.

This property is read/write.

Note: The portal registry API never uses the ValidTo and ValidFrom fields to determine what to return in a collection. You must check for these values in your application.

Link Collection

A Links collection is returned by the Links content reference property.

Related Links

[Links](#)

Link Collection Methods

In this section, we discuss the link collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First ()
```

Description

The First method returns the first link object in the link collection.

Parameters

None.

Returns

A link object.

Next**Syntax**

`Next ()`

Description

The Next method returns the next link object in the collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A link object.

Link Collection Property

In this section, we discuss the link collection property Count.

Count**Description**

This property returns the number of link objects in the link collection, as a number.

This property is read-only.

Link Class

A Link object is returned by the First and Next Link collection methods.

Related Links

[Link Collection Methods](#)

Link Properties

In this section, we discuss the link properties. The properties are discussed in alphabetical order.

LinksObjectName

Description

This property returns the object name of the link as a string.

This property is read-only.

LinksObjectType

Description

This property returns the object type as a string. Valid value is CONTENTREF.

This property is read-only.

LinksPortalName

Description

This property returns the name of the portal from which the link originated.

This property is read-only.

TabDefinition Class

The TabDefinition class provides access to the homepage tab defined for the portal.

TabDefinition objects are instantiated from a TabDefinition Collection with the First, InsertItem, ItemByName, or Next methods.

See [TabDefinition Collection](#).

TabDefinition Class Methods

In this section, we discuss the Save method.

Save

Syntax

```
Save ()
```

Description

The Save method saves any changes you made to the TabDefinition, for example, a changed description. It also performs some validation.

Using this method also saves any changes you made to DynamicCategories and AssignedPagelets objects associated with this TabDefinition.

Parameters

None.

Returns

A Boolean value: True if the TabDefinition and its associated object saved successfully, False otherwise.

Example

```
If NOT(&MyTabDefn.Save()) Then  
    /* save failed, do error processing */  
End-If;
```

TabDefinition Class Properties

In this section, we discuss the TabDefinition class properties. The properties are discussed in alphabetical order.

AssignedPagelets

Description

This property returns a reference to an AssignedPagelet Collection for this TabDefinition object.

This property is read-only.

Related Links

[AssignedPagelet Collection](#)

AvailableCategories

Description

This property returns a reference to an AvailableCategory Collection for this TabDefinition object.

This property is read-only.

Related Links

AvailablePagelets

Description

This property returns a reference to an AvailablePagelet Collection for this TabDefinition object.

This property is read-only.

Related Links

[AvailablePagelet Collection](#)

Attributes

Description

This property returns an Attribute Collection containing the AttributeValues for this TabDefinition object.

This property is read-only.

Related Links

[Attribute Collection](#)

Author

Description

This property returns the author (PeopleSoft user ID) for this TabDefinition object as a string.

This property is read-only.

AuthorAccess

Description

This property specifies whether the author of the TabDefinition has access to the TabDefinition. This property takes a Boolean value. The default value for this property is True.

This property is read/write.

ColumnLayout

Description

This property indicates whether the tab layout is for two or three columns. This property takes a string value.

The values for this property are:

<i>Value</i>	<i>Description</i>
2	Two-column table
3	Three-column table

This property is read/write.

CreationDate

Description

This property returns the creation date for this TabDefinition object as a string.

This property is read-only.

Description

Description

This property returns or sets the description for this TabDefinition object as a string.

The length of this property is 256 characters.

This property is translatable.

This property is read/write.

DynamicCategories

Description

This property returns a reference to a DynamicCategory Collection for this TabDefinition object.

This property is read-only.

Related Links

[DynamicCategory Collection](#)

HelpID

Description

This property returns the help system identifier for this tab. It enables the help system to provide tab-specific help. This property takes a string value.

This property is read/write.

HtmlText

Description

This property returns the HTML text associated with this tab definition as a string.

This property is read-only.

IsHideActionBar

Description

This property hides all pagelet action bar images for all pagelets used on this tab. This property overrides any properties for the pagelets used on this tab. This property takes a Boolean value: True, hide images, False, display images

This property is read/write.

IsLayoutLocked

Description

This property indicates whether the user can change the tab's default number of columns. This property takes a Boolean value: True, the user can change the tab columns, False, the columns can't be changed by the user.

This property is read/write.

IsRenameable

Description

This property indicates whether the tab's label can be changed by the user. This property takes a Boolean value: True, the user can change the label, False, the user can't.

This property is read/write.

Label

Description

This property returns or sets the label for this TabDefinition object as a string.

The length of this property is 30 characters.

This property is translatable.

This property is read/write.

LayoutBehavior

Description

This property indicates whether the user can change when and how the tab displays. This property takes a string value.

The values are:

<i>Value</i>	<i>Description</i>
4OPT	The user can choose to add this tab to their homepage. It doesn't show up by default.
3DEF	The user sees this tab the first time they log in, however, they can remove this tab if they'd like.
2REQ	The user can't remove this tab from their homepage. However, they are allowed to change its sequence or order on the page.
1FIX	The user can't remove this tab or change its position on the page.

This property is read/write.

Name

Description

This property returns the name for this TabDefinition object as a string. The name is a unique identifier for each TabDefinition object.

Every TabDefinition name must be unique in the portal, not just in the parent folder.

This property is read-only.

OwnerId

Description

This property returns or sets the owner ID of the TabDefinition object as a string.

This property is read/write.

Product

Description

This property returns or sets the PeopleSoft product for this TabDefinition object as a string.

The length of this property is 4 characters.

This property is read/write.

PublicAccess

Description

This property indicates whether a TabDefinition is generally accessible, that is, if it is always included in the general TabDefinition collection. This property takes a Boolean value.

The default value for this property is False.

This property is read/write.

QualifiedURL

Description

This property returns an absolute URL. If the TabDefinition has a ContentProvider associated with it, the URI from the ContentProvider is concatenated with the URL from the TabDefinition. If there is no ContentProvider, this property returns the text in the URL property.

This property is read-only.

Related Links

[URL](#)

SequenceNumber

Description

The sequence number is used when returning a collection. The default order of the returned TabDefinitions is based on the sequence number. Use this property to reorder TabDefinitions. This property takes a number value.

If there are duplicates in the sequence number, the TabDefinitions are returned alphabetically.

The length of this property is 4 characters.

This property is read/write.

StyleSheet

Description

This property defines the style sheet to use for this tab. This property takes a string value. This property is 30 characters long.

If no style sheet is specified, the default style sheet PSSTYLEDEF is used.

This property is read/write.

ValidFrom

Description

This property returns or sets the date this TabDefinition is valid from as a string.

This property is read/write.

ValidTo

Description

This property returns or sets the date this TabDefinition is valid until as a string.

This property is read/write.

Note: The portal registry API never uses the ValidTo and ValidFrom fields to determine what to return in a collection. You must check for these values in your application.

TabDefinition Collection

A TabDefinition collection is the collection of all TabDefinitions for a portal.

A TabDefinition collection is returned by the TabDefinitions PortalRegistry property.

See [TabDefinitions](#).

TabDefinition Collection Methods

This section describes the TabDefinition collection methods in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(TabDefinitionName)
```

Description

The DeleteItem method deletes the TabDefinition object identified by *TabDefinitionName* from the TabDefinition Collection.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for deletion, then actually deleted later. The item is deleted from the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TabDefinitionName</i>	Specify the name of a TabDefinition existing in the TabDefinition collection.

Returns

A Boolean value: True if the TabDefinition was deleted, False otherwise.

Example

```
If Not &MyColl.DeleteItem("TabDefnTest") Then
  /* do error processing */
End-If;
```

First

Syntax

```
First()
```

Description

The First method returns the first TabDefinition object in the TabDefinition collection.

Parameters

None.

Returns

A TabDefinition object.

Example

```
&MyTabDefinition = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(TabDefinitionName)
```

Description

The InsertItem method inserts the TabDefinition object identified by *TabDefinitionName* into the TabDefinition Collection.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for insertion, then actually inserted later. The item is inserted into the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TabDefinitionName</i>	Specify the name of an existing permission list.

Returns

A reference to the new TabDefinition object if the method executed successfully, NULL otherwise.

Example

```
&MyTabDef = &MyColl.InsertItem("Empl_Homepage");

If Not &MyTabDef Then
    /* do error processing */
End-If;
```

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the TabDefinition object with the name *Name*.

Parameters

Parameter	Description
<i>Name</i>	Specify the name of an existing TabDefinition within the TabDefinition collection. If you specify an invalid name, the object is NULL.

Returns

A TabDefinition object if successful, NULL otherwise.

Example

```
&MyTabDefn = &MyColl.ItemByName("Empl_Homepage");
```

Next

Syntax

Next ()

Description

The Next method returns the next TabDefinition object in the TabDefinition collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

TabDefinition object.

Example

```
&MyTabDefinition = &MyCollection.Next();
```

TabDefinition Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of TabDefinition objects in the TabDefinition Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

AssignedPagelet Class

An AssignedPagelet is a pagelet object that has been assigned to a particular tab. This pagelet also contains the layout data that is specific to the pagelet and tab.

AssignedPagelet objects are instantiated from an AssignedPagelet Collection with the First, InsertItem, ItemByName, or Next methods.

See [AssignedPagelet Collection](#).

AssignedPagelet Class Properties

In this section, we discuss the AssignedPagelet class properties. The properties are discussed in alphabetical order.

Column

Description

This property returns the column in which this pagelet is displayed, as a number.

This property is read/write.

LayoutBehavior

Description

This property indicates whether the user can change when and how the pagelet displays. This property takes a string value.

The values are:

Value	Description
4OPT	The user can choose to add this pagelet to their tab. It doesn't show up by default. The user can remove and reposition this pagelet on the tab.
3DEF	The user sees this pagelet the first time they log in, however, they can remove or reposition this pagelet if they'd like.
2REQ	The user can't remove this pagelet from the tab. However, they are allowed to reposition the pagelet on the tab.
1FIX	The user can't remove this pagelet or change its position on the tab.

This property is read/write.

PageletName

Description

This property returns the name for this Pagelet object as a string. The name is a unique identifier for each Pagelet object.

This property is read-only.

Row

Description

This property returns the row in which this pagelet is displayed, as a number.

This property is read/write.

AssignedPagelet Collection

An AssignedPagelet collection is returned by the AssignedPagelet TabDefinition method.

It contains a collection of all the pagelets explicitly assigned to the tab.

See [AssignedPagelets](#).

See [AssignedPagelet Class](#).

AssignedPagelet Collection Methods

In this section, we discuss the AssignedPagelet collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(PageletName)
```

Description

The DeleteItem method deletes the AssignedPagelet object identified by *PageletName* from the AssignedPagelet Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PageletName</i>	Specify the name of an AssignedPagelet existing in the AssignedPagelet collection.

Returns

A Boolean value: True if the AssignedPagelet was deleted, False otherwise.

Example

```
If Not &MyColl.DeleteItem("Weather_411") Then
  /* do error processing */
End-If;
```

First

Syntax

```
First()
```

Description

The First method returns the first AssignedPagelet object in the AssignedPagelet collection.

Parameters

None.

Returns

An AssignedPagelet object.

Example

```
&MyAssignedPagelet = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(PageletName, Column, Row, LayoutBehavior)
```

Description

The InsertItem method inserts the AssignedPagelet object identified by the parameters into the AssignedPagelet Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

Parameter	Description
<i>PageletName</i>	Specify the name of the pagelet that you want to insert.
<i>Column</i>	Specify the column that you want this pagelet to display in, as a number.
<i>Row</i>	Specify the row that you want this pagelet to display in, as a number. You can specify a zero if you don't know which row.
<i>LayoutBehavior</i>	Specify whether the user can change when and how the pagelet displays. This property takes a string value. The values are:

Value	Description
4OPT	The user can choose to add this pagelet to their tab. It doesn't show up by default. The user can remove and reposition this pagelet on the tab.

Value	Description
3DEF	The user sees this pagelet the first time they log in, however, they can remove or reposition this pagelet if they'd like.
2REQ	The user can't remove this pagelet from the tab. However, they are allowed to reposition the pagelet on the tab.
1FIX	The user can't remove this pagelet or change its position on the tab.

Returns

A reference to the new AssignedPagelet object if the method executed successfully, NULL otherwise.

Example

```
&MyPagelet = &MyColl.InsertItem("Weather_411");

If Not &MyPagelet Then
    /* do error processing */
End-If;
```

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the AssignedPagelet object with the name *Name*.

Parameters

Parameter	Description
<i>Name</i>	Specify the name of an existing AssignedPagelet within the AssignedPagelet collection. If you specify an invalid name, the object is NULL.

Returns

An AssignedPagelet object if successful, NULL otherwise.

Example

```
&MyPagelet = &MyColl.ItemByName("Dictionary");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next AssignedPagelet object in the AssignedPagelet collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

An AssignedPagelet object.

Example

```
&MyAssignedPagelet = &MyCollection.Next();
```

AssignedPagelet Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of AssignedPagelet objects in the AssignedPagelet Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

AvailableCategory Class

An AvailableCategory class is composed of a category name and an AvailablePagelet Collection, that is, a collection of all the available pagelets associated with that category.

AvailableCategory objects are instantiated from an AvailableCategory Collection with the First, ItemByName, or Next methods.

See [AvailableCategory Collection](#).

AvailableCategory Class Properties

In this section, we discuss the AvailableCategory class properties. The properties are discussed in alphabetical order.

AvailablePagelets

Description

This property returns a reference to an AvailablePagelet Collection associated with the specified CategoryName.

This property is read-only.

Related Links

[AvailablePagelet Collection](#)

CategoryName

Description

Use this property to return the name of a category to be associated with the TabDefinition, as a string.

This property is read-only.

AvailableCategory Collection

An AvailableCategory is composed of a category name and an AvailablePagelet Collection, that is, a collection of all the available pagelets associated with that category.

An AvailableCategory collection is returned by the AvailableCategories TabDefinition property.

See [AvailableCategory Collection](#).

AvailableCategory Collection Methods

In this section, we discuss the AvailableCategory collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The First method returns the first AvailableCategory object in the AvailableCategory collection.

Parameters

None.

Returns

An AvailableCategory object.

Example

```
&MyAvailableCategory = &MyCollection.First();
```

ItemByName

Syntax

```
ItemByName (Name)
```

Description

The ItemByName method returns the AvailableCategory object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing AvailableCategory within the AvailableCategory collection. If you specify an invalid name, the object is NULL.

Returns

An AvailableCategory object if successful, NULL otherwise.

Example

```
&MyCat = &MyColl.ItemByName("Dictionary");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next AvailableCategory object in the AvailableCategory collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

AvailableCategory object.

Example

```
&MyAvailableCategory = &MyCollection.Next();
```

AvailableCategory Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of AvailableCategory objects in the AvailableCategory Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

AvailablePagelet Class

An AvailablePagelet is a pagelet object can be assigned to a particular tab. This includes all pagelets from the dynamic categories, and assigned pagelets. Each pagelet also contains the layout data that is specific to that pagelet.

AvailablePagelet objects are instantiated from an AvailablePagelet Collection with the First, ItemByName, or Next methods.

See [AvailablePagelet Collection](#).

AvailablePagelet Class Properties

In this section, we discuss the AvailablePagelet class properties. The properties are discussed in alphabetical order.

CategoryLabel

Description

This property turns the label of the category to which the pagelet is assigned, as a string.

This property is read-only.

CategoryName

Description

This property returns the name of the category to which the pagelet is assigned, as a string.

This property is read-only.

Column

Description

This property returns the column in which this pagelet is displayed, as a number.

This property is read-only.

LayoutBehavior

Description

This property indicates whether the user can change when and how the pagelet displays. This property takes a string value.

The values are:

Value	Description
4OPT	The user can choose to add this pagelet to their tab. It doesn't show up by default. The user can remove and reposition this pagelet on the tab.
3DEF	The user sees this pagelet the first time they log in, however, they can remove or reposition this pagelet if they'd like.
2REQ	The user can't remove this pagelet from the tab. However, they are allowed to reposition the pagelet on the tab.
1FIX	The user can't remove this pagelet or change its position on the tab.

This property is read only.

PageletLabel

Description

This property returns the label for this property as a string.

This property is read-only.

PageletName

Description

This property returns the name for this Pagelet object as a string. The name is a unique identifier for each Pagelet object.

This property is read-only.

Row

Description

This property returns the row in which this pagelet is displayed, as a number.

This property is read-only.

AvailablePagelet Collection

An AvailablePagelet collection is returned by the AvailablePagelet TabDefinition method.

It contains a collection of all the pagelets that could be assigned to the tab. It's an aggregation of the pagelets in the `AssignedPagelets` collection and all the pagelets in each of the categories in the `DynamicCategories` collection. Pagelet category sequence numbers, followed by pagelet sequence numbers, then name, sort this collection.

If you have two pagelets assigned with the same name (that is, an assigned pagelet and a dynamic category pagelet), the assigned pagelet takes precedence over the dynamic category one, and is the only one listed.

See [AvailablePagelets](#).

See [AvailablePagelet Class](#).

AvailablePagelet Collection Methods

In this section, we discuss the `AvailablePagelet` collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The `First` method returns the first `AvailablePagelet` object in the `AvailablePagelet` collection.

Parameters

None.

Returns

An `AvailablePagelet` object.

Example

```
&MyAvailablePagelet = &MyCollection.First();
```

ItemByName

Syntax

```
ItemByName(Name)
```

Description

The `ItemByName` method returns the `AvailablePagelet` object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing <code>AvailablePagelet</code> within the <code>AvailablePagelet</code> collection. If you specify an invalid name, the object is <code>NULL</code> .

Returns

An `AvailablePagelet` object if successful, `NULL` otherwise.

Example

```
&MyPagelet = &MyColl.ItemByName("DICTIONARY");
```

Next

Syntax

```
Next ()
```

Description

The `Next` method returns the next `AvailablePagelet` object in the `AvailablePagelet` collection. You can use this method only after you have used the `First` method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

`AvailablePagelet` object.

Example

```
&MyAvailablePagelet = &MyCollection.Next();
```

AvailablePagelet Collection Property

In this section, we discuss the `Count` property.

Count

Description

This property returns the number of AvailablePagelet objects in the AvailablePagelet Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

DynamicCategory Collection

A DynamicCategory collection contains a collection of PageletCategory names associated with a TabDefinition. The collection is initially ordered by category name.

When a PageletCategory is dynamic, it is immediately available to an end-user.

A DynamicCategory Collection is instantiated by the DynamicCategories property of a TabDefinition.

See [DynamicCategories](#).

DynamicCategory Collection Methods

In this section, we discuss the DynamicCategory collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(Name)
```

Description

The DeleteItem method deletes the PageletCategory object identified by *Name* from the DynamicCategory Collection. This does *not* delete the PageletCategory from the database, just from the DynamicCategory collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Note: If you delete a DynamicCategory, tabs with the attribute PORTAL_HPTAB_DYN lists must be searched for and updated (if necessary) to reflect the deleted category.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing category in the DynamicCategory collection.

Returns

A Boolean value: True if the PageletCategory was deleted from the DynamicCategory collection, False otherwise.

Example

```
If Not &MyColl.DeleteItem("Dictionaries") Then
    /* do error processing */
End-If;
```

First

Syntax

```
First()
```

Description

The First method returns the name of the first PageletCategory in the DynamicCategory collection.

Parameters

None.

Returns

A string.

Example

```
&MyDynamicCategory = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(Name)
```

Description

The `InsertItem` method inserts the `PageletCategory` object identified by *Name* into the `DynamicCategory` Collection. This does *not* insert the `PageletCategory` into the database, just into the `DynamicCategory` collection. After a `PageletCategory` is marked as dynamic, it is immediately available to the end-user.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the <code>DynamicCategory</code> to insert.

Returns

A string containing the name of the new `DynamicCategory` object if the method executed successfully, Null otherwise.

Example

```
&MyCat = &MyColl.InsertItem("User_Info");
```

ItemByName

Syntax

```
ItemByName (Name)
```

Description

The `ItemByName` method returns the name of the `PageletCategory` object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing <code>DynamicCategory</code> within the <code>DynamicCategory</code> collection. If you specify an invalid name, this method returns a Null string.

Returns

A string.

Example

```
&MyPagelet = &MyColl.ItemByName("Dictionary");
```

Next

Syntax

```
Next()
```

Description

The Next method returns the name of the next PageletCategory object in the DynamicCategory collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A string.

Example

```
&MyDynamicCategory = &MyCollection.Next();
```

DynamicCategory Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of PageletCategory names in the DynamicCategory Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

PageletCategory Class

A PageletCategory is a group of related pagelets, such as Weather, News, Reference, and so on. Each PageletCategory has a collection of pagelets associated with it.

A PageletCategory is instantiated from a PageletCategory Collection with the First, InsertItem, ItemByName, or Next methods.

All PageletCategory objects that are dynamic are contained in the DynamicCategory collection. The methods from this collection return the names of the PageletCategory objects only, not references to the objects themselves.

See [PageletCategory Collection](#).

PageletCategory Class Method

In this section, we discuss the Save method.

Save

Syntax

```
Save ()
```

Description

The Save method saves any changes you made to the PageletCategory, for example, a changed description or sequence number.

Parameters

None.

Returns

A Boolean value: True if the PageletCategory object is successfully saved, False otherwise.

Example

```
If Not (&MyPageletCategory.Save ()) Then  
    /* do error checking */  
End-If;
```

PageletCategory Class Properties

In this section, we discuss the PageletCategory class properties. The properties are discussed in alphabetical order.

Attributes

Description

This property returns an Attribute Collection containing the AttributeValues for this PageletCategory object.

This property is read-only.

Related Links

[Attribute Collection](#)

Author

Description

This property returns the author (PeopleSoft user ID) for this PageletCategory as a string.

This property is read-only.

AuthorAccess

Description

This property specifies whether the author of the PageletCategory has access to the PageletCategory. This property takes a Boolean value. The default value for this property for a newly created object is True. This property is not cascaded.

This property is read/write.

Authorized

Description

This property specifies whether the user is authorized to view this PageletCategory.

The initial value of this property depends on the other permission properties (PublicAccess and AuthorAccess) and the permission list values in the PermissionValue object associated with this PageletCategory.

This property is read-only.

CascadedPermissions

Description

This property returns a `PermissionValue` Collection. This collection contains the value of the permissions for all the child and parent objects (up to the root `PageletCategory`). To determine only the permissions of the object use the `Permission` property instead.

Note: The `PORTAL_PAGELETS` folder is the parent folder for all `PageletCategories`. Its security is set to public. PeopleSoft does not recommend cascading any permissions from this folder object. Cascade permissions only from the pagelet category (folder). You *cannot* add any `PermissionValue` objects to a collection returned by the `CascadedPermissions` property. You can add values only to the collection returned by the `Permissions` property.

This property is read-only.

Related Links

[PermissionValue Collection](#)

[Permissions](#)

CreationDate

Description

This property returns the creation date for this `PageletCategory` as a string.

This property is read-only.

Description

Description

This property returns or sets the description for this `PageletCategory` as a string.

The length of this property is 256 characters.

This property is translatable.

This property is read/write.

Label

Description

This property returns or sets the label for this `PageletCategory` as a string.

The length of this property is 30 characters.

This property is translatable.

This property is read/write.

Name

Description

This property returns the name for this PageletCategory as a sting. The name is a unique identifier for each PageletCategory.

Every PageletCategory name must be unique in across the portal, not just in the parent PageletCategory.

This property is *not* translatable. However, the values for the Label and Description properties are translatable.

This property is read-only.

Related Links

[Label](#)

OwnerId

Description

This property returns or sets the owner ID of the PageletCategory object as a string.

This property is read/write.

Pagelets

Description

This property returns a reference to a Pagelet Collection for this PageletCategory.

This property is read-only.

Related Links

[Pagelet Collection](#)

Permissions

Description

This property returns a PermissionValue Collection. This collection contains the value of the permissions for this PageletCategory.

Note: The PORTAL_PAGELETS folder is the parent folder for all PageletCategories. Its security is set to public. PeopleSoft does not recommend cascading any permissions from this folder object. Cascade permissions only from the pagelet category (folder).

This property is read-only.

Related Links

[PermissionValue Collection](#)

Product

Description

This property returns or sets the PeopleSoft product for this PageletCategory as a string.

The length of this property is 4 characters.

This property is read/write.

PublicAccess

Description

This property indicates whether a PageletCategory is generally accessible, that is, if this property is set to True, any user can access the PageletCategory. This property is not cascaded.

This property takes a Boolean value.

The default value for this property for a newly created object is False.

This property is read/write.

SequenceNumber

Description

The sequence number is used when returning a collection. The default order of the returned PageletCategory objects is based on the sequence number. Use this property to reorder PageletCategory objects.

If there are duplicates in the sequence number, the PageletCategory objects are returned in alphabetical order.

The length of this property is 4 characters.

This property is read/write.

PageletCategory Collection

The PageletCategory Collection provides access to a collection of PageletCategory objects in a PageletCategory object.

The PageletCategory Collection is instantiated from the PageletCategories PortalRegistry property.

See [PageletCategories](#).

PageletCategory Collection Methods

In this section, we discuss the PageletCategory collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem (PageletCategoryName)
```

Description

The DeleteItem method deletes the PageletCategory object identified by *PageletCategoryName* from the database.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for deletion, then actually deleted later. The item is deleted from the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PageletCategoryName</i>	Specify the name of a PageletCategory existing in the PageletCategory collection.

Returns

A Boolean value: True if the PageletCategory was deleted, False otherwise.

Example

```
If Not &MyPageletCategoryColl.DeleteItem("MYPAGELETCATEGORY") Then
  /* PageletCategory not deleted. Do error checking */
End-If;
```

First

Syntax

```
First ()
```

Description

The First method returns the first PageletCategory object in the PageletCategory collection.

Parameters

None.

Returns

PageletCategory object.

Example

```
&MyPageletCategory = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(PageletCategoryName, Label)
```

Description

The InsertItem method inserts the PageletCategory object identified by *PageletCategoryName* from the PageletCategory Collection. You must specify both a name and a label for each PageletCategory. This method returns a reference to the new PageletCategory object. You must specify a unique *PageletCategoryName*, or you receive an error.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for insertion, then actually inserted later. The item is inserted into the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PageletCategoryName</i>	Specify the name of a PageletCategory existing in the PageletCategory collection. This parameter takes a string value.
<i>Label</i>	Specify a label for the new PageletCategory. This parameter takes a string value.

Returns

A reference to the new PageletCategory object if the method executed successfully, False otherwise.

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the PageletCategory object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing PageletCategory within the PageletCategory collection. If you specify an invalid name, the object is NULL. You must specify a name, not a label.

Returns

A PageletCategory object if successful, NULL otherwise.

Next

Syntax

Next ()

Description

The Next method returns the next PageletCategory object in the PageletCategory collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A PageletCategory object.

PageletCategory Collection Property

In this section, we discuss the PageletCategory collection properties. The properties are discussed in alphabetical order.

Count

Description

This property returns the number of PageletCategory objects in the PageletCategory Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

Pagelet Class

A pagelet represents a URL that renders a section of content for a homepage. Pagelets are assigned to specific categories.

A pagelet is instantiated from the First, InsertItem, ItemByName, and Next Pagelet Collection methods.

See [Pagelet Collection](#).

Pagelet Class Method

In this section, we discuss the Save method.

Save

Syntax

```
Save ()
```

Description

The Save method saves any changes you made to the Pagelet, for example, a changed description or sequence number.

Parameters

None.

Returns

A Boolean value: True if the Pagelet object is successfully saved, False otherwise.

Example

```
If Not (&MyPagelet.Save()) Then
    /* do error checking */
End-If;
```

Pagelet Class Properties

In this section, we discuss the Pagelet class properties. The properties are discussed in alphabetical order.

Attributes

Description

This property returns an Attribute Collection containing the AttributeValues for this pagelet object.

This property is read-only.

Related Links

[Attribute Collection](#)

Author

Description

This property returns the author (PeopleSoft user ID) for this pagelet object as a string.

This property is read-only.

AuthorAccess

Description

This property specifies whether the author of the pagelet has access to the pagelet. This property takes a Boolean value. The default value for this property is True.

This property is read/write.

Authorized

Description

This property specifies whether the user is authorized to view this pagelet.

The initial value of this property depends on the other permission properties (PublicAccess and AuthorAccess) and the permission list values in the PermissionValue object associated with this pagelet.

This property is read-only.

CascadedPermissions

Description

This property returns a `PermissionValue` collection. This collection contains the value of the permissions for all the parent objects (up to the root folder). To determine only the permissions of the object use the `Permission` property instead.

Note: You *cannot* add any `PermissionValue` objects to a collection returned by the `CascadedPermissions` property. You can add values only to the collection returned by the `Permissions` property.

This property is read-only.

Related Links

[PermissionValue Collection](#)

[Permissions](#)

ContentProvider

Description

This property returns or sets the name of the node for the pagelet as a string.

If no node was specified when the pagelet was created, this property returns `Null`.

This property is read/write.

CreationDate

Description

This property returns the creation date for this pagelet object as a string.

This property is read-only.

DefaultColumn

Description

This property returns or sets the default column this pagelet displays in. This property takes a number value.

The default value for this property is 1.

This property is read/write.

Description

Description

This property returns or sets the description for this pagelet object as a string.

The length of this property is 256 characters.

This property is translatable.

This property is read/write.

EditPageContentProvider

Description

This is the node part of the URL to the page that enables a user to personalize a page. The default value is an empty string.

This property is read/write.

EditPageQueryString

Description

This is the query string part of the URL to the page that enables a user to personalize a page. The default value for this property is an empty string.

This property is read/write.

HelpID

Description

This property returns the help system identifier for this pagelet. It enables the help system to provide pagelet specific help. This property takes a string value.

This property is read/write.

IsHideMinimize

Description

This property specifies if the minimize image icon displays. This property takes a Boolean value: True, display the icon, False, hide the icon. The default value is True.

This property is read/write.

Label

Description

This property returns or sets the label for this pagelet object as a string.

The length of this property is 30 characters.

This property is translatable.

This property is read/write.

Name

Description

This property returns the name for this pagelet object as a string. The name is a unique identifier for each pagelet object.

Every pagelet name must be unique in the portal, not just in the parent folder.

This property is not translatable. However, the values for the Label and Description properties are.

This property is read-only.

OwnerId

Description

This property returns or sets the owner ID of the pagelet object as a string.

This property is read/write.

ParentName

Description

This property returns the parent folder name for this pagelet object as a string.

This property is read/write.

Permissions

Description

This property returns a PermissionValue Collection. This collection contains the value of the permissions for this pagelet. To determine the permissions for all the parent objects (up to the root folder) use the CascadedPermissions property.

This property is read-only.

Related Links

[PermissionValue Collection](#)

[CascadedPermissions](#)

Product

Description

This property returns or sets the PeopleSoft product for this pagelet object as a string.

The length of this property is 4 characters.

This property is read/write.

PublicAccess

Description

This property indicates whether a pagelet is generally accessible, that is, if it will always be included in the general pagelet collection. This property takes a Boolean value.

The default value for this property is False.

This property is read/write.

QualifiedURL

Description

This property returns an absolute URL. If the pagelet has a node associated with it, the URI from the node is concatenated with the URL from the pagelet. If there is no ContentProvider, this property returns the text in the URL property.

This property is read-only.

Related Links

[URL](#)

SequenceNumber

Description

The sequence number is used when returning a collection. The default order of the returned pagelets is based on the sequence number. Use this property to reorder pagelets. This property takes a number value.

If there are duplicates in the sequence number, the pagelets are returned alphabetically.

The length of this property is 4 characters.

This property is read/write.

URL

Description

This property returns or sets the URL for this pagelet object as a string. The URL returns *exactly* as it appears in the database.

If you're setting a URL, you must use a unique URL.

The absolute URL, that is, the URL from the ContentProvider concatenated with this URL must be unique.

You receive an error if the URL you use is already registered.

To retrieve a qualified URL, that is, one that contains the node URI, use the AbsoluteContentURL property.

The length of this property depends on your system database limit for LONG fields.

The format of the value for this property depends on the setting of other properties.

This property is read/write.

URLType

Description

This property indicates what kind of PeopleCode definition is used to retrieve the content of the pagelet. This property takes a string value.

Values are:

URLType Value	Meaning
UEXT	URL points to a non-PeopleSoft (external) URL
UPGE	URL points to a component.
UGEN	URL points to a generic PeopleSoft URL
USCR	URL points to an iScript

UPGE is the default value on a new pagelet.

This property is read/write.

Pagelet Collection

The Pagelet Collection provides access to the collection of pagelets in a category.

The Pagelet Collection is instantiated from the Pagelets PageletCategory property.

See [Pagelets](#).

Pagelet Collection Methods

In this section, we discuss the Pagelet collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem (PageletName)
```

Description

The DeleteItem method deletes the pagelet object identified by *PageletName* from the pagelet Collection.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for deletion, then actually deleted later. The item is deleted from the database as soon as the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PageletName</i>	Specify the name of a pagelet existing in the pagelet collection.

Returns

A Boolean value: True if the pagelet was deleted, False otherwise.

Example

```
If Not &MyColl.DeleteItem("Test_Pagelet") Then
  /* can't delete test data. Do error processing */
End-if;
```

First

Syntax

```
First()
```

Description

The First method returns the first pagelet object in the pagelet collection.

Parameters

None.

Returns

A reference to a pagelet object if successful, NULL otherwise.

Example

```
&MyCRef = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(PageletName, Label, NodeName, URL)
```

Description

The InsertItem method inserts the pagelet object identified by *PageletName* into the pagelet Collection.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for insertion, then actually inserted later. The item is inserted into the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PageletName</i>	Specify the name of a new pagelet. This parameter takes a string value. If you specify a name that already exists in the collection, you receive an error.
<i>Label</i>	Specify the label for the new pagelet. This parameter takes a string value.

Parameter	Description
<i>nodeName</i>	Specify a node. This parameter takes a string value. If you specify a fully qualified URL, you can specify a Null (that is, two quotation marks with no space between them ("")).
<i>URL</i>	Specify a URL that contains the content. The format of this parameter depends on other properties, such as the type of pagelet, where the data is stored, and so on.

Returns

A reference to the new pagelet object if the method executed successfully, NULL otherwise.

Related Links

[Using Content References](#)

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the pagelet object with the name *Name*.

Parameters

Parameter	Description
<i>Name</i>	Specify the name of an existing pagelet within the pagelet collection. If you specify an invalid name, the object will be NULL.

Returns

A reference to a pagelet object if successful, NULL otherwise.

Example

```
&MyPagelet = &CRefColl.ItemByName ("PORTAL_ADMIN");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next pagelet object in the pagelet collection. You can only use this method after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a pagelet object if successful, NULL otherwise.

Example

```
&MyPagelet = &MyCollection.Next ();
```

Pagelet Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of pagelet objects in the pagelet Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

UserHomepage Class

The UserHomepage represents a homepage for a user. It contains all the tabs and pagelets the user has selected for their homepage.

A UserHomepage is instantiated from the Homepage PortalRegistry property.

See [Homepage](#).

UserHomepage Class Method

In this section, we discuss the Save method.

Save

Syntax

```
Save ()
```

Description

The Save method saves any changes you made to the UserHomepage, for example, a changed greeting.

Using this method also saves any changes you've made to any UserTab or SelectedPagelet objects associated with this UserHomepage.

Parameters

None.

Returns

A Boolean value: True if the UserHomepage object is successfully saved, False otherwise.

Example

```
If Not (&MyHP.Save ()) Then  
    /* do error checking */  
End-If;
```

UserHomepage Class Properties

In this section, we discuss the UserHomepage properties. The properties are discussed in alphabetical order.

Greeting

Description

This property is a user-definable message that appears on their homepage when they login, such as "My Homepage" or "Welcome." This property takes a text string. The length of this character is 254.

This property is read/write.

UserId

Description

This property returns the UserId for this UserHomepage as a string.

This property is read-only.

UserTab

Description

This property returns a reference to a UserTab collection.

This property is read-only.

Related Links

[UserTab Collection](#)

UserTab Class

A UserTab is a personalized tab for a specific user. This user can potentially change the pagelets that appear on the tab, the name of the tab, and the order of the tab. All these changes can be allowed or denied on the TabDefinitions Class. The UserTab is used in place of the TabDefinition whenever a user has personalized a tab.

A UserTab object is instantiated from the First, ItemByName, InsertItem, or Next UserTab Collection methods.

See [UserTab Collection](#).

UserTab Class Properties

In this section, we discuss the UserTab class properties. The properties are discussed in alphabetical order.

ColumnLayout

Description

This property specifies how many columns the UserTab contains. This property takes a numeric value. The values are:

<i>Value</i>	<i>Description</i>
2	Two-column layout
3	Three-column layout. This is the default value.

This property is read/write.

Label

Description

This property returns or sets the label for this UserTab object as a string. This value is initially set to the Label of the TabDefinition.

The length of this property is 30 characters.

This property is translatable.

This property is read/write.

QualifiedURL

Description

This property returns an absolute URL as a string. This URL includes the URI from the TabDefinition's node and the URL that points to the actual content of the tab.

This property is read-only.

SelectedPagelets

Description

This property returns a SelectedPagelets Collection, containing the pagelets that have been selected by the user to appear on this tab.

This property is read-only.

Related Links

[SelectedPagelet Collection](#)

SequenceNumber

Description

This property specifies the order that this tab should appear as on the homepage. This property takes a number value. This value is initially set by the referenced TabDefinition.

This property is read/write.

TabName

Description

This property returns the tab name as a sting.

This property is read-only.

UserTab Collection

The UserTab collection is the collection of personalized tabs for a user.

The UserTab Collection is instantiated from the UserTabs UserHomepage property.

See [UserTab](#).

UserTab Collection Methods

In this section, we discuss the UserTab collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(UserTabName)
```

Description

The DeleteItem method deletes the UserTab object identified by *UserTabName* from the UserTab Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>UserTabName</i>	Specify the name of a UserTab existing in the UserTab collection.

Returns

A Boolean value: True if the UserTab was deleted, False otherwise.

Example

```
If Not &MyColl.DeleteItem("Test_UserTab") Then
    /* can't delete test data. Do error processing */
End-if;
```

First

Syntax

```
First()
```

Description

The First method returns the first UserTab object in the UserTab collection.

Parameters

None.

Returns

A UserTab object.

Example

```
&MyUserTab = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(UserTabName)
```

Description

The `InsertItem` method inserts the `UserTab` object identified by *UserTabName* into the `UserTab` Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

The new user tab must be unique within the portal.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>UserTabName</i>	Specify the name of a new <code>UserTab</code> . This parameter takes a string value. If you specify a name that already exists in the collection, you get an error.

Returns

A reference to the new `UserTab` object if the method executed successfully, `NULL` otherwise.

ItemByName

Syntax

`ItemByName` (*Name*)

Description

The `ItemByName` method returns the `UserTab` object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
Name	Specify the name of an existing <code>UserTab</code> within the <code>UserTab</code> collection. If you specify an invalid name, the object is <code>NULL</code> .

Returns

A `UserTab` object if successful, `NULL` otherwise.

Example

```
&MyUserTab = &MyColl.ItemByName("PORTAL_ADMIN");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next UserTab object in the UserTab collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A UserTab object.

Example

```
&MyUserTab = &MyCollection.Next ();
```

UserTab Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of UserTab objects in the UserTab Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

SelectedPagelet Class

The SelectedPagelet class contains data on pagelets selected by the user that display on this tab.

A SelectedPagelet object is instantiated by the First, InsertItem, ItemByName, and Next SelectedPagelet Collection methods.

See [SelectedPagelet Collection](#).

SelectedPagelet Class Properties

In this section, we discuss the SelectedPagelet class properties. The properties are discussed in alphabetical order.

CategoryName

Description

This property returns the category of the pagelet as a string.

This property is read-only.

Column

Description

This property returns the number of the column the pagelet displays in, as a number.

The values are:

<i>Value</i>	<i>Description</i>
1	First column
2	Second column
3	Third column

This property is read/write.

IsMinimized

Description

This property specifies whether the pagelet is displayed minimized. This property takes a Boolean value: True, the pagelet is minimized, False otherwise.

This property is read/write.

PageletName

Description

This property returns the name of the pagelet as a string.

This property is read-only.

Row

Description

This property specifies which row the pagelet is displayed in, as a number.

This property is read/write.

SelectedPagelet Collection

The SelectedPagelet collection contains a collection of all the selected pagelets for a tab.

A SelectedPagelet collection is instantiated by the SelectedPagelets UserTab property.

See [SelectedPagelets](#).

SelectedPagelet Collection Methods

In this section, we discuss the SelectedPagelet collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(SelectedPageletName)
```

Description

The DeleteItem method deletes the SelectedPagelet object identified by *SelectedPageletName* from the SelectedPagelet Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SelectedPageletName</i>	Specify the name of a SelectedPagelet existing in the SelectedPagelet collection.

Returns

A Boolean value: True if the SelectedPagelet was deleted, False otherwise.

Example

```
If Not &MyColl.DeleteItem("Test_SelectedPagelet") Then
    /* can't delete test data. Do error processing */
End-if;
```

First

Syntax

```
First()
```

Description

The First method returns the first SelectedPagelet object in the SelectedPagelet collection.

Parameters

None.

Returns

A SelectedPagelet object.

Example

```
&MySelectedPagelet = &MyCollection.First();
```

InsertItem

Syntax

```
InsertItem(SelectedPageletName, Column, Row)
```

Description

The InsertItem method inserts the SelectedPagelet object identified by *SelectedPageletName* into the SelectedPagelet Collection.

This method is not executed automatically. It is executed only when the parent object is saved.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SelectedPageletName</i>	Specify the name of a new SelectedPagelet. This parameter takes a string value. If you specify a name that already exists in the collection, you get an error.
<i>Column</i>	Specify the column number for this pagelet.
<i>Row</i>	Specify the row number for this pagelet.

Returns

A reference to the new SelectedPagelet object if the method executed successfully, NULL otherwise.

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the SelectedPagelet object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
Name	Specify the name of an existing SelectedPagelet within the SelectedPagelet collection. If you specify an invalid name, the object is NULL.

Returns

A SelectedPagelet object if successful, NULL otherwise.

Example

```
&MySelectedPagelet = &MyColl.ItemByName("PORTAL_ADMIN");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next SelectedPagelet object in the SelectedPagelet collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A SelectedPagelet object.

Example

```
&MySelectedPagelet = &MyCollection.Next();
```

SelectedPagelet Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of SelectedPagelet objects in the SelectedPagelet Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

Favorite Class

A favorite represents a content reference the user wants to keep a shortcut to. It contains the name of the content reference and the label the user wants to see displayed for this favorite. Labels must be unique in each favorite collection.

Use the Save method of the Favorite class to save any changes you made to any favorite objects.

A favorite object is instantiated by the First, InsertItem, ItemByName, and Next Favorite Collection methods.

See [Favorite Collection](#).

Favorite Class Properties

In this section, we discuss the Favorite class properties. The properties are discussed in alphabetical order.

CRefName

Description

This property returns the name of the content reference as a string.

This property is read-only.

IsFolder

Description

This property specifies a Boolean value indicating whether the favorite is a folder object. True, the favorite is a folder, False otherwise.

This property is read-only.

Label

Description

This property specifies the description of the favorite that's displayed to the user. This label must be unique for the favorite collection.

This property is read/write.

QualifiedURL

Description

This property returns the qualified URL for the content reference based on the Node and the URL for the name of the content reference, as a string.

This property is read-only.

SequenceNumber

Description

This property returns the sequence number used to order favorites.

This property is read/write.

URL

Description

This property returns the relative URL for this favorite as a string.

For example, the following code:

```
&URL = &MyFavorite.URL;
```

could return the following string:

```
c/PORTAL_PERS_HOMEPAGE.PORTAL_HOMEPAGE.GBL?PORTALPARAM_PAGE=CONTENT&tab=DEFAULT&Por=&MyFavorite=QEDMO
```

This property is read/write.

Favorite Collection

The favorite collection provides access to the favorites for a particular user.

A favorite collection is instantiated by the Favorites PortalRegistry property.

See [Favorites](#).

Favorite Collection Methods

In this section, we discuss the Favorite collection methods. The methods are discussed in alphabetical order.

DeleteItem

Syntax

```
DeleteItem(FavoriteLabel)
```

Description

The DeleteItem method deletes the Favorite object identified by *FavoriteLabel* from the Favorite Collection.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for deletion, then actually deleted later. The item is deleted from the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>FavoriteLabel</i>	Specify the label of a Favorite existing in the Favorite collection, that is, the text used to identify the favorite to the end-user.

Returns

A Boolean value: True if the Favorite was deleted, False otherwise.

Example

```
If Not &MyColl.DeleteItem("My Local Test") Then
    /* can't delete test data. Do error processing */
End-if;
```

First

Syntax

```
First()
```

Description

The First method returns the first Favorite object in the Favorite collection.

Parameters

None.

Returns

A Favorite object.

Example

```
&MyFav = &MyCollection.First();
```

InsertFolderItem

Syntax

```
InsertFolderItem(FavoriteLabel, FavoriteName)
```

Description

Use the InsertFolderItem method to insert the Favorite folder object identified by FavoriteName into the Favorite collection.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for insertion, then actually inserted later. The item is inserted to the database as soon as the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>FavoriteLabel</i>	Specify a label for the new Favorite folder as a string. This is the text by which the favorite is identified to the end user.
<i>FavoriteName</i>	Specify the name for the new Favorite folder as a string. If you specify a name that already exists in the collection, you get an error.

Returns

A reference to the new Favorite object if the method executes successfully, Null otherwise.

InsertItem

Syntax

```
InsertItem(FavoriteLabel, FavoriteName)
```

Description

The InsertItem method inserts the Favorite object identified by *FavoriteName* into the Favorite Collection.

Note: The portal registry classes execute some methods "interactively", that is, as they happen. The item won't be marked for insertion, then actually inserted later. The item is inserted to the database *as soon as* the method is executed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>FavoriteLabel</i>	Specify a label for the new Favorite. This is the text by which the favorite is identified to the end-user.
<i>FavoriteName</i>	Specify the name of a new Favorite. This parameter takes a string value. If you specify a name that already exists in the collection, you get an error.

Returns

A reference to the new Favorite object if the method executed successfully, NULL otherwise.

ItemByLabel

Syntax

```
ItemByLabel(FavoriteLabel)
```

Description

The ItemByLabel method returns the Favorite object with the label *FavoriteLabel*. The label is the text used to identify the favorite to the end-user.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>FavoriteLabel</i>	Specify the label of an existing Favorite within the Favorite collection. If you specify an invalid favorite, the object returned is Null.

Returns

A Favorite object if successful, Null otherwise.

Example

```
&MyFavorite = &MyColl.ItemByLabel("My Local Login");
```

Next

Syntax

```
Next()
```

Description

The Next method returns the next Favorite object in the Favorite collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A Favorite object.

Example

```
&MyFavorite = &MyCollection.Next();
```

Save

Syntax

```
Save ()
```

Description

Use the Save method to save any changes you made to the Favorite collection.

Parameters

None.

Returns

A Boolean value: True, the collection saved successfully, False otherwise.

Favorite Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of Favorite objects in the Favorite Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count
```

Portal Registry Classes Example

There are several actions you may want to perform using a PortalRegistry, such as adding a folder, changing permissions, and so on. The following examples discuss the most common tasks. In addition, there are example programs of accessing the PortalRegistry classes using language environments other than PeopleCode.

Changing PortalRegistry Properties

This example shows how to change the default template used by a PortalRegistry. The following is the complete code sample: the steps explain each line.

```
Local ApiObject &MySession;
Local ApiObject &MyPortal, &MyPortalColl;

/* Access the current session */

&MySession = %Session;
If NOT &MySession Then
    /* do error processing */
End-if;

&MyPortalColl = &MySession.FindPortalRegistries();

For &I = 1 to &MyPortalColl.Count

    &MyPortal = &MyPortalColl.Item(&I);

    If &MyPortal.DefaultTemplate = "HR99" Then
        &MyPortal.DefaultTemplate = "HR00"
        &MyPortal.Save();
    End-If

End-For;
```

To change PortalRegistry properties:

1. Get a Session object.

Before you can access a PortalRegistry object, you must get a session object. The session controls access to the registry, provides error tracing, enables you to set the runtime environment, and so on. Because you want to use the existing session, use the %Session system variable (instead of the GetSession function.)

```
&MySession = %Session;
```

2. Get a PortalRegistry collection.

Use the FindPortalRegistries method with no parameters to return a collection of all the PortalRegistries because you want to check all the registries for the invalid template.

```
&MyPortalColl = &MySession.FindPortalRegistries();
```

Use the Count property on the collection to loop through all the registries.

```
For &I = 1 to &MyPortalColl.Count
```

3. Get a PortalRegistry object.

You can access a PortalRegistry object from the PortalRegistry collection using the Item method.

```
&MyPortal = &MyPortalColl.Item(&I);
```

4. Check for the invalid template and correct if necessary.

Use the DefaultTemplate property both to check for the invalid template name, and to set the correct template. Save the PortalRegistry when you make a correction.

```
If &MyPortal.DefaultTemplate = "HR99" Then
    &MyPortal.DefaultTemplate = "HR00"
    &MyPortal.Save();
End-If;
```

You may want to do error checking after you save the PortalRegistry.

Adding a ContentProvider

The following example adds a ContentProvider to an existing PortalRegistry. The following is the complete code sample: the steps explain each line.

```
Local ApiObject &MyPortal;
Local ApiObject &MyCPColl, &MyCProvider;

&MyPortal = %Session.GetPortalRegistry();

If NOT &MyPortal.Open(MYRECORD.PORTAL_NAME) Then
    /* Do error handling */
End-if;

/* Add a ContentProvider */

&MyCPColl = &MyPortal.ContentProviders;

&MyCProvider = &MyCPColl.InsertItem("HRMS_00");

&MyCProvider.URI = "http://MYMACHINE103100/servlets/iclientservlet/HRMS/";
&MyCProvider.DefaultTemplate = "MYPORAL_HRMS";
&MyCProvider.Description = "Updated Content Provider for HRMS";

If NOT(&MyPortal.Save()) Then
    &ErrorCol = &MySession.PSMessages;
    For &I = 1 to &ErrorCol.Count
        &Error = &ErrorCol.Item(&I);
        /* do error processing */
    End-For;
&ErrorCol.DeleteAll();
End-If;
```

To add a ContentProvider:

1. Get a Session object and a PortalRegistry.

Before you can access a PortalRegistry object, you must get a session object. The session controls access to the registry, provides error tracing, enables you to set the runtime environment, and so on. Because you want to use the existing session, use the %Session system variable (instead of the

GetSession function.) In addition, you want to get a PortalRegistry. Using the GetPortalRegistry method returns a reference to an unpopulated PortalRegistry object.

```
&MyPortal = %Session.GetPortalRegistry();
```

2. Open the PortalRegistry.

After you get a PortalRegistry object, you want to open it, that is, populate it with data. Use the Open method to do this. The Open method returns a Boolean value, and this example uses that value to do error checking to make sure that the PortalRegistry is actually opened. In addition, the name of the PortalRegistry is kept in the record MYRECORD, in the field PORTAL_NAME.

```
If NOT &MyPortal.Open(MYRECORD.PORTAL_NAME) Then
  /* Do error handling */
End-if;
```

3. Access the ContentProvider collection.

You can only add a ContentProvider to a ContentProvider collection. So you must access a ContentProvider collection first, using the ContentProviders property on a PortalRegistry.

```
&MyCPColl = &MyPortal.ContentProviders;
```

4. Add the ContentProvider.

You must use the name of the ContentProvider with the InsertItem method. This example uses HRMS_00. This method does *not* execute automatically, that is, the ContentProvider isn't actually inserted into the database until the PortalRegistry is saved.

```
&MyCProvider = &MyCPColl.InsertItem("HRMS_00");
```

5. Further define the ContentProvider.

The URI of a ContentProvider is used in conjunction with content references to define the location of content. So you should define the URI. If a template isn't found for any of the content references on a page at runtime, the system next tries to use the DefaultTemplate defined for a ContentProvider, so you should define a default template.

```
&MyCProvider.URI = "http://MYMACHINE103100/servlets/iclientservlet/HRMS/";
&MyCProvider.DefaultTemplate = "MYPORTAL_HRMS";
&MyCProvider.Description = "Updated Content Provider for HRMS";
```

6. Save the PortalRegistry and check for errors.

Because there is no Save method with a ContentProvider, you must save the PortalRegistry to complete your changes.

You can check if there were any errors using the PSMessages property on the session object.

```
If NOT(&MyPortal.Save()) Then
  /* save didn't complete */
  &ErrorCol = &MySession.PSMessages;
  For &I = 1 to &ErrorCol.Count
    &Error = &ErrorCol.Item(&I);
    /* do error processing */
  End-For;
  &ErrorCol.DeleteAll();
End-if;
```

If there are multiple errors, all errors are logged to the PSMessages collection, not just the first occurrence of an error. As you correct each error, delete it from the PSMessages collection.

Note: If you've called the portal registry API from an Application Engine program, all errors are also logged in the Application Engine error log tables.

See [Error Handling](#).

Adding a Folder

The following example checks to see if a folder for a user exists. If it doesn't, it creates one.

The folder hierarchy for this example is as follows. The Users folder is where the portal stores things such as user homepages:

```
Root folder
  Users folder
    UserId1 folder
    UserId2 folder
    UserId3 folder
    . . .
```

The following is the complete code sample: the steps explain each line.

```
Local ApiObject &MyPortal;
Local ApiObject &UserFldrColl, &UserFldr;

&MyPortal = %Session.GetPortalRegistry();

If NOT &MyPortal.Open(MYRECORD.PORTAL_NAME) Then
  /* Do error handling */
End-if;

&UserFldrColl = &MyPortal.RootFolder.Folders.ItemByName("Users").Folders;
&UserFldr = &UserFldrColl.ItemByName(%UserId);

If &UserFldr = Null Then
  /* add Folder */

  &UserFldr = &UserFldrColl.InsertItem(%UserId, %UserId);
  &UserFldr.Description = %UserId;

  /* Set dates */

  &UserFldr.ValidFrom = %Date;
  &ToDate = AddToDate(%Date, 1, 1, 0);
  &UserFldr.ValidTo = &ToDate;

  /* Set properties */

  &UserFldr.PublicAccess = True;

  /* save the folder */

  &UserFldr.Save();

End-If;
```

To add a folder:

1. Get a Session object and a PortalRegistry.

Before you can access a PortalRegistry object, you must get a session object. The session controls access to the registry, provides error tracing, enables you to set the runtime environment, and so on. Because you want to use the existing session, use the %Session system variable (instead of the GetSession function.) In addition, you want to get a PortalRegistry. Using the GetPortalRegistry method returns a reference to an unpopulated PortalRegistry object.

```
&MyPortal = %Session.GetPortalRegistry();
```

2. Open the PortalRegistry.

After you get a PortalRegistry object, you want to open it, that is, populate it with data. Use the Open method to do this. The Open method returns a Boolean value, and this example uses that value to do error checking to make sure that the PortalRegistry is actually opened. In addition, the name of the PortalRegistry is kept in the record MYRECORD, in the field PORTAL_NAME.

```
If NOT &MyPortal.Open(MYRECORD.PORTAL_NAME) Then
    /* Do error handling */
End-if;
```

3. Access the User folder collection.

One of the strengths of dot notation is being able to string together many methods and properties into a single line of code. The result of this single line of code is to return a reference to the folder collection within the Users folder.

```
&UserFldrColl = &MyPortal.RootFolder.Folders.ItemByName("Users").Folders;
```

Note that in this kind of code, you must access the RootFolder for the PortalRegistry before you can access the folders collection.

If there were additional folders in your hierarchy, you could continue in the same way, using ItemByName and Folders.

4. Check if the user already has a folder.

The system variable %UserId returns the user ID of the current user. Then this example uses the ItemByName method on the folder collection to see if the user already has a folder. This assumes that the user folders are names according to the UserId. The ItemByName method returns a reference to the folder if it exists. If the folder does not exist, ItemByName returns NULL.

```
&UserFldr = &UserFldrColl.ItemByName(%UserId);
```

```
If &UserFldr = Null Then
```

5. Add a folder if one doesn't exist.

Use the UserId as the name of the folder, as well as for the label and the description.

```
&UserFldr = &UserFldrColl.InsertItem(%UserId, %UserId);
&UserFldr.Description = %UserId;
```

6. Set the ValidFrom and ValidTo dates.

For this example, the folder should be accessible from the date it's created, so the example sets the ValidFrom property to be today's date.

When you first create a folder, the ValidTo date, that is, the date that this folder "expires", is set to null, that is an empty string. This means it never expires. In this example, we set the ValidTo date to one year and one day after the current date.

```
&UserFldr.ValidFrom = %Date;
&ToDate = AddToDate(%Date, 1, 1, 0);
&UserFldr.ValidTo = &ToDate;
```

7. Set permissions for the folder.

There are several properties that work together to determine the access of a folder or content reference. This example sets the PublicAccess property to True, which means that everyone has access to it, and it's included in all collections of folders.

```
&UserFldr.PublicAccess = True;
```

This example sets only the permission properties on the folder. It doesn't set all the possible permissions, such as the PermissionValue objects for the folder.

8. Save the folder.

After you have finished your changes to the folder, save it.

```
&UserFldr.Save();
```

You may want to check for errors after you save each folder.

See [Using Security](#).

Adding a Content Reference

The following code example adds a content reference that's a target component to the Approve Expenses folder.

The folder hierarchy for this example is:

```
Root folder
  Expenses folder
    Create Expenses folder
    Review Expenses folder
    Approve Expenses folder
```

The following is the complete code sample: the steps explain each line.

```
Local ApiObject &MyPortal;
Local ApiObject &CRef, &CRefColl;
Local ApiObject &Fldr;

&MyPortal = %Session.GetPortalRegistry();

If NOT &MyPortal.Open(MYRECORD.PORTAL_NAME) Then
  /* Do error handling */
End-if;

&Fldr = &MyPortal.RootFolder.Folders.ItemByName("Expenses").Folders.ItemByName("Approve Expenses");
```

```

/* add content reference */

&CRef = &Fldr.ContentRefs.InsertItem(&CRefname, MYCP, MYRECORD.MYURL);
    &CRef.Description = &CRefname;

/* Set dates */
&CRef.ValidFrom = %Date;
&ToDate = AddToDate(%Date, 1, 1, 0);
&CRef.ValidTo = &ToDate;

/* Set content reference types */
&CRef.UsageType = "TARG"; /* Target content reference */
&CRef.URLType = "UPGE"; /* Component type of content reference */
&CRef.StorageType = "RMTE"; /* Template is remote. */
&CRef.Template = "EXPENSES_TEMPLATE"; /* name of template */
&CRef.TemplateType = "HTML"; /* type of Template */
/* Set URL */
&CRef.URL = "ICType=Panel&Menu=MANAGE_EXPENSES&Market=GBL&Component=APPROVE_FINAL"

/* Save the content reference */

&CRef.Save();

```

To add a content reference:

1. Get a Session object and a PortalRegistry.

Before you can access a PortalRegistry object, you must get a session object. The session controls access to the registry, provides error tracing, enables you to set the runtime environment, and so on. Because you want to use the existing session, use the %Session system variable (instead of the GetSession function.) In addition, you want to get a PortalRegistry. Using the GetPortalRegistry method returns a reference to an unpopulated PortalRegistry object.

```
&MyPortal = %Session.GetPortalRegistry();
```

2. Open the PortalRegistry.

After you get a PortalRegistry object, you want to open it, that is, populate it with data. Use the Open method to do this. The Open method returns a Boolean value, and this example uses that value to do error checking to make sure that the PortalRegistry is actually opened. In addition, the name of the PortalRegistry is kept in the record MYRECORD, in the field PORTAL_NAME.

```

If NOT &MyPortal.Open(MYRECORD.PORTAL_NAME) Then
    /* Do error handling */
End-if;

```

3. Access the folder collection.

One of the strengths of dot notation is being able to string together many methods and properties into a single line of code. The result of this single line of code is to return a reference to the folder collection within the folder.

```

&Fldr = &MyPortal.RootFolder.Folders.ItemByName("Expenses").Folders.ItemByName=>
("Approve Expenses");

```

The Adding a Folder example has more explanation on the break down of this line of code.

4. Add the content reference.

You can only add content references from the collection of content references for the folder. After you have the content reference collection, use the InsertItem method to add the content reference.

The ContentProvider for this content reference is named MYCP. The URL is stored in the record MYRECORD in the field MYURL.

```
&CRef = &Fldr.ContentRefs.InsertItem(&CRefname, MYCP, MYRECORD.MYURL);
&CRef.Description = &CRefname;
```

Note that the InsertItem method adds the content reference to the database as soon as it's executed. You could check for errors at this point to see if the content reference was added correctly.

5. Set the ValidFrom and ValidTo dates.

For this example, the content reference should be accessible from the date it's created, so the example sets the ValidFrom property to be today's date.

When you first create a content reference, the ValidTo date, that is, the date that this content reference "expires", is set to null, that is an empty string. This means it never expires. In this example, we set the ValidTo date to one year and one day after the current date.

```
&CRef.ValidFrom = %Date;
&ToDate = AddToDate(%Date, 1, 1, 0);
&CRef.ValidTo = &ToDate;
```

6. Set the type parameters.

Many content reference properties work together to set the type of content reference.

In this example, the content reference is a target. It's a component type of content reference, which means it's a PeopleSoft definition. The template to be used for displaying this content reference is stored remotely, its name is EXPENSES_TEMPLATE, and it's an HTML template.

```
&CRef.UsageType = "TARG"; /* Target content reference */
&CRef.URLType = "UPGE"; /* Component type of content reference */
&CRef.StorageType = "RMTE"; /* Template is remote. */
&CRef.Template = "EXPENSES_TEMPLATE"; /* name of template */
&CRef.TemplateType = "HTML"; /* type of Template */
```

7. Set the URL.

The URL property of the content reference indicates where the content actually is. As this content reference is referencing a page, the URL has a specific format to indicate which page.

```
&CRef.URL = "ICType=Panel&Menu=MANAGE_EXPENSES&Market=GBL&Component=APPROVE_FI⇒
NAL"
```

8. Save the content reference.

After you have finished adding the content reference, you should save it.

```
&CRef.Save();
```

You may want to check for errors after you save each content reference.

See [Adding a Folder](#).

Setting Permissions Using the PermissionValue Object

The following code example adds permissions for a folder through the PermissionValue object.

The following is the complete code sample: the steps explain each line.

```

Local ApiObject &MyPortal;
Local ApiObject &UserFldr;
Local ApiObject &PermV, &PermVColl;

&MyPortal = %Session.GetPortalRegistry();

If NOT &MyPortal.Open(MYRECORD.PORTAL_NAME) Then
  /* Do error handling */
End-if;

&UserFldr = &MyPortal.RootFolder.Folders.ItemByName("Users");

&CascadedColl = &UserFldr.CascadedPermissions;

&PermV = &CascadedColl.ItemByName("VENDOR1");

If NOT &PermV Then
  &PermVColl = &UserFldr.Permissions;
  &PermVColl.InsertItem("VENDOR1");
  &UserFldr.Save();
End-if;

```

To set permissions for a folder, using the PermissionValue object:

1. Get a Session object and a PortalRegistry.

Before you can access a PortalRegistry object, you must get a session object. The session controls access to the registry, provides error tracing, enables you to set the runtime environment, and so on. Because you want to use the existing session, use the %Session system variable (instead of the GetSession function.) In addition, you want to get a PortalRegistry. Using the GetPortalRegistry method returns a reference to an unpopulated PortalRegistry object.

```
&MyPortal = %Session.GetPortalRegistry();
```

2. Open the PortalRegistry.

After you get a PortalRegistry object, you want to open it, that is, populate it with data. Use the Open method to do this. The Open method returns a Boolean value, and this example uses that value to do error checking to make sure that the PortalRegistry is actually opened. In addition, the name of the PortalRegistry is kept in the record MYRECORD, in the field PORTAL_NAME.

```

If NOT &MyPortal.Open(MYRECORD.PORTAL_NAME) Then
  /* Do error handling */
End-if;

```

3. Access the User folder.

One of the strengths of dot notation is being able to string together many methods and properties into a single line of code. The result of this single line of code is to return a reference to the folder named Users.

```
&UserFldr = &MyPortal.RootFolder.Folders.ItemByName("Users");
```

4. Access the entire, cascaded PermissionValue collection.

There are two types of PermissionValue collections you can access for a folder.

- One contains only the permission list values that are set at that folder. This collection is returned with the Permissions property.

- The other contains all the permission list values for folder, that is, it contains any permission list values set in any parent folder and cascaded. This collection is returned with the CascadedPermissions property.

Note: You *cannot* add any PermissionValue objects to a collection returned by the CascadedPermissions property. You can add values only to the collection returned by the Permissions property.

This example uses the CascadedPermissions collection to check if the permission exists, because we don't want to add a permission if it already exists. Then it uses the Permissions collection to add the value.

```
&CascadedColl = &UserFldr.CascadedPermissions;
```

1. Check to see if the permission list value exists.

Before adding the new PermissionValue object, you want to make sure one by that name doesn't already exist.

```
&PermV = &CascadedColl.ItemByName("VENDOR1");
```

2. If the PermissionValue doesn't exist, add it.

The ItemByName returns a reference to a PermissionValue object if it exists, or NULL if it doesn't. So this example checks for NULL, and adds the PermissionValue if it doesn't exist.

Notice that this example is *not* changing the Cascaded property with the PermissionValue object. The default value for a new PermissionValue object is False. As this example does not want to cascade the permissions for this permission list, it retains the default value.

In addition, if the PermissionValue object is added, the folder is saved. The InsertItem method executes only after the parent object, the folder, is saved.

```
If NOT &PermV Then
    &PermVColl = &UserFldr.Permissions;
    &PermVColl.InsertItem("VENDOR1");
    &UserFldr.Save();
End-If;
```

You may want to check for errors after you save the folder.

See [Permissions](#), [CascadedPermissions](#).

See [Using PermissionValue](#), [RolePermissionValue](#), [Cascading Permissions and CascadingRolePermissions](#).

Using Attributes

The following example uses attributes for a folder to determine what is displayed to an end-user. The end-user still has access to the content, however, it isn't displayed. This program doesn't discuss how to hide or display content: it just shows the function used to determine if a folder should be displayed.

The following is the complete code sample: the steps explain each line.

```
Function checkVisible(&FolderId As ApiObject) Returns Boolean
    &colAttrib = &FolderId.Attributes;

    If &colAttrib.ItemByName("PORTAL_HIDE_FROM_NAV") <> Null Then
```

```

        If &colAttrib.ItemByName("PORTAL_HIDE_FROM_NAV").value = "TRUE" Then
            &display = False;
        End-If;
    End-If;

    Return &display;
End-Function;

```

To use attributes for a folder:

1. Access the folder attribute collection.

A reference to a folder is passed into the function. Then the example uses the `Attributes` property on the folder to access the attribute collection for the folder.

```
&colAttrib = &FolderId.Attributes;
```

2. Check to see if the folder should be hidden.

This step is actually two checks. The first check is to see if there is an attribute with the folder called `PORTAL_HIDE_FROM_NAV`. If the folder has such an attribute, the second check determines the value of this attribute. If both are true, the folder should be hidden, so the variable `&display` is set to `True`, and returned.

```

If &colAttrib.ItemByName("PORTAL_HIDE_FROM_NAV") <> Null Then
    If &colAttrib.ItemByName("PORTAL_HIDE_FROM_NAV").value = "TRUE" Then
        &display = False;
    End-If;
End-If;

Return &display;

```

Visual Basic Example

The following is an example referencing a `PortalRegistry` object using Visual Basic.

```

Dim oCref As ContentRef
Dim oCrefColl As ContentRefCollection

Set oSession = CreateObject("PeopleSoft.Session")
iResult = oSession.Connect(1, AppServStr, OperID, OperPasswd, 0)

Set oPortal = oSession.GetPortalRegistry
iResult = oPortal.Open("PORTAL")

Set oCrefColl = oPortal.RootFolder.ContentRefs
Set oCref = oCrefColl.InsertItem("papi012")
iResult = oPortal.Close

iResult = oPortal.Open("PORTAL")

Set oCref = oPortal.FindCRefByName("papi012")

oPortal.Close
oSession.Disconnect
Exit Sub

```

C/C++ Example

The following is a C/C++ example.

```

PostReport Class

PostReport Class Overview

The PostReport class provides properties and method for posting reports to the Report Repository. This class enables you to create reports outside of Process Scheduler and have them posted in the Report Repository.

The request to post reports creates an entry to the Report Manager table. The Distribution Agent polls the Report Manager table for any new requests and proceeds with any request it finds by transferring the files to the repository server. The report can then be accessed from the Report Manager after the Distribution Agent successfully processes the post request.

Related Links

"Understanding Report Manager" (Process Scheduler)

Determining the Distribution List

Use the AddDistributionOption method to authorize users to view the report from the Report Manager. This function enables you to grant access to the report either specifying a User ID or Role. However, if no distribution list is specified in the request, the class queries the system for the distribution list as follows:

1. If the Process Instance is specified, the system checks for the distribution list in the Process Request table. The system assumes in this case that the request was scheduled through the Process Request Dialog, but was processed by a third-party scheduler.
 2. If a Process Name and Process Type properties were specified, the system checks if a distribution list was predefined in the Process Definition table.
 3. If no list was found using the above queries, the user who submitted the request has sole access to the report.
-

Data Type of a PostReport Object

A PostReport object is declared using the PostReport data type. For example:

```
Local PostReport &POSTRQST;
```

Scope of a PostReport Object

A PostReport object can only be instantiated from PeopleCode. However, if you need to access the Process Schedule Manger from outside of PeopleCode, like in a Visual Basic program, you can use the Process Schedule Manager API.

This object can be used anywhere you have PeopleCode, that is, in an application class, Component Interface PeopleCode, record field PeopleCode, and so on.

PostReport Class Methods

In this section, we discuss the PostReport class methods. The methods are discussed in alphabetical order.

AddDistributionOption

Syntax

```
AddDistributionOption(DistIdType, DistId)
```

Description

Use the AddDistributionOption method to specify the users authorized to view the report once it is available in the Report Manager.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>DistIdType</i>	Specify the distribution ID type as a string. This identifies if the value passed in the DistID is either a user or role. Values for this parameter are: <ul style="list-style-type: none"> User Role
<i>DistID</i>	Specify the distribution ID as a string.

Returns

Returns a number: 0 if successful, 1 if the system detected an error in the parameter passed.

Example

The following example grants access to the VP1 user and all users associated with the MANAGERS role.

```
&POSTRQST.AddDistributionOption("User", "QEDMO" );
&POSTRQST.AddDistributionOption("Role", "MANAGERS");
```

Put

Syntax

```
Put ( )
```

Description

The Put method inserts a request in the Report Manager table which runs according to the values in the properties of the PostReport object. In order to successfully schedule a process or job, certain properties are required.

Parameters

None.

Returns

None. If you want to verify that the method executed successfully, check the value of the Status property.

Example

```
&POSTRQST.Put ( );
&RPTINSTANCE = &POSTRQST.ReportId;
If (&RPTINSTANCE > 0) Then
    MessageBox(0, "", 63, 119, "Successfully processed request with Rpt. ID %1 fo⇒
r Process %2 to post from directory %3", &RPTINSTANCE, &POSTRQST.ProcessName, &POST⇒
RQST.SourceReportPath);
Else
    MessageBox(0, "", 63, 122, "Not successful for process request for Process %1⇒
to post from directory %2", &POSTRQST.ProcessName, &POSTRQST.SourceReportPath);
End-If;
```

"SetPostReport" (PeopleCode Language Reference)

PostReport Class Properties

In this section, we discuss the PostReport class properties. The properties are discussed in alphabetical order.

ExpirationDate

Description

This property specifies the date the report will be deleted from the Report Manager table. If the expiration date is not specified, the system calculates the expiration date based on the Retention Days specified in the Process Scheduler's System Settings.

This property is read/write.

Example

```
&MYRQST.ExpirationDate = "2003/01/01";
```

Related Links

"Defining System Settings" (Process Scheduler)

OutDestFormat

Description

This property specifies the output format of the file that is posted to the Report Repository. If format is not specified, the system determines the format based on the extension of the file being posted to the Report Repository.

This property is read/write.

Example

```
&MYRQST.OutDestFormat = "PDF";
```

Related Links

[Values for Output Type and Format](#)

ProcessInstance

Description

This property specifies the instance number assigned to request. This property is only required if the report was initially submitted through the Process Request Dialog, but was processed by a third-party scheduler.

This property is read/write.

Related Links

[Determining the Distribution List](#)

ProcessName

Description

This property specifies the name of a predefined process as a string.

This property is read/write.

Example

```
&MYRQST.ProcessName = "XRFWIN";
```

Related Links

[ProcessType](#)

[RunControlID](#)

ProcessType

Description

This property specifies the name of a predefined process type as a string.

This property is read/write.

Example

Note that spaces are included in the string for ProcessType.

```
&MYRQST.ProcessType = "Application Engine";
```

Related Links

[ProcessName](#)

[RunControlID](#)

ReportDescr

Description

This property specifies the description as a string.

If the ReportDescr property is not specified, and both Process Name and Process Type are not null, the description is extracted from the Process Definition table.

This property is read/write.

Example

```
&MYRQST.ReportDescr = "Panel Cross Reference Report";
```

ReportFolder

Description

This property specifies the name of the report folder as a string. If you specify a folder, the folder that you specify must have already been defined using Process Scheduler's Report Folders Administration.

This property is read/write.

Related Links

"Understanding Report Folders" (Process Scheduler)

ReportId

Description

This property is a system-generated identification number. The system assigns a ReportId after the Put method processed the request.

This property is read/write.

Example

```
&MYRQST.Put();
if &MYRQST.ReportId > 0 then
    MessageBox(o, "", 63, 119, "Sucessfully processed request with Rpt. ID %1", &M⇒
YRQST.ReportId);
Else
    /* do error processing */
End-If;
```

ServerName

Description

This property specifies the Process Scheduler Server name that posts the report. This property takes a string value.

This property is read/write.

Example

```
&MYRQST.ServerName = "PSNT";
```

Related Links

"Defining System Settings" (Process Scheduler)

SourceReportPath

Description

This property specifies the path that contains the source report. You need to specify an absolute path.

This property is read/write.

PostReport Class Examples

The following example posts files found in the directory 'c:\temp\SQRDIR' and can be accessed by VP1 and users in the MANAGERS role.

```
Local PostReport &RPTINFO;
  Local number &RPTINSTANCE

  /*****
  * Construct a PostReport Object.
  *****/
  &RPTINFO = SetPostReport();

  &RPTINFO.ProcessName = "GLS7009";
  &RPTINFO.ProcessType = "SQR Report";
  &RPTINFO.ReportFolder = "Financial";
  &RPTINFO.SourceReportPath = "c:\temp\SQRDIR";
  &RPTINFO.ExpirationDate = "2005/01/01";
  &RPTINFO.ReportDescr = "Journal Posting Summary Report";
  &RPTINFO.ServerName = "PSNT";

  &RPTINFO.AddDistributionOption("USER", "VP1");
  &RPTINFO.AddDistributionOption("ROLE", "MANAGERS");

  &RPTINFO.Put();
  &RPTINSTANCE = &RPTINFO.ReportId;

  If (&RPTINSTANCE > 0) Then
    MessageBox(0, "", 63, 119, "Successfully processed request with Rpt. ID %1 fo→
r Process %2 to post from directory %3", &RPTINSTANCE, &RPTINFO.ProcessName, &RPTIN→
FO.SourceReportPath);
  Else
    MessageBox(0, "", 63, 122, "Not successful for process request for Process %1→
to post from directory %2", &RPTINFO.ProcessName, &RPTINFO.SourceReportPath);
  End-If;
```

Process Request Classes

Understanding Process Request Classes

The `ProcessRequest` class provides properties and a method for scheduling a pre-defined process or job. You must define the process or the job (using Process Scheduler Manager) *before* you can schedule it using the `ProcessRequest` class.

The properties of this class contain the same values as those required by Process Scheduler Manager for scheduling a process or job. Values you provide for these properties may override the equivalent values set in Process Scheduler Manager, depending on the override settings you make in PeopleSoft Process Scheduler pages.

Starting with PeopleSoft 8.4, PeopleSoft supports only the `ProcessRequest` class to schedule a process or a job in PeopleCode. The `ScheduleProcess` PeopleCode function is no longer supported. Any existing PeopleCode functions containing this deprecated function must be modified to use the `ProcessRequest` class to schedule a request.

This topic assumes that the reader has working knowledge of PeopleSoft Process Scheduler.

[ProcessRequest Class Examples](#)

Data Type of a ProcessRequest Object

A `ProcessRequest` object is declared using the `ProcessRequest` data type. For example:

```
Local ProcessRequest &RQST;
```

Scope of a ProcessRequest Object

A `ProcessRequest` object can be instantiated only from PeopleCode. However, if you need to access the Process Scheduler Manager from outside of PeopleCode, for example, in a Visual Basic program, you can use the Process Scheduler Manager API.

This object can be used anywhere you have PeopleCode, that is, in an application class, Component Interface PeopleCode, record field PeopleCode, and so on.

Options for Items In Jobs and Jobsets

A key feature of PeopleSoft Process Scheduler is the option to create a Job Definition consisting of other jobs. A job containing a job is called a *jobset*. Process Scheduler Server schedules the items within these jobs according to how the jobset is defined through the Process Scheduler Manager.

The ProcessRequest class requires the following properties to handle jobsets:

- JobName: indicates the name of the job that an item belongs to.
- PrcsItemLevel: indicates a job item’s process item level within a jobset.
- JobSeqNo: indicates a job item’s job sequence number within the Process Item Level.

The following is a simple example of a job containing only a single process:

This example illustrates the fields and controls on the Sample job with single process. You can find definitions for the fields and controls later on this page.

Job Name: 3SQR SQR Job

 **3SQR**

-  1 XRFAPFL: Applications and Fields Cross (SQR Report)
-  2 XRFANEL: Panel Cross Reference Report (SQR Report)
-  3 XRFPCFL: PeopleCode and Field Cross Ref (SQR Report)

<i>Process</i>	<i>PrcsItemLevel</i>	<i>JobName</i>	<i>JobSeqNo</i>
3SQR	0		0
XRFAPFL	1	3SQR	1
XRFANEL	2	3SQR	2
XRFPCFL	3	3SQR	3

The following is an example of a jobset containing multiple jobs:

This example illustrates the fields and controls on the Sample jobset containing multiple jobs. You can find definitions for the fields and controls later on this page.

<i>Process</i>	<i>PrclsItemLevel</i>	<i>JobName</i>	<i>JobSeqNo</i>
MULTIJOB	0		0
AP_APY2015	1	MULTIJOB	1
AP_PSTPYMNT	1	MULTIJOB	2
BI JOBS	1	MULTIJOB	3
BIJOB01	2	BI JOBS	1
BIIVC000	3	BIJOB01	1
BIIVCLN	3	BIJOB01	2

Process	PrclsItemLevel	JobName	JobSeqNo
BIIVCPN	3	BIJOB01	3
BIIVCEN	3	BIJOB01	4
BIJOB02	2	MULTIJOB	2
BIIVC000	3	BIJOB02	1
BIIVCLC	3	BIJOB02	2
BIIVCPC	3	BIJOB02	3
BIIVCEN	3	BIJOB02	4
BIJOB03	2	MULTIJOB	3
BIIVC000	3	BIJOB03	1
BIIVCLN	3	BIJOB03	2
BIIVCPN	3	BIJOB03	3
BIIVCEN	3	BIJOB03	4
BICURCNV	3	BIJOB03	5
BILDAR01	3	BIJOB03	6
BILDGL01	3	BIJOB03	7
BIGNAP01	3	BIJOB03	8

All the class methods that are used to change options for items within a job or jobset, use these attributes as optional parameters.

If a method is used without specifying any of these parameters, the system assumes the changes apply to *all* items within a jobset.

If one or more of these attributes are specified, the method applies the changes to items matching the value of these attributes.

In the case where a JobName is specified, the changes apply to all items within the specified job.

Specific methods used to manipulate options within a job or jobset include:

- AddDistributionOption
- SetEmailOption
- SetItemFolder
- SetOutputOption

When manipulating the options within a job or jobset, you must specify the process type and process name in the CreateProcessRequest function when instantiating a ProcessRequest object. This is required as the class needs to retrieve the job item information from the job definition for a specific job or jobset. The class uses this information to alter items within the job or jobset based on subsequent method calls made prior to scheduling the request. If the process type and process name are not specified when instantiating the ProcessRequest object, all PeopleCode programs trying to use any of the methods return an error message:

```
The method can not be used because the ProcessRequest is not properly initialized
```

In the previous jobset example, the ProcessRequest must be instantiated as follows:

```
Local ProcessRequest &RQST;
&RQST = CreateProcessRequest("PSJob", "MULTIJOB");
```

The following code examples use the previous example MULTIJOB, and show how items can be altered within a job or jobset:

- Change all items in the Jobset to “Web” with reports generated in PDF format:

```
&RQST.SetOutputOption("Web", "PDF", "", "MULTIJOB");
```

Alternatively, this can also be coded as follows:

```
&RQST.SetOutputOption("Web", "PDF", "");
```

- Change the output option for job BIJOB02 to “Email” with reports generated in HTM format:

```
&RQST.SetOutputOption("Email", "HTM", "", "BIJOB02");
```

- Change the output option for BIIVCPN in job BIJOB01 to “File” in LP (LinePrinter) format:

```
&RQST.SetOutputOption("File", "LP", "BIJOB01", 3, 3);
```

- Change all items in level three to “Web” in PS (PostScript) format:

```
&RQST.SetOutputOption("Web", "PS", "", "", 3);
```

Values for Output Type and Format

The values for output type and format are based on the generic process type assigned to a process type definition. The following table provides a cross-reference listing for all delivered process type definitions.

Generic Process Type	Process Type
AppEngine	Application Engine, Optimization Engine
COBOL	COBOL SQL
Cube	CubeBuilder, HyperCube Builder
SQR	SQR Process, SQR Report
Winword	Winword
nVision	nVision, nVision-Report, nVision-ReportBook
Data Mover	Data Mover
Other	Essbase

The following table lists all the values for OutDestType delivered with PeopleTools.

However, the values and defaults can be customized through Process Scheduler Manager. Please refer to the PeopleSoft Process Scheduler documentation for additional information on how to accurately determine the values for your system.

Generic ProcessType	Valid OutDestTypes	Defaults
AppEngine	FILE, WEB, WINDOW	WEB
COBOL	NONE, WINDOW, WEB	NONE
Cube	NONE	NONE
nVision	WEB, WINDOW, EMAIL, FILE, PRINTER, DEFAULT	DEFAULT
SQR	WEB, WINDOW, EMAIL, FILE, PRINTER	WEB
WinWord	WINDOW, WEB	WEB
Data Mover	WEB, WINDOW, FILE	WEB
OTHER	WEB, WINDOW, EMAIL, FILE, PRINTER, NONE	NONE

Similar to the OutDestType, the formats and defaults for a generic process type can be customized through Process Scheduler Manager. The following table lists the values and defaults as delivered.

Generic ProcessType	OutDestType	Valid OutDestFormats	Default
AppEngine	WINDOW	PDF, XLS, TXT, HTM	TXT
AppEngine	FILE	PDF, XLS, TXT, HTM	TXT
AppEngine	WEB	PDF, XLS, TXT, HTM	TXT
COBOL	NONE	NONE	NONE
COBOL	WEB	TXT	TXT
COBOL	WINDOW	TXT	TXT
Cube	NONE	NONE	NONE
Data Mover	FILE	TXT	TXT
Data Mover	WINDOW	TXT	TXT
Data Mover	WEB	TXT	TXT
nVision	EMAIL	HTM, XLS	XLS
nVision	FILE	HTM, XLS	XLS
nVision	PRINTER	HTM, XLS	XLS
nVision	WINDOW	HTM, XLS	XLS
nVision	WEB	HTM, XLS	XLS
nVision	DEFAULT	DEFAULT	DEFAULT
SQR	EMAIL	CSV, HP, HTM, LP, PDF, PS, SPF,OTHER	PDF
SQR	FILE	CSV, HP, HTM, LP, PDF, PS, SPF,OTHER	PDF
SQR	PRINTER	HP, LP, PS, WP	PS

Generic ProcessType	OutDestType	Valid OutDestFormats	Default
SQR	WEB	CSV, HP, HTM, LP, PDF, PS, SPF,OTHER	WEB
SQR	WINDOW	CSV, HP, HTM, LP, PDF, PS, SPF,OTHER	WEB
WinWord	NONE	NONE	NONE
WinWord	WEB	DOC	DOC
WinWord	WINDOW	DOC	DOC
OTHER	NONE	NONE	NONE

Alternative Options to Specify Email or Web Attributes

To set the email or web attributes in PeopleTools versions prior to release 8.4, your PeopleCode program was similar to the following:

To Set Attributes for Web (Prior to 8.4)

The following example shows how to set web attributes in PeopleTools versions prior to release 8.4:

```
&RQST.OutDestType = "Web";
&RQST.OutDestFormat = "PDF";
&RQST.OutDest = "User : VP1,Role :Managers";
```

Set Attributes for Email (Prior to 8.4)

The following example shows how to set email attributes in PeopleTools versions prior to release 8.4:

```
Local string &Subject ;
Local string &Text;

&Subject = "SQR Report: Cross Reference Listing";
&Text = "This text will be displayed as the text of this email ";
&RQST.OutDestType = "Email";
&RQST.OutDestFormat = "PDF";
&RQST.OutDest = "User : VP1,Role : MANAGERS";
&RQST.EmailSubject = &Subject;
&RQST.EmailText = &Text;
&RQST.EmailAttachLog = False;
```

Set Attribute for Web (8.4 and Later)

The following example shows how to set web attributes in PeopleTools versions release 8.4 and later:

```
&RQST.SetOutputOption("Web", "PDF", "");
&RQST.AddDistributionOption("User", "QEDMO");
&RQST.AddDistributionOption("Role", "MANAGERS");
```

Set Attribute for Email (8.4 and Later)

The following example shows how to set web attributes in PeopleTools versions release 8.4 and later:

```
Local string &Subject ;
Local string &Text;

&Subject = "SQR Report: Cross Reference Listing";
&Text = "This text will be displayed as the text of this email ";
&RQST.SetOutputOption("Email", "PDF", "");
&RQST.SetEmailOption(&Subject, &Text, "abc@xyz.com", "False", "False");
&RQST.AddDistributionOption("User", "QEDMO");
&RQST.AddDistributionOption("Role", "MANAGERS");
```

File Dependant Processing

You can define a process to be file dependent, which means associating a file with a process that gets scheduled once the system detects the presence of the file.

You can use the `PrcsApi` class methods for detecting files associated with a process, as well as for displaying additional messages about the process as it's running.

The `PrcsApi` class is an Application Package class that you must import into your PeopleCode in order to use its methods.

For example, you could use the `PrcsApi` class with a Application Engine program. In the Application Engine process `PROCESS_EDI`, you could create a file dependency (using the `FileName` `ProcessRequest` property) and make the process dependent on the file `/vendor/edi*.data`.

On 10/23, the system detects the file `/vendor/edi_1023.data` and schedules the process `PROCESS_EDI`. In the Application Engine program, you can refer to the file that started the process using the `getAllFileNames` `PrcsApi` class method.

On 10/24, the system detects the file `/vendor/edi_1024.data` and schedules the process `PROCESS_EDI`. The process is started from a different file, and can access that file, so duplicate processing doesn't occur.

ProcessRequest Class Methods

In this section, we discuss the ProcessRequest class methods. The methods are discussed in alphabetical order.

AddDistributionOption

Syntax

```
AddDistributionOption(DistIdType, DistId [, JobName] [, PrcsItemLevel] [, JobSeqNo]⇒  
[, ItemJobSeq])
```

Description

Use the AddDistributionOption method to set the distribution options for any job item in the main job. Distribution options enable you to distribute output in different formats (HTML, PDF, Excel, and so on) to other users based on their user ID or role ID.

This function is valid only if the output destination for the request is routed either to Web or Email.

Parameters

Parameter	Description
<i>DistIdType</i>	Specify the distribution ID type as a string. This identifies if the value passed in the DistID is either a user or role. Values for this parameter are: <ul style="list-style-type: none"> • User • Role
<i>DistID</i>	Specify the distribution ID as a string.
<i>JobName</i>	Specify the name of the job that this item belongs to as a string.
<i>PrcsItemLevel</i>	Specify the job item's process item level within the main job as a number.
<i>JobSeqNo</i>	Specify the job item's job sequence number within the process item level as a number.
<i>ItemJobSeq</i>	Specify the job item's sequence within its parent job as a number

Returns

Returns a number: 0 if successful, 1 if system detected an error in the parameter passed.

Example

The following example grants access to the QEDMO user all reports in MULTIJOB from the Web, while users with role of MANAGERS have access to reports created in the BIJOB03 job.

```
&RQST.SetOutputOption("Web", "PDF", "");
&RQST.AddDistributionOption("User", "QEDMO", "MULTIJOB" );
&RQST.AddDistributionOption("Role", "MANAGERS", "BIJOB03");
```

Related Links

[SetEmailOption](#)

[SetOutputOption](#)

AddNotifyInfo

Syntax

```
AddNotifyInfo(field_name, field_value [, JobName] [, PrclsItemLevel] [, JobSeqNo])
```

Description

Use the AddNotifyInfo method to specify name-value pair data to be included in the process status notification message.

Parameters

Parameter	Description
<i>field_name</i>	Specify the field name data as a string.
<i>field_value</i>	Specify the field value data as a string.
<i>JobName</i>	Specify the name of the job that this item belongs to as a string.
<i>PrclsItemLevel</i>	Specify the job item's process item level within the main job as a number.
<i>JobSeqNo</i>	Specify the job item's job sequence number within the process item level as a number.

Returns

None.

Example

```
&RQST.AddNotifyInfo("AEMINITEST Name", "Status");  
&RQST.AddNotifyInfo("AEMINITEST Descr", "Status Notify");  
&RQST.AddNotifyInfo("AEMINITEST OutType", "EMAIL");
```

[SetNotifyAppMethod](#)

[SetNotifyService](#)

PrintJobHTMLRpt

Syntax

```
PrintJobHTMLRpt ()
```

Description

Use the PrintJobHTMLRpt method to generate an HTML report file displaying all items in a job or jobset in a tree as defined in the Job Definition component.

Parameters

None.

Returns

An HTML report as a string

Example

The following code:

```
Local ProcessRequest &JobRQST;  
Local string &sHTML;  
  
&JobRQST = CreateProcessRequest("PSJob", "SQRXRF");  
&sHTML = &JobRQST.PrintJobHTMLRpt ();
```

generates the following HTML file:

The following image is an example of an HTML file generated after executing the above mentioned PeopleCode program:

[PrintJobRqstRpt](#)

[PrintSchdlHTMLRpt](#)

PrintJobRqstRpt

Syntax

```
PrintJobRqstRpt(ProcessInstance, ItemInstance [, PrintJobTree] [, PrintDistList] [,⇒  

  PrintNotifyList] [, PrintSystemMessage] [, PrintApplicationMessage] [, PrintParamL⇒  

  ist])
```

Description

Use the `PrintJobRqstRpt` method to generate an HTML report file displaying the current status of a specific process, job, or jobset.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ProcessInstance</i>	Specify the <code>ProcessInstance</code> number assigned to the process, job, or jobset

Parameter	Description
<i>ItemInstance</i>	<p>Specify either to display all items in a job or jobset, or just a specific item.</p> <ul style="list-style-type: none"> To display all items, specify 0. To display a specific item, specify the ProcessInstance number assigned to that item. <p>For a process, set this parameter to 0.</p>
<i>PrintJobTree</i>	<p>Specify whether to have the job tree displayed in the HTML report. This parameter takes a string value:</p> <ul style="list-style-type: none"> "1" to display the tree. "0" to not display the tree. <p>Default value is "1".</p>
<i>PrintDistList</i>	<p>Specify whether you want the list of Users and Roles who will be the recipient of a report generated for a job item displayed in the HTML report. This parameter takes a string value:</p> <ul style="list-style-type: none"> "1" to display the list. "0" to not display the list. <p>Default value is "0".</p>
<i>PrintSystemMessage</i>	<p>Specify whether you want to have the message specified from the Process Definition or Job Definition page displayed in the HTML report. This parameter takes a string value:</p> <ul style="list-style-type: none"> "1" to display the system message. "0" to not display the system message. <p>Default value is "0".</p>
<i>PrintApplicationMessage</i>	<p>Specify whether you want the application messages displayed in the HTML report. These are the application messages that can be viewed from the Message Log subpage of the Process Monitor Detail page. This parameter takes a string value:</p> <ul style="list-style-type: none"> "1" to display application messages. "0" to not display application messages. <p>Default value is "0".</p>

Parameter	Description
<i>PrintParamList</i>	<p>Specify whether you want the parameter list for a job item displayed in the HTML report. This parameter takes a string value:</p> <ul style="list-style-type: none"> • "1" to display the parameter list. • "0" to display the parameter list. <p>Default value is "0".</p>

Returns

An HTML report as a string.

Example

The following PeopleCode program:

```

Local ProcessRequest &JobRQST;
Local string &sHTML;
Local string &sPRINT_JOBTREE;
Local string &sPRINT_DISTLIST;
Local string &sPRINT_SYSMESSAGE;
Local string &sPRINT_APPLMESSAGE;
Local string &sPRINT_PARAMLIST;

&sPRINT_JOBTREE = "0";
&sPRINT_DISTLIST = "1";
&sPRINT_SYSMESSAGE = "1";
&sPRINT_APPLMESSAGE = "1";
&sPRINT_PARAMLIST = "1";
&JobRQST = CreateProcessRequest();
&sHTML = &JobRQST.PrintJobRqstRpt(PMN_PRCSLIST.PRC SINSTANCE, 0, &sPRINT_JOBTREE, &s⇒
PRINT_DISTLIST, &sPRINT_SYSMESSAGE, &sPRINT_APPLMESSAGE, &sPRINT_PARAMLIST);

```

The following screen image is an example of a HTML report created after executing the above mentioned PeopleCode program:

Job Name: 3MIX - Mix Jobs

[PrintJobHTMLRpt](#)

[PrintSchdlHTMLRpt](#)

PrintSchdlHTMLRpt

Syntax

```
PrintSchdlHTMLRpt([PrintJobTree] [, PrintDistList] [, PrintNotifyList] [, PrintMess→
ageList] [, PrintParamList])
```

Description

Use the PrintSchdlHTMLRpt method to generate an HTML report file displaying all items in a job or jobset as defined in the Scheduled Jobset Definition component.

Parameters

Parameter	Description
<i>PrintJobTree</i>	<p>Specify whether to have the job tree displayed in the HTML report. This parameter takes a string value:</p> <ul style="list-style-type: none"> • "1" to display the tree. • "0" to not display the tree. <p>Default value is "1".</p>
<i>PrintDistList</i>	<p>Specify whether you want the list of Users and Roles who will be the recipient of a report generated for a job item displayed in the HTML report. This parameter takes a string value:</p> <ul style="list-style-type: none"> • "1" to display the list. • "0" to not display the list. <p>Default value is "0".</p>
<i>PrintNotifyList</i>	<p>Specify whether you want the list of Users and Roles who will be notified for the status of a job item displayed in the HTML report. This parameter takes a string value:</p> <ul style="list-style-type: none"> • "1" to display the list. • "0" to not display the list. <p>Default value is "0".</p>
<i>PrintMessageList</i>	<p>Specify whether you want the messages that will be sent as email upon completion of a job item displayed in the HTML report. This parameter takes a string value:</p> <ul style="list-style-type: none"> • "1" to display messages. • "0" to not display messages. <p>Default value is "0".</p>
<i>PrintParamList</i>	<p>Specify whether you want the parameter list for a job item displayed in the HTML report. This parameter takes a string value:</p> <ul style="list-style-type: none"> • "1" to display the parameter list. • "0" to display the parameter list. <p>Default value is "0".</p>

Returns

An HTML report as a string

Example

The following code:

```

Local string &sHTML;
Local string &sPRINT_JOBTREE;
Local string &sPRINT_DISTLIST;
Local string &sPRINT_NOTIFYPYLIST;
Local string &sPRINT_MESSAGELIST;
Local string &sPRINT_PARAMLIST;

&sPRINT_JOBTREE = "1";
&sPRINT_DISTLIST = "0";
&sPRINT_NOTIFYPYLIST = "0";
&sPRINT_MESSAGELIST = "0";
&sPRINT_PARAMLIST = "0";
&JobRQST = SetupScheduleDefnItem("Sample", "MULTIJOB");
&sHTML = &JobRQST.PrintSchdlHTMLRpt(&sPRINT_JOBTREE, &sPRINT_DISTLIST, &sPRINT_NOTI⇒
FYLIST, &sPRINT_MESSAGELIST, &sPRINT_PARAMLIST);
    
```

Creates the following HTML report:

The following screen image is an example of a HTML report created after executing the above mentioned PeopleCode program:

Job Name: MULTIJOB - Jobset Example									
Mode: Serial									
Seq.	Process Name	Description	Process Type	Run Control ID	Type	Output Format	Destination	Server Option	Run Time

RunJobSetNow

Syntax

```
RunJobSetNow ()
```

Description

Use the RunJobSetNow method to schedule a jobset based on settings defined in the Scheduled Jobset Definition component.

Parameters

None.

Returns

None. To verify that the method executed successfully, check the value of the Status property.

Example

```
/* Create the ProcessRequest Object & Run the Scheduled JobSet Now */
Local ProcessRequest &JobRQST;
Local integer &instanceList;

&JobRQST = SetupScheduleDefnItem("Sample", "MULTIJOB");
&JobRQST.RunJobSetNow();
&instanceList = &JobRQST.ProcessInstance;
```

Related Links

[Status](#)

Schedule

Syntax

```
Schedule ()
```

Description

Use the Schedule method to insert a request in the Process Request table which runs according to the values in the properties of the ProcessRequest object. To successfully schedule a process or job, certain properties are required.

- If you're scheduling a single process, you must assign values to the following properties:

- RunControlID
- ProcessName
- ProcessType
- If you're scheduling a job where job item changes are not made, you must assign values to the following properties:
 - RunControlID
 - JobName
- If you're scheduling a job where job item changes are made, you must assign values to the RunControlID.

Note: You don't have to assign the JobName in this instance because it's set with the CreateProcessRequest function.

Parameters

None.

Returns

None. To verify that the method executed successfully, check the value of the Status property.

Example

```
&MYRQST.Schedule();
If &MYRQST.Status = 0 then
  /* Schedule succeeded. */
Else
  /* Process (job) not scheduled, do error processing */
End-If;
```

SetEmailOption

Syntax

```
SetEmailOption(EmailSubject, EmailText, EmailAddress, EmailWebReport, EmailAttachLo→
```

```
g [, JobName] [, PrcsItemLevel] [, JobSeqNo] [, ItemJobSeq])
```

Description

Use the SetEmailOption method to set the email options for all job items in the main job.

Parameters

Parameter	Description
<i>EmailSubject</i>	Specify the text used in the subject of the email sent at completion of this job email subject as a string. You can specify a Null ("") for this parameter.
<i>EmailText</i>	Specify the email text sent at completion of this job as a string. You can specify a Null ("") for this parameter.
<i>EmailAddress</i>	Specify the email address of the person you want an email sent to at the completion of this job. To send more than one email address, separate the addresses with a semicolon.
<i>EmailWebReport</i>	Specify whether to attach the web report to the email sent at the completion of this job. This parameter takes a string value: "True", attach the web report, "False", don't attach the web report. This parameter can be set only to "True" when the OutDestType property for the request is "Web".
<i>EmailAttachLog</i>	Specify whether to attach the log file to the email sent at the completion of this job. This parameter takes a string value: "True", attach the log file, "False", don't attach the log file.
<i>JobName</i>	Specify the name of the job that this item belongs to as a string.
<i>PrclsItemLevel</i>	Specify the job item's process item level within the main job as a number.
<i>JobSeqNo</i>	Specify the job item's job sequence number within the process item level as a number.
<i>ItemJobSeq</i>	Specify the job item's sequence within its parent job as a number

Returns

None.

SetItemFolder

Syntax

```
SetItemFolder(PortalFolder [, JobName] [, PrclsItemLevel] [, JobSeqNo] [, ItemJobSeq→
])
```

Description

Use the SetItemFolder method to associate a report folder with any job items jobset.

The folder that you specify must have already been created using the System Settings component in Process Scheduler Manager.

Parameters

Parameter	Description
<i>PortalFolder</i>	Specify the name of the report folder to use for the job item as a string. The folder that you specify must have already been created using Report Manager.
<i>JobName</i>	Specify the name of the job that this item belongs to as a string.
<i>PrclsItemLevel</i>	Specify the job item's process item level within the main job as a number.
<i>JobSeqNo</i>	Specify the job item's job sequence number within the process item level as a number.
<i>ItemJobSeq</i>	Specify the job item's sequence within its parent job as a number

Returns

None.

Example

```
&RQST.SetItemFolder("GENERAL", "MULTIJOB", 1, 2);
```

Related Links

[AddDistributionOption](#)

SetNotifyAppMethod

Syntax

```
SetNotifyAppMethod(app_class_name, app_class_method [, JobName] [, PrcsItemLevel] ⇒
[, JobSeqNo])
```

Description

Use the SetNotifyAppMethod method to invoke your own custom application class and method to handle process status notification and the information you want to send. This method triggers the delivered PRCS_STATUS_OPER service operation, which invokes the custom method.

Important! The constructor for the application class cannot require parameters.

Note: Alternatively, you can create a custom service operation and trigger that service operation using the SetNotifyService method. Your PeopleCode program should call only one of these methods: either SetNotifyAppMethod or SetNotifyService. If both methods are used, the last method called takes precedence over the former.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>app_class_name</i>	Specify the fully qualified application class name to be invoked on the target system as a string.
<i>app_class_method</i>	Specify the name of the method to be invoked on the target system as a string.
<i>JobName</i>	Specify the name of the job that this item belongs to as a string.
<i>PrclsItemLevel</i>	Specify the job item's process item level within the main job as a number.
<i>JobSeqNo</i>	Specify the job item's job sequence number within the process item level as a number.

Returns

None.

Example

The following example contains two programs. The first program generates the process request setting process status notification through the SetNotifyAppMethod method. The second program defines the application class and method that does additional processing after the status notification has been received by the subscribing system.

Setting process status notification:

```

/*****
* Construct a ProcessRequest Object. *
*****/
&RQST = CreateProcessRequest();
&RQST.ProcessType = "Application Engine";
&RQST.Processname = "AEMINITEST";
&RQST.RunControlID = "AEMINI";
&RQST.OutDestType = "WEB";
&RQST.OutDestFormat = "PDF";
&RQST.NotifyTextMsgSet = 65;
&RQST.NotifyTextMsgNum = 237;
&RQST.RunDateTime = %Datetime;
&RQST.TimeZone = %ServerTimeZone;
&RQST.SetNotifyAppMethod("RECEIVE_NOTIFICATION:ProcessNotificati⇒
cation");
&RQST.AddNotifyInfo("AEMINITEST Name", "Status");
&RQST.AddNotifyInfo("AEMINITEST Descr", "Status Notify");
&RQST.AddNotifyInfo("AEMINITEST OutType", "EMAIL");
&RQST.Schedule();
&PRCSSTATUS = &RQST.Status;
&PRCSINSTANCE = &RQST.ProcessInstance;
If &PRCSSTATUS = 0 Then
    MessageBox(%MsgStyle_OK, "", 65, 366, "Process Instance", "AEMINITEST", &PRCSINS⇒
TANCE);
Else
    MessageBox(%MsgStyle_OK, "", 65, 0, "Process Instance", "Process Not submitted")⇒
;
End-If;

```

Application class and method definition:

```

class ProcessNotification
    method ProcessNotification();
    method ReceiveNotification(&_MSG As Message);
end-class;

/* Class constructor can have no parameters */
method ProcessNotification
end-method;

method ReceiveNotification
    /* + &_MSG as Message + */
    Local Rowset &rs_msg, &NotifyInfo;
    Local Message &message;
    Local string &sName, &sValue, &sName2, &sValue2;
    &rs_msg = &_MSG.GetRowset();
    /*****
    /* Add logic you want to execute upon receiving notification */
    /* For example : */
    /* &RQST.SetNotifyAppMethod("RECEIVE_NOTIFICATION: */
    /* ProcessNotification", "ReceiveNotification"); */
    /* &RQST.AddNotifyInfo("SQR Report", "XRFMENU"); */
    If &rs_msg(1).PRCS_STATUS.RUNSTATUS.Value = "9" Then
        /* process ran to success */

```

```

&NotifyInfo = &rs_msg.GetRow(1).GetRowset(Scroll.PRCSNOTIFYATTR);

/* if you have more name-value pairs */
/* add code to traverse the rows from the PRCSNOTIFYATTR rowset*/

/* e.g. Get the first name-value pair */
&sName = &NotifyInfo(1).PRCSNOTIFYATTR.PRCs_ATTRIBUT_NAME.Value;
&sValue = &NotifyInfo(1).PRCSNOTIFYATTR.PRCs_ATTRIBUT_VALU.Value;

/* e.g. submit a process request */
Local number &PrcsInstance;
Local ProcessRequest &RQST;
&RQST = CreateProcessRequest();
&RQST.ProcessType = &sName;
&RQST.ProcessName = &sValue;
&RQST.RunControlID = "test";
&RQST.RunLocation = "PSNT";
&RQST.OutDestType = "WEB";
&RQST.OutDestFormat = "PDF";
&RQST.RunDateTime = %Datetime;
&RQST.TimeZone = %ServerTimeZone;

&RQST.Schedule();

Else
  /* other processing */
End-If;
/*****/

end-method

```

[Understanding Application Classes](#)

"Using Process Status Notifications" (Process Scheduler)

SetNotifyService

Syntax

```
SetNotifyService(svrc_op_name [, JobName] [, PrcsItemLevel] [, JobSeqNo])
```

Description

Use the SetNotifyService method to invoke your own custom service operation to handle process status notification and the information you want to send. Your custom service operation must use the PRCs_STATUS_MSG message definition.

Note: Alternatively, you can create a custom application class and method and invoke that method using the SetNotifyAppMethod method. Your PeopleCode program should call only one of these methods: either SetNotifyAppMethod or SetNotifyService. If both methods are used, the last method called takes precedence over the former.

Parameters

Parameter	Description
<i>srvc_op_name</i>	Specify the name of the custom service operation as a string.
<i>JobName</i>	Specify the name of the job that this item belongs to as a string.
<i>PrclsItemLevel</i>	Specify the job item's process item level within the main job as a number.
<i>JobSeqNo</i>	Specify the job item's job sequence number within the process item level as a number.

Returns

None.

Example

```

/*****
* Construct a ProcessRequest Object. *
*****/
&RQST = CreateProcessRequest();
&RQST.ProcessType = "Application Engine";
&RQST.Processname = "AEMINITEST";
&RQST.RunControlID = "AEMINI";
&RQST.OutDestType = "WEB";
&RQST.OutDestFormat = "PDF";
&RQST.NotifyTextMsgSet = 65;
&RQST.NotifyTextMsgNum = 237;
&RQST.RunDateTime = %Datetime;
&RQST.TimeZone = %ServerTimeZone;
&RQST.SetNotifyService("PRCS_STATUS_OPER_TEST");
&RQST.AddNotifyInfo("AEMINITEST Name", "Status");
&RQST.AddNotifyInfo("AEMINITEST Descr", "Status Notify");
&RQST.AddNotifyInfo("AEMINITEST OutType", "EMAIL");
&RQST.Schedule();
&PRCSSTATUS = &RQST.Status;
&PRCSINSTANCE = &RQST.ProcessInstance;
If &PRCSSTATUS = 0 Then
    MessageBox(%MsgStyle_OK, "", 65, 366, "Process Instance", "AEMINITEST", &PRCSINS⇒
TANCE);
Else
    MessageBox(%MsgStyle_OK, "", 65, 0, "Process Instance", "Process Not submitted")⇒
;
End-If;

SetOutputOption

Syntax

```
SetOutputOption (OutputType, OutputFormat, OutputDest [, JobName] [, PrclsItemLevel] ⇒  
[, JobSeqNo] [, ItemJobSeq])
```

Description

Use the SetOutputOption method to modify the output option of one or more job items in the main job.

Note: This method can also be used for a single process.

The job sequence number and job level are optional. They are required only when the same process name is referenced more than once in a job and the user intends to modify the output option of only one item.

If the ProcessRequest object contains an invalid output type for a process, you won't be able to successfully schedule a process or job.

The values for *OutputType*, *OutDestFormat*, and *OutputDestination* are dependent upon each other as well as on other values.

See [Values for Output Type and Format](#).

Parameters

Parameter	Description
<i>OutputType</i>	Specify the output type as a string.
<i>OutputFormat</i>	Specify the output format as a string.
<i>OutputDestination</i>	Specify the output destination as a string.
<i>JobName</i>	Specify the name of the job that this item belongs to as a string.
<i>PrclsItemLevel</i>	Specify the job item's process item level within the main job as a number.
<i>JobSeqNo</i>	Specify the job item's job sequence number within the process item level as a number.
<i>ItemJobSeq</i>	Specify the job item's sequence within its parent job as a number.

Returns

None.

Example

```
&RQST.SetOutputOption("Email", "HTM", "", "MULTIJOB", 1, 2);
```

Related Links

UpdateRunStatus

Syntax

```
UpdateRunStatus ()
```

Description

Use the UpdateRunStatus method to change the RunStatus for a specific process, job, or jobset.

Parameters

None.

Returns

None.

Example

```
Local ProcessRequest &RQST;  
  
&RQST = CreateProcessRequest();  
&RQST.ProcessInstance = 5;  
&RQST.RunStatus = 1; /* Cancel the request */  
&RQST.UpdateRunSttus();
```

[RunStatus](#)

ProcessRequest Class Properties

In this section, we discuss the ProcessRequest class properties. The properties are discussed in alphabetical order.

EmailAttachLog

Description

This property specifies whether or not a log file is attached to the email sent at completion of this job (or process). This property takes a Boolean value.

This property is read/write.

Example

```
&RQST.EmailAttachLog = False; /* Do not attach Log File */
```

EmailSubject

Description

This property specifies the text used in the subject of the email sent at completion of this job (or process). This property takes a string value.

This property is read/write.

Example

```
&RQST.EmailSubject = "SQL Report: Cross Reference Listing";
```

EmailText

Description

This property specifies the text of the email sent at the completion of this job (or process). This property takes a string value.

This property is read/write.

Example

```
&RQST.EmailText = "This text will be displayed as the text of this email ";
```

You can also use the text from a message in the message catalog for this property.

```
&RQST.EmailText = MsgGetText(65, 117, "Sample text for email with two parameters", =>
&MessageParm1, &MessageParm2);
```

EmailWebReport

Description

This property specifies whether an email is sent to recipients of the report after it is posted to the report repository. The URL for the report is included in the email. This option is applicable only when the OutDesType for the request is Web. This property takes a Boolean value: True, the web report should be attached, False otherwise.

This property is read/write.

FileName

Description

This property contains the name of a file to be used with file dependant processing, that is, processes which are initiated only after a file becomes available.

For a file dependent process, the FileName property is set to override the file name specified in the process definition. You must specify the complete file path and extension for the file, as a string.

This property works with the RunLocation property. If you don't specify a run location, any value assigned to this property is ignored.

This property is read/write.

Example

The following code example initiates QE_AETESTPRG once the c:\import\ediData.dat file becomes available on PSNT server.

```
Local ProcessRequest &rqst1;  
  
&rqst1 = CreateProcessRequest();  
&rqst1.RunControlId = "2";  
&rqst1.ProcessType = "Application Engine";  
&rqst1.ProcessName = "QE_AETESTPRG";  
&rqst1.RunLocation = "PSNT";  
&rqst1.FileName="c:\import\ediData.dat";  
&rqst1.Schedule();
```

Related Links

[RunLocation](#)

"Setting Process Definition Options" (Process Scheduler)

JobName

Description

This property contains the name of a job that you've defined in PeopleSoft Process Scheduler.

To schedule a job, you must assign values to JobName and RunControlID for the Schedule method to succeed.

If you're scheduling a job, you don't need to set the ProcessType property.

This property is read/write.

Example

```
&MYRQST.JobName = "3SQR";
```

Related Links

[RunControlID](#)

LanguageCd

Description

This property enables you to specify a language code for the process or job. If you don't specify a language code, PeopleSoft Process Scheduler first looks in the process run control table to retrieve a language code. If there isn't a value there, PeopleSoft Process Scheduler uses the user's language code specified in the User Definition table.

This property takes a string value.

This property is read/write.

Example

```
&MYRQST.LanguageCd = "ESP" /* Spanish */
```

NotifyTextMsgNum

Description

Use the NotifyTextMsgNum property to specify the message that should be displayed to the end user in the Event Notification popup display. This property takes a numeric value.

Note: You must specify both the message set and message number for the message to be displayed to the end user.

This property is read/write.

Example

```
&RQST.NotifyTextMsgSet = 65;  
&RQST.NotifyTextMsgNum = 237;
```

Related Links

[NotifyTextMsgSet](#)

NotifyTextMsgSet

Description

Use this property to specify the message set of the text message to be displayed to the end user in the Event Notification popup display. This property takes a numeric value.

Note: You must specify both the message set and message number for the message to be displayed to the end user.

This property is read/write.

Example

```
&RQST.NotifyTextMsgSet = 65;  
&RQST.NotifyTextMsgNum = 237;
```

Related Links

[NotifyTextMsgNum](#)

OutDest

Description

This property specifies the output destination for the process or job to be scheduled as a string.

Values depend on the setting for the OutDestType property:

- If OutDestType is FILE, OutDest must be the name of a directory. If the OutDest property isn't set, it defaults to the setting in the Process profile. If the Process Profile was not updated with a default destination, the Process Scheduler server that picked up the request sets the directory based on the Log/Output Directory setting found in the Process Scheduler Configuration file.
- If OutDestType is PRINTER, OutDest must be the name of a printer. If the OutDest property isn't set, it defaults to the setting in the Process profile. If the Process Profile was not updated with a default printer, the Process Scheduler server that picked up the request sets the printer based on the Default Printer setting found in the Process Scheduler Configuration file.
- If OutDestType is WEB or EMAIL, OutDest should contain the list of User IDs, Role IDs, or email addresses (for email only). If you don't set this property, it's automatically assigned to the person who submitted the request.
- If OutDestType is WEB, PeopleSoft Process Scheduler uses the OutDest property to determine who has access to the output.
- If OutDestType is EMAIL, PeopleSoft Process Scheduler uses the OutDest property to determine who to send the report output to.

In both these cases, to identify whether it's a User ID or a Role ID, the value has to be preceded by one of the following:

U: *Username* or **User:** *Username* for a user ID

R: *Rolename* or **Role:** *Rolename* for a role ID

If the ID is not preceded by either of these identifiers, Process Scheduler assumes it's an email address.

Note: Each ID must be separated by a semicolon (;).

The following are two examples:

```
&RQST.OutDest = "U:PTDMO;R:Employee;robert_smith@example.com"
```

```
&RQST.OutDest = "User:PS;Role:Employee;sue_line@XYZ.com;simon_gree@example.com=>
"
```

- For any other value of `OutDestType`, this property has no effect.

You can specify directory and printer names using the UNC (Uniform Naming Convention) protocol.

This property is read/write.

Example

```
&MYRQST.OutDest = "C:\TEMP";
```

Related Links

[OutDestType](#)

"Understanding the Management of PeopleSoft Process Scheduler" (Process Scheduler)

OutDestFormat

Description

This property specifies the output format for the process or job to be scheduled as a string. Values depend on your settings for the `ProcessType` and `OutDestType` properties:

The values for `OutDestType`, `OutDestFormat`, and `OutDest` are dependent upon each other as well as on other values.

See [Values for Output Type and Format](#).

This property is read/write.

Example

```
&MYRQST.OutDestFormat = "RTF";
```

Related Links

[ProcessType](#)

[OutDestType](#)

OutDestType

Description

This property specifies the type of output for the process or job to be scheduled as a string.

If the ProcessRequest object contains an invalid output type for a process, you won't be able to successfully schedule a process or job.

The value specified for this property is used only if the Output Destination Type for the defined process or job defined in PeopleSoft Process Scheduler is specified as Any. Otherwise any value specified for this property is ignored.

The values for OutDestType, OutDestFormat, and OutDest are dependent upon each other as well as on other values.

See [Values for Output Type and Format](#).

This property is read/write.

Example

```
&MYRQST.OutDestType = "FILE";
```

Related Links

[ProcessType](#)

[RunControlID](#)

PortalFolder

Description

This property specifies the name of the report folder associated with a job item as a string. If you're specifying a folder, the folder that you specify must have already been created using Report Manager.

This property is read/write.

ProcessInstance

Description

This property is a system-generated identification number. PeopleSoft Process Scheduler assigns a ProcessInstance at runtime to each process or job it successfully schedules.

This property is read/write.

Example

```
&MYRQST.Schedule();  
If &MYRQST.Status = 0 then  
    /* process successfully scheduled */
```

```
&ProcInst = &MYRQST.ProcessInstance;  
Else  
  /* do error processing */  
End-If;
```

ProcessName

Description

This property specifies the name of a predefined process as a string.

To successfully schedule a process, you must assign values to ProcessName, ProcessType, and RunControlID (that is, for the Schedule method to succeed.)

This property is read/write.

Example

```
&MYRQST.ProcessName = "XRFWIN";
```

Related Links

[ProcessType](#)

[RunControlID](#)

ProcessType

Description

This property specifies the name of a predefined process type as a string.

To successfully schedule a process, you must assign values to ProcessName, ProcessType, and RunControlID (that is, for the Schedule method to succeed.)

The values for ProcessType depend on the types of processes you have defined in your system. There are generic process types that are delivered with your installation of PeopleSoft. These process types may include the following:

- Application Engine
- COBOL
- Cube
- nVision
- SQR
- WinWord
- Other

If you define your own processes, you can use the name of that process with the `ProcessType` property. For example, suppose you create a custom process named "Custom CBL Programs." You could use this as follows:

```
&MyRqst.ProcessType = "Custom CBL Programs";
```

Note that spaces are included in the string for `ProcessType`.

This property is read/write.

Example

Note that spaces are included in the string for `ProcessType`.

```
&MYRQST.ProcessType = "Application Engine";
```

Related Links

[ProcessName](#)

[RunControlID](#)

RunControlID

Description

This property returns a string that serves, along with the user ID, as a key that identifies a predefined group of parameters to be used by a process or a job at runtime.

To successfully schedule a process, you must provide values for `RunControlID`, `ProcessName`, and `ProcessType`.

To successfully schedule a job, you must provide values for `RunControlID` and `JobName`.

This property is read/write.

Example

```
&MYRQST.RunControlID = "MYRUNCONTROLID";  
or  
&MYRQST.RunControlID = PRCSAMPLEREC.RUN_CNTL_ID;
```

Related Links

[JobName](#)

[ProcessName](#)

[ProcessType](#)

RunDateTime

Description

This property contains a `DateTime` value that specifies when the scheduled process or job will run.

If you don't specify a value for this property, and there is no date time set for the pre-defined process or job, the process or job runs as soon as the Schedule method is executed.

This property is read/write.

Example

The following example schedules the process or job to run as soon as the Schedule method is executed:

```
&MYRQST.RunDateTime = %Datetime;
```

RunLocation

Description

This property specifies the Process Scheduler Server name the request should be scheduled on. This property takes a string value. Values for RunLocation is a specific server name, such as PSNT.

If no RunLocation is specified, the request is scheduled based on both the default operating system and load balancing options set in the System Settings page.

This property is read/write.

Example

```
&MYRQST.RunLocation = "SERVER";  
or  
&MYRQST.RunLocation = "PSNT";
```

Related Links

"Viewing the Status of Processes" (Process Scheduler)

RunRecurrence

Description

This property specifies the frequency with which a process or job is to be run as a string. The RunRecurrence value you use must be the name of a Recurrence Definition defined in Process Scheduler Manager to successfully schedule a job or process (that is, for the Schedule method to succeed.)

This property is read/write.

Example

```
&MYRQST.RunRecurrence = "M-F at 5pm";
```

RunStatus

Description

This property specifies the run status of a process request as a number. This property is used with the UpdateRunStatus method to change the status of a request. Values are:

<i>RunStatus</i>	<i>Description</i>
1	Cancel
2	Delete
3	Error
4	Hold
5	Queued
6	Initiated
7	Processing
8	Cancelled
9	Success
10	Not Successful
11	Posted
12	Unable to post
13	Resend
14	Posting
15	Generated
16	Pending

This property is read/write.

Example

```
&MYRQST.RunStatus = 1;
```

Related Links

[UpdateRunStatus](#)

Status

Description

This property returns a number based on the result of the last execution of the Schedule method.

Valid returns are:

- Zero if the method succeeded
- Non-zero otherwise

This property is read-only.

Example

```
&MYRQST.Schedule();
If &MYRQST.Status = 0 then
  /* Schedule succeeded. */
Else
  /* Process (job) not scheduled, do error processing */
End-If;
```

TimeZone

Description

This property contains a time-zone value that specifies when the scheduled process or job will run. If no value is used for this property, the server time zone is used. This property takes a string value.

This property is read/write.

Example

```
&MyRqst.TimeZone = "EST";
```

ProcessRequest Class Examples

The following section contains examples for scheduling processes and jobs using the ProcessRequest class.

Scheduling a Single Process

The following example is when you're scheduling a single process:

```
Local ProcessRequest &RQST;

/* Create the ProcessRequest Object */
&RQST = CreateProcessRequest();

/* Set all the Required Properties */
&RQST.RunControlID = &sRunCntlId;
&RQST.ProcessType = &sProcessType;
&RQST.ProcessName = &sProcessName;

/* Set any Optional Properties for this Process */
&RQST.RunLocation = &sRunLocation;
&RQST.RunDateTime = &dtmRunDateTime;
&RQST.TimeZone = &sTimeZone;
&RQST.PortalFolder = &sPortalFolder;
&RQST.RunRecurrence = &sRecurrence;
&RQST.OutDestType = &sOutDestType;
&RQST.OutDestFormat = &sOutDestFormat;
&RQST.OutDest = &sOutputDirectory;
&RQST.EmailAttachLog = &bEmailAttachLog;
&RQST.EmailWebReport = &bEmailWebReport;
&RQST.EmailSubject = &sEmailSubject;
&RQST.EmailText = &sEmailText;

/* Schedule the Process */
&RQST.Schedule();
```

Scheduling a Job Where Job Item Changes Are Not Made

The following example is when job item changes aren't made.

```
Local ProcessRequest &RQST;

/* Create the ProcessRequest Object */
&RQST = CreateProcessRequest();

/* Set all the Required Properties */
&RQST.RunControlID = &sRunCntlId;
&RQST.JobName = &sJobName;

/* Set any Optional Main Job Properties */
&RQST.RunLocation = &sRunLocation;
&RQST.RunDateTime = &dtmRunDateTime;
&RQST.TimeZone = &sTimeZone;
&RQST.PortalFolder = &sPortalFolder;
&RQST.RunRecurrence = &sRecurrence;
&RQST.OutDestType = &sOutDestType;
&RQST.OutDestFormat = &sOutDestFormat;
&RQST.OutDest = &sOutputDirectory;
&RQST.EmailAttachLog = &bEmailAttachLog;
&RQST.EmailWebReport = &bEmailWebReport;
&RQST.EmailSubject = &sEmailSubject;
&RQST.EmailText = &sEmailText;

/* Schedule the Job */
&RQST.Schedule();
```

Scheduling a Job Where Job Item Changes Are Made

The following example is when job item changes are made.

```
Local ProcessRequest &RQST;
```

```

/* Create the ProcessRequest Object */
&RQST = CreateProcessRequest("PSJob", &sJobName);

/* Set all the Required Properties */
/* Note: the JobName Property has already */
/* been set in the call above, so you don't */
/* have to set it here */
&RQST.RunControlID = &sRunCntlId;

/* Set any Optional Job Item Properties */
&RQST.SetOutputOption(&sOutputType, &sOutputFormat, &sOutputDest, &sJobName, &nPrcsItemLevel, &nJobSeqNo);

&RQST.SetEmailOption(&sEmailSubject, &sEmailText, &sEmailAddress, &sEmailWebReport, &sEmailAttachLog, &sJobName, &nPrcsItemLevel, &nJobSeqNo);
&RQST.SetItemFolder(&sPortalFolder, &sJobName, &nPrcsItemLevel, &nJobSeqNo);
&RQST.AddDistributionOption(&sDistIdType, &sDistId, &sJobName, &nPrcsItemLevel, &nJobSeqNo);

/* Set any additional Optional Main Job Properties */
&RQST.RunLocation = &sRunLocation;
&RQST.RunDateTime = &dtmRunDateTime;
&RQST.TimeZone = &sTimeZone;
&RQST.PortalFolder = &sPortalFolder;
&RQST.RunRecurrence = &sRecurrence;
&RQST.OutDestType = &sOutDestType;
&RQST.OutDestFormat = &sOutDestFormat;
&RQST.OutDest = &sOutputDirectory;
&RQST.EmailAttachLog = &bEmailAttachLog;
&RQST.EmailWebReport = &bEmailWebReport;
&RQST.EmailSubject = &sEmailSubject;
&RQST.EmailText = &sEmailText;

/* Schedule the Job */
&RQST.Schedule();

```

PracsApi Class

Use the PracsApi class with file dependant processing. This section includes:

- Scope of a PracsApi object.
- Data type of PracsApi object.
- How to import a PracsApi object
- How to create a PracsApi object
- PracsApi reference

See [File Dependant Processing](#).

Scope of a PracsApi Object

A PracsApi object can be instantiated only from PeopleCode.

A PrcsApi object can be called from a component, an internet script, or an Application Engine program.

PrcsApi class objects can be of Local, Global, or Component scope.

Data Type of a PrcsApi Object

PrcsApi objects are of type PrcsApi.

```
Local PrcsApi &api = create PrcsApi();
```

How to Import the PrcsApi Class

The PrcsApi class is *not* a built-in class, like Rowset, Field, Record, and so on. It is an Application Class. Before you can use this class in your PeopleCode program, you must import it to your program.

An import statement names either all the classes in a package or one particular application class. For importing the PrcsApi class, PeopleSoft recommends that you import the API class.

The import statement you should use is as follows:

```
import PT_PRCs:API:*;
```

Using the asterisks after the package name makes all the application classes directly contained in the named package available.

[Understanding Application Classes](#)

How to Create a PrcsApi Object

After you've imported the PrcsApi class, you instantiate an object of that class using the constructor for the class and the *Create* function.

The following example creates a new instance of the PrcsApi class, as the variable &api, with local scope:

```
import PT_PRCs:API:*;  
Local PrcsApi &api = create PrcsApi();
```

PrcsApi Class Constructor

You must use the constructor for the PrcsApi class to instantiate an instance of that class. The following is the constructor for the PrcsApi class.

PrcsApi

Syntax

```
PrcsApi ()
```

Description

Use the PrcsApi constructor to create an instance of the PrcsApi class.

Parameters

None.

Returns

A reference to a PrcsApi object.

PrcsApi Class Methods

In this section, we discuss the PrcsApi class methods. The methods are discussed in alphabetical order.

getAllFileNames

Syntax

```
getAllFileNames (PrcsInstance)
```

Description

Use the getAllFileNames method to return a list of all the files names detected by the scheduler to initiate this process. The names are returned in an array of string, as full path names.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PrcsInstance</i>	Specify the process instance for which you want to get all the associated file names, as a number.

Returns

An array of string containing all the files names associated with the specified process.

Example

The following example returns a list of file names.

```

/* QE_OPT_AET is the state record for the application engine program in this exampl⇒
e */

import PT_PRCS:API:*;

Local PrcsApi &api = create PrcsApi();

Local File &FileIO, &FileLog;

Local array of string &strList = &api.getAllFileNames(QE_OPT_AET.PROCESS_INSTANCE);⇒

/* api call needs process instance as parameter */

/* the api returns list of file names matched by the scheduler for this instance */
For &i = 1 To &strList.Len
    &IOFilename = &strList [&i];

    &FileIO = GetFile(&IOFilename, "r", "UTF8", %FilePath_Absolute);

    &FileIO.Delete();

    &FileIO.Close();
End-For;

```

notifyToWindow

Syntax

```
notifyToWindow(PrCsInstance, Message)
```

Description

Use the notifyToWindow method to display additional messages to the window.

If a process is not defined as going to Window, using this method has no effect. The purpose of this method is to display additional messages to the window when an Application Engine process (no other process type) is run to Window.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PrCsInstance</i>	Specify the process instance for which you want to display messages, as a number.
<i>Message</i>	Specify the message you want displayed, as a string.

Returns

A number: 0 if method failed.

Example

The following PeopleCode would be in a step in an application engine program.

```
import PT_PRCs:API:*;  
Local PrcsApi &api = create PrcsApi();  
/* QE_AESTATUS_AET is the state record for this Application Engine program */  
&nret = &api.notifyToWindow(QE_AESTATUS_AET.PROCESS_INSTANCE, "Hi There! this is Fi→  
rst step.");  
/* this displays the message on the window */
```

PSSpreadsheet Class

Understanding the PSSpreadsheet Class

The PSSpreadsheet class provides methods to facilitate interaction with Excel workbook files and spreadsheets. The PSSpreadsheet class enables PeopleSoft applications to read, update, and write Excel files. However, the PSSpreadsheet class does not read the row or column level data.

The following methods of the PSSpreadsheet class are used for interacting with Excel workbook files and spreadsheets:

- Workbook operations: Open, Save, SaveAs, GetFileContent methods to operate on the Excel workbook file.
- Sheet operations — CreateSheet, SetActiveSheetName, and SetSheetActivate methods.
- Cell operations: Six SetCellxxx methods to set the value and format of a cell.
- Row and column operations — InsertColumns, InsertRows, RangeColOutline, RangeRowOutline, and SetColumnWidth methods.
- Rowset operations — SetRowSetData method read data from a rowset object.

"Testing PeopleCode APIs" (PS/nVision)

Instantiating the PSSpreadsheet Class

You must use the CreateObject built-in function to instantiate an object of the PSSpreadsheet class:

```
Local object &ssObject;  
&ssObject = CreateObject("PSSpreadsheet");
```

Related Links

"CreateObject" (PeopleCode Language Reference)

PSSpreadsheet Class Methods

In this section, the PSSpreadsheet class methods are presented in alphabetical order.

CreateSheet

Syntax

```
CreateSheet(sheetname)
```

Description

Use the CreateSheet method to create and name a new spreadsheet within the open Excel workbook.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>sheetname</i>	Specifies a String value representing the name of the new spreadsheet.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets Addresses as the name of the new spreadsheet.

```
&sheetname = "Addresses";
&ssObject.CreateSheet(&sheetname);
```

DeleteSheet

Syntax

```
DeleteSheet(sheetname)
```

Description

Use the DeleteSheet method to delete the specified sheet within an open Excel workbook.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>sheetname</i>	Specifies a String value representing the name of the sheet to be deleted.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example deletes the Addresses sheet.

```
&sheetname = "Addresses";
&ssObject.DeleteSheet(&sheetname);
```

GetFileContent

Syntax

```
GetFileContent(filename)
```

Description

Use the GetFileContent method to read the Excel workbook file content.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>filename</i>	Specifies a string representing the name of the Excel workbook file from which you want to read the data.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example gets the content of the specified Excel workbook file.

```
&filename = "filedata.xlsx";
&ssObject.GetFileContent(&filename);
```

InsertColumns

Syntax

```
InsertColumns(startcol, colcount)
```

Description

Use the InsertColumns method to insert one or more columns into the active spreadsheet.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>startcol</i>	Specifies the starting column number.
<i>colcount</i>	Specifies the number of columns to be inserted.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example inserts three columns into the spreadsheet.

```
&startcol = 2;
&colcount = 3;
&ssObject.InsertColumns(&startcol, &colcount);
```

InsertRows

Syntax

```
InsertRows(startrow, rowcount)
```

Description

Use the InsertRows method to insert one or more rows into the active spreadsheet.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>startrow</i>	Specifies the starting row number.
<i>rowcount</i>	Specifies the number of rows to be inserted.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example inserts three rows into the spreadsheet.

```
&startrow = 2;
&rowcount = 3;
```

```
&ssObject.InsertRows(&startrow, &rowcount);
```

Open

Syntax

```
Open(filename, enable_rowsetprocessing)
```

Description

Use the Open method to open or create an Excel workbook file.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>filename</i>	Specifies the name of the Excel workbook file to be opened or created.
<i>enable_rowsetprocessing</i>	Specifies a Boolean value indicating whether to enable rowset processing or disable rowset processing.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example opens an existing or creates a new Excel workbook file.

```
&filename = "myfile.xlsx";
&ssObject.Open(&filename, True);
```

RangeApplyStyle

Syntax

```
RangeApplyStyle(StyleName, startrow, rowcount, startcol, colcount)
```

Description

Use the RangeApplyStyle method to set the style of the range of cells.

Note: Due to Apache POI restrictions for user defined style lookup, the implementation of the RangeApplyStyle method is based on the following:

Every workbook should contain a sheet named PSSTYLE SHEET.

The STYLE SHEET sheet must create unique names on the first row in different cells.

The custom style sheet must be applied to the cell that contains the unique names.

Parameters

Parameter	Description
<i>StyleName</i>	<p>Specifies the style for the Excel sheet.</p> <p>Possible style names are:</p> <ul style="list-style-type: none"> • PSChar - Character fields (such as names). • PSDate - Dates. • PSDec - Numbers with decimal places, such as dollar amounts. • PSInt - Integers (such as years). • PSHeading - Column headings. • PSSpacer - Space between data columns.
<i>startrow</i>	Specifies the starting row number.
<i>rowcount</i>	Specifies the number of rows.
<i>startcol</i>	Specifies the starting column number.
<i>colcount</i>	Specifies the number of columns.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

```
&StyleName = "PSInt";
&startrow = 2;
&rowcount = 3;
&startcol = 2;
&colcount = 3;
&ssObject.RangeApplyStyle(&StyleName, &startrow, &rowcount, &startcol, &colcount);
```

RangeColOutline

Syntax

```
RangeColOutline(startcol, colcount, collapse)
```

Description

Use the RangeColOutline method to expand or collapse a range of columns in the active spreadsheet.

Parameters

Parameter	Description
<i>startcol</i>	Specifies the starting column number.
<i>colcount</i>	Specifies the number of columns to be expanded or collapsed.
<i>collapse</i>	Specifies a Boolean value indicating whether to collapse or expand the columns.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example collapses three columns.

```
&startcol = 2;
&colcount = 3;
&b_collapse = True;
&ssObject.RangeColOutline(&startcol, &colcount, &b_collapse);
```

RangeRowOutline

Syntax

RangeRowOutline(*startrow*, *rowcount*, *collapse*)

Description

Use the RangeRowOutline method to expand or collapse a range of rows in the active spreadsheet.

Parameters

Parameter	Description
<i>startrow</i>	Specifies the starting row number.
<i>rowcount</i>	Specifies the number of rows to be expanded or collapsed.
<i>collapse</i>	Specifies a Boolean value indicating whether to collapse or expand the rows.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example collapses three rows.

```
&startrow = 2;  
&rowcount = 3;  
&b_collapse = True;  
&ssObject.RangeRowOutline(&startrow, &rowcount, &b_collapse);
```

Save

Syntax

```
Save ()
```

Description

Use the Save method to save the Excel workbook file.

Parameters

None.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example saves the Excel workbook file.

```
&ssObject.Save ();
```

SaveAs

Syntax

```
SaveAs (filename)
```

Description

Use the SaveAs method to save the Excel workbook file with a new file name.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>filename</i>	Specifies the new name for the Excel workbook file.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example saves the Excel workbook file with a new name.

```
&filename = "newfile.xlsx";
&ssObject.SaveAs (&filename);
```

SetActiveSheetName

Syntax

```
SetActiveSheetName (sheetname)
```

Description

Use the SetActiveSheetName method to rename the active sheet within the Excel workbook file.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>sheetname</i>	Specifies the new name for the active sheet within the Excel workbook file.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets the name of the active sheet to Accounts.

```
&sheetname = "Accounts";
&ssObject.SetActiveSheetName (&sheetname);
```

SetCellDate

Syntax

```
SetCellDate(rownum, colnum, date, locale, timezone, format)
```

Description

Use the SetCellDate method to set a date value and format for the specified cell in the active spreadsheet.

Parameters

Parameter	Description
<i>rownum</i>	Specifies the row number for the cell.
<i>colnum</i>	Specifies the column number for the cell.
<i>date</i>	Specifies the date value to be set in the cell.
<i>locale</i>	Specifies the locale for the date cell value.
<i>timezone</i>	Specifies the time zone for the date cell value.
<i>format</i>	Specifies the date format for the cell value.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets a date value and format for the cell within the spreadsheet.

```
&rownum = 2;
&colnum = 2;
&data = 120223323;
&locale = "EN";
&timezone = "Americas/Los_Angeles";
&format = "m/d/yy h:mm";
&ssObject.SetCellDate(&rownum, &colnum, &data, &locale, &timezone, &format);
```

SetCellFormula

Syntax

```
SetCellFormula(rownum, colnum, data)
```

Description

Use the SetCellFormula method to set a formula value for the specified cell in the active spreadsheet.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>rownum</i>	Specifies the row number for the cell.
<i>colnum</i>	Specifies the column number for the cell.
<i>data</i>	Specifies the formula value to be set in the cell.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets a formula as the value for the specified cell within the spreadsheet.

```
&rownum = 2;
&colnum = 2;
&data = "=2+4";
&ssObject.SetCellFormula(&rownum, &colnum, &data);
```

SetCellHeaderStyle

Syntax

```
SetCellHeaderStyle(rownum, colnum, redvalue, greenvalue, bluevalue, boldweight, col⇒
or,
fontheight, fontname)
```

Description

Use the SetCellHeaderStyle method to set the format for the specified cell in the active spreadsheet.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>rownum</i>	Specifies the row number for the cell.
<i>colnum</i>	Specifies the column number for the cell.

Parameter	Description
<i>redvalue</i>	Specifies the red color value (from 0 to 256) for the specified cell.
<i>greenvalue</i>	Specifies the green color value (from 0 to 256) for the specified cell.
<i>bluevalue</i>	Specifies the blue color value (from 0 to 256) for the specified cell.
<i>boldweight</i>	Specifies the bold weight for the specified cell.
<i>color</i>	Specifies the color value for the specified cell.
<i>fontheight</i>	Specifies the font height for the specified cell.
<i>fontname</i>	Specifies the name of the font for the specified cell.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets the format for the specified cell within the spreadsheet.

```
&rownum = 2;
&colnum = 2;
&red = 100;
&green = 100;
&blue = 100;
&boldweight = 10;
&color = 100;
&fontheight = 10;
&fontname = "Helvetica";
&ssObject.SetCellHeaderStyle(&rownum, &colnum, &red, &green, &blue, &boldweight, &c⇒
olor, &fontheight, &fontname);
```

SetCellHyperlink

Syntax

```
SetCellHyperlink(rownum, colnum, link)
```

Description

Use the SetCellHyperlink method to set a hyperlink for the specified cell in the active spreadsheet.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>rownum</i>	Specifies the row number for the cell.
<i>colnum</i>	Specifies the column number for the cell.
<i>link</i>	Specifies the hyperlink value to be set for the specified cell.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets the hyperlink value of the specified cell within the spreadsheet.

```
&rownum = 2;
&colnum = 2;
&link = "http://www.oracle.com";
&ssObject.SetCellHyperlink(&rownum, &colnum, &link);
```

SetCellNumber

Syntax

```
SetCellNumber(rownum, colnum, data, format)
```

Description

Use the SetCellNumber method to set a double precision floating point value for the specified cell in the active spreadsheet.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>rownum</i>	Specifies the row number for the cell.
<i>colnum</i>	Specifies the column number for the cell.
<i>data</i>	Specifies the double precision floating point value to be set for the specified cell.
<i>format</i>	Specifies the numeric format of the data.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets a numeric value and format for the specified cell within the spreadsheet.

```
&rownum = 2;
&colnum = 2;
&data = 120;
&format = "0.00";
&ssObject.SetCellNumber(&rownum, &colnum, &data, &format);
```

SetCellString

Syntax

```
SetCellString(rownum, colnum, string)
```

Description

Use the SetCellString method to set a string value for the specified cell in the active spreadsheet.

Parameters

Parameter	Description
<i>rownum</i>	Specifies the row number for the cell.
<i>colnum</i>	Specifies the column number for the cell.
<i>string</i>	Specifies the string value to be set in the cell.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets a string value for the cell.

```
&rownum = 2;
&colnum = 2;
&data = "Accounting Department";
&ssObject.SetCellString(&rownum, &colnum, &data);
```

SetColumnWidth

Syntax

```
SetColumnWidth(colnum, width)
```

Description

Use the SetColumnWidth method to set the width of the specified column in the active spreadsheet.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>colnum</i>	Specifies the column number. Column number must be zero-based.
<i>width</i>	Specifies the width of the column. Set the width in units of 1/256th of a character width.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets the column width within the spreadsheet.

```
&colnum = 2;
&width = 10;
&ssObject.SetColumnWidth(&colnum, &width);
```

SetRowSetData

Syntax

```
SetRowSetData(&rowset)
```

Description

Use the SetRowSetData method to read the data from a standalone rowset into the spreadsheet.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&rowset</i>	Specifies an already instantiated standalone Rowset object.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets the PeopleSoft rowset data into the spreadsheet.

```
Local number &idx = 1;

Local Rowset &rs;
&rs = CreateRowset(Record.MY_DATA_TBL);
Local integer &rowNum, &colNum, &cellType;
Local string &cellData;

While (&qSQL.Fetch(&rowNum, &colNum, &cellType, &cellData))
  If &idx <> 1 Then
    &rs.InsertRow(&rs.ActiveRowCount);
  End-If;

  &rs(&idx).MY_DATA_TBL.ROWNUM.Value = &rowNum;
  &rs(&idx).MY_DATA_TBL.COLNUM.Value = &colNum;
  &rs(&idx).MY_DATA_TBL.CELLDATA.Value = &cellData;
  &rs(&idx).MY_DATA_TBL.CELLTYPE.Value = &cellType;
  &idx = &idx + 1;
End-While;

&ssObject.SetRowSetData(&rs);
```

Related Links

"CreateRowset" (PeopleCode Language Reference)

SetSheetActivate

Syntax

```
SetSheetActivate (sheetnum)
```

Description

Use the SetSheetActivate method to activate the specified sheet in the Excel workbook.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>sheetnum</i>	Specifies the number of sheet to be activated in the Excel workbook.

Returns

(Optional) A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example activates sheet 2 within the Excel workbook.

```
&sheetnum = 2;  
&ssObject.SetSheetActivate (&sheetnum);
```

PTDirectTransferObject Class

Understanding the PTDirectTransferObject Class

The PTDirectTransferObject class provides methods and built-in functions for real-time indexing using DirectTransfer. Application developers can use this class to do a synchronous cURL transfer to the Elasticsearch server to update their indexes when they save a component. The built-in functions handle the synchronous communication to the target URL. Any return code (Success/Failure) should be handled by the calling code.

PTDirectTransferObject Class Methods

These methods are used by the PTDirectTransferObject class. The methods are listed in alphabetical order.

SetAuth

Syntax

```
SetAuth(Authorization)
```

Description

Use the SetAuth method to set the authorization for a request.

Note: The SetAuth method is optional. If you do not use this method, the authorization of the default search instance is used.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Authorization</i>	Specifies the authorization as a String.

Returns

An Integer value indicating the libcurl error code.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirectttransferObject();
Local integer &ret = &PTDObject.SetAuth("<user>:<password>");
```

SetBody

Syntax

```
SetBody (Body)
```

Description

Use the SetBody method to set the JSON body as string for POST or PUT requests. You can use the CreateJsonBuilder function to form seamless JSON structures.

Note: For PeopleSoft application use, the attributes in the search engine are standardized with a specific suffix to support various analyzers. For example, the DESCR attribute in a search definition is created as DESCR_ORCL_ES_ENG in Elasticsearch. Related language fields should use the appropriate language code as a suffix. For example, DESCR_ORCL_ES_FRA for DESCR field in French. DirectTransfer expects the attribute name to be provided as it exists in the search engine. If not, a new field of default mapping is created in the search engine.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Body</i>	Specifies the body of a request as a String.

Returns

An Integer value indicating the libcurl error code.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirectttransferObject();
Local JsonBuilder &jb = CreateJsonBuilder();
&jb.StartObject("");
&jb.AddProperty("FIRST_NAME", "MyFirstName");
&jb.AddProperty("LAST_NAME", "MyLastName");
&jb.EndObject("");
Local string &sBody = &jb.ToString();
Local integer &return = &PTDObject.SetBody(&sBody);
```

SetDocId

Syntax

```
SetDocId (Document_ID)
```

Description

Use the SetDocId method to set the document ID for a document to be indexed.

Note: For PeopleSoft use, the document ID is the component URL as drilling url. A complete URL similar to the drilling URL generated through PeopleSoft Query should be provided as input. An update to an existing search document expects the same document ID to be provided in the request, otherwise the search document will be indexed as a new document.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Document_ID</i>	Specifies a document ID as a String.

Returns

An Integer value indicating the libcurl error code.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirecttransferObject();
Local integer &return = &PTDObject.SetDocId("1");
```

SetHeader

Syntax

SetHeader (*Header*)

Description

Use the SetHeader method to set the header for the cURL request.

Note: The SetHeader method is optional. The built-in functions internally handle some of the default headers such as, authentication and content type.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Header</i>	Specifies a header as a String.

Returns

An Integer value indicating the libcurl error code.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirecttransferObject();
Local integer &ret = &PTDObject.SetHeader("Host: myhost.com");
```

SetIndex

Syntax

```
SetIndex (Index_Name)
```

Description

Use the SetIndex method to set the name of an index.

Note: Use the database name as a suffix for the index. For example, hc_hrs_app_index_hcmdb01, where hcmdb01 is the name of the database.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index_Name</i>	Specifies the name of the index as a String.

Returns

An Integer value indicating the libcurl error code.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirecttransferObject();
Local integer &return = &PTDObject.SetIndex("testindex");
```

SetMethod

Syntax

```
SetMethod (HTTP_Method)
```

Description

Use the SetMethod method to set the HTTP method (such as GET, POST, PUT and so on) for the cURL request.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>HTTP_Method</i>	Specifies the HTTP method as a String.

Returns

An Integer value indicating the libcurl error code.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirecttransferObject();
Local integer &return = &PTDObject.SetMethod("POST");
```

SetOption

Syntax

```
SetOption(Option_Name, Option_Value)
```

Description

Use the SetOption method to set various options such as USERPWD, MAXREDIRS, MAXFILESIZE and so on.

Note: The SetOption method is optional.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Option_Name</i>	Specifies the name of the option as a String.
<i>Option_Value</i>	Specifies the value of the option as a String.

Returns

An Integer value indicating the libcurl error code.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirecttransferObject();
Local integer &return = &PTDObject.SetOption("MAXREDIRS", "2");
```

SetURL

Syntax

```
SetURL (URL)
```

Description

Use the SetURL method to set the target URL to which the request is triggered.

Note: This method is optional. If the method is not used, the target URL is set to the URL of the default search instance.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>URL</i>	Specifies the URL as a String.

Returns

An Integer value indicating the libcurl error code.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirecttransferObject();  
Local integer &return = &PTDObject.SetURL("http://host:port/");
```

SyncTransfer

Syntax

```
SyncTransfer ()
```

Description

Use the SyncTransfer method to submit a synchronous curl transfer request.

Parameters

None.

Returns

A String value containing the curl response.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirectttransferObject();  
Local string &return = &PTDObject.SyncTransfer();
```

Reset

Syntax

```
Reset ()
```

Description

Use the Reset method to reset the Direct Transfer object.

Parameters

None.

Returns

None.

Example

```
Local PTDirectTransferObject &PTDObject = CreateDirectttransferObject();  
&PTDObject.Reset();
```

PTDirectTransferObject Class Built-in Functions

"CreateDirectttransferObject()" (PeopleCode Language Reference)

PTOCInferenceSupervised Class

Understanding the PTOCInferenceSupervised Class

The PTOCInferenceSupervised class is used for PeopleTools Data Distribution Framework. It provides a mechanism to extract and flatten PeopleSoft data.

This data can be used for the purpose of machine learning. The data is hosted on the search engine server and the machine learning server pulls the data from the search engine to train the machine learning model.

PTOCInferenceSupervised Class Methods

In this section, the PTOCInferenceSupervised class method is discussed.

PredictRun

Syntax

```
PredictRun (&rs, &modelName)
```

Description

The PredictRun method runs prediction endpoint using the collected data and model name. The method converts the rowset data to JSON format and passes it to OCI Data Science.

Instead of using rowset data, you can also use JSON object to provide data to the method. In this case, the syntax is as follows:

```
PredictRun (modelName, json object)
```

Parameters

Parameter	Description
<i>&rs</i>	Specify the rowset.
<i>&modelName</i>	Specify the name of the model as a String value.

Returns

A String value, which is the prediction result from the OCI Data Science service.

Example

The following example uses a rowset to provide data:

```
import PTMLINFERENCE:PTOCInferenceSupervised;
Local PTMLINFERENCE:PTOCInferenceSupervised &ociInf;
Local string &mdlname = "M1";
&ociInf = create PTMLINFERENCE:PTOCInferenceSupervised(&mdlname);
Local Rowset &rs = CreateRowset(Record.EMPLOYEE_TBL);
/* Fill the Rowset */
&ociInf.PredictRun(&rs, &mdlname);
```

The following example uses a JSON object to provide data:

```
Local File &MYFILE;
Local array of string &MYARRAY;
Local string &TEXT;

&MYFILE = GetFile("ES_DUMP_DATA_02.json", "R");
&MYARRAY = CreateArrayRept("", 0);
While &MYFILE.ReadLine(&TEXT);
    &MYARRAY.Push(&TEXT);
End-While;
&MYFILE.Close();

Local object &oci;
&oci = CreateObject("PSOCIDatascience");

Local string &resp = &oci.PredictRun("M1", &TEXT);
WinMessage(&resp);
```

Push Notification Classes

Understanding the PSEvent Class

The PSEvent class provides all of the methods for publishing and subscribing to notifications from the Push Notification Framework. This framework updates the user with real-time changes, known as events, that have occurred on the application server tier. The framework enables PeopleSoft applications to push data directly to the user's display.

Methods of the PSEvent class are used for publishing, subscribing to, and unsubscribing from notifications:

- Publishing a notification — Setxxx methods, Publish method.
- Subscribing to a notification:
 - Subscription — Subscribe method.
 - Callback method — Getxxx methods.
- Unsubscribing to a notification — Unsubscribe method.

"Understanding the Push Notification Framework" (Fluid User Interface Developer's Guide)

Instantiating the PSEvent Class

You must use the CreateObject built-in function to instantiate an object of the PSEvent class:

```
Local object &EventObject;  
&EventObject = CreateObject("PSEvent");
```

Related Links

"CreateObject" (PeopleCode Language Reference)

PSEvent Class Methods

In this section, the PSEvent class methods are presented in alphabetical order.

AddRecipient

Syntax

```
AddRecipient(name, type)
```

Description

Use the AddRecipient method to set a specific recipient to receive the notification. Either a user ID or a role name can be specified, but not both.

Note: If no recipients are set for a notification, all the users who have subscribed for that notification will receive the notification.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>name</i>	A string representing the name of the recipient (user ID or role name).
<i>type</i>	A number representing the type of the recipient: <ul style="list-style-type: none"> • 1 — If the <i>name</i> parameter represents a user ID. • 2 — If the <i>name</i> parameter represents a role name.

Returns

A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets the user PTUSER as the recipient.

```
&name = "PTUSER";
&EventObject.AddRecipient(&name, 1);
```

Related Links

[AddRecipients](#)

[GetRecipients](#)

[RemoveRecipients](#)

AddRecipients

Syntax

```
AddRecipients(names, type)
```

Description

Use the `AddRecipients` method to set multiple recipients to receive the notification. Either user IDs or a role names can be specified, but not both.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>names</i>	A string array representing the name of the recipients (either user IDs or role names).
<i>type</i>	A number representing the type of the recipients: <ul style="list-style-type: none"> • 1 — If the <i>names</i> parameter represents user IDs. • 2 — If the <i>names</i> parameter represents role names.

Returns

A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets an array of user IDs as the recipients.

```
Local array of string &USERIDS;
Local string &ROLENAME;

&ROLENAME = "Portal Administrator";
Local Rowset &rs = CreateRowset(Record.PSROLEUSER);
&rs.Fill("WHERE ROLENAME=:1", &ROLENAME);
&USERIDS = CreateArrayRept("", 0);
For &i = 1 To &rs.RowCount
    &USERIDS.Push(&rs(&i).PSROLEUSER.ROLEUSER.Value);
End-For;

&EventObject.AddRecipients(&USERIDS, 1);
```

Related Links

[AddRecipient](#)

[GetRecipients](#)

[RemoveRecipients](#)

GetRecipients

Syntax

```
GetRecipients (type)
```

Description

Use the `GetRecipients` method to get all the recipients of a particular type from the notification.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>type</i>	A number representing the type of recipients: <ul style="list-style-type: none"> • 1 — For user IDs. • 2 — For role names.

Returns

An array of string representing the recipients for the specified type.

Example

The following example retrieves all role-type recipients:

```
Local array of string &RoleNames;
&type = 2;
RoleNames= &EventObject.GetRecipients(&type);
```

GetRowSetData

Syntax

```
GetRowSetData ()
```

Description

Use the `GetRowSetData` method to get the rowset data from the notification.

Parameters

None.

Returns

A Rowset object.

Example

The following example retrieves the rowset data.

```
Local Rowset &oRowset;
&oRowset = &EventObject.GetRowSetData();
```

Related Links[SetRowSetData](#)["Defining Events" \(Fluid User Interface Developer's Guide\)](#)**GetValueOfKey****Syntax**`GetValueOfKey(key)`**Description**

Use the GetValueOfKey method to get the value for a key from the notification data.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>key</i>	Specify the string representing the name of the key. Key names are defined in the Data Structure field on the Define Server Side Events page.

Returns

A valid string representing the corresponding value for the key, if the key exists. An empty string if the key does not exist.

Example

The following example gets the value for the key named ID.

```
&Key = "ID";
&Value = &EventObject.GetValueOfKey(&Key);
```

Related Links[SetKeyValuePair](#)["Defining Events" \(Fluid User Interface Developer's Guide\)](#)**Publish****Syntax**`Publish(event_name)`**Description**

Use the Publish method to publish a notification for an event.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>event_name</i>	A string representing the name of the event as defined on the Define Server Side Events page.

Returns

A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example uses a method definition to set event data and then publish a notification named WORKFLOWAPPROVAL.

```
method SendApprovalNotification
  /+ &category as String, +/
  /+ &message as String, +/
  /+ &actionsLink as String, +/
  Local object &EventObject;

  &EventObject = CreateObject("PSEvent");
  &EventObject.SetKeyValuePair("CATEGORYNAME", &category);
  &EventObject.SetKeyValuePair("MESSAGE", &message);
  &EventObject.SetKeyValuePair("ACTIONSLINK", &actionsLink);
  &EventObject.Publish("WORKFLOWAPPROVAL");
end-method;
```

[Subscribe](#)

[Unsubscribe](#)

"Defining Events" (Fluid User Interface Developer's Guide)

RemoveRecipients

Syntax

```
RemoveRecipients (type)
```

Description

Use the RemoveRecipients method to remove all the recipients of a particular type from the notification.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>type</i>	A number representing the type of recipients: <ul style="list-style-type: none"> • 1 — For user IDs. • 2 — For role names.

Returns

None.

Example

The following example removes recipients of type "role names" from the notification.

```
&type = 2;
&EventObject.RemoveRecipients(&type);
```

Related Links

[AddRecipient](#)

[AddRecipients](#)

[GetRecipients](#)

SetKeyValuePair

Syntax

```
SetKeyValuePair(key, value)
```

Description

Use the SetKeyValuePair method to add data in the form key-value pair to the notification.

Note: Notification data can be represented as either key-value pairs or as a rowset, not both. The event definition on the Define Server Side Events page determines the type of data for the notification and therefore the Setxxx method to be used.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>key</i>	Specify the string representing the name of the key. Key names are defined in the Data Structure field on the Define Server Side Events page.

Parameter	Description
<i>value</i>	Specify the string representing the value.

Returns

A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets the value for the key named "ID".

```
&Key = "ID";
&Value = "100";
&EventObject.SetKeyValuePair(&Key, &Value);
```

Related Links

[GetValueOfKey](#)

"Defining Events" (Fluid User Interface Developer's Guide)

SetRowSetData

Syntax

```
SetRowSetData (&rowset)
```

Description

Use the SetRowSetData method to set a Rowset object as the data for the notification.

Note: Notification data can be represented as either key-value pairs or as a rowset, not both. The event definition on the Define Server Side Events page determines the type of data for the notification and therefore the Setxxx method to be used.

Parameters

Parameter	Description
<i>&rowset</i>	An already instantiated Rowset object, which acts as the notification data.

Returns

A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example sets rowset data from the QE_CHART_RECORD record.

```
Local Rowset &oRowset;
&oRowset = CreateRowset(Record.QE_CHART_RECORD);
&oRowset.Fill("where QE_CHART_REGION= :1", "MIDWEST");
&EventObject.SetRowSetData(&oRowset);
```

Related Links

[GetRowSetData](#)

"Defining Events" (Fluid User Interface Developer's Guide)

Subscribe

Syntax

```
Subscribe(event_name, callback_method)
```

Description

Use the Subscribe method to have the PeopleCode program running on the application server subscribe to a notification for an event. Alternatively, JavaScript provides different mechanisms for subscribing to a notification for an event from a PeopleSoft page.

Parameters

Parameter	Description
<i>event_name</i>	A string representing the name of the event as defined on the Define Server Side Events page.
<i>callback_method</i>	A string value representing the method to be invoked when the notification is received by the subscriber. The string must be a fully qualified method name in the form: APP_PKG:App_Class:Method_Name

Returns

A Boolean value: True if the method completes successfully, False otherwise.

Example

The following example subscribes to a notification named PROCESSSTATUSCHANGE:

```
&EventObject.Subscribe("PROCESSSTATUSCHANGE", "PT_PRCs:ProcessMonitor:OnProcessStat⇒
usChange");
```

This example requires the implementation of a callback method named `OnProcessStatusChange` in the `PT_PRCs:ProcessMonitor` application class:

```
class ProcessMonitor
  method OnProcessStatusChange (&EventObject As object);
end-class;
method OnProcessStatusChange
  /* &EventObject as Object */
  Local string &ID;
  Local string &PROCESSNAME;
  Local string &KEY;

  &KEY = "ID";
  &ID = &EventObject.GetValueOfKey (&KEY);

  &KEY = "PROCESSNAME";
  &PROCESSNAME = &EventObject.GetValueOfKey (&KEY);
end-method;
```

"Defining Events" (Fluid User Interface Developer's Guide)

"Subscribing to Events" (Fluid User Interface Developer's Guide)

Unsubscribe

Syntax

```
Unsubscribe(event_name)
```

Description

Use the `Unsubscribe` method to unsubscribes from a notification for an event..

Parameters

Parameter	Description
<i>event_name</i>	A string representing the name of the event as defined on the Define Server Side Events page.

Returns

None.

Example

The following example unsubscribes from a notification named `PROCESSSTATUSCHANGE`.

```
&eventName = "PROCESSSTATUSCHANGE";
&EventObject.Unsubscribe (&eventName);
```

"Defining Events" (Fluid User Interface Developer's Guide)

PTNotification Class

This section provides an overview of the PTNotification class and discusses its methods.

The PTNotification application class can be used to send notifications based on the user preferences. It also provides option to send notifications without considering the user preferences, which can be used to send notifications to non-PeopleSoft users.

PTNotification Class Methods

In this section, the PTNotification methods are described in alphabetical order.

AddAction

Syntax

```
AddAction(Label, URL)
```

Description

Use the AddAction method to collate all the actions and to invoke the SetArrayOfActions of the PublishToWindow method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Label</i>	Specifies the label of an action as a String value.
<i>URL</i>	Specifies the URL as a String value.

Returns

None.

AddAttachment

See [AddAttachment](#).

AddHeader

See [AddHeader](#).

AddRecipient

Syntax

```
AddRecipient(recipient_type, value)
```

Description

Use this method to add a single recipient.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>recipient_type</i>	<p>Specify the recipient type as a numeric value or a constant value:</p> <ul style="list-style-type: none"> Operator ID: Use either 1 or %Recipient_OPRID. Role name: Use either 2 or %Recipient_Role. External email address: Use either 3 or %Recipient_Mail. External phone number: Use either 4 or %Recipient_Phone.
<i>value</i>	<p>Specifies the value for the selected recipient type, for example, PeopleSoft OPRID for operator.</p> <p>Specify a number in E164 format for external phone number.</p>

Returns

None.

Example

```
import PTNOTIFICATIONS:PTNotification;

Local object &objBroadcast = create PTNOTIFICATIONS:PTNotification("BROADCAST");
&objBroadcast.AddRecipient(1, "PTDMO");
&objBroadcast.AddRecipient(2, "Peoplesoft User");
&objBroadcast.AddRecipient(3, "external@peoplesoft.com");
&objBroadcast.AddRecipient(4, "+91000000000");
&objBroadcast.SetMessage("This is for demo", 0);
&objBroadcast.SetCategory("FYI");

&bRetCode = &objBroadcast.Send();
```

Related Links

[AddRecipients](#)

AddRecipients

Syntax

```
AddRecipients(recipient_type, value)
```

Description

Use this method to add multiple recipients of the same type.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>recipient_type</i>	Specify the recipient type as a numeric value or a constant value: <ul style="list-style-type: none"> Operator ID: Use either 1 or %Recipient_OPRID. Role name: Use either 2 or %Recipient_Role. External email address: Use either 3 or %Recipient_Mail. External phone number: Use either 4 or %Recipient_Phone.
<i>value</i>	Specifies the values for the recipient type as an array. Specify a number in E164 format for external phone number.

Returns

None.

Related Links

[AddRecipient](#)

AddTextAttachment

Syntax

```
AddTextAttachment(URLIdentifier, FileName, IsUserSpecific)
```

Description

Use this method to add an attachment to a text message, but the attachment should be limited to one. If the attachment count is not limited to one, the URL to access the attachments will be long and may be split into multiple messages thereby making it difficult to access the file. The method creates a URL to access the attachment. The URL is iScript based, and you should ensure that necessary permissions are granted to the users to access the iScript library. If the access is not granted, users will not be able to download the attachment.

When a user clicks the URL that they receive, the user is authenticated. If the authentication is successful, a verification process checks whether the URL is created for the logged in user. On successful verification, the attachment is streamed to the user. The attachment is first copied from the repository to a temporary store and then streamed to the user. On completing the streaming process, the file is cleared from the temporary store.

This method does not evaluate whether the attachment exists in the specified URL. Whether the file exists in the specified URL is validated when a user accesses the file.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>URLIdentifier</i>	Specify a URL Identifier.
<i>FileName</i>	Specify the name of the file that you want to attach, as a string. You must include the file extension as well. FileName can include %UserId% as a template variable, which at runtime is replaced with the actual user ID of the recipient.
<i>IsUserSpecific</i>	This parameter, as a Boolean value, controls how the URL is generated. <ul style="list-style-type: none"> • True - The application class dynamically creates URL for each user. Use this option when recipients are passed as a role or when multiple recipients are specified. • False - The application class creates URL without user context. The generated URL is valid for any PeopleSoft user with permissions to access the web library.

Returns

A Boolean value, True if an attachment is added to the text message; False otherwise.

Example

```
&bRetCode = &objBroadcast.AddTextAttachment (@ ("URL.URLIDENTIFIER"), "%UserId%_attachmment.pdf", true );
```

Related Links

[AddTextMedia](#)

AddTextMedia

Syntax

```
AddTextMedia (FilePath)
```

Description

Twilio supports adding media to text message through its media URL. Use this method to specify the path of the file and add it to the Twilio media URL. You should ensure that the URL is a direct link to the file. Ensure that the file or media is supported by the Twilio MIME types and that you provide valid HTTP or HTTPS URLs conforming to Twilio standards. For information on supported MIME types and valid URLs, refer to the Twilio documentation (www.twilio.com).

Parameters

<i>Parameter</i>	<i>Description</i>
<i>FilePath</i>	Specify the path to the file.

Returns

None.

Example

```
&objBroadcast.AddTextMedia ("https://www.w3.org/WAI/ER/tests/xhtml/testfiles/resources/pdf/dummy.pdf");
```

Related Links

[AddTextAttachment](#)

DisableIndividualMail

Syntax

```
DisableIndividualMail ()
```

Description

Use this method to insert all the recipients in the To list and send one mail to all users based on the user preferences. If not, each user receives an individual mail.

Parameters

None.

Returns

None.

EnableTracking

Syntax

```
EnableTracking()
```

Description

Use this method to track the delivery status (of In-app, email, and text notifications) for each user, however tracking the delivery status may impact performance.

You should invoke the EnableTracking method before calling the Send method. By default, status tracking is not enabled, so you should enable tracking explicitly.

The tracking status can be fetched by calling the GetNotificationStatus or GetUserNotificationStatus method after the notification is sent successfully. The status does not imply that the user received the message. The status only indicates whether the message is successfully sent out of the PeopleSoft system or not. You can check the actual status on corresponding servers, for example, Twilio message monitor for text notifications.

Parameters

None.

Returns

None.

Example

```
&objBroadcast.EnableTracking();
```

GenerateKey

Syntax

```
GenerateKey()
```

Description

Use this method to generate a key, which should be used with the `SetMsgKey` method.

Parameters

None.

Returns

A string containing the generated key.

Related Links

[SetMsgKey](#)

GetFailedPhoneNumbers

Syntax

```
GetFailedPhoneNumbers ()
```

Description

Use this method to retrieve phone numbers to which text message could not be sent.

Parameters

None.

Returns

An array of string containing phone numbers.

Related Links

[GetSentToPhoneNumbers](#)

GetInvalidMailAddresses

Syntax

```
GetInvalidMailAddresses ()
```

Description

Use this method to retrieve invalid mail addresses from the `MCFOutboundEmail` object.

Parameters

None.

Returns

A string containing mail address from the MCFOutboundEmail object.

Related Links

GetNotificationStatus

Syntax

```
GetNotificationStatus()
```

Description

Use the GetNotificationStatus method to retrieve the notification channels that are enabled for a list of recipients. You should invoke this method after calling the Send method.

Parameters

None.

Returns

A two-dimensional array containing the user ID of the recipient and a string representing the enabled channels in the order of In-app, mail, and text.

The following table describes the character representation of the return string.

<i>In-app</i>	<i>Mail</i>	<i>Text</i>	<i>Return String</i>
Not enabled	Not enabled	Not enabled	NNN
Not enabled	Not enabled	Enabled	NNY
Not enabled	Enabled	Not enabled	NYN
Not enabled	Enabled	Enabled	NYY

<i>In-app</i>	<i>Mail</i>	<i>Text</i>	<i>Return String</i>
Enabled	Not enabled	Not enabled	YNN
Enabled	Not enabled	Enabled	YNY
Enabled	Enabled	Not enabled	YYN
Enabled	Enabled	Enabled	YYY

Example

```
&arStatus = &objBroadcast.GetNotificationStatus();
```

GetUserNotificationStatus

Syntax

```
GetUserNotificationStatus (oprid)
```

Description

Use the GetUserNotificationStatus method to retrieve the notification channels that are enabled for a specified recipient. You should invoke this method after calling the Send method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>oprid</i>	Specifies the user ID of the recipient as a String.

Returns

A string representing the enabled channels in the order of In-app, mail, and text.

The following table describes the channels enabled for a recipient and the returned String value.

<i>In-app</i>	<i>Mail</i>	<i>Text</i>	<i>Return String</i>
Not enabled	Not enabled	Not enabled	NNN
Not enabled	Not enabled	Enabled	NNY

<i>In-app</i>	<i>Mail</i>	<i>Text</i>	<i>Return String</i>
Not enabled	Enabled	Not enabled	NYN
Not enabled	Enabled	Enabled	NYY
Enabled	Not enabled	Not enabled	YNN
Enabled	Not enabled	Enabled	YNY
Enabled	Enabled	Not enabled	YYN
Enabled	Enabled	Enabled	YYY

Example

```
&status = &objBroadcast.GetUserNotificationStatus( "USERID");
```

PTNotification

Syntax

```
PTNotification(Notification_name)
```

Description

PTNotification is a constructor method for the PTNotification class. Use PTNotification to instantiate an instance of the class.

The default event name is SENDNOTE.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Notification_name</i>	Specifies the notification as a String value.

Returns

None.

Example

```
import PTNOTIFICATIONS:PTNotification;

Local object &objBroadcast = create PTNOTIFICATIONS:PTNotification("BROADCAST");
&objBroadcast.AddRecipient(1, "PTDMO");
&objBroadcast.AddRecipient(2, "Peoplesoft User");
&objBroadcast.AddRecipient(3, "external@peoplesoft.com");
&objBroadcast.AddRecipient(4, "+91000000000");
```

```

&objBroadcast.SetMessage("This is for demo", 0);
&objBroadcast.SetCategory("FYI");

&bRetCode = &objBroadcast.Send();

```

Send

Syntax

```
Send()
```

Description

Use this method to send notifications as per user personalization.

Parameters

None.

Returns

A Boolean value. True if the notification is sent successfully; False otherwise.

Example

```
&bRetCode = &objBroadcast.Send();
```

SetBounceTo

Syntax

```
SetBounceTo(mail_ID)
```

Description

Use the method to specify the email address the system should direct all bounced mail to.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>mail_ID</i>	Specifies the email address as a String value.

Returns

None.

SetCategory

Syntax

```
SetCategory(Type)
```

Description

Use this method to specify a category for notifications.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Type</i>	<p>Specifies the category for a notification as a String value.</p> <p>Valid values are:</p> <ul style="list-style-type: none"> • FYI • ACTIONABLE • ACK • WORKABLE <p>Use the Workable category to place a notification, with a Mark Complete button, under Actions in the Notification panel. The Mark Complete button enables a user to dismiss the item from the list directly.</p> <p>See "Using the Notifications Panel" (Applications User's Guide).</p>

Returns

None.

Example

```
&objBroadcast.SetCategory("FYI");
```

SetMessage

Syntax

```
SetMessage(message, channel)
```

Description

Use this method to set the message payload per channel. For mail channel, content type and encoding are configured separately.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>message</i>	Specifies the message payload as a String value.
<i>channel</i>	Specifies the message channel as a Number value. The channels are as follows: <ul style="list-style-type: none"> • 0 - All • 1 - Push notification • 2 - Mail notification • 3 - Text notification

Returns

None.

Example

```
&objBroadcast.SetMessage("This is for demo", 0);
```

SetMsgKey

Syntax

```
SetMsgKey ()
```

Description

Use this method to set a key for a message in In-app notifications. If a key is not provided, a key will be generated automatically through the `GenerateKey` method. The message key is required when you want to track the message and update the status for In-app notifications.

Parameters

None.

Returns

None.

Related Links

[GenerateKey](#)

SetOnClickUrl

Syntax

```
SetOnClickUrl (URL)
```

Description

Use this method to set the redirect URL.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>URL</i>	Specifies the redirect URL as a String value.

Returns

None.

SetPriority

Syntax

```
SetPriority (priority)
```

Description

Use this method to set the priority for In-app and mail notifications.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>priority</i>	Specifies the priority for push and mail notifications as a Number. The priority values are as follows: <ul style="list-style-type: none">• 0 - Normal. This is the default priority.• 1 - High• 2 - Low

Returns

None.

SetReplyTo

Syntax

```
SetReplyTo(mail_ID)
```

Description

Use this method to specify the email address where the reply should be sent.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>mail_ID</i>	Specifies the email address to send the reply as a String value.

Returns

None.

SetSender

Syntax

```
SetSender(mail_ID)
```

Description

Use this method to specify the email address of the author of the message.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>mail_ID</i>	Specifies the sender's email address as a String value.

Returns

None.

SetSMTPParam

Syntax

```
SetSMTPParam(parameter_name, parameter_value)
```

Description

Use this method to set parameters for the SMTP session to be used for sending the email.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>parameter_name</i>	Specify the name of the parameter you want to overwrite as a String value.
<i>parameter_value</i>	Specify the value for the named parameter that you want used instead of the existing value as a String value..

Returns

None.

SetSubject

Syntax

```
SetSubject (Subject)
```

Description

Use this method to specify the subject of an email.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Subject</i>	Specifies the subject of mail notification as a String value. By default, the description in notification configuration is set as the subject of the mail notification,

Returns

None.

SetTimeToWait

Syntax

```
SetTimeToWait (wait_time)
```

Description

Use this method to specify the number of milliseconds to wait for the result of send email process. Default value from application server configuration.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>wait_time</i>	Specifies the number of milliseconds.

Returns

None.

SetURLIdForText

Syntax

```
SetURLIdForText (&urlIdentifier)
```

Description

Use this method to overwrite the Twilio account details. By default, system uses the Twilio account configured on PeopleTools, Notification, Notification Administrator, Global Settings page.

If any application wants to use a different From Number, a new URLIdentifier can be configured and used by passing the URLID to this method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&urlIdentifier</i>	Specifies the URL identifier as a String value.

Returns

None.

NotificationManager Class

This section provides an overview of the NotificationManager class and discusses its methods.

The NotificationManager class is used to perform create, edit, and delete operations on notification configurations. This class also enables you to maintain user personalizations.

NotificationManager Class Methods

In this section, the NotificationManager methods are described in alphabetical order.

AddPersonalizationList

Syntax

```
AddPersonalizationList(&nType, &value)
```

Description

Use the AddPersonalizationList method to add a permission list or role for a user. It also enables personalizations, if not enabled already.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&nType</i>	Specifies permission list or role. Valid values: <ul style="list-style-type: none"> • 1 - Permission List • 2 - Role
<i>&value</i>	Specifies the permission list or role name.

Returns

None.

Example

```
import PTNC_UTILITY:NotificationManager;

Local object &objNotif = create PTNC_UTILITY:NotificationManager("DEMONOTIFICATION"⇒
);

&objNotif.SetEventName("SENDNOTE");
&objNotif.SetDescription("Demo Notifications");
&objNotif.SetFuncCategory("Demo");
&objNotif.SetOwnerId("PT");
&objNotif.SetMandatory( True);

&objNotif.EnablePush( True);
&objNotif.EnableMail( False);
&objNotif.DisableText();

&objNotif.EnablePersonalization( True);
&objNotif.AddPersonalizationList(2, "PeopleSoft User");
```

```
&objNotif.AddPersonalizationList(1, "PTPT1200");
Local boolean &bReturn = &objNotif.Save();
```

[AddPersonalizationLists](#)

AddPersonalizationLists

Syntax

```
AddPersonalizationLists(&nType, &arrValue)
```

Description

Use the AddPersonalizationLists method to add multiple permission lists or roles for a user. It also enables personalizations, if not enabled already.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&nType</i>	Specifies permission list or role. Valid values: <ul style="list-style-type: none"> • 1 - Permission list • 2 - Role
<i>&arrValue</i>	Specifies multiple permission lists or role names as an array of string.

Returns

None.

Related Links

[AddPersonalizationList](#)

ClearPersonalizationList

Syntax

```
ClearPersonalizationList()
```

Description

Use the `ClearPersonalizationList` method to clear all the personalization permission lists and roles.

Note: This operation is executed immediately and cannot be rolled back. It does not depend on the `Save` method.

Parameters

None.

Returns

A Boolean value; True if the personalization is cleared successfully, False otherwise.

Related Links

[AddPersonalizationList](#)

Delete

Syntax

```
Delete ()
```

Description

Use this method to delete a personalization.

Note: The delete operation is executed immediately and it cannot be rolled back.

Parameters

None.

Returns

A Boolean value; True if the delete completes successfully, False otherwise.

DisableMail

Syntax

```
DisableMail ()
```

Description

Use this method to disable email notifications.

Parameters

None.

Returns

None.

Example

```
&objNotif.DisableMail();
```

Related Links

[EnableMail](#)

DisablePush

Syntax

```
DisablePush()
```

Description

Use this method to disable In-app notifications, that is, to disable notifications that appear on the Notifications panel on PIA. It will reset the default value too.

Parameters

None.

Returns

None.

Example

```
&objNotif.DisablePush();
```

Related Links

DisableText

Syntax

```
DisableText()
```

Description

Use this method to disable text notifications. It will reset the default value too.

Parameters

None.

Returns

None.

Example

```
&objNotif.DisableText();
```

Related Links

[EnableText](#)

EnableMail

Syntax

```
EnableMail(default)
```

Description

Use the EnableMail method to enable mail in notifications.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>default</i>	Specifies whether mail in notifications is available to users as default.

Returns

A Boolean value. True for mail as default; False otherwise.

Example

```
&objNotif.EnableMail(False);
```

[DisableMail](#)

EnablePersonalization

Syntax

```
EnablePersonalization(&state)
```

Description

Use the EnablePersonalization method to activate personalizations for a user.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&state</i>	Specifies whether to enable personalization as a Boolean value.

Returns

A Boolean value. True to enable personalization; False otherwise.

Example

```
&objNotif.EnablePersonalization( True);
```

EnablePush

Syntax

```
EnablePush(default)
```

Description

Use the EnablePush method to enable In-app notifications. It will reset the default value too.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>default</i>	Specifies whether In-app notifications are available to users as default.

Returns

A Boolean value. True if In-app notifications is the default; False otherwise.

Example

```
&objNotif.EnablePush (True);
```

Related Links

[DisablePush](#)

EnableText

Syntax

```
EnableText (default)
```

Description

Use the EnableText method to enable text notifications. It will reset the default value too.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>default</i>	Specifies whether text notifications is available to users as default..

Returns

A Boolean value. True if text notifications is the default; False otherwise.

Example

```
&objNotif.EnableText (True);
```

GetEventName

Syntax

```
GetEventName ()
```

Description

Use this method to retrieve the name of a notification.

Parameters

None.

Returns

A string containing the name of an event.

Example

```
&objNotif.GetEventName();
```

Related Links

[SetEventName](#)

GetOwnerDescr

Syntax

```
GetOwnerDescr()
```

Description

Use the GetOwnerDescr method to retrieve the description of an owner, for example, PeopleTools for the PT owner.

Parameters

None.

Returns

A string containing the long description of the owner.

Example

```
&objNotif.GetOwnerDescr();
```

Related Links

[GetOwnerId](#)

GetOwnerId

Syntax

```
GetOwnerId()
```

Description

Use the GetOwnerId method to retrieve the owner of a notification.

Parameters

None.

Returns

A string containing the owner ID.

Example

```
&objNotif.GetOwnerId();
```

Related Links

[GetOwnerDescr](#)

IsMailAvailable

Syntax

```
IsMailAvailable()
```

Description

Use this method to determine whether mail notification is available or not.

Parameters

None.

Returns

A Boolean value; True if mail notification is available, False otherwise.

Related Links

[IsPushAvailable](#)

[IsTextAvailable](#)

IsMailDefault

Syntax

```
IsMailDefault()
```

Description

Use this method to determine whether mail notification is enabled by default for a notification or not. This method can be true only if the IsMailAvailable method is set to True.

Parameters

None.

Returns

A Boolean value; True if mail notification is enabled by default for a notification, False otherwise.

Related Links

[IsTextDefault](#)

IsMandatory

Syntax

```
IsMandatory()
```

Description

Use this method to determine whether a notification is mandatory.

Parameters

None.

Returns

A Boolean value; True if a notification is mandatory, False otherwise.

IsNew

Syntax

```
IsNew()
```

Description

Use this method to determine whether a notification is new.

Parameters

None.

Returns

A Boolean value; True if a notification is new, False if a notification with the same name already exists.

IsPersonalizationAllowed

Syntax

```
IsPersonalizationAllowed()
```

Description

Use the IsPersonalizationAllowed method to specify whether personalization is allowed for a user or not.

Parameters

None.

Returns

A Boolean value; True if personalization is allowed, False otherwise.

IsPersonalized

Syntax

```
IsPersonalized(&user)
```

Description

Use this method to determine whether a user has set personalizations or not.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&user</i>	Specifies a user as a String value.

Returns

A Boolean value; True if the user has set personalizations, False otherwise.

IsPushAvailable

Syntax

```
IsPushAvailable()
```

Description

Use this method to determine whether in-app notification is available or not.

Parameters

None.

Returns

A Boolean value; True if in-app notification is available, False otherwise.

Related Links

NotificationManager

Syntax

```
NotificationManager(Notification_name)
```

Description

NotificationManager is a constructor method for the NotificationManager class. Use the NotificationManager method to instantiate an instance of the class.

Parameters

Parameter	Description
<i>Notification_name</i>	Specifies a notification as a String value.

RemoveFromPersonalizationList

Syntax

```
RemoveFromPersonalizationList(&nType, &value)
```

Description

Use this method to remove permission lists or roles from personalization set for a user. The actual deletion takes place on Save.

Parameters

Parameter	Description
<i>&nType</i>	Specifies permission list or role. Valid values: <ul style="list-style-type: none"> • 1 - Permission list • 2 - Role
<i>&value</i>	Specifies the name of the permission list or role.

Returns

A Boolean value. True if permission list or role is marked for deletion; False otherwise.

Example

```
&objNotif.RemoveFromPersonalizationList(2, "PeopleSoft User");
```

[AddPersonalizationList](#)

[AddPersonalizationLists](#)

ResetUserPersonalization

Syntax

```
ResetUserPersonalization(user)
```

Description

Use this method to reset the personalizations for an individual user.

Note: This operation is executed immediately and cannot be rolled back. It does not depend on the Save method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>user</i>	Specifies a user as a String value.

Returns

None.

Related Links

[ResetUserPersonalizations](#)

ResetUserPersonalizations

Syntax

```
ResetUserPersonalizations()
```

Description

Use this method to reset personalizations for all users.

Note: This operation is executed immediately and cannot be rolled back. It does not depend on the Save method.

Parameters

None.

Returns

None.

Related Links

[ResetUserPersonalization](#)

Save

Syntax

```
Save ()
```

Description

Use the Save method to commit changes to the database.

Parameters

None.

Returns

A Boolean value; True if the Save operation is successful, False otherwise.

Example

```
Local boolean &bReturn = &objNotif.Save();
```

SetDescription

Syntax

```
SetDescription(Description)
```

Description

Use this method to specify the description for a notification.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Description</i>	Specifies the description for a notification as a string.

Returns

None.

Example

```
&objNotif.SetDescription("Demo Notifications");
```

Related Links

[GetDescription](#)

SetEventName

Syntax

```
SetEventName (Event_Name)
```

Description

Use this method to set an event.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Event_name</i>	Specifies the name of an event as a string.

Returns

None.

Example

```
&objNotif.SetEventName("SENDNOTE");
```

Related Links

[GetEventName](#)

SetFuncCategory

Syntax

```
SetFuncCategory (FuncCategory)
```

Description

Use this method to specify a functional category for notifications.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>FuncCategory</i>	Specifies a functional category as a string.

Returns

None.

Example

```
&objNotif.SetFuncCategory("Demo");
```

SetMailAvailable

Syntax

```
SetMailAvailable()
```

Description

Use the SetMailAvailable method to set mail notification as available. This setting has no impact if the mail notification is already available.

Parameters

None.

Returns

None.

Related Links

[SetPushAvailable](#)

[SetTextAvailable](#)

SetMandatory

Syntax

```
SetMandatory(mandatory)
```

Description

Use this method to set a notification as mandatory.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>mandatory</i>	Specifies whether a notification is mandatory or not as a Boolean value.

Returns

None.

SetOwnerId

Syntax

```
SetOwnerId (Owner_ID)
```

Description

Use this method to specify the owner of a notification.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Owner_ID</i>	Specifies the owner of a notification as a string.

Returns

None.

Example

```
&objNotif.SetOwnerId("PT");
```

Query Classes

Understanding Query Classes

You create queries using PeopleSoft Query Manager to extract the data you need from the PeopleSoft database. You can use the query classes in PeopleCode to create a new query, or to modify or delete an existing query. You can also use methods in the Query class to execute the query and have the result set returned as either a rowset or have it format and write the result set to a file. You can also use the query classes to create a SQL statement to be used with the SQL object. In fact, the query classes expose all of the attributes and methods needed by the PeopleSoft Query Manager and Query Viewer applications.

Creating or deleting a query object does not create or delete query information. You must call the appropriate method for that query object directly to create or delete database information, that is, the Create or Delete method.

All of the classes, and most of the properties and methods that make up the query classes, have a GUI representation in PeopleSoft Query Manager. This document assumes that the reader has working knowledge of PeopleSoft Query Manager.

There aren't any external built-in functions for the query classes: objects are instantiated from other objects or from a session object.

Related Links

[Understanding Session Class](#)

"PeopleSoft Query Overview" (Query)

Collections in the Query Classes

A *collection* is a set of similar things, like a group of already existing queries or QueryRecords. As with everything else in the query classes, collections have a GUI representation in PeopleSoft Query.

For example, when you want to open a query, the search page returns a list of all the available queries. This is equivalent to using the FindQueries session class method to get a Query collection.

The following collections are part of the query classes:

- QuerySelect collection
- QueryDBRecord collection
- QueryDBRecordField collection
- Query collection
- QueryRecord collection

- QueryOutputField collection
- QuerySelectedField collection
- QueryCriteria collection
- QueryExpression collection
- QueryPrompt collection

Life Cycle of a Query

At runtime, there are certain things you want to do with a query, like creating one from scratch, updating the criteria for an existing query, running a query, and so on. The following is an overview of this process, and assumes the most common method to use the query API. These steps are expanded in other sections.

1. Invoke the GetQuery method on the PeopleSoft session object to get a query.
2. Either open the specific query you want using Open, or create a new query using Create.
3. Read the query statistics, or make changes as appropriate, adding records, field, criteria, and so on.
4. Save the changes.
5. (Optional) Use the RunToRowset method to run the query.

Note: Be careful whenever you write a PeopleCode program that uses the RunToRowset method because this method could return a large amount of data that could potentially exceed the memory available. For this reason, RunToRowset should be used only when you know that the query being executed returns a reasonable amount of data, or be sure to use the MaxRows parameter to control the maximum amount of data that can be returned.

Alternatively, you can:

- Use the RunToFile method to execute a scheduled query.
 - Use the RunToString method to run a query and return the result as a formatted string.
6. Close the query.
 7. If you want, you can navigate to PeopleSoft Query Manager, Query Viewer or the Query Designer to run the query.

The following diagram is an overview of life cycle of a Query object , illustrates the most common method to use the query API.

Query API Overview

The query API is made up of many classes. The following are the primary parts, generally used when updating a query:

Field or Control	Description
Query	The query definition.
QuerySelect	A query SELECT statement. There can be multiple QuerySelect objects for queries that involve unions or subqueries. Each select (or union or subquery) consists of QueryRecords, QueryOutputFields, QuerySelectedFields, and QueryCriteria.

Field or Control	Description
QueryRecords	The records that are part of the existing QuerySelect definition.
QueryOutputFields	The fields that you've selected to be displayed when the results of the query are run.
QuerySelectedFields	All the fields that make up the QuerySelect Definition. These include the fields selected as output fields, and fields added as part of Query Expressions.
QueryCriteria	The criteria for the query.
QueryExpression	The Query expressions that can contain SQL functions or other SQL fragments.
QueryList	The lists used in the in-list functionality for criteria.
QueryPrompt	The prompts used in criteria.
QueryDBRecords and QueryDBRecordFields	All the records available to be used as QueryRecords, and all the fields available. This list is restricted based on a user's Query Access Security Groups.

Query

A database query. You must get a query before you can access any of the other query classes. You can then create a new query and save it to the database, or open an existing query and modify it.

QuerySelect

Each query is composed of one or more select statements:

Field or Control	Description
Main Select	The instance of the first SELECT statement of the Query is the Main Select. There can only be one Main Select statement in the Query. This instance consists of the QueryOutputFields, QueryCriteria, and the QueryExpressions for the Main Select statement.
Union	In addition to the Main Select, a query can have one or more unions. The Unions are added by using the AddUnion method.

Field or Control	Description
Sub-Select	A subquery used in the criteria of the Main Select or in a Union.

QueryRecords

The records that are part of an existing query definition. In PeopleSoft Query, these are the records listed on the query tab. Each QuerySelect has its own set of QueryRecords.

QueryOutputFields

The fields that you've selected to be part of the query definition. They're called output fields because when you run the query, these are the fields that make up the output columns.

In PeopleSoft Query, these are the fields listed on the Fields tab.

The collection of QueryOutputFields does *not* necessarily include all columns returned in query resultset. This collection only includes columns that have been added to query output collection using the query classes or by an end-user designing a query.

PeopleSoft Query can also add additional columns for related language processing and also for translate labels on fields, and so you cannot use the Query Output Collections as a way to discover all of the columns that are returned in the resultset or by executing the SQL generated from a query.

QuerySelectedFields

All the fields that make up the query definition. These include the fields selected as output fields, and fields added as QueryExpressions.

QueryCriteria

The selection criteria for the query. Each QueryCriteria object is made up of the following:

Field or Control	Description
Logical	Any criteria objects after the first must include have a Logical value, either AND or OR.
Expression 1	A field or value that you want to base the selection criterion on, that is, Expression1 is the left-hand side of the criterion's comparison.
Operator	A mathematical or other operator used to specify the relationship between Expression 1 and Expression 2.

<i>Field or Control</i>	<i>Description</i>
Expression 2	A field or other value, also called a comparison value, used with Expression 1, that is, Expression2 is the right-hand side of the criterion's comparison.

In PeopleSoft Query, a QueryCriteria is under the Criteria tab.

Expression can be made up of constant values, fields, subqueries, and so on.

Related Links

[Working With Query Criteria and Expressions](#)

QueryDBRecords and QueryDBRecordFields

A QueryDBRecord is a record in the database that can be used as a QueryRecord. The list of records is controlled by security: the only records displayed as QueryDBRecords are records accessible by the user.

The QueryDBRecordFields are the fields that make up the QueryDBRecords.

In PeopleSoft Query, the QueryDBRecords are under the Record tab. After you click on the plus sign next to a record, the QueryDBRecordFields are displayed.

Working With Query Criteria and Expressions

If you run a query after selecting the QueryFields (which executes a SQL statement, such as SELECT EMPLID, DEPTID from PS_QE_EMPLOYEE), the system retrieves *all* the data in those columns; that is, it retrieves the data from every row in the QueryRecord or records because there is no filter limiting the number of rows.

You can select which *rows* of data you want by adding selection criteria to the query.

This document assumes that you know how to use selection criteria. This section discusses working with the QueryCriteria and QueryExpression objects in the query API only.

Related Links

"Choosing Selection Criteria" (Query)

Setting the Expression Type

Before you can add a new expression (either Expression 1 or Expression 2) to your QueryCriteria, you must set the type for the expression.

The following code example adds a new criteria, sets the type for the first expression, adds the first expression to the main select of the query definition, then does the same thing for the second expression.

```
&MyQuerySelect = &MyQuery.QuerySelect;
&MyCriteria = &MyQuerySelect.AddCriteria();
```

```

/* make expression 1 a field */
&MyCriteria.Expr1Type = %Query_ExprField;

/* add the ABSENCE_TYPE field */
&MyCriteria.AddExpr1Field("A", "ABSENCE_TYPE");

/* make it not equal to */
&MyCriteria.Operator = %Query_CondNotEqual;

/* Make expression 2 a constant */
&MyCriteria.Expr2Type = %Query_ExprConstant;
&MyCriteria.Expr = &MyCriteria.AddExpr2Expression1();
&MyCriteria.Expr.Text = "VAC";

```

Adding New Expressions

When you use any of the QueryCriteria methods to add either a new Expression 1 or Expression 2, you destroy the existing value.

In general, you should use the QueryCriteria methods to add a new Expression 1 or Expression 2 only when you're adding a new criteria to a query.

Adding an Operator and Expression 2 Dependencies

Which values are valid for the Expression 2 type (Expr2Type property) depend on the value of the Operator property.

The following table describes which Expr2Type values are valid with which values of Operator.

Operator	Expression 2
equal to	Constant
not equal to	Field
greater than	Expression
not greater than	Subquery
less than	Prompt
not less than	
Exists	Subquery
not exists	
Like	Constant (with wildcards)
not like	Prompt
is null	
is not null	

Operator	Expression 2
in tree	Tree Option
not in tree	Tree Prompt Option
Eff Date <=	Field
Eff Date >=	Expression
Eff Date <	Constant
EffDate >	Current Date
First Eff Date	
Last Eff Date	
in list	In list
not in list	Subquery
Between	Const-Const
Not Between	Const-Field
	Const-Expr
	Field-Const
	Field-Field
	Field-Expr
	Expr-Const
	Expr-Field
	Expr-Expr

[Operator](#)

Setting a Drilling URL

A *drilling* URL provides a clickable link in query results allowing a user to drill from the query results to another query, to another component, or to an external site. A drilling URL is defined as a special type of query expression. Like other query expressions, the user can set the drilling URL on the Edit Expression Properties page, or the drilling URL can be set in a PeopleCode program as follows:

```
/* Setting a drilling URL */
&aQueryExpr = &aQuerySelect.AddExpression(&sExprName);
/* Set the expression type to drilling URL */
```

```

&aQueryExpr.Type = %FieldType_URL;

/* Set the expression text and number from record fields */
/* The Text property must conform to expected formats */
&aQueryExpr.Text = &rRecordExpr.QRYCRIT1EXPRTTEXT.Value;
&aQueryExpr.ExpNum = &rRecordExpr.QRYCRIT1EXPNUM.Value;

```

Note: Run-time processing of drilling URLs is backward compatible. Therefore, drilling URLs that were defined in previous releases are expanded correctly in the current release without the need to redefine them.

For a drilling URL, the Text property of the QueryExpression object must conform to one of three expected formats. The value of the Text property is not validated; therefore, it is the calling program's responsibility to ensure that value is complete and correctly formatted. Each of the drilling URL types has a different format as follows:

- The drilling URL for a component requires the following format:

```
'/c/menu.component.market?Action=Usearch_key=unique_field:unique_field_URL_is_⇒
mapped_to'
```

For example:

```
'/c/QE_SAMPLE_APPS.QE_DEPT_TBL.GBL?Action=U&DEPTID=A.DEPTID&SETID=A.SETID:A.SE⇒
TID'
```

- The drilling URL for a query requires the following format:

```
'/q/?ICAction=ICQryNameURL={PUBLIC|PRIVATE}.query_name&unique_prompt_key=uniqu⇒
e_field:unique_field_URL_is_mapped_to'
```

For example:

```
'/q/?ICAction=ICQryNameURL=PUBLIC.DESTINATION&BIND1=A.DEPTID:B.DEPTID'
```

- The drilling URL for an external site requires the following format:

```
'/e/?url=[full_external_URL]:unique_field_URL_is_mapped_to'
```

For example:

```
'/e/?url=[http://www.yahoo.com]:A.SETID'
```

"Defining Query Drilling URLs" (Query)

Query Monitor

The query classes provide many methods and properties for examining the QueryStatistics, which you can use to report on the average execution time, the last date and time the query was run, and so on.

You can view the statistics for a query before you save it to the database.

Related Links

"PeopleSoft Query Overview" (Query)

Using Query Metadata

There are two ways of accessing information about a query:

- The query classes (QueryOutputField, QueryRecord, and so on).
- The Metadata property.

If you use the Metadata property, the information is presented in a different format. It is also read-only. Using this property can be a quick and easy way to access information about a query.

Each Query Metadata object is a name-value pair. *Name* is an indicator of which Query Metadata property you're accessing, and *Value* is the value of that property.

While the value of each Query Metadata property is unique, the name may or may not be. For example, there is only one description (Descr) for each query, so there is only one Query Metadata property with *name* equal to Descr and *value* equal to the description for the query.

However, there may be more than one record for a query. A Query Metadata property exists for each record, with *name* equal to Record and *value* equal to one of the records in the query. The same is true for Input Param, Expression, Field, and Heading.

The following is a simple PeopleCode program to get the Query Metadata for a private query, ADDRESS_TEMP:

```
Local ApiObject &MyQuery, &MyMetacol, &MyMetadata;
Local File &MyFile;

&MyFile = GetFile("Metadata.Txt", "A", "UTF8");

&MyQuery = %Session.GetQuery();

&Rlst = &MyQuery.Open("ADDRESS_TEMP", False, 1);

If &Rlst = 0 Then
    &MyMetacol = &MyQuery.metadata;
    &MyFile.WriteLine("Name           Value");
    &MyFile.WriteLine("-----");

    For &i = 1 To &MyMetacol.count
        &MyMetadata = &MyMetacol.item(&i);
        &Name = &MyMetadata.name;
        &Value = &MyMetadata.Value;
        &MyFile.WriteLine(&Name | "           " | &Value);
    End-For;
```

```

Else
    WinMessage("Open query not successful");
End-If;

```

Here is the sample output:

Name	Value
Descr	Temporary address query for testing
LongDescr	
Public/Private	QEDMO
LastUpdDttm	2001-11-19-15.06.22.930000
LastUpdOprId	QEDMO
Record	QE_PERS_DATA
Field	QE_EMPLID
Field	QE_NAME
Field	ADDRESS1
Field	ADDRESS2
Field	ADDRESS3
Field	ADDRESS4
Field	CITY
Field	COUNTY
Field	STATE
Field	QE_ZIP
Field	QE_COUNTRY
Heading	ID
Heading	Name
Heading	Address 1
Heading	Address 2
Heading	Address 3
Heading	Address 4
Heading	City
Heading	County
Heading	St
Heading	QE_ZIP
Heading	QE_COUNTRY

Running a Query

With query API, you have the following options for running a query:

- Using the RunToRowset method.

This method takes a QueryPrompt record as input and returns a PeopleCode rowset containing the query result. You should always use a standalone rowset (that is, one that was created using CreateRowset).

- Using the RunToFile method.

This method takes a QueryPrompt record and a file name as input and writes the query result to the file.

- Using the RunToString method.

This method takes a QueryPrompt record and writes the query result to a formatted string.

Note: For the query classes, all Date, Time, and DateTime fields that are part of a query are now required fields when running a query.

Considerations Using the RunTo Methods

RunToRowset may require a lot of memory for the Rowset object; therefore, it also takes more processing time. PeopleSoft recommends that RunToRowset not be used for retrieving large result sets, on the order of 50,000 or more items.

All of the RunTo methods can be called to run a query before saving it—that is, it isn't necessary to first save the query.

The last parameter of all of the RunTo methods is the maximum number of rows to fetch.

- -1 returns all rows regardless of the setting on the security profile.
- 0 returns the maximum number of rows allowed by the security profile.
- >0 is the limit on the number of rows.

Specifying the User's Language

For scheduled queries, the system uses the language specified in the user's profile. It does not use the language selected during signin. The system also uses the International and Regional settings the user specified using My Personalizations. If no personal setting have been specified, the system uses the default installation international settings.

Note: Most PeopleSoft components can default to international settings from the browser if the user has not set any user specific settings. However, this is not available for scheduled queries or any Process Scheduler processes.

Query Security

Security is critical for your business data. Typically, you don't want everyone in your company to have access to all the data. All the standard security features used with PeopleSoft applications are integrated in the PeopleSoft Query, as well as the query classes.

In addition, you can use the QuerySecurityProfile Class to view the current user's security profile for PeopleSoft Query. This class doesn't contain any methods, and all the properties are read-only.

"Security Basics" (Security Administration)

Error Handling With Query Classes

All errors for the query classes, like the other APIs, are logged in the PSMessages collection, instantiated from a session object. In addition, some methods return error codes. See the individual method description to see if it returns anything.

The query classes log errors "interactively", that is, as they happen. For example, suppose you specified an invalid query name. The error would be logged in the PSMessages collection as soon as you executed the GetQuery method.

When to check for errors is application-specific. However, if you check for errors after every assignment, you may see a performance degradation.

PeopleSoft recommends that you check for invalid prompts after using any of the following methods or properties:

- Save, RunToRowset, or RunToFile Query class methods.
- SQL, RuntimePrompts, or Prompts Query class properties.
- Any of the methods or properties in the QueryPrompts collection.

The easiest way to check for errors is to check the number of messages in the PSMessages collection, using the Count property. If the Count is 0, there are no errors.

```

Local ApiObject &MySession;
Local ApiObject &ERRORCOL;
Local ApiObject &Query, &QueryList;

&MySession = %Session;

If &MySession Then
  /* connection is good */

  &QueryList = &MySession.SearchPublicQueries(%Query_ListQuery, %Query_FindName, ">
%\"", True);

  For &I = 1 to &QueryList.Count
    &Query = &QueryList.Item(&I);

    /* Do processing */

    /* Do error checking */

    &ERRORCOL = &MySession.PSMessages;
    If (&ERRORCOL.Count <> 0) Then
      /* errors occurred - do processing */
    Else
      /* no errors */
    End-If;

  End-For;
Else
  /* do processing for no connection */
End-If;

```

Understanding QueryOutputFields and QuerySelectedFields

If you select a field from a Query Record, it becomes a QueryOutputField, that is, it becomes one of the columns in the SQL output. QuerySelectedFields consist of displayed fields and Query Expression Fields.

QuerySelectedFields and QueryOutputFields have all the same methods and properties, so in this documentation, they're described together under the heading QueryField.

The collection of QueryOutputFields does *not* necessarily include all columns returned in query resultset. This collection only includes columns that have been added to query output collection using the query classes or by an end-user designing a query.

PeopleSoft Query can also add additional columns for related language processing and also for translate labels on fields, and so you cannot use the Query Output Collections as a way to discover all of the columns that are returned in the resultset or by executing the SQL generated from a query.

Understanding Having Criteria

You can have where (simple) criteria or having criteria in a query. In most cases, you have a WHERE clause only—that is, simple criteria. Having criteria is only used in some special cases of aggregation queries. They represent the HAVING clause of the SQL statement, similar to the following:

```
select A.DEPTID, COUNT(A.EMPLID)
from PS_QE_EMPLOYEE A
group by A.DEPTID
having COUNT(A.EMPLID)>5
```

Having criteria are separated from simple criteria. They're accessed as follows:

- Having criteria are accessed using either the AddHavingCriteria QuerySelect method or HavingCriteria QuerySelect property
- Simple criteria are accessed using either the AddCriteria QuerySelect method or the Criteria QuerySelect property.
- However, the having criteria and the simple criteria have all the same methods and properties, so in this documentation, they're described together under the heading QueryCriteria.

Related Links

"Defining HAVING Criteria" (Query)

Data Type of Query Objects

All query objects, like a query collection, a QueryDBRecord, a QueryExpression, and so on, are declared as type ApiObject. For example,

```
Global ApiObject &MyQuery;
```

```
Local ApiObject &MyExpression;
```

Scope of Query Objects

All query objects can be instantiated from PeopleCode only.

You can use this object anywhere you have PeopleCode—that is, in an application class, Application Engine PeopleCode, record field PeopleCode, and so on.

You can only instantiate a query object from a Session object. You *must* instantiate the Session object before you can instantiate a query object or query collection. Use the %Session system variable to connect to the existing session.

```
Local ApiObject &QueryList;
Local ApiObject &MySession;

&MySession = %Session;

If &MySession <> Null Then
    /* connection is good */
    /* Search for public queries of type QUERY, search both the name and*/
    /* description for the pattern MyQ%, and do a case insensitive search */

    &QueryList = &MySession.SearchPublicQueries(1, 3, "MyQ%", False);
Else
    /* do error processing */
End-if;
```

Query Classes Reference

AdvancedSearchQueries

Syntax

```
AdvancedSearchQueries(GetFavorites, QueryName, QueryNameOp, Descr, DescrOp, FolderName, FolderNameOp, RecordName, RecordNameOp, FieldName, FieldNameOp, TreeName, TreeNameOp, P, QueryType, OwnerType, CaseSensitive)
```

Description

Use the AdvancedSearchQueries method to do more complex searches for queries.

Using Search Operators

All of the parameters for this method work in pairs, with the value in the first of the paired parameters further distinguished by the search operator used in the second parameter. For example, the value specified in *FieldName* is paired with the value specified in *FieldNameOp*.

All of the search operator parameters use the following values. Note that the format of the value of the first parameter is sometimes affected by the value of the search operator parameter.

Constant	Description
%Query_AdvSrchBegins	Name begins with the values specified.
%Query_AdvSrchContains	Name contains the value specified.
%Query_AdvSrchEquals	Name equals the value specified.
%Query_AdvSrchNotEquals	The name does not equal the value specified.
%Query_AdvSrchLessThan	The name is less than the value specified.
%Query_AdvSrchLessEquals	The name is less than or equal to the value specified.
%Query_AdvSrchGreaterThan	The name is greater than the value specified.
%Query_AdvSrchGreaterEquals	The name is greater than or equal to the value specified.
%Query_AdvSrchBetween	The name is between two values specified by a comma. Do not use quotation marks. For example, ACCT1,ACCT9.
%Query_AdvSrchIn	The name is in the list specified list. The values are separated with commas. Do not use quotation marks. For example, ACCT1, ACCT2, ACCT3

Parameters

Parameter	Description
<i>GetFavorites</i>	Specify whether to return only queries marked as favorites. This parameter takes a Boolean value: true if you only want favorite queries returned, false otherwise. If you specify true for this parameter, all other parameters are ignored.

Parameter	Description
<i>QueryName</i>	Specify the name of the query you want returned, as a string. Use this parameter with the <i>QueryNameOp</i> parameter.
<i>QueryNameOp</i>	Specify the operator to be used with the <i>QueryName</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>Descr</i>	Specify the description you want returned, as a string. Use this parameter with the <i>DescrOp</i> parameter.
<i>DescrOp</i>	Specify the operator to be used with the <i>Descr</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>FolderName</i>	Specify the name of the folder of the query or queries you want returned, as a string. Use this parameter with the <i>FolderNameOp</i> parameter.
<i>FolderNameOp</i>	Specify the operator to be used with the <i>FolderName</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>RecordName</i>	Specify the name of the record used with the query (queries) you want returned, as a string. Use this parameter with the <i>RecordNameOp</i> parameter.
<i>RecordNameOp</i>	Specify the operator to be used with the <i>RecordName</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>FieldName</i>	Specify the name of the field associated with the query (queries) you want returned, as a string. Use this parameter with the <i>FieldNameOp</i> parameter.
<i>FieldNameOp</i>	Specify the operator to be used with the <i>FieldName</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>TreeName</i>	Specify the name of the tree associated with the query (queries) you want returned, as a string. Use this parameter with the <i>TreeNameOp</i> parameter.
<i>TreeNameOp</i>	Specify the operator to be used with the <i>TreeName</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>QueryType</i>	Specify the type of query, as a string. See below.

Parameter	Description
<i>OwnerType</i>	Specify the type of owner, whether the query is public or private.
<i>CaseSensitive</i>	This parameter has not yet been implemented.

The values for *QueryType* can be as follows:

Numeric Value	Constant Value	Description
1	%Query_Query	Find queries of the type Query.
5	%Query_DBAgent	Find queries of the type Process.
4	%Query_Role	Find queries of the type Role
7	%Query_Archive	Find queries of the type Archive.

Returns

A reference to a Query collection containing zero or more queries.

Note: If the result set contains more than 300 rows, only the first 300 rows are returned.

AdvancedSearchRecords

Syntax

```
AdvancedSearchRecords(RecordName, RecordNameOp, Descr, DescrOp, FieldName, FieldNameOp, TreeName, TreeNameOp, CaseSensitive)
```

Description

Use the AdvancedSearchRecords method to do more complex searches for records.

Security applies to the results of this list, that is, you have access to all the records your user ID (permission list) allows you to access.

Using Search Operators

All of the parameters for this method work in pairs, with the value in the first of the paired parameters further distinguished by the search operator used in the second parameter. For example, the value specified in *FieldName* is paired with the value specified in *FieldNameOp*.

All of the search operator parameters use the following values. Note that the format of the value of the first parameter is sometimes affected by the value of the search operator parameter.

Constant	Description
%Query_AdvSrchBegins	Name begins with the values specified.
%Query_AdvSrchContains	Name contains the value specified.
%Query_AdvSrchEquals	Name equals the value specified.
%Query_AdvSrchNotEquals	The name does not equal the value specified.
%Query_AdvSrchLessThan	The name is less than the value specified.
%Query_AdvSrchLessEquals	The name is less than or equal to the value specified.
%Query_AdvSrchGreaterThan	The name is greater than the value specified.
%Query_AdvSrchGreaterEquals	The name is greater than or equal to the value specified.
%Query_AdvSrchBetween	The name is between two values specified by a comma. Do not use quotation marks. For example, ACCT1,ACCT9.
%Query_AdvSrchIn	The name is in the list specified list. The values are separated with commas. Do not use quotation marks. For example, ACCT1, ACCT2, ACCT3

Parameters

Parameter	Description
<i>RecordName</i>	Specify the name of the record you want returned, as a string. Use this parameter with the <i>RecordNameOp</i> parameter.
<i>RecordNameOp</i>	Specify the operator to be used with the <i>RecordName</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>Descr</i>	Specify the description you want returned, as a string. Use this parameter with the <i>DescrOp</i> parameter.

Parameter	Description
<i>DescrOp</i>	Specify the operator to be used with the <i>Descr</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>FolderName</i>	Specify the name of the folder of the records you want returned, as a string. Use this parameter with the <i>FolderNameOp</i> parameter.
<i>FolderNameOp</i>	Specify the operator to be used with the <i>FolderName</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>FieldName</i>	Specify the name of the field associated with the record you want returned, as a string. Use this parameter with the <i>FieldNameOp</i> parameter.
<i>FieldNameOp</i>	Specify the operator to be used with the <i>FieldName</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>TreeName</i>	Specify the name of the tree associated with the record you want returned, as a string. Use this parameter with the <i>TreeNameOp</i> parameter.
<i>TreeNameOp</i>	Specify the operator to be used with the <i>TreeName</i> parameter. The valid values for this parameter are found in the Using Search Operators section, above.
<i>CaseSensitive</i>	<hr/> <p>Note: This parameter has not been implemented yet.</p> <hr/> <p>Specify whether the search is case-sensitive. This parameter takes a Boolean value: True, the search is case-sensitive, False, it isn't.</p>

Returns

A reference to a QueryDBRecord collection containing zero or more records.

Note: If the result set contains more than 300 rows, only the first 300 rows are returned.

FindQueryDBRecords

Syntax

FindQueryDBRecords ()

Description

The FindQueryDBRecords method returns a reference to a QueryDBRecord collection, filled with zero or more records.

Security applies to the results of this list, that is, you have access to all the records your user ID (permission list) allows you to access.

Parameters

None.

Returns

A reference to a QueryDBRecord collection containing zero or more records.

FindQueries

Syntax

```
FindQueries()
```

Description

The FindQueries method returns a reference to a Query collection, filled with zero or more queries.

FindQueries Considerations

FindQueries returns both public and private queries. It depends on your database whether the private query is returned first or the public query. If you have two queries with the same name, it depends on your database whether the first use of Item returns the private or the public query.

Parameters

None.

Returns

A reference to a Query collection containing zero or more queries.

Example

In the following example, all available queries are returned:

```
Local ApiObject &MySession;
```

```
Local ApiObject &MyList;

&MySession = %Session
&MyList = &MySession.FindQueries();
```

Related Links

[Open](#)

[FindQueriesDateRange](#)

[Query Collection](#)

FindQueriesDateRange

Syntax

```
FindQueriesDateRange(StartDateString, EndDateString)
```

Description

The FindQueriesDateRange method returns a reference to a Query collection, filled with zero or more queries that match the specified date range.

FindQueriesDateRange Considerations

FindQueriesDateRange returns both public and private queries. It depends on your database whether the private query is returned first or the public query. If you have two queries with the same name, it depends on your database whether the first use of Item returns the private or the public query.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>StartDateString</i>	Specify the year, month, and day of the beginning date that you want to look for. This parameter takes a string value. You can specify the date either as YYYY-MM-DD or YYYY/MM/DD.
<i>EndDateString</i>	Specify the year, month, and day of the end date. This parameter takes a string value. You can specify the date either as YYYY-MM-DD or YYYY/MM/DD.

Returns

A reference to a Query collection containing zero or more queries.

Example

```
Local ApiObject &MySession, &QueryList;

&MySession = %Session;

&Start = GetField(VOLUN_ACT_WRK.START_DT_STR).Value;
```

```
&End = GetField(VOLUN_ACT_WRK.END_DT_STR).Value;  
&QueryList = &MySession.FindQueriesDateRange(&Start, &End);
```

GetQuery

Syntax

```
GetQuery ()
```

Description

The GetQuery method returns an empty query object. After you have an empty query object, you can use it to open an existing query (using the Open method) or to create a new query definition (using the Create method).

Parameters

None.

Returns

A reference to an empty query object if successful, NULL otherwise.

Example

```
&MyQuery = &MySession.GetQuery();  
If &MyQuery.Open("PHONELIST") Then
```

Related Links

[FindQueries](#)

[FindQueriesDateRange](#)

[Open](#)

[Create](#)

GetQuerySecurityProfile

Syntax

```
GetQuerySecurityProfile ()
```

Description

Use `GetQuerySecurityProfile` to return the current user's security profile for PeopleSoft Query. You can then use the `QuerySecurityProfile` properties to determine if the user can modify queries, the maximum number of rows to fetch for this user, and so on.

Parameters

None.

Returns

A reference to a `QuerySecurityProfile` if successful, NULL otherwise.

Example

```
&MySecProfile = %Session.GetQuerySecurityProfile();
If &MySecProfile.CanModifyQuery Then
    /* do some processing */
End-If;
```

Related Links

[QuerySecurityProfile Class](#)

SearchQueryDBRecords

Syntax

```
SearchQueryDBRecords(SearchType, Pattern, CaseSensitive)
```

Description

The `SearchQueryDBRecords` method returns a reference to a `QueryDBRecord` collection, filled with zero or more records.

Security applies to the results of this list, that is, you have access to all the records your user ID (permission list) allows you to access.

You can use wildcard characters `%` and `_` when searching. `%` means find all characters, while `_` means find a single character. For example, if you wanted to find all queries that started with the letter M, use "M%" for *Pattern*. To find either DATE or DATA, use "DAT_" for *Pattern*.

These characters can be escaped (that is, ignored) using a `\`. For example, to search for a query that contains the character `%`, use `\%` in *Pattern*.

If *Pattern* is an empty string, this method retrieves all queries of the specified type (that is, specifying "" for *Pattern* is the same as specifying "%").

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SearchType</i>	Specify the type of search to be used with the given pattern. You can use either a constant or a number value for this parameter. See below.
<i>Pattern</i>	Specify the pattern to be used when searching for records.
<i>CaseSensitive</i>	Specify whether the search is case-sensitive. This parameter takes a Boolean value: True, the search is case-sensitive, False, it isn't.

The values for *SearchType* can be as follows:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_FindName	Search for records with the name matching the given pattern.
2	%Query_FindDescr	Search for records with the description matching the given pattern.
3	%Query_FindNameDescr	Search for records with either the name or the description matching the given pattern.

Returns

A reference to a QueryDBRecord collection containing zero or more records.

Example

```
Local ApiObject &MySession, &DBRecList;
&MySession = %Session;
DBRecList = &MySession.SearchQueryDBRecords(%Query_FindName, "A%", False);
```

Related Links

[FindQueryDBRecords](#)

SearchPrivateQueries

Syntax

```
SearchPrivateQueries(QueryType, UserId, SearchType, Pattern, CaseSensitive)
```

Description

The `SearchPrivateQueries` method returns a reference to a Query collection, filled with zero or more Private queries that match the specified *SearchType*, *UserId*, *Pattern*, and *CaseSensitive* choice

Parameters

Parameter	Description
<i>QueryType</i>	Specify the type of query to be searched for. You can specify either a constant or number value for this parameter. See below.
<i>UserId</i>	Specify the user Id to be used to find currently signed-on user's private queries.
<i>SearchType</i>	Specify the type of search to be used with the given pattern. You can use either a constant or a number value for this parameter. See below.
<i>Pattern</i>	Specify the pattern to be used when searching for queries.
<i>CaseSensitive</i>	Specify whether the search is case-sensitive. This parameter takes a Boolean value: True, the search is case-sensitive, False, it isn't.

The values for *QueryType* can be as follows:

Numeric Value	Constant Value	Description
1	%Query_Query	Find queries of the type Query.
3	%Query_DBAgent	Find queries of the type Process.
4	%Query_Role	Find queries of the type Role
10	N/A	Find queries of the type Archive.

The values for *SearchType* can be as follows:

Numeric Value	Constant Value	Description
1	%Query_FindName	Search for queries with the name matching the given pattern.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
2	%Query_FindDescr	Search for queries with the description matching the given pattern.
3	%Query_FindNameDescr	Search for queries with either the name or the description matching the given pattern.

Returns

A reference to a Query collection containing zero or more queries.

Example

The following example retrieves all private queries of type Query which start with A and do a case-insensitive search, that is, get all queries starting with A or a.

```
Local ApiObject &MySession, &DBRecList;
&MySession = %Session;
DBRecList = &MySession.SearchPrivateQueries(%Query_ListQuery, %UserId, %Query_FindNameDescr, "A%", False);
```

Related Links

[FindQueries](#)

[FindQueriesDateRange](#)

[SearchPublicQueries](#)

SearchPublicQueries

Syntax

```
SearchPublicQueries(QueryType, SearchType, Pattern, CaseSensitive)
```

Description

The SearchPublicQueries method returns a reference to a Query collection, filled with zero or more Public queries that match the specified *SearchType*, *Pattern*, and *CaseSensitive* choice.

Parameters

Parameter	Description
<i>QueryType</i>	Specify the type of query to be searched for. You can specify either a constant or number value for this parameter. See below.
<i>SearchType</i>	Specify the type of search to be used with the given pattern. You can use either a constant or a number value for this parameter. See below.
<i>Pattern</i>	Specify the pattern to be used when searching for queries.
<i>CaseSensitive</i>	Specify whether the search is case-sensitive. This parameter takes a Boolean value: True, the search is case-sensitive, False, it isn't.

The values for *QueryType* can be as follows:

Numeric Value	Constant Value	Description
1	%Query_ListQuery	Find queries of the type Query.
3	%Query_ListDBAgent	Find queries of the type Process
4	%Query_ListRole	Find queries of the type Role
10	N/A	Find queries of type Archive

The values for *SearchType* can be as follows:

Numeric Value	Constant Value	Description
1	%Query_FindName	Search for queries with the name matching the given pattern.
2	%Query_FindDescr	Search for queries with the description matching the given pattern.
3	%Query_FindNameDescr	Search for queries with either the name or the description matching the given pattern.

Returns

A reference to a Query collection containing zero or more queries.

Example

The following example retrieves all public queries of type Query that start with A and does a case-insensitive search, that is, get all queries starting with A or a.

```
Local ApiObject &MySession, &DBRecList;  
  
&MySession = %Session;  
  
DBRecList = &MySession.SearchPublicQueries(%Query_ListQuery, %Query_FindName, "A%", =>  
    False);
```

Query Collection Methods

In this section, we discuss each query collection method.

First

Syntax

```
First()
```

Description

The First method returns the first Query object in the Query collection.

Parameters

None.

Returns

A reference to a Query object if successful, NULL otherwise.

Example

```
&MyQuery = &MyCollection.First();
```

Item

Syntax

```
Item(number)
```

Description

The Item method returns the Query object that exists at the *number* position in the Query collection.

Item Considerations

FindQueries and FindQueriesDateRange return both public and private queries. It depends on your database whether the private query is returned first or the public query. If you have two queries with the same name, it depends on your database whether the first use of Item returns the private or the public query.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the collection of the Query object that you want returned.

Returns

A reference to a Query object if successful, NULL otherwise.

Example

```
For &I = 1 to &QueryColl.Count;
    &MyQuery = &QueryColl.Item(&I);
    /* do processing */
End-For;
```

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the Query object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing Query within the Query collection. If you specify an invalid name, the object is NULL. The length of this parameter is 30 characters.

Returns

A reference to a Query object if successful, NULL otherwise.

Example

```
&MyQuery = &MyCollection.ItemByName("PHONELIST");
```

Next

Syntax

Next ()

Description

The Next method returns the next Query object in the Query collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a Query object if successful, NULL otherwise.

Example

```
&MyQuery = &MyCollection.Next();
```

Query Collection Property

In this section, we discuss the Count query collection property.

Count

Description

This property returns the number of Query objects in the Query collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

Query Class

A query object is returned from the following:

- The GetQuery session method.
- The Query collection methods First, Item, ItemByName, or Next.

See [GetQuery](#).

See [Query Collection](#).

Query Class Methods

In this section, we discuss each Query class method in alphabetical order.

AddPrompt

Syntax

`AddPrompt (PromptName)`

Description

The AddPrompt method adds a prompt with the given name to the query definition. This method returns a new QueryPrompt object that you can then use to specify details about the prompt.

Note: Prompt names are *not* checked for uniqueness. Each new prompt is just added to the list of prompts.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PromptName</i>	Specify the name of the new prompt with a string. The length of this parameter is 30 characters.

Returns

A reference to a QueryPrompt object.

Related Links

[Prompts](#)

[QueryPrompt Class](#)

AddQuerySelect

Syntax

`AddQuerySelect ()`

Description

Use the AddQuerySelect method to add the first Query Select statement into the query definition. This method returns the instance of the newly created QuerySelect.

Parameters

None.

Returns

A reference to a QuerySelect object. If the query already contains the Main Select, it returns NULL.

Related Links

[QuerySelect Collection](#)

AddTrackingURL

Syntax

AddTrackingURL (*URLString*)

Description

Use this method to define the base URL used to construct a fully qualified drilling URL. A base URL consists of the following elements:

```
http://server_name/servlet_name/site_name/portal_name/node_name
```

For example:

```
http://example.com:8080/ps/ps_2/EMPLOYEE/EMP_LOCAL
```

Because a base URL can be set or derived in several ways, the use of AddTrackingURL is required only when the calling program does not have current context to identify the site, portal, and node and the elements of the base URL (portal name, node name, and content type) were not defined when the drilling URL was defined. Specifically, the base URL can be set or derived as follows:

- The portal name, node name, and content type can be defined as optional elements of the query drilling URL definition.
- The portal name, node name, and content type can be derived from the current context (that is, from the URL of the logged in user who is executing the query).
- Finally, these elements can be defined programmatically through AddTrackingURL. If either of the first two bullets is true, then the value specified by AddTrackingURL is ignored.

Note: The string passed in as the base URL is not validated; therefore, it is the application developer's responsibility to ensure that the value is complete and correctly formatted.

Use this method for batch programs such as Application Engine programs do not operate in the context of a site, portal, and node. Consequently, prior to invoking an Application Engine program, the calling program needs to define and store the base URL so that the Application Engine program can use this stored value with the AddTrackingURL method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>URLString</i>	Specify the base URL as a string. The base URL is used to construct a fully qualified drilling URL.

Returns

None.

Example

The ExecQry step of the PSQUERY Application Engine program invokes the AddTrackingURL method using a value stored in the run control table prior to executing the query.

```
&aQry = %Session.GetQuery();
If &aQry.Open(PSQUERY_AET.QRYNAME, &bPublic, False) = 0 Then
    &aQry.AddTrackingURL(PSQUERY_AET.URL);
    ...
    &Result = &aQry.RunToFile(&rcdQryPrompts, &sOutFile, %OutDestFormat, 0);
End-if;
```

Related Links

[SetTrackingURL](#)

[Setting a Drilling URL](#)

"Defining Query Drilling URLs" (Query)

Close

Syntax

```
Close ()
```

Description

The Close method closes the query, freeing the memory associated with that object, and discarding any changes made to the query since the last save. The Close method can be used only on an open query, not a closed query. This means you must have opened the query with the Open or Create methods before you can close it. To save any changes, you must use the Save method before using Close.

It's very important to close your query when you're finished processing. Canceling out of a page does *not* close a query. You may receive error messages every other time you run your program if you haven't closed your queries.

Parameters

None.

Returns

None.

Related Links

[Open](#)

[Save](#)

[Create](#)

CopyPrivateQuery

Syntax

```
CopyPrivateQuery(QueryName, QryType, TargetUserID)
```

Description

The CopyPrivateQuery method copies the query from the current user to a user specified by the target user ID.

Parameters

Parameter	Description
<i>QueryName</i>	Name of the query to be copied, as a string.
<i>QryType</i>	Specify the type of query. This parameter takes either a numeric or constant value. See below.
<i>TargetUserID</i>	The user ID to which the query is to be copied, as a string.

The values for *QryType* can be as follows:

Numeric Value	Constant Value	Description
1	%Query_Query	Find queries of the type Query.
4	%Query_Role	Find queries of the type Role.
5	%Query_DBAgent	Find queries of the type Process.
7	%Query_Archive	Find queries of the type Archive.

Returns

0 if successful.

Create

Syntax

```
Create(QueryName, Public, Type, Description, LongDescription)
```

Description

The Create method creates a new query, based on the parameters passed with the method. The specified query must be a *new* query.

Warning! If you specify the name of a query that already exists, the existing query is overwritten by the new query.

The Create method can be used only with a closed query, it cannot be used on an open query.

After you create a new query, you don't have to open it with the Open method. The existing query object points to the new query.

Creating a new query doesn't create the query in the database. You must save the query (with the Save method) to commit it to the database.

Parameters

Parameter	Description
<i>QueryName</i>	Name of the query to be created. This parameter takes a string value. This parameter takes 30 characters. A query name can contain only US ASCII alphabetic and numeric characters, as well as underscores.
<i>Public</i>	Specify if the query is public or private. This parameter takes a Boolean value: True if the query is public, False if it's a private query.
<i>Type</i>	Specify the type of query. This parameter takes either a numeric or constant value. See below.
<i>Description</i>	Specify a short description for the query. This parameter takes a string value. This parameter takes 30 characters.
<i>LongDescription</i>	Specify a long description for the query. This parameter takes a string value. The length of this parameter depends on your system database limit for LONG fields.

The values for *Type* can be as follows:

Numeric Value	Constant Value	Description
1	%Query_Query	Query
3	%Query_View	View
4	%Query_Role	Role
5	%Query_DBAgent	Process
7	%Query_Archive	Archive

Returns

An integer value: 0 means the query was created successfully.

Example

```

/* Use the existing session */
&MySession = %Session;
&MyQry = &MySession.GetQuery();
/* create a new query : public type-User */
&Rslt = &MyQry.Create("MYQUERY", True, %Query_Query, "My Query", "My first Query");⇒

If &Rslt = 0 Then
    /* Query created successfully */
Else
    /* do error processing */
End-If;

```

[Close](#)

[Save](#)

Delete

Syntax

```
Delete ()
```

Description

The Delete method deletes the specified query from the database. The Delete method can be used only with an open query, it cannot be used on a closed query. Before you use the Delete method, you must explicitly open the query object to be deleted (with either the Open or Create method.)

Parameters

None.

Returns

An integer value: 0 means the query was deleted successfully.

Related Links

[Save](#)

DeletePrompt

Syntax

`DeletePrompt` (*PromptNumber*)

Description

The DeletePrompt method deletes a prompt from a query definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PromptNumber</i>	Specify the numeric location in the query definition of the prompt that you want to delete.

Returns

An integer value: 0 means the query was deleted successfully.

Related Links

[AddPrompt](#)

[Prompts](#)

[QueryPrompt Class](#)

FindExpression

Syntax

FindExpression (*ExpressionNumber*)

Description

Use the FindExpression method to search the query definition for an expression with the given expression number. Although expressions are associated with the QuerySelect in which they are defined, PeopleSoft Query doesn't qualify expressions by Select number. Therefore, each expression has a unique number across all QuerySelect objects.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ExpressionNumber</i>	Specify the numeric value of the expression number to be searched for in the query definition.

Returns

A QueryExpression object if successful, NULL otherwise.

Related Links

[AddPrompt](#)

[Prompts](#)

[QueryPrompt Class](#)

FormatBinaryResultString

Syntax

FormatBinaryResultString (&Rowset, *Output_Format*, *Start_Row*, *End_Row*)

Description

Use the FormatBinaryResultString method to generate a string containing the content of the input (the rowset) in XLS format. You can specify the range of rows to be in the rowset to be used as input. The rowset object is created using the RunToRowset method.

Parameters

Parameter	Description
<i>&Rowset</i>	Specify an already instantiated and populated rowset object containing the query result. This rowset is created using the <code>RunToRowset</code> method.
<i>Output_Format</i>	Specify the format of the output. You can specify either a numeric or constant value. See below.
<i>Start_Row</i>	Specify the first row in the rowset that you want to use for output. This parameter takes a numeric value.
<i>End_Row</i>	Specify the last row in the rowset that you want to use for output. This parameter takes a numeric value.

The values for *Output_Format* can be as follows:

Numeric Value	Constant Value	Description
8	<code>%Query_XLS</code>	The output for Excel in HTML format.

Returns

A binary object containing the formatted output.

Example

```
/* Use RowCount, not ActiveRowCount, to get the total number of rows. */
&End = &MyRowset.RowCount;
&FormString = &MyQuery.FormatBinaryResultString (&MyRowset, %Query_XLS, 1, &End);
```

Related Links

[RunToFile](#)

[RunToRowset](#)

FormatResultString

Syntax

```
FormatResultString(&Rowset, Output_Format, StartRow, EndRow)
```

Description

Use the `FormatResultString` method to generate a string containing the content of the input (the rowset) in HTML, PDF, XLS, or CSV format. You can specify the range of rows to be in the rowset to be used as input. The rowset object is created using the `RunToRowset` method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Rowset</i>	Specify an already instantiated and populated rowset object containing the query result. This rowset is created using the <code>RunToRowset</code> method.
<i>Output_Format</i>	Specify the format of the output. You can specify either a numeric or constant value. See below.
<i>Start_Row</i>	Specify the first row in the rowset that you want to use for output. This parameter takes a numeric value.
<i>End_Row</i>	Specify the last row in the rowset that you want to use for output. This parameter takes a numeric value.

The values for *Output_Format* can be as follows:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
2	<code>%Query_PDF</code>	The output is in PDF format.
5	<code>%Query_HTML</code>	The output is in HTML format.
8	<code>%Query_XLS</code>	The output for Excel in HTML format.
14	<code>%Query_TXT</code>	The output for text in CSV format.
20	<code>%Query_XML_XmlP</code>	The output is in XMLP format.

Returns

A string containing the formatted output.

Example

```
/* Use RowCount, not ActiveRowCount, to get the total number of rows. */
&End = &MyRowset.RowCount;
&FormString = &MyQuery.FormatResultString(&MyRowset, %Query_TXT, 1, &End);
```

[RunToFile](#)

[RunToRowset](#)

GetTreePromptCount

Syntax

```
GetTreePromptCount()
```

Description

Use the GetTreePromptCount method to get the number of tree prompts if available in the query.

Parameters

None.

Returns

A number that indicates the count of tree prompts used in the query. -1 in case of an error.

Example

In this example, the ExecQry step of the PSQUERY Application Engine program invokes the GetTreePromptCount() method using a value stored in the run control table prior to executing the query.

```
&aQry = %Session.GetQuery();  
If &aQry.Open(PSQUERY_AET.QRYNAME, &bPublic, False) = 0 Then  
    &nTreePromptCount = &aQry.GetTreePromptCount();  
End-if;
```

Open

Syntax

```
Open(QueryName, Public, Update)
```

Description

The Open method opens the query object specified by the parameters. The Open method can be used only with a closed query, it cannot be used on an open query. You cannot read or set any properties of a query until after you open it.

Considerations for Opening Different Types of Queries

When you use the Open method, the system tries to open queries according to the type of query. The following is the order used for searching for the query to open:

1. Query (User)

2. View
3. Role
4. Process
5. Archive

All query names are unique. You can't have two queries with the same name, just of different types.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>QueryName</i>	Specify the name of the query to be opened. You must specify an existing query. This parameter takes a string value.
<i>Public</i>	Specify if the query is public or private. This parameter takes a Boolean value: True if the query is public, False if it's a private query.
<i>Update</i>	This parameter is required, but is unused in this release. You must specify a either True or False.

Returns

An integer value: 0 means the query was opened successfully.

[Save](#)

Rename

Syntax

Rename (*NewQueryName*)

Description

The Rename method renames the existing query definition with *NewQueryName*. The Rename method can be used only with an open query, it cannot be used on a closed query. Before you use the Rename method, you must explicitly open the query object to be renamed (with either the Open or Create method.)

Note: The Rename method takes place immediately. You don't have to save the query for the rename to occur.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NewQueryName</i>	Specify the new name for the existing query. The maximum length of this parameter is 30 characters.

Returns

An integer value: 0 means the query was renamed successfully.

[Save](#)

RunToFile

Syntax

```
RunToFile(&PromptRecord, Destination, OutputFormat, MaxRows)
```

Description

Use the RunToFile method to execute the Query and return the result to the file specified with *Destination*. The query should be an existing query in the database, or it should have been saved using the Save method.

Because a Query may have runtime prompts (that is, criteria defined using Prompt), this method requires those values to be passed in when you execute this method. *PromptRecord* is a PeopleCode record object containing the prompt values as fields in the record. You can use the PromptRecord property to obtain this object.

Destination must include the absolute path name of where the file is to be created.

If the specified subdirectory does not exist, this method does *not* automatically create them for you, and you receive an error.

If you specify HTML as the output format, the PeopleSoft Query style sheet PSQUERYSTYLEDEF is used for formatting the output.

Related Links

"Understanding Style Sheets and Style Classes" (Application Designer Developer's Guide)

Parameters

Parameter	Description
<i>&PromptRecord</i>	Specify an instance of a PeopleCode record that contains the runtime prompts and values required for running the query.
<i>Destination</i>	Specify the absolute path name of where the files are to be created.
<i>OutputFormat</i>	Specify the format of the data being written to the file. You can use either a constant or a numeric value for this parameter. See below.
<i>MaxRows</i>	Specify the maximum number of rows to be fetched. This parameter takes a numeric value. The values are: <ul style="list-style-type: none"> -1 returns all rows <i>regardless</i> of the setting on the Query security profile (MaxRowsFetched). 0 returns the maximum number of rows allowed by the Query security profile. >0 is the limit on the number of rows.

The values for *OutputFormat* can be as follows:

Numeric Value	Constant Value	Description
2	%Query_PDF	The output is in PDF format.
5	%Query_HTML	The output is in HTML format.
8	%Query_XLS	The output for Excel in HTML format.
14	%Query_TXT	The output for txt in CSV format.
17	%Query_XML_WebRowset	The output is in web rowset XML format.
20	%Query_XML_XmlP	The output is in XMLP format.

Returns

Returns 0 if successful.

Example

To run a query using the query API RunToFile method:

1. Open the query.

```
&aRunQry = %Session.GetQuery();
&aRunQry.Open(&sQryName, False, False);
```

2. Obtain the PromptRecord for the query.

```
&aQryPromptRec = &aRunQry.PromptRecord;
```

This instance of the PromptRecord can be passed to the PeopleCode Prompt function to prompt the user for the runtime values, as follows:

```
&nResult = Prompt(&strQryName | " Prompts", "", &aQryPromptRec);
```

3. Run the query.

Now that you have the runtime values, the query can be run, as follows:

```
&aRowSet = &aRunQry.RunToFile(&aQryPromptRec, "c:\temp\QueryOutput.html", %Que⇒
ry_PDF, 0);
```

4. Access the data of the rowset.

You can now manipulate the rowset using the data buffer access methods and properties:

```
&aRowSet(&i).GetRecord(1).GetField(&j).Value
```

The following is a complete sample code example:

```
Local Rowset &aRowSet;
Local Row &aRow;
Local Record &aQryPromptRec;
Local Record &aRec;
Local ApiObject &aRunQry;
&strHTML = "";
&aRunQry = %Session.GetQuery();
If (&aRunQry.Open(&sQryName, False, False) <> 0) Then
    &strHTML = "Error in opening query";
Else
    &aQryPromptRec = &aRunQry.PromptRecord;
    &strQryName = &aRunQry.Name;
    If &aQryPromptRec <> Null Then
        &nResult = Prompt(&strQryName | " Prompts", "", &aQryPromptRec);
    End-If;
    If (&aRunQry.RunToFile(&aQryPromptRec, "c:\temp\" | &aRunQry.Name, 3, 0) = 0) Th⇒
en
    &strHTML = "Resultset saved into file successfully.";
Else
    &strHTML = "Failed to save Resultset into file.";
End-If;
End-If;
```

[RunToRowset](#)

[PromptRecord](#)

"Prompt" (PeopleCode Language Reference)

"Understanding Data Buffer Access" (PeopleCode Developer's Guide)

RunToRowset

Syntax

RunToRowset (&PromptRecord, MaxRows)

Description

Use the RunToRowset method to execute the Query and return the result to a rowset. The query should be an existing query in the database, or it should have been saved using the Save method.

Because a Query may have runtime prompts (that is, criteria defined using Prompt), this method requires those values to be passed in when you execute this method. *PromptRecord* is a PeopleCode record object containing the prompt values as fields in the record. The PromptRecord property can be used to obtain this object.

Parameters

Parameter	Description
<i>&PromptRecord</i>	Specify an instance of a PeopleCode record that contains the runtime prompts and values required for running the query.
<i>MaxRows</i>	<p>Specify the maximum number of rows to be fetched. This parameter takes a numeric value. The total number of rows fetched is the minimum value of this parameter's value, and the application server configuration parameter Max Fetch Size (which is specified in KB.)</p> <p>The values are:</p> <ul style="list-style-type: none"> -1 returns all rows <i>regardless</i> of the setting on the Query security profile (MaxRowsFetched). 0 returns the maximum number of rows allowed by the Query security profile. >0 is the limit on the number of rows.

Returns

If successful, the query result is returned as a populated PeopleCode rowset. If the query wasn't successful, the method returns NULL. If unsuccessful, check the PSMessages collection for errors.

Example

To run a query using the query API RunToRowset method:

1. Open the Query.

```
&aRunQry = %Session.GetQuery();
&aRunQry.Open(&sQryName, False, False);
```

2. Get the PromptRecord for the Query.

```
&aQryPromptRec = &aRunQry.PromptRecord;
```

This instance of the PromptRecord can be passed to the PeopleCode Prompt function to prompt the user for the runtime values, as follows:

```
&nResult = Prompt(&strQryName | " Prompts", "", &aQryPromptRec);
```

3. Run the query.

Now that you have the prompt values, you can run the query:

```
&aRowSet = &aRunQry.RunToRowset(&aQryPromptRec, 0);
```

4. Access the data of the rowset.

You can now manipulate the rowset using the data buffer access methods and properties:

```
&aRowSet(&i).GetRecord(1).GetField(&j).Value
```

The following is a complete sample code example:

```
Local Rowset &aRowSet;
Local Row &aRow;
Local Record &aQryPromptRec;
Local Record &aRec;
Local ApiObject &aRunQry;
&strHTML = "";
&aRunQry = %Session.GetQuery();
If (&aRunQry.Open(&sQryName, False, False) <> 0) Then
    &strHTML = "Error in opening query";
Else
    &aQryPromptRec = &aRunQry.PromptRecord;
    &strQryName = &aRunQry.Name;
    If &aQryPromptRec <> Null Then
        &nResult = Prompt(&strQryName | " Prompts", "", &aQryPromptRec);
        &aRowSet = &aRunQry.RunToRowset(&aQryPromptRec, 0);
        If &aRowSet <> Null Then
            &strHTML = &strHTML | "<table cellpadding='2' cellspacing='0' width=>
'90%'>";
            &aRec = &aRowSet(1).GetRecord(1);
            &QrySelOutputFldCol = &aRunQry.QuerySelect.QueryOutputFields;
            If &QrySelOutputFldCol <> Null Then
                &strHTML = &strHTML | "<TR><TD>";
                &strHTML = &strHTML | "<table border='1' cellpadding='2' cellspac=>
ing='0' width='100%'>";
                &strHTML = &strHTML | "<TR><TH>&nbsp;</TH>";
                For &j = 1 To &QrySelOutputFldCol.count
                    &strHTML = &strHTML | "<TH><B>" | &QrySelOutputFldCol.Item(&j)>
.LongName | "</B></TH>";
                End-For;
                &strHTML = &strHTML | "</TR>";
                &strHTML = &strHTML | "</TD></TR>";
            End-If;
            &strHTML = &strHTML | "<TR><TD>";
            If &aRowSet.RowCount > 0 Then
                For &i = 1 To &aRowSet.RowCount
```

```

        &aRow = &aRowSet(&i);
        &strHTML = &strHTML | "<TR>" | "<TD>" | &i | "</TD>";
        For &j = 1 To &aRow.GetRecord(1).FieldCount
            &strHTML = &strHTML | "<TD>" | &aRow.GetRecord(1).GetField(⇒
&j).Value | "</TD>";
        End-For;
        &strHTML = &strHTML | "</TR>";
    End-For;
    Else
        &strHTML = &strHTML | "No records retrieved.";
    End-If;
    &strHTML = &strHTML | "</TD></TR>";
    &strHTML = &strHTML | "</TABLE>";
    &strHTML = &strHTML | "</TABLE>";
    Else
        &strHTML = "Failed to retrieve result set.";
    End-If;
End-If;
End-If;

```

RunToString

Syntax

```
RunToString(&PromptRecord, ChunkSize, OutputFormat, MaxRows)
```

Description

Use the RunToString method to execute the query and return the result as a formatted string.

When “chunking” is active, RunToString is intended to be called in a recursive fashion until the result set has been completely traversed. A Boolean property, MoreRowsAvailable, is included in the Query class to control recursive execution of this method.

See [MoreRowsAvailable](#).

Parameters

Parameter	Description
<i>&PromptRecord</i>	Specify an instance of a PeopleCode record that contains the runtime prompts and values required for running the query.
<i>ChunkSize</i>	Specify the desired chunking size in characters as a number. 0 means no chunking.

Parameter	Description
<i>OutputFormat</i>	Specify the format of the data being written to the file. You can use either a constant or a numeric value for this parameter. See below.
<i>MaxRows</i>	Specify the maximum number of rows to be fetched. This parameter takes a numeric value. The values are: <ul style="list-style-type: none"> -1 returns all rows regardless of the setting on the query security profile (MaxRowsFetched). 0 returns the maximum number of rows allowed by the query security profile. >0 is the absolute limit on the number of rows.

The values for *Output_Format* can be as follows:

Numeric Value	Constant Value	Description
2	%Query_PDF	The output is in PDF format.
5	%Query_HTML	The output is in HTML format.
8	%Query_XLS	The output for Excel in HTML format.
14	%Query_TXT	The output for text in CSV format.
17	%Query_XML_WebRowset	The output is in web rowset XML format.
20	%Query_XML_XmlP	The output is in XMLP format.

Returns

A string containing the formatted output. If an error occurs, an empty string will be returned.

If there are no errors, but no data is in the query result set, the string will have system-defined header and footer information, but no rows will be present.

Example

The following example runs a query without chunking.

```
&queryname = "XRFWIN";

rem &querytype = %Query_XLS;
rem &querytype = %Query_PDF;
rem &querytype = %Query_HTML;
```

```

rem &querytype = %Query_TXT;
&querytype = %Query_XML_XmlP;
rem &querytype = %Query_XML_WebRowset;

&aRunQry = %Session.GetQuery();
If (&aRunQry.Open(&queryname, False, False) <> 0) Then
    MessageBox(0, "", 0, 0, "Error opening query");
Else
    &aQryPromptRec = &aRunQry.PromptRecord;

    &chunksize = 0;

    &filename = "C:\QueryWork850\output\" | &querytype | "_runtostring.xml";

    &resultString = &aRunQry.RunToString(&aQryPromptRec, &chunksize, &querytype, 0);

    &myfile = GetFile(&filename, "w", "UTF8", %FilePath_Absolute);
    &myfile.writestring(&resultString);
    &myfile.close();

    MessageBox(0, "", 0, 0, "Success!");

End-If;

```

The following example runs a query with chunking.

```

&queryname = "XRFWIN";
rem &querytype = %Query_XLS;
rem &querytype = %Query_PDF;
rem &querytype = %Query_HTML;
rem &querytype = %Query_TXT;
&querytype = %Query_XML_XmlP;
rem &querytype = %Query_XML_WebRowset;

&aRunQry = %Session.GetQuery();
If (&aRunQry.Open(&queryname, False, False) <> 0) Then
    MessageBox(0, "", 0, 0, "Error opening query");
Else
    &aQryPromptRec = &aRunQry.PromptRecord;
    &counter = 0;

    &chunksize = 1000;

    Repeat
        &counter = &counter + 1;
        &filename = "C:\QueryWork850\output\" | &querytype | &counter | "_runtostring=>
.xml";

        &resultString = &aRunQry.RunToString(&aQryPromptRec, &chunksize, &querytype, =>
0);

        If (Len(&resultString) > 0) Then

            &myfile = GetFile(&filename, "w", "UTF8", %FilePath_Absolute);
            &myfile.writestring(&resultString);
            &myfile.close();

        Else

            /* edge condition; if there are no more rows AND the */
            /* returned string is empty this is not an error.      */

            If (&aRunQry.MoreRowsAvailable) Then
                /* we have an error... Yikes! */
                MessageBox(0, "", 0, 0, "Something bad has happened!");
            Else

```

```
        /* no worries, just ignore it */  
        End-If;  
  
        End-If  
        Until (Not &aRunQry.MoreRowsAvailable);  
  
        MessageBox(0, "", 0, 0, "Success!");  
  
    End-If;
```

[MoreRowsAvailable](#)

Save

Syntax

Save ()

Description

The Save method writes any changes to the existing query to the database.

The Save method can be used only on an open query, not on a closed query. This means you must have opened the query with the Open method before you can save it.

The query object remains open after executing Save. You must execute the Close method on the object before it is closed and the memory freed.

Note: If you're calling the query API from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a COMMIT.

Parameters

None.

Returns

An integer value: 0 means the query was saved successfully.

Related Links

[Open](#)

[Close](#)

SetTrackingURL

Syntax

SetTrackingURL (*ExpressionText*, *ExpressionNumber*)

Description

Use the `SetTrackingURL` method to re-establish the drilling URL if the current execution context is different from the context in which the drilling URL was initially set.

For example, a drilling URL is set as a query expression by the program that executes the query. After query execution, a different program—an iScript program—allows the user to download the query results to an Excel spreadsheet. This iScript program needs to include the drilling URL in the spreadsheet data. In order for the iScript program to have access to the drilling URL query expression values, these values must be defined as global objects by the program that executes the query. Then, the iScript program can re-establish the drilling URL by calling the `SetTrackingURL` method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ExpressionText</i>	Specify the drilling URL as a string by reference to an established query expression.
<i>ExpressionNumber</i>	Specify the drilling URL as a numeric value by reference to an established query expression.

Returns

None.

Example

```

If &rsURLList <> Null And
    &rsURLList.ActiveRowCount >= 1 And
    All(&rsURLList(1).QRY_URL_WRK.QRYCRIT1EXPRTEXT.Value) Then
    For &nCount = 1 To &rsURLList.ActiveRowCount;
        &rRecordExpr = &rsURLList(&nCount).QRY_URL_WRK;
        &QryObj.SetTrackingURL(&rRecordExpr.QRYCRIT1EXPRTEXT.Value, &rRecordExpr.QRYC⇒
RIT1EXPRNUM.Value);
    End-For;
End-If;

```

Query Class Properties

In the following section, we discuss each Query class property.

Approved

Description

This property returns a string indicating whether a query is approved, unapproved, or modified. This is useful for query administration. The values are:

<i>Value</i>	<i>Description</i>
U	Query is unapproved. This is the default value. The query administrator can prevent execution of unapproved queries.
A	Query has been approved by the query administrator.
M	Query has been modified.

This property is read/write.

ApproveOprId

Description

Note: This property has been deprecated, and remains for backward compatibility only. Use the `ApproveUserId` property instead.

This property returns a string containing the user ID of the user who approved the query. This can be useful for query administration.

This property is read/write.

Related Links

[ApproveUserId](#)

ApproveUserId

Description

This property returns a string containing the user ID of the user who approved the query. This can be useful for query administration.

This property is read/write.

ApproveDtTm

Description

This property returns the date-time stamp when the query was most recently approved. This can be useful for query administration.

This property is read-only.

CreateOprId

Description

Note: This property has been deprecated, and remains for backward compatibility only. Use the `CreateUserId` property instead.

This property returns a string containing the User Id of the user who created the query. This can be useful for query administration.

This property is read-only.

Related Links

[CreateUserId](#)

CreateDtTm

Description

This property returns a string containing the date-time stamp indicating when the query was created. This property is set by the query runtime when a new query is saved. This can be useful for query administration.

This property is read-only.

CreateUserId

Description

This property returns a string containing the User Id of the user who created the query. This can be useful for query administration.

This property is read-only.

Description

Description

This property returns or sets the short description for the query.

The length of this property is 30 characters.

This property is read/write.

Disabled

Description

This property indicates if the query is active or not. This property returns a string value:

<i>Value</i>	<i>Description</i>
Y	This query is not active
Blank or any other value	This query is active

This property is read/write.

ExecAppName

Description

This property specifies the name of the application executing the query. This property isn't required. This means this property is used only if the query will be executed. This name is stored in the query execution log. This property returns a blank value when the query is opened.

When executing a query using the query API, this property should be set to the Application name that's executing it, so that the Query Monitor can track query execution. Doing this makes this property useful for query administration. If you try to read this property before setting it, you receive a NULL string.

This property should be set before using RunToRowset or RunToFile.

This property is read/write. However, this property is generally used only to set the name, rather than to read it.

ExecLogging

Description

This property indicates whether an execution log should be created when the query is executed. This can be useful for query administration. This property takes a Boolean value: True, create a log, False, don't create one.

The execution log, which is created by setting this property, can be viewed from the Query Monitor. The logging is done in a PeopleSoft Table. It stores, along with other relevant information, the Execution DateTime, Total Execution Time for the query, and Total Fetch Time for the query.

If you try to read this property before setting it, you receive a NULL string.

This property is read/write. However, this property is generally used only to set logging, rather than read.

Folder

Description

This property is used to group queries together. This parameter takes a string value, up to 18 characters.

This property is read/write.

LastSQLErrorCode

Description

This property returns the last SQL error code returned by the database as a number. The session object contains the error text and any other errors encountered while executing the query.

PeopleSoft recommends checking this value after using RunToRowset or RunToFile.

This property is read-only.

LastUpdDttm

Description

This property returns the most recent date-time when the query was updated as a string.

This property is read-only.

LastUpdOprId

Description

This property returns the User Id of the user who updated the query most recently as a string.

This property is read-only.

LongDescription

Description

This property returns or sets the long description for the query.

The length of this property is 256 characters.

This property is read/write.

Metadata

Description

This property returns a metadata collection.

This property is read-only.

Example

```
&MetadataList = &MyQuery.Metadata;
```

Related Links

[Query Metadata Collection](#)

MetaSQL

Description

This property returns the SQL that represents the query, unresolved for any platform.

For example, the MetaSQL property returns the following:

```
SELECT %DATEOUT(A.ASOF_DT)
FROM PS_AEREQUESTTBL A
WHERE A.ASOF_DT = %DATEIN('1900-01-01')
```

This property is read-only.

MoreRowsAvailable

Description

This property returns a Boolean value indicating whether “chunking” is turned on for the query.

This property is read-only.

Chunking Considerations

Every time a row is retrieved from the query result set, it is added to the internal output string managed by `RunToString`. At this point, the method can check to see if chunking is active. If so, and if the current size of the output string is larger than the `ChunkSize` parameter, then the query context is stored and the output string is returned. If not, then the next row is retrieved from the result set and the process continues.

When chunking is active, `RunToString` is intended to be called in a recursive fashion until the result set has been completely traversed. A Boolean property, `MoreRowsAvailable`, is included in the `Query` class to control recursive execution of these methods.

Related Links

[RunToString](#)

Name

Description

This property returns the name of the query as a string.

The length of this property is 30 characters.

This property is read-only.

OutputUnicode

Description

Use this property to set or return a Boolean value indicating whether the RunToFile method will create a Unicode-encoded CSV file as output. This property is applicable only if the output format is set to %Query_TXT. Because the default value is false, OutputUnicode must be set before calling RunToFile.

Note: Because Microsoft Excel does not support UTF-8 encoding, the CSV file is written in binary mode with UCS-2 encoded data. Moreover, Excel does not automatically recognize Unicode-encoded, comma-delimited files even if they have a .csv extension. Therefore, the user receiving the file will not be able to open it by double-clicking. Instead, he or she must open it with Excel's File, Open menu and choose the comma delimiter.

This property is read/write.

Example

```
&aQry.OutputUnicode = True;
&Result = &aQry.RunToFile(&rcdQryPrompts, &sOutFile, %Query_TXT, 0);
```

Related Links

[RunToFile](#)

PDFFont

Description

This property is used to set the PDF Font number required for generating PDF using RunToFile. This property takes either a numeric or constant value. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%PDFFont_None	Default value
2	%PDFFont_TraditionalChinese	The output must be written using the Traditional Chinese Font.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
3	%PDFFont_SimplifiedChinese	The output must be written using the Simplified Chinese Font.
1	%PDFFont_Japanese	The output must be written using the Japanese Font
4	%PDFFont_Korean	The output must be written using the Korean Font

If you try to read this property before setting it, you receive a NULL string.

This property is read/write.

Related Links

[RunToFile](#)

[RunToRowset](#)

Prompts

Description

This property returns all the prompts defined for the Query in a QueryPrompt Collection. If you just want the prompts used in the criteria, use the RunTimePrompts property.

This property is read-only.

Related Links

[RunTimePrompts](#)

[QueryPrompt Collection](#)

PromptRecord

Description

This property returns the runtime prompts of a query as an instance of a PeopleCode record object. This can be used with the Prompt built-in function to prompt for bind values. This record instance can also be used as the first input parameter for the RunToRowset and RunToFile methods.

This property is read-only.

Related Links

[RunToFile](#)

[RunToRowset](#)

PublicPrivate

Description

This property specifies whether the query is public or private.

You can use either a constant or numeric value for this property. The values are:

Numeric Value	Constant Value	Description
0	%Query_Private	The query is a private query.
1	%Query_Public	The query is a public query.

This property is read/write.

Example

```
If &QryObj.PublicPrivate = %Query_Public Then
    /* code when working with Public Query */
Else
    /* code when working with Private Query */
End-if;
```

QuerySelect

Description

This property returns the Main Select (that is, the first select) of the query definition as a QuerySelect object. For a new query which does not have any selects, it returns NULL.

The Query Records, Query Criteria, QueryOutput fields, and QuerySelected Fields can be obtained using the QuerySelect object only. Hence, after opening a query, this property serves as the starting point for getting the different components of the Select statement.

This property is read-only.

Related Links

[QuerySelect Class](#)

QueryStatistics

Description

This property returns statistical information pertaining to the query's execution as a QueryStatistics object.

This property is read-only.

Related Links

[QueryStatistics Class](#)

RunTimePrompts

Description

This property returns the prompts used in the Query Definition's criteria in a QueryPrompt Collection. To return all the prompts defined for the query, use the Prompts property.

This property is read-only.

Related Links

[Prompts](#)

[QueryPrompt Collection](#)

SQL

Description

This property returns the SQL statement as generated from the query definition as a character string.

Note: The value of the SQL property is never stored as part of the query definition. Instead, it's generated by the system whenever it's needed for one of the RunTo methods or for the SQL property.

In the PeopleSoft Query, this is located under the SQL tab.

This property is read-only.

Considerations Using the SQL Property

This property returns a basic SQL statement. This statement does not include logic for doing related language record transactions or translate descriptions. PeopleSoft does not recommend using this SQL for selecting data. Instead, PeopleSoft recommends using the RunToRowset method for selecting data.

Type

Description

This property specifies the type of query. This parameter takes either a constant or number value. Values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_Query	Query of type Query

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
3	%Query_View	Query of type View
4	%Query_Role	Role
5	%Query_DBAgent	Process
7	%Query_Archive	Archive

This property is read/write.

QuerySelect Collection

A QuerySelect collection is returned from the QuerySelects property of each QuerySelect instance. It contains the unions and subqueries, which are children of the current select statement. PeopleSoft Query allows unions only for the main select. The QuerySelect instance for any subqueries cannot have any unions.

See [QuerySelects](#).

QuerySelect Collection Methods

In this section, we discuss the QuerySelect collection methods. The methods are discussed in alphabetical order.

AddUnion

Syntax

```
AddUnion()
```

Description

The AddUnion method adds a new QuerySelect object of type Union in the current QuerySelect collection. You can use AddUnion only with the first QuerySelect Collection because PeopleSoft Query doesn't support Unions for subqueries. All unions are considered children of the Main Select.

Parameters

None.

Returns

A reference to a QuerySelect object if successful. If the current QuerySelect Collection does not belong to the first Select statement, it returns NULL. If it fails, it returns NULL.

Example

```
&QryMainSel = &Query.QuerySelect;
&QryMainSelCol = &QryMainSel.QuerySelects;
&QryUnion = &QryMainSelCol.AddUnion();
```

DeleteQuerySelect

Syntax

```
DeleteQuerySelect (SelNumber)
```

Description

The DeleteQuerySelect method deletes the QuerySelect instance represented *SelNumber*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SelNumber</i>	Specify the numeric value containing the Select Number of the QuerySelect that you want to delete.

Returns

Returns 0 if successful.

Example

```
&QryMainSel = &Query.QuerySelect;
&QryMainSelCol = &QryMainSel.QuerySelects;
&QryMainSelCol.DeleteQuerySelect(3);
```

First

Syntax

```
First ()
```

Description

The First method returns the first child QuerySelect object in the current QuerySelect's collection.

Parameters

None.

Returns

A reference to a QuerySelect object if successful, NULL otherwise.

Example

```
&MyChildQrySel = &MySelCollection.First();
```

Item

Syntax

Item (*number*)

Description

The Item method returns the QuerySelect object that exists at the *number* position in the current QuerySelect collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the collection of the QuerySelect object that you want returned.

Returns

A reference to a QuerySelect object if successful, NULL otherwise.

Example

```
For &I = 1 to &QrySelCol.Count;
    &MyChildQrySel = &QrySelCol.Item(&I);
    /* do processing */
End-For;
```

ItemBySelNum

Syntax

ItemBySelNum (*SelNumber*)

Description

The `ItemBySelNum` method returns the `QuerySelect` object specified by *the Select Number*. Each Select Statement in a Query Definition is identified by a unique select number.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SelNumber</i>	Specify the numeric value of the Select Number.

Returns

A reference to a `QuerySelect` object if successful, NULL otherwise.

Example

```
&MyChildQuerySelect = &MySelCol.ItemBySelNum(3);
```

Next

Syntax

```
Next ()
```

Description

The `Next` method returns the next `QuerySelect` object in the current `QuerySelect` collection. You can use this method only after you have used the `First` method: otherwise the system returns a NULL.

Parameters

None.

Returns

A reference to a `QuerySelect` object if successful, NULL otherwise.

Example

```
&MyChildQuerySelect = &MySelCol.Next();
```

QuerySelect Collection Property

In this section, we discuss the `Count` property.

Count

Description

This property returns the total number of QuerySelect objects in the current QuerySelect Collection, as a number.

This property is read-only.

Example

```
&COUNTCHILDSELS = &MYSELCOL.Count;
```

QuerySelect Class

The QuerySelect class represents the select statement of the SQL used in the query definition. This can be any of the following:

- The main select statement.
- The select statement in each union.
- The select statement in each subquery.

Consider the following SQL statement:

```
select ACCOUNT_NUM from GL_ACCOUNT_TBL_00
where PRODUCT_ID in (select DISTINCT PRODUCT_ID FROM ORDER_TBL)
union
select ACCOUNT_NUM from GL_ACCOUNT_TBL_01
```

In this example, there are three select statements. The first select statement is the main statement. The second select statement is a subquery, which is then used in the criterion for the first select statement. The union contains the third select statement. There are records and fields associated with each select statement. In the query API, the first select is accessible using Query.QuerySelect, which can be obtained as shown:

```
&MainSelect = &Qry.QuerySelect;
```

The union can be obtained from the main select, as shown:

```
/* There can be more than one union, hence there is collection of selects */
/* in the main select */
&Union1 = &MainSelect.QuerySelects.Item(1);
```

The subquery is obtained from the main select as shown:

```
/* belongs to first criteria of the select */
&SubQry1 = &MainSelect.Criteria.Item(1).Expr2SubQuery;
```

Therefore, there is one QuerySelect instance for the main select of the query, one instance per union defined in the query, and one instance per subquery.

In PeopleSoft Query, the first select (that is, the main select) is the parent of all the unions and subqueries. The main select is obtained with the QuerySelect property. The unions and subqueries are obtained from the QuerySelects property of each QuerySelect instance.

A QuerySelect object is returned from the following:

- The QuerySelect collection methods AddUnion, First, Item, ItemBySelNum, or Next
- The QuerySelect Query property

See [QuerySelect Collection](#), [QuerySelects](#).

QuerySelect Methods

In this section, we discuss each QuerySelect method. The methods are arranged in alphabetical order.

AddAllFields

Syntax

AddAllFields (*QueryRecord*)

Description

The AddAllFields method adds all the fields in the specified query record to the query definition, that is, makes them all QueryOutputFields. The query record must already be a part of the query definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>QueryRecord</i>	Specify the instance of an existing record in the query from which you want to add all the fields from to the query definition. This instance can be obtained from the QueryRecords collection of the QuerySelect.

Returns

An integer: 0 if successfully added.

Related Links

[AddQuerySelectedField](#)

AddCriteria

Syntax

AddCriteria (*Name*)

Description

The AddCriteria method adds new criterion to the query definition. This method returns a reference to a new QueryCriteria object that you can then use to specify details about the criteria.

Note: If you do not specify a unique name for *Name* when adding a criteria, a criteria object referencing the new criteria is returned, not the existing criteria object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify a string containing the name of the criteria that you want to add. The maximum length of this parameter is 30 characters.

Returns

A reference to a QueryCriteria object.

AddExpression

Syntax

AddExpression (*Name*)

Description

The AddExpression method adds an expression to the query definition. It returns a reference to a new QueryExpression object you can use to specify details about the expression.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify a string containing the name of the expression that you want to add. This maximum length of this parameter is 30 characters.

Returns

A reference to a QueryExpression object.

AddHavingCriteria

Syntax

AddHavingCriteria (*Name*)

Description

The AddHavingCriteria method adds new criterion to the query definition, which is intended for use in the HAVING clause of the SELECT statement. This method returns a reference to a new QueryCriteria object that you can then use to specify details about the having criteria.

Note: If you do not specify a unique name for *Name* when adding a criterion, a criteria object referencing the new criteria is returned, not the existing criteria object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify a string containing the name of the criteria that you want to add. The maximum length of this parameter is 30 characters.

Returns

A reference to a QueryCriteria object.

Related Links[DeleteHavingCriteria](#)[HavingCriteria](#)[QueryCriteria Class](#)**AddQueryOutputField****Syntax**`AddQueryOutputField(QueryRecord, index)`**Description**

The AddQueryOutputField method adds a query output field to the query definition. This method returns a reference to a new QueryOutputField object that you can then use to specify attributes for the query definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>QueryRecord</i>	Specify the QueryRecord instance that contains the field that you want to include in the query definition. This instance can be obtained from the QueryRecords collection of the QuerySelect.
<i>Index</i>	Specify the numeric position in the QueryRecord of the field that you want to add.

Returns

A reference to a QueryOutputField object.

Related Links[AddAllFields](#)[QueryField Class](#)**AddQueryRecord****Syntax**`AddQueryRecord(QueryRecordName)`

Description

The `AddQueryRecord` method adds a query record to the query definition. You must specify a valid record name in the string parameter *QueryRecordName*. This method returns a reference to the record as a `QueryRecord`.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>QueryRecordName</i>	Specify a string containing the name of a record to be added to the query definition. You must specify a valid record name. The maximum allowed length for this parameter is 15 characters.

Returns

A reference to the record as a `QueryRecord` object.

[QueryRecord Class](#)

AddQuerySelectedField

Syntax

```
AddQuerySelectedField(QueryRecordName, RecordAlias, FieldName, Heading)
```

Description

The `AddQuerySelectedField` method adds a query field to the query definition, as a `QuerySelectedField`. This method returns a reference to a new `QuerySelectedField` object that you can then use to specify attributes for the query definition. At the time it's added, it isn't an output field. This can be changed by setting the column number of the field to a value greater than zero.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>QueryRecordName</i>	Specify the name of the query record to which the field that you want to add belongs.
<i>RecordAlias</i>	Specify the alias of the record (such as A, B, C, and so on.) The length of this parameter is 1.
<i>FieldName</i>	Specify the name of the field that's being added. The maximum allowed length for a field name is 18 characters.

<i>Parameter</i>	<i>Description</i>
<i>Heading</i>	Specify the heading of the field that's being added. The maximum allowed length for a heading is 30 characters.

Returns

A reference to a QuerySelectedField object.

QuerySelect Properties

In this section, we discuss the QuerySelect properties. The properties are discussed in alphabetical order.

Criteria

Description

This property returns a reference to a QueryCriteria Collection for the simple criteria of the SELECT (that is, the criteria that are used in the where clause of the select statement.)

This property is read-only.

Related Links

[QueryCriteria Collection](#)

Distinct

Description

This property specifies if the Select is distinct or not.

This property takes a Boolean value: True if the query is distinct, False if the query isn't distinct.

This property is read/write.

Expressions

Description

This property returns a reference to a QueryExpression Collection.

This property is read-only.

Related Links

[QueryExpression Collection](#)

HavingCriteria

Description

This property returns a reference to a QueryCriteria collection populated with Having criteria.

This property is read-only.

Related Links

[QueryCriteria Collection](#)

ParentSelectNum

Description

This property returns the select number of the parent select of the current select object. Every QuerySelect is assigned a unique number indicating its place in the hierarchy of select statements. For the Main Select, this number is zero. For unions, this number is 1 (unions aren't allowed in subqueries.)

This property is read-only.

QueryOutputFields

Description

This property returns a reference to a QueryField Collection made up of QueryOutputFields.

The collection of QueryOutputFields does *not* necessarily include all columns returned in query resultset. This collection only includes columns that have been added to query output collection using the query classes or by an end-user designing a query.

PeopleSoft Query can also add additional columns for related language processing and also for translate labels on fields, and so you cannot use the Query Output Collections as a way to discover all of the columns that are returned in the resultset or by executing the SQL generated from a query.

This is property is read-only.

[QueryField Collection](#)

QuerySelects**Description**

This property returns all the QuerySelect objects that are children of the current select statement as a QuerySelect collection. If the query contains unions, this property contains unions and subqueries (if any criteria contain subqueries). For all other selects, this property contains only the subqueries (because PeopleSoft Query doesn't allow unions for sub-queries).

This property is read-only.

Related Links

[QuerySelect Collection](#)

SelectNum**Description**

This property returns the select number of the current select. Every QuerySelect is assigned a unique number indicating its place in the hierarchy of select statements. For the Main Select, this number would be 1.

This property is read-only.

SelectType**Description**

This property specifies what type of select statement. You can check for either a numeric or a constant value. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_SelectMain	This is the Main Select of the query definition.
2	%Query_SubQuery	This is a subquery in the query definition.
3	%Query_Union	This is a Union in the query definition.

This property is read-only.

QueryRecord Collection

A QueryRecord collection is returned from the QueryRecords QuerySelect class method.

See [QueryRecords](#).

QueryRecord Collection Methods

In this section, we discuss each QueryRecord collection method. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The First method returns the first QueryRecord object in the QueryRecord collection.

Parameters

None.

Returns

A reference to a QueryRecord object if successful, NULL otherwise.

Example

```
&MyQueryRecord = &MyCollection.First();
```

Item

Syntax

Item (*number*)

Description

The Item method returns the QueryRecord object that exists at the *number* position in the QueryRecord collection.

Parameters

Parameter	Description
<i>Number</i>	Specify the position number in the collection of the QueryRecord object that you want returned.

Returns

A reference to a QueryRecord object if successful, NULL otherwise.

Example

```
For &I = 1 to &QueryRecordColl.Count;
    &MyQueryRecord = &QueryRecordColl.Item(&I);
    /* do processing */
End-For;
```

ItemByAlias

Syntax

ItemByAlias (*Alias*)

Description

The ItemByAlias method returns the QueryRecord object specified by *Alias*.

Parameters

Parameter	Description
<i>Alias</i>	Specify the record alias (for example, A, B, C, and so on), used in the SQL statement as a TableName alias.

Returns

A reference to a QueryRecord object if successful, NULL otherwise.

Example

```
&MyQueryRecord = &MyCollection.ItemByAlias("A");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next QueryRecord object in the QueryRecord collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a QueryRecord object if successful, NULL otherwise.

Example

```
&MyQueryRecord = &MyCollection.Next ();
```

QueryRecord Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of QueryRecord objects in the QueryRecord Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

QueryRecord Class

A QueryRecord object is returned from the following:

- The QueryRecord Collection methods First, Item, ItemByName, or Next.
- The AddQueryRecord QuerySelect class method.
- The QueryRecord QueryField class method.

See [QueryRecord Collection](#), [AddQueryRecord](#), [QueryRecord](#).

QueryRecord Class Method

In this section, we discuss the GetField method.

GetField

Syntax

```
GetField(Index)
```

Description

The GetField method returns the QueryField object specified by *index* from the QueryRecord collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the number of the field to be accessed.

Returns

A reference to a QueryField object if successful, NULL otherwise.

Example

```
&QryFieldColl = &QryRec.QueryFields;

For &I = 1 to &QryFieldColl.Count
    &QryField = &QryRec.GetField(&I);
    /* do processing */
End-For;
```

QueryRecord Class Properties

In this section, we discuss each QueryRecord class property. The properties are discussed in alphabetical order.

Description

Description

This property returns the short description of the record as a string.

The length of this property is 30 characters.

This property is read-only.

JoinAlias

Description

This property returns or sets the join record's alias, that is, A, B, C, and so on.

This is applicable in any type of join. The value is a string. The length of this property is 1 character.

This property is read/write.

JoinFieldName

Description

This property returns or sets the join record's field used in the join criteria. This is applicable in lookuptable joins. The value is a string.

The length of this property is 18 characters.

This property is read/write.

JoinType

Description

This property returns or sets the join type. This is applicable in any type of join. You can use either a constant or numeric value.

The values for the join type are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_JoinNone	Query record isn't joined with any other record.
2	%Query_JoinHierarchy	Query record has a hierarchy join with another record.
3	%Query_JoinRelated	Query record has a lookup table join with another record.
4	%Query_JoinTree	Query record has a tree join with another record.
5	%Query_JoinLeftOuter	Query record has a left outer join with another record.

This property is read/write.

Name

Description

This property returns the name of the record as a string.

The length of this property is 15 characters.

This property is read-only.

QueryFields

Description

This property returns a reference to a QueryField Collection that contains instances of all the fields belonging to the record definition.

This property is read-only.

Related Links

[QueryField Collection](#)

RecordAlias

Description

This property returns the alias used for the record in the query (that is, A, B, C, and so on.)

The length of this property is 1 character.

This property is read/write.

QueryField Collection

A QueryField collection is returned from the following:

- The QueryOutputFields of QuerySelect class method.
- The QuerySelectedFields of QuerySelect class method.
- The QueryFields QueryRecord class method.

The collection of QueryOutputFields does *not* necessarily include all columns returned in query resultset. This collection only includes columns that have been added to query output collection using the query classes or by an end-user designing a query.

PeopleSoft Query can also add additional columns for related language processing and also for translate labels on fields, and so you cannot use the Query Output Collections as a way to discover all of the columns that are returned in the resultset or by executing the SQL generated from a query.

See [QueryOutputFields](#), [QuerySelectedFields](#), [QueryFields](#).

QueryField Collection Methods

In this section, we discuss each QueryField method. The methods are discussed in alphabetical order.

First

Syntax

```
First ()
```

Description

The First method returns the first QueryField object in the QueryField collection.

Parameters

None.

Returns

A reference to a QueryField object if successful, NULL otherwise.

Example

```
&MyQueryField = &MyCollection.First();
```

Item

Syntax

```
Item(number)
```

Description

The Item method returns the QueryField object that exists at the *number* position in the QueryField collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the collection of the QueryField object that you want returned.

Returns

A reference to a QueryField object if successful, NULL otherwise.

Example

```
For &I = 1 to &QueryFieldColl.Count;
    &MyQueryField = &QueryFieldColl.Item(&I);
    /* do processing */
End-For;
```

ItemByNameAndAlias

Syntax

```
ItemByNameAndAlias(Name, RecordAlias)
```

Description

The ItemByNameAndAlias method returns the QueryField object with the given *Name* and *Record Alias*.

Parameters

<i>Parameter</i>	<i>Description</i>
Name	Specify the name of an existing QueryField within the QueryField collection. If you specify an invalid name, the object is NULL.
RecordAlias	Alias of the record to which the field belongs

Returns

A reference to a QueryField object if successful, NULL otherwise.

Example

```
&MyQueryField = &MyCollection.ItemByNameAndAlias("PHONELIST", "A");
```

ItemByExpNum

Syntax

```
ItemByExpNum (ExpNum)
```

Description

The ItemByExpNum method returns the QueryField object with the given Expression Number, *ExpNum*.

Parameters

<i>Parameter</i>	<i>Description</i>
ExpNum	Expression Number for the given expression field. Non-expression fields have 0 value for the Expression Number.

Returns

A reference to a QueryField object if successful, NULL otherwise.

Example

```
&QryFld = &QryFldCol.ItemByExpNum(1);
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next QueryField object in the QueryField collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a QueryField object if successful, NULL otherwise.

Example

```
&MyQueryField = &MyCollection.Next ();
```

QueryField Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of QueryField objects in the QueryField Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

QueryField Class

A QueryField object is returned by the following:

- The AddQuerySelectedField of QuerySelect class method.
- The AddQueryOutputField of QuerySelect class method.

- The QueryField collection methods First, Item, ItemByName or Next.

See [AddQuerySelectedField](#), [AddQueryOutputField](#).

See [QueryField Collection](#).

QueryField Class Methods

In this section, we discuss each QueryField method. The methods are discussed in alphabetical order.

AddTranslateExpression

Syntax

```
AddTranslateExpression(ExpressionName)
```

Description

Use the AddTranslateExpression method to add Translate Effective Date Logic expressions for translatable fields.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ExpressionName</i>	Specify the name of the expression name that you want to add.

Returns

A reference to a QueryExpression object.

Related Links

[Expressions](#)

[DeleteExpression](#)

[AddExpression](#)

[AddTranslateField](#)

[QueryExpression Class](#)

AddTranslateField

Syntax

```
AddTranslateField(FieldName)
```

Description

Use the AddTranslateField method to add a Translate Effective Date Logic field for a translatable field.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>FieldName</i>	Specify the name of the translate field that you want to add. The maximum allowed length of this parameter is 18 characters.

Returns

A reference to a QueryField object.

Related Links

[Expressions](#)

[DeleteExpression](#)

[AddExpression](#)

[AddTranslateExpression](#)

[QueryExpression Class](#)

GetImageFormat

Syntax

```
GetImageFormat ()
```

Description

Use the GetImageFormat method to differentiate between images and files, both stored as binary large objects (BLOBs) in the database.

Note: Because images and files share the field type value 8, this method is required to differentiate between the two types.

Parameters

None.

Returns

A number. A value 16 indicates that the field is of type file (or attachment).

Related Links

[Type](#)

QueryField Class Properties

In this section, we discuss the QueryField class properties. The properties are discussed in alphabetical order.

Aggregate

Description

This property returns or sets the aggregate type for the query field.

This property takes either a constant or numeric value. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_TtlNone	Query field has no total
2	%Query_TtlSum	Query field is for Sum
3	%Query_TtlCount	Query field is for Count
4	%Query_TtlMin	Query field is for Minimum
5	%Query_TtlMax	Query field is for Maximum
6	%Query_TtlAvg	Query field is for Average

This property is read/write.

ColumnNumber

Description

This property returns or sets the column number for the query field as a number. If the column number is greater than zero, the field is an output field.

This property is read/write.

Description

Description

This property returns the long description of the field as a string. This same value is returned by the Description property of the QueryDBRecordField class.

The length of this property is 30 characters.

This property is read-only.

Decimal

Description

This property returns the decimal positions QueryField as a number. This same value is returned by the Decimal property of the QueryDBRecordField class.

This property is read-only.

ExpNum

Description

This property returns or sets the Expression Number for the field. This value is 0 for non-expression fields. If the field is created for an expression, this value is the same as the expression number of the corresponding expression. This property takes a number value.

This property is read/write.

Flag

Description

This property returns the Use Edit flag for the Query Field. It has the same values as returned by the Flag property of the QueryDBRecordField. This property takes a number value.

This property is read-only.

Format

Description

This property returns the field format for the query field. This property returns a string value. This property is useful for displaying the data type in a string format.

Values are:

Data Type	Value Returned
Character	"CHAR "
Long character	"LONG CHAR "
Number	"NUMBER "
Signed number	"SIGNED "
Date	"DATE "
Time	"TIME "
DateTime	"DATE/TIME "
Image	"IMAGE "

This property is read-only.

HeadingText

Description

This property returns or sets the heading text for the query field as a string.

The length of this property is 30 characters.

This property is read/write.

HeadingType

Description

This property returns or sets the heading type for the query field. This property takes either a numeric or constant value. The values are:

Numeric Value	Constant Value	Description
1	%Query_HdgNone	Query field has no heading.
2	%Query_HdgText	Query field has a text heading.
3	%Query_HdgRftShort	Query field uses the short RFT heading.

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
4	%Query_HdgRftLong	Query fields uses the long RFT heading.

This property is read/write.

HeadingUniqueFieldName

Description

This property returns or sets the unique field name for the heading. The default value for this property is the record alias combined with the field name.

The length of this property is 30 characters.

This property is read/write.

Length

Description

This property returns the length of the Query Field. The same value is returned by the Length property of the QueryDBRecordField. This property takes a numeric value.

This property is read-only.

LongName

Description

This property returns the long name of the Query Field. The same value is returned by the Long Name property of the QueryDBRecordField. This property takes a string value.

The length of this property is 30 characters.

This property is read-only.

Name

Description

This property returns the name of the query field as a string.

The length of this property is 18 characters.

This property is read-only.

OrderByDirection

Description

This property returns or sets the order by direction. This property takes a numeric value. The constants are the ASCII codes for space (" ") and "D".

Values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
32	Code(" ")	Ascending
68	Code("D")	Descending

This property is read/write.

Example

The following sets the order by direction to be ascending.

```
&QueryField.OrderByDirection = Code(" ");
```

The following sets the order by direction to be descending.

```
&QueryField.OrderByDirection = Code("D");
```

OrderByNumber

Description

Use this property to specify whether a field is used as part of an 'Order By' statement in the SQL. The number value of this property indicates which is the first field in the order by statement, which is the second, and so on.

This property is read/write.

Example

To order a query by one field, you must set the OrderByNumber property for the other QueryFields as well, specifying the primary field as 1, the next field as 2, and so on.

```
&QryFld = &MainQrySel.AddQuerySelectedField("PSRECDEFN", "A", "RECNAME", "Record Name");
&QryFld.ColumnNumber = 1;
&QryFld.OrderByNumber = 1;

&QryFld = &MainQrySel.AddQuerySelectedField("PSRECDEFN", "A", "RECDESCR", "Record Description");
&QryFld.ColumnNumber = 2;
&QryFld.OrderByNumber = 2;
```

```
&QryFld = &MainQrySel.AddQuerySelectedField("PSRECDEFN", "A", "RELLANGRECNAME", "Re⇒  
cord Lang Rec");  
&QryFld.ColumnNumber = 3;  
&QryFld.OrderByNumber = 3;
```

QueryRecord

Description

This property returns a reference to the QueryRecord containing this QueryField. If the field has no QueryRecord (that is, that this field is an expression field), this property returns NULL.

This property is read-only.

Example

```
&QryRcd = &QryFld.QueryRecord;
```

RecordAlias

Description

This property returns the record alias for the Query Field as a string. This value is usually a value like "A", "B", and so on. The same value is returned by the RecordAlias property for QueryRecord.

The length of this property is 1 character.

This property is read-only.

ShortName

Description

This property returns the short name of the Query Field. The same value is returned by the ShortName property for QueryDBRecordField. This property takes a string value.

The length of this property is 15 characters.

This property is read-only.

TranslateEffDtLogic

Description

This property returns or sets the effective date logic for the QueryField.

The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_ExprCurDt	Current Date
2	%Query_ExprField	Field
3	%Query_Expression	Expression

This property is read/write.

TranslateExpression

Description

This property returns a reference to an expression object based on a translate field if the Translate Effective Date option refers to an Expression

This property is read-only.

Related Links

[QueryExpression Class](#)

TranslateField

Description

This property returns a reference to a QueryField object for a translate field if the Translate Effective Date Option refers to a field.

This property is read-only.

Related Links

[QueryField Class](#)

TranslateOption

Description

This property returns or sets the translate value for the QueryField. This property takes a numeric or constant value. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_XlatNone	None

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
2	%Query_XlatShort	Short
3	%Query_XlatLong	Long

This property is read/write.

Type

Description

This property returns the type of the field. You can use either a numeric or constant value. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%FieldType_Char	Character
1	%FieldType_LongChar	Long Character
2	%FieldType_Number	Number
3	%FieldType_SignedNumber	Signed number
4	%FieldType_Date	Date
5	%FieldType_Time	Time
6	%FieldType_DateTime	DateTime
8	%FieldType_Image	Image
8	%FieldType_File	File
9	%FieldType_ImageRef	ImageReference

Note: The Image and File types can be differentiated using the `GetImageFormat` method of the `QueryField` class.

This property is read-only.

Related Links

[GetImageFormat](#)

QueryCriteria Collection

A QueryCriteria collection is returned from the Criteria QuerySelect class property.

See [Criteria](#).

QueryCriteria Collection Methods

In this section, we discuss the QueryCriteria collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The First method returns the first QueryCriteria object in the QueryCriteria collection.

Parameters

None.

Returns

A reference to a QueryCriteria object if successful, NULL otherwise.

Example

```
&MyQueryCriteria = &MyCollection.First();
```

Item

Syntax

```
Item(number)
```

Description

The Item method returns the QueryCriteria object that exists at the *number* position in the QueryCriteria collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the collection of the QueryCriteria object that you want returned.

Returns

A reference to a QueryCriteria object if successful, NULL otherwise.

Example

```
For &I = 1 to &MyCollection.Count;
    &MyQueryCriteria = &MyCollection.Item(&I);
    /* do processing */
End-For;
```

ItemByName

Syntax

```
ItemByName (CriteriaName)
```

Description

The ItemByName method returns the QueryCriteria object that exists with the passed CriteriaName in the QueryCriteria collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>CriteriaName</i>	Specify the name of the Criteria to be searched. This name is the same as the one used while creating the criteria using QuerySelect.AddCriteria(CriteriaName).

Returns

A reference to a QueryCriteria object if successful, NULL otherwise.

Example

```
&MyQueryCriteria = &MyCollection.ItemByName("PHONELIST");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next QueryCriteria object in the QueryCriteria collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a QueryCriteria object if successful, NULL otherwise.

Example

```
&MyQueryCriteria = &MyCollection.Next ();
```

QueryCriteria Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of QueryCriteria objects in the QueryCriteria Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

QueryCriteria Class

A QueryCriteria object is returned from the following:

- The AddCriteria and AddHavingCriteria QuerySelect class method.
- The First, Item, and Next method of the QueryCriteria Collection.

See [AddCriteria](#), [AddHavingCriteria](#).

See [QueryCriteria Collection](#).

See [Working With Query Criteria and Expressions](#).

See "Choosing Selection Criteria" (Query)"Defining Criteria" (Query).

QueryCriteria Class Methods

In this section, we discuss the QueryCriteria class methods. The methods are discussed in alphabetical order.

AddExpr1Expression

Syntax

```
AddExpr1Expression ()
```

Description

The AddExpr1Expression method returns a reference to a new a QueryExpression object to be used as an expression for Expression 1. You can then use this object to specify details about the expression using the methods and properties of the QueryExpression Class.

Note: You must set the type for Expression 1 using the Expr1Type property before you can use this method.

Parameters

None.

Returns

A reference to a blank QueryExpression object.

Related Links

[Expr1Expression](#)

[AddExpr1Field](#)

[Expr1Type](#)

[QueryExpression Class](#)

AddExpr1Field

Syntax

```
AddExpr1Field (QueryRecordAlias, FieldName)
```

Description

The `AddExpr1Field` method returns a reference to a new `QueryField` object to be used as a field for Expression 1. You can then use this object to specify details about the expression using the methods and properties of the `QueryField` Class.

Note: You must set the type for Expression 1 using the `Expr1Type` property before you can use this method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>QueryRecordAlias</i>	Specify the alias of the <code>QueryRecord</code> that contains the <code>QueryField</code> that you want to use.
<i>FieldName</i>	Specify the name of the <code>QueryField</code> in the <code>QueryRecord</code> that you want to use.

Returns

A reference to a blank `QueryField` object.

Related Links

[Expr1Field](#)

[AddExpr1Expression](#)

[Expr1Type](#)

[QueryField Class](#)

AddExpr2Expression

Syntax

```
AddExpr2Expression()
```

Description

The `AddExpr2Expression` method returns a reference to a new `QueryExpression` object to be used as an expression for Expression 2. You can then use this object to specify details about the expression using the methods and properties of the `QueryExpression` Class.

Parameters

None.

Returns

A reference to a blank QueryExpression object.

Related Links

[QueryExpression Class](#)

AddExpr2Field1

Syntax

```
AddExpr2Field1 (QueryRecordAlias, FieldName)
```

Description

Expression 2 has two field expressions because when the Between relational operator is used in a criteria, there can be two expression fields. The AddExpr2Field1 method returns a reference to a new QueryField object to be used as a *field 1* for Expression 2. You can then use this object to specify details about the expression using the methods and properties of the QueryField Class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>QueryRecordAlias</i>	Specify the alias of the QueryRecord that contains the QueryField that you want to use.
<i>FieldName</i>	Specify the name of the QueryField in the QueryRecord that you want to use.

Returns

A reference to a blank QueryField object.

Related Links

[QueryRecord Class](#)

[QueryField Class](#)

AddExpr2Field2

Syntax

```
AddExpr2Field2 (QueryRecordAlias, FieldName)
```

Description

Expression 2 has two field expressions because when the Between relational operator is used in a criteria, there can be two expression fields. The AddExpr2Field2 method returns a reference to a new a QueryField object to be used as a *field 2* for Expression 2. You can then use this object to specify details about the expression using the methods and properties of the QueryField Class.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>QueryRecordAlias</i>	Specify the alias of the QueryRecord that contains the QueryField that you want to use.
<i>FieldName</i>	Specify the name of the QueryField in the QueryRecord that you want to use.

Returns

A reference to a blank QueryField object.

Related Links

[QueryRecord Class](#)

[QueryField Class](#)

AddExpr2List

Syntax

```
AddExpr2List ()
```

Description

Expression 2 can have a list of values when the Operator is of type In List (or Not In List). The AddExpr2List method returns a reference to a new QueryList, which can be used to add a list of values to the criteria.

Parameters

None.

Returns

A reference to a blank QueryList object.

Related Links

[QueryList Class](#)

AddExpr2Subquery

Syntax

```
AddExpr2Subquery ()
```

Description

The AddExpr2Subquery method is used to create a subquery for Expression2. This method returns a new QuerySelect object you can use to specify details about the new subquery.

Warning! The new subquery created with this method replaces any existing subquery (for this criteria), destroying any existing properties or values.

Parameters

None.

Returns

A reference to a new QuerySelect object.

Related Links

[QuerySelect Class](#)

QueryCriteria Class Properties

In this section, we discuss the QueryCriteria class properties. The properties are discussed in alphabetical order.

Expr1Expression

Description

This property returns a reference to the QueryExpression object that's used as Expression 1.

This property is valid only when Expression 1 exists as an expression. If you want to add an expression for Expression 1, use the AddExpr1Expression method.

This property is read/write.

Related Links

[AddExpr1Expression](#)

Expr1Field

Description

This property returns a reference to the QueryField object that's used as Expression 1.

This property is valid only when Expression 1 exists as a field. You can then use the QueryField Class methods and property to manipulate this object.

If you want to add a field for Expression 1, use the AddExpr1Field method.

This property is read-only.

Related Links

[QueryField Class](#)

[AddExpr1Field](#)

Expr1Type

Description

This property returns or sets the type for Expression 1.

Note: You *must* set the type of expression for every new criteria.

The values are:

Numeric Value	Constant Value	Description
2	%Query_ExprField	Field
3	%Query_Expression	Expression

This property is read/write.

Example

The following is used to test the expression to determine the property to use to retrieve it:

```
&MyExpr1 = &MyCrtColl.Next();
If &MyExpr1.Expr1Type = %Query_ExprField Then /* Expression is a Field */

    &OldExpr1Value = &MyExpr1.Expr1Field;
    /* do processing */

Else /* Expression 1 is an expression */

    &OldExpr1Value = &MyExpr1.Expr1Expression;
    /* Do processing */

End-if;
```

The following is an example showing how to add a field for Expression 1.

```
/* add a new criteria */
&MyCriteria = &MyQuery.AddCriteria();

/* set the type of the first expression to be a field */
&MyCriteria.Expr1Type = %Query_ExprField;

/* add the field EMPLID from the ABSENCE_HIST record */
&MyField = &MyCriteria.AddExpr1Field("A", "EMPLID");
```

Expr2Constant1

Description

If the Between relational operator is used in the criteria, there can be two constants for Expression 2. This property returns or sets the constant value for the first constant for Expression 2. This property takes a string value.

This property is valid only when Expression 2 is defined as a constant.

This property is read/write.

Expr2Constant2

Description

If the Between relational operator is used in the criteria, there can be two constants for Expression 2. This property returns or sets the constant value for the second constant for Expression 2. This property takes a string value.

This property is valid only when Expression 2 is defined as a constant.

This property is read/write.

Expr2Expression1

Description

If the Between relational operator is used in the criteria, there can be two expressions for Expression 2. This property returns a reference to the first QueryExpression object that's used as Expression 2.

This property is valid only when Expression 2 exists as an expression. To add an expression for Expression 2, use the AddExpr2Expression method.

This property is read/write.

Related Links

[AddExpr2Expression](#)

Expr2Expression2

Description

If the Between relational operator is used in the criteria, there can be two expressions for Expression 2. This property returns a reference to the second QueryExpression object that's used as Expression 2.

This property is valid only when Expression 2 exists as an expression. To add an expression for Expression 2, use the AddExpr2Expression method.

This property is read/write.

Related Links

[AddExpr2Expression](#)

Expr2Field1

Description

If the Between relational operator is used in the criteria, there can be two fields for Expression 2. This property returns a reference to the first QueryField object that's used as Expression 2.

This property is only valid when Expression 2 exists as a field. You can then use the QueryField Class methods and property to manipulate this object.

To add a field for Expression 2, use the AddExpr2Field1 method.

This property is read-only.

Related Links

[AddExpr2Field1](#)

[QueryField Class](#)

Expr2Field2

Description

If the Between relational operator is used in the criteria, there can be two fields for Expression 2. This property returns a reference to the second QueryField object that's used as Expression 2.

This property is valid only when Expression 2 exists as a field. You can then use the QueryField Class methods and property to manipulate this object.

To add a field for Expression 2, use the AddExpr2Field2 method.

This property is read-only.

Related Links

[AddExpr2Field2](#)

QueryField Class**Expr2List****Description**

This property returns a reference to the QueryList object of Expression 2 that's used when the Operator is of type In List (or Not In List).

This property is read-only.

Expr2Subquery**Description**

This property returns a reference to the QuerySelect object that's used as a subquery for Expression 2.

This property is valid only when Expression 2 exists as a subquery. To add a subquery for Expression 2, use the AddExpr2Subquery method.

This property is read-only.

Related Links

[AddExpr2Subquery](#)

Expr2Type**Description**

This property returns or sets the type for Expression 2. The following table lists all of possible values for this property. However, the values for this property are dependent upon the Operator property.

This property is read/write.

See [Operator](#), [Working With Query Criteria and Expressions](#).

You can use either a constant or numeric value for this property. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_ExprConstant	Constant
2	%Query_ExprField	Field
3	%Query_Expression	Expression
4	%Query_ExprSubQuery	Subquery

Numeric Value	Constant Value	Description
5	%Query_ExprList	List
6	%Query_ExprCurDt	Current date
7	%Query_ExprTree	Tree
8	%Query_ExprBind	Bind
9	%Query_ExprBothConst	The criterion's operator is Between and both values on the right-hand side are constants. (Const-Const)
10	%Query_ExprConstFld	The criterion's operator is Between, the first value on right-hand side is a constant and the second value is a field. (Const-Field)
11	%Query_ExprConstExpr	The criterion's operator is Between, the first value on right-hand side is a constant and the second value is an expression. (Const-Expr)
12	%Query_ExprFieldConst	The criterion's operator is Between, the first value on right-hand side is a field and the second value is a constant. (Field-Const)
13	%Query_ExprBothFld	The criterion's operator is Between and both values on the right-hand side are constants. (Field-Field)
14	%Query_ExprFldExpr	The criterion's operator is Between, the first value on right-hand side is a field and the second value is an expression. (Field-Expr)
15	%Query_ExprExprConst	The criterion's operator is Between, the first value on right-hand side is an expression and the second value is a constant. (Expr-Const)
16	%Query_ExprExprFld	The criterion's operator is Between, the first value on right-hand side is an expression and the second value is a field. (Expr-Field)

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
17	%Query_ExprBothExpr	The criterion's operator is Between and both values on the right-hand side are expressions. (Expr-Expr)
18	%Query_ExprTreePrompt	Tree prompt

The following table describes how to access or change Expression 2 depending on the Expression2 Type.

<i>Expression2 Type</i>	<i>Method or Property for Changing the Expression</i>	<i>Method or Property for Accessing the Expression</i>
Constant	Expr2Constant	Expr2Constant
Field	AddExpr2Field()	Expr2Field
Expression	AddExpr2Expression()	Expr2Expression
In List	AddExpr2List	Expr2List
In Tree	AddExpr2Expression	Expr2Expression
Subquery	AddExpr2Subquery()	Expr2Subquery
Const-Const	Expr2Constant, Expr2Constant	Expr2Constant, Expr2Constant
Const-Field	Expr2Constant, AddExpr2Field()	Expr2Constant, Expr2Field
Const-Expr	Expr2Constant, AddExpr2Expression()	Expr2Constant, Expr2Expression
Field-Const	AddExpr2Field(), Expr2Constant	Expr2Field, Expr2Constant
Field-Field	AddExpr2Field(), AddExpr2Field()	Expr2Field, Expr2Field

Expression2 Type	Method or Property for Changing the Expression	Method or Property for Accessing the Expression
Field-Expr	AddExpr2Field(), AddExpr2Expression()	Expr2Field, Expr2Expression
Expr-Const	AddExpr2Expression(), Expr2Constant	Expr2Expression, Expr2Constant
Expr-Field	AddExpr2Expression(), AddExpr2Field()	Expr2Expression, Expr2Field
Expr-Expr	AddExpr2Expression(), AddExpr2Expression()	Expr2Expression, Expr2Expression

Example

The following is used to test the expression to determine the property to use to retrieve it:

```
&MyExpr2 = &MyCriteria.Expr2Expression;

If &MyExpr2.Expr2Type = %Query_ExprConstant Then /* Expression is a constant */
    &OldValue = &MyExpr2.Expr2Constant;
    /* do processing */
End-if;
```

The following is an example showing how to add a field for Expression 2:

```
( )
/* After setting the first expression, set the operator for the criteria*/
&MyCriteria.Operator = %Query_CondEqual;

/* Set the type of the second expression to be a field */
&MyCriteria.Expr2Type = %Query_ExprField;

/* Add the EMPLID field from the ABSENCE_HIST record whose record alias is A */
&MyField = &MyCriteria.AddExpr2Field("A", "EMPLID" );
```

Logical

Description

This property returns or sets the logical portion of a criteria.

Note: This property is valid only when there are more than one criteria for a query. Also, this property is required when there is more than one criteria for a query.

The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_CombAnd	Logical And for non-having criteria
2	%Query_CombOr	Or for non-having criteria
3	%Query_CombNotUsed	No logical operator. Used for the first non-having criteria.
4	%Query_CombHaveAnd	Logical And for having criteria
5	%Query_CombHaveOr	Logical Or for having Criteria
6	%Query_CombHaveNotUsed	No logical operator. Used for the first having criteria.

This property is read/write.

LParenLvl

Description

This property returns or sets the left parenthesis level used for grouping criteria. This property takes a numeric value.

This property is read/write.

Name

Description

This property returns the name of the Query Criteria, as a string.

This property is read-only.

Negation

Description

This property returns a Boolean value, indicating whether a criterion is negated: True if the criterion is negated, False if it isn't.

This property is read/write.

Operator

Description

This property returns or sets the operator for the criteria.

The value of this property determines the valid types of the Expression 2, set with the Expr2Type property.

This property is read/write.

See [Expr2Type](#), [Working With Query Criteria and Expressions](#).

You can use either a constant or numeric value for this property. The values are:

Numeric Value	Constant Value	Description
1	%Query_CondNone	None (used for initializing a new criteria.)
2	%Query_CondEqual	Criteria's left-hand side is equal to right-hand side (= operator)
3	%Query_CondNotEqual	Criteria's left-hand side is not equal to right-hand side (<> operator)
4	%Query_CondGreaterThan	Criteria's left-hand side is greater than right-hand side (> operator)
5	%Query_CondNotGreaterThan	Criteria's left-hand side is not greater than right-hand side (<= operator)
6	%Query_CondLessThan	Criteria's left-hand side is less than right-hand side (< operator)
7	%Query_CondNotLessThan	Criteria's left-hand side is not less than right-hand side (>= operator)
8	%Query_CondInList	Criteria's left-hand side is in the given list (IN operator)
9	%Query_CondNotInList	Criteria's left-hand side is not in the given list (Not IN operator)
10	%Query_CondBetween	Criteria's left-hand side is between the two values of right-hand side (BETWEEN operator)

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
11	%Query_CondNotBetween	Criteria's left-hand side is not between the two values of right-hand side (BETWEEN operator)
12	%Query_CondExists	Criteria's left-hand side is the output of the subquery of right-hand side (EXISTS operator)
13	%Query_CondNotExists	Criteria's left-hand side doesn't exist in the output of the subquery of right-hand side (NOT EXISTS operator)
14	%Query_CondLike	Criteria's left-hand side is like (wildcard search) the right-hand side (LIKE operation)
15	%Query_CondNotLike	Criteria's left-hand side is not like (wildcard search) the right-hand side (NOT LIKE operation)
16	%Query_CondNull	Criteria's left-hand side is NULL (NULL operation)
17	%Query_CondNotNull	Criteria's left-hand side is not NULL (IS NOT NULL operation)
18	%Query_CondInTree	Criteria's left-hand side is from a list of nodes in Tree (IN operation)
19	%Query_CondNotInTree	Criteria's left-hand side is not from a list of nodes in Tree (NOT IN operation)
20	%Query_CondEffDtLessEqual	Criteria's left-hand side is an Effective Date and is less than or equal to the date on the right-hand side (<= operation)
21	%Query_CondEffDtGreaterEqual	Criteria's left-hand side is an Effective Date and is greater than or equal to the date on the right-hand side (>= operation)
22	%Query_CondEffDtLess	Criteria's left-hand side is an Effective Date and is less than the date on the right-hand side (< operation)

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
23	%Query_CondEffDtGreater	Criteria's left-hand side is an Effective Date and is greater than the date on the right-hand side (> operation)
24	%Query_CondFirstEffDt	Criteria's left-hand side is the first effective date (Function MIN())
25	%Query_CondLastEffDt	Criteria's left-hand side is the last effective date (Function MAX())
26	%Query_CondInTreeJoin	Criteria's left-hand side is an In Tree Join.

R1ExprNum

Description

This property returns or sets the expression number for the first expression of Expression 2. This property takes a numeric value.

This property is read/write.

R2ExprNum

Description

This property returns or sets the expression number for the second expression of Expression 2. This property takes a numeric value.

This property is read/write.

R1ExprType

Description

This property returns the expression type for the first expression of Expression 2. This property takes a numeric value and is the same range of values as the Expr2Type. It helps distinguish the type of an expression based on the value of Expr2Type. For instance, if the Expr2Type is Field-Expr, R1Expr2Type is of type Field and R2Expr2Type is of type Expression.

This property is read-only.

R2ExprType

Description

This property returns the expression type for the second expression of Expression 2. This property takes a numeric value and is the same range of values as the Expr2Type. It helps distinguish the type of an expression based on the value of Expr2Type. For instance, if the Expr2Type is Field-Expr, R1Expr2Type is of type Field and R2Expr2Type is of type Expression.

This property is read-only.

RParenLvl

Description

This property returns or sets the right parenthesis level used for grouping criteria. This property takes a numeric value.

This property is read/write.

QueryExpression Collection

A QueryExpression Collection is returned from the Expressions Query class property.

See [Expressions](#).

QueryExpression Collection Methods

In this section, we discuss the QueryExpression collection methods. The methods are described in alphabetical order.

First

Syntax

```
First ()
```

Description

The First method returns the first QueryExpression object in the QueryExpression collection.

Parameters

None.

Returns

A reference to a QueryExpression object if successful, NULL otherwise.

Example

```
&MyQueryExpression = &MyCollection.First();
```

Item

Syntax

Item(*number*)

Description

The Item method returns the QueryExpression object that exists at the *number* position in the QueryExpression collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the collection of the QueryExpression object that you want returned.

Returns

A reference to a QueryExpression object if successful, NULL otherwise.

Example

```
For &I = 1 to &QueryExpressionColl.Count;
    &MyQueryExpression = &QueryExpressionColl.Item(&I);
    /* do processing */
End-For;
```

ItemByName

Syntax

ItemByName(*ExpressionName*)

Description

The ItemByName method returns the QueryExpression object in the QueryExpressionCollection with the given expression name.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ExpressionName</i>	The name of the required expression.

Returns

A reference to a QueryExpression object if successful, NULL otherwise.

Example

```
&QryExpr = &QryExprCol.Item("Exp-6");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next QueryExpression object in the QueryExpression collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a QueryExpression object if successful, NULL otherwise.

Example

```
&MyQueryExpression = &MyCollection.Next();
```

QueryExpression Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of QueryExpression objects in the QueryExpression Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

QueryExpression Class

A QueryExpression object is returned by the following:

- The AddExpression method of the Query class.
- The First, Item and Next methods of the QueryExpression collection.
- Some of the QueryCriteria class methods.
- The Expr1Expression and Expr2Expression1 properties of the QueryCriteria class.

See [AddExpression](#), [QueryExpression Collection](#), [QueryCriteria Class Methods](#), [Expr1Expression](#), [Expr2Expression1](#).

See [Working With Query Criteria and Expressions](#).

QueryExpression Class Properties

In this section, we discuss the QueryExpression class properties. The properties are discussed in alphabetical order.

Aggregate

Description

This property specifies whether the expression is an aggregate function.

This property takes a Boolean value: True if the expression is an aggregate function, False, otherwise.

This property is read/write.

BindFlag

Description

This property specifies whether the expression contains a bind value, as Boolean value.

This property is mainly used while reading a query, to determine whether a Query Expression contains a bind value. It isn't necessary to set this value while saving a query to the database.

Values are:

<i>Value</i>	<i>Description</i>
False	Expression doesn't have a bind value
True	Expression has a bind value

This property is read/write.

Decimal

Description

This property returns or sets the decimal value of the expression.

This property is only valid with numeric fields.

This property is read/write.

ExpNum

Description

This property returns or sets the unique expression number, as a numeric value.

This property is read/write.

IsXlatExpression

Description

This property indicates whether the expression is for a translate field. This property takes a Boolean value: True, the expression is based on a translated field.

This property is read-only.

Length

Description

This property returns or sets the length of the expression, as a number.

This property is read/write.

Name

Description

This property returns the name of the expression, as a string.

This property is read-only.

OutputField

Description

This property returns the instance of the displayed expression field, as a QueryField. This property returns a NULL when the expression isn't used in a displayed (output) field.

This property is read/write.

RightExprFlag

Description

This property specifies whether an expression is used in the right-hand side of a criteria (that is, is it an Expr2 expression), as a Boolean value.

This property is typically used while reading a query to determine whether a Query Expression is used in the right-hand side of criteria. It's not necessary to set this value while saving a query to the database.

Values are:

Value	Description
False	Expression is not used in the right-hand side of the criteria
True	Expression is used in the right-hand side of the criteria

This property is read/write.

SelectedField

Description

This property returns the instance of the expression field, as a QueryField. This property returns a NULL when the expression is used only in the right-hand side of a criteria.

This property is read/write.

Text

Description

This property returns or sets the text of the expression, as a character string.

This property is read/write.

Using ORACLE Hints in Expressions

Oracle hints can be included in expressions using the following considerations:

- Expression containing a hint must begin with /*+.
- Expression can only contain one hint. For example, only one set of /* */ is allowed in each expression.
- Each /* must precede an */.
- Each expression must contain a complete hint. For example, an expression can't have only /* or */. Both must be in same expression.

Type

Description

This property returns or sets the field type of the expression.

You can specify either a constant or a numeric value. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%FieldType_Char	Character
1	%FieldType_LongChar	Long Character
2	%FieldType_Number	Number
3	%FieldType_SignedNumber	Signed number

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
4	%FieldType_Date	Date
5	%FieldType_Time	Time
6	%FieldType_DateTime	DateTime
7	%FieldType_Image	Image
11	%FieldType_URL	Drilling URL

This property is read/write.

QueryList Class

A QueryList Class is returned from the Expr2List property and AddExpr2List method of the QueryCriteria Class.

See [Expr2List](#), [AddExpr2List](#).

QueryList Class Methods

In this section, we discuss the QueryList class methods. The methods are discussed in alphabetical order.

AddListValue

Syntax

AddListValue (*Value*, *IsPrompt*)

Description

The AddListValue method adds a new List Value into the QueryList instance.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Value</i>	Specify the string value to be added to the list

<i>Parameter</i>	<i>Description</i>
<i>IsPrompt</i>	Specify whether the string specified by <i>Value</i> is a bind variable. This parameter takes a Boolean value: True, <i>Value</i> is a bind variable.

Returns

A reference to a QueryListValue object if successful, NULL otherwise.

Example

```
&MyListValue = &MyList.AddListValue("1", False);
```

First

Syntax

```
First ()
```

Description

The First method returns the first QueryListValue object in the QueryList instance.

Parameters

None.

Returns

A reference to a QueryListValue object if successful, NULL otherwise.

Example

```
&MyListValue = &MyList.First();
```

Item

Syntax

```
Item (number)
```

Description

The Item method returns the QueryListValue object that exists at the *number* position in the QueryList instance.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the QueryList object that you want returned.

Returns

A reference to a QueryListValue object if successful, NULL otherwise.

Example

```
For &I = 1 to &QueryList.Count;
    &QryListVal = &QueryList.Item(&I);
    /* do processing */
End-For;
```

Next

Syntax

Next ()

Description

The Next method returns the next QueryListValue object in the QueryList instance. This method should be called after calling First, else it returns NULL.

Parameters

None.

Returns

A reference to a QueryListValue object if successful, NULL otherwise.

Example

```
&MyNextListValue = &MyList.Next();
```

QueryList Class Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of QueryListValue objects in the QueryList Collection, as a number.

This property is read-only.

Example

```
&ListValueCount = &MYList.Count;
```

QueryListValue Class

A QueryListValue instance is returned from the AddListValue, First, Item, or Next QueryList Class methods.

See [QueryList Class Methods](#).

QueryListValue Class Properties

In this section, we discuss the QueryListValue class properties. These properties are discussed in alphabetical order.

IsPrompt

Description

This property indicates whether the value is a bind variable (such as :1). This property returns a Boolean value: True, this property is a bind variable.

This property is read-only.

Value

Description

This property returns a string for the value stored in the list.

This property is read-only.

QueryRecordHierarchy Collection

A QueryRecordHierarchy collection is returned from the RecordHierarchy QueryDBRecord property.

The order of each QueryRecordHierarchy object in the collection maps to the order of each tree node as it appears in the tree hierarchy from top to bottom.

See [RecordHierarchy](#).

QueryRecordHierarchy Collection Methods

In this section, we discuss the QueryRecordHierarchy collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First ()
```

Description

The First method returns the first QueryRecordHierarchy object in the QueryRecordHierarchy collection.

Parameters

None.

Returns

A reference to a QueryRecordHierarchy object if successful, NULL otherwise.

Example

```
&MyQueryRecordHierarchy = &MyCollection.First ();
```

Item

Syntax

```
Item (number)
```

Description

The Item method returns the QueryRecordHierarchy object that exists at the *number* position in the QueryRecordHierarchy collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the collection of the QueryRecordHierarchy object that you want returned.

Returns

A reference to a QueryRecordHierarchy object if successful, NULL otherwise.

Example

```
For &I = 1 to &QueryRecordHierarchyColl.Count;
    &MyQueryRecordHierarchy = &QueryRecordHierarchyColl.Item(&I);
    /* do processing */
End-For;
```

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the QueryRecordHierarchy object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing QueryRecordHierarchy within the QueryRecordHierarchy collection. If you specify an invalid name, the object is NULL.

Returns

A reference to a QueryRecordHierarchy object if successful, NULL otherwise.

Example

```
&MyQueryRecordHierarchy = &MyCollection.ItemByName("PHONELIST");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next QueryRecordHierarchy object in the QueryRecordHierarchy collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a QueryRecordHierarchy object if successful, NULL otherwise.

Example

```
&MyQueryRecordHierarchy = &MyCollection.Next ();
```

QueryRecordHierarchy Collection Property

In this section, we discuss the QueryRecordHierarchy properties. These properties are discussed in alphabetical order.

Count

Description

This property returns the number of QueryRecordHierarchy objects in the QueryRecordHierarchy Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

QueryRecordHierarchy Class

A reference to a QueryRecordHierarchy object is returned by the First, Item, ItemByName, and Next QueryRecordHierarchy Collection methods.

Every QueryRecordHierarchy object returned from a collection represents a record node in the Record Hierarchy tree in Query tab of PeopleSoft Query.

The QueryRecordHierarchy object returned from the QueryField represents the prompt table for the record field.

See [QueryRecordHierarchy Collection](#).

QueryRecordHierarchy Class Properties

In this section, we discuss the QueryRecordHierarchy class properties. The properties are discussed in alphabetical order.

Description

Description

This property returns a description of the record node as a string.

This property is read-only.

Level

Description

This property returns the level of the record node in the record hierarchy. 1 is the root node, 2 is a node beneath the root node, 3 is a child of that, and so on.

This property is read-only.

Name

Description

This property returns the name of the record node as a string.

This property is read-only.

ParentFlag

Description

This property returns the parent flag. The values are:

<i>Value</i>	<i>Description</i>
0	Record node contains no children nodes.
1	Record node contains children nodes

This property is read-only.

Query Metadata Collection

A Query Metadata collection is returned by the Metadata Query class property.

See [Metadata](#).

See [Using Query Metadata](#).

Query Metadata Collection Methods

In this section, we discuss the Query Metadata collection methods. These methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The First method returns the first Query Metadata object in the Query Metadata collection.

Parameters

None.

Returns

A reference to a Query Metadata object if successful, NULL otherwise.

Example

```
&MyMetadata = &MyCollection.First();
```

Item

Syntax

Item (*number*)

Description

The Item method returns the Query Metadata object that exists at the *number* position in the Query Metadata collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>number</i>	Specify the position number in the collection of the Query Metadata object that you want returned.

Returns

A reference to a Query Metadata object if successful, NULL otherwise.

Example

```
For &I = 1 to &MetadataColl.Count;
    &MyMetadata = &MetadataColl.Item(&I);
    /* do processing */
End-For;
```

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the Query Metadata object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing Query Metadata within the Query Metadata collection. If you specify an invalid name, the object is NULL.

Returns

A reference to a Query Metadata object if successful, NULL otherwise.

Example

```
&MyMetadata = &MyQuery.Metadata.ItemByName("Descr");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next Query Metadata object in the Query Metadata collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a Query Metadata object if successful, NULL otherwise.

Example

```
&MyMetadata = &MyCollection.Next();
```

Query Metadata Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of Query Metadata objects in the Query Metadata Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

Query Metadata Class

A Query Metadata object is returned from the Query Metadata Collection methods `First`, `Item`, `ItemByName`, or `Next`.

See [Query Metadata Collection](#).

See [Using Query Metadata](#).

Query Metadata Class Properties

In this section, we discuss the Query Metadata class properties. The properties are discussed in alphabetical order.

Name

Description

This property returns the name of each Query Metadata property as a string.

Values for this property are:

<i>Value</i>	<i>Description</i>
Descr	Description
LongDescr	Long description
Public/Private	Specifies if the query is public or private. If the query is private, the name of the owner is listed in <i>Value</i> .
LastUpdDttm	Last updated date and time
LastUpdOprId	The <i>UserId</i> of the user who updated the value last
Record	Record name. May be more than one.
Input Param	Input parameter. May be more than one.
Expression	Expression. May be more than one.
Field	Record field name for the output column. May be more than one.

Value	Description
Heading	Heading name for the output column. May be more than one.

This property is read-only.

Value

Description

This property returns the value for the Query Metadata property as a string.

This property is read-only.

QueryStatistics Class

The QueryStatistics class is used to view statistical information about a query's execution. It can be useful for query administration. You can view query statistics for a query before you save it to the database.

A QueryStatistics Class is returned from the QueryStatistics Query property.

See [QueryStatistics](#).

QueryStatistics Class Properties

In this section, we discuss the QueryStatistics properties. The properties are discussed in alphabetical order.

AvgExecTime

Description

This property returns the average execution time for the query as a number.

This property is read-only.

AvgFetchTime

Description

This property returns the average fetch time for the query as a number.

This property is read-only.

AvgNumRows

Description

This property returns the average number of rows fetched for the query.

This property is read-only.

ExecCount

Description

This property returns the total number of times the query has been executed.

This property is read-only.

LastExecDtTm

Description

This property returns the last date and time the query was executed, as a string.

This property is read-only.

QuerySecurityProfile Class

The QuerySecurityProfile class is used to view the current user's security profile for PeopleSoft Query. This class doesn't contain any methods, and all the properties are read-only. An instance of this class is returned by the GetQuerySecurityProfile Session method.

See [GetQuerySecurityProfile](#).

QuerySecurityProfile Class Properties

In this section, we discuss the QuerySecurityProfile properties. The properties are discussed in alphabetical order.

AllowAnyJoin

Description

This property indicates whether the user is allowed to define queries with any join. This property takes a Boolean value: True, the user can define such queries.

This property is read-only.

AllowDistinct

Description

This property indicates whether the user can define queries with a Distinct clause in a SELECT statement. This property takes a Boolean value: True, the user can define such queries.

This property is read-only.

AllowExpressions

Description

This property indicates whether the user is allowed to define expressions in queries. This property takes a Boolean value: True, the user can define such queries.

This property is read-only.

AllowSubqueries

Description

This property indicates whether the user is allowed to define criteria containing subqueries. This property takes a Boolean value: True, the user can define such queries.

This property is read-only.

AllowUnions

Description

This property indicates whether the user is allowed to define queries containing unions. This property takes a Boolean value: True, the user can define such queries.

This property is read-only.

ApprovePrivateQuery

Description

This property indicates whether the user is allowed to approve private queries. This property takes a Boolean value: True, the user can approve such queries. This property is meant for query administration.

This property is read-only.

ApprovePublicQuery

Description

This property indicates whether the user is allowed to approve public queries. This property takes a Boolean value: True, the user can approve such queries. This property is meant for query administration.

This property is read-only.

CanCreatePublic

Description

This property indicates whether the user can create public queries. This property takes a Boolean value: True, the user can create such queries.

This property is read-only.

CanCreateWorkFlow

Description

This property indicates whether the user can create or run any workflow queries. Workflow queries are of the following types:

- Archive
- Process
- Role

This property takes a Boolean value: True, the user can create such queries.

This property is read-only.

CanModifyQuery

Description

This property indicates whether the user can modify queries. This property takes a Boolean value: True, the user can modify queries.

This property is read-only.

CanRunQuery

Description

This property indicates whether the user can run queries. This property takes a Boolean value: True, the user can run queries.

This property is read-only.

CanRunToExcel

Description

This property indicates whether the user can run queries to an Excel spreadsheet. This property takes a Boolean value: True, the user can run queries.

This property is read-only.

LimitUnapproved

Description

This property indicates whether there is a limit on the number of rows returned for unapproved queries. This property is meant for query administration. This property takes a Boolean value: True, limit the number of rows. The MaxUnapprovedRows property is active only if this property is specified as True.

This property is read-only.

Related Links

[MaxUnapprovedRows](#)

MaxInTreeCriteria

Description

This property indicates the maximum number of In Tree Criteria that can be used in the queries defined by the current user. This property takes a numeric value.

This property is read-only.

MaxJoins

Description

This property indicates the maximum number of joins allowed in the queries defined by the current user. This property takes a numeric value.

This property is read-only.

MaxRowsToFetch

Description

This property indicates the maximum number of rows to fetch for the current user when a query is executed. This property takes a numeric value.

This property is read-only.

MaxUnapprovedRows

Description

This property indicates the maximum number of rows that can be returned for unapproved queries. This property takes a numeric value. This property is meant for query administration. This property is active only if the property `LimitUnapproved` is `True`.

This property is read-only.

Related Links

[LimitUnapproved](#)

QueryDBRecord Collection

A `QueryDBRecord` collection is returned from the `FindQueryDBRecords` session method.

See [FindQueryDBRecords](#).

QueryDBRecord Collection Methods

In this section, we discuss the `QueryDBRecord` collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The `First` method returns the first `QueryDBRecord` object in the `QueryDBRecord` collection.

Parameters

None.

Returns

A reference to a QueryDBRecord object if successful, NULL otherwise.

Example

```
&MyQueryDBRecord = &MyCollection.First();
```

Item

Syntax

Item (*number*)

Description

The Item method returns the QueryDBRecord object that exists at the *number* position in the QueryDBRecord collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the collection of the QueryDBRecord object that you want returned.

Returns

A reference to a QueryDBRecord object if successful, NULL otherwise.

Example

```
For &I = 1 to &QueryDBRecordColl.Count;
    &MyQueryDBRecord = &QueryDBRecordColl.Item(&I);
    /* do processing */
End-For;
```

ItemByName

Syntax

ItemByName (*Name*)

Description

The `ItemByName` method returns the `QueryDBRecord` object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing <code>QueryDBRecord</code> within the <code>QueryDBRecord</code> collection. If you specify an invalid name, the object is <code>NULL</code> .

Returns

A reference to a `QueryDBRecord` object if successful, `NULL` otherwise.

Example

```
&MyQueryDBRecord = &MyCollection.ItemByName("PHONELIST");
```

Next

Syntax

```
Next ()
```

Description

The `Next` method returns the next `QueryDBRecord` object in the `QueryDBRecord` collection. You can use this method only after you have used the `First` method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a `QueryDBRecord` object if successful, `NULL` otherwise.

Example

```
&MyQueryDBRecord = &MyCollection.Next();
```

QueryDBRecord Collection Property

In this section, we discuss the `Count` property.

Count

Description

This property returns the number of QueryDBRecord objects in the QueryDBRecord Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

QueryDBRecord Class

A QueryDBRecord object is returned from the QueryDBRecord Collection methods First, Item, ItemByName, or Next.

See [QueryDBRecord Collection](#).

QueryDBRecord Class Methods

In this section, we discuss the QueryDBRecord class methods. The methods are discussed in alphabetical order.

QueryDBRecordFieldByIndex

Syntax

```
QueryDBRecordFieldByIndex (Index)
```

Description

The QueryDBRecordFieldByIndex method returns the QueryDBRecordField object that exists at the *index* position in the QueryDBRecordField collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the position number in the collection of the QueryDBRecordField object that you want returned.

Returns

A reference to a QueryDBRecordField object if successful, NULL otherwise.

Related Links

[QueryDBRecordFieldByName](#)

[QueryDBRecordField Class](#)

QueryDBRecordFieldByName

Syntax

`QueryDBRecordFieldByName` (*Name*)

Description

The QueryDBRecordFieldByName method returns the QueryDBRecordField object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the QueryDBRecordField object that you want returned.

Returns

A reference to a QueryDBRecordField object if successful, NULL otherwise.

Related Links

[QueryDBRecordFieldByIndex](#)

QueryDBRecord Class Properties

In this section, we discuss the QueryDBRecord class properties. The properties are discussed in alphabetical order.

Description

Description

This property returns the description of the QueryDBRecord as a string.

This property is read-only.

Name

Description

This property returns the name of the QueryDBRecord as a string.

This property is read-only.

QueryDBRecordFields

Description

This property returns a reference to a QueryDBRecordField Collection.

This property is read-only.

Related Links

[QueryDBRecordField Collection](#)

RecordHierachy

Description

This property returns a reference to a QueryRecordHierarchy Collection.

The record hierarchy is not related to the query tree hierarchy shown when viewing access groups. Instead, it reflects an actual relationship between the record components, as defined in Application Designer using the Parent Record Name feature.

This property is read-only.

Related Links

[QueryRecordHierarchy Collection](#)

QueryDBRecordField Collection

A QueryDBRecordField collection is returned from the QueryDBRecordFields QueryDBRecord property.

See [QueryDBRecordFields](#).

QueryDBRecordField Collection Methods

In this section, we discuss the QueryDBRecordField collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The First method returns the first QueryDBRecordField object in the QueryDBRecordField collection.

Parameters

None.

Returns

A reference to a QueryDBRecordField object if successful, NULL otherwise.

Example

```
&MyQueryDBRecordField = &MyCollection.First();
```

Item

Syntax

```
Item(number)
```

Description

The Item method returns the QueryDBRecordField object that exists at the *number* position in the QueryDBRecordField collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the collection of the QueryDBRecordField object that you want returned.

Returns

A reference to a QueryDBRecordField object if successful, NULL otherwise.

Example

```
For &I = 1 to &Coll.Count;
    &MyQueryDBRecordField = &Coll.Item(&I);
```

```

        /* do processing */
    End-For;

```

ItemByName

Syntax

```
ItemByName (Name)
```

Description

The ItemByName method returns the QueryDBRecordField object with the name *Name*.

Parameters

Parameter	Description
<i>Name</i>	Specify the name of an existing QueryDBRecordField within the QueryDBRecordField collection. If you specify an invalid name, the object is NULL.

Returns

A reference to a QueryDBRecordField object if successful, NULL otherwise.

Example

```
&MyQueryDBRecordField = &MyCollection.ItemByName ("PHONELIST");
```

Next

Syntax

```
Next ()
```

Description

The Next method returns the next QueryDBRecordField object in the QueryDBRecordField collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a QueryDBRecordField object if successful, NULL otherwise.

Example

```
&MyQueryDBRecordField = &MyCollection.Next();
```

Sort

Syntax

```
Sort(SortCriteria)
```

Description

Use the Sort method to sort the fields within the QueryDBRecordField collection, based on the sort criteria specified with the method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SortCriteria</i>	Specify the sort order for the list. This parameter can take either a constant or numeric value. See below.

The values for *OutputFormat* can be as follows:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_SortNameAsc	Sort database fields in ascending order based on field name.
2	%Query_SortNameDesc	Sort database fields in descending order based on field name.
3	%Query_SortFldNumAsc	Sort database fields in ascending order based on field number.
4	%Query_SortFldNumDesc	Sort database fields in descending order based on field number.

Returns

0

QueryDBRecordField Collection Property

In this section, we discuss the Count property.

Count

Description

This property returns the number of QueryDBRecordField objects in the QueryDBRecordField Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

QueryDBRecordField Class

A QueryDBRecordField object is from the QueryDBRecord Collection methods First, Item, ItemByName or Next.

See [QueryDBRecord Collection](#).

QueryDBRecordField Class Method

In this section, we discuss the QueryDBRecordField class methods in alphabetical order.

GetImageFormat

Syntax

```
GetImageFormat ()
```

Description

Use the GetImageFormat method to differentiate between images and files, both stored as BLOBs in the database.

Note: Because images and files share the field type value 8, this method is required to differentiate between the two types.

Parameters

None.

Returns

A number. A value 16 indicates that the field is of type file (or attachment).

Related Links

[Type](#)

QueryDBRecordField Class Properties

In this section, we discuss the QueryDBRecordField class properties. The properties are discussed in alphabetical order.

Decimal

Description

This property returns the decimal positions for a field. This indicates how many numbers are allowed on the right side of the decimal.

This property is read-only.

Example

```
&FldDecs = &QryDBRcdFlds.Decimal;
```

Description

Description

This property returns the long description of the field as a string.

This is property is read-only.

Flag

Description

This property returns the Use and Edit Flags of the field, which are set when the Field is defined in Application Designer, as a numeric value.

Values for Use Flags are:

<i>Value</i>	<i>Description</i>
1	Key
2	Duplicate Key
4	System

Value	Description
8	Audit Field Add
16	Alternate Key
32	List Item
64	Descending Key
128	Audit Field Change
1024	Audit Field Delete
2048	Search Item
32768	Auto Update

Values for Edit Flags are:

Value	Description
256	Required
512	Edit Translate
4096	Date Range Edit
8192	Yes/No Table Edit
16384	Edit Table
262144	From Search Field
524288	Through Search Field
8388608	Use Default Label Flag
16777216	Default Search Field

This is a read-only property.

Format

Description

This property returns the field format for a field. Values are:

Value	Description
1	No format
2	Name
3	Phone Number North America
4	Zip/Postal Code North America
5	Social Security Number (SSN)
6	Uppercase
7	Mixed case
8	Raw binary
9	Numbers only
10	Canadian Social Insurance Number (SIN)
11	Phone Number International
12	Zip/Postal Code International
13	Seconds
14	Microseconds
15	Custom

This property is read-only.

Length

Description

This property returns the length of the field as a number.

This property is read-only.

LongName

Description

This property returns the long name of the field as a string.

This property is read-only.

LookupTableName

Description

If the field has a lookup table associated with it, this property returns the name of that Lookup Table, else it returns an empty string.

This is a read-only property.

LookupTableRecord

Description

If the field has a lookup table associated with it, this property returns the instance of the QueryDBRecord for that Lookup Table, else it returns NULL.

This is a read-only property.

Name

Description

This property returns the name of the field as a string.

This property is read-only.

Shortname

Description

This property returns the short name of the field as a string.

This property is read-only.

Type

Description

This property returns the type of the field. You can specify either a constant or a numeric value for this property. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%FieldType_Char	Character
1	%FieldType_LongChar	Long Character
2	%FieldType_Number	Number
3	%FieldType_SignedNumber	Signed number
4	%FieldType_Date	Date
5	%FieldType_Time	Time
6	%FieldType_DateTime	DateTime
8	%FieldType_Image	Image
8	%FieldType_File	File
9	%FieldType_ImageRef	ImageReference

Note: The Image and File types can be differentiated using the GetImageFormat method of the QueryField class.

This property is read-only.

Related Links

[GetImageFormat](#)

QueryPrompt Collection

A QueryPrompt collection is returned from the Prompts and RuntimePrompts Query class properties.

See [Prompts](#), [RunTimePrompts](#).

QueryPrompt Collection Methods

In this section, we discuss the QueryPrompt collection methods. The methods are discussed in alphabetical order.

First

Syntax

```
First()
```

Description

The First method returns the first QueryPrompt object in the QueryPrompt collection.

Parameters

None.

Returns

A reference to a QueryPrompt object if successful, NULL otherwise.

Example

```
&MyQueryPrompt = &MyCollection.First();
```

Item

Syntax

```
Item(number)
```

Description

The Item method returns the QueryPrompt object that exists at the *number* position in the QueryPrompt collection.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Number</i>	Specify the position number in the collection of the QueryPrompt object that you want returned.

Returns

A reference to a QueryPrompt object if successful, NULL otherwise.

Example

```
For &I = 1 to &QueryPromptColl.Count;
    &MyQueryPrompt = &QueryPromptColl.Item(&I);
    /* do processing */
End-For;
```

ItemByName

Syntax

ItemByName (*Name*)

Description

The ItemByName method returns the QueryPrompt object with the name *Name*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of an existing QueryPrompt within the QueryPrompt collection. If you specify an invalid name, the object is NULL.

Returns

A reference to a QueryPrompt object if successful, NULL otherwise.

Example

```
&MyQueryPrompt = &MyCollection.ItemByName("PHONELIST");
```

Next

Syntax

Next ()

Description

The Next method returns the next QueryPrompt object in the QueryPrompt collection. You can use this method only after you have used the First method: otherwise the system doesn't know where to start.

Parameters

None.

Returns

A reference to a QueryPrompt object if successful, NULL otherwise.

Example

```
&MyQueryPrompt = &MyCollection.Next ();
```

QueryPrompt Collection Property

In this section, we discuss the QueryPrompt collection properties. The properties are discussed in alphabetical order.

Count

Description

This property returns the number of QueryPrompt objects in the QueryPrompt Collection, as a number.

This property is read-only.

Example

```
&COUNT = &MY_COLLECTION.Count;
```

QueryPrompt Class

A reference to a QueryPrompt is returned by the following:

- The First, Item, ItemByName, and Next methods of a QueryPrompt Collection.
- The AddPrompt Query class method.

See [QueryPrompt Collection](#), [AddPrompt](#).

See "Defining Prompts" (Query).

QueryPrompt Properties

In this section, we discuss the QueryPrompt properties. The properties are discussed in alphabetical order.

EditType

Description

This property returns or sets the edit type for the field. This property takes a number value. The values are:

<i>Value</i>	<i>Description</i>
0	No table edit
16384	Prompt table
512	Translate table
8192	Yes/No

This property is read/write.

FieldDecimal

Description

This property returns or sets the decimal value for the field.

This property is only valid with number fields.

This property is read/write.

FieldFormat

Description

This property returns the field format for a field. This property takes a number value. Values are:

<i>Value</i>	<i>Description</i>
0	None
1	Name
2	Phone
3	Zip Code

Value	Description
4	Social Security Number
5	Upper
6	Mixed Case
7	Century
8	Number Only
9	Social Insurance Number
10	International Phone Number
11	International Postal Code
12	Seconds
13	Microseconds
14	Century/Seconds
15	Century/Microseconds

This property is read-only.

FieldLength

Description

This property returns or sets the field length.

This property is read/write.

FieldName

Description

This property returns or sets the field name used with the prompt.

This property is read/write.

FieldType

Description

This property returns or sets the field type of the field used with the prompt.

This property returns the type of the field. You can specify either a constant or a numeric value. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%FieldType_Char	Character
1	%FieldType_LongChar	Long Character
2	%FieldType_Number	Number
3	%FieldType_SignedNumber	Signed number
4	%FieldType_Date	Date
5	%FieldType_Time	Time
6	%FieldType_DateTime	DateTime
7	%FieldType_Image	Image

This property is read/write.

HeadingText

Description

This property returns or sets the heading text for the prompt field.

This property is read/write.

HeadingType

Description

This property returns or sets the heading type for the query field. This property takes either a constant or numeric value. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%Query_HdgNone	Query field has no heading.
2	%Query_HdgText	Query field has a text heading.
3	%Query_HdgRftShort	Query field uses the short RFT heading.
4	%Query_HdgRftLong	Query fields uses the long RFT heading.

This property is read/write.

LangCount

Description

This property returns the total count of the language records for the current prompt.

This property is read-only.

Name

Description

This property returns a string containing the Prompt name. When an existing query is read, this name is the same as the Field Name. When a new prompt is added using AddPrompt, this is the *Name* parameter used with that method.

This property is read-only.

PromptRecordFieldName

Description

When you have more than one field with the same name in the prompt collection, the system generates a unique prompt field name for each repeated field. The generated names are of the form Bind1, Bind2, and so on. This property returns the unique name for the prompt record field.

This property is read-only.

PromptTable

Description

This property returns or sets the prompt table name for the prompt field.

This property is read/write.

UniquePromptName

Description

This property returns or sets the unique prompt name for the prompt field.

This property is read/write.

UseCount

Description

This property returns the total count of the usage of the current prompt.

This property is read-only.

The following are examples of the usual actions that you perform using the query classes.

Query Classes Examples

The following are examples of the usual actions that you perform using the query classes.

Creating a New Query

In this example, you are creating a new query, adding a record and two fields. The following is the complete code sample: the steps explain each line.

```

Local ApiObject &aQuery, &aQrySelCol;
Local ApiObject &COLL, &ERROR;
Local String &TEXT;
Local Session &MySession;
Local Record &aQryRcd;
Local Field &aQryFld;

&MySession = %Session;

If &MySession <> Null Then

    &aQuery = &MySession.GetQuery();

    &aQuery.Create("TEST1", False, %Query_Query, "PIA Test 1", "Creating Test Query =>
1 from PIA Page");

    &aQrySel = &aQuery.AddQuerySelect();

    &aQryRcd = &aQrySel.AddQueryRecord("ABSENCE_HIST");
    &aQryFld = &aQrySel.AddQuerySelectedField("ABSENCE_HIST", "A", "EMPLID", "ID");

    If &aQryFld <> Null Then
        &aQryFld.ColumnNumber = 1;
        &aQryFld.HeadingType = %Query_HdgRftShort;
    End-If;

```

```

&Rslt = &aQuery.Save();

If &Rslt <> 0 Then
  /* save didn't complete */
  &COLL = &MySession.PSMessages;

  For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item(&I);
    &TEXT = &ERROR.Text;
    /* do error processing */
  End-For;

  &COLL.DeleteAll();
End-if;
/* error processing for not getting a session */
End-if;

```

To create a new query:

1. Get a session object.

Before you can create a query, you have to get a session object. The session controls access to the query, provides error tracing, enables you to set the runtime environment, and so on. Then this program checks to verify that the session object is valid.

```

&MySession = %Session;

&aQuery = &MySession.GetQuery();

If &MySession <> Null Then

```

2. Create the query.

Use the Create method to create the query. This query is a private query, of type query.

```

&aQuery.Create("TEST1", False, %Query_Query, "Test 1", "Creating Test Query");=>

```

3. Add a QuerySelect.

The QuerySelect contains the main query statement for the query. There can be multiple QuerySelect objects for queries that involve unions or subqueries. Each select (or union or subquery) consists of QueryRecords, QueryOutputFields, QuerySelectedFields, and QueryCriteria and is treated as a child of the MAIN select statement.

```

&aQrySel = &aQuery.AddQuerySelect();

```

4. Add a record and a field.

The AddQueryRecord method adds a query record to the query. The AddQuerySelectedField adds a field, using the record alias "A". The ID is what gets displayed in the heading for the query.

```

&aQryRcd = &aQrySel.AddQueryRecord("ABSENCE_HIST");
&aQryFld = &aQrySel.AddQuerySelectedField("ABSENCE_HIST", "A", "EMPLID", "ID")=>
;

```

5. Make the field an output field.

The field was added as a selected field. By setting the ColumnNumber to a number greater than one, the field is now an output field. The text that's displayed in the heading comes from the RFT short description of the field.

```
If &aQryFld <> Null Then
    &aQryFld.ColumnNumber = 1;
    &aQryFld.HeadingType = %Query_HdgRftShort;
End-If;
```

6. Save the data.

When you execute the Save method, the new query is saved to the database.

```
&Rslt = &aQuery.Save();

If &Rslt <> 0 Then
```

The Save method returns a numeric value: 0 if successful. You can use this value to do error checking.

7. Check Errors.

You can check if there were any errors using the PSMessages property on the session object.

```
/* save didn't complete */
&COLL = &MySession.PSMessages;
For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item(&I);
    &TEXT = &ERROR.Text;
    /* do error processing */
End-For;
&COLL.DeleteAll();
End-if;
```

If there are multiple errors, all errors are logged to the PSMessages collection, not just the first occurrence of an error. As you correct each error, you may want to delete it from the PSMessages collection.

Adding Criteria

In this example, you are accessing an existing query, then adding criteria both as part of the query as well as part of a subquery. The SQL statement created by this subquery is as follows:

```
SELECT RECNAME, RECDESCR, RELLANGRECNAME, PARENTRECNAME, DESCRLONG from PSRECDEFN w⇒
here RECNAME IN (select OBJECTVALUE1 from PSPROJECTITEM where PROJECTNAME = 'PPLTOO⇒
LS') AND RECTYPE = 0 order by RECNAME
```

The following is the complete code sample: the steps explain each line.

```
Local ApiObject &MyQuery, &MainQrySel, &Criteria1, &MyCrit2Expr2, &MyCriteria2;
Local ApiObject &SubQrySel, &SubQryCrit1, &SubQryExpr1, &MyCrit2Expr2;
Local Record &SubQryRec;
Local Session = &MySession;
Local ApiObject &COLL, &ERROR;
Local String &TEXT;

&MySession = %Session;

If &MySession <> Null Then

&MyQuery = &MySession.GetQuery();
```

```

&MyQuery.Open("Table", False, True);

&MainQrySel = &MyQuery.QuerySelect;

/* Add query record, add fields, then make selected fields output fields */
&MainRec = &MainQrySel.AddQueryRecord("PSRECDEFN");

&QryFld = &MainQrySel.AddQuerySelectedField(&MainRec.Name, &MainRec.RecordAlias, "R⇒
ECNAME", "Record Name");
&QryFld.ColumnNumber = 1;
&QryFld.OrderByNumber = 1;

&QryFld = &MainQrySel.AddQuerySelectedField(&MainRec.Name, &MainRec.RecordAlias, "R⇒
ECDESCR", "Record Descr");
&QryFld.ColumnNumber = 2;
&QryFld.OrderByNumber = 2;

&QryFld = &MainQrySel.AddQuerySelectedField(&MainRec.Name, &MainRec.RecordAlias, "R⇒
ELLANGRECNAME", "Record Lang Rec");
&QryFld.ColumnNumber = 3;
&QryFld.OrderByNumber = 3;

&QryFld = &MainQrySel.AddQuerySelectedField(&MainRec.Name, &MainRec.RecordAlias, "P⇒
ARENTRECNAME", "Parent Record Name");
&QryFld.ColumnNumber = 4;

&QryFld = &MainQrySel.AddQuerySelectedField(&MainRec.Name, &MainRec.RecordAlias, "D⇒
ESCRLONG", "Long Descr");
&QryFld.ColumnNumber = 5;

&QryFld = &MainQrySel.AddQuerySelectedField(&MainRec.Name, &MainRec.RecordAlias, "E⇒
MPLID", "ID");
&QryFld.ColumnNumber = 6;

/* adding first criteria */
&Criterial = &MainQrySel.AddCriteria("FirstCriteria");

/* First criteria will not have any logical AND/OR */
&Criterial.Logical = %Query_CombNotUsed;

&Criterial.Expr1Type = %Query_ExprField;
&Criterial.AddExpr1Field(&MainRec.RecordAlias, "RECNAME");

/* So that the criteria is constructed as - RECNAME IN (...)*
&Criterial.Operator = %Query_CondInList;
&Criterial.Expr2Type = %Query_ExprSubQuery;

&SubQrySel = &Criterial.AddExpr2SubQuery();
&SubQryRec = AddQueryRecord("PSPROJECTITEM");
&SubQryFld1 = &SubQrySel.AddQuerySelectedField(&SubQryRec.Name, &SubQryRec.RecordAl⇒
ias, "OBJECTVALUE1", "Join Object")
&SubQryFld1.ColumnNumber = 1;

/* Need criteria - PROJECTNAME = 'PPLTOOLS' - in the subquery */
&SubQryCrit1 = &SubQrySel.AddCriteria("FirstSubCrit");

/* First criteria will not have any logical AND/OR */
&SubQryCrit1.Logical = %Query_CombNotUsed;

&SubQryCrit1.Expr1Type = %Query_ExprField;
&SubQryCrit1.AddExpr1Field(&SubQryRec.RecordAlias, "PROJECTNAME");

```

```

&SubQryCrit1.Operator = %Query_CondEqual;

/* So that the criteria is constructed as - PROJECTNAME = 'PPLTOOLS'*/
&SubQryCrit1.Expr2Type = %Query_ExprConstant;
&SubQryExpr1 = &SubQryCrit1.AddExpr2Expression();
&SubQryExpr1.Text = "PPLTOOLS";
&SubQryCrit1.Expr2Expression1 = &SubQryExpr1;

/* Second Criteria, which is for RECTYPE = 0 */
&MyCriteria2 = &MainQrySel.AddCriteria("SecondCriteria");

&MyCriteria2.Expr1Type = %Query_ExprField;
&MyCriteria2.AddExpr1Field(&MainRec.RecordAlias, "RECTYPE");

/* Since this is second criteria, we need a logical AND to state that */
/* - AND RECTYPE = 0 */

&MyCriteria2.Logical = %Query_CombAnd;

&MyCriteria2.Operator = %Query_CondEqual;
&MyCriteria2.Expr2Type = %Query_ExprConstant;
&MyCrit2Expr2 = &MyCriteria2.AddExpr2Expression();
&MyCriteria2.Expr2Expression1 = &MyCrit2Expr2;
&MyCrit2Expr2.Text = "0";

&Rslt = &MyQuery.Save();

If &Rslt <> 0 Then
  /* save didn't complete */
  &COLL = &MySession.PSMessages;

  For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item(&I);
    &TEXT = &ERROR.Text;
    /* do error processing */
  End-For;

  &COLL.DeleteAll();
End-if;

Else

/* do error processing for not getting session */

End-if;

```

To add criteria to a query:

1. Get a session object.

Before you can create a query, you have to get a session object. The session controls access to the query, provides error tracing, enables you to set the runtime environment, and so on. Then this program checks to verify that the session object is valid.

```

&MySession = %Session;

&MyQuery = &MySession.GetQuery();

If &MySession <> Null Then

```

2. Access an existing query and get the main query select statement.

Use the Open method to get the existing query. Then access the main select statement with the QuerySelect property.

```

&MyQuery.Open("Table", False, True);

&MainQrySel = &MyQuery.QuerySelect;

```

3. Add Query Record in the Main Select.

Add the query record that you want to use.

```
&MainRec = &MainQrySel.AddQueryRecord("PSRECDEFN");
```

4. Add the displayed fields.

You want to add the selected fields. Note instead of hardcoding the name of the record, this code example uses the Name property. Also, the code uses the RecordAlias property instead of hardcoding the alias. This makes the code easier to read, as well as easier to maintain. Specifying a column number also makes this an output field.

```
&QryFld = &MainQrySel.AddQuerySelectedField(&MainRec.Name, &MainRec.RecordAlias, "RECNAME", "Record Name");
&QryFld.ColumnNumber = 1;
```

5. Specify the OrderBy value.

Because we need to order by this field, the OrderByNumber of that field must be set also.

```
&QryFld.OrderByNumber = 1;
```

6. Add the first criteria.

Add the first criteria. You don't want it added with any kind of operator, like an AND or an OR, so the Logical property of the first criteria is set with %Query_CombNotUsed. This is also used because it's the first non-having criteria of a query.

```
/* adding first criteria */
&Criterial = &MainQrySel.AddCriteria("FirstCriteria");

/* First criteria will not have any logical AND/OR */
&Criterial.Logical = %Query_CombNotUsed;
```

7. Add the first criteria field.

The first field for the criteria is a QueryExpression type field. The type of the field *must* be set before the field is added.

```
&Criterial.Expr1Type = %Query_ExprField;
&Criterial.AddExpr1Field(&MainRec.RecordAlias, "RECNAME");
```

8. Add the condition for the first criteria and the subquery.

The first criteria is the WHERE RECNAME IN portion of the SQL statement. The condition is considered 'in list', where the list is the result of the subquery. The expression is a subquery. Again, you have to set the type again before adding the subquery.

```
&Criterial.Operator = %Query_CondInList;
&Criterial.Expr2Type = %Query_ExprSubQuery;
&SubQrySel = &Criterial.AddExpr2SubQuery();
```

9. Add the records for the subquery.

Add the query record and the field from the query field, and make it an output field.

```
&SubQryRec = AddQueryRecord("PSPROJECTITEM");
&SubQryFld1 = &SubQrySel.AddQuerySelectedField(&SubQryRecName.Name, &SubQryRecName.RecordAlias, "OBJECTVALUE1", "Join Object");
```

```
&SubQryFld1.ColumnNumber = 1;
```

10. Add the criteria in the subquery.

The following code adds the criteria for the subquery. Because this is the first non-having criteria in a select statement, the Logical property is set as %Query_CombNotUsed. Then the first expression is added as a field, and set to be equal to the second expression, PPLTOOLS. This is the where PROJECTNAME = 'PPLTOOLS' portion of the SQL statement.

```
/* Need criteria - PROJECTNAME = 'PPLTOOLS' - in the subquery */
&SubQryCrit1 = &SubQrySel.AddCriteria("FirstSubQryCrit");

/* First criteria will not have any logical AND/OR */
&SubQryCrit1.Logical = %Query_CombNotUsed;

&SubQryCrit1.Expr1Type = %Query_ExprField;
&SubQryCrit1.AddExpr1Field(&SubQryRec.RecordAlias, "PROJECTNAME");
&SubQryCrit1.Operator = %Query_CondEqual;

/* So that the criteria is constructed as - PROJECTNAME = 'PPLTOOLS'*/
&SubQryCrit1.Expr2Type = %Query_ExprConstant;
&SubQryExpr1 = &SubQryCrit1.AddExpr2Expression();
&SubQryExpr1.Text = "PPLTOOLS";
&SubQryCrit1.Expr2Expression1 = &SubQryExpr1;
```

11. Add the second criteria to the main select.

Add the second criteria. Remember to set the type for the expression field first. Because this is the second criteria, we need a logical AND to state that this criteria is used with the first criteria.

```
/* Second Criteria, which is for RECTYPE = 0 */
&MyCriteria2 = &MainQrySel.AddCriteria("SecondCriteria");

&MyCriteria2.Expr1Type = %Query_ExprField;
&MyCriteria2.AddExpr1Field(&MainRec.RecordAlias, "RECTYPE");

/* Since this is second criteria, we need a logical AND to state that*/
/* - AND RECTYPE = 0 */

&MyCriteria2.Logical = %Query_CombAnd;

&MyCriteria2.Operator = %Query_CondEqual;
&MyCriteria2.Expr2Type = %Query_ExprConstant;

&MyCrit2Expr2 = &MyCriteria2.AddExpr2Expression();
&MyCriteria2.Expr2Expression1 = &MyCrit2Expr2;
&MyCrit2Expr2.Text = "0";
```

12. Save the data.

When you execute the Save method, the new query is saved to the database.

```
&Rslt = &MyQuery.Save();

If &Rslt <> 0 Then
```

The Save method returns a numeric value: 0 if successful. You can use this value to do error checking.

13. Check Errors

You can check if there were any errors using the PSMessages property on the session object.

```
/* save didn't complete */
&COLL = &MySession.PSMessages;
For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item(&I);
```

```

        &TEXT = &ERROR.Text;
        /* do error processing */
    End-For;
    &COLL.DeleteAll();
End-if;

```

If there are multiple errors, all errors are logged to the PSMessages collection, not just the first occurrence of an error. As you correct each error, you may want to delete it from the PSMessages collection.

Using Outer Joins

The following PeopleCode query uses outer joins:

```

Local ApiObject &aQuery, &aQrySelCol;
Local ApiObject &aQryRcd, &aQryRcd2;
Local ApiObject &aQryFld, &aQryFld2;
Local ApiObject &aQrySel, &Criterial;
Local number &Rslt;

&aQuery = %Session.GetQuery();
&aQuery.Create("TEST1", False, %Query_Query, "PIA Test 1", "Creating Test Query1=>
from PIA Page");

&aQrySel = &aQuery.AddQuerySelect();

&aQryRcd = &aQrySel.AddQueryRecord("JOB");
&aQryRcd.RecordAlias = "A";

&aQryRcd2 = &aQrySel.AddQueryRecord("PERSONAL_DATA");
&aQryRcd2.RecordAlias = "B";
&aQryRcd2.JoinType = %Query_JoinLeftOuter;
&aQryRcd2.JoinAlias = "A";

&aQryFld = &aQrySel.AddQuerySelectedField("JOB", "A", "EMPLID", "EMPLID");
&aQryFld.ColumnNumber = 1;
&aQryFld.HeadingType = %Query_HdgRftShort;

&aQryFld2 = &aQrySel.AddQuerySelectedField("PERSONAL_DATA", "B", "NAME", "NAME")=>
;
&aQryFld2.ColumnNumber = 2;
&aQryFld.HeadingType = %Query_HdgRftShort;

&Criterial = &aQrySel.AddCriteria("JoinCriteria");
&Criterial.Logical = %Query_CombNotUsed;
&Criterial.Expr1Type = %Query_ExprField;
&Criterial.AddExpr1Field("A", "EMPLID");
&Criterial.Operator = %Query_CondEqual;
&Criterial.Expr2Type = %Query_ExprField;
&Criterial.AddExpr2Field1("B", "EMPLID");
&Criterial.OJAlias = "B";

&Rslt = &aQuery.Save();

```

The above PeopleCode program produces the following SQL:

```

SELECT A.EMPLID, B.NAME
FROM (PS_JOB A LEFT OUTER JOIN PS_PERSONAL_DATA B ON A.EMPLID=B.EMPLID)

```

Record Class

Understanding Record Class

A record object, instantiated from the Record class, is a single instance of a data within a row and is based on a record definition. A record object consists of one to n fields.

If a record object is instantiated using `GetRecord` (either the function or the method), the record object that is instantiated references the record from the current row in the data buffers, and its associated data.

If a record object is instantiated using the `CreateRecord` function, the record object that's instantiated is a freestanding record definition with its component set of field objects in the data buffer. The fields created by this function are initialized to null values, that is, they do *not* contain any data. Default processing is not performed. You can select into this record object using the `SelectByKey` method. You can also select into this record object using `SQLExec`.

`CopyFieldsTo` is a commonly used method for the record class. `Name`, `IsChanged`, and `FieldCount` are commonly used properties.

The record class is one of the data buffer access classes.

Related Links

"Understanding Data Buffer Access" (PeopleCode Developer's Guide)

Shortcut Considerations

An expression of the form

```
RECORD.recname.property
```

or

```
RECORD.recname.method(. . .)
```

is converted to an object expression by using `GetRecord(RECORD.recname)`. For example, the following two lines of code are equivalent:

```
&MyRow = RECORD.EMPL_CHKLIST_ITEM.ParentRow;
```

```
&MyRow = GetRecord(RECORD.EMPL_CHKLIST_ITEM).ParentRow;
```

In addition, the default method for the Record class is the GetField method. This means you can access a field by just specifying the field name, instead of using GetField. For example, the following two lines of code, which both disable the EMPLID field, are equivalent:

```
&MyRec.EMPLID.Enabled = False;  
  
&MyRec.GetField(FIELD.EMPLID).Enabled = False;
```

Note: If the field you're accessing has the same name as a record property (such as, Name) you can't use this method for accessing the field. You must use the GetField method.

Record Methods Used to Create SQL Statements

You can use the following record object methods to build and execute SQL statements:

- Delete
- SelectByKey
- Insert
- Save
- Update

The methods that result in a database update (specifically, UPDATE, INSERT, and DELETE) can only be issued in the following events:

- SavePreChange
- WorkFlow
- SavePostChange
- FieldChange

Remember that record UPDATES, INSERTS, and DELETES go directly to the database server, not to the Component Processor (although you can *view* data in the buffer using the PeopleCode debugger and other data buffer access classes). If a record method assumes that the database has been updated based on changes made in the component, that record method can be issued only in the SavePostChange event, because before SavePostChange none of the changes made to page data has actually been written back to the database.

If your application is repeating the same instruction many times, such as doing a million INSERTS, you should use the SQL object with the BulkMode property set to True, rather than the record SQL methods.

Data Type of a Record Object

Record objects are declared as type Record. For example,

```
Local Record &MYRECORD;
```

Scope of a Record Object

A record can only be instantiated from PeopleCode.

This object can be used anywhere you have PeopleCode, that is, in an application class, Application Engine PeopleCode, Component Interface PeopleCode, and so on.

Record Class Built-in Functions

"CreateRecord" (PeopleCode Language Reference)

"GetRecord" (PeopleCode Language Reference)

Record Class Methods

In this section, we discuss each Record class method. The methods are discussed in alphabetical order.

CompareFields

Syntax

```
CompareFields (recordobject)
```

Description

The CompareFields method compares all like-named fields of the record object executing the method with the specified record object *recordobject*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>recordobject</i>	Specify a record object for use in the comparison. The specified record object does not have to refer to the same record as the record object executing the method.

Returns

A Boolean value; True if all like-named fields have the same value.

Example

```
&REC = GetRecord(RECORD.OP_METH_VW);
&REC2 = GetRecord(RECORD.OPC_METH);
If &REC2.CompareFields(&REC) Then
    WinMessage("All liked named fields have the same value");
End-If;
```

Related Links

[CopyChangedFieldsTo](#)

[CopyFieldsTo](#)

CopyChangedFieldsTo

Syntax

```
CopyChangedFieldsTo (recordobject)
```

Description

The CopyChangedFieldsTo method copies all like-named field values that have changed from the record object executing the method to the specified record object *recordobject*. This copies only changed field values. To copy all field values, use the CopyFieldsTo method.

Note: This method works only with database records. The Component Processor doesn't track the contents of work records, so there is no changed value to use for copying changed fields.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>recordobject</i>	Specify a record object to be copied to. The specified record object does not have to refer to the same record as the record object executing the method.

Returns

None.

Example

```
Local Record &REC, &REC2;

&REC = GetRecord(RECORD.OPC_METH);

/* make changes to the values of fields in the record */
```

```
&REC2 = CreateRecord(RECORD.OPC_METH_WORK);
&REC.CopyChangedFieldsTo(&REC2);
```

Related Links

[CompareFields](#)

[CopyFieldsTo](#)

CopyFieldsTo

Syntax

```
CopyFieldsTo(recordobject[, DontCopyUnusedInSource [, DontCopyUnusedInDestination]]⇒
[, IsBatch])
```

Description

The CopyFieldsTo method copies all like-named field values from the record object executing the method to the specified record object *recordobject*. This copies all field values.

To copy only changed field values, use the CopyChangedFieldsTo method.

To restrict the copy to fields that have been marked as unused (set using the SetDBFieldNotUsed function) you can specify either *DontCopyUnusedInSource* or *DontCopyUnusedInDestination*.

Note: If you are copying to a derived work record, the IsChanged flag for the record is not set. Copying fields to a database record does set the IsChanged flag to True.

Parameters

Parameter	Description
<i>recordobject</i>	Specify a record object to be copied to. The specified record object does not have to refer to the same record as the record object executing the method.
<i>DontCopyUnusedInSource</i>	Specify this parameter to be True if you want to restrict the copy of fields to not include fields marked as unused in the record of the object performing the CopyFieldsTo method. This is the source record. The default value for this parameter is False, which means that there are no restrictions on the copy of unused fields as defined in the source record.

Parameter	Description
<i>DontCopyUnusedInDestination</i>	<p>Specify this parameter to be True if you want to restrict the copy of fields to not include fields marked as unused in the recordobject record which is the destination record.</p> <hr/> <p>Note: To specify this record to be true you must specify a value for <i>DontCopyUnusedInSource</i>.</p> <hr/> <p>The default value for this parameter is False meaning that there are no restrictions on the copy of unused fields as defined in the destination record.</p>
<i>IsBatch</i>	<p>Specify whether this method is being called from an online program or from a batch program (such as an Application Engine program.) The default is false. Using this method may improve batch performance. When set to true, the system uses the FieldNotUsed information directly from the field properties already in the memory</p>

Returns

None.

Example

```
Local Record &REC, &REC2;

&REC = GetRecord(RECORD.OPC_METH);
&REC2 = CreateRecord(RECORD.OPC_METH_WORK);
&REC.CopyFieldsTo(&REC2);
```

In the following example, records are copied into a record after being fetched.

```
Component number &displayNum;
Local SQL &sql;
Local Rowset &rs, &rs2;

&level0 = GetLevel0();
&displayNum = WS_NUM_ORDERS;

&rs = GetRowset(Record.WS_ORD_HDR_VW);
&rs.Flush();
WinMessage("1");
&sql = CreateSQL("%selectall(:1) where BUSINESS_UNIT=:2", Record.WS_ORD_HDR_VW, "M0⇒
4");
WinMessage("2");
&rec = CreateRecord(Record.WS_ORD_HDR_VW);

For &i = 1 To &displayNum

    If &sql.Fetch(&rec) Then

        &rs.InsertRow(&i);

        &rec.copyfieldsto(&rs.GetRow(&i).WS_ORD_HDR_VW);

        &rs2 = &rs.GetRow(&i).GetRowset(1);
        &rs2.Select(Record.WS_ORD_LINE_VW, "where BUSINESS_UNIT=:1 and ORDER_NO=:2", ⇒
```

```

&rec.BUSINESS_UNIT.value, &rec.ORDER_NO.value);

    /* Hide rows that do not contain Products */
    If &rs2 = Null Or None(&rs2.GetRow(1).WS_ORD_LINE_VW.ORDER_INT_LINE_NO.Value)⇒
    Then
        For &j = 1 To &rs2.ActiveRowCount
            &rs2.GetRow(&j).Visible = False;
        End-For;
    End-If;
End-For;

&rs.GetRow(&i).Visible = False;

```

The following example is for unused record fields:

```

Local Record &From = CreateRecord(Record.QE_UPS_TIME);

/* setup the initial values */

&From.QE_FROM_ZIP.Value = "12345";
&From.QE_TO_ZIP.Value = "67890";
&From.QE_UPS_TIME_BUTTON.Value = "A";
&From.DESCRLONG.Value = "This is the from record.";

/* Now make one of the fields unused */
Local string &ToZip_Value = "77777";

/* start out clean with &To */
Local Record &To = CreateRecord(Record.QE_UPS_TIME);
&To.QE_TO_ZIP.Value = &ToZip_Value;
If SetDBFieldNotUsed(Field.QE_TO_ZIP, True) <> %MetaDataChange_Success Then
    MessageBox(0, "", 0, 0, "SSetDBFieldNotUsed(Field.QE_TO_ZIP, TRUE) fails??");
End-If;
/* Copy no unused fields from the source record */
&From.CopyFieldsTo(&To, True /* no unused fields from source */);

/* Copy to no unused fields in the destination */
&From.CopyFieldsTo(&To, False /* all fields from source */, True /* no unused field⇒
s in dest */);

/* Copy no unused fields either in source or destination */

&From.CopyFieldsTo(&To, True /* no unused fields from source */, True /* no unused ⇒
fields in dest */);

/* Now finally make that field good again */

If SetDBFieldNotUsed(Field.QE_TO_ZIP, False) <> %MetaDataChange_Success Then
    MessageBox(0, "", 0, 0, "SSetDBFieldNotUsed(Field.QE_TO_ZIP, False) fails??");
End-If;

```

[CompareFields](#)

[CopyChangedFieldsTo](#)

[IsChanged](#)

"SetDBFieldNotUsed" (PeopleCode Language Reference)

Delete

Syntax

```
Delete ()
```

Description

The Delete method uses the key fields of the record and their values to build and execute a DELETE SQL statement which deletes the record (row of data) from the SQL data table.

This method, like the DeleteRow Rowset class method, initially marks the record or row as needing to be deleted. At save time the row is actually deleted from the database and cleared from the buffer.

Because this method results in a database change, it can be issued only in the following events:

- SavePreChange
- WorkFlow
- SavePostChange

If your application is repeating the same instruction multiple times, such as doing a million DELETES, use the SQL object with the BulkMode property set to True, rather than the record SQL methods.

For every record deleted by the Delete method, if the set language is not the base language and the record has related language records, the Delete method tries to do related language processing.

Parameters

None.

Returns

The result is True on successful completion, False if the record was not found. Any other conditions cause termination.

Example

Suppose that KEYF1 and KEYF2 are the two key fields of record definition MYRECORD. The following code deletes the database record that has KEYF1 equal to "A" and KEYF2 equal to "X":

```
Local record &REC;  
&REC = CreateRecord(RECORD.MYRECORD);  
&REC.KEYF1.Value = "A";  
&REC.KEYF2.Value = "B";  
&REC.MYRF3.Value = "X";  
&REC.MYRF4.Value = "Y";  
&REC.Insert();
```

ExecuteEdits

Syntax

```
ExecuteEdits ([editlevel]);
```

where *editlevels* is a list of values in the form:

```
editlevel1 [+ editlevel2] . . .];
```

and where *editleveln* is one of the following constants:

%Edit_DateRange

%Edit_OneZero

%Edit_PromptTable

%Edit_Required

%Edit_TranslateTable

%Edit_YesNo

Description

The ExecuteEdits method executes the standard system edits on every field in the record. The types of edits performed depends on the *editlevel*. If no *editlevel* is specified, all system edits are executed. All *editlevels* are already defined for the record definition or for the field definition, that is:

- Reasonable Date Range (Is the date contained within the specified reasonable date range?)
- 1/0 (Do all 1/0 fields contain only a 1 or 0?)
- Prompt Table (Is field data contained in the specified prompt table?)
- Required Field (Do all required fields contain data? For numeric or signed fields, it checks that they do not contain NULL or 0 values.)
- Translate Table (Is field data contained in the specified translate table?)
- Yes/No (Do all yes/no fields only contain only yes or no data?)

Note: ExecuteEdits does not perform any validation on DateTime fields.

If any of the edits fail, the status of the property IsEditError is set to False for the record. The field property EditError is set to True for any fields that are in error. In addition, the Field class properties MessageNumber and MessageSetNumber are set to the number of the returned message and message set number of the returned message, for each field in error.

You must use the `SetEditTable` method to set the prompt tables for fields that are defined with `%EditTable` in the record definition.

If you're running an Application Engine program, and you want to do set based `ExecuteEdits` (as opposed to row-by-row) consider using the meta-SQL construct `%ExecuteEdits`.

See [SetEditTable](#), [EditError](#), [MessageNumber](#), [MessageSetNumber](#), "Using Application Engine Meta-SQL" (Application Engine).

Considerations for ExecuteEdits and SetEditTable

If an effective date is a key on the prompt table, and the record being edited doesn't contain an `EFFDT` field, the current date and time is used as the key value.

If a `SETID` is a key on the prompt table, and the record being edited doesn't contain a `SETID` field, the system looks for `SETID` on the other records in the current row first, then searches parent rows.

For all other keys, the value used to "select" the correct row in the prompt table record comes only from the record executing the method. No other records (or key field values) are used. You may get unexpected results if not all the keys for the prompt table are filled in (or filled in correctly.)

Considerations for ExecuteEdits and Numeric Fields

A zero (0) might or might not be a valid value for a numeric field. `ExecuteEdits` processes numeric fields in different ways, depending on whether the field is required:

- If the numeric field is required: 0 is considered invalid.
- If the numeric field is not required: 0 is considered valid.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>editlevel</i>	<p>Specifies the standard system edits to be performed against every field on every record. If <i>editlevel</i> isn't specified, all system edits are performed. <i>editlevel</i> can be any of the following system variables.</p> <ul style="list-style-type: none"> • <code>%Edit_DateRange</code> • <code>%Edit_OneZero</code> • <code>%Edit_PromptTable</code> • <code>%Edit_Required</code> • <code>%Edit_TranslateTable</code> • <code>%Edit_YesNo</code>

Returns

None.

Example

The following is an example of a call to execute Required Field and Prompt Table edits:

```
&REC.ExecuteEdits(%Edit_Required + %Edit_PromptTable);
```

The following is an example showing how ExecuteEdits() could be used:

```
&REC.ExecuteEdits();
If &REC.IsEditError Then
    LogError(); /*application specific call */
End-If;
```

[SetEditTable](#)

[IsEditError](#)

[EditError](#)

[MessageNumber](#)

[MessageSetNumber](#)

GetField

Syntax

```
GetField({n | FIELD.fieldname})
```

Description

The GetField method instantiates a field object for the specified field associated with the record. This is the default method for the record object. This means that any record object, followed by a parameter list, acts as if GetField is specified.

Note: If the field you're accessing has the same name as a record property (that is, Name or FieldCount) you can't use the default method for accessing the field. You must specify GetField.

For example, the following is invalid for accessing the value of a field called NAME:

```
&NUMBER = &REC.NAME.Value;
```

You must use the following code to get the value of a field called NAME:

```
&NUMBER= &REC.GetField(FIELD.NAME).Value;
```

Parameters

Parameter	Description
<i>n</i> FIELD . <i>fieldname</i>	Specify a field to be used for instantiating the field object. You can specify either <i>n</i> or FIELD . <i>fieldname</i> . Specifying <i>n</i> creates a field object for the <i>n</i> th field in the record. This might be used if writing code that needs to examine all fields in a record without being aware of the name. Specifying FIELD . <i>fieldname</i> creates a field object for the field <i>fieldname</i> .

Note: There is no way to predict the order the fields will be accessed. Use the *n* option only if the order in which the fields are processed doesn't matter.

Returns

A field object.

Example

```
&REC.GetField(FIELD.CHARACTER).Value = "Hello";
```

As GetField is the default method for a record object, the following code is identical to the previous code:

```
&REC.CHARACTER.VALUE = "Hello";
```

The following code creates an array containing all the names of all the fields in a related language record.

```
Local array of string &FIELD_LIST_ARRAY;
&FIELD_LIST_ARRAY = CreateArray();
For &I = 1 To &REC_RELATED_LANG.FieldCount
    &FIELD_LIST_ARRAY.Push(&REC_RELATED_LANG.GetField(&I).Name);
End-For;
```

The GetField method requires either FIELD.fieldname or a number. It won't take a string field name. However, you can use the @ operator to convert the string field name into a **FIELD**.*fieldname* reference, as follows:

```
&REC = GetRecord();
&REC2 = GetLevel0(1).EMPL_CHECKLIST;
&FIELD2 = &REC.GetField(@ "FIELD." | &REC2.getfield(&I).Name);
```

The following code converts field name strings (using the @ symbol) to component names to get the value of all the fields in a subrecord. Note the code in **Keyword style**.

```
Function get_draft_dst_codes
    /* Load dst id codes into record structures */
    &DSTCODES = CreateRecord(RECORD.DR_DST_CODE_SBR);
    &DRAFTITEM = GetRecord(RECORD.DRAFT_ITEM);
    &DRAFTITEM.CopyFieldsTo(&DSTCODES);
    /* If any missing get from AR dist code, then Draft Type-BU, then BU */
    For &I = 1 To &DSTCODES.FieldCount
        If None(&DSTCODES.GetField(&I).Value) Then
            get_ar_dst_code();
            &NAME = &DSTCODES.GetField(&I).Name;
            If All(&DST.GetField(@ ("FIELD." | &NAME)).Value) Then
                &DSTCODES.GetField(&I).Value = &DST.GetField(@ ("FIELD." | &NAME)).Value⇒
        ;
    ;
```

```

Else
  If All(&R_DRAFTBU.GetField(@"FIELD." | &NAME)).Value Then
    &DSTCODES.GetField(&I).Value = &R_DRAFTBU.GetField(@"FIELD." | &NAME)⇒
E) .Value;
  Else
    &DSTCODES.GetField(&I).Value = &R_ARBU.GetField(@"FIELD." | &NAME)⇒
.Value;

    End-If;
  End-If;
End-For;
/* Copy the defaulted values back to draft item */
&DSTCODES.CopyFieldsTo (&DRAFTITEM);
End-Function;

```

Related Links

"GetField" (PeopleCode Language Reference)

Insert

Syntax

```
Insert ()
```

Description

The Insert method uses the field names of the record and their values to build and execute an Insert SQL statement which adds the given record (row of data) to the SQL table.

Because this method results in a database change, it can only be issued in the following events:

- SavePreChange
- WorkFlow
- SavePostChange

If your application is repeating the same instruction many times, such as doing a million INSERTs, use the SQL object with the BulkMode property set to True, rather than the record SQL methods.

If you're using a record created using CreateRecord, all fields are initially set to "", 0, or NULL, depending on the type of field. If you don't specify values for these fields, these initial values are written to the database when the insert is executed. If you want the default values for the fields inserted instead, use the SetDefault method prior to using the Insert method.

For every record inserted with the Insert method, if the set language is not the base language and the record has related language records, the Insert method tries to do related language processing.

Related Links

[Understanding SQL Class](#)

"Understanding Related Language Tables" (Global Technology)

[SetDefault](#)

Parameters

None.

Returns

The result is True on successful completion, False if there was a record with those keys already in the database, that is, if a duplicate record was found. Any other conditions cause termination.

Example

Suppose that KEYF1 and KEYF2 are the key fields of record definition MYRECORD, and that this record definition also contains the field definitions MYRF3, MYRF4. The following code adds a MYRECORD record (row of data) to the database, with KEYF1 set to "A", KEYF2 set to "B", MYRF3 set to "X", and MYRF4 set to "Y":

```
Local record &REC;  
&REC = CreateRecord(RECORD.MYRECORD);  
&REC.KEYF1.Value = "A";  
&REC.KEYF2.Value = "B";  
&REC.MYRF3.Value = "X";  
&REC.MYRF4.Value = "Y";  
&REC.Insert();
```

[SelectByKey](#)

[Update](#)

Save

Syntax

```
Save ([CopyToOriginal])
```

Description

The Save method saves the record to the database in two steps.

1. Check to see that it is safe to save this record to the database.
2. Either insert this record or update an existing record.

To accomplish the first step and determine that it is safe to save the record, this method uses similar logic to that used in the component processor when it saves a record. To do that a “select for update” SQL statement is executed. If, as a result of this statement, the record does not exist in the database, this method simply inserts the record into the database. All the processing that occurs for the insert method then occurs.

If the result of the “select for update” statement returns a record, the values of all the fields in the database record are compared to the original values of the record executing this method. If they are equal, indicating that no other user has updated the record, the record in the database is updated. All the

processing that occurs for the update method then occurs. If the result of the above comparison fails, indicating that there has been an update of the database record in the meantime, perhaps by some other user, the save method fails and returns a false result.

For the update process to succeed, the record object must contain both original and changed values of the data. It is crucial to get data loaded into the record object correctly. To do this, do one of the following:

- Derive the record object from the component buffers.
- Derive the record object from a rowset filled using the Fill method.
- Load the data using the record class `SelectByKey` and `SelectByKeyEffdt` methods specifying the optional Boolean parameter to be `False`.

See the note and example below.

Of course when you use `Save` to simply insert data you do not need load data into the record object this way.

Use this method when you are writing applications that do not use the facilities that come predelivered with the component processor and you must deal with issues of data contention.

For example, suppose you are writing an application that deals with course registration. You have to handle changing the number of students who are registered carefully if it is possible for more than one user to be registering for the same course at the same time. The normal way is to use the component processor to handle data contention by placing the record that deals with the number of students registering on some page. Then if two users try to update the same record one of them receives a message indicating that the page has been updated by another user.

If you write an application, outside the component processor, that relies on the record class to manage the number of students enrolled, it is not sufficient to use the record class `Insert` or `Update` methods to maintain data integrity. Suppose one user registers for the course and sees there are 10 other registrants. At the same time another user registers for the course and sees that there are also 10 registrants. Suppose the maximum is 11 students. Both users at this point believe they can register since at the point they accessed the data from the database there were only 10 students. So far, so good. The trouble comes when they save their registrations. If the application uses the update method, after simply adding one to the number of registrants, both updates will succeed indicating there are now 11 students in the course when in fact there are now 12. It is for cases such as these that the `Save` method applies since it guarantees that one of the save calls will fail. It is up to the application then to let the user know that while they were thinking about it someone else registered for the course and took the last spot.

The `Save` method is important to maintain data integrity. However, it can execute more slowly than saving within the component processor.

Since this method results in a database change, and does either insert or update processing, all the considerations and implications of using the `Insert` or `Update` methods apply. See the description of those methods for more detail.

The parameter *CopyToOriginal* indicates what action should occur on a successful save. If this parameter is true, the system copies the current changed buffers for the record into the original buffers for the record. This means that subsequent Saves, without reloading data from the database will run correctly. However if there are database specific updates to this record occurring outside of this application's control (such as, using database specific triggers,) it is always advisable to reload the data from the database.

The default value for this optional parameter is false, indicating that no update of the original buffers for this record occurs. If you are certain that there are no database updates occurring outside of your application's on save processing, you can specify this optional parameter to be true and save the overhead of having to reload the data for this record from the database. If you are unsure you should always reload the record data after calling the Save method.

Note: This method does *not* update fields marked as **System maintained** in the record definition in Application Designer.

Since this save is done outside the component processor save processing, no save processing PeopleCode that is associated with this record is executed.

Use of this method that results in an update, and requires that the data in the record object is such that both a before and after image of the data is kept. When the system loads data into the component buffers there is a concept of the “original data” (data loaded from the database) and “changed data” (data changed by the user or the application). This allows the system to determine when saving, whether the data has been changed by another user. If you use this method with record objects not derived from the component buffers you need to make sure that the data in the record object has both a before and after image otherwise the save method fails. Record objects derived from rowsets that have been populated using the Fill method will not produce an error. However if you load data into a record object using either the SelectByKey or SelectByKeyEffdt record class methods, you need to specify the *CopyToOriginal* parameter so the system will load the data into the original data buffers, not the changed data buffers. To do that specify the optional parameter to be False. See the example below.

[Insert](#)

[Update](#)

"Understanding Data Editing in Related Language Tables and Base Tables" (Global Technology)

Parameters

<i>Parameter</i>	<i>Description</i>
<i>CopyToOriginal</i>	Specify what action should occur on a successful save. This parameter takes a Boolean value: true, then the system copies the current changed buffers for the record into the original buffers for the record, false, the buffers are not copied. The default value is false.

Returns

The result is True on successful completion, False if there were no changed fields in the record or it was not safe to save this record (see above for details). Any other conditions cause termination.

Note: It is not possible to ignore the return code from the Save method in your PeopleCode.

Example

Suppose that KEYF1 and KEYF2 are the key fields of record definition MYRECORD, and that this record definition also contains the record field definitions MYRF3, MYRF4. The following code tries to

save MYRECORD record in the database with KEYF1 set to "A", KEYF2 set to "B", setting MYRF3 to "X" and MYRF4 to "Y". This example works with a brand new record object and results in an insert if successful.

```

/* First -- create a brand new record */
Local record &REC;
&REC = CreateRecord(RECORD.MYRECORD);
&REC.KEYF1.Value = "A";
&REC.KEYF2.Value = "B";

/* Second -- update values as needed */
&REC.MYRF3.Value = "X";
&REC.MYRF4.Value = "Y";
/* Finally save it */
if &REC.Save() then
    /* handle the successful return */
else
    /* handle the unsuccessful return message to user? Try again? */
end-if;

```

This example works with an existing record and results in an update if successful.

```

/* First - create the record and get the data from the db */
Local record &REC;
&REC = CreateRecord(RECORD.MYRECORD);
&REC.KEYF1.Value = "A";
&REC.KEYF2.Value = "B";
&REC.SelectByKey(False);
/* False retrieves data into the original, not changed buffers. */

/* Second - update values as needed */
&REC.MYRF3.Value = "X";
&REC.MYRF4.Value = "Y";
/* Finally save it */
if &REC.Save() then
    /* handle the successful return */
else
    /* handle the unsuccessful return - message to user? Try again? */
end-if;

```

[SelectByKey](#)

[Update](#)

[SelectByKeyEffDt](#)

SearchClear

Syntax

```
SearchClear()
```

Description

The SearchClear method clears the field values for all search keys for a record.

Considerations Using SearchClear and SearchDefault

The field property SearchDefault sets a field to its default value (if there is one) immediately after SearchInit PeopleCode finishes. SearchDefault overrides SearchClear. If you call SearchClear for a record, then use SearchDefault for a field, the field is set to its default value and the search key values for the rest of the record are cleared.

Parameters

None.

Returns

None.

Example

```
Local Record &REC;  
  
&REC = GetRecord();  
&REC.SearchClear();
```

Related Links

[SearchDefault](#)

[SearchClear](#)

SelectByKey

Syntax

```
SelectByKey([UseChangedBuffers])
```

Description

The SelectByKey method uses the key field names of the record and their values to build and execute a Select SQL statement. The field values are then fetched from the database SQL table into the record object executing the method, and the Select statement is closed.

Note: You can't use this method in dynamic views.

If you don't specify all the key fields for a record, those you exclude are added to the Where clause with the condition equal to a blank value. If not all keys are set and more than one row is retrieved, you won't receive an error and SelectByKey won't fetch any data.

SelectByKey returns a single row of data. To fetch more than one row, use the SQL object.

For every record read by the SelectByKey method, if the set language is not the base language and the record has related language records, the SelectByKey method tries to do related language processing.

You can also select into a record using SQLExec and meta-SQL. For example, if you need to use SelectByKey with an effective date, you can use the meta-SQL %SelectByKeyEffDt in a SQLExec

statement. In the following example, &RECOBJ is the name of a record created using the CreateRecord function.

```
SQLExec ("%SelectByKeyEffDt (:1, :2)", &RECOBJ, %Date, &RECOBJ);
```

Related Links

[Understanding SQL Class](#)

"Understanding Data Editing in Related Language Tables and Base Tables" (Global Technology)

"SQLExec" (PeopleCode Language Reference)

Parameters

<i>Parameter</i>	<i>Description</i>
<i>UseChangedBuffers</i>	<p>Specify whether to retrieve the data into the changed or original buffers. The system keeps track of the original and changed values. This parameter takes a Boolean value: true, retrieve into the changed buffers, False, use the original buffers. The default value is true. That is, to retrieve the data into the changed buffers.</p> <p>To use this parameter with the Save method, it is important that data be loaded into the original buffers in order for the save logic to work. To do that specify a value of false for this parameter.</p> <p>See Save.</p>

Returns

The result is true on successful completion, false if the record was not found. Any other conditions cause termination.

If false is returned, the system resets the record values to their default values for scrolls that are not derived. If you do a manual insert afterwards (using the Insert method) you may insert a record with null keys.

Example

Suppose that KEYF1 and KEYF2 are the two key fields of record definition MYRECORD. The following code reads the database record that has KEYF1 equal to "A" and KEYF2 equal to "X" into the &REC record object:

```
Local record &REC;
&REC = CreateRecord (RECORD.MYRECORD);
&REC.KEYF1.Value = "A";
&REC.KEYF2.Value = "X";
&REC.SelectByKey ();
```

The following example verifies if the method completes successfully before using the Insert method.

```
if not &Rec.SelectByKey() then
    /* Must duplicate this key field population before the Insert - else can get '⇒
```

```

blank' row */

    &Rec.KEY1.Value = ...;
    &Rec.KEY2.Value = ....;
    ....

    &Rec.Insert();

end-if;

```

[Delete](#)

[Insert](#)

[Update](#)

[Save](#)

SelectByKeyEffDt

Syntax

```
SelectByKeyEffDt(Date[, UseChangedBuffers])
```

Description

Use the SelectByKeyEffDt to build and execute a SQL Select statement to get the current effective row based on an "as of date". The field values are then fetched from the database SQL table into the record object executing the method, and the Select statement is closed.

Note: You can't use this method in dynamic views.

SelectByKeyEffDt returns a single row of data. To fetch more than one row, use the SQL object.

For every record read by the SelectByKeyEffDt method, if the set language is not the base language and the record has related language records, the SelectByKeyEffDt method tries to do related language processing. The system assumes that both the base table and the related language table are effective-dated and that the effective-date keys are the same in each.

To use other keys, more than just the effective date, use the SelectByKey Record class method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Date</i>	Specify the "as of" date you want to use as the effective date for the Select statement.

Parameter	Description
<i>UseChangedBuffer</i>	<p>Specify whether to retrieve the data into the changed or original buffers. The system keeps track of the original and changed values. This parameter takes a Boolean value: true, retrieve into the changed buffers, False, use the original buffers. The default value is true. That is, to retrieve the data into the changed buffers.</p> <p>To use this parameter with the Save method, it is important that data be loaded into the original buffers in order for the save logic to work. To do that specify a value of false for this parameter.</p> <p>See Save.</p>

Returns

The result is True on successful completion, False if the record was not found. Any other conditions cause termination.

If false is returned, the system resets the record values to their default values for scrolls that are not derived. If you do a manual insert afterwards (using the Insert method) you may insert a record with null keys.

Example

```

Local Record &Rec;
Local any &Date;

&Date = %Date;
&Rec = CreateRecord(Record.COMPANY_TBL);
&Rec.COMPANY.Value = "CCB";

If &Rec.SelectByKeyEffDt(&Date) Then
    &Out = &Rec.DESCR.Value | " as of " | &Rec.EFFDT.Value | "->" | &Rec.STREET1.Val⇒
ue;
    WinMessage("Found this company: " | &Out);
Else
    WinMessage("Not there!");
End-If;

```

[Update](#)

[Save](#)

[SelectByKey](#)

[Understanding SQL Class](#)

"Understanding Data Editing in Related Language Tables and Base Tables" (Global Technology)

SetDefault

Syntax

```
SetDefault()
```

Description

SetDefault sets the value of every field in the record to a null value, or to a default, depending on the type of field.

- If this method is used against data from the Component buffers, the next time default processing occurs, it is set to its default value: either a default specified in its record field definition or one set programmatically by PeopleCode located in a FieldDefault event. If neither of these defaults exist, the Component Processor leaves the field blank.
- If this method is used with a field that isn't part of the data buffer (for example, a field in a record object instantiated with CreateRecord) the field is automatically set to its default value if one is set for the field, not for the record field. Any FieldDefault PeopleCode does not run on these types of fields. To set the default values for just one field, use the SetDefault field class method.

Blank numbers correspond to zero on the database. Blank characters correspond to a space on the database. Blank dates and long characters correspond to NULL on the database. SetDefault gives each field data type its proper value.

Parameters

None.

Returns

None.

Example

```
&CHARACTER.SetDefault();
```

Related Links

[SetDefault](#)

"Default Processing" (PeopleCode Developer's Guide)

SetEditTable

Syntax

```
SetEditTable(%PromptField, RECORD.recordname)
```

Description

The SetEditTable method works with the ExecuteEdits method. It sets the value of a field on a record that has its prompt table defined as *%PromptField* value. *%PromptField* values are used to dynamically change the prompt record for a field.

There are several steps to setting up a field so that you can dynamically change its prompt table.

To set up a field with a dynamic prompt table:

1. Define a field in the DERIVED record called *fieldname*.
2. In the record definition for the field you want to have a dynamic prompt table, define the prompt table for the field as *%PromptField*, where *PromptField* is the name of the field you created in the DERIVED record.

Note: When you use SetEditTable, you don't have to add a hidden field to the page.

3. Use SetEditTable to dynamically set the prompt table.

%PromptField is the name of the field on the DERIVED work record. *RECORD.recordname* is the name of the record to be used as the prompt table.

```
&REC.SetEditTable("%EDITTABLE1", Record.DEPARTMENT);
&REC.SetEditTable("%EDITTABLE2", Record.JOB_ID);
&REC.SetEditTable("%EDITTABLE3", Record.EMPL_DATA);
&REC.ExecuteEdits();
```

Every field on a record that has the prompt table field %EDITTABLE1 will have the same prompt table, that is, DEPARTMENT.

See [ExecuteEdits](#), "Understanding Record Definitions" (Application Designer Developer's Guide).

Considerations for SetEditTable and ExecuteEdits

The keys used to "select" the correct row in the prompt table record come only from the record object executing the method. All the keys from the component are not used. You may get unexpected results if not all the keys for the prompt table are filled in (or filled in correctly.)

Parameters

Parameter	Description
<i>%PromptField</i>	Specifies the name of the field in the DERIVED record that has been defined as the prompt table for a field in the record definition.
RECORD.recordname	Specifies the name of the record definition that contains the correct standard system edits to be performed for that field in the record.

Returns

None.

Example

```

/* To Set the Prompt Table */
&Der_EditRec = &TSKPRF_Det_Row.GetRecord(Record.DERIVED);
&Prompt_Editname = &Der_EditRec.EDITTABLE.Value;
&Prompt_Edittable = "Record." | &Prompt_Editname;
&TSKPRF_Det_Rec.SetEditTable("%EDITTABLE", @&Prompt_Edittable);

&Prompt_Editname2 = &Der_EditRec.EDITTABLE2.Value;
&Prompt_Edittable2 = "Record." | &Prompt_Editname2;
&TSKPRF_Det_Rec.SetEditTable("%EDITTABLE2", @&Prompt_Edittable2);

&Prompt_Editname3 = &Der_EditRec.EDITTABLE3.Value;
&Prompt_Edittable3 = "Record." | &Prompt_Editname3;
&TSKPRF_Det_Rec.SetEditTable("%EDITTABLE3", @&Prompt_Edittable3);

&Prompt_Editname4 = &Der_EditRec.EDITTABLE4.Value;
&Prompt_Edittable4 = "Record." | &Prompt_Editname4;
&TSKPRF_Det_Rec.SetEditTable("%EDITTABLE4", @&Prompt_Edittable4);

&Prompt_Editname5 = &Der_EditRec.EDITTABLE5.Value;
&Prompt_Edittable5 = "Record." | &Prompt_Editname5;
&TSKPRF_Det_Rec.SetEditTable("%EDITTABLE5", @&Prompt_Edittable5);

&Prompt_Editname6 = &Der_EditRec.EDITTABLE6.Value;
&Prompt_Edittable6 = "Record." | &Prompt_Editname6;
&TSKPRF_Det_Rec.SetEditTable("%EDITTABLE6", @&Prompt_Edittable6);

&TSKPRF_Det_Rec.ExecuteEdits(%Edit_Required + %Edit_PromptTable);

```

[MessageSetNumber](#)

Update

Syntax

```
Update ([KeyRecord])
```

Description

The Update method uses the changed fields of the record and their values to build and execute an Update SQL statement, updating the SQL table. If you are updating the key fields of the record, you must supply a record object *KeyRecord* that contains the old values of the key record fields.

Because this method results in a database change, it can only be issued in the following events:

- SavePreChange

- Workflow
- SavePostChange

If your application is repeating the same instruction many times, such as doing a million UPDATES, use the SQL object with the BulkMode property set to True, rather than the record SQL methods.

For every record updated by the Update method, if the set language is not the base language and the record has related language records, the Update method tries to do related language processing.

Note: This method does not update fields marked as **system maintained** in Application Designer.

Related Links

Understanding SQL Class

"Understanding Data Editing in Related Language Tables and Base Tables" (Global Technology)

Parameters

<i>Parameter</i>	<i>Description</i>
<i>KeyRecord</i>	If you're updating the key fields of the record, you must supply the old key field values in the record object <i>KeyRecord</i> .

Returns

The result is True on successful completion, False if the record was not found or (when updating the key fields) a duplicate record was found. Any other conditions cause termination.

Example

Suppose that KEYF1 and KEYF2 are the key fields of record definition MYRECORD, and that this record definition also contains the record field definitions MYRF3, MYRF4. The following code updates the MYRECORD record in the database with KEYF1 set to "A", KEYF2 set to "B", setting MYRF3 to "X" and MYRF4 to "Y":

```
Local record &REC;
&REC = CreateRecord(RECORD.MYRECORD);
&REC.KEYF1.Value = "A";
&REC.KEYF2.Value = "B";
&REC.MYRF3.Value = "X";
&REC.MYRF4.Value = "Y";
&REC.Update();
```

This code updates the MYRECORD record in the database with KEYF1 of "A" and KEYF2 of "B", setting KEYF2 to "C", MYRF3 to "M" and MYRF4 to "N":

```
Local record &REC1, &REC2;
&REC1 = CreateRecord(RECORD.MYRECORD);
&REC2 = CreateRecord(RECORD.MYRECORD);
&REC1.KEYF1.Value = "A";
&REC1.KEYF2.Value = "B";
&REC2.KEYF1.Value = "A";
&REC2.KEYF2.Value = "C";
&REC2.MYRF3.Value = "M";
```

```
&REC2.MYRF4.Value = "N";
&REC2.Update(&REC1);
```

Record Class Properties

In this section, we discuss the Record class properties. The properties are listed in alphabetical order.

FieldCount

Description

This property returns the total number of fields contained in the record. This value is a number.

This property is read-only.

Example

```
WinMessage("This record has this many fields : " | &REC.FieldCount);
```

fieldname

Description

If a field name is used as a property, it accesses the field object with that name. This means the following code:

```
&REC.fieldname
```

acts the same as

```
&REC.GetField(FIELD.fieldname);
```

Note: If the field you're accessing has the same name as a record property (such as, Name) you can't use this method for accessing the field. You must use the GetField method.

If you combine the *fieldname* property with the *recname* property, you obtain the specified field object associated with that record from the row.

```
&ROW.recname.fieldname
```

This property is read-only.

Example

```
&REC.CHARACTER.Enabled = True;
```

IsChanged

Description

This property returns True if any field value on the primary database record of the row has been changed.

Note: This property is for use only with the primary database record. It does not return valid results if used with a work record.

This property is read-only.

Considerations Using IsChanged

This property and the IsChanged row property do not always return identical values.

If a row in a scroll contains multiple records (such as a primary database record and one or more work records), the IsChanged row property returns True if any of the records in the row are changed. The IsChanged record property returns True only if a specific record, namely, the primary database record, is changed.

If a row is deleted from a scroll, only the primary database record has its IsChanged property marked to False (since the row has been deleted.) Any work records in the row still have their IsChanged properties set to True.

Example

```
If &REC.IsChanged Then
    Warning("This Record has been changed");
End-if;
```

IsDeleted

Description

This property is True if the record has been deleted. For a level zero record, it is possible for a record to be deleted without the whole row being deleted. For other levels, this property is the same as the row property IsDeleted.

This property is read-only.

Example

```
&tmp = &REC.IsDeleted;
```

Related Links

[IsDeleted](#)

IsEditError

Description

This property is True if an error has been found for any field associated with the record after executing the ExecuteEdits method. This property can be used with the Field class properties EditError (to find out which field is in error), and MessageSetNumber and MessageNumber to find the error message set number and error message number.

The IsEditError property returns True when a field with a Null value is encountered.

This property is read-only.

Example

The following is an example showing how IsEditError, along with the ExecuteEdits method could be used:

```
&REC.ExecuteEdits();
If &REC.IsEditError Then
  For &I = 1 to &REC.FieldCount
    If &REC.GetField(&I).EditError Then
      LOG_ERROR(); /* application specific call */
    End-If;
  End-For;
End-If;
```

Related Links

[ExecuteEdits](#)

[IsEditError](#)

[EditError](#)

[MessageNumber](#)

[MessageSetNumber](#)

Name

Description

This property returns the name of the record definition of the record as a string.

To access an SQL table name for a record, use the %Table meta-SQL construct.

This property is read-only.

Example

```
WinMessage("The name of this record is : " | &REC.Name);
```

Related Links

["%Table"](#) (PeopleCode Language Reference)

ParentRow

Description

This property returns the row object for the row containing the record. If the record object was created with the CreateRecord built-in function, the value for ParentRow is null because the record object isn't part of a row.

This property is read-only.

Example

```
&ROWOBJECT = &REC.ParentRow;
    &TMP = "The row number of the parent row is " | &ROWOBJECT.RowNumber;
/* note that RowNumber is a property of the row class */
```

Related Links

"CreateRecord" (PeopleCode Language Reference)

RelLangRecName

Description

This property returns the name of the related language record as a string. The value will be a null string ("") if there is no related language record.

Example

```
Local Record &REC;

&REC = GetRecord();
&RECNAME_BASE = &REC.Name;
&RELLANGRECNAME = &REC.RelLangRecName;
SQLExec("select RELLANGRECNAME from PSRECDEFN where RECNAME = :1", &RECNAME_BASE, &⇒
RELLANGRECNAME);
```

SystemIDFieldName

Description

Note: PeopleSoft Mobile Agent is a deprecated product. This mobile property currently exists for backward compatibility only.

This property returns the name of the System ID field as a string. If there is no defined value (the default) the value is a null string ("").

This property accesses the System ID field name value specified on the Use tab of the Record Properties dialog box.

The System ID field is used to create a unique way to identify the record for mobile synchronization purposes. This property is used exclusively for mobile applications. This property is not available for subrecords.

This property is read-only.

Example

```
Local Record &REC;  
  
&REC = GetRecord();  
&sSystemID = &REC.SystemIDFieldName;
```

[TimeStampFieldName](#)

"Setting Record Properties" (Application Designer Developer's Guide)

TimeStampFieldName

Description

Note: PeopleSoft Mobile Agent is a deprecated product. This mobile property currently exists for backward compatibility only.

This property returns the name of the Timestamp field as a string. If there is no defined value (the default) the value is a null string ("").

This property accesses the Timestamp field name value specified on the Use tab of the Record Properties dialog box.

The Timestamp field is used to specify a field that is automatically updated with the date and time when there's a change to the record. This property is used exclusively for mobile applications.

This property is not available for subrecords. This property is read-only.

Example

```
Local Record &REC;  
  
&REC = GetRecord();  
&sTimeStamp = &REC.TimeStampFieldName;
```

Chapter 47

Row Class

Understanding Row Class

A *row* object, instantiated from the Row class, is a single row of data that consists of one to n records of data. A single row in a component scroll is a row.

A row object is always associated with a rowset object, that is, you cannot instantiate a row object without first either explicitly or implicitly instantiating a rowset object.

A row may have one to n child rowsets. For example, a row in a level two scroll may have n level three child rowsets.

CopyTo and GetRecord are two commonly use methods for this class. Visible and IsChanged are two commonly used properties for this class.

The row class is one of the data buffer access classes.

If a rowset object is instantiated using the CreateRowset function, the rowset object that's instantiated is a standalone rowset. Delete and insert activity on these types of rowsets aren't automatically applied at save time. Use standalone rowsets for work records.

Related Links

"Understanding Data Buffer Access" (PeopleCode Developer's Guide)

"Using Standalone Rowsets" (PeopleCode Developer's Guide)

Shortcut Considerations

The default method for the row class is GetRecord. This means you can specify just a record name to access a record on the row. For example, the following two lines of code are equivalent:

```
&Count = &MyRow.EMPL_CHECKLIST.FieldCount;  
&Count = &MyRow.GetRecord(RECORD.EMPL_CHECKLIST).FieldCount;
```

In addition, the row class has a method *scrollname*. This enables you to access a specific child rowset *and* row within that rowset. This isn't a default method: you're not accessing a child object, but rather, something within that object. For example, the following two lines of code are equivalent:

```
&ChildRow = &MyRow.EMPL_CHKLST_ITM(&I);  
&ChildRow = &MyRow.GetRowset(SCROLL.EMPL_CHKLST_ITM).GetRow(&I);
```

Data Type of a Row Object

Row objects are declared as type Row. For example,

```
Local Row &MYROW;
```

Scope of a Row Object

A Row can only be instantiated from PeopleCode.

This object can be used anywhere you have PeopleCode, that is, in an application class, Application Engine PeopleCode, Component Interface PeopleCode, and so on.

Row Class Built-in Function

"GetRow" (PeopleCode Language Reference)

Row Class Methods

In this section, we discuss each Row class method. The methods are discussed in alphabetical order.

CopyTo

Syntax

```
CopyTo (&row)
```

Description

The CopyTo method copies *from* the row executing the method *to* the specified target row, copying *like-named* record fields and subscrolls at corresponding levels. The target Row object must be from a "related" rowset—that is, built from the same records—but it can be under a different parent at higher levels.

This method copies *all* the records from the Row object executing the method to the target Row object, not just the primary data record associated with the rowset.

In order to copy all of the properties of the fields from the source row, the source and target scrolls must have exactly the same shape:

- The names of the records in the source and target scrolls must be the same.
- If there are subscrolls in the source scroll, then the same number of subscrolls must exist in the target scroll.

- The names of the records in any source subscrolls and target subscrolls must be the same.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>row</i>	Specify a target row. This must be a Row object, not a row number.

Returns

None

Example

The following example copies rows from a child rowset (DERIVED_HR) to the current rows.

```
Local Row &ROW;
Local Rowset &RS1;

&RS1 = GetRowset();
For &I = 1 to &RS1.ActiveRowCount
    &ROW = GetRowset(SCROLL.DERIVED_HR).GetRow(&I);
    &ROW.CopyTo(GetRow(&I));
End-For;
```

Related Links

[ParentRowset](#)

[CopyFieldsTo](#)

[CopyChangedFieldsTo](#)

GetNextEffRow

Syntax

```
GetNextEffRow()
```

Description

The GetNextEffRow method finds the row, in the same rowset as the row executing the method, that has the next effective date (when compared to the row executing the method.)

Parameters

None

Returns

A row object. If there is no row with a later effective date, this method returns a null object.

Example

```
&ROW2 = &ROW.GetNextEff();  
  
If &ROW2 <> NULL Then  
    &TMP = &ROW2.RowNumber;  
    /* other processing */  
Else  
    /* no effective dated row - do error processing */  
End-if;
```

Related Links

[GetPriorEffRow](#)

[GetCurrEffRow](#)

[DeleteEnabled](#)

GetPriorEffRow

Syntax

```
GetPriorEffRow()
```

Description

The `GetPriorEffRow` method finds the row, from the same rowset as the row executing the method, that has the prior effective date to the row executing the method.

Parameters

None

Returns

A row object. If there is no row with a prior effective date, this method returns a null object.

Example

```
&TMP = &ROW.GetPriorEffrow().RowNumber;
```

Related Links

[GetNextEffRow](#)

[GetCurrEffRow](#)

[DeleteEnabled](#)

GetRecord

Syntax

```
GetRecord({n | RECORD.recname})
```

Description

The `GetRecord` method creates a record object that references the specified record within the current row object. This is the *default method* for a row object. This means that any row object, followed by a parameter list, acts as if `GetRecord` is specified.

Parameters

Parameter	Description
<i>n</i> <code>RECORD.recname</code>	Specify a record to be used for instantiating the record object. You can specify either <i>n</i> or <code>RECORD.recname</code> . Specifying <i>n</i> creates a record object for the <i>n</i> th record in the row. This might be used if writing code that needs to examine all records in a row without being aware of the record name. Specifying <code>RECORD.recname</code> creates a record object for the record <i>recname</i> .

Note: There is no way to predict the order the records will be accessed. Use the *n* option only if the order in which the records are processed doesn't matter.

Returns

A record object.

Example

The following example gets a record, then assigns the name of the record to the variable `&TMP`:

```
&REC = &ROW.GetRecord(RECORD.QEPC_LEVEL1_REC);
&TMP = &REC.NAME; /* note that NAME is a property of the record class */
```

Because `GetRecord` is the default method for a row, the following code is identical to the previous:

```
&REC = &ROW.QEPC_LEVEL1_REC;
&TMP = &REC.NAME;
```

The following example loops through all the records for a row:

```
Local rowset &LEVEL1;
Local row &ROW;
Local record &REC;

&LEVEL1 = GetRowset(SCROLL.EMPL_CHECKLIST);
For &I = 1 to &LEVEL1.ActiveRowCount
  &ROW = &LEVEL1.GetRow(&I);
  For &J = 1 to &ROW.RecordCount
    &REC = &ROW.GetRecord(&J);
    /* do processing */
  End-For;
End-For;
```

The following function takes a rowset and a record, passed in from another program. GetRecord won't take a variable for the record, however, using the @ symbol you can convert the string to a component record name.

```
Function Get_My_Row(&PASSED_ROWSET, &PASSED_RECORD)

  For &ROWSET_ROW = 1 To &PASSED_ROWSET.RowCount
    &UNDERLYINGREC = "RECORD." | &PASSED_ROWSET.DBRecordName;
    &ROW_RECORD = &PASSED_ROWSET.GetRow(&ROWSET_ROW).GetRecord(@&UNDERLYINGREC);

    /* Do other processing */

  End-For;
End-Function;
```

Related Links

"GetRecord" (PeopleCode Language Reference)

"CreateRecord" (PeopleCode Language Reference)

GetRowset

Syntax

```
GetRowset({n | SCROLL.scrollname})
```

Description

The GetRowset method creates a rowset object that references a child rowset of the current row. *scrollname* must specify the primary record for the child rowset.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n</i> SCROLL. <i>scrollname</i>	Specify a rowset to be used for instantiating the rowset object. You can specify either <i>n</i> or SCROLL. <i>scrollname</i> . Specifying <i>n</i> creates a rowset object for the <i>n</i> th child rowset in the row. This might be used if you are writing code that examines all rowsets in a row without being aware of the name. Specifying SCROLL. <i>scrollname</i> creates a rowset object for the record <i>scrollname</i> . <i>scrollname</i> must specify the primary record for the child rowset.

Note: There is no way to predict the order the rowsets will be accessed. Use the *n* option only if the order in which the rowsets are processed doesn't matter.

Returns

A rowset object.

Example

```
&CHILDROWSET = &ROW.GetRowset (SCROLL.QEPC_LEVEL1_REC);
```

Related Links

[scrollname](#)

"GetRowset" (PeopleCode Language Reference)

scrollname

Syntax

```
scrollname (n)
```

Description

If *scrollname* is used as a method name for a row, it is used to select a child rowset and a row within that rowset.

```
&ROW.scrollname (n)
```

acts the same as

```
&ROW.GetRowset (SCROLL.scrollname) .GetRow (n)
```

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n</i>	Must be a valid row number for the selected child rowset.

Returns

A row object.

Example

```
&SUBROW1 = &ROW.QEPC_LEVEL1_REC (1);
```

Related Links

"GetRowset" (PeopleCode Language Reference)

Row Class Properties

In this section, we discuss the Row class properties. The properties are discussed in alphabetical order.

ChildCount

Description

This property returns the number of child rowsets of the row. It is defined by the "structure" of the scroll, so it is the same for all rows of the rowset.

It might be used, in conjunction with the GetRowset method, to write code that examines all child rowsets.

This property is read-only.

Example

```
For &I = 1 to &ROW.ChildCount
    &ROWSET = &ROW.GetRowset(&I);
    /* do processing */
End-For;
```

DeleteEnabled

Description

This property determines whether a row can be deleted (the equivalent of the user pressing ALT+8 and ENTER). This property takes a Boolean value.

Note: This property controls only whether an end-user can delete a row. Rows can still be deleted using PeopleCode.

This property is typically used to prevent deletion of an individual row that the other properties controlling deletion would allow to be deleted. The following table goes through the Boolean logic.

<i>Will delete be allowed by user?</i>	<i>Others enable</i>	<i>Others disable</i>
DeleteEnabled = True	Yes	No
DeleteEnabled = False	No	No

The initial value of this property is True.

Note: If No Row Delete is selected in Application Designer, setting the DeleteEnabled row property to True will *not* override this value. If you want to control whether a row can be deleted at runtime, you should *not* select No Row Delete at design time. Likewise, if the DeleteEnabled Rowset property is False, setting the DeleteEnabled Row property to True will *not* override the rowset property. If you want to control whether an individual row can be deleted at runtime, you should not set the DeleteEnabled rowset property to False.

For consistency, PeopleSoft recommends that either all rows at a level should disable deletions, or they should all allow deletions.

For rows created with non-Component Processor data (such as message rowsets, Application Engine rowsets, and so on) this property has no effect.

Note: Don't use this property with rows from rowsets created using `CreateRowset`. Rowsets created using the `CreateRowset` function are standalone rowsets, not tied to the database, so there are no database updates when they are manipulated. Delete and insert activity on these types of rowsets aren't automatically applied at save time.

This property is read/write.

Related Links

[DeleteEnabled](#)

"Using Scroll Areas and Scroll Bars" (Application Designer Developer's Guide)

"Using Standalone Rowsets" (PeopleCode Developer's Guide)

IsChanged

Description

This property returns True if any field value on the primary database record of the row has been changed.

Note: Use this property only with the primary database record. It doesn't return valid results if used with a work record. This property returns True only if the existing row object has a field that has changed. If a field in a lower level rowset has changed, this property returns False.

This property is read-only.

Considerations Using IsChanged

This property and the `IsChanged` record property do *not* always return identical values.

If a row in a scroll contains multiple records (such as a primary database record and one or more work records), the `IsChanged` row property returns True if *any* of the records in the row are changed. The `IsChanged` record property returns True *only* if a specific record, namely, the primary database record, is changed.

If a row is deleted from a scroll, *only* the primary database record has its `IsChanged` property marked to False (since the row has been deleted.) Any work records in the row *still* have their `IsChanged` properties set to True.

Example

```
&tmp = &ROW.IsChanged;  
if &tmp = True then  
    Warning("A Field on this row has been changed");  
End-If;
```

IsDeleted

Description

This property returns True if the row has been deleted.

This property is read-only.

Note: This property also returns True if the row is new and hasn't been changed.

Example

```
&tmp = &ROW.IsDeleted;
```

IsEditError

Description

This property is True if an error has been found for any field associated with any record in the current row or on any row in any child rowset of the current row after executing the ExecuteEdits method. This property can be used with the Field class properties EditError (to find out which field is in error), and MessageSetNumber and MessageNumber to find the error message set number and error message number.

This property is read-only.

Example

The following is an example showing how IsEditError, along with the ExecuteEdits method could be used:

```
&MSG.ExecuteEdits();
If &MSG.IsEditError Then
&RS = &MSG.GetRowset();
  For &J = 1 to &RS.RowCount
    &ROW = &RS.GetRow(&J);
    If &ROW.IsEditError Then
      &REC = &ROW.GetRecord();
      For &I = 1 to &REC.FieldCount
        If &REC.GetField(&I).EditError Then
          LOG_ERROR(); /* application specific call */
        End-If;
      End-For;
    End-If;
  End-For;
End-If;
```

Related Links

[ExecuteEdits](#)

[IsEditError](#)

[EditError](#)

[MessageNumber](#)

[MessageSetNumber](#)

IsNew

Description

This property is True if the row is a new (inserted) row.

This property is read-only.

Example

```
&tmp = &ROW.IsNew;
```

ParentRowset

Description

This property returns a rowset object referencing the rowset containing the row.

This property is read-only.

Example

```
&tmp = &ROW.ParentRowset.RowCount;
/* note that rowcount is a property of the Rowset class */
```

rename

Description

If a record name is used as a property, it accesses the record object with that name. This means the following code:

```
&ROW.somerecname
```

acts the same as

```
&ROW.GetRecord(RECORD.somerecname);
```

This property is read-only.

Example

```
&REC = &ROW.QEPC_LEVEL1_REC;
```

RecordCount

Description

This property returns the number of records in the row. It is defined by the "structure" of the scroll, so it is the same for all rows of the rowset.

This property might be used in conjunction with the `GetRecord` method to write code that examines all records in some way.

This property is read-only.

Example

```
For &I = 1 to &ROW.RecordCount
    &REC = &ROW.GetRecord(&I);
    /* do processing */
End-For;
```

RowNumber

Description

This property returns the row number (starting from 1) of the row within its rowset.

This property is read-only.

Example

The following returns the row number of the current effective-date row.

```
&NUMBER = GetRowset(SCROLL.MYRECORD).GetCurrEffRow().RowNumber;
```

Selected

Description

This property returns `True` if the row is part of a grid and has been selected either by the user or programmatically.

This property is meaningful in PIA only if the grid or scroll area attribute has been set to provide the selection control. In this case, the property reflects the state of the check box or radio button used for selection.

This property is read/write.

Example

The following example determines how many rows in a grid are selected.

```
Function Count_Child_Assets(&GRIDLEVEL1 As Rowset, &NUM_CHILDREN)
    REM *** How many child assets are selected? *;
    &GRIDLEVEL1 = GetRowset(SCROLL.PARENT_CHILD_VW);
    For &CHILDROW_COUNT = 1 To &GRIDLEVEL1.ActiveRowCount
        If &GRIDLEVEL1.GetRow(&CHILDROW_COUNT).Selected = True Then
            &NUM_CHILDREN = &NUM_CHILDREN + 1;
        End-If;
    End-For;
End-Function;
```

Style

Description

This property returns the name of the style class if one has been set for the row. You can also use this property to change the style of a row. This property takes a string value.

Note: This property *overrides* only the existing style. It doesn't *change* it. The next time the page is accessed the original style is used.

The PSSTYLE style sheet does *not* contain a default style class for a row. The Style property for all rows is initially NULL (that is, two quotation marks with no space between them ("")). The row assumes the style of the grid alternate row style. Fields in the row assume field styles if set.

Setting the property for a row overrides the grid alternate row style and any page field styles (field styles that were set in Application Designer). It does *not* override any field styles set (using the Field class Style property) for fields in the row.

Setting the Style property back to NULL (that is, two quotation marks with no space between them ("")) turns off the override.

Note: This property is *not* valid for Windows Client applications.

Example

```
&Scroll = GetLevel0().GetRow(1).GetRowset(Scroll.IC_PC_STYLE_2);
&row_class = &Scroll.GetRow(&row);
&row_class.Style = &style;
```

Related Links

[Style](#)

"Understanding Field Definitions" (Application Designer Developer's Guide)

Visible

Description

If this property is True, the row is visible if displayed on the current page. This property can be set False to hide the row.

When Visible is set to False to hide a row, the row moves to the end of the rowset. This means that the row number of the row being hidden, and any subsequent rows, *changes* as a result of hiding a row. If the row is later made visible again, it is *not* moved back to its original position, but remains at the end of the rowset. It is just moved to the start of all the other hidden rows.

For example, if there are 4 rows in a rowset and row 2 is hidden (that is, Visible = False), that row now becomes row 4. In order to make that row visible again, row 4 must be set to Visible = True. Alternatively, you can use a row object reference: this remains valid even though the row number of the row may have been changed.

Note: If you use the Sort method on a rowset with hidden rows, the hidden rows aren't sorted. Only visible rows are sorted.

You cannot hide rows in the current context of the executing program. This means Visible cannot hide the row containing the executing program, or in a child rowset and be executed against its parent rowset. Place your PeopleCode in a parent rowset and execute it against a child rowset.

Example

```
&ROW.Visible = False;
```

The following code uses the Visible property to determine if a row is visible or not before updating the value of the row.

```
&ROWSET = GetRowset(SCROLL.LD_SHP_INV_VW)
```

```
For &I = 1 To &ROWSET.ActiveRowCount
  If &ROWSET(&I).Visible Then
    ITEM_SELECTED.value = "N";
  End-If;
End-For;
```

The following code starts with the last row and works forward to the first. If any changes are made they don't impact the position of rows that still have to be processed.

```
For &I = &ACTIVE_STREAMS to 1 Step -1
  &Row = &STREAM_ROWSET(&I);
  If &Row.QS_STREAM8.STREAM_ROOT_ID.Value <> &STREAM_ROOT_ID Then
    &Row.Visible = False;
  End-if;
End-For;
```

Related Content Framework Classes

Understanding the Related Content Framework Classes

The PeopleCode API for the related content framework consists of the following application packages and classes:

- PTCS_SRVDEFN:

- RCTestDefinition class

Use the PTCS_SRVDEFN:RCTestDefinition class to manage related content service definitions.

- RCTestParameter class

Use the PTCS_SRVDEFN:RCTestParameter class to manage URL parameters associated with related content service definitions.

- PTCS_SERVICE:

Use the PTCS_SERVICE:RCTestService application class to manage all related content service configurations (PTCS_SRVCONFIG:RCTestServiceConfig) for a given component or pivot grid.

- PTCS_SRVCONFIG:

- RCTestServiceConfig class

Use the PTCS_SRVCONFIG:RCTestServiceConfig class to manage service configurations for related content for classic components and fluid components; for related actions for classic components, fluid components, and pivot grids; and for mapping custom PeopleCode application classes to component events.

Note: The RCTestServiceConfig class does not support managing related action configurations for MAP layouts.

- RCTestMapFields class

Use the PTCS_SRVCONFIG:RCTestMapFields class to map page contextual fields to the URL parameters of the service definition.

- PTCS_MENULAYOUT:

- RCTestMenuLayout class

Use the PTCS_MENULAYOUT:RCTestMenuLayout class to manage menu layouts for related content and related actions.

- RCMenueFolder class

Use the PTCS_MENULAYOUT:RCMenuFolder class to manage menu folders for related content and related actions.

- RCMenueLink class

Use the PTCS_MENULAYOUT:RCMenuLink class to manage the menu links for related content and related actions.

RCServiceDefinition Class

Use the PTCS_SRVDEFN:RCServiceDefinition class to maintain related content service definitions. Use the methods and properties of this class to create, update, and delete service definitions.

Related Links

"Creating and Managing Related Content Service Definitions" (Portal Technology)

[RCParameter Class](#)

RCServiceDefinition Class Methods

In this section, the RCServiceDefinition class methods are presented in alphabetical order.

AppendRCParam

Syntax

AppendRCParam (*name*)

Description

Use the AppendRCParam method to add a service URL parameter by name to the related content service definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>name</i>	Specifies the name of the service URL parameter as a string value.

Returns

A PTCS_SRVDEFN:RCParameter object.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("SERVICE_DEFN", "ENG");
Local string &rcParam1 = "APPTTEST_PARAM1";
Local PTCS_SRVDEFN:RCParameter &rcParam1Ret = &rcServDefn.AppendRCParam(&rcParam1);
Local boolean &Ret = &rcServDefn.Save();
```

Related Links

[DeleteRCParam](#)

[Save](#)

[RCParameter Class](#)

CloneForNew

Syntax

```
CloneForNew(&RCSrvcDefn)
```

Description

Use the CloneForNew method to create an identical copy of the related content service definition executing this method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&RCSrvcDefn</i>	Specifies an already instantiated PTCS_SRVDEFN:RCServiceDefinition object that is to be copied to.

Returns

A boolean value: True if the copy is successful, False otherwise.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;
Component PTCS_SRVDEFN:RCServiceDefinition &rcCloneServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("SERVICE_DEFN", "ENG");
&rcCloneServDefn = create PTCS_SRVDEFN:RCServiceDefinition("NEW_SERVICE_DEFN", "ENG⇒
```

```
");
Local boolean &bRet = False;
If ( True = &rcServDefn.CloneForNew(&rcCloneServDefn) ) Then
    &bRet = &rcCloneServDefn.Save();
End-If;
```

Related Links

[Save](#)

Delete

Syntax

```
Delete()
```

Description

Use the Delete method to delete this related content service definition.

Parameters

None.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCSserviceDefinition &rcServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCSserviceDefinition("SERVICE_DEFN", "ENG");
Local boolean &bRet = False;
If (&rcServDefn <> Null) Then
    &bRet = &rcServDefn.Delete();
End-If;
```

DeleteRCPParam

Syntax

```
DeleteRCPParam(nItem)
```

Description

Use the DeleteRCPParam method to delete the *n*th service URL parameter from the related content service definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>nItem</i>	Specifies which service URL parameter as a number value.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("SERVICE_DEFN", "ENG");
Local boolean &delRcParamRet = False;
Local number &rcParamCount = &rcServDefn.GetRCParamCount();
&delRcParamRet = &rcServDefn.DeleteRCParam(&rcParamCount - 1);
If ( True = &delRcParamRet) Then
    /* do some processing */
    Local boolean &Ret = &rcServDefn.Save();
End-If;
```

Related Links

[AppendRCParam](#)

[GetRCParamCount](#)

[GetRCParameter](#)

[Save](#)

GetRCParamCount

Syntax

```
GetRCParamCount ()
```

Description

Use the GetRCParamCount method to return the number of service URL parameters defined for this related content service definition.

Parameters

None.

Returns

A number value.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCSERVICEDEFINITION &rcServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCSERVICEDEFINITION("SERVICE_DEFN", "ENG");
Local number &rcParamCount = &rcServDefn.GetRCParamCount();
If (&rcParamCount > 0) Then
    /* do some processing */
End-If;
```

Related Links

[AppendRCParam](#)

[DeleteRCParam](#)

[GetRCParameter](#)

GetRCParameter

Syntax

```
GetRCParameter(nItem)
```

Description

Use the GetRCParameter method to return a PTCS_SRVDEFN:RCParameter object representing the *n*th parameter of this related content service definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>nItem</i>	Specifies which service URL parameter as a number value.

Returns

A PTCS_SRVDEFN:RCParameter object.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCSERVICEDEFINITION &rcServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCSERVICEDEFINITION("SERVICE_DEFN", "ENG");
Local number &rcParamCount = &rcServDefn.GetRCParamCount();
Local PTCS_SRVDEFN:RCParameter &rcSvcParam = &rcServDefn.GetRCParameter(&rcParamCo→
unt);

RCSERVICEDEFINITION

Syntax

```
RCSERVICEDEFINITION(service_ID, lang_CD)
```

Description

Use the RCSERVICEDEFINITION constructor method to instantiate a PTCS_SRVDEFN:RCSERVICEDEFINITION object. Use the IsNew property to determine whether the object was instantiated from an existing service definition (that is, the *service_ID* parameter corresponds to an existing definition) or as a new service definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>service_ID</i>	Specifies the unique identifier for the service definition as a string value.
<i>lang_CD</i>	Specifies the language code for this definition as a three-character string.

Returns

A PTCS_SRVDEFN:RCSERVICEDEFINITION object.

Example

```
import PTCS_SRVDEFN:*;
Component PTCS_SRVDEFN:RCSERVICEDEFINITION &rcServDefn;
&rcServDefn = create PTCS_SRVDEFN:RCSERVICEDEFINITION("SERVICE_DEFN", "ENG");
```

Related Links

[Save](#)

[IsNew](#)

[LanguageCD](#)

Rename

Syntax

Rename (*new_srvc_ID*)

Description

Use the Rename method to rename the related content service definition.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>new_srvc_ID</i>	Specifies the new service ID as a string value.

Returns

A boolean value: True if the rename is successful, False otherwise.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("SERVICE_DEFN", "ENG");
Local boolean &bRet = False;
If ( True = &rcServDefn.Rename("NEW_SERVICE_DEFN")) Then
    &bRet = &rcServDefn.Save();
End-If;
```

Related Links

[Save](#)

Save

Syntax

Save ()

Description

Use the Save method to save the related content service definition to the database. Invoke the Save method after instantiating a new service definition, after updating service definition properties, or after invoking any of these methods: AppendRCParam, CloneForNew, DeleteRCParam, or Rename.

Parameters

None.

Returns

A boolean value: True if the save is successful, False otherwise.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;
Component PTCS_SRVDEFN:RCServiceDefinition &rcCloneServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("SERVICE_DEFN", "ENG");
&rcCloneServDefn = create PTCS_SRVDEFN:RCServiceDefinition("NEW_SERVICE_DEFN", "ENG⇒
");
Local boolean &bRet = False;
If ( True = &rcServDefn.CloneForNew(&rcCloneServDefn) ) Then
    &bRet = &rcCloneServDefn.Save();
End-If;
```

RCSERVICEDEFINITION Class Properties

In this section, the RCSERVICEDEFINITION class properties are presented in alphabetical order.

AppclassId

Description

When the related content service definition type is application class (ServiceUrlType = UAPC), use the AppclassId property to set or return a string value representing the name of the application class.

Note: The full path to the application class is constructed from three properties: PackageRoot, QualifyPath, and AppclassId.

This property is read/write.

Example

```
&rcServDefn.PackageRoot = "MY_PACKAGE";
&rcServDefn.QualifyPath = ":";
&rcServDefn.AppclassId = "My_Class";
```

Related Links

[PackageRoot](#)

[QualifyPath](#)

Descr

Description

Use the Descr property to set or return a string value representing the description of the related content service definition.

This property is read/write.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("SERVICE_DEFN", "ENG");
Local string &old_descr = &rcServDefn.Descr; /* Get */
&rcServDefn.Descr = "New Service Definition"; /* Set */
```

EscapeParam

Description

Use the EscapeParam property to set or return a Y/N string value indicating whether to escape, or encode, the service URL parameters and values when the system forms the complete service URL.

Note: The default value is Y.

This property is read/write.

Example

```
&rcServDefn.EscapeParam = "N"; /* Set Y/N value */
```

FieldName

Description

When the related content service definition type is PeopleSoft script (ServiceUrlType = USCR), use the FieldName property to set or return a string value representing the name of the record field storing the iScript.

Note: The full path to the iScript function is constructed from four properties: PortalRecName, FieldName, PcEventType, and PcFunctionName.

This property is read/write.

Example

```
&rcServDefn.PortalRecName = "WEBLIB_MYREC";
&rcServDefn.FieldName = "ISCRIP1";
&rcServDefn.PcEventType = "FieldFormula";
```

```
&rcServDefn.PcFunctionName = "IScript_MyFunction";
```

Related Links

[PcEventType](#)

[PcFunctionName](#)

[PortalRecName](#)

IsBulkAction

Description

Use the IsBulkAction property to set or return a Y/N string value indicating whether the related content service definition is defined as a bulk action. Bulk actions are supported for three service types:

- Application class (UAPC).
- PeopleSoft component (UPGE).
- PeopleSoft script (USCR).

Note: The default value is N.

This property is read/write.

Example

```
&rcServDefn.IsBulkAction = "Y"; /* Set Y/N values */
```

IsNew

Description

Use the IsNew property to return whether the instantiation of this related content service definition is for a new definition. This property returns True only after the RCTestDefinition constructor is invoked with the *service_ID* parameter set to a new and unique ID or when CloneForNew is invoked. All other times and after a Save is invoked, IsNew returns False.

This property is read-only.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCTestDefinition &rcServDefn;

&rcServDefn = create PTCS_SRVDEFN:RCTestDefinition("NEW_SERVICE_DEFN", "ENG");
If &rcServDefn.IsNew Then
    /* Set properties of the new definition. */
Else
    /* Examine properties of the existing definition. */
End-If;
```

Related Links

[CloneForNew](#)

[RCServiceDefinition](#)

[Save](#)

LanguageCD

Description

Use the LanguageCD property to return the language code in use for this related content service definition as a three-character string.

This property is effectively read-only.

Example

```
Local string &langCD = &rcServDefn.LanguageCD;
```

Related Links

[RCServiceDefinition](#)

Market

Description

When the related content service definition type is PeopleSoft component (ServiceUrlType = UPGE), use the Market property to set or return a string value representing the market for this component definition.

Note: The full component name is constructed from four properties: PortalMenuName, PnlGrpName, Market and PnlName (optional).

This property is read/write.

Example

```
&rcServDefn.PortalMenuName = "PORTAL_MENU_1";  
&rcServDefn.Market = "GBL";  
&rcServDefn.PnlGrpName = "COMPONENT_TEST";  
&rcServDefn.PnlName = "MAIN_PAGE";
```

Related Links

[PnlGrpName](#)

[PnlName](#)

[PortalMenuName](#)

MsgNodeName

Description

Use the MsgNodeName property to set or return the name of the portal node as a string value.

Note: This property is used with all service types except for application class (ServiceUrlType = UAPC).

This property is read/write.

Example

```
&rcServDefn.MsgNodeName = "HRMS";
```

PackageRoot

Description

When the related content service definition type is application class (ServiceUrlType = UAPC), use the PackageRoot property to set or return a string value representing the name of the application package that contains the application class.

Note: The full path to the application class is constructed from three properties: PackageRoot, QualifyPath, and AppclassId.

This property is read/write.

Example

```
&rcServDefn.PackageRoot = "MY_PACKAGE";  
&rcServDefn.QualifyPath = ":";  
&rcServDefn.AppclassId = "My_Class";
```

Related Links

[AppclassId](#)

[QualifyPath](#)

PcEventType

Description

When the related content service definition type is PeopleSoft script (ServiceUrlType = USCR), use the PcEventType property to set or return a string value representing the name of the PeopleCode event storing the iScript. Typically, iScripts are stored in the FieldFormula event.

Note: The full path to the iScript function is constructed from four properties: PortalRecName, FieldName, PcEventType, and PcFunctionName.

This property is read/write.

Example

```
&rcServDefn.PortalRecName = "WEBLIB_MYREC";  
&rcServDefn.FieldName = "ISCRIP1";  
&rcServDefn.PcEventType = "FieldFormula";  
&rcServDefn.PcFunctionName = "IScript_MyFunction";
```

Related Links

[FieldName](#)

[PcFunctionName](#)

[PortalRecName](#)

PcFunctionName

Description

When the related content service definition type is PeopleSoft script (ServiceUrlType = USCR), use the PcFunctionName property to set or return a string value representing the name of the function that is the iScript.

Note: The full path to the iScript function is constructed from four properties: PortalRecName, FieldName, PcEventType, and PcFunctionName.

This property is read/write.

Example

```
&rcServDefn.PortalRecName = "WEBLIB_MYREC";  
&rcServDefn.FieldName = "ISCRIP1";  
&rcServDefn.PcEventType = "FieldFormula";  
&rcServDefn.PcFunctionName = "IScript_MyFunction";
```

[PortalRecName](#)

PnlGrpName

Description

When the related content service definition type is PeopleSoft component (ServiceUrlType = UPGE), use the PnlGrpName property to set or return a string value representing the component for this component definition.

Note: The full component name is constructed from four properties: PortalMenuName, PnlGrpName, Market and PnlName (optional).

This property is read/write.

Example

```
&rcServDefn.PortalMenuName = "PORTAL_MENU_1";  
&rcServDefn.Market = "GBL";  
&rcServDefn.PnlGrpName = "COMPONENT_TEST";  
&rcServDefn.PnlName = "MAIN_PAGE";
```

[PnlName](#)

[PortalMenuName](#)

PnlName

Description

When the related content service definition type is PeopleSoft component (ServiceUrlType = UPGE), use the PnlName property to set or return a string value representing the page name for this component definition. Use this optional property to open a specific page in the component.

Note: The full component name is constructed from four properties: PortalMenuName, PnlGrpName, Market and PnlName (optional).

This property is read/write.

Example

```
&rcServDefn.PortalMenuName = "PORTAL_MENU_1";  
&rcServDefn.Market = "GBL";  
&rcServDefn.PnlGrpName = "COMPONENT_TEST";  
&rcServDefn.PnlName = "MAIN_PAGE";
```

PortalMenuName

Description

When the related content service definition type is PeopleSoft component (ServiceUrlType = UPGE), use the PortalMenuName property to set or return a string value representing the page name for this component definition. Use this optional property to open a specific page in the component.

Note: The full component name is constructed from four properties: PortalMenuName, PnlGrpName, Market and PnlName (optional).

This property is read/write.

Example

```
&rcServDefn.PortalMenuName = "PORTAL_MENU_1";  
&rcServDefn.Market = "GBL";  
&rcServDefn.PnlGrpName = "COMPONENT_TEST";  
&rcServDefn.PnlName = "MAIN_PAGE";
```

Related Links

[Market](#)

[PnlGrpName](#)

[PnlName](#)

PortalRecName

Description

When the related content service definition type is PeopleSoft script (ServiceUrlType = USCR), use the PortalRecName property to set or return a string value representing the name of the record storing the iScript.

Note: The full path to the iScript function is constructed from four properties: PortalRecName, FieldName, PcEventType, and PcFunctionName.

This property is read/write.

Example

```
&rcServDefn.PortalRecName = "WEBLIB_MYREC";  
&rcServDefn.FieldName = "ISCRIP1";  
&rcServDefn.PcEventType = "FieldFormula";  
&rcServDefn.PcFunctionName = "IScript_MyFunction";
```

Related Links

[FieldName](#)

[PcEventType](#)

[PcFunctionName](#)

PortalUrlAdm

Description

When the related content service definition type is non-PeopleSoft URL (ServiceUrlType = UEXT), use the PortalUrlAdm property to set or return a string value representing the full or partial URL external to the PeopleSoft application.

This property is read/write.

Example

The following example sets a full, external URL value:

```
&rcServDefn.PortalUrlAdm = "http://www.bing.com";
```

PortalUriText

Description

When the related content service definition type is generic PeopleSoft URL (`ServiceUrlType = UGEN`), use the `PortalUriText` property to set or return a string value representing the full or partial URL to the PeopleSoft definition.

This property is read/write.

Example

The following example sets a partial URL value. The complete URL is constructed by the system by appending this URL value to the URI text defined for the portal node specified by the `MsgNodeName` property.

```
&rcServDefn.PortalUriText = "c/PTCSSERVICES.PTCSSERVICES.GBL";
```

PostMapdata

Description

Use the `PostMapdata` property to set or return a Y/N string value indicating whether to have the mapping definition data, such as the parameter name and its mapping page field or key field name, and the parameter's actual mapped value posted with the service request.

Note: The default value is N.

This property is read/write.

Example

```
&rcServDefn.PostMapdata = "Y"; /* Set Y/N values */
```

PtppbPageletId

Description

When the related content service definition type is either embeddable pagelet (`ServiceUrlType = PEP`) or OBIEE pagelet (`ServiceUrlType = POP`), use the `PtppbPageletId` property to set or return a string value representing the pagelet ID.

This property is read/write.

Example

```
&rcServDefn.PtppbPageletId = "MY_PAGELET";
```

QualifyPath

Description

When the related content service definition type is application class (ServiceUrlType = UAPC), use the QualifyPath property to set or return a string value representing the names of each subpackage in the application class hierarchy that define the location of the application class. Separate subpackage names by a colon. If the class is defined in the top-level application package, use a colon only.

Note: The full path to the application class is constructed from three properties: PackageRoot, QualifyPath, and AppclassId.

This property is read/write.

Example

```
&rcServDefn.PackageRoot = "MY_PACKAGE";  
&rcServDefn.QualifyPath = ":";  
&rcServDefn.AppclassId = "My_Class";
```

Related Links

[AppclassId](#)

[PackageRoot](#)

Queryname

Description

When the related content service definition type is PeopleSoft query (ServiceUrlType = UQRY), use the Queryname property to set or return a string value representing the query ID.

This property is read/write.

Example

```
&rcServDefn.Queryname = "USER_QRY";
```

SecUseEdit

Description

Use the SecUseEdit property to set or return an integer value indicating which security options are available when the service is assigned and configured for an application page.

Use the following integer values, which can be summed to indicate that more than one security option is available:

Value	Description
1	Public access, which provides access to the service based on the permissions of the public user
2	Related content provider security, which uses the security implemented by the content provider system.
4	Related content consumer security, which uses the security implemented by the consuming system—that is, the basic PeopleTools transaction security model (user-role-permission list).
16	App Class Required, which indicates that a service filter is required when this service is assigned to an application page. Important! Service filters are deprecated and this option is retained for backward compatibility only. Do not select this option for new service definitions.

This property is read/write.

Example

In the following example, a value of 7 is the sum of the public (1), provider (2), and consumer (4) options:

```
&rcServDefn.SecUseEdit = 7; /* Allow multiple security options */
```

ServiceId

Description

Use the ServiceId property to return the unique identifier for the related content service definition.

This property is effectively read-only.

Example

In the following example, ServiceId returns SERVICE_DEFN, the value used to instantiate the service definition object:

```
Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;
&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("SERVICE_DEFN", "ENG");
Local string &serviceId = &rcServDefn.ServiceId;
```

Related Links

[RCServiceDefinition](#)

ServiceName

Description

Use the ServiceName property to set or return the service name for the related content service definition as a string value.

Note: This string is limited to 18 characters or less.

This property is read/write.

Example

```
Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;
&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("SERVICE_DEFN", "ENG");
&rcServDefn.ServiceName = "My RC Service";
```

Related Links

[InstanceLbl](#)

ServiceType

Description

Use the ServiceType property to set or return or return a string value representing the service type of this related content service definition.

For explicit service definitions, use the value of S. For anonymous service definitions (that is, an ad hoc service definition based on an existing content reference definition), use the values of C, P, or G. See "Explicit Definition Versus Anonymous Services" (Portal Technology) for more information.

Note: The default value is S.

This property can have the following values:

<i>Value</i>	<i>Description</i>
C	Component content reference (anonymous).
G	Tile content reference (anonymous).
P	Pagelet content reference (anonymous).
S	Service definition (explicit).

This property is read/write.

ServiceUrlType

Description

Use the ServiceUrlType property to set or return a string value specifying the URL type for this related content service definition:

Value	Description
PEP	Embeddable Pagelet
POP	OBIEE Pagelet
UAPC	Application Class
UEXT	Non-PeopleSoft URL
UGEN	Generic PeopleSoft URL
UPGE	PeopleSoft Component
UQRY	PeopleSoft Query
USCR	PeopleSoft Script
UTIL	PeopleSoft Tile

This property is read/write.

Example

```
&rcServDefn.ServiceUrlType = "UPGE";
```

SrvcAttribute

Description

When the related content service definition type is application class (ServiceUrlType = UAPC), use the SrvcAttribute property to set or return a string value indicating the type of application class service:

Value	Description
GNRL	Used for all application class services except simplified analytics. Note. This is the default value.
MSTR	Used to specify the simplified analytics master (template) definition.
CLON	Used to specify a clone of the simplified analytics master.

This property is read/write.

Example

```
&rcServDefn.SrvcAttribute = "CLON";
```

Related Links

[SrvcAttribute](#)

SrvHelpText

Description

Use the SrvHelpText property to set or return a string value representing the HTML-formatted help text (as entered in the rich text editor) for this related content service definition.

This property is read/write.

Example

```
&rcServDefn.SrvHelpText = "<p>Some <em>help</em> text.<p>";
```

TileCategory

Description

When the related content service definition type is PeopleSoft tile (ServiceUrlType = UTIL), use the TileCategory property to set or return a string value indicating the content reference ID for the tile definition.

This property is read/write.

Example

```
&rcServDefn.TileCategory = "EP_BI_BILLINGNC_FL_GBL";
```

Useedit

Description

Use the Useedit property to set or return an integer value representing which display options are available when configuring classic related content for the bottom frame.

Use the following integer values, which can be summed to indicate that both display options available:

<i>Value</i>	<i>Description</i>
1	New window
2	Refresh

This property is read/write.

Example

```
&rcServDefn.Useedit = 3; /* Make both options available for configuration */
```

ValFromDt

Description

Use the ValFromDt property to set or return the start date when a related content or a related action service is available.

This property is read/write.

Example

```
import PTCS_SRVDEFN:RCServiceDefinition;

Local PTCS_SRVDEFN:RCServiceDefinition &rcServDefn = create PTCS_SRVDEFN:RCServiceD⇒
efinition(&service_id, %Language);

Local date &ValFromDate = &rcServDefn.ValFromDt;
Local date &ValToDate = &rcServDefn.ValToDt;
```

ValToDt

Description

Use the ValToDt property to set or return the end date when a related content or a related action service is available.

This property is read/write.

Example

```
import PTCS_SRVDEFN:RCServiceDefinition;

Local PTCS_SRVDEFN:RCServiceDefinition &rcServDefn = create PTCS_SRVDEFN:RCServiceD⇒
efinition(&service_id, %Language);

Local date &ValFromDate = &rcServDefn.ValFromDt;
Local date &ValToDate = &rcServDefn.ValToDt;
```

RCPParameter Class

Use the RCPParameter class to maintain the properties of service URL parameters for related content service definitions. Do not instantiate a PTCS_SRVDEFN:RCPParameter object directly. Instead, use the

AppendRCParam or GetRCParameter methods of the PTCS_SRVDEFN:RCServiceDefinition class to instantiate and return a RCParameter object.

Related Links

[AppendRCParam](#)

[GetRCParameter](#)

"Understanding Service URL Parameters" (Portal Technology)

RCParameter Class Properties

In this section, the RCParameter class properties are presented in alphabetical order.

Descr

Description

Use the Descr property to set or return a string value representing the description for this URL parameter.

This property is read/write.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;
Component PTCS_SRVDEFN:RCParameter &oRCDefnParam;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("GOOGLE", "ENG");
&oRCDefnParam = &rcServDefn.AppendRCParam("q");
&oRCDefnParam.Descr = "Search terms";
```

ParameterName

Description

Use the ParameterName property to set or return a string value representing the parameter name for this URL parameter.

This property is read/write.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;
Component PTCS_SRVDEFN:RCParameter &oRCDefnParam;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("GOOGLE", "ENG");
&oRCDefnParam = &rcServDefn.AppendRCParam("q");
/* Change the parameter name */
&oRCDefnParam.ParameterName = "as_q";
&oRCDefnParam.Descr = "Advanced search terms";
```

RequiredFlg

Description

Use the RequiredFlg property to set or return a Y/N string value indicating whether this URL parameter is required. When a URL parameter is designated as required, a value must be mapped to the parameter when the service is configured.

Note: The default value is N.

This property is read/write.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;
Component PTCS_SRVDEFN:RCParameter &oRCDefnParam;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("GOOGLE", "ENG");
&oRCDefnParam = &rcServDefn.AppendRCParam("q");
&oRCDefnParam.Descr = "Search terms";
&oRCDefnParam.RequiredFlg = "Y"; /* Set Y/N value */
&oRCDefnParam.SeqNum = 1;
```

SeqNum

Description

Use the SeqNum property to set or return a number value specifying the sequence number for this URL parameter.

This property is read/write.

Example

```
import PTCS_SRVDEFN:*;

Component PTCS_SRVDEFN:RCServiceDefinition &rcServDefn;
Component PTCS_SRVDEFN:RCParameter &oRCDefnParam;

&rcServDefn = create PTCS_SRVDEFN:RCServiceDefinition("GOOGLE", "ENG");
&oRCDefnParam = &rcServDefn.AppendRCParam("q");
&oRCDefnParam.Descr = "Search terms";
&oRCDefnParam.RequiredFlg = "Y"; /* Set Y/N value */
&oRCDefnParam.SeqNum = 1;
```

RCSERVICE Class

Use the PTCS_SERVICE:RCSERVICE application class to manage all related content service configurations (PTCS_SRVCONFIG:RCSERVICECONFIG) for a given component or pivot grid. Use the methods and properties of this class to create and delete service configurations and service instances.

Related Links

"Managing Related Content Configurations and Data" (Portal Technology)

[RCServiceConfig Class](#)

RCService Class Methods

In this section, the RCService class methods are presented in alphabetical order.

AddNewService

Syntax

```
AddNewService(service_ID, instance_ID)
```

Description

Use the AddNewService method to instantiate and return a PTCS_SRVCONFIG:RCServiceConfig object. The object returned depends on the value of the *instance_ID* parameter:

- When the *instance_ID* parameter is 0, the PTCS_SRVCONFIG:RCServiceConfig object represents a new related content service configuration and a new instance ID is automatically generated.
- When the *instance_ID* parameter corresponds to an existing value, the PTCS_SRVCONFIG:RCServiceConfig object is instantiated from this existing configuration.
- When either the *service_ID* parameter or the *instance_ID* parameter is invalid and does not correspond to an existing value, Null is returned.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>service_ID</i>	Specifies a string value representing the service ID of an existing related content service definition.
<i>instance_ID</i>	Specifies an integer value representing the instance ID for a specific related content service configuration.

Returns

A PTCS_SRVCONFIG:RCServiceConfig object.

Example 1

The following example demonstrates how to instantiate an `RCSERVICECONFIG` object for a new service configuration:

```
import PTCS_SERVICE:RCSERVICE;
import PTCS_SRVCONFIG:RCSERVICECONFIG;

Component PTCS_SERVICE:RCSERVICE &pgRFFlRcService;

&pgRFFlRcService = create PTCS_SERVICE:RCSERVICE("EMPLOYEE", "QE_NUI_RI_GBL");
Local PTCS_SRVCONFIG:RCSERVICECONFIG &rcRFFlServConfig = &pgRFFlRcService.AddNewService("APPTTEST_UTIL_SERVID", 0);
Local boolean &bRetSav = &pgRFFlRcService.Save();
```

Example 2

The following example demonstrates how to instantiate an `RCSERVICECONFIG` object for an existing service configuration:

```
import PTCS_SERVICE:RCSERVICE;
import PTCS_SRVCONFIG:RCSERVICECONFIG;
import PTCS_SRVCONFIG:RCMAPFIELDS;

Component PTCS_SERVICE:RCSERVICE &pgRFFlRcService;
Component PTCS_SRVCONFIG:RCMAPFIELDS &rcMapFields;

&pgRFFlRcService = create PTCS_SERVICE:RCSERVICE("EMPLOYEE", "QE_NUI_RI_GBL");
&pgRFFlRcService.LanguageCd = "ENG";
Local PTCS_SRVCONFIG:RCSERVICECONFIG &rcRFFlServConfig = &pgRFFlRcService.AddNewService("APPTTEST_UTIL_SERVID", 569863);
&rcMapFields = &rcRFFlServConfig.GetMapField(1);
If (&rcMapFields <> Null) Then
    /* do some processing */
End-If;
```

[ServiceId](#)

[RCSERVICEDEFINITION Class](#)

[ServiceId](#)

Delete

Syntax

```
Delete ()
```

Description

Use the Delete method to delete all related content service configurations for this component.

Parameters

None.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;

Component PTCS_SERVICE:RCService &pgRFFlRcService;

&pgRFFlRcService = create PTCS_SERVICE:RCService("EMPLOYEE", "QE_NUI_RI_GBL");
Local boolean &bRetDel = &pgRFFlRcService.Delete();
```

DeleteService

Syntax

DeleteService(*service_ID*)

Description

Use the DeleteService method to delete all related content service instances from this component for the given *service_ID* parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>service_ID</i>	Specifies a string value representing the service ID of an existing related content service definition.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;

Component PTCS_SERVICE:RCService &pgRFFlRcService;

&pgRFFlRcService = create PTCS_SERVICE:RCService("EMPLOYEE", "QE_NUI_RI_GBL");
Local boolean &bRetDel = &pgRFFlRcService.DeleteService("APPTTEST_UTIL_SERVID");
Local boolean &bRetSav = &pgRFFlRcService.Save();

DeleteServiceInstance

Syntax

```
DeleteServiceInstance(instance_ID)
```

Description

Use the DeleteServiceInstance method to delete a specific service configuration instance from this component.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>instance_ID</i>	Specifies an integer value representing the instance ID for a specific related content service configuration.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;

Component PTCS_SERVICE:RCService &pgRFFlRcService;

&pgRFFlRcService = create PTCS_SERVICE:RCService("EMPLOYEE", "QE_NUI_RI_GBL");
Local PTCS_SRVCONFIG:RCServiceConfig &rcRFFlServConfig = &pgRFFlRcService.AddNewSer⇒
vice("APPTTEST_UTIL_SERVID", 0);
Local boolean &bRetDel = &pgRFFlRcService.DeleteServiceInstance(&rcRFFlServConfig.I⇒
nstanceId);
Local boolean &bRetSav = &pgRFFlRcService.Save();
```

Related Links

[GetInstanceId](#)

GetInstanceId

Syntax

```
GetInstanceId(service_ID)
```

Description

Use the GetInstanceId method to return an array of integer representing the instance IDs associated with the specified *service_ID* parameter.

Parameters

Parameter	Description
<i>service_ID</i>	Specifies a string value representing the service ID of an existing related content service definition.

Returns

An array of integer.

Example

```
Local array of integer &instArr = &pgRFFlRcService.GetInstanceId("APPTTEST_UTIL_SERV⇒
ID");
If All(&instArr) Then
  For &i = 1 To &instArr.Len
    /* do something */
  End-For;
End-If;
```

GetServiceInfo

Syntax

```
GetServiceInfo(service_ID)
```

Description

Use the GetServiceInfo method to return all service configurations for the given *service_ID* parameter as an array of PTCS_SRVCONFIG:RCServiceConfig objects.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>service_ID</i>	Specifies a string value representing the service ID of an existing related content service definition.

Returns

An array of PTCS_SRVCONFIG:RCServiceConfig objects.

Example

```
Local array of PTCS_SRVCONFIG:RCServiceConfig &rcServCfg = &pgRFFlRcService.GetServiceInfo("APPTTEST_UTIL_SERVID");
If All(&rcServCfg) Then
  For &i = 1 To &rcServCfg.Len
    /* do something */
  End-For;
End-If;
```

RCService

Syntax

```
RCService(portal_name, CREF_name)
```

Description

Use the RCService constructor method to instantiate a PTCS_SERVICE:RCService object to manage all related content service configurations for the specified component.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>portal_name</i>	Specifies a string value representing the portal name.
<i>CREF_name</i>	Specifies a string value representing the component using its content reference ID (also referred to as its portal object name).

Returns

None.

Example

```
import PTCS_SERVICE:RCService;  
  
Component PTCS_SERVICE:RCService &pgRFFlRcService;  
  
&pgRFFlRcService = create PTCS_SERVICE:RCService("EMPLOYEE", "QE_NUI_RI_GBL");
```

[IsNew](#)

Save

Syntax

Save ()

Description

The Save method saves the related content service configurations for this component to the database. Invoke the Save method after instantiating a new component configuration, after updating configuration properties for the component, or after invoking any of these methods: AddNewService, DeleteService, or DeleteServiceInstance.

Parameters

None.

Returns

A boolean value: True if the save is successful, False otherwise.

Example

```
Local boolean &bRet = &pgRFFlRcService.Save();
```

RCService Class Properties

In this section, the RCService class properties are presented in alphabetical order.

ExpandFrame

Description

Use the ExpandFrame to set or return a Y/N string value indicating whether the classic related content frame at the bottom of the page is expanded by default. In addition, one of the service configurations for this component must be selected as the default service.

Note: The default value is N.

This property is read/write.

Example

```
&pgRFFlRcService.ExpandFrame = "Y";
```

Related Links

[IsDefault](#)

IsNew

Description

Use the IsNew property to return whether the instantiation of this service configuration is for a new definition. This property returns True only after the RCService constructor is invoked with the combination of *portal_name* and *CREF_name* parameters set to a new combination. All other times and after a Save is invoked, IsNew returns False.

This property is read-only.

Related Links

[RCService](#)

MenuName

Description

Use the MenuName property to set or return the menu name for this component as a string value.

Note: The value of MenuName must relate to the content reference ID (or portal object name) used to instantiate the object.

This property is read/write.

Example

```
import PTCS_SERVICE:RCService;  
  
Component PTCS_SERVICE:RCService &pgRFFlRcService;
```

```
&pgRFFlRcService = create PTCS_SERVICE:RCService("EMPLOYEE", "USERMAINT_GBL");  
&pgRFFlRcService.MenuName = "MAINTAIN_SECURITY";
```

Related Links

[RCService](#)

MinPagelets

Description

Use the `MinPagelets` property to set or return an integer value representing the maximum number pagelets that can appear minimized when the classic related content frame appears at the right of the page. If a user minimizes more than this number, the pagelets move to the More drop-down list at the bottom of the frame.

This property is read/write.

Example

```
&pgRFFlRcService.MinPagelets = 2;
```

PnlGrpName

Description

Use the `PnlGrpName` to set or return the component name for this component as a string value.

Note: The value of `PnlGrpName` is derived from the content reference ID (or portal object name) used to instantiate the object.

This property is read/write.

Example

In the following example, the value of `PnlGrpName` is `USERMAINT`:

```
import PTCS_SERVICE:RCService;  
  
Component PTCS_SERVICE:RCService &pgRFFlRcService;  
  
&pgRFFlRcService = create PTCS_SERVICE:RCService("EMPLOYEE", "USERMAINT_GBL");  
Local string &comp_name = &pgRFFlRcService.PnlGrpName;
```

Related Links

[RCService](#)

RCFrameLoc

Description

Use the RCFrameLoc property to set or return the location of the classic related content frame as one of the following string values:

<i>Value</i>	<i>Description</i>
B	Display related content in the bottom frame.
S	Display related content in the right frame.

This property is read/write.

Example

```
&pgRFFlRcService.RcFrameLoc = "B";
```

RCServiceConfig Class

Use the PTCS_SRVCONFIG:RCServiceConfig application class to maintain the related content service configurations associated with a specific component. Use the methods and properties of this class to create, update, and delete service configurations.

You can instantiate an object of this class three different ways:

- Invoking the AddNewService method of the PTCS_SERVICE:RCService class to return a PTCS_SRVCONFIG:RCServiceConfig object representing either a new or an existing configuration for that component.
- Invoking the GetServiceInfo method of the PTCS_SERVICE:RCService class to return an array of PTCS_SRVCONFIG:RCServiceConfig objects representing all service configurations for that component.
- Invoking the CloneForNewFull method to instantiate a new PTCS_SRVCONFIG:RCServiceConfig object by copying the current related content service configuration (the system generates a new instance ID).

Note: The RCServiceConfig class does not support managing related action configurations for MAP layouts.

RCServiceConfig Class Methods

In this section, the RCServiceConfig class methods are presented in alphabetical order.

AddPageFieldMenu

Syntax

```
AddPageFieldMenu(page_fld_ID, pg_rec_fld_ID)
```

Description

Use the AddPageFieldMenu method to instantiate and return a PTCS_MENULAYOUT:RCMenuLayout object. The object can represent an existing menu layout configuration or a new configuration depending on the parameters passed.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>page_fld_ID</i>	<p>Specifies a string value representing the page field's ID in the following format:</p> <pre><i>PAGE_NAME.field_ID</i></pre> <p>The field ID can be obtained from the Order tab of the page definition in Application Designer. For example:</p> <pre>QE_BOOK.2</pre>
<i>pg_rec_fld_ID</i>	<p>Specifies a string value representing the page record field's ID in the following format:</p> <pre><i>occurs_lvl.RECORD_NAME.FIELD_NAME.field_ID</i></pre> <p>The occurs level, record name, field name, and field ID can be obtained from the Order tab of the page definition in Application Designer. For example:</p> <pre>0.QE_BOOK.QE_BOOK_NAME.2</pre>

Returns

A PTCS_MENULAYOUT:RCMenuLayout object.

Example

```

import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_SRVCONFIG:RMapFields;
import PTCS_MENULAYOUT:RCMenuLayout;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_SRVCONFIG:RMapFields &rcMapFields;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout;

&rcService = create PTCS_SERVICE:RCService("EMPLOYEE", "QE_NUI_RI_GBL");
&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcMapFields = &rcServConfig.AppendMapField("0.QE_BOOK.QE_BOOK_NAME.2");
/* Required value for the ParameterName property */
&rcMapFields.ParameterName = "PTCS_MENUFIELD";
&rcMapFields.PnlName = "QE_BOOK";
&rcMapFields.MapFieldType = "PF";
&rcMapFields.RefreshService = "N";
&rcMapFields.MapNullValue = "N";
&rcMapFields.FieldMenuOpt = "Y";
&bRet = &rcMapFields.Save();
&bRet = &rcServConfig.Save();
&rcMenuLayout = &rcServConfig.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME⇒
.2");
If (&rcMenuLayout <> Null) Then
    /* do some processing */
    &bRet = &rcServConfig.Save();
End-If;

```

AppendMapField

Syntax

```
AppendMapField(pg_rec fld_ID)
```

Description

Use the AppendMapField method to instantiate a PTCS_SRVCONFIG:RMapFields object. This method associates the page record field passed in as the *pg_rec fld_ID* parameter to a map parameter.

Parameters

Parameter	Description
<i>pg_rec fld_ID</i>	<p>Specifies a string value representing the page record field's ID in the following format:</p> <pre>occurs_lvl.RECORD_NAME.FIELD_NAME.field_⇒ ID</pre> <p>The occurs level, record name, field name, and field ID can be obtained from the Order tab of the page definition in Application Designer. For example:</p> <pre>0.QE_BOOK.QE_BOOK_NAME.2</pre>

Returns

A PTCS_SRVCONFIG:RMapFields object.

Example

```
import PTCS_SERVICE:RService;
import PTCS_SRVCONFIG:RServiceConfig;
import PTCS_SRVCONFIG:RMapFields;

Component PTCS_SERVICE:RService &rcService;
Component PTCS_SRVCONFIG:RServiceConfig &rcServConfig;
Component PTCS_SRVCONFIG:RMapFields &rcMapFields;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcMapFields = &rcServConfig.AppendMapField("0.QE_BOOK.QE_BOOK_NAME.2");
Local boolean &bRet = &rcServConfig.Save();
If (&rcMapFields <> Null) Then
    /* do some processing */
End-If;
```

Related Links

CloneForNew

Syntax

```
CloneForNew(&RCsrvc_cnfg)
```

Description

Use the CloneForNew method to create an identical copy of the related content service configuration executing this method to an already instantiated PTCS_SRVCONFIG:RServiceConfig object but without copying the menu layout. Use this method when the menu layout need not be copied—for example, with the service configuration for pivot grids.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&RCsrv_cfg</i>	Specifies an already instantiated PTCS_SRVCONFIG:RCServiceConfig object that the configuration is copied to.

Returns

A boolean value: True if the copy is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig, &rcServConfigClone;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&bRet = &rcServConfig.CloneForNew(&rcServConfigClone);
If (&rcServConfigClone <> Null) Then
    /* do some processing */
    &bRet = &rcServConfigClone.Save();
End-If;
```

[Save](#)

CloneForNewFull

Syntax

```
CloneForNewFull(service_lbl, service_ID, &dest_cmp, page_fld_ID, pg_rec_fld_ID, fol⇒  
der_lbl)
```

Description

Use the CloneForNewFull method to instantiate a new PTCS_SRVCONFIG:RCServiceConfig object by copying the current related content service configuration object executing the method. (The system generates a new instance ID.)

Parameters

Parameter	Description
<i>service_lbl</i>	Specifies the service label for the new service configuration as a string value.
<i>service_ID</i>	Specifies the service ID for the new service configuration as a string.
<i>&dest_cmp</i>	Specifies destination portal and component to copy the service configuration to as an already instantiated PTCS_SERVICE:RCService object.
<i>page_fld_ID</i>	Specifies a string value representing the page field's ID in the following format: <i>PAGE_NAME.field_ID</i> The field ID can be obtained from the Order tab of the page definition in Application Designer. For example: QE_BOOK.2
<i>pg_rec_fld_ID</i>	Specifies a string value representing the page record field's ID in the following format: <i>occurs_lvl.RECORD_NAME.FIELD_NAME.field_ID => ID</i> The occurs level, record name, field name, and field ID can be obtained from the Order tab of the page definition in Application Designer. For example: 0.QE_BOOK.QE_BOOK_NAME.2
<i>folder_lbl</i>	Specifies the menu folder label name as a string value.

Returns

A PTCS_SRVCONFIG:RCServiceConfig object.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuLayout;
import PTCS_MENULAYOUT:RCMenuFolder;
import PTCS_MENULAYOUT:RCMenuLink;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig, &rcServConfigClone;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout;
Component PTCS_MENULAYOUT:RCMenuFolder &rcMenuFolder;
Component PTCS_MENULAYOUT:RCMenuLink &rcMenuLink;
```

```

&rcService = create PTCS_SERVICE:RCService("EMPLOYEE", "PT_USERMAINT_GBL");

Delete

Syntax

Delete ()

Description

Use the Delete method to delete this related content service configuration.

Parameters

None.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;

&rcService = create PTCS_SERVICE:RCService("EMPLOYEE", "QE_BOOK");
&rcService.MenuName = "QE_NUI";
&rcService.PnlGrpName = "QE_BOOK";
&rcService.ExpandFrame = "N";
&rcService.MinPagelets = 0;
&rcService.RcFrameLoc = "S";
&rcService.LanguageCd = "ENG";
&bRet = &rcService.Save();

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
If (&rcServConfig <> Null) Then
  &rcServConfig.IsCompService = "C";
  &rcServConfig.PnlName = "";
  &rcServConfig.SeqNum = 0;
  &rcServConfig.HideFromSearch = "N";
  &rcServConfig.IsDefault = "N";
  &rcServConfig.MapSecOptions = "P";
  &rcServConfig.HandlerName = "";
  &rcServConfig.InstanceLbl = "APPTTEST_TIL_SERVID";
  &rcServConfig.UrlTarget = "RCF";
  &rcServConfig.MenuOpt = "Y";
  &rcServConfig.MainMenuOpt = "N";
  &rcServConfig.nSeqNumMmnu = 0;
  &rcServConfig.nSeqNumRmnu = 0;
  &rcServConfig.PackageRoot = "";
  &rcServConfig.QualifyPath = "";
  &rcServConfig.AppClassId = "";
  &rcServConfig.cInitMin = "N";
  &rcServConfig.cEnable = "Y";
  &rcServConfig.SrvcOpenOpt = "";
  &rcServConfig.IsEmbeddable = "";
  &rcServConfig.IsSingleUOW = "";
  &rcServConfig.MasterTemplate = "";
  &rcServConfig.AllowPersonalization = "Y";
  &rcServConfig.CompEvent = "";
  &rcServConfig.CompRecEvent = "";
  &rcServConfig.ProcessSeq = "";
  &rcServConfig.cEnable = "Y";
End-If;
&bRet = &rcServConfig.Save();

If (&rcServConfig <> Null) Then
  &bRet = &rcServConfig.Delete();
End-If;
```

DeleteMapField

Syntax

```
DeleteMapField(n_index)
```

Description

Use the DeleteMapField method to delete the mapped page field from the related content service configuration.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n_index</i>	Specifies the mapped page field by index as a number value.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

In the following example, after execution of DeleteMapField, &rcMapFields is an invalid object:

```
import PTCS_SERVICE:RCSERVICE;
import PTCS_SRVCONFIG:RCSERVICECONFIG;
import PTCS_SRVCONFIG:RCMAPFIELDS;
import PTCS_MENULAYOUT:RCMENULAYOUT;

Component PTCS_SERVICE:RCSERVICE &rcSERVICE;
Component PTCS_SRVCONFIG:RCSERVICECONFIG &rcSERVCONFIG;
Component PTCS_SRVCONFIG:RCMAPFIELDS &rcMAPFIELDS;
Component PTCS_MENULAYOUT:RCMENULAYOUT &rcMENULAYOUT;

&rcSERVICE = create PTCS_SERVICE:RCSERVICE("EMPLOYEE", "QE_NUI_RI_GBL");
&rcSERVCONFIG = &rcSERVICE.AddNewService("MY_SERVICE", 0);
&rcMAPFIELDS = &rcSERVCONFIG.AppendMapField("0.QE_BOOK.QE_BOOK_NAME.2");
/* Required value for the ParameterName property */
&rcMAPFIELDS.ParameterName = "PTCS_MENUFIELD";
&rcMAPFIELDS.PnlName = "QE_BOOK";
&rcMAPFIELDS.MapFieldType = "PF";
&rcMAPFIELDS.RefreshService = "N";
&rcMAPFIELDS.MapNullValue = "N";
&rcMAPFIELDS.FieldMenuOpt = "Y";
Local boolean &bRet = &rcMAPFIELDS.Save();
&bRet = &rcSERVCONFIG.Save();
&rcMENULAYOUT = &rcSERVCONFIG.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME=>
.2");

&bRet = &rcSERVCONFIG.DeleteMapField(1);
/* After execution of DeleteMapField, &rcMapFields is an invalid object. */

GetMapField

Syntax

```
GetMapField(n_index)
```

Description

Use the GetMapField method to return the mapped page field of the related content service configuration as a newly instantiated PTCS_SRVCONFIG:RMapFields object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n_index</i>	Specifies the mapped page field by index as a number value.

Returns

A PTCS_SRVCONFIG:RMapFields object.

Example

```
import PTCS_SERVICE:RService;
import PTCS_SRVCONFIG:RServiceConfig;
import PTCS_SRVCONFIG:RMapFields;

Component PTCS_SERVICE:RService &pgRFFlRcService;
Component PTCS_SRVCONFIG:RMapFields &rcMapFields;

&pgRFFlRcService = create PTCS_SERVICE:RService("EMPLOYEE", "QE_NUI_RI_GBL");
Local PTCS_SRVCONFIG:RServiceConfig &rcRFFlServConfig = &pgRFFlRcService.AddNewSer→
vice("APPTTEST_UTIL_SERVID", 569863);

GetMapFieldCount

Syntax

```
GetMapFieldCount()
```

Description

Use the `GetMapFieldCount` method to return the number of mapped page fields for this related content service configuration as a number value.

Parameters

None.

Returns

A number value.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_SRVCONFIG:RMapFields;
import PTCS_MENULAYOUT:RCMenuLayout;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_SRVCONFIG:RMapFields &rcMapFields;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout;

&rcService = create PTCS_SERVICE:RCService("EMPLOYEE", "QE_NUI_RI_GBL");
&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);

/* Required value for the ParameterName property */
&rcMapFields.ParameterName = "PTCS_MENUFIELD";
&rcMapFields.PnlName = "QE_BOOK";
&rcMapFields.MapFieldType = "PF";
&rcMapFields.RefreshService = "N";
&rcMapFields.MapNullValue = "N";
&rcMapFields.FieldMenuOpt = "Y";
Local boolean &bRet = &rcMapFields.Save();
&bRet = &rcServConfig.Save();
&rcMenuLayout = &rcServConfig.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME⇒
.2");

Local number &rcMapFldCnt = &rcServConfig.GetMapFieldCount();
If (&rcMapFldCnt > 0) Then
    /* do some processing */
End-If;
```

Save

Syntax

```
Save ()
```

Description

Use the `Save` method to save changes to this related content service configuration into the database. Invoke the `Save` method after updating properties for the service configuration or after invoking any of these methods: `AddPageFieldMenu`, `AppendMapField`, `CloneForNew`, `CloneForNewFull`, or `DeleteMapField`.

Parameters

None.

Returns

A boolean value: True if the save is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcServConfig.IsCompService = "P";

RCServConfig Class Properties

In this section, the RCServConfig class properties are presented in alphabetical order.

AllowPersonalization

Description

Use the AllowPersonalization property to set or return a Y/N string value to indicate whether user personalization is allowed for this item of fluid related content. “Personalization” allows the user to show or hide an item of fluid related content.

Note: The default value is Y.

This property is read/write.

Example

```
&rcServConfig.AllowPersonalization = "N"; /* Set Y/N string value */
```

cEnable

Description

Use the cEnable property to set or return a Y/N string value to indicate whether this related content service configuration is enabled.

Note: The default value is Y.

This property is read/write.

Example

```
&rcServConfig.cEnable = "N"; /* Set Y/N string value */
```

cInitMin

Description

Use the cInitMin property to set or return a Y/N string value to indicate whether this service appears in the closed state when the user initially accesses the Related Content frame at the right of the page.

Note: The default value is N.

This property is read/write.

Example

```
&rcServConfig.cInitMin = "Y"; /* Set Y/N string value */
```

CompEvent

Description

Use the CompEvent property to set or return a string value representing the component level event for which application class PeopleCode is mapped.

Note: The PeopleSoft Related Content Framework can also be used to map application class PeopleCode programs to component level, page level, and component record level events. This allows custom PeopleCode programs to be defined for a component without customizing the component definition in Application Designer. These custom PeopleCode programs can be configured to run before or after any PeopleCode program defined for the same event from the component definition. See "Mapping Application Class PeopleCode to Component Events" (Portal Technology) for more information.

Following values can be assigned to this property:

Value	Description
POST	Component PostBuild event.
PRE	Component PreBuild event.
SPOS	Component SavePostChange event.
SPRE	Component SavePreChange event.
WFLO	Component WorkFlow event.

Example

```
&rcServConfig.CompEvent = "SPRE";
```

[CompRecEvent](#)

CompRecEvent

Description

Use the CompRecEvent property to set or return a string value representing the component record level event for which application class PeopleCode is mapped.

Note: The Activate event is actually at the page level, and not the component record level.

Note: The PeopleSoft Related Content Framework can also be used to map application class PeopleCode programs to component level, page level, and component record level events. This allows custom PeopleCode programs to be defined for a component without customizing the component definition in Application Designer. These custom PeopleCode programs can be configured to run before or after any PeopleCode program defined for the same event from the component definition. See "Mapping Application Class PeopleCode to Component Events " (Portal Technology) for more information.

Following values can be assigned to this property:

Value	Description
RDEL	Component record RowDelete event.
RINI	Component record RowInit event.

Value	Description
RINS	Component record RowInsert event.
RSEL	Component record RowSelect event.
SEDT	Component record SaveEdit event.
SPOS	Component record SavePostChange event.
SPRE	Component Record SavePreChange event.
PACT	Page Activate event.
RFCH	Component record FieldChange Event.

This property is read/write.

Example

```
&rcServConfig.CompRecEvent = "RINI";
```

Related Links

[EventRecName](#)

[FieldName](#)

EventRecName

Description

Use the EventRecName property to set or return a string value representing the component record for which application class PeopleCode is mapped.

Note: The PeopleSoft Related Content Framework can also be used to map application class PeopleCode programs to component level, page level, and component record level events. This allows custom PeopleCode programs to be defined for a component without customizing the component definition in Application Designer. These custom PeopleCode programs can be configured to run before or after any PeopleCode program defined for the same event from the component definition. See "Mapping Application Class PeopleCode to Component Events " (Portal Technology) for more information.

This property is read/write.

Example

```
&rcServConfig.EventRecName = "QE_RCF_EM_REC";
```

```
&rcServConfig.CompRecEvent = "RINI";
```

Related Links

[CompRecEvent](#)

[FieldName](#)

FieldName

Description

Use the FieldName property to set or return a string value representing the component record for which application class PeopleCode is mapped.

Note: The PeopleSoft Related Content Framework can also be used to map application class PeopleCode programs to component level, page level, and component record level events. This allows custom PeopleCode programs to be defined for a component without customizing the component definition in Application Designer. These custom PeopleCode programs can be configured to run before or after any PeopleCode program defined for the same event from the component definition. See "Mapping Application Class PeopleCode to Component Events" (Portal Technology) for more information.

This property is read/write.

Example

```
&rcServConfig.EventRecName = "QE_RCF_EM_REC";  
&rcServConfig.FieldName = "QEPC_LEVEL0_KEY";  
&rcServConfig.CompRecEvent = "RINI";
```

[CompRecEvent](#)

[EventRecName](#)

InstanceId

Description

Use the InstanceId property to return the instance ID for the related content service configuration as a number value.

This property is effectively read-only.

Related Links

[AddNewService](#)

InstanceLbl

Description

Use the InstanceLbl property to set or return the label of the related content service configuration as a string value.

This property is read/write.

Example

```
&rcServConfig.InstanceLbl= "My Service Instance";
```

Related Links

[ServiceName](#)

IsCompService

Description

Use the IsCompService property to set or return a one-character string value indicating whether the service is configured at the component level or at the page level.

Following values can be assigned to this property:

<i>Value</i>	<i>Description</i>
P	Page level service.
C	Component level service.

This property is read/write.

Example

```
&rcServConfig.IsCompService = "C";
```

IsDefault

Description

Use the IsDefault property to set or return a Y/N string value to indicate whether this related content service configuration is the default service when classic related content is configured for the bottom frame. A default service must be selected only when the classic related content frame at the bottom of the page is configured to initially display expanded.

Note: The default value is N.

This property is read/write.

Example

```
&rcSrcv.ExpandFrame = "Y";  
&rcServConfig.IsDefault= "Y";
```

Related Links

[ExpandFrame](#)

IsEmbeddable

Description

Use the IsEmbeddable property to set or return a Y/N string value to indicate whether this fluid related content service configuration is embeddable related content.

Note: The default value is N.

This property is read/write.

Example

```
&rcServConfig.IsEmbeddable = "Y";
```

IsNew

Description

Use the IsNew property to return whether the instantiation of this service configuration is for a new related content service configuration. This property returns True only in the following circumstances:

- After invoking the AddNewService method of the PTCS_SERVICE:RCSvc class with the *instance_ID* parameter set to 0 to return a PTCS_SRVCONFIG:RCSvcConfig object representing a new configuration for that component.
- After invoking the CloneForNewFull method to return a PTCS_SRVCONFIG:RCSvcConfig object (with a system-generated new instance ID).

For all other instantiated objects and after a Save is invoked, IsNew returns False.

This property is read-only.

Example

```
Local boolean &isNew = &rcServConfig.IsNew;
```

Related Links

[CloneForNewFull](#)

[AddNewService](#)

LanguageCD

Description

Use the LanguageCD property to set or return the language code for this related content service configuration as a three-character string.

This property is read/write.

Example

```
&rcServConfig.LanguageCD = "FRA";
```

MainMenuOpt

Description

Use the MainMenuOpt property to set or return a Y/N string value. Set this property to Y for two scenarios only:

- For a related action configured at the component level that is to be displayed in search results.
- For component level event mapping'

In all other cases, set this property to N.

Note: The default value is N.

This property is read/write.

Example

```
&rcServConfig.MainMenuOpt = "Y";
```

MenuOpt

Description

Use the MenuOpt property to set or return a Y/N string value. Set this property to Y only when configuring classic component-level related content in the right frame.

Note: The default value is N.

This property is read/write.

Example

```
&rcService.RcFrameLoc = "S";  
&rcServConfig.IsCompService = "C";  
&rcServConfig.MenuOpt = "Y";
```

Related Links

[IsCompService](#)

[RCFrameLoc](#)

PnlName

Description

Use the PnlName property to set or return the page name for which the service is configured only when IsCompService is set to P.

This property is read/write.

Example

```
&rcServConfig.IsCompService = "P";  
&rcServConfig.PnlName= "USER_GENERAL";
```

Related Links

[IsCompService](#)

PortalName

Description

Use the PortalName property to return the name of the portal for this related content configuration as a string value.

This property is effectively read-only.

Example

```
Local string &sPortalName = &rcServConfig.PortalName;
```

Related Links

[RCService](#)

PortalObjName

Description

Use the PortalObjName property to return the name of the component for this related content configuration as a string value.

This property is effectively read-only.

Example

```
Local string &sPortalObjName = &rcServConfig.PortalObjName;
```

Related Links

[RCService](#)

ProcessSeq

Description

Use the ProcessSeq property to set or return a string value representing whether this application class PeopleCode is executed before or after any PeopleCode program defined for the same event from the component definition.

Note: The PeopleSoft Related Content Framework can also be used to map application class PeopleCode programs to component level, page level, and component record level events. This allows custom PeopleCode programs to be defined for a component without customizing the component definition in Application Designer. These custom PeopleCode programs can be configured to run before or after any PeopleCode program defined for the same event from the component definition. See "Mapping Application Class PeopleCode to Component Events " (Portal Technology) for more information.

Following values can be assigned to this property:

<i>Value</i>	<i>Description</i>
PRE	The custom application class PeopleCode will be executed before any PeopleCode program defined for the same event from the component definition.
POST	The custom application class PeopleCode will be executed after any PeopleCode program defined for the same event from the component definition.

This property is read/write.

Example

```
&rcServConfig.ProcessSeq = "PRE";
```

SeqNum

Description

Use the SeqNum property to set or return an integer value representing the sequence number for this application class PeopleCode only when more than one custom application class program is mapped to the same event.

Note: The PeopleSoft Related Content Framework can also be used to map application class PeopleCode programs to component level, page level, and component record level events. This allows custom PeopleCode programs to be defined for a component without customizing the component definition in Application Designer. These custom PeopleCode programs can be configured to run before or after any PeopleCode program defined for the same event from the component definition. See "Mapping Application Class PeopleCode to Component Events " (Portal Technology) for more information.

This property is read/write.

Example

```
&rcServConfig.SeqNum= 3;
```

ServiceId

Description

Use the ServiceId property to return the ID for the related content service definition as a string value.

This property is effectively read-only.

Example

```
&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
Local string &serviceId = &rcServConfig.ServiceId;
```

Related Links

[AddNewService](#)

SrvcAttribute

Description

Use the SrvcAttribute property to set or return the service type as a string value:

<i>Value</i>	<i>Description</i>
GNRL	Used for service configurations except for the simplified analytics master (template) definition. Note. This is the default value.
MSTR	Used to specify the simplified analytics master (template) definition.
CLON	Used to specify a clone of the simplified analytics master.

This property is read/write.

Example

```
&rcServConfig.SrvcAttribute= "GNRL";
```

Related Links

[SrvcAttribute](#)

UrlTarget

Description

Use the UrlTarget property to set or return service target as a string value:

<i>Value</i>	<i>Description</i>
RCF	For all classic and fluid related content, this is the default value. Open the content in the related content frame.
MDLW	For classic and fluid related actions, open the related action in a modal window.
NWIN	For classic and fluid related actions, open the related action in a new window.
TGTF	For classic and fluid related actions, open the related action in the target content area replacing the current page. <hr/> Note: For all related actions except those based on an application class service definition, this is the default value. <hr/>
TOPF	For classic and fluid related actions, open the related action by replacing the entire browser window.
USRD	For classic and fluid related actions based on an application class service definition, open the related action in the manner specified in the application class code.

This property is read/write.

Example

```
&rcServConfig.UrlTarget= "MDLW";
```

RMapFields Class

Use the PTCS_SRVCONFIG:RMapFields application class to map related content service parameters to page fields, key fields, fixed values, or system variables.

Do not instantiate an object of this class directly. Instead, use either the AppendMapField or GetMapField methods of the PTCS_SRVCONFIG:RServiceConfig class.

RMapFields Class Methods

In this section, the RMapFields class methods are presented in alphabetical order.

CopyFrom

Syntax

```
CopyFrom(&SrcMapField)
```

Description

Use the CopyFrom method to copy the attributes of the specified PTCS_SRVCONFIG:RMapFields object into the object invoking this method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&SrcMapField</i>	Specifies the source to copy from as an already instantiated PTCS_SRVCONFIG:RMapFields object.

Returns

A boolean value: True if the copy is successful, False otherwise.

Example

```
import PTCS_SERVICE:RService;
import PTCS_SRVCONFIG:RServiceConfig;
import PTCS_SRVCONFIG:RMapFields;

Component PTCS_SERVICE:RService &rcService;

Local PTCS_SRVCONFIG:RServiceConfig &rcServConfigSrc = &rcService.AddNewService("A⇒
PPTEST_UTIL_SERVID", 0);
Local PTCS_SRVCONFIG:RMapFields &rcMapFldsSrc = &rcServConfigSrc.AppendMapField("⇒
0.OPRID_VW2.OPRID.2");

Local PTCS_SRVCONFIG:RServiceConfig &rcServConfigDst = &rcService.AddNewService("A⇒
PPTEST_UTIL_SERVID", 0);
```

```

Local PTCS_SRVCONFIG:RMapFields &rclMapFldsDst = &rcServConfigDst.AppendMapField("⇒
0.OPRID_VW4.CUSTID.4");
Local boolean &bRetx = &rclMapFldsDst.CopyFrom(&rclMapFldsSrc);
Local boolean &bRets = &rclMapFldsDst.Save();

```

Related Links

[Save](#)

Save

Syntax

```
Save ()
```

Description

Use the Save method to save the PTCS_SRVCONFIG:RMapFields object to the database. Invoke the Save method after updating properties for the mapping configuration or after invoking the CopyFrom method.

Parameters

None.

Returns

A boolean value: True if the save is successful, False otherwise.

Example

```

import PTCS_SERVICE:RService;
import PTCS_SRVCONFIG:RServiceConfig;
import PTCS_SRVCONFIG:RMapFields;

Component PTCS_SERVICE:RService &rcService;
Component PTCS_SRVCONFIG:RServiceConfig &rcServConfig;
Component PTCS_SRVCONFIG:RMapFields &rcMapFields;

&rcServConfig = &rcService.AddNewService("APPTTEST_UTIL_SERVID", 0);
Local PTCS_SRVCONFIG:RMapFields &rcMapFlds = &rcServConfig.AppendMapField("0.OPRID⇒
_VW2.OPRID.2");
Local boolean &bRet = &rcServConfig.Save();
&rcMapFlds.ParameterName = "PTCS_MENUFIELD";
&rcMapFlds.PnlName = "QE_RI_GROUPLET";
Local boolean &bRet2 = &rcMapFlds.Save();

```

RMapFields Class Properties

In this section, the RMapFields class properties are presented in alphabetical order.

FieldMenuOpt

Description

Use the FieldMenuOpt property to set or return a Y/N string value indicating whether the menu is associated with a page field.

Set this property to Y for related content with a mapping type of page field when you want to display the related content in the page field menu. Also set this property to Y when mapping related actions to a page field menu. When this parameter is set to Y, you must set the MapFieldType to PF. In addition, you must also set the ParameterName property to PTCS_MENUFIELD, a required value.

Note: The PnlFieldName property is also required, and is set by the invocation of the AppendMapField method.

Note: The default value is N.

This property is read/write.

Example

```
&rcMapFields = &rcServConfig.AppendMapField("0.QE_BOOK.QE_BOOK_NAME.2");
/* Required value for the ParameterName property */
&rcMapFields.ParameterName = "PTCS_MENUFIELD";
&rcMapFields.PnlName = "QE_BOOK";
&rcMapFields.MapFieldType = "PF";
&rcMapFields.FieldMenuOpt = "Y";
```

Related Links

[MapFieldType](#)

[ParameterName](#)

[PnlFieldName](#)

[AppendMapField](#)

MapFieldType

Description

Use the MapFieldType property to set or return a string value representing the mapping type:

<i>Value</i>	<i>Description</i>
KF	Key field.

Value	Description
FV	Fixed value.
SV	System variable.
PF	Page field (valid only for a page-level configuration—that is, when the IsCompService property of the parent RCTServiceConfig object is set to P).
DC	Data column (valid only for a pivot grid configuration).
ML	Menu location (valid only for chart field in a pivot grid configuration).

This property is read/write.

Example

```
&rcMapFlds.MapFieldType = "PF";
```

MapNullValue

Description

Use the MapNullValue property to set or return a Y/N string value indicating whether a parameter value is required.

Note: The default value is N.

This property is read/write.

Example

```
&rcMapFlds.MapNullValue = "Y";
```

ParameterName

Description

Use the ParameterName property to return a string value representing the name of the service parameter from the related content service definition.

Important! Only when the FieldMenuOpt property is set to Y, set the ParameterName property to PTCS_MENUFIELD, a required value.

This property is typically read-only.

Related Links

[FieldMenuOpt](#)

PnlFieldName

Description

Use the PnlFieldName property to set or return the mapped data value as a string value. The value specified—for example, the mapped page field name, key field name, fixed value, system variable, and so on—depends on the value of the MapFieldType property.

This property is read/write.

Example 1

```
Local PTCS_SRVCONFIG:RMapFields &rcMapFlds = &rcServConfig.AppendMapField("0.OPRID⇒
_VW2.OPRID.2");
&rcMapFields.MapFieldType = "PF";
Local string &sPnlFieldName = &rcMapFlds.PnlFieldName;
```

Example 2

```
Local PTCS_SRVCONFIG:RMapFields &rcMapFlds = &rcServConfig.AppendMapField("0.OPRID⇒
_VW2.OPRID.2");
&rcMapFields.MapFieldType = "SV";
&rcMapFlds.PnlFieldName = "%UserId";
```

Related Links

[MapFieldType](#)

[PnlName](#)

PnlName

Description

Use the PnlName property to set or return the page name as a string value. This property is required only when the value of the MapFieldType property is set to PF (page field); otherwise, it is an empty string.

This property is read/write.

Example

```
Local PTCS_SRVCONFIG:RMapFields &rcMapFlds = &rcServConfig.AppendMapField("0.OPRID⇒
_VW2.OPRID.2");
&rcMapFlds.PnlName = "QE_RI_GROUplet";
&rcMapFlds.MapFieldType = "PF";
Local boolean &bRet = &rcMapFlds.Save();
```

Related Links

[MapFieldType](#)

[PnlFieldName](#)

RefreshService

Description

Use the RefreshService property to set or return a Y/N string value that indicates whether to have the service data refreshed automatically when the key values on the transaction page changes.

Note: The default value is N.

This property is read/write.

Example

```
&rcMapFlds.RefreshService = "Y";
```

RCMenuLayout Class

Use the PTCS_MENULAYOUT:RCMenuLayout application class to manage the menu layout for related content, related action, and page field contextual menus.

Do not instantiate an object of this class directly. Instead, use the AddPageFieldMenu method of the PTCS_SRVCONFIG:RCServiceConfig class to instantiate a menu layout object representing an existing menu layout configuration or a new configuration depending on the parameters passed. Use the CloneForNewFull method of this class to instantiate a menu layout object by copying the menu layout from an existing related content service configuration.

RCMenuLayout Class Methods

In this section, the RCMenuLayout class methods are presented in alphabetical order.

AddFolder

Syntax

```
AddFolder(folder_lbl, folder_seqnum)
```

Description

Use the AddFolder method to instantiate a PTCS_MENULAYOUT:RCMenuFolder object to add a new menu folder to the menu layout.

Note: Folders cannot be created for the related content menu.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>folder_lbl</i>	Specifies the label for the folder as a string value.
<i>folder_seqnum</i>	Specifies the sequence number for the folder as an integer value.

Returns

A PTCS_MENULAYOUT:RCMenuFolder object.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuLayout;
import PTCS_MENULAYOUT:RCMenuFolder;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcMenuLayout = &rcServConfig.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME=>
.2");
Local PTCS_MENULAYOUT:RCMenuFolder &lclMenuFolder = &rcMenuLayout.AddFolder("CRM", =>
2);
Local boolean &bRet = &rcMenuLayout.Save();
```

Related Links

[Save](#)

[RCMenuFolder Class](#)

CloneForNew

Syntax

```
CloneForNew(&RCmenu_layout)
```

Description

Use the CloneForNew method to create an identical copy of the menu layout executing this method to an already instantiated PTCS_MENULAYOUT:RCMenuLayout object—for example, a standalone RCMenuLayout object, one associated with this RCServiceConfig object, or one associated with a different RCServiceConfig object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&RCmenu_layout</i>	Specifies an already instantiated PTCS_MENULAYOUT:RCMenuLayout object that the configuration is copied to.

Returns

A boolean value: True if the copy is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuLayout;
import PTCS_MENULAYOUT:RCMenuFolder;
import PTCS_MENULAYOUT:RCMenuLink;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout, &rcMenuLayoutNew;
Component PTCS_MENULAYOUT:RCMenuFolder &rcMenuFolder;
Component PTCS_MENULAYOUT:RCMenuLink &rcMenuLink;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcServConfig.IsCompService = "C";
&rcServConfig.PnlName = "";
&rcServConfig.SeqNum = 0;
&rcServConfig.HideFromSearch = "N";
&rcServConfig.IsDefault = "N";
&rcServConfig.MapSecOptions = "P";
&rcServConfig.HandlerName = "";
&rcServConfig.InstanceLbl = "CLONERCPGLT";
&rcServConfig.UrlTarget = "RCF";
&rcServConfig.MenuOpt = "Y";
&rcServConfig.MainMenuOpt = "N";
&rcServConfig.nSeqNumMmnu = 0;
&rcServConfig.nSeqNumRmnu = 0;
&rcServConfig.PackageRoot = "";
&rcServConfig.QualifyPath = "";
&rcServConfig.AppClassId = "";
&rcServConfig.cInitMin = "N";
&rcServConfig.cEnable = "Y";
```

```

&rcServConfig.SrvcOpenOpt = "";
&rcServConfig.IsEmbeddable = "";
&rcServConfig.IsSingleUOW = "";
&rcServConfig.MasterTemplate = "";
&rcServConfig.AllowPersonalization = "Y";
&rcServConfig.CompEvent = "";
&rcServConfig.ProcessSeq = "";
Local boolean &bRet1 = &rcServConfig.Save();

&rcMenuLayout = &rcServConfig.AddPageFieldMenu("", "");
&rcMenuFolder = &rcMenuLayout.AddFolder("Root", Value(&rcServConfig.SeqNum));
&rcMenuLink = &rcMenuFolder.AppendMenuLink(&rcServConfig.ServiceId, &rcServConfig.I⇒
nstanceId);
Local boolean &bRet2 = &rcMenuLayout.Save();

Local boolean &bRet3 = &rcMenuLayout.CloneForNew(&rcMenuLayoutNew);
If (&bRet3) Then
    /* do some processing */
    Local boolean &bRet4 = &rcMenuLayoutNew.Save();
End-If;

```

Related Links

[Save](#)

CloneForNewFull

Syntax

```
CloneForNewFull (&rcServiceConfig, page_fld_ID, pg_rec_fld_ID)
```

Description

Use the CloneForNewFull method to instantiate a new PTCS_MENULAYOUT:RCMenuLayout object associated with the specified service configuration object. The menu layout of the object executing this method is copied to the new object.

Parameters

Parameter	Description
<i>&rcServiceConfig</i>	Specifies an already instantiated PTCS_SRVCONFIG:RCServiceConfig object that this new menu layout will be associated with.
<i>page_fld_ID</i>	Specifies a string value representing the page field's ID in the following format: <i>PAGE_NAME.field_ID</i> The field ID can be obtained from the Order tab of the page definition in Application Designer. For example: QE_BOOK.2

Parameter	Description
<i>pg_rec fld_ID</i>	<p>Specifies a string value representing the page record field's ID in the following format:</p> <pre><i>occurs_lvl.RECORD_NAME.FIELD_NAME.field_→ID</i></pre> <p>The occurs level, record name, field name, and field ID can be obtained from the Order tab of the page definition in Application Designer. For example:</p> <pre>0.QE_BOOK.QE_BOOK_NAME.2</pre>

Returns

A PTCS_MENULAYOUT:RCMenuLayout object.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuLayout;
import PTCS_MENULAYOUT:RCMenuFolder;
import PTCS_MENULAYOUT:RCMenuLink;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout, &rcMenuLayoutNew;
Component PTCS_MENULAYOUT:RCMenuFolder &rcMenuFolder;
Component PTCS_MENULAYOUT:RCMenuLink &rcMenuLink;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcServConfig.IsCompService = "C";
&rcServConfig.PnlName = "";
&rcServConfig.SeqNum = 0;
&rcServConfig.HideFromSearch = "N";
&rcServConfig.IsDefault = "N";
&rcServConfig.MapSecOptions = "P";
&rcServConfig.HandlerName = "";
&rcServConfig.InstanceLbl = "CLONERCPGLT";
&rcServConfig.UrlTarget = "RCF";
&rcServConfig.MenuOpt = "Y";
&rcServConfig.MainMenuOpt = "N";
&rcServConfig.nSeqNumMmnu = 0;
&rcServConfig.nSeqNumRmnu = 0;
&rcServConfig.PackageRoot = "";
&rcServConfig.QualifyPath = "";
&rcServConfig.AppClassId = "";
&rcServConfig.cInitMin = "N";
&rcServConfig.cEnable = "Y";
&rcServConfig.SrvcOpenOpt = "";
&rcServConfig.IsEmbeddable = "";
&rcServConfig.IsSingleUOW = "";
&rcServConfig.MasterTemplate = "";
&rcServConfig.AllowPersonalization = "Y";
&rcServConfig.CompEvent = "";
&rcServConfig.ProcessSeq = "";
Local boolean &bRet1 = &rcServConfig.Save();

&rcMenuLayout = &rcServConfig.AddPageFieldMenu("", "");
&rcMenuFolder = &rcMenuLayout.AddFolder("Root", Value(&rcServConfig.SeqNum));
```

```

    &rcMenuItem = &rcMenuItem.AppendMenuItem(&rcServConfig.ServiceId, &rcServConfig.I⇒
nstanceId);
    Local boolean &bRet2 = &rcMenuItem.Save();

    &rcMenuItemNew = &rcMenuItem.CloneForNewFull(&rcServConfig, "QE_BOOK.2", "0.QE_⇒
BOOK.QE_BOOK_NAME.2");
    If (&rcMenuItemNew <> Null) Then
        /* do some processing */
    End-If;

```

Delete

Syntax

```
Delete()
```

Description

Use the Delete method to delete the menu layout.

Parameters

None.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```

import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuItem;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_MENULAYOUT:RCMenuItem &rcMenuItem;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcMenuItem = &rcServConfig.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME⇒
.2");
Local boolean &bRet = &rcMenuItem.Delete();
If (&bRet) Then
    /* do some processing */
End-If;

```

DeleteFolder

Syntax

```
DeleteFolder(nItem)
```

Description

Use the DeleteFolder method to delete the specified menu folder from this menu layout.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>nItem</i>	Specifies the menu folder as a number value.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuLayout;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcMenuLayout = &rcServConfig.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME⇒
.2");
Local boolean &bRet = &rcMenuLayout.DeleteFolder(2);
Local boolean &bRet = &rcMenuLayout.Save();
```

[RCMenuFolder Class](#)

DeleteMenuLink

Syntax

```
DeleteMenuLink(service_ID, instance_ID)
```

Description

Use the DeleteMenuLink method to delete the specified menu link from the layout.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>service_ID</i>	Specifies a string value representing the service ID for the parent related content service configuration.
<i>instance_ID</i>	Specifies an integer value representing the instance ID for the parent related content service configuration.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuLayout;
import PTCS_MENULAYOUT:RCMenuLink;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout;
Component PTCS_MENULAYOUT:RCMenuLink &rcMenuLink;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcMenuLayout = &rcServConfig.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME⇒
.2");
If (&rcMenuLayout <> Null) Then
    &bRet = &rcMenuLayout.DeleteMenuLink("MY_SERVICE", &rcServConfig.InstanceId);
    If (&bRet) Then
        /* do some processing */
        Local boolean &bRet2 = &rcMenuLayout.Save();
    End-If;
End-If;
```

GetFolder

Syntax

GetFolder (*nItem*)

Description

Use the GetFolder method to instantiate a PTCS_MENULAYOUT:RCMenuFolder object for the specified menu folder.

Note: Folders cannot be created for the related content menu.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>nItem</i>	Specifies the menu folder as a number value.

Returns

A PTCS_MENULAYOUT:RCMenuFolder object.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuLayout;
import PTCS_MENULAYOUT:RCMenuFolder;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcMenuLayout = &rcServConfig.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME=>
.2");
Local PTCS_MENULAYOUT:RCMenuFolder &lclMenuFolder = &rcMenuLayout.GetFolder(1);
```

GetFolderCount

Syntax

```
GetFolderCount()
```

Description

Use the GetFolderCount method to return the count of menu folders for this menu layout as a number value.

Parameters

None.

Returns

A number value.

Example

```
import PTCS_SERVICE:RCSERVICE;
import PTCS_SRVCONFIG:RCSERVICECONFIG;
import PTCS_MENULAYOUT:RCMENU_LAYOUT;

Component PTCS_SERVICE:RCSERVICE &rcSERVICE;
Component PTCS_SRVCONFIG:RCSERVICECONFIG &rcSERVCONFIG;
Component PTCS_MENULAYOUT:RCMENU_LAYOUT &rcMENU_LAYOUT;

&rcSERVCONFIG = &rcSERVICE.AddNewService("MY_SERVICE", 0);
&rcMENU_LAYOUT = &rcSERVCONFIG.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME=>
.2");
Local number &n, &fld_cnt;
&fld_cnt = &rcMENU_LAYOUT.GetFolderCount();
For &n = 1 To &fld_cnt
    /* Do some processing */
End-For;
```

GetFolderFromFolderId

Syntax

```
GetFolderFromFolderId(folder_lbl)
```

Description

Use the GetFolderFromFolderId method to return a PTCS_MENULAYOUT:RCMenuFolder object representing the menu folder for the specified *folder label*.

Parameters

Parameter	Description
<i>folder_lbl</i>	Specifies the <i>label</i> for the folder as a string value.

Returns

A PTCS_MENULAYOUT:RCMenuFolder object.

Example

```
import PTCS_SERVICE:RCSERVICE;
import PTCS_SRVCONFIG:RCSERVICECONFIG;
import PTCS_MENULAYOUT:RCMENU_LAYOUT;
import PTCS_MENULAYOUT:RCMENU_FOLDER;

Component PTCS_SERVICE:RCSERVICE &rcSERVICE;
Component PTCS_SRVCONFIG:RCSERVICECONFIG &rcSERVCONFIG;
Component PTCS_MENULAYOUT:RCMENU_LAYOUT &rcMENU_LAYOUT;

&rcSERVCONFIG = &rcSERVICE.AddNewService("MY_SERVICE", 0);
&rcMENU_LAYOUT = &rcSERVCONFIG.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME=>
.2");
Local PTCS_MENULAYOUT:RCMENU_FOLDER &lclMenuFolder = &rcMENU_LAYOUT.GetFolderFromFold=>
```

```
erId("CRM");
```

Save

Syntax

```
Save()
```

Description

Use the Save method to save the menu layout to the database. Invoke the Save method after updating any configuration properties for the menu layout or after invoking any of the following methods: AddFolder, CloneForNew, DeleteFolder, or DeleteMenuLink

Parameters

None.

Returns

A boolean value: True if the save is successful, False otherwise.

Example

```
&rcMenuLayout = &rcServConfig.AddPageFieldMenu("", "");  
&rcMenuFolder = &rcMenuLayout.AddFolder("Root", Value(&rcServConfig.SeqNum));  
&rcMenuLink = &rcMenuFolder.AppendMenuLink(&rcServConfig.ServiceId, &rcServConfig.I⇒  
nstanceId);  
Local boolean &bRet = &rcMenuLayout.Save();
```

RCMenuLayout Class Properties

In this section, the RCMenuLayout class properties are presented in alphabetical order.

IsNew

Description

Use the IsNew property to return a boolean value indicating whether the menu layout is a new configuration. This property returns True after calling CloneForNew to update the target menu layout object.

Note: This property returns False after instantiating a new menu layout object with either AddPageFieldMenu or CloneForNewFull.

This property is read-only.

Related Links

[CloneForNew](#)

LanguageCD

Description

Use the LanguageCD property to set or return the language code for this menu layout as a three-character string.

This property is read/write.

Example

```
&rcMenuLayout.LanguageCD = "GER";
```

MenuId

Description

Use the MenuId property to return the ID for this menu layout as a string value in the following format:

```
PAGE_NAME.field_ID
```

This property is set by the CloneForNewFull method and the AddPageFieldMenu method of the RCTestServiceConfig class.

This property is effectively read-only.

Example

```
Local string &menu_ID = &rcMenuLayout.MenuId;
```

Related Links

[CloneForNewFull](#)

[AddPageFieldMenu](#)

MenuType

Description

Use the MenuType property to return the type of menu as a string value:

Value	Description
FLDM	Page field level related action and related content configuration.
MMNU	Component level related action configuration.
PGBM	Pivot grid related action configuration.
RCMU	Component level related content menu configuration.

This property is set by the AddPageFieldMenu method of the RCServiceConfig class.

This property is effectively read-only.

Example

```
Local String &sMenu_Type = &rcMenuLayout.MenuType;
```

Related Links

[AddPageFieldMenu](#)

PnlFldName

Description

Use the PnlFldName property to return the mapped data value as a string value. The value specified—for example, the page field name, key field name, fixed value, system variable, and so on—depends on the value of the MapFieldType property of the RCMapFields class.

This property is read/write.

Related Links

[MapFieldType](#)

[PnlFldName](#)

PnlName

Description

Use the PnlName property to return the page name as a string value. This property is set in the RCMaPFields object and is only required when the value of the MapFieldType property is set to PF (page field); otherwise, it is an empty string.

This property is effectively read-only.

Example

```
Local String &pg_name = &rcMenuLayout.PnlName;
```

Related Links

[AddPageFieldMenu](#)

[PnlName](#)

PortalName

Description

Use the PortalName property to return the portal specified for this menu layout as a string value.

This property is set by the AddPageFieldMenu method of the RCServiceConfig class.

This property is effectively read-only.

Example

```
Local string &portal_name = &rcMenuLayout.PortalName;
```

Related Links

[AddPageFieldMenu](#)

PortalObjName

Description

Use the PortalObjName property to return the content reference ID (portal object name) specified for this menu layout as a string value.

This property is set by the AddPageFieldMenu method of the RCServiceConfig class.

This property is effectively read-only.

Example

```
Local string &CREF_ID = &rcMenuLayout.PortalObjName;
```

RCMenuFolder Class Methods

In this section, the RCMenuFolder class methods are presented in alphabetical order.

AppendMenuItem

Syntax

```
AppendMenuItem(service_ID, instance_ID)
```

Description

Use the AppendMenuItem method to instantiate a PTCS_MENULAYOUT:RCMenuItem object and append that link as the last link in the menu folder.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>service_ID</i>	Specifies a string value representing the service ID for the parent related content service configuration.
<i>instance_ID</i>	Specifies an integer value representing the instance ID for the parent related content service configuration.

Returns

A PTCS_MENULAYOUT:RCMenuItem object.

Example

```

import PTCS_SRVDEFN:RCServiceDefinition;
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuItem;
import PTCS_MENULAYOUT:RCMenuItemFolder;
import PTCS_MENULAYOUT:RCMenuItemLink;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_MENULAYOUT:RCMenuItem &rcMenuItem;
Component PTCS_MENULAYOUT:RCMenuItemFolder &rcMenuItemFolder;
Component PTCS_MENULAYOUT:RCMenuItemLink &rcMenuItemLink;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcMenuItem = &rcServConfig.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME=>
.2");
&rcMenuItemFolder = &rcMenuItem.GetFolder(1);
If (&rcMenuItemFolder <> Null) Then
    For &n = 1 To &rcMenuItemFolder.GetMenuItemCount()
        &rcMenuItemLink = &rcMenuItemFolder.AppendMenuItemLink("MY_SERVICE", &rcServConfig.Instan=>
ceId);
        If (&rcMenuItemLink <> Null) Then
            /* Do some processing */
        End-If;
    End-For;
End-If;

```

DeleteMenuItem

Syntax

```
DeleteMenuItem(nItem)
```

Description

Use the DeleteMenuItem method to delete the specified link from the menu folder.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>nItem</i>	Specifies the index of the link as a number value.

Returns

A boolean value: True if the delete is successful, False otherwise.

Example

```
import PTCS_SERVICE:RCService;
import PTCS_SRVCONFIG:RCServiceConfig;
import PTCS_MENULAYOUT:RCMenuLayout;
import PTCS_MENULAYOUT:RCMenuFolder;
import PTCS_MENULAYOUT:RCMenuLink;

Component PTCS_SERVICE:RCService &rcService;
Component PTCS_SRVCONFIG:RCServiceConfig &rcServConfig;
Component PTCS_MENULAYOUT:RCMenuLayout &rcMenuLayout;
Component PTCS_MENULAYOUT:RCMenuFolder &rcMenuFolder;
Component PTCS_MENULAYOUT:RCMenuLink &rcMenuLink;
Local number &n;

&rcServConfig = &rcService.AddNewService("MY_SERVICE", 0);
&rcMenuLayout = &rcServConfig.AddPageFieldMenu("QE_BOOK.2", "0.QE_BOOK.QE_BOOK_NAME⇒
.2");
&rcMenuFolder = &rcMenuLayout.GetFolder(1);
If (&rcMenuFolder <> Null) Then
  For &n = 1 To &rcMenuFolder.GetMenuLinkCount()
    Local boolean &bRet = &rcMenuFolder.DeleteMenuLink(&n);
    If (&bRet) Then
      /* Do some processing */
    End-If;
  End-For;
End-If;
```

Additional PeopleCode Examples

This section provides additional code examples for the Related Content Framework: Creating Service Definitions and Service Configurations.

Creating Service Definitions and Service Configurations

The following PeopleCode program:

- Creates a service definition (APPTTEST_UGEN_SERVID).
- Creates a configuration for a component (PCODEEAPI_MAINCOMP_GBL).
- Adds a related action to the component (REL_CONTENT Comp).

- Maps the related action to a page field (0.RELCONT_PCODE.RELATED_ACT.4).
- Configures the menu layout for the same page field.

```

Rowset Class

Understanding Rowset Class

A *rowset* object, instantiated from a Rowset class, is a collection of rows associated with buffer data. A component scroll is a rowset. You can also have a level zero rowset.

If a rowset object is instantiated using `GetRowset` (either the function or one of the methods) the rowset object that is instantiated is populated with data according to the context in which it was instantiated.

If a rowset object is instantiated using the `CreateRowset` function, the rowset object that's instantiated is a standalone rowset. Any records and field references created by this function are initialized to null values, that is, they do *not* contain any data. You can populate this rowset object using the `CopyTo`, `Fill`, or `FillAppend` methods.

Default processing isn't performed on a standalone rowset. In addition, a standalone rowset isn't tied to the Component Processor. When you fill it with data, no PeopleCode runs (for example, `RowInsert`, `FieldDefault`, and so on.) Delete and insert activity on these types of rowsets aren't automatically applied at save time. Use standalone rowsets for work records.

You might use a rowset object and the `ActiveRowCount` property to iterate over all the rows of the rowset, or to access a specific row (using the `GetRow` method) or to find the name of the primary record associated with the scroll (the `DBName` property).

The Rowset class is one of the data buffer access classes.

Related Links

"Using Standalone Rowsets" (PeopleCode Developer's Guide)

"Understanding Data Buffer Access" (PeopleCode Developer's Guide)

Shortcut Considerations

The default method for the Rowset class is `GetRow`. This means you can specify just a row number, and not use the `GetRow` method. For example, the following two lines of code are equivalent:

```
&MyRow = GetRowset () (5) ;
```

```
&MyRow = GetRowset () .GetRow (5) ;
```

Data Type of a Rowset Object

Rowset objects are declared as type Rowset. For example,

```
Local Rowset &MYROWSET;
```

Scope of a Rowset Object

A Rowset can be instantiated from PeopleCode or using Java.

This object can be used anywhere you have PeopleCode, that is, in an Application Class, record field PeopleCode, and so on.

You can't pass a rowset object in as part of a Component Interface user-defined method. (Rowsets aren't common data structures outside of a PeopleSoft system.) However, within a user-defined method for a Component Interface you can use rowset objects.

In an Application Engine program, a rowset object is the equivalent of a record object that contains one row and a single record, that is, the State Record. PeopleSoft suggests using the Record object instead of a rowset object to obtain access to the State Record.

Messages have the same structure as rowsets, that is, hierarchical data structures composed of rows, records, and fields.

File objects can have the same structure as rowsets, that is, hierarchical data structures composed of rows, records, and fields.

Rowset Class Methods

In this section, we discuss the Rowset class methods. The methods are discussed in alphabetical order.

ClearDeletesChanges

Syntax

```
ClearDeletesChanges ()
```

Description

Use the ClearDeletesChanges method to clear deleted rows and changed from a standalone rowset.

Note: This method works only with standalone rowsets, that is, rowsets created using the CreateRowset function.

This method differs from Flush in a number of ways:

- it does not remove *all* rows from the rowset, only deleted rows
- it only applies to standalone rowsets

This method first clears the deleted rows, that is, all rows that have been deleted using DeleteRow are removed from the rowset and their associated buffers are freed.

This method then clears changed rows. That means any changes done on a row (such as field values changed) or newly inserted rows are now propagated into their original state and the changed buffers, if any, are freed.

After executing this method on a standalone rowset, any row that was previously new or changed no longer has that state. The IsNew and IsChanged properties of a row return false.

This method does *not* do any database updates.

How would you use this method? Suppose you use a standalone rowset to track changes you need to make to some business process or object. After doing the appropriate database updates to reflect changes recorded in the rowset (that is, inserts or deletes or changes), you call this method to clean up the rowset in preparation for further processing. Without this method, newly inserted rows and changed rows preserve their IsNew and IsChanged status indefinitely, complicating program logic and potentially leading to duplicate inserts or deletes.

Parameters

None.

Returns

None.

Example

```
REM +-----+;
REM | Function to Update the DB for a Standalone Rowset|;
REM +-----+;
Function ProcessDatabaseUpdateforRowset (&rsIn As Rowset)

    For &i = 1 To &rsIn.RowCount
```

```

&rwTMP = &rsIn.GetRow(&i);
If &rwIn.IsDeleted And
    Not &rwIn.IsNew Then
    &rTMP = &rwIn.GetRecord(1);
    &rTMP.Delete();
End-If;

If &rwTMP.IsNew And
    &rwTMP.IsChanged And
    Not &rwTMP.IsDeleted Then

    &rTMP = &rwTMP.GetRecord(1);
    &rTMP.Insert();
End-If;

If Not &rwTMP.IsNew And
    &rwTMP.IsChanged And
    Not &rwTMP.IsDeleted Then

    &rTMP = &rwTMP.GetRecord(1);
    &rTMP.Update();
End-If;

End-For;

REM +-----+;
REM | Now we need to reset the Rowset flags and      |;
REM | remove deleted rows                          |;
REM +-----+;
&rsIn.ClearDeletesChanges();

End-Function;

```

CopyTo

Syntax

```
CopyTo(&DestRowset [, record_list])
```

Where *record_list* is a list of record names in the form:

```
[RECORD.source_recname1, RECORD.target_recname1
[, RECORD.source_recname2, RECORD.target_recname2]]. . .
```

Description

The CopyTo method copies *from* the rowset executing the method *to* the specified destination rowset, copying *like-named* record fields and subscrolls at corresponding levels.

The CopyTo method uses the current data in the rowset. This might be different from the original data values if the rowset was retrieved from the database and values in it have been changed either by an end-user or a PeopleCode program

If pairs of source and destination record names are given, these are used to pair up the records and subscrolls *before* checking for like-named record fields. Then, after copying the named records pairs, this method copies *all* identically named records.

Note: This method does not work for Application Engine state records. If you don't specify *record_list*, *both* the record name *and* the field name have to match exactly for data to be copied from one record field to another. If you specify *record_list*, after the records have been paired up, the field names have to match before any data is copied.

If the rowset you are copying *from* has the field level `EditError`, as well as the `MessageNumber` and `MessageSetNumber` properties set, these values are copied to the rowset you are copying to. For example, suppose you had an application message that had errors. Using the `GetSubContractInstance` function, these errors would be copied into the message object. From there, you could instantiate a message rowset, copy the message rowset into a work rowset, and use the work rowset to populate Component buffers. (After the field properties are set, the `Record`, `Row`, and `Rowset` properties `IsEditError` also get set.)

In order to copy all of the properties of the fields from the source rowset, the source and target scrolls must have exactly the same shape:

- The names of the records in the source and target scrolls must be the same.
- If there are subscrolls in the source scroll, then the same number of subscrolls must exist in the target scroll.
- The names of the records in any source subscrolls and target subscrolls must be the same.

Parameters

Parameter	Description
<i>&DestRowset</i>	Specify the rowset to be copied to. This Rowset object must have already been instantiated.
<i>SourceRename</i>	Specify a record to be copied from, in the Rowset object being copied from.
<i>DestRename</i>	Specify a record to be copied to, in the Rowset object to be copied to.

Returns

None.

Example

If you set one rowset equal to another, you haven't made a copy of the rowset. Instead, you have two variables pointing to the *same* data.

To make a clone of an existing rowset, that is, to make two distinct copies, you can do the following:

```
&RS2 = CreateRowset (&RS);
```

```
&RS.CopyTo (&RS2);
```

The following example copies data from one rowset object to another. Because no like-named records exist between the two rowsets, the record names are specified. Only the like-named fields are copied from one rowset to the other:

```
Local Rowset &RS1, &RS2;
Local String &EMPLID;

&RS1 = CreateRowset (RECORD.PERSONAL_DATA);
&RS2 = CreateRowset (RECORD.PER_VENDOR_DATA);
&EMPLID = "8001";
&RS1.Fill ("WHERE EMPLID =: 1", &EMPLID);
&RS1.CopyTo (&RS2, RECORD.PERSONAL_DATA, RECORD.PER_VENDOR_DATA);
```

The following example copies data from a message into the Component buffers, then calls the page (using TransferPage) to redraw the page. You could do this to fill a page with message data that is in error, so that an end-user can make corrections to the message data. &WRK_ROWSET0 is the level zero rowset and &WRK_ROWSET1 is where the data is copied to.

```
/* Get the Message */
&MSG = GetSubContractInstance (&PUBID, &PUBNODE, &CHNLNAME, &MSGNAME, &SUBNAME);

/* Get the Message Rowset */
&MSG_ROWSET = &MSG.GetRowset ();

/* Get Level 0 */
&WRK_ROWSET0 = GetLevel0 ();

/* Create Work rowset */
&WRK_ROWSET1 = GetLevel0 () (1).GetRowset (SCROLL.EN_REVISION_TMP);

/* Populate Work Rowset */
&MSG_ROWSET.CopyTo (&WRK_ROWSET1, RECORD.EN_REVISION, RECORD.EN_REVISION_TMP);

SetNextPage ("EN_REVISION_MSG");

TransferPage ();
```

"Assigning Objects" (PeopleCode Developer's Guide)

DeleteRow

Syntax

```
DeleteRow (n)
```

Description

The DeleteRow method deletes the row in the rowset identified by the parameter.

If the program is being run from a component against Component buffer data, a RowDelete PeopleCode event also fires, followed by the events that normally follow a RowDelete, as if the user had manually pressed **ALT+8** and **ENTER**.

This method initially marks the row as needing to be deleted. At save time the row is actually deleted from the database and cleared from the buffer. When the row is marked as deleted, it is ignored by other methods, such as `GetCurrEffRow`, `Sort`, and so on.

`DeleteRow` cannot be executed from the same rowset where the deletion takes place, or from a child rowset against a parent. Place your `PeopleCode` in a parent rowset and execute it against a child rowset.

When `DeleteRow` is used in a loop, you have to process rows from high to low to achieve the correct results, that is, you must delete from the bottom up rather than from the top down. This is necessary because the rows are renumbered after they are deleted (if you delete row one, row two becomes row one).

Note: If you use `DeleteRow` on a rowset created using the `CreateRowset` function, the row isn't automatically deleted in the database when the page is saved. Rowsets created using the `CreateRowset` function are standalone rowsets, not tied to the database, so there are no database updates when they are manipulated. Delete and insert activity on these types of rowsets aren't automatically applied at save time.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n</i>	An integer identifying a row within the rowset object. This must be ≥ 1 and \leq the number of active rows in the rowset (see <code>ActiveRowCount</code>).

Returns

An optional Boolean value: True if row is deleted, False otherwise.

Example

In the following example `DeleteRow` is used in a For loop. The example checks a value in each row, then conditionally deletes the row. Note the syntax of the For loop, including the use of the -1 in the Step clause to loop from the highest to lowest values. This ensures that the renumbering of the rows do not affect the loop.

```
For &I = &RS2.ActiveRowCount To 1 Step -1
  If None(&CHECK_SEQ) Then
    &RS2.DeleteRow(&I);
  End-If;
End-For;
```

[FlushRow](#)

[InsertRow](#)

[Insert](#)

"Using Standalone Rowsets" (PeopleCode Developer's Guide)

Fill

Syntax

```
Fill([wherestring [, bindvalue] . . . .])
```

Description

The Fill method flushes the rowset then reads records from the database into successive rows. The records are read from the database tables corresponding to the primary database record of the scroll into that record. The records are selected by the optional *wherestring* SQL clause, in which the optional *bindvalues* are substituted, using the usual bind placeholders (:*n*).

In general, use this method only with rowsets that were created using the CreateRowset function.

Note: Because Flush always leaves one row in the scroll, there will be one row in the scroll even if you don't read any records.

The actual number of records read into the rowset is an optional return of this method.

Note: This method does not work with Application Engine state records. Also, you cannot use this method in dynamic views.

When this method executes, unlike the Select method, it does *not* cause any associated PeopleCode to run as part of reading data into the rowset.

Note: Fill reads only the primary database record. It does not read any related records, nor any subordinate rowset records.

For every record read with the Fill method, if the set language is not the base language and the record has related language records, the Fill method tries to read the related language record and does related language processing.

The Fill method uses a correlation ID of FILL for the table it reads. You must use the correlation ID if you want to refer to the rowset table name as part of the *wherestring*. You receive a runtime error if you use the table name as a column prefix instead of the correlation ID.

Sorting Considerations

Rows come unsorted from the database when using Fill. This is not a problem for SQL server, however, it can be a problem for DB2 for OS/390 and z/OS and Oracle.

See [Sort](#).

Parameters

<i>Parameter</i>	<i>Description</i>
<i>wherestring</i>	Specify a SQL WHERE clause to use for selecting records to fill the rowset. This can be a string or a SQL definition.

Parameter	Description
<i>bindvalue</i>	Specify optional bind variables to be used with the WHERE clause.

Returns

The number of records read into the rowset.

Example

The following example reads all of the QA_MYRECORD records into a rowset, and returns the number of rows read:

```
&RS = CreateRowset(RECORD.QA_MYRECORD);
&NUM_READ = &RS.Fill();
```

The following example reads all of the QA_MYRECORD records that have a MYRECORD field equal to the value of &UVAL into a rowset, and returns the number of rows read:

```
&NUM_READ = &RS.Fill("where MYRECORD = :1", &UVAL);
```

To re-use a WHERE clause for the *wherestring* you can use the SQL repository, and a SQL object.

```
&NUM_READ = &RS.Fill(SQL.MYWHERE, &UVAL);
```

The following example gets all the SET_CNTRL_REC rows related to the row on the page, then updates SETID with the value from the page. Fill is used with a rowset that was created from a message that was just created, that is, a rowset that was unpopulated.

```
If FieldChanged(SETID) Then
    &MSG = CreateMessage(OPERATION.SET_CNTRL_REC);
    &MSG_ROWSET = &MSG.GetRowset();
    &MSG_ROWSET.Fill("where SETCNTRLVALUE =:1 and REC_GROUP_ID =:2", SETCNTRLVALUE, =>
REC_GROUP_ID);

For &I = 1 To &MSG_ROWSET.ActiveRowCount
    &MSG_ROWSET.GetRow(&I).SET_CNTRL_REC.SETID.Value = SETID;
    &MSG_ROWSET.GetRow(&I).PSCAMA.AUDIT_ACTN.Value = "C";
End-For;

&MSG.Publish();

End-If;
```

When using the Fill method, the IsChanged property of each field in a part rowset is not set to true. Because the fields appear to be unchanged, this can create a problem for publication of data from Message rowsets. A technique to avoid this problem is to create a second rowset and use the CopyTo method to copy the changes to the Message rowset as shown in the following example:

```
&a = CreateMessage(Operation.MY_ASYNC);
&rs = &a.GetPartRowset(1);

&trs = CreateRowset(Record.PSPMAGENT);
&trs.Fill("where PM_AGENTID >= 12345");

&trs.CopyTo(&rs);
%IntBroker.Publish(&a);
```

The following example uses a correlation ID for the table in the Fill SELECT, to enable the use of correlated subqueries in the WHERE clause, such as the usual effective-date subquery:

```
&RSOWNER_NAME = CreateRowset (RECORD.PERSONAL_D00);
&RSOWNER_NAME.Fill ("where SETID=:1 AND EMPLID=:2 AND %EffDtCheck (PERSONAL_D00,FILL,=>
:3)", &SETID, &EMPLID, &EFFDT);
```

The Fill method implicitly uses Fill as an alias for the Rowset record. This is helpful for complex Fill *where* clauses with subqueries.

```
&oprclasscountries = CreateRowset (Record.SCRTY_TBL_GBL);
&oprclasscountries.Fill ("WHERE FILL.OPRCLASS = :1 AND NOT EXISTS (SELECT 'X' FROM P=>
S_SCRTY_SEC_GBL GBL2 WHERE GBL2.OPRCLASS = FILL.OPRCLASS AND GBL2.COUNTRY = FILL.CO=>
UNTRY AND GBL2.PNLNAME = :2)", &OPRCLASS, %Component);
```

In the following example, the necessary key field values are loaded into a rowset, then the following function is called, and the values are used as part of the Fill method.

```
Function FillRS2 ();

    Local SQL &MySql;
    Local string &MySqlString;
    Local Record &ElemDefnRec;
    Local string &ElemDefnRecName, &fldname;
    Local Rowset &CompRec2RS;

    /* Build the record object that is used for building the SQL and executing the s=>
select */
    &ElemDefnRec = CreateRecord (@ ("Record." | &pkgRecName));

    /* Initialize the SQL string */
    &MySqlString = "%SelectByKey (:1 A)";

    /* Create a SQL to select a rows based on the key fields. */
    For &i = 1 To &ElemDefnRec.FieldCount
        If &ElemDefnRec.GetField (&i).IsKey Then
            &fldname = &ElemDefnRec.GetField (&i).Name;
            &ElemDefnRec.GetField (&i).Value = &CompRec2RS.GetRow (1).GetRecord (@ ("Recor=>
d." | &pkgRecName)).GetField (@ ("Field." | &fldname)).Value;
        End-If;
    End-For;

    /* Create the SQL and execute the select */
    &MySql = CreateSQL (&MySqlString);
    &MySql.Execute (&ElemDefnRec);

    /* Copy each selected row into the rowset */
    While &MySql.Fetch (&ElemDefnRec)
        &ElemDefnRec.CopyFieldsTo (&CompRec2RS (&CompRec2RS.ActiveRowCount).GetRecord (1=>
));
    End-While;

End-Function;
```

Understanding SQL Class

"CreateRowset" (PeopleCode Language Reference)

"Understanding Related Language Tables" (Global Technology)

FillAppend**Syntax**

```
FillAppend([wherestring [, bindvalue] . . .])
```

Description

The FillAppend method reads records from the database into successive rows of the rowset starting *after* the last row that exists in the rowset. Unlike Fill, it doesn't first flush the rowset.

Note: FillAppend appends rows after the last *active* row in the rowset. If you have deleted rows in the rowset, they will still be the last rows.

When a rowset is selected into, any autoselected child rowsets are also read. The child rowsets are read using a where clause that filters the rows according to the where clause used for the parent rowset, using a subselect.

When a rowset is created using CreateRowset, it contains one empty row. If the rowset hasn't been filled with data, FillAppend fills that row also (so you don't have an empty row at the start of your rowset.)

The records are read from the database tables corresponding to the primary database record of the scroll into that record. The records are selected by the optional *wherestring* SQL clause, in which the optional *bindvalues* are substituted, using the usual bind placeholders (:n).

In general, use this method only with rowsets that were created using the CreateRowset function.

The actual number of records read into the rowset is an optional return of this method.

Note: This method does not work with Application Engine state records. Also, you cannot use this method in dynamic views.

When this method executes, unlike the Select method, it does *not* cause any associated PeopleCode to run as part of reading data into the rowset.

Note: FillAppend reads only the primary database record. It does not read any related records, nor any subordinate rowset records.

For every record read with the FillAppend method, if the set language is not the base language and the record has related language records, the FillAppend method tries to read the related language record and does related language processing.

The FillAppend method uses a correlation ID of FILLAPPEND for the table it reads. You must use the correlation ID if you want to refer to the rowset table name as part of the *wherestring*. You receive a runtime error if you use the table name as a column prefix instead of the correlation ID.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>wherestring</i>	Specify a SQL WHERE clause to use for selecting records to fill the rowset. This can be a string or a SQL definition.
<i>bindvalue</i>	Specify optional bind variables to be used with the WHERE clause.

Returns

The number of records read into the rowset.

Example

The following example reads all of the QA_MYRECORD records that have a MYRECORD field equal to the value of &UVAL into a rowset, and returns the number of rows read:

```
&NUM_READ = &RS.FillAppend("where MYRECORD = :1", &UVAL);
```

To re-use a WHERE clause for the *wherestring* you can use the SQL repository, and a SQL object.

```
&NUM_READ = &RS.FillAppend(SQL.MYWHERE, &UVAL);
```

FillChunk

Syntax

```
FillChunk([[wherestring] [orderbystring] [, bindvalue] . . .], begin_row, end_row⇒  
w)
```

Description

Use the FillChunk method to read records from the database into successive rows of the rowset starting at *begin_row*. Unlike Fill, FillChunk doesn't first flush the rowset. In general, use this method only with rowsets that were created using the CreateRowset function.

When a rowset is selected into, any autoselected child rowsets are also read. The child rowsets are read using a where clause that filters the rows according to the where clause used for the parent rowset, using a subselect.

The records are read from the database tables corresponding to the primary database record of the scroll into that record. The records are selected by the optional *wherestring* SQL clause, in which the optional bind values are substituted, using the usual bind placeholders (:n).

The actual number of records read into the rowset is an optional return of this method.

Note: This method does not work with Application Engine state records. Also, you cannot use this method in dynamic views.

When this method executes, unlike the Select method, it does not cause any associated PeopleCode to run as part of reading data into the rowset.

Note: FillChunk reads only the primary database record. It does not read any related records, nor any subordinate rowset records.

For every record read with the FillChunk method, if the set language is not the base language and the record has related language records, the FillChunk method tries to read the related language record and does related language processing.

The FillChunk method uses a correlation ID of FILLAPPEND for the table it reads. You must use the correlation ID if you want to refer to the rowset table name as part of the *wherestring*. You receive a runtime error if you use the table name as a column prefix instead of the correlation ID.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>wherestring</i>	Specifies an optional SQL WHERE clause to use for selecting records to fill the rowset. This can be a string or a SQL definition.
<i>orderbystring</i>	Specifies an optional SQL ORDER BY clause.
<i>bindvalue</i>	Specifies optional bind variables to be used with the WHERE clause.
<i>begin_row</i>	Specifies the start row location in the target rowset as an integer value.
<i>end_row</i>	Specifies the end row location in the target rowset as an integer value.

Returns

(Optional) The number of rows read into the rowset.

Example

```
&RS = CreateRowset (Record.PSAUTHITEM);  
&RS.FillChunk("where FILL.CLASSID = :1 order by FILL.CLASSID, :2, :3 ", "PTMSF_CLIE⇒  
NT_USER", 6, 10);
```

Flush

Syntax

Flush ()

Description

Use the Flush method to remove all rows from the rowset and free its associated buffer. Rows that are flushed are not deleted from the database. This function is often used to clear a work scroll before using the Select method.

Note: Flush always leaves one row in the scroll.

You cannot flush the current context of the executing program. This means Flush cannot be used for the rowset containing the executing program, or in any child rowset and executed against the parent rowset. Place your PeopleCode in a parent rowset and execute it against a child rowset.

For rowsets corresponding to component buffer data, the Flush method executes in turbo mode only—that is, default processing is performed, but only on the row being flushed. Additional information on turbo mode and non-turbo mode is available in the documentation with the InsertRow PeopleCode built-in function.

See "InsertRow" (PeopleCode Language Reference).

Considerations When Initializing New Rows

Flush removes all rows and inserts a row.

If you want to initialize the row, that is, have the defaults and any RowInit PeopleCode run, you must do something to invoke the default value processing. This can be as simple as setting the value of another field on the same page that has a PeopleCode program associated with it.

If the rowset is created from message data, an Application Engine program, and so on, the rows are flushed but the row that is inserted is not initialized.

Considerations for User-Sorted Grids

If a grid has a user personalized sort defined for it and your PeopleCode program flushes that grid and then repopulates it (for instance, through a Fill, a Select, or a series of InsertRow calls), this could invalidate the user's personalized sort and the current row in the user's view unless your PeopleCode program makes arrangements to reapply these user personalizations.

After flushing and repopulating the rowset, your PeopleCode program should re-sort the rowset (that is, re-sort the grid). If the user has a personalized sort, then the user's personalized sort will be reapplied via the PeopleCode sort.

In addition, *for classic applications only*, after flushing and repopulating a grid, it will be important to manage which row is deemed the current row. This can be managed using methods such as `IsUserSorted`, `GetFirstUserSortedRow`, `MapBufRowToUserSortRow`, and then by setting the `TopRowNumber` property accordingly.

For example:

```
Local Rowset &rsGridResults = GetLevel0() (1).GetRowset(Scroll.PSWORKLIST);
&rsGridResults.Sort(PSWORKLIST.BUSPROCNAME);

/* For classic only, also identify the top row. */
If &rsGridResults.IsUserSorted("WORKLIST.PSWORKLIST") Then
    &rsGridResults.TopRowNumber = &rsGridResults.GetFirstUserSortedRow("WORKLIST.PSW⇒
ORKLIST").RowNumber;
End-If;
```

See [IsUserSorted](#).

Parameters

None.

Returns

None.

Example

The following example checks for the value of the field `CHECKLIST_CD`. If something exists in this field, the second level rowset is flushed and new values are selected into it.

```
If All(CHECKLIST_CD) Then
    &RS1H.Flush();
    &RS1H.Select(RECORD.CHECKLIST_ITEM, "where Checklist_CD = :1 and EffDt = (Select⇒
    Max(EffDt) from PS_CHECKLIST_ITEM Where CheckList_CD = :2)", CHECKLIST_CD, CHECKLI⇒
ST_CD);
End-If;
```

[FlushRow](#)

[DeleteRow](#)

[InsertRow](#)

FlushRow

Syntax

FlushRow (*n*)

Description

Use the FlushRow method to remove a specific row from a rowset and from the Component buffer. Rows that are flushed are not deleted from the database.

FlushRow is a specialized and infrequently used method. In most situations, you want to use DeleteRow to remove a row from the Component buffer and remove it from the database as well when the component is saved.

You cannot flush the current context of the executing program. This means FlushRow cannot be used for the rowset containing the executing program, or in any child rowset and executed against the parent rowset. Place your PeopleCode in a parent rowset and execute it against a child rowset.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n</i>	An integer identifying a row within the rowset object. This must be ≥ 1 and \leq the number of rows in the rowset (see property RowCount).

Returns

None.

Example

```
&ROWSET.FlushRow (&ROWNUMBER);
```

Related Links

[DeleteRow](#)

[Flush](#)

[InsertRow](#)

GetCurrEffRow

Syntax

```
GetCurrEffRow ()
```

Description

GetCurrEffRow returns a row object for the row with the current effective date. This includes dates equal to the current date, but not dates in the future. If the primary record associated with the rowset is not effective-dated this method returns a null object.

Newly inserted rows are intentionally skipped when looking for the current effective-dated row. This is to find the current effective row from the data that already exists in the database. In other words, a row

cannot be considered as a current effective row until it is saved. To find the current effective-dated row in data that has been newly inserted and not yet saved, use the `GetNewEffRow` method instead.

Parameters

None.

Returns

A row object for the row with the current effective date.

Example

```
&tmp = &ROWSET.GetCurrEffRow().RowNumber;
/* note RowNumber is a property of the row class */
```

Related Links

[DeleteEnabled](#)

[GetRow](#)

[GetNextEffRow](#)

[GetNewEffRow](#)

"GetRow" (PeopleCode Language Reference)

GetFirstUserSortedRow

Syntax

```
GetFirstUserSortedRow (GridName)
```

Description

Use this method to get the first row from a sort view.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>GridName</i>	Specify the grid name as a string in PAGE.RECORD format in which PAGE is the page name and RECORD is the name of the grid as defined in Application Designer. (In Application Designer, select Page Field Properties, General tab to view the value for the Page Field Name field. The Page Field Name field's value defaults to the primary record name for the level at which the grid occurs; however, the value can be changed by the application developer.)

Returns

A row object for the first row from the sort view.

If the grid has not been sorted, the output row object is equivalent to the first row from the rowset.

Related Links

[IsUserSorted](#)

GetLastUserSortedRow

Syntax

```
GetLastUserSortedRow(GridName [, visible])
```

Description

Use this method to get the last row from a sort view.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>GridName</i>	Specify the grid name as a string in PAGE.RECORD format in which PAGE is the page name and RECORD is the name of the grid as defined in Application Designer. (In Application Designer, select Page Field Properties, General tab to view the value for the Page Field Name field. The Page Field Name field's value defaults to the primary record name for the level at which the grid occurs; however, the value can be changed by the application developer.)
<i>visible</i>	Specify, as an optional Boolean parameter, whether to return the absolute last row from the rowset, which could be hidden, or the last visible row from the sort view. If true, the last visible row is returned; otherwise, the absolute last row from the rowset is returned. The default value is false—that is, return the absolute last row.

Returns

A row object for the last row from the sort view (*visible* is true) or the absolute last row from the rowset (*visible* is false).

Related Links

[IsUserSorted](#)

GetNewEffRow

Syntax

```
GetNewEffRow()
```

Description

GetNewEffRow returns a row object for the row with the effective date closest to the current date, including newly inserted rows. This means dates equal to the current date, but not future dates. If the primary record associated with the rowset is not effective-dated this method returns a null object.

To find the current effective-dated row from the data that already exists in the database, that is, only from saved rows and *not* a newly created row, use the GetCurEffRow method instead.

Parameters

None.

Returns

A row object for the row with the current effective date.

Example

```
Local Row &MyRow = &ROWSET.GetNewEffRow();
```

Related Links

[GetRow](#)

[GetNextEffRow](#)

[GetCurrEffRow](#)

[DeleteEnabled](#)

"GetRow" (PeopleCode Language Reference)

GetRow

Syntax

```
GetRow(n)
```

Description

GetRow returns a row object from a rowset. This is a default method for rowsets. This means that any rowset object, followed by a parameter list, acts as if GetRow is specified.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n</i>	An integer identifying a row within the rowset object. This must be ≥ 1 and \leq the number of rows in the rowset (see property RowCount).

Returns

Returns a row object for the specified row of the rowset.

Example

In the following example, all of the lines of code do the same thing: they return the 5th row from the rowset (&ROWSET is a rowset object.)

```
&ROW = GetRowset().GetRow(5);
&ROW = GetRowset()(5);
&ROW = &ROWSET.GetRow(5);
&ROW = &ROWSET(5);
```

The following example loops through all the rows in a rowset:

```
Local rowset &LEVEL1;
Local row &ROW;

&LEVEL1 = GetRowset(SCROLL.EMPL_CHECKLIST);
For &I = 1 to &LEVEL1.ActiveRowCount
    &ROW = &LEVEL1.GetRow(&I);
    /* do some processing */
End-For;
```

Related Links

"GetRow" (PeopleCode Language Reference)

HideAllRows

Syntax

```
HideAllRows()
```

Description

HideAllRows hides all rows of the rowset. Using this method is equivalent to a loop setting the visible property of each row of the rowset to False.

You cannot hide rows in the current context of the executing program. This means HideAllRows cannot hide the rowset containing the executing program, or in any child rowsets and be executed against the parent rowset. Place your PeopleCode in a parent rowset and execute it against a child rowset.

Parameters

None.

Returns

None.

Example

The following example hides the second level scroll if a value exists in the NO_COMMENTS field in the first level of the scroll. The code is running from the first level of the scroll.

```
Local Rowset &RS1, &RS2;

&RS1 = GetRowset();
&RS2 = GetRowset(SCROLL.EMPL_CHKLIST_ITM);

For &I = 1 to &RS1.ActiveRowCount
  If ALL(&RS1.GetRow(&I).EMPLOYEE_CHECKLIST.NO_COMMENTS) Then
    &RS2.HideAllRows();
  End-If;
/*other processing */
End-For;
```

Related Links

[ShowAllRows](#)

[Visible](#)

InsertRow

Syntax

```
InsertRow(n)
```

Description

InsertRow programmatically performs the **ALT+7** and **ENTER** (RowInsert) function. InsertRow inserts a new row in the current rowset *after* the row specified by the parameter if the primary record for the rowset is not effective-dated or a standalone rowset. If the primary record for the rowset is effective-dated or a standalone rowset, the new row is inserted *before* the current row, and all values from the current row are copied into the new row, except for EFFDT, which is set to the current date.

In addition, InsertRow propagates the keys from the higher level (if any) into the inserted row.

If the program is being run from a component against Component buffer data, a RowInit PeopleCode event also fires, followed by the events that normally follow a RowInsert, as if the user had manually pressed **ALT+7** and **ENTER**.

The InsertRow method can be executed against the same rowset where the insertion will take place.

For rowsets corresponding to component buffer data, the InsertRow method executes in turbo mode only—that is, default processing is performed, but only on the row being inserted. Additional information on

turbo mode and non-turbo mode is available in the documentation with the InsertRow PeopleCode built-in function.

See "InsertRow" (PeopleCode Language Reference).

InsertRow cannot be executed from the same rowset where the insertion will take place, or from a child rowset against a parent. Place your PeopleCode in a parent rowset and execute it against a child rowset.

Note: If you use InsertRow on a rowset created using the CreateRowset function, the row isn't automatically inserted in the database when the page is saved. Rowsets created using the CreateRowset function are standalone rowsets, not tied to the database, so there are no database updates when they are manipulated. Delete and insert activity on these types of rowsets aren't automatically applied at save time.

Effective-Dated Row Considerations

When a row is inserted, if that row contains child scrolls, this method also inserts an empty row for any child scrolls. The effective-date field for this empty row is also empty. The current date is *not* used.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>n</i>	An integer identifying a row within the rowset object. This must be ≥ 0 and \leq the number of active rows in the rowset (see property ActiveRowCount). A value of 0 inserts in front of the first row.

Returns

An optional Boolean value: True if the row is inserted, False if the row is not inserted.

Example

In the following example, as the primary database record isn't effective-dated, the new row is inserted *after* the second row in the rowset.

```
&ROWSET.InsertRow(2);
```

[Delete](#)

"Using Standalone Rowsets" (PeopleCode Developer's Guide)

IsUserSorted

Syntax

```
IsUserSorted(GridName)
```

Description

Use this method to determine whether a user sort has been performed on the specified grid.

A *user sort* is defined as a user either having clicked on a column heading on the grid or having applied a sort order on the grid's customization page. In the case of a user sort, a *sort view* is created based on the sort order defined by the user. Since this sort view is for display purposes only, the underlying buffer is not sorted and remains in the non-sorted order. Four additional methods (`GetFirstUserSortedRow`, `GetLastUserSortedRow`, `MapBufRowToUserSortRow`, and `MapUserSortRowToBufRow`) enable you to interrogate this sort view. These methods can be used to map the sort view to the buffer, to map the buffer to the sort view, to retrieve the first user-sorted row, and to retrieve the last user-sorted row.

Note: When a grid includes a hyperlink field that is user-sortable, the hyperlink label must be set in `PeopleCode` prior to allowing the user to perform the sort. Alternatively, the buffer can be sorted on the hyperlink field in `PeopleCode` upon entry into the page.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>GridName</i>	Specify the grid name as a string in PAGE.RECORD format in which PAGE is the page name and RECORD is the name of the grid as defined in Application Designer. (In Application Designer, select Page Field Properties, General tab to view the value for the Page Field Name field. The Page Field Name field's value defaults to the primary record name for the level at which the grid occurs; however, the value can be changed by the application developer.)

Returns

A Boolean value: true if a user sort has been performed on the grid, false otherwise.

[MapUserSortRowToBufRow](#)

[Sort](#)

MapBufRowToUserSortRow

Syntax

```
MapBufRowToUserSortRow(GridName, number)
```

Description

Use this method to return the sort view row number that corresponds to the specified buffer row number.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>GridName</i>	Specify the grid name as a string in PAGE.RECORD format in which PAGE is the page name and RECORD is the name of the grid as defined in Application Designer. (In Application Designer, select Page Field Properties, General tab to view the value for the Page Field Name field. The Page Field Name field's value defaults to the primary record name for the level at which the grid occurs; however, the value can be changed by the application developer.)
<i>number</i>	Specify the row number of the row in the buffer.

Returns

The row number, as a number, of the row in the sort view.

If the grid has not been sorted, the output row number is the same as the buffer row number.

Example

```
&szSortViewName = "QE_PIA_SORT_GRID1.L2RSSORTTEST";
Local Rowset &rsCurrent = GetLevel0() (1).GetRowset(Scroll.QE_PIA_SORTEST2) (1).GetRowset(Scroll.QE_PIA_SORTEST3);

If &rsCurrent.IsUserSorted(&szSortViewName) Then
    WinMessage("QE_PIA_SORT_GRID1-Rowset1 User Sorted");
Else
    WinMessage("QE_PIA_SORT_GRID1-Rowset1 Not User Sorted");
End-If;

For &I = 1 To &rsCurrent.ActiveRowCount
    &index = &rsCurrent.MapBufRowToUserSortRow(&szSortViewName, &I);
    WinMessage("QE_PIA_SORT_GRID1-Rowset1, Buffer Row Index: " | &I | ", Sort Row =>
Index: " | &index | ", Description: " | &rsCurrent(&I).QE_PIA_SORTEST3.DESCR30.Value);
End-For;
```

Related Links

[IsUserSorted](#)

MapUserSortRowToBufRow

Syntax

```
MapUserSortRowToBufRow(GridName, number)
```

Description

Use this method to return the buffer row number that corresponds to the specified sort view row number.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>GridName</i>	Specify the grid name as a string in PAGE.RECORD format in which PAGE is the page name and RECORD is the name of the grid as defined in Application Designer. (In Application Designer, select Page Field Properties, General tab to view the value for the Page Field Name field. The Page Field Name field's value defaults to the primary record name for the level at which the grid occurs; however, the value can be changed by the application developer.)
<i>number</i>	Specify the row number of the row in the sort view.

Returns

The row number, as a number, of the row in the buffer.

If the grid has not been sorted, the output row number is the same as the buffer row number.

Example

```
&szSortViewName = "QE_PIA_SORT_GRID1.L2RSSORTTEST";
Local Rowset &rsCurrent = GetLevel0() (1).GetRowset(Scroll.QE_PIA_SORTEST2) (2).GetRowset(Scroll.QE_PIA_SORTEST3);

If &rsCurrent.IsUserSorted(&szSortViewName) Then
    WinMessage("QE_PIA_SORT_GRID1-Rowset2 User Sorted");
Else
    WinMessage("QE_PIA_SORT_GRID1-Rowset2 Not User Sorted");
End-If;

For &I = 1 To &rsCurrent.ActiveRowCount
    &index = &rsCurrent.MapUserSortRowToBufRow(&szSortViewName, &I);
    WinMessage("QE_PIA_SORT_GRID1-Rowset2, Description: " | &rsCurrent(&index).QE_PIA_SORTEST3.DESCR30.Value);
End-For;
```

[IsUserSorted](#)

Refresh

Syntax

Refresh ()

Description

Refresh reloads the rowset object from the database using the current page keys. This causes the page to be redrawn. The following code example refreshes the entire page:

```
GetLevel0().Refresh()
```

Important! Do not call `GetLevel0().Refresh()` from any context that is not at level 0. You are likely to leave invalid pointers to objects that have been cleared from the buffer, which can result in an application server crash.

If you only want a specific scroll to be redrawn, you can use the refresh method with that rowset. You don't have to use a level zero rowset with this method. This is particularly useful after using `RemoteCall`.

Note: If a scroll is marked as No Auto Select in Application Designer, Refresh will not work on it. The Refresh method clears the existing buffers and does a refresh from the database. You do *not* want to use this method if your rowset is based on message data. Instead, you can use the `CopyTo Rowset` method combined with `TransferPage`.

Parameters

None.

Returns

None.

Example

The following example refreshes the entire page.

```
&MyLevel0 = GetLevel0().Refresh();
```

The following example refreshes only the second level scroll of the page:

```
&RowSetLevel2.Refresh();
```

Related Links

[CopyTo](#)

"RemoteCall" (PeopleCode Language Reference)

"TransferPage" (PeopleCode Language Reference)

Select

Syntax

```
Select([paramlist], RECORD.selrecord [, wherestr, bindvars])
```

Where *paramlist* is a list of child rowsets, given in the following form:

```
SCROLL.scrollname1 [, SCROLL.scrollname2] . . .
```

The first *scrollname* must be a child rowset of the rowset object executing the method, the second *scrollname* must be a child of the first child, and so on.

Description

Select, like the related method SelectNew, reads data from the database tables or views into either a row or rowset object.

Note: This method is valid only when used with rowsets that reference data from the component buffers. You cannot use this method with a message rowset, a rowset from an Application Engine state record, and so on. You can't use this method with rowsets created using the CreateRowset function (use the Fill method instead.)

Select automatically places child rowsets in the rowset object executing the method under the correct parent row. If it cannot match a child rowset to a parent row, an error occurs.

When a rowset is selected into, any autoselected child rowsets is also read. The child rowsets are read using a where clause that filters the rows according to the where clause used for the parent rowset, using a subselect.

If you don't specify any child rowsets in *paramlist*, Select selects from a SQL table or view specified by *selrecord* into the rowset object executing the method.

If you specify a child rowset in *paramlist*, Select selects from a SQL table or view specified by *selrecord* into the child rowset specified in *paramlist*, under the appropriate row of the rowset executing the method.

If the rowset executing the method is a level zero rowset, and you specify Select without specifying any child rowsets with *paramlist*, the method reads only a single row, because only one row is allowed at level zero.

The rowset executing the method *does not* have to be a level zero rowset, so the Select method can produce the functionality of both the ScrollSelect and RowScrollSelect functions.

Note: For developers familiar with previous releases of PeopleCode: If the rowset executing the method is a level zero rowset, and you specify a child rowset with *paramlist*, this method functions exactly like ScrollSelect. If the rowset executing the method is not a level zero rowset, and no child rowsets are specified with *paramlist*, the method acts like RowScrollSelect.

The record definition of the table or view being selected from is called the *select record*, and identified with **RECORD**. *selrecord*. The select record can be the same as the primary database record associated with the rowset, or it can be a different record definition that has compatible fields. If you define a select record that differs from the primary database record for the rowset, you can restrict the number of fields that are loaded into the buffers on the client workstation by including only the fields that you actually need.

Select accepts a SQL string that can contain a WHERE clause restricting the number of rows selected into the object. The SQL string can also contain an ORDER BY clause to sort the rows.

Select and its related methods generate a SQL SELECT statement at runtime, based on the fields in the select record and the WHERE clause passed to them in the method parameters.

For rowsets corresponding to component buffer data, the Select method executes in turbo mode only—that is, default processing is performed, but only on the row being selected. Additional information on turbo mode and non-turbo mode is available in the documentation with the InsertRow PeopleCode built-in function.

See "InsertRow" (PeopleCode Language Reference).

Parameters

Parameter	Description
<i>paramlist</i>	An optional parameter list, for specifying children rowsets of the rowset executing the method, as the rowset to be selected into. The first <i>scrollname</i> in <i>paramlist</i> must be a child rowset of the rowset executing the method, the second <i>scrollname</i> must be a child of the first child, and so on.
RECORD . <i>selrecord</i>	Specifies the select record. The <i>selrecord</i> record must be defined in Application Designer and be a build SQL table (using Build, Project) as a table or a view, unless <i>selrecord</i> is the same record as the primary database record associated with the rowset. <i>selrecord</i> can contain fewer fields than the primary record associated with the rowset, although it must contain any key fields to maintain dependencies with other records.
<i>wherestr</i>	Contains a WHERE clause to restrict the rows selected from <i>selrecord</i> and/or an ORDER BY clause to sort the rows. The WHERE clause can contain the PeopleSoft meta-SQL functions such as %DateIn() or %CurrentDateIn. It can also contain inline bind variables.
<i>bindvars</i>	A list of bind variables to be substituted in the WHERE clause. The same restrictions that exist for SQLExec exist for these variables. See SQLExec for further information.

Returns

The number of rows read (optional.) This counts only the lines read into the specified rowset. It does not include any additional rows read into any child rowsets of the rowset.

Example

The following example selects into the level zero rowset, only one row. Depending on the autoselect settings on any child scrolls, they may be reselected too.

```
&LEVEL0 = GetLevel0();
&LEVEL0.Select(RECORD.PERSONAL_DATA, "WHERE. . .");
```

The following example selects into the level one scroll specified. Depending on the autoselect settings on any child (level two) scrolls, they may also be selected.

```
&LEVEL0.Select(SCROLL.EMPL_CHECKLIST, RECORD.EMPL_CHECKLIST, "WHERE. . .");
```

The following example selects into the child scroll of the level one rowset. Each row fetched is placed under the appropriate row in &LEVEL1. Note that instead of hard-coding the WHERE clause, the SQL repository is used to access a SQL definition named SELECT_WHERE.

```
&LEVEL1 = &LEVEL0 () (1).GetRowset (SCROLL.EMPL_CHECKLIST);
&LEVEL1.Select (SCROLL.EMPL_CHKLIST_ITM, RECORD.EMPL_CHKLIST_ITM, SQL.SELECT_WHERE);
```

The following example first flushes the hidden work scroll, then selects into it based on a field on the page.

```
&RS1H.Flush();
&RS1H.Select (RECORD.CHECKLIST_ITEM, "where Checklist_CD = :1 and EffDt = (Select Ma⇒
x(EffDt) from PS_CHECKLIST_ITEM Where CheckList_CD = :2)", CHECKLIST_CD, CHECKLIST_⇒
CD);
```

Related Links

[SelectNew](#)

[SelectByKey](#)

SelectNew

Syntax

```
SelectNew([parmlist], RECORD.selrecord [, wherestr, bindvars])
```

Where *parmlist* is a list of child rowsets, given in the following form:

```
SCROLL.scrollname1 [, SCROLL.scrollname2] . . .
```

The first *scrollname* must be a child rowset of the rowset executing the method, the second *scrollname* must be a child of the first child, and so on.

Description

The SelectNew method is similar to the Select method, except that all rows read into the rowset are marked *new* so they are automatically inserted into the database at Save time. This capability can be used, for example, to insert new rows into the database by selecting data using a view of columns from other database tables.

Note: This method is valid only when used with rowsets that reference data from the Component buffers. You cannot use this method with a message rowset, a rowset from an Application Engine state record, and so on. You can't use this method with rowsets created using the CreateRowset function (use the Fill method instead.)

Parameters

Parameter	Description
<i>paramlist</i>	An optional parameter list, for specifying children rowsets of the rowset executing the method, as the rowset to be selected into. The first <i>scrollname</i> in <i>paramlist</i> must be a child rowset of the rowset executing the method, the second <i>scrollname</i> must be a child of the first child, and so on.
RECORD . <i>selrecord</i>	Specifies the select record. The <i>selrecord</i> record must be defined in Application Designer and be a build SQL table (using Build, Project) as a table or a view, unless <i>selrecord</i> is the same record as the primary database record associated with the rowset. <i>selrecord</i> can contain fewer fields than the primary record associated with the rowset, although it must contain any key fields to maintain dependencies with other records.
<i>wherestr</i>	Contains a WHERE clause to restrict the rows selected from <i>selrecord</i> and/or an ORDER BY clause to sort the rows. The WHERE clause can contain the PeopleSoft meta-SQL functions such as %DateIn() or %CurrentDateIn. It can also contain inline bind variables.
<i>bindvars</i>	A list of bind variables to be substituted in the WHERE clause. The same restrictions that exist for SQLExec exist for these variables. See SQLExec for further information.

Returns

The number of rows read (optional.) This counts only the lines read into the specified rowset. It does not include any additional rows read into any child rowsets of the rowset.

Example

The following example selects rows from DATA2 and reads them into a level one scroll. If the user saves the page, these rows are inserted into DATA1.

```
&LEVEL0.SelectNew(SCROLL.DATA1, RECORD.DATA2, "Where SETID = :1 and CUST_ID =:2", C⇒
USTOMER.SETID, CUSTOMER.CUST_ID);
```

If you use the same WHERE clause in more than one Select, you may want to use the SQL repository to store the SQL fragment. That way, if you ever want to change it, you will have to change it in only one place.

```
&LEVEL0.SelectNew(SCROLL.DATA1, RECORD.DATA2, SQL.Select_New);
```

Related Links

[Select](#)

[SelectByKey](#)

SetDefault

Syntax

```
SetDefault (recname.fieldname)
```

Description

The SetDefault method sets the value of the specified *recname.fieldname* to a null value in every row of the rowset. If this method is being run from a component against Component buffer data, the next time default processing is performed, this value is reinitialized to its default value: either a default specified in its record field definition or one set programmatically by PeopleCode located in a FieldDefault event. If neither of these defaults exist, the Component Processor leaves the field blank.

No default processing is performed against data that is not in the Component buffers.

Blank numbers correspond to zero on the database. Blank characters correspond to a space on the database. Blank dates and long characters correspond to NULL on the database. SetDefault gives each field data type its proper value.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>recname.fieldname</i>	Specifies a field. The field must be in the specified record, on the rows of the rowset.

Returns

None.

Example

This example resets the PROVIDER to its null value. This field is reset to its default value when default processing is next performed:

```
If COVERAGE_SELECT = "W" Then
    &ROWSET.SetDefault(INS_NAME_TBL.PROVIDER);
End-if;
```

Related Links

[SetDefault](#)

"Default Processing" (PeopleCode Developer's Guide)

ShowAllRows

Syntax

```
ShowAllRows ()
```

Description

ShowAllRows "unhides" all rows of the rowset object executing the method. Using this method is equivalent to a loop setting the visible property of each row of the rowset to True.

ShowAllRows cannot be executed from the same rowset you want to display, or from a child rowset against a parent. Place your PeopleCode in a parent rowset and execute it against a child rowset.

Parameters

None

Returns

None.

Example

```
&ROWSET.ShowAllRows();
```

Related Links

[HideAllRows](#)

[Visible](#)

Sort

Syntax

```
Sort([paramlist,] sort_fields)
```

Where *paramlist* is a list of child rowsets, given in the following form:

```
SCROLL.scrollname1 [, SCROLL.scrollname2] . . .
```

The first *scrollname* must be a child rowset of the rowset executing the method, the second *scrollname* must be a child of the first child, and so on.

And where *sort_fields* is a list of field specifiers in the form:

```
[recordname.]field_1, order_1 [, [recordname.]field_2, order_2]_
```

Description

Sort programmatically sorts the rows in a rowset. The rows can be sorted on one or more fields.

If you specify a child rowset in *paramlist*, Sort selects a set of child rowsets to be sorted. If you don't specify a child rowset in *paramlist*, the rowset executing the method is sorted.

The type of sort done by this function, that is, whether it is a linguistic or binary sort, is determined by the Sort Order Option on the PeopleTools Options page.

Note: The Sort method sorts only *visible* rows in a rowset. If the rowset you're sorting has hidden rows, the hidden rows are not sorted. Rows marked for deletion are also not sorted.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>paramlist</i>	An optional parameter list, for specifying children rowsets of the rowset executing the method, as the rowset to be sorted. The first <i>scrollname</i> in <i>paramlist</i> must be a child rowset of the rowset executing the method, the second <i>scrollname</i> must be a child of the first child, and so on.
<i>sort_fields</i>	A list of field and order specifiers which act as sort keys. The rows in the rowset will be sorted by the first field in either ascending or descending order, then by the second field in either ascending or descending order, and so on.
[<i>recordname</i>]. <i>field_n</i>	Specifies a sort key field in the rowset. The <i>recordname</i> prefix is required if you've specified a field that is not on the current record.
<i>order_n</i>	A single-character string. "A" specifies ascending order; "D" specifies descending order.

Returns

None.

Example

The first example repopulates a rowset in a page programmatically by first flushing its contents, selecting new contents using Select, then sorting the rows in ascending order by EXPORT_OBJECT.NAME:

```
Function populate_rowset;

    &RS1 = GetLevel0() (1).GetRowset(Scroll.EXPORT_OBJECT);
    &RS1.Flush();
    &RS1.Select(Record.EXPORT_OBJECT, "where export_type =:EXPORT_TYPE_VW.EXPORT_TYP⇒
E");
    &RS1.Sort(EXPORT_OBJECT.NAME, "A");

End-Function;
```

[IsUserSorted](#)

[Select](#)

[GetRowset](#)

Rowset Class Properties

In this section, we discuss the Rowset class properties. The properties are discussed in alphabetical order.

ActiveRowCount

Description

This property returns the number of active (non-deleted) rows in the rowset.

This property returns a value of 1 for an empty scroll (Flush always leaves an empty row.) You can use the `IsChanged` or `IsNew` properties to verify if the row is new.

This property is read-only.

Example

```
&tmp = &ROWSET.ActiveRowCount;
```

ChangeOnInit

Description

Normally, if a field value is changed, whether through `PeopleCode` or by an end user, the `IsChanged` property for the row is set to `True`. The exception to this is when a change is done in the `FieldDefault` or `FieldFormula` event, that is, if a value is set in one of these events, the row is not marked as changed.

At save time, all newly inserted *and* changed rows are written to the database. All newly inserted but *not* changed rows are *not* written to the database.

Use this property to specify whether a change made to a new row from `RowInit` or `RowInsert` `PeopleCode` is marked as changed. This property takes a Boolean value. The default value is `True`.

Setting this property to `False` causes changes to fields for the rowset done in `RowInit` and `RowInsert` `PeopleCode` to *not* mark a new row as `IsChanged`.

This property is read/write.

Runtime Considerations

You must set this property *before* anything is changed for a row, otherwise the row is marked as changed.

This property propagates to child rowsets. That is, if it's set for a parent rowset before doing an insert row, it's automatically set on any and all child rowsets.

In addition, parent rows are marked as changed if this property is set only for the child rowset. That is, if you've changed a level three child of a level two row, the level two and level one rows are marked as changed to maintain data integrity.

DataAreaCollapsed

Description

This property specifies whether the view of a data area is collapsed or expanded.

Note: You must set the Collapsible Data Area field on the properties for the level-based control for this property to have any effect.

This property changes to reflect the current state of the data area, according to whether the user has collapsed or expanded it. Changing the value collapses or expands the data area, but it does *not* prevent the user from collapsing (or expanding) it themselves.

Note: Because the user can change the value of this property, whatever value is set in PeopleCode isn't guaranteed to be still set the next time it is checked, because the user may have collapsed or expanded the data area in the meantime.

This property overwrites the value of the Default Initial View to Expanded field set in Application Designer. For example, if Default Initial View to Expanded is selected in Application Designer, then the value for the DataAreaCollapsed property is set to True, the control initially displays collapsed.

This property takes a Boolean value: True, initially display the data area collapsed, False, initially display the data area expanded.

This property is read/write.

Note: To collapse just a group box, use the DataAreaCollapsed field method.

Related Links

[DataAreaCollapsed](#)

Example

The following example checks the number of rows in the level one rowset. If the number of rows returned is larger than 100, the data area is initially displayed collapsed.

```
If &Level1.RowCount > 100 Then
    &Level1.DataAreaCollapsed = True;
Else
    &Level1.DataAreaCollapsed = False;
End-If;
```

DBRecordName

Description

This property returns the name of the primary database record as a string for the rowset.

This property is read-only.

Example

```
&DBNAME = &ROWSET.DBRecordName;
```

DeleteEnabled

Description

This property determines whether a rowset allows rows to be deleted (the equivalent of the user pressing **ALT+8** and **ENTER**). This property takes a Boolean value.

Note: This property controls only whether an end-user can delete a row. Rows can still be deleted using PeopleCode.

The initial value of this property depends on how the scroll was created at design time. If the No Row Delete setting is selected on the Use tab of the scroll properties dialog box, DeleteEnabled will be False; otherwise it will be True.

Note: If No Row Delete is selected in Application Designer, setting DeleteEnabled to True will *not* override this value. To control whether a rowset allows deletions at runtime, you should *not* select No Row Delete at design time.

For consistency, PeopleSoft recommends that either all rowsets at a level should disable deletions, or they should all allow deletions.

For rowsets created with non-Component Processor data (such as message rowsets, Application Engine rowsets, and so on) this property has no effect.

Note: Don't use this property with rowsets that are created using CreateRowset. Rowsets created using the CreateRowset function are standalone rowsets, not tied to the database, so there are no database updates when they are manipulated. Delete and insert activity on these types of rowsets aren't automatically applied at save time.

This property is read/write.

Related Links

[DeleteEnabled](#)

[InsertEnabled](#)

"Using Scroll Areas and Scroll Bars" (Application Designer Developer's Guide)

"Using Standalone Rowsets" (PeopleCode Developer's Guide)

EffDt

Description

This property references the effective date of the primary record associated with the rowset. If the primary record associated with the rowset is not effective-dated, this property has a null value. To find the primary record associated with a rowset object, you can use the DBRecordName property.

Note: This property isn't valid with rowsets created using the `CreateRowset` function.

This property is read-only.

Example

```
&tmp = &ROWSET.EffDt;
```

"CreateRowset" (PeopleCode Language Reference)

EffSeq

Description

This property references the effective-sequence number of the primary record associated with the rowset. If the primary record associated with the rowset does not have an effective-sequence number, this property has the value 0. To find the primary record associated with a rowset object, you can use the `DBRecordName` property.

Note: This property isn't valid with rowsets created using the `CreateRowset` function.

This property is read-only.

Example

```
&tmp = &ROWSET.EffSeq;
```

Related Links

"CreateRowset" (PeopleCode Language Reference)

InsertEnabled

Description

This property determines whether a rowset allows rows to be inserted (the equivalent of the user pressing **ALT+7** and **ENTER**). This property takes a Boolean value.

Note: This property controls only whether an end-user can insert a row. Rows can still be inserted using PeopleCode.

The initial value of this property depends on a value set at design time. If the No Row Insert setting is selected on the Use tab of the scroll properties dialog box, `InsertEnabled` is `False`; otherwise it is `True`.

Note: If No Row Insert is selected in Application Designer, setting `InsertEnabled` to `True` does *not* override this value. To control whether a rowset allows inserts at runtime, you should *not* select No Row Insert at design time.

For consistency, PeopleSoft recommends that either all rowsets at a level should disable inserts, or they should all allow inserts.

For rowsets created with non-Component Processor data (such as message rowsets, Application Engine rowsets, and so on) this property has no effect.

Note: Don't use this property with rowsets created using `CreateRowset`. Rowsets created using the `CreateRowset` function are standalone rowsets, not tied to the database, so there are no database updates when they are manipulated. Delete and insert activity on these types of rowsets aren't automatically applied at save time.

This property is read/write.

"Using Standalone Rowsets" (PeopleCode Developer's Guide)

IsEditError

Description

This property is True if an error has been found on any field in any record in any row or child rowset of the current rowset after executing the `ExecuteEdits` method on either a message object or a record object. This property can be used with the Field Class properties `EditError` (to find the field that's in error), `MessageSetNumber` and `MessageNumber` to find the error message set number and error message number.

This property is read-only.

Example

The following is an example showing how `IsEditError`, along with `ExecuteEdits` could be used:

```
&REC.ExecuteEdits();
If &ROWSET.IsEditError Then
  For &I = 1 to &ROWSET.ActiveRowCount
    &ROW = &ROWSET(&I);
    For &J to &ROW.RecordCount
      &REC = &ROW.GetRecord(&J);
      For &K = 1 to &REC.FieldCount
        If &REC.GetField(&K).EditError Then
          LOG_ERROR();
          /* application specific call */
        End-If;
      End-For;
    End-For;
  End-For;
End-If;
```

Related Links

[ExecuteEdits](#)

[IsEditError](#)

EditError
MessageNumber
MessageSetNumber

Level

Description

This property returns the level, that is, the nesting depth, of the rowset object. The top-level rowset has a level number of 0.

This property is read-only.

Example

```
&tmp = &ROWSET.Level;
```

Name

Description

This property refers to the name of the rowset. This property returns different values, based on the type of rowset.

<i>Type of Rowset</i>	<i>Returns</i>
Rowset created using GetLevel0	returns an empty string
Component buffer rowset	returns primary record name
Message rowset	returns primary record name
Component Interface rowset	returns primary record name
Application Engine rowset	always returns AESTATE

This property is read-only.

Example

```
&tmp = &ROWSET.Name;
```

ParentRow

Description

This property returns a row object containing a reference to the parent row, that is, the row containing the rowset. If this is a top-level rowset (level zero), the ParentRow property has a null value.

This property is read-only.

Example

```
&tmp = &ROWSET.ParentRow.RowNumber;  
/* note that RowNumber is a property of the row class */
```

ParentRowset

Description

This property returns a rowset object containing a reference to the parent rowset, that is, the rowset containing the rowset. If this is a top-level rowset (level zero), the ParentRowset property has a null value.

This property is read-only.

Example

```
&tmp = &ROWSET.ParentRowset.Level;  
/* note Level is another property of the rowset class */
```

RowCount

Description

This property returns the total number of rows in the rowset. It includes deleted rows. (The ActiveRowCount property doesn't include deleted rows.)

This property is read-only.

Example

```
&tmp = &ROWSET.RowCount;
```

SetComponentChanged

Description

This property determines whether any changes to the rowset using PeopleCode marks the component as changed and the data written to the database if the rowset is not based on a derived/work record.

This property takes a Boolean value: true, changes to the rowset mark the component as changed, false, the component is treated as if unchanged. The default is true.

If you set this property to false, this means that no row insert, row delete, field change on the rowset using `PeopleCode` would cause the system to treat the component data as changed.

The `SetComponentChanged` rowset class property overrides the `SetComponentChanged` field class property. If a field has `SetComponentChanged` set to true, but its associated rowset has `SetComponentChanged` set to false, any change to the field does not mark the component as changed.

This property is read/write.

Related Links

[SetComponentChanged](#)

TopRowNumber

Description

This property returns the row that is being displayed at the top of the scroll (if any) for the rowset.

Generally, this property is used to return the top row number of a scroll. However, sometimes you want to reposition the scroll. For example, if you use `SetCursorPos` to move the focus to a given field, there is no guarantee that the row containing the field is at the top of the scroll.

This property is read/write.

RowsetCache Class

Understanding a Rowset Cache

Many PeopleSoft applications use a metadata based design, where application PeopleCode reads metadata from a database record or some other source, then presents the user with an interface that is modified based on the metadata.

PeopleTools stores application data in a database cache to increase system performance. The RowsetCache class enables you to access this memory structure, created at runtime, and shared by all users.

Data that would qualify as metadata and would be appropriate for the RowsetCache class would be data that was commonly used yet fairly static, for example, country or currency tables.

The RowsetCache class does not provide a mechanism for synchronizing the data between database tables and the cache. If the underlying data changes, you must repopulate the rowset cache.

Note: Non-base language users may see different performance due to language table considerations.

Related Links

"Setting MaxCacheMemory" (PeopleCode Developer's Guide)

"Cache Settings" (System and Server Administration)

Using the RowsetCache Class

The first time a user accesses a database, the rowset cache for that database is automatically created and populated. After that first user, all users and applications can take advantage of the rowset cache.

If the underlying data for a rowset cache changes, at the very least your application must delete the existing rowset cache. Your application can also delete, then recreate and repopulate the rowset cache if it changes the underlying data. For example:

```
Local Rowset &RS;  
Local RowsetCache &CRS;  
Local Boolean &RSLT = False;  
  
Repeat  
    &I = &I + 1;  
    If &RS (&I).IsChanged Then  
        &RSLT = True;  
    End-If;  
Until &RSLT or  
    &RS.RowCount = &I;  
  
If &RSLT Then  
    &CRS = GetRowsetCache (&RS);
```

```

    &CRS.Delete();
    &CRS = CreateRowsetCache(&RS);
    &CRS.Save();
End-if;

```

PeopleSoft recommends that any standard operations used by your application, such as deleting and repopulating the rowset cache, be encapsulated in an application class.

See [Understanding Application Classes](#).

The RowsetCache contains a rowset, and serializes the contained rowset to binary form for speed. As with most PeopleTools objects, RowsetCache objects are cached to memory and file, but they are also cached to the data base.

RowsetCache objects are intended to be local to a data base : they should not be transferred to another data base.

Error Handling

Every time you use the GetRowsetCache function, you should verify that the function executed successfully by testing for a null object. For example:

```

Local RowsetCache &RSC;

&RSC = GetRowsetCache(Rowset.MyRowset);

If (&RSC <> NULL) Then
    /* do processing */
Else
    /* call to populate rowset cache */
End-if;

```

Data Type of a RowsetCache Object

Cached rowset objects are declared as type RowsetCache. For example,

```
Local RowsetCache &Cache;
```

Scope of a RowsetCache Object

A RowsetCache object can only be instantiated from PeopleCode.

This object can be used anywhere you have PeopleCode, that is, in an application class, Application Engine PeopleCode, Component Interface PeopleCode, and so on.

Note: PeopleSoft recommends that you do not specify RowsetCache objects as Global, due to their potential size.

RowsetCache Class Built-in Functions

"CreateRowsetCache" (PeopleCode Language Reference)

"GetRowsetCache" (PeopleCode Language Reference)

RowsetCache Class Methods

In this section, we discuss the RowsetCache class methods. These methods are discussed in alphabetical order.

Delete

Syntax

```
Delete ()
```

Description

Use the Delete method to delete the RowsetCache from memory. The RowsetCache must have already been created, either using the CreateRowsetCache and saving the RowsetCache, or by a user using the application.

If this method is called as part of a larger transaction, such as in the SavePreChange or SavePostChange event, the commit is tied to the commit of the outer transaction. If an error occurs in this method, the outer transaction will be rolled back.

If this method is invoked in a non-transactional PeopleCode event (such as RowInit) the commit is controlled by the regular Component Processor flow.

Parameters

None.

Returns

A Boolean value: True if the delete was successful, False if the specified RowsetCache wasn't found.

This method terminates with an error message if there was another problem.

Example

```
Local RowsetCache &CRS;  
Local Boolean &RSLT;  
  
&CRS = GetRowsetCache (Rowset.MyRowset) ;  
  
/* do processing*/  
  
If (&CRS <> NULL) Then
```

```

    &RSLT = &CRS.Delete();
End-If;

```

Related Links

"CreateRowsetCache" (PeopleCode Language Reference)

"GetRowsetCache" (PeopleCode Language Reference)

Get

Syntax

```
Get()
```

Description

Use the Get method to convert a RowsetCache object into a rowset object. After using this method, you can manipulate the data in the rowset like you would any other rowset, using the regular rowset methods and properties.

Parameters

None.

Returns

A rowset object populated with the cached rowset data.

Example

```

Local Rowset &RS;
Local RowsetCache &CRS;

&CRS = GetRowsetCache(Rowset.MyRowset);

If (&CRS <> NULL) Then
    &RS = &CRS.Get();
Else
    /* do error processing */
End-if;

```

Related Links

"GetRowsetCache" (PeopleCode Language Reference)

[Understanding Rowset Class](#)

Save

Syntax

```
Save([[Rowset.]name] [, Description] [, Lang])
```

Description

Use the Save method to save a new or existing rowset to the cache. If a rowset of the specified name already exists, it will be replaced. Otherwise, the rowset will be added.

If this method is called as part of a larger transaction, such as in the SavePreChange or SavePostChange event, The commit is tied to the commit of the outer transaction. If an error occurs in this method, the outer transaction will be rolled back.

If this method is invoked in a non-transactional PeopleCode event (such as RowInit) the commit is controlled by the regular Component Processor flow.

Parameters

Parameter	Description
Rowset. <i>name</i>	Specify the name of the rowset to be saved to the cache. If you just specify <i>name</i> , you must enclose the name in quotation marks.
<i>Description</i>	Specify a text string describing the rowset.
<i>Lang</i>	Specify the language to use when saving the rowset. See the values below.

The values for the *Lang* parameter are:

Value	Description
%RowsetCache_SignonLang	Attempt to save the rowset to the cache using the sign-in language. However, if the base language rowset doesn't already exist in the cache, then the save to the sign-in language fails. This is because the system requires that base language data exist before related language data can be saved. If the <i>Lang</i> parameter is omitted, this is the default behavior.
%RowsetCache_BaseLang	Save the rowset to the cache using the base language.
%RowsetCache_SignonOrBaseLang	Attempt to save the rowset to the cache using the sign-in language. If that fails, then save the rowset using the base language.

Returns

A Boolean value: True if the save was successful, False otherwise.

Example

The following code caches &RS as a rowset definition.

```
Local RowsetCache &CRS;
Local Rowset &RS;

&CRS = GetRowsetCache(Rowset.MyRowset);

If (&CRS <> Null) Then
    &RS = &CRS.Get();
    . . . /* do processing */
Else
    /* do error processing */
End-if;

&CRS.Save();
```

Related Links

"GetRowsetCache" (PeopleCode Language Reference)

RowsetCache Class Properties

In this section, we discuss the RowsetCache class properties. These properties are discussed in alphabetical order.

Content

Description

Use this property to specify the contents of a RowsetCache object.

This property is read/write.

Example

The following code example verifies if the rowset cache is populated. If it isn't, the Else statement populates the rowset cache.

```
&Cache2 = GetRowsetCache("CACHE1");
If &Cache2.Get() <> Null Then
    WinMessage("Cache found");
Else
    &RS = CreateRowset(Record.PSLANGUAGES);
    &NUM_READ = &RS.Fill();
    &Cache2.Content = &RS;
    &Cache2.Description = "test " | %Language_Data;
    &RSLT = &Cache2.Save();
End-If;
```

Description

Description

This property can be used to set the description of the rowset cache as a string.

This property is read/write.

Security Authorization Classes

Understanding the Security Authorization Classes

The security authorization classes are used in conjunction with the PeopleTools security authorization service to authorize access to PeopleSoft objects (components or content references) or to authorize access to row-level data on local and remote PeopleSoft nodes.

Note: While the security authorization service can be used to provide basic authorization for PeopleSoft queries, pagelets, iScripts, components, or content references, the security authorization classes, and in a broader sense row-level security, are only applicable to components or content references, and not to PeopleSoft queries, pagelets, or iScripts.

Related Links

"Understanding Using Web Services for Object and Row-Level Data Authorization" (Security Administration)

Importing the Security Authorization Classes

The security authorization classes are application classes (not a built-in class, like Rowset, Field, Record, and so on). Therefore, before you can use these classes in your implementation, you must import the security authorization classes into your program.

An import statement either names a particular application class or imports all the classes in a package.

Using the asterisks after the package name makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are not made available.

For the security authorization classes, use an import statement similar to the following to import all classes in the Security subpackage:

```
import PTCS_SECURITY:Security:*;
```

AuthRequest Class

This section provides an overview of the AuthRequest class and discusses:

- AuthRequest class methods.
- AuthRequest class properties.

An AuthRequest object represents the instantiation of an authorization request. An array of AuthRequest objects is instantiated when an authorization request message is processed by the PeopleTools security authorization service.

In this section, one method and two properties of the AuthRequest class are documented:

- GetParameterValue method
- Access property
- UserId property

In addition to these items, the AuthRequest class includes numerous read-only properties that are populated from the authorization request message if the corresponding parameter is specified in the message. You can also access the string value of these undocumented, read-only AuthRequest properties as needed:

- CompItemName.
- Component.
- CrefId.
- KeyVal (access the value of a KeyVal array element with the GetParameterValue method).
- Market.
- Menu.
- Mode.
- Node.
- Portal.
- ServiceId.
- ServiceInstId.
- ServiceType.

This topic includes an example of an authorization request message and how that message could be evaluated by a custom security authorization handler.

See [Implementing a Security Authorization Handler](#).

Related Links

"Developing the Security Authorization Service Application Class" (Security Administration)

AuthRequest Class Methods

In this section, the AuthRequest class methods are presented in alphabetical order.

GetParameterValue

Syntax

```
GetParameterValue(name)
```

Description

Use this method to return the value of a key as a string.

Note: If the specified key name is undefined in the request message, this method returns a null string.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>name</i>	Specifies the name of the key as a string.

Returns

A string representing the key value.

Example

```
&emplid = &arrAuthReq [&i].GetParameterValue("EMPLID");
```

AuthRequest Class Properties

In this section, the AuthRequest class properties are presented in alphabetical order.

Access

Description

Use this property to set or return a string representing the authorization status for this request. "T" indicates that the request is authorized; "F" indicates that the request is not authorized. "F" is the default value.

This property is read/write.

Example

```
&arrAuthReq [&i].Access = "T";
```

Userld

Description

Use this property to return the user ID of the user who invoked the authorization request as a string. This property is equivalent to the Username found in the SOAP message header.

This property is read-only.

Example

```
&userid = &arrAuthReq [i].UserId;
```

SecurityHandler Class

This section provides an overview of the SecurityHandler class and discusses SecurityHandler class methods.

The SecurityHandler class is a generic interface class without a native implementation. Therefore, you must implement this interface by developing your own class to handle your specific authorization requirements.

SecurityHandler Class Methods

In this section, the SecurityHandler class methods are presented in alphabetical order.

GetAuthorization

Syntax

```
GetAuthorization (&AuthReq_array)
```

Description

Implement this method to access the information in the AuthRequest object and return whether the authorization request is authorized.

An AuthRequest object represents the instantiation of an authorization request. An array of AuthRequest objects is instantiated when an authorization request message is processed by the PeopleTools security authorization service.

This topic includes an example of an authorization request message and how that message could be evaluated by a custom security authorization handler.

See [Implementing a Security Authorization Handler](#).

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&AuthReq_array</i>	Specifies an array of AuthRequest objects.

Returns

None.

Related Links

[AuthRequest Class](#)

Implementing a Security Authorization Handler

An AuthRequest object represents the instantiation of an authorization request. An array of AuthRequest objects is instantiated when an authorization request message is processed by the PeopleTools security authorization service.

An authorization request message has many standard elements such as, SERVICEID, SERVICE_TYPE, PORTAL, NODE, CREFID, and so on. In addition, an authorization request message will have one or more KEYVAL elements. Typically, you as the implementer of the GetAuthorization method should determine the structure of the corresponding authorization request message, and specifically, the number and type of KEYVAL elements. You will use the value of these KEYVAL elements along with other data in the authorization request to determine whether a specific request is authorized.

Example Scenario

In this example, employee details are available in Application A while employee performance and appraisal data resides in Application B. The user Rodrigo is the manager of a team. Rodrigo makes a request to view employee performance information for two employees: Callahan and Daniel. Rodrigo is Callahan's manager while Daniel is a higher level manager in a different part of the organization.

The PeopleTools security authorization service can be used to determine whether these requests are authorized.

Authorization Request Message

Application A will send the following authorization request as a SOAP message to Application B requesting that user Rodrigo be given access to the performance data for employees Callahan and Daniel. The authorization request message is contained between the <PARAMARRAY> </PARAMARRAY> delimiters.

```
<?xml version="1.0"?>

          <MARKET>GBL</MARKET>
          <COMP_ITEM_NAME>PERFORMANCE_DTL</COMP_ITEM_NAME>
          <KEYVAL>EMPLID=DANIEL</KEYVAL>
        </PARAMS>
      </PARAMARRAY>
    </FindAccess>
  </soapenv:Body>
</soapenv:Envelope>

```

Example Security Handler

The PeopleTools security authorization service receives the message and first performs basic PeopleTools security authorization (user-role-permission list). If basic PeopleTools security authorization is valid for the requested object (a component, for example), the PeopleTools security authorization service will pass the request on to the security handler defined for this object. The PeopleTools security authorization service will encapsulate all the message elements such as user ID, node, component, and, key values into an AuthRequest object.

The following code provides an example security handler class that evaluates whether a user is authorized to see the performance details for a given employee ID. If the employee is a subordinate of the invoking user, then access granted; access is denied in all other instances such as a peer requesting performance data for a peer, an employee requesting access to his or her supervisor's performance data, or an employee requesting performance data from another department in the organization.

```

import PTCS_SECURITY:Security:*;

class SampleSecurityHandler extends PTCS_SECURITY:Security:SecurityHandler
  /*method AuthRequestHandler(&arrAuthReq As array of PTCS_SECURITY:Security:AuthR

```

```

equest);*/
    method GetAuthorization(&arrAuthReq As array of PTCS_SECURITY:Security:AuthReque⇒
st);
    method isEmpSubordinate(&userid As string, &emplid As string) Returns boolean;
end-class;

/*method AuthRequestHandler*/
method GetAuthorization
    /+ &arrAuthReq as Array of PTCS_SECURITY:Security:AuthRequest +/
    /+ Extends/implements PTCS_SECURITY:Security:SecurityHandler.GetAuthorization +/

    Local string &emplid;
    Local string &userid;
    Local integer &i;

    For &i = 1 To &arrAuthReq.Len

        &emplid = &arrAuthReq [&i].GetParameterValue("EMPLID");
        &userid = &arrAuthReq [&i].UserId;
        /* If the employee ID to which access is requested is a subordinate of the   ⇒
*/
        /* invoking user, grant access; otherwise, deny access for all other requests.⇒
*/
        If %This.isEmpSubordinate(&userid, &emplid) Then
            &arrAuthReq [&i].Access = "T";
        Else
            &arrAuthReq [&i].Access = "F";
        End-If;

    End-For;
end-method;

method isEmpSubordinate
    /+ &userid as String, +/
    /+ &emplid as String +/
    /+ Returns Boolean +/

    /* Use the organizational hierarchy to determine whether employee ID is a   *⇒
/
    /* subordinate of the invoking user.   *⇒
/
    /* The following example uses a simplified expression to make this   *⇒
/
    /* determination. In most organizations, this would not be a valid test.   *⇒
/

    If &userid > &emplid Then
        Return True
    Else
        Return False
    End-If;
end-method

```

Response Message

The preceding security handler class sets the Access property of the AuthRequest object to T when access is granted. It sets the Access property to F for requests that are not authorized. Then, the security

handler class returns the AuthRequest object array to the PeopleTools security authorization service. The PeopleTools security authorization service returns a SOAP message similar to the following to the invoking application (Application A). The authorization request response is contained between the <PARAMARRAY> </PARAMARRAY> delimiters.

```
<?xml version="1.0"?>
<soapenv:Envelope xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/" xmlns:s=
oapenv="http://schemas.xmlsoap.org/soap/envelope/" xmlns:wsa="http://schemas.xmlsoa

Session Class

Understanding Session Class

PeopleTools provides a family of APIs for external access into the PeopleSoft system. The Session class is the root of the APIs. It controls access to the PeopleSoft system, controls the environment, and enables you to do error handling for all APIs from a central location.

The PeopleSoft APIs are intended to be used, and are supported, in the following environments.

- PeopleSoft Windows client with either an existing two-tier connection or an existing connection to an application server.
- Application Engine batch program.
- Non-PeopleSoft program connecting to an application server.

The PeopleSoft APIs are exposed to the following language environments:

- PeopleCode
- OLE/COM
- C/C++
- Java

The APIs that are accessible using a session object are:

- Component Interface Classes
- PortalRegistry Classes
- Query Classes
- Search Class
- Tree Classes

Note: Tree Classes are accessible only through PeopleCode.

A session object controls the following:

- Security and access to the PeopleSoft system.
- Errors and error handling .
- Regional settings (that is, internationalization) for language, dates, times, and numbers.

- Tracing.

Security and Access to the PeopleSoft System

A session object controls security and access to the PeopleSoft system. You must "sign-on" to the PeopleSoft session with a valid user ID and password when you use the Connect method. In addition, there's an external authentication parameter that you can use with the connect.

Note: Additional authentication will be available after this release.

Error Handling

The session object handles error processing for all the APIs, such as Component Interfaces, the Query API, and so on. From the session object, you can check if there have been any errors.

Note: The exception to this is Subscription PeopleCode. All errors for Subscription PeopleCode get logged to the application message error table.

Error messages include system error messages or messages from the message catalog (a common set of error messages used by all PeopleSoft applications.) For a Component Interface, the session object level errors also contain any text errors that may have occurred from running ExecuteEdits.

On the session object, you can use the following properties to initially check for errors:

- ErrorPending indicates whether there are API errors
- WarningPending indicates whether there are API warnings

All errors are contained in the PSMessages collection. (The PSMessages property on a Session object returns this collection.)

Each item in this collection is a PSMMessage object. A PSMMessage object contains information about the specific error that has occurred, such as the explain text for the error, the message set number, and so on. (The type of information depends on the type of error.)

If the error was caused by a Component Interface, a contextual string is attached to the end of the Text property of the PSMMessage object. This contextual string contains the exact location of the error, that is, which field in which data collection, on which row, caused the error. This string is also accessible (by itself) using the Source property.

When errors are loaded into the PSMessages collection depends on the type of error. System errors (that is, errors in the connection to the PeopleSoft Session) are logged as they occur. When an API error is logged depends on the API, as some APIs can be run in either interactive mode (meaning errors are logged as they happen) or in non-interactive mode (so errors are logged only when a particular method is run.)

If you are using Visual Basic or another COM environment, the PeopleSoft API system raises a COM exception the first time ErrorPending changes from False to True. It will *not* raise another exception until the PSMessages collection is cleared, which sets ErrorPending back to False.

Note: If you've called an API from an Application Engine program, all errors are also logged in the Application Engine error log tables.

[Accessing a PSMessages Collection](#)

Displaying Error Messages

Use the following PeopleCode to display messages from the PSMessages collection:

```
Local ApiObject &Session, &PSMessages;
    &Session = %Session;
    &PSMessages = &Session.PSMessages;
    If (&Session <> Null ) Then
        If &PSMessages.Count > 0 Then
            For &i = 1 To &PSMessages.Count
                &MsgSetNbr = &PSMessages.Item(&i).MessageSetNumber;
                &MsgNbr = &PSMessages.Item(&i).MessageNumber;
                MessageBox( 0 , " ", &MsgSetNbr, &MsgNbr, "Message not found");
            End-For;
            &PSMessages.DeleteAll();
        End-If;
    End-If;
```

Regional Settings

Regional settings enable the user to set the display of numbers, dates, times, and currencies to comply with usage in a specific locale. The session object exposes some of these values to the API through the RegionalSettings property. This property returns a regional settings object that has properties you can use to change these settings.

Related Links

[Regional Settings Class Properties](#)

Trace Settings

The PeopleSoft debug pages enables you to control the environment in which your PeopleTools session is running. These pages include:

- Trace PeopleCode

- Trace SQL

These pages enable you to select the SQL trace options and the PeopleCode trace options that you want. The TraceSettings object (assessable from a session object) lets you control many of the same options during your session.

This example illustrates the fields and controls on the Trace PeopleCode page. You can find definitions for the fields and controls later on this page.

Trace PeopleCode

Select PeopleCode Trace options below; then select Save.

Options	
<input checked="" type="checkbox"/> Trace Entire Program	<input checked="" type="checkbox"/> Show Assignments to Variables
<input type="checkbox"/> Trace Start of Programs	<input checked="" type="checkbox"/> Show Fetched Values
<input type="checkbox"/> Trace Internal Function Calls	<input type="checkbox"/> Show Parameter Values
<input type="checkbox"/> Trace External Function Calls	<input type="checkbox"/> Show Return Parameter Values
	<input type="checkbox"/> Show Stack
	<input type="checkbox"/> List the Program

Not every option on the debug pages is represented with a trace settings property.

"Using Debug Utilities" (System and Server Administration)

Session Object Declaration

All session objects are declared as type ApiObject. For example,

```
Local ApiObject &MYSESSION;
Global ApiObject &PSMessage;
```

The following session objects can be declared as Global or Component:

- Session
- PSMessages Collection
- PSMessage

All other session objects *must* be declared as Local.

In this section, we discuss the following topics:

- State considerations.
- Considerations for declaring conditions.

State Considerations

In the PeopleSoft Pure Internet Architecture, all processing occurs on the server. If you do something in your PeopleCode program that causes a trip back to the user before the end of your PeopleCode program, the PeopleCode program *cannot* regain its state, that is, it can't reset local variables, and so on. This applies to all APIs that use the Session object.

If you must go back to the user before the end of your PeopleCode program, you must set all your objects to NULL before you go, or else you receive a runtime error.

For example, the following code causes an error:

```
&Session = %Session;
Rem &Session = Null;
WinMessage("Hello");
```

The following example does *not* cause an error:

```
&Session = %Session;
&Session = Null;
WinMessage("Hello");
```

Considerations for Declaring Collections

You *must* declare all collections for C/C++ and COM as objects, or else you receive errors at runtime.

For example if you're using RegionalSettings, include the following your declarations for a VB program:

```
Dim oRegionalSettings As Object
```

Then, use the following code to populate this variable:

```
Set oRegionalSettings = oCISession.RegionalSettings
oRegionalSettings.LanguageCd = "GER"
```

Scope of a Session Object

A Session can be instantiated from PeopleCode, from a Visual Basic program, from C++, COM, and so on.

See the example section in Connect for more details.

This object can be used anywhere you have PeopleCode, that is, in Application Engine PeopleCode, record field PeopleCode, and so on.

Session Class Built-in Function

"%Session" (PeopleCode Language Reference)

"GetSession" (PeopleCode Language Reference)

Session Class Methods

In this section, we discuss the Session class methods. The methods are discussed in alphabetical order.

Connect

Syntax

```
(version, {"EXISTING" | //PSoftApplicationServer:JoltPort}, UserID, Password, ExtAuth)
```

Description

The Connect method connects a session object to a PeopleSoft application server.

Note: This function remains for backward compatibility only. Use the %Session system variable to return a reference of a session object instead.

If you already have a PeopleSoft session running (you are already connected to a PeopleSoft application server and are running a component, and so on) you must specify EXISTING, and not the //PSoftApplicationServer:JoltPort. Typically, use the parameter value of EXISTING from PeopleCode, not from other language environments.

If you are using an existing connection to the application server, you *cannot* specify a different user ID or password. If you don't specify these values as NULL string, you must specify the exact same user ID (and password) as the one that originally started the session.

Parameters

Parameter	Description
<i>version</i>	Specify the API version that the client is expecting. Future releases will use this parameter. For now, you must use a 1.
EXISTING //PSoftApplicationServer:JoltPort	Specify EXISTING if you're currently connected to an application server. Otherwise, specify the named application server machine and the IP port to connect to on an application server machine.
<i>UserID</i>	Specify the PeopleSoft user ID to use for the connection. This must be a valid user ID. If you are using an existing connection, you can specify a NULL string (that is, two quotation marks with no blank space between them ("")) for this parameter.

Parameter	Description
<i>Password</i>	Specify the password associated with the user ID to use for the connection. This must match the password assigned for this user ID <i>exactly</i> . If you are using an existing connection, you can specify a NULL string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>ExtAuth</i>	This parameter is required, but it is unused in this release. You must enter a 0 for this parameter.

Returns

A Boolean value: True if the connection completed successfully, False otherwise.

Example

The following is an example of the code you would use if there is an existing connection to the application server:

```
Local ApiObject &MYSESSION;

&MYSESSION = GetSession();
&MYSESSION.Connect(1, "EXISTING", "", "", 0);
```

The following is an example connecting to a PeopleSoft system using a Visual Basic program. It first checks for error messages. If there are any errors, the text of the error is displayed to the user.

```
On Error GoTo eMessage

    Dim oSession As Object
    Dim oPSMessage As Object

    Dim oBC As Object

    Set oSession = CreateObject("PeopleSoft.Session")

    oSession.Connect 1, "//PSSOFT0061998:7000", "PTDMO", "PTDMO", 0

    &lsquo;Application Specific Processing

eMessage:
    If (oSession.PSMessages.Count > 0) Then
        For i = 1 To oSession.PSMessages.Count
            Set oPSMessage = oSession.PSMessages.Item(i)
            MsgBox (oPSMessage.Text)
        Next i
    End If
```

Related Links

"%Session" (PeopleCode Language Reference)

Disconnect

Syntax

`Disconnect()`

Description

The Disconnect method disconnects the session associated with the session object executing the method from that PeopleSoft session.

This method returns a Boolean value: True if successfully disconnected, False otherwise.

API Instantiation Methods

The following is a list of the other methods used with the session object to instantiate an API object such as a Component Interface, a tree structure, and so on.

Component Interface:

- `FindCompIntfcs(ComponentName)`: returns a collection of component interfaces based on the partial Component Interface name.
- `GetCompIntfc(COMPINTFC.ComponentName)`: returns a Component Interface object.
- `ValidateCompIntfc(ComponentInterfaceName)`: indicates the success or failure of component interface validations.

Portal Registry:

- `FindPortalRegistries(partial_name)`: returns a collection of PortalRegistry objects.
- `GetLocalNode()`: returns a node object.
- `GetNodes()`: returns a collection of node objects.
- `GetPortalRegistry()`: returns a PortalRegistry object.
- `GetRemoteNodes()`: returns a collection of node objects.
- `GetActualRemoteNodes()`: returns a collection of remote node objects only.

Query:

- `FindQueryDBRecords()`: returns a reference to a QueryDBRecord collection, filled with zero or more records.
- `FindQueries()`: returns a reference to a Query collection, filled with zero or more queries.
- `FindQueriesDateRange(StartDateString, EndDateString)`: returns a reference to a Query collection, filled with zero or more queries that match the specified date range.
- `GetQuery()`: returns a query object.

- `GetQuerySecurityProfile()`: a `QuerySecurityProfile` object.
- `SearchQueryDBRecord(SearchType, Pattern, CaseSensitive)`: returns a `QueryDBRecord` collection.
- `SearchPrivateQueries(QueryType, SearchType, Pattern, CaseSensitive)`: a query collection.
- `SearchPublicQueries(QueryType, SearchType, Pattern, CaseSensitive)`: a query collection.

Search:

- `GetSearchIndexes()`: returns a `SearchIndexes` collection.
- `GetSearchQuery()`: returns a search query object.

Tree:

- `GetTree()`: returns a tree object.
- `GetTreeStructure()`: returns a tree structure object.

Session Class Properties

This section describes the Session class properties. The properties are discussed in alphabetical order.

ErrorPending

Description

This property indicates whether there are any error messages pending for the API that is currently running. After this property has been set, it returns `True` until the `PSMessages` collection is cleared (or deleted.)

This property is read-only.

Example

```

If &MYSESSION.ErrorPending Then
    &COUNT = &MYSESSION.PSMessages.Count;
    For &I = 1 To &COUNT
        &ERROR = &MYSESSION.PSMessages.Item(&I);
        &TEXT = &ERROR.Text;
        WinMessage("Error text " | &TEXT);
    End-For;

&MYSESSION.PSMessages.DeleteAll();

```

PSMessages

Description

This property returns a reference to a `PSMessages` collection object. If there are no messages, this property returns an object reference to `PSMessages` with a count of zero.

This property is read-only.

Example

```
If &SESSION.PSMessages.Count > NULL Then
    /* there are messages do processing */
End-if;
```

Related Links

[PSMessages Collection Methods](#)

PSMessagesMode

Description

This property is used to determine how messages are output. This property takes either a numeric value or a constant. The default value is 1 (%PSMessages_CollectionOnly).

You must set this property before you check the type of message, that is, you can't check the type of message, then decide how it's displayed.

This property sets the value for the session. You can change modes during a session, such as, if you're starting a Component Interface. However, after you run the Component Interface, you should set the value back. For example:

```
&OldMode = &Session.PSMessagesMode;
&Session.PSMessagesMode = 1;
...
&Session.PSMessagesMode = &OldMode;
```

You can specify either a numeric value or a constant. The values are:

Numeric Value	Constant Value	Description
0	%PSMessages_None	None.
1	%PSMessages_CollectionOnly	PSMessage Collection only (default).
2	%PSMessages_MessageBoxOnly	Message box only.
3	%PSMessages_Both	Both collection and message box.

Note: If you set this property to 0 (%PSMessages_None), *all* messages are ignored. Use this option with caution.

This property is read/write.

Example

```
Local ApiObject &SESSION;
```

```
&SESSION = %Session;  
&MMODE = &SESSION.PSMessagesMode;  
&SESSION.PSMessagesMode = %PSMessages_MessageBoxOnly;
```

RegionalSettings

Description

This property returns a reference to a RegionalSettings collection object.

This property is read-only.

Related Links

[Regional Settings Class Properties](#)

Repository

Description

This property returns a reference to a Repository object.

Related Links

[Understanding the PeopleSoft API Repository](#)

SuspendFormatting

Description

This property turns off the PeopleSoft automatic formatting when coercing a string into a field. Formatting is typically necessary for external Component Interface users (such as for a Visual Basic program,) yet should be suspended for a PeopleCode program. You should not typically need to set this value yourself, as it's set appropriately based on where the session object is created.

This property takes a Boolean value: True means formatting is suspended, False means it isn't suspended. If you start your session from a PeopleCode program, the default for this property is True. If you don't start the session from a PeopleCode program, the default is False.

This property is read/write.

TraceSettings

Description

This property returns a reference to a TraceSettings collection object.

This property is read-only.

Related Links

[Trace Setting Class Properties](#)

WarningPending

Description

This property indicates whether there are any warning messages pending for the API that is currently running.

This property is read-only.

Accessing a PSMessages Collection

Use the PSMessages collection to return all of the messages that occur during the session. The following example finds all the messages listed in the PSMessages collections when the Component Interface Save methods fails. The example assumes that &CI is the Component Interface object reference.

```
If Not &CI.Save() Then
    /* save didn't complete */
    &COLL = &MYSESSION.PSMessages;
    For &I = 1 to &COLL.Count
        &ERROR = &COLL.Item(&I);
        &TEXT = &ERROR.Text;

        /* do message processing */

    End-For;
    &COLL.DeleteAll(); /* Delete all messages in queue */
End-if;
```

As you evaluate each message, delete it from the PSMessages collection. Or, delete all the messages in the queue at once using DeleteAll.

If there are multiple errors when saving a Component Interface, all errors are logged to the PSMessages collection, not just the first occurrence of an error.

Considerations for Declaring Collections

You *must* declare all collections for C/C++ and COM as objects, or else you receive errors at runtime.

PSMessages Collection Methods

This section describes the PSMessages collection methods. The methods are discussed in alphabetical order.

DeleteAll

Syntax

```
DeleteAll ()
```

Description

The DeleteAll method deletes all the PSMessages objects in the PSMessages collection executing the method. You should use this property after you have processed all the errors in the collection. This method also resets the status of ErrorPending to False.

Returns

This method returns a Boolean value: True if all PSMessages in the collection were successfully deleted, False otherwise.

Related Links

[ErrorPending](#)

DeleteItem

Syntax

```
DeleteItem (number)
```

Description

The DeleteItem method deletes the PSMessages object that exists at the *number* position in the PSMessages collection executing the method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>number</i>	Specify the position number in the collection of the PSMessages object that you want to delete. All other items within the collection are renumbered.

Returns

This method returns a Boolean value: True if the PSMessages object was successfully deleted, False otherwise.

Example

```
&ERROR.DeleteItem (&I) ;
```

First

Syntax

```
First ()
```

Description

The First method returns the first PSMesssage object in the PSMessages collection object executing the method.

Example

```
&ERROR = &PSMESSAGE.First ();
```

Item

Syntax

```
Item (number)
```

Description

The Item method returns a PSMesssage object that exists at the *number* position in the PSMessages collection executing the method

Parameters

<i>Parameter</i>	<i>Description</i>
<i>number</i>	Specify the position number in the collection of the PSMesssage object that you want returned.

Returns

A reference to a PSMesssage object, NULL otherwise.

Example

```
&PSMSGCOL = &SESSION.PSMessages;
For &I = 1 to &PSMSGCOL.Count;
  &PSMESSAGE = &PSMSGCOL.Item(&I);
  /* do error processing */
End-For;
```

Next

Syntax

`Next ()`

Description

The Next method returns the next PSMMessage object in the PSMessages collection object executing the method. You can use this method only after you have used either the First or Item methods: otherwise the system doesn't know where to start.

PSMessages Collection Property

This section describes the PSMessages collection property.

Count

Description

This property returns the number of PSMMessage objects in the PSMessages collection object.

This property is read-only.

Example

```
&COUNT = &PSMESSAGE.Count;
```

PSMessage Class Properties

This section describes the PSMessages class properties. The properties are discussed in alphabetical order.

ExplainText

Description

This property returns the explanation text (as a string) for the error message associated with the PSMMessage object. You can use this property in conjunction with the MessageNumber property (which contains the error message number) and the MessageSetNumber property (which contains the error message set number.)

Note: ExplainText should be accessed only when necessary because it requires a second database read or application server round trip.

This property is read-only.

MessageNumber

Description

This property returns the error message number (as a number) for the error message associated with the PSMMessage object. You can use this property in conjunction with the MessageSetNumber property (which contains the error message set number) and the ExplainText property (which contains text explaining the error.)

This property is read-only.

MessageSetNumber

Description

This property returns the error message set number (as a number) for the error message associated with the PSMMessage object. You can use this property in conjunction with the MessageNumber property (which contains the error message number) and the ExplainText property (which contains text explaining the error.)

This property is read-only.

MessageType

Description

This property indicates the type of the message, whether it's from the message catalog, if it's a warning, error, or information error.

This property returns a numeric value. The values are:

Value	Description
0	Message is not a message catalog entry or there is no message.
1	Message has a severity of Error.
2	Message has a severity of Warning.
3	Message has a severity of Information.

This property is read-only.

Source

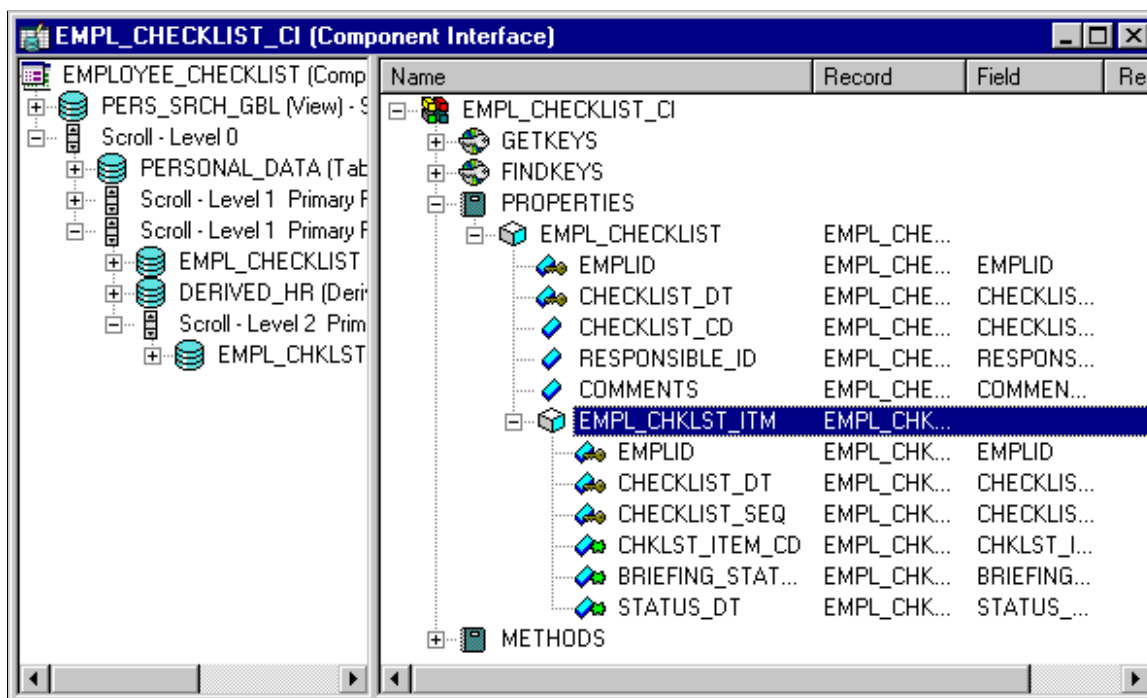

Description

This property returns a string indicating the actual field that's in error. The syntax of the string that's returned is as follows:

```
ComponentInterfaceName.[CollectionName (Row) . [CollectionName (Row) . [CollectionName (Row) . . . . PropertyName
```

The following image is an example of Sample Component Interface. The string here is also returned as part of the Text property.

For example, suppose you had a Component Interface named EMPL_CHKLST_CI.

The following indicates that the first level field, EMPLID, has the error:

```
EMPL_CHKLST_CI.EMPLID
```

The Component Interface EMPL_CHKLST_BC has a data collection (scroll) called EMPL_CHKLST_ITM. Suppose that it has 3 rows, and the STATUS_DT field was in error. The **Source** property would return the following string:

```
EMPL_CHKLST_CI.EMPL_CHKLST_ITM(3) .STATUS_DT
```

You can use the Source property in conjunction with the MessageNumber property (which contains the error message number), the MessageSetNumber property (which contains the error message set number), the ExplainText property (which contains text explaining the error), and the Text property (which contains the text of the message.)

This property is read-only.

Example

The following example code finds the error messages and displays them to the user. It finds the field that caused the error and displays that also.

```

Local ApiObject &PSMESSAGE;
Local Boolean &FIND;
Local string &SOURCE, &FIELD, &TEXT;
Local number &START, &LEN, &NSTART, &FLEN;
.
.
.
For &I = 1 to &SESSION.PSMessages.Count;
    &PSMESSAGE = &SESSION.PSMessages.Item(&I);
    /* only display errors, not warnings, to user */
    If &PSMESSAGE.Type = 1 Then
        &TEXT = &PSMESSAGE.Text;
        /* find name of field in error */
        &SOURCE = &PSMESSAGE.Source;
        &LEN = Len(&SOURCE);
        /* find last dot before field */
        &FIND = False;
        &START = Find(".", &SOURCE);
        While Not (&FIND)
            &NSTART = Find(".", &SOURCE, &START + 1);
            If &NSTART = 0 Then
                &FIND = True;
            Else
                &START = &NSTART;
            End-If;
        End-While;
        &FLEN = &LEN - &START;
        &FIELD = Substring(&SOURCE, &START + 1, &FLEN);
        /* display text and field to user */
        Winmessage("You received the following error: " | &TEXT | "For field " | &⇒
FIELD);
        End-If;
    End-For;

```

Text

Description

This property returns the text of the message (as a string) for the error message associated with the PSMMessage object. It also includes a contextual string that contains the name of the field that generated the error. The contextual string has the following syntax:

```
{ComponentInterfaceName.[CollectionName (Row) . [CollectionName (Row) . [CollectionName (R⇒
ow) ] ] ] .PropertyName}
```

The contextual string (by itself) is available using the Source property of the PSMMessage.

You can use the Text property in conjunction with the MessageNumber property (which contains the error message number), the MessageSetNumber property (which contains the error message set number), and the ExplainText property (which contains text explaining the error.)

This property is read-only.

Example

```

Local ApiObject &MYSESSION, &COL, &ERROR;
Local string &TEXT;
.
.
.
If &MYSESSION.ErrorPending Then
  /* received error */
  &COLL = &MYSESSION.PSMessages;
  For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item(&I);
    &TEXT = &ERROR.Text;
    /* do error processing */
  End-For;
End-if;

```

[Source](#)

Regional Settings Class Properties

This section describes the regional settings class properties. The properties are discussed in alphabetical order.

ClientTimeZone

Description

This property specifies the client time zone. This property takes a string value.

This property is read/write.

CurrencyFormat

Description

This property specifies how currency values are displayed. This property takes a number value. The default value is 1.

In the following values, @ represents the character specified with the CurrencySymbol property.

<i>Value</i>	<i>Description</i>
0	@1.1
1	1.1@
2	@.1.1

Value	Description
3	1.1.@

This property is read/write.

CurrencySymbol

Description

This property specifies the currency symbol. This property takes a string value. The default value is "\$".

This property is read/write.

DateFormat

Description

This property specifies the date format defaults. PeopleTools supports the Short Date Format specification (MDY, DMY, or YMD), and the Date separator setting. When you add a Date field in a record definition, you indicate whether you want to display the century. PeopleTools Date and DateTime fields always show leading zeros for month, day, and year.

This property takes a number value. The values for this property are:

Value	Description
0	MDY (default)
1	DMY
2	YMD
3	Default value on system

This property is read/write.

DateSeparator

Description

This property specifies the character used to separate the month, day, year in the date. This property takes a string value. The default value is "/".

This property is read/write.

DecimalSymbol

Description

This property specifies the character used to separate the fractional of the number from the whole. This property takes a string value. The default value for this property is ".".

Note: If you change the value of this property to a comma (,), you should adjust the DigitGroupingSymbol to a different character or some applications may not operate correctly.

This property is read/write.

DigitGroupingSymbol

Description

This property specifies the character used as a thousand or other grouping separator. This property takes a string value. The default value for this property is ",".

This property is read/write.

LanguageCD

Description

This property specifies the language to be used for the transaction. This property takes a string value. The default value for this property is the user's base language.

This property is read/write.

Note: If you change this value dynamically using PeopleCode, this value will *not* change back to the original value when you disconnect. You must manually set it back to the original value.

Example

The following example sets the language code, then at the end of the program, sets it back to the original value.

```
Local ApiObject &SESSION;
Local ApiObject &CI;

/** Get Session ApiObject **/
&SESSION = %Session;

/** Get Message ApiObject **/
&MSG = %IntBroker.GetMessage();
&RS = &MSG.GetRowset();

/** Get Component Interface **/
&CI = &SESSION.GetCompIntfc(compIntfc.NAMES_CI);

&REG_LNG = &SESSION.RegionalSettings.LanguageCd;

For &TRANS_NUM = 1 To &RS.RowCount
```

```

/** Store Language Code in Temp Var */
&LNG = &RS(&TRANS_NUM).PSCAMA.LANGUAGE_CD.Value;

/** Set the Language for this Transaction */
If &LNG <> &REG_LNG Then
&SESSION.RegionalSettings.LanguageCd = &LNG;
End-If;
/* application specific processing */

&SESSION.RegionalSettings.LanguageCd = &REG_LNG;
&SESSION.Disconnect();
End-For

```

UseLocalTime

Description

This property specifies whether the local time zone of the client should be used to format time fields. This property takes a Boolean value. The default value is True.

This property is read/write.

1159Separator

Description

This property specifies the morning designator. This property takes a string value up to five characters. The default value is AM.

Use the 2359Separator property to specify the afternoon designator.

This property is read/write.

Considerations Using the 1159Separator Property

You cannot use this property as you would other properties. You must use the ObjectGetProperty function for accessing the property. For example:

```

Local ApiObject &SESSION;
Local ApiObject &reg;

/** Get Session ApiObject */
&SESSION = %Session;
&reg = &SESSION.RegionalSettings;

&REG_LNG = &SESSION.RegionalSettings.LanguageCd;
&MornDesignation = ObjectGetProperty(&reg, "1159Separator");

```

Related Links

"ObjectGetProperty" (PeopleCode Language Reference)

[2359Separator](#)

2359Separator

Description

This property specifies the afternoon designator. This property takes a string value up to five characters. The default value is PM.

Use the 1159Separator property to specify the morning designator.

This property is read/write.

Considerations Using the 2359Separator Property

You cannot use this property as you would other properties. You must use the ObjectGetProperty function for accessing the property. For example:

```
Local ApiObject &SESSION;
Local ApiObject &reg;

/** Get Session ApiObject */
&SESSION = %Session;
&reg = &SESSION.RegionalSettings;

&REG_LNG = &SESSION.RegionalSettings.LanguageCd;
&AfternoonDesignation = ObjectGetProperty(&reg, "2359Separator");
```

Trace Setting Class Properties

Each of the following properties relates to the debug pages in PeopleTools.

This section describes the trace setting class properties. The properties are discussed in alphabetical order.

Related Links

"Using Debug Utilities" (System and Server Administration)

API

Description

This property is part of the PeopleSoft API trace and sets the **API Information** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

COBOLStmtTimings

Description

This property is part of the SQL trace and sets the **COBOL Statement Timings** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

ConnDisRollbackCommit

Description

This property is part of the SQL trace and sets the **Connect, disconnect, rollback, and commit** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

DBSpecificCalls

Description

This property is part of the SQL trace and sets the **Database API-specific Calls** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

ManagerInfo

Description

This property is part of the SQL trace and sets the **Manager Information** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

NetworkServices

Description

This property is part of the SQL trace and sets the **Network Services** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

NonSSBs

Description

This property is part of the SQL trace and sets the **All Other API Calls besides SSBs** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

OutputUNICODE

Description

This property specifies if the trace file is written in ANSI or UNICODE (for example, **Output Unicode Trace File**).

This property takes a Boolean value: True means the file will be written in UNICODE, False means it will be ANSI.

This property is read/write.

PCExtFcnCalls

Description

This property is part of the PeopleCode trace and sets the **Trace External Function Calls** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCFcnReturnValues

Description

This property is part of the PeopleCode trace and sets the **Show Function Return Value** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCFetchedValues

Description

This property is part of the PeopleCode trace and sets the **Show Fetched Values** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCIntFcnCalls

Description

This property is part of the PeopleCode trace and sets the **Trace Internal Function Calls** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCListProgram

Description

This property is part of the PeopleCode trace and sets the **List the Program** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCParameterValues

Description

This property is part of the PeopleCode trace and sets the **Show Parameter Values** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCProgramStatements

Description

This property is part of the PeopleCode trace and sets the **Trace Each Statement in Program** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCStack

Description

This property is part of the PeopleCode trace and sets the **Show Stack** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCStartOfPrograms

Description

This property is part of the PeopleCode trace and sets the **Trace Start of Programs** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCTraceProgram

Description

This property is part of the PeopleCode trace and sets the **Trace Evaluator Instructions** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

PCVariableAssignments

Description

This property is part of the PeopleCode trace and sets the **Show Assignments to Variables** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

RowFetch

Description

This property is part of the SQL trace and sets the **Row Fetch** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

SQLStatement

Description

This property is part of the SQL trace and sets the **SQL Statement** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

SQLStatementVariables

Description

This property is part of the SQL trace and sets the **SQL Statement Variables** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

SSBs

Description

This property is part of the SQL trace and sets the **Set Select Buffers** value.

This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

SybBindInfo

Description

Note: This property has been deprecated, and remains for backward compatibility only.

This property is part of the SQL trace and sets the **Sybase Bind Information** value. This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

SybFetchInfo

Description

Note: This property has been deprecated, and remains for backward compatibility only.

This property is part of the SQL trace and sets the **Sybase Fetch Information** value. This property takes a Boolean value: True means the trace will be run, False means it won't.

This property is read/write.

TraceFile

Description

This property specifies the location of the trace file (that is, **PeopleTools Trace File** value.)

This property takes a string value.

This property is read/write.

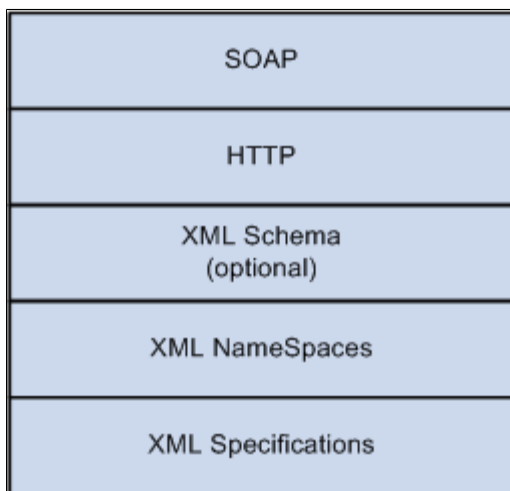

SOAPDoc Class

Understanding the SOAPDoc Class

The Simple Object Access Protocol (SOAP) is a lightweight protocol for defining synchronous messages in a distributed Web environment. It's an XML based protocol that can be used in combination with other protocols such as HTTP using URLs as endpoints for a message. SOAP is an application of XML and XML namespaces and optionally uses XML Schemas.

SOAP is an industry standard, defined by the World Wide Web Consortium (W3C), that defines an XML grammar for identifying a method name and the method parameters and for returning the results.

More specific information about SOAP can be found in the W3C specification on SOAP. The SOAP serialization rules can also be found in the complete specifications and aren't outlined in this topic. Also included in the W3C specification are sections on using SOAP with HTTP, which is also outside the domain of this topic. You can also send and receive HTTP messages through the Integration Gateway.

Related Links

"Understanding Sending and Receiving Messages" (Integration Broker)

SOAP Message Exchange Model

SOAP messages are always synchronous. They can implement Request/Response synchronous messages with the response having the output parameters returned in another SOAP document to the sender.

SOAP supports HTTP-POST and HTTP-GET formats. PeopleSoft supports only HTTP, using the Integration Gateway.

Processing the message requires validation of the mandatory sections of the SOAP XML document and understanding SOAP namespaces.

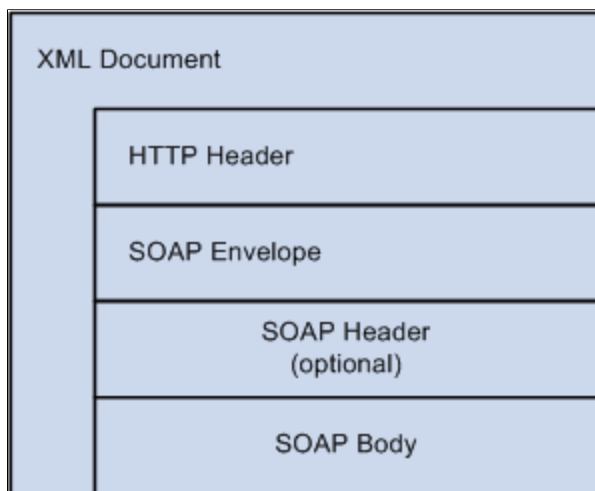

SOAP Message Document

A SOAP Message is an ordinary XML document that consists of the following parts:

- A mandatory SOAP envelope.
- An optional SOAP header.
- A mandatory SOAP body.

SOAP Message Part	Description
SOAP Envelope	Is the top element of the XML document representing the message. It defines the content of the message, as well as the framework of what is in a message, how to process it, who should deal with it and whether it is optional or mandatory.
SOAP Header	Contains header information, and attributes that can be set to encode and further identify the type of processing as well as additional features of the message. This portion is optional.
SOAP Body	Contains the call and response information intended for the recipient of the message. A SOAP Fault element can appear in the body of the SOAP message to carry error or status information.

The following image illustrates SOAP parts in an XML document.

The following are *required* for a SOAP message:

- Encoded using XML.

- Have a SOAP envelope.
- Have a SOAP body.
- Use the SOAP encoding and envelope namespaces.

The following are optional for a SOAP message:

- SOAP Header.
- XML Schema use.

The following are *invalid* for a SOAP message:

- DTD references.
- XML Processing Instructions.
- XML CData Sections.

The SOAPDoc Class

The SOAPDoc class is a separate class in PeopleCode that works similarly to the XmlDocument and XmlNode classes. Many of the same methods and properties that work with an XmlDocument or XmlNode object also work with a SOAPDoc object. However, there are also methods and properties that don't apply to a SOAPDoc object.

The following XmlDocument and XmlNode methods do *not* apply to a SOAPDoc object:

- AddCDataSection
- AddProcessInstruction
- CopyToPSFTMessage
- CreateDocumentType
- InsertCDataSection
- InsertProcessInstruction
- LoadIBContent

If a Merchant Profile has been created it can be used with the SOAPDoc class and the Message class. You can use the XmlDocument property to convert the message object to an SOAPDoc object, then use the SOAPDoc methods and properties, as well as the XmlDocument methods and properties that are applicable.

You can only use the message object when the XmlDocument object is structured.

It should be noted that a SOAPDoc object is really an extension of the XmlDocument class. You have the option of getting portions of the SOAPDoc—like the body node—and accessing it or manipulating it as if it were a standard element in an XML document, because in actuality it is.

SOAPDoc Object Creation

There are a few steps to creating a SOAPDoc. The following is an overview of these steps. More detail about the methods and properties mentioned in this section can be found in the reference section of this topic.

SOAP Header Section

Because the SOAP header is optional, the header is not validated when you use the `ValidateSOAPDoc` method.

A SOAP header must be added *before* any other parts of the SOAPdoc.

Use the `AddHeader` method to add a header to a SOAPDoc.

Use the `HeaderNode` property to access an existing SOAPDoc header.

After you have a reference to the header, you can use `XmlDoc` methods to read the contents of the header (like any node.)

Related Links

[AddHeader](#)

[HeaderNode](#)

SOAP Envelope Section

A SOAP envelope is a required portion of the XML Message and is generated automatically using the SOAP schema as specified by SOAP W3C.

A SOAP envelope must be added *before* you add a SOAP body or a SOAP method. This is an optional method. You need to use this method only if you need to set any additional attributes for the Envelope section. The default SOAP schemas are added automatically.

To set additional custom attributes or schemas on the Envelope element, use the `AddEnvelope` method. This method adds the envelope element tags and the default schemas for either SOAP or UDDI depending on the value of the parameter passed in. The default encoding styles are also set here. Only one envelope section can be set within one PeopleSoft SOAP `XmlDoc`.

The SOAPDoc adds only a default URL to the envelope. For some UDDI sites, you may need to add a specific schema yourself. To do this, generate the envelope with no schema, then access the envelope section and add the specific schema URL using the `AddAttribute` method.

Related Links

[AddEnvelope](#)

SOAP Body Section

The body is the `XmlDoc` where the method is defined. The method `AddBody` starts the body section of the XML SOAPDoc and must be in the `XmlDoc` before adding in method sections of the message. Only

one body section can be set within one SOAPDoc. This is an optional method and must be called only if you need to set any additional attributes for the body section. Otherwise the body section is automatically generated in the XmlDocument.

The SOAP body must be added *after* you add the SOAP envelope, and *before* you add any methods.

Related Links

[AddBody](#)

SOAP Method Section

The AddMethod method adds the name of the method element being processed. Additional attributes for this method can be set using the AddAttribute and InsertAttribute XmlNode methods.

You don't have to specifically add a SOAP body section. The body is automatically added when you call the AddMethod method.

The AddParm method sets the parameters for the parameter element of the method as a name, value pair. Multiple parameters can be set and are used in the order that this method is called. If an XML Schema is defined, types can be used using the AddAttribute XmlNode method. Any number of parameter name-value pairs can be added for a method and are added to the XmlDocument in the order that the AddParm methods are called.

You can add parameters to a method only *after* you add the method. The parameters are added in the order you add them in the PeopleCode program.

Related Links

[AddMethod](#)

[AddParm](#)

[AddAttribute](#)

SOAPDoc Section Access

Use the following properties to access the different parts of a SOAPDoc object. All of these properties return an XmlNode object.

- BodyNode
- EnvelopeNode
- MethodNode

After you have access to the portion of the SOAPDoc that you want, use the XmlNode properties and methods to manipulate the SOAPDoc.

Use the XmlDocument property to convert a SOAPDoc object to an XmlDocument object, and vice-versa.

The MethodName property returns the name of the method in the SOAPDoc object.

Note: If you use the MethodName property, you receive only the method name, as a string, not a reference to an XmlNode object that represents the method.

Use the `GetParmName` and `GetParmValue` methods to get the name and the values in a `SOAPDoc` object for each output parameter. You must use the index number of the parameter you want with these methods. You can determine the total number of parameters with the `ParmCount` property.

[MethodNode](#)

[GetParmValue](#)

PeopleCode to Create a SOAPDoc

The following is the order in which the Soap methods *must* be called in order to create a valid `SOAPDoc`.

```
&SOAPDoc = CreateSOAPDoc(); /* required */
&SOAPDoc.AddEnvelope(0); /* optional */
&SOAPDoc.AddBody(); /* optional */
&SOAPDoc.AddMethod("GetQuote", 1); /* required */
&SOAPDoc.AddParm("symbols", "PSFT");
&SOAPDoc.AddParm("format", "11c1d1t1");
&OK = &SOAPDoc.ValidateSOAPDoc(); /* optional */
```

SOAPDoc Fault Section

In the body of a SOAP XML response document, you can define a fault section. Generally this is used if an inbound message has been processed and some sort of error occurred. The text of the message gives further information about the error.

Use the `AddFault` method to add a fault code and a fault string to the body of a `SOAPDoc`. Only one fault section can be set within one SOAP XML document.

If you receive a response message that contains a fault, use the `FaultCode` and `FaultString` methods to return these values.

Related Links

[AddFault](#)

[FaultCode](#)

[FaultString](#)

The ValidateSOAPDoc Method

Use the `ValidateSOAPDoc` method to validate the SOAP document for correctness as follows:

- Encoded using XML.
- Has SOAP envelope.
- Has SOAP Body.

- Has a SOAP Method.
- Used SOAP encoding and envelope namespaces.

Related Links

[ValidateSOAPDoc](#)

SOAPDoc Objects and Messages

To publish the data of a SOAPDoc, you must first transform the SOAPDoc into an XmlDocument object by using the XmlDocument property. After you do this, you can use the XmlDocument object with the SyncRequestXmlDoc, PublishXmlDoc, or GetXmlDoc functions, to publish the data either synchronously or asynchronously.

All XmlDocument messages must be associated with a message definition. An XmlDocument message must be associated with an *unstructured* message, that is, a message definition that's created without any record definitions.

Use the SOAPDoc class if all of the following are true:

- Your third-party source or target node requires SOAP-compliant messages.
- Your third-party source or target node requires synchronous transactions.
- Your message conforms to the SOAP specification.

Related Links

[Understanding XmlDocument Classes](#)

"Understanding Sending and Receiving Messages" (Integration Broker)

Data Type of a SOAPDoc Object

SOAPDoc objects are declared as type SOAPDoc. For example,

```
Local SOAPDoc &MyDoc;  
Global SOAPDoc &SOAPDoc;
```

Scope of a SOAPDoc Object

A SOAPDoc object can only be instantiated from PeopleCode.

This object can be used anywhere you have PeopleCode, that is, in an application class, Application Engine PeopleCode, record field PeopleCode, and so on.

Note: Do not extend a SOAPDoc with an application class. This is currently not supported.

SOAPDoc Built-In Functions

"CreateSOAPDoc" (PeopleCode Language Reference)

SOAPDoc Class Methods

In addition to the methods listed here, most of the XmlDocument and XmlNode class methods can be used with a SOAPDoc object. The methods are discussed in alphabetical order.

Related Links

[Understanding XmlDocument Classes](#)

AddBody

Syntax

```
AddBody ()
```

Description

Use the AddBody method to add the body section of the SOAP XML document.

This method is optional when you're creating a SOAP document. Use it only if you must set any additional attributes for the body. Otherwise, the body section is automatically generated in the XML document.

If you're going to add a body section, you must do it *after* you've added the envelope section. If you are going to modify the body section, you must do this *before* you add the method sections of the SOAP XML document by calling the BodyNode property and using XmlNode methods and properties.

Note: Only one body section can be set within one PeopleSoft SOAP XML document.

Parameters

None.

Returns

None.

Example

From the following code:

```
&MyDoc.AddBody ();
```

the following XML is created:

```
<SOAP-ENV:Body >
</SOAP-ENV:Body>
```

Related Links

[AddMethod](#)

[AddEnvelope](#)

[AddAttribute](#)

AddEnvelope

Syntax

```
AddEnvelope(SOAP_Schema)
```

Description

Use the AddEnvelope method to add the envelope element tags and the default schema. The default encoding styles are also set with this method.

Note: Only one envelope section can be set within one PeopleSoft SOAP XML document.

If you're going to be adding an envelope section, you must do this *before* you add the body section or any methods by calling the EnvelopeNode property and using XmlNode methods and properties.

Parameters

Parameter	Description
<i>SOAP_Schema</i>	Specify whether to use the default SOAP schema or the UDDI schema. You can specify either a numeric value or a constant for this property. The values are:

Numeric Value	Constant Value	Description
0	%SOAP_Schema	Use the SOAP schema. Specifying this value adds the following attributes to the SOAP envelope: <pre>xmlns:SOAP-ENV= "http://schemas.xmlsoap.org/soap/envelope/=> " xmlns:SOAP-ENV= "http://schemas.xmlsoap.org/soap/encoding/=> "</pre>

Numeric Value	Constant Value	Description
1	%SOAP_UDDI	Use the UDDI schema. Specifying this value adds the following attribute to the SOAP envelope: xmlns:SOAP-ENV= "urn:uddi-org:api"
2	%SOAP_Custom	Specify this value to add custom Namespace schemas to the SOAP envelope instead of the default SOAP schemas. Note: You must create the custom schema before you use it. See XML Schema . You must add the SOAP_ENV URI (as an attribute, using AddAttribute) before adding any other SOAP attributes. Note: For highly customized SOAP documents, PeopleSoft recommends using the XmlDoc class and creating the tags yourself.

Returns

None.

Example

The following example uses the default SOAP schema. The following PeopleCode program:

```
&MyDoc.AddEnvelope(%SOAP_Schema);
```

Creates the following XML:

```
<?xml version="1.0"?>
<SOAP-ENV:Envelope xmlns:SOAP-ENV= "http://schemas.xmlsoap.org/soap/envelope/"
xmlns:SOAP-ENV= "http://schemas.xmlsoap.org/soap/encoding/"
</SOAP-ENV:Envelope>
```

The following example creates an envelope and validates it.

The following PeopleCode program:

```
&soapReq = CreateSOAPDoc(); /* required */
/* manually add SOAP XML envelope, header, body, method and parameters */
/* &soapReq.AddHeader(); MUST come before any other section, but is optional */
&soapReq.AddEnvelope(%SOAP_Custom);
&EnvNode = &soapReq.EnvelopeNode;
&AddEnvelopeAttribute = &EnvNode.AddAttribute("xmlns:SOAP-ENV", "urn:MyCustomSchema=>
.org");
&AddEnvelopeAttribute = &EnvNode.AddAttribute("xmlns:xsi", http://www.w3.org/2001/X=>
MLSchema-instance);
&AddEnvelopeAttribute = &EnvNode.AddAttribute("xmlns:xsd", http://www.w3.org/2001/X=>
MLSchema);
```

```

&AddEnvelopeAttribute = &EnvNode.AddAttribute("xmlns:soap", http://schemas.xmlsoap.⇒
org/soap/envelope/);
&soapReq.AddMethod("requestAccessCode", 1);

/* Validate the message */
MessageBox(%MsgStyle_OK, "", 0, 0, "Validate the message");
&OK = &soapReq.ValidateSOAPDoc();
MessageBox(%MsgStyle_OK, "", 0, 0, "Message Validated and &OK = " | &OK);

/* Convert SOAP XML to XML */
MessageBox(%MsgStyle_OK, "", 0, 0, "Sending the message next");

&string = &soapReq.GenXmlString();
MessageBox(%MsgStyle_OK, "", 0, 0, "SOAP XML = " | &string);

```

Creates the following XML:

```

<?xml version="1.0"?>
<SOAP-ENV:Envelope xmlns:xsd= "http://www.w3.org/2001/XMLSchema"
xmlns:xsi= "http://www.w3.org/2001/XMLSchema-instance"
xmlns:soap= "http://schemas.xmlsoap.org/soap/envelope/"
xmlns:SOAP-ENV= "urn:MyCustomSchema.org">
<SOAP-ENV:Body>
  <requestAccessCode/>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

Related Links

[AddBody](#)

AddFault

Syntax

```
AddFault(Fault_Code, Fault_String)
```

Description

Use the AddFault method to add a fault code, with its corresponding fault string, to a SOAPDoc. Use this method only in a Response SOAP XML Document. The Envelope and Body sections of the XML Document are automatically added if they don't exist.

Parameters

Parameter	Description
<i>Fault_Code</i>	Specify the fault code to add, as a string.
<i>Fault_String</i>	Specify the fault string to add, as a sting.

The following fault codes are supported:

<i>Fault Code</i>	<i>Fault String</i>	<i>Description</i>
100	Version Mismatch	The XML version or SOAP version is not supported by the current implementation.
300	Client error	An error occurred on the client while processing the SOAP document.
400	Server error	An error occurred on the server while processing the SOAP document.

Returns

None.

Example

The following example program:

```
&SOAPDoc = CreateSOAPDoc();
&SOAPDoc.AddFault("400", "Server Error");

/* ==> The following statement executes this instance: */
&FaultCode = &SOAPDoc.FaultCode;
&FaultString = &SOAPDoc.FaultString;
&OK = &SOAPDoc.ValidateSOAPDoc();
```

Creates the following XML:

```
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
- <SOAP-ENV:Body>
- <SOAP-ENV:Fault>
  <faultcode>400</faultcode>
  <faultstring>SOAP Server Error</faultstring>
</SOAP-ENV:Fault>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

Related Links

[FaultCode](#)

[FaultString](#)

[FaultCodeS](#)

AddHeader

Syntax

AddHeader ()

Description

Use the AddHeader method to add the header section of the SOAP XML document.

This method is optional when you're creating a SOAP document. Use it only if you want to include a header in your SOAP XML document.

If you're going to add a header, you must do it *before* you've added any other sections, such as the envelope or the body.

After you've created the header, you can access it using the HeaderNode property. Once you have a reference to the node, you must use the XmlDocument methods to add specifics to the header section such as encryption, as well as any required child nodes.

Note: Only one header section can be set within one PeopleSoft SOAP XML document.

Parameters

None.

Returns

None.

Example

The following test adds a header section into a SOAP XML document where all sections are created explicitly:

```
Local SOAPDoc &Sdoc;
Local XMLNode &Node;

/* ==> Add inputs: */
&Sdoc = CreateSOAPDoc(); /* required */
&Sdoc.AddEnvelope(0); /* optional */
&Sdoc.AddHeader(); /* optional */
&Sdoc.AddBody(); /* optional */
&Sdoc.AddMethod("SOAPXml", 1); /* required */
&Sdoc.AddParm("symbols", "PSFT");

&OK = &Sdoc.ValidateSOAPDoc();

/*Append to TEMP file*/
&Xstring = &Sdoc.GenXmlString();
&myfile = GetFile("cmsDoc.xml", "A", "UTF8");
&myfile.WriteLine(&Xstring);
&myfile.Close();

&METHOD = &Sdoc.MethodName;
&ParmCnt = &Sdoc.ParmCount;
&HdrNode= &Sdoc.HeaderNode;

&HdrName = &HdrNode.NodeName; //returns SOAP-ENV:Header

/* Echo out the Returned Outputs */
out_BI_results("SOAP Header test 1");
out_BI_results(" ");
out_BI_results("Validated: " | &OK);
out_BI_results("Method: " | &METHOD);
out_BI_results("Parm Count: " | &ParmCount);
```

```
out_BI_results("Header : " | &HdrName);
out_BI_results("End-of-Test");
```

Related Links

[HeaderNode](#)

AddMethod

Syntax

```
AddMethod(MethodName, IsRequest)
```

Description

Use the AddMethod method to set the name of the method element being processed. Additional attributes for the added method can be set using the AddAttribute and InsertAttribute method. Executing AddMethod automatically adds any missing Envelope and Body sections.

Note: Only one method can be set within one PeopleSoft SOAP XML document.

The SOAPDoc method can be used only *after* the envelope and body sections have been added.

Set the parameters for the method using the AddParm method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>MethodName</i>	Specify the name of the method element being added.
<i>IsRequest</i>	Specify if the message is a request message. This parameter takes a numeric value: <ul style="list-style-type: none"> • 1 if the message is a request message • 0 if the message is a response message

Returns

None.

Example

The following sample program:

```
&MyDoc.AddMethod("GetPrice", 0);
```

Creates the following XML:

```
<GetPrice>
```

```
</GetPriceResponse>
```

The following sample program:

```
&MyDoc.AddMethod("GetPrice", 1);
```

Creates the following XML:

```
<GetPrice>
</GetPrice>
```

[AddParm](#)

[MethodName](#)

[MethodNode](#)

[AddAttribute](#)

AddParm

Syntax

```
AddParm(ParmName, ParmValue)
```

Description

Use the AddParm method to set the parameters for the parameter element of the current method. To set more than one parameter, use the method more than once. The parameters are set and used in the order that this method is called. Any number of parameter name-value pairs can be set for a method and are added to the XML document in the order that this method is called from the PeopleCode program.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ParmName</i>	Specify the name of the parameter as a string.
<i>ParmValue</i>	Specify the value of the parameter as a string.

Returns

None.

Example

The following PeopleCode:

```
&MyDoc.AddParm("Item", "Apples");
```

Creates the following XML:

```
<Item >Apples</Item>
```

Related Links

[AddMethod](#)

GetParmName

Syntax

```
GetParmName (Index)
```

Description

Use the GetParmName method access the parameter names for a method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the number of the parameter that you want to access. Values start at 1.

Returns

A string.

Example

```
For &I = 1 to &SOAPDoc.ParmCount
    &ParmName = &SOAPDoc.GetParmName (&I);
    &ParmValue = &SOAPDoc.GetParmValue (&I);

    /* Do processing */
End-For;
```

GetParmValue

Syntax

```
GetParmValue (Index)
```

Description

Use the `GetParmValue` method to access the parameter values for a method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify the number of the parameter you want to access. Values start at 1.

Returns

A string.

Example

```
For &I = 1 to &SOAPDoc.ParmCount
    &ParmName = &SOAPDoc.GetParmName(&I);
    &ParmValue = &SOAPDoc.GetParmValue(&I);

    /* Do processing */
End-For;
```

[GetParmName](#)

[ParmCount](#)

ValidateSOAPDoc

Syntax

```
ValidateSOAPDoc ()
```

Description

Use the `ValidateSOAPDoc` method to validate the SOAP document for correctness as follows:

SOAP message is:

- Encoded using XML.
- Has SOAP envelope.
- Has SOAP body.
- Used SOAP encoding and envelope namespaces.

Returns

This method returns either a number or a constant. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%SOAP_Valid	The SOAPDoc is valid.
1	%SOAP_NoEnvelope	Missing or invalid envelope section in XML document.
2	%SOAP_InvalidEnvelope	Envelope has improper Namespace used. Should be: SOAP-ENV or SOAP-ENC
3	%SOAP_NoBody	Missing body section in XML document.
4	%SOAP_NoMethod	Missing or invalid method section in XML document.
6	%SOAP_InvalidXml	Invalid XML syntax in SOAPDoc.

Example

```
&Return = &MyDoc.ValidateSOAPDoc();
If &Return <> 0 Then
    /* do error processing */
End-if;
```

SOAPDoc Class Properties

In addition to the properties listed here, most of the XmlDocument and XmlNode class properties can be used with a SOAPDoc object. The properties are discussed in alphabetical order.

Related Links

[Understanding XmlDocument Classes](#)

BodyNode

Description

This property returns a reference to the body section of a SOAPDoc, as an XmlNode.

This property is read-only.

Related Links

[Understanding XmlDocument Classes](#)

EnvelopeNode

Description

This property returns a reference to the envelope section of a SOAPDoc, as an XmlNode.

This property is read-only.

Related Links

[Understanding XmlDocument Classes](#)

FaultCode

Description

Use the FaultCode property to return the fault code if the SOAP message has one. Not every message has a fault code. It is returned only when the SOAP method has had an error in processing *and* the SOAP method supports fault codes. This property returns a number.

If the fault code in the message cannot be converted to a number, the value 0 is returned. Use FaultCodeS to get the fault code value as a string.

This property is read-only.

Example

```
Local SOAPDoc &MyDoc;  
Local integer &Fault;  
  
&MyDoc = CreateSOAPDoc();  
&MyDoc.AddFault("400", "Server Error");  
  
&Fault = &MyDoc.FaultCode;
```

Related Links

[FaultString](#)

[FaultCodeS](#)

[AddFault](#)

FaultCodeS

Description

Use the FaultCodeS property to return the fault code if the SOAP message has one. Not every message has a fault code. It is returned only when the SOAP method has had an error in processing *and* the SOAP method supports fault codes. This property returns a string.

This property is read-only.

Example

```
Local SOAPDoc &MyDoc;  
Local string &Fault;  
  
&MyDoc = CreateSOAPDoc();  
&MyDoc.AddFault("400", "Server Error");  
  
&Fault = &MyDoc.FaultCodeS;
```

Related Links

[AddFault](#)

[FaultCode](#)

[FaultString](#)

FaultString

Description

Use the FaultString property to return the fault string if the reply has one. Not every SOAP message has a fault string. It is only returned when the SOAP method has had an error in processing *and* the SOAP method supports fault strings.

Example

```
&Fault = &MyDoc.FaultString;
```

Related Links

[FaultCode](#)

[FaultCodeS](#)

[AddFault](#)

HeaderNode

Description

Use the HeaderNode property to return a reference to the header node. After you have a reference, you can use the XmlDocument methods to read and make changes to the node.

This property is read/write.

Example

The following test adds a header section, validates the SOAPDoc, then access the header.

```
Local SOAPDoc &Sdoc;
Local XmlNode &Node;

/* ==> Add inputs: */
&Sdoc = CreateSOAPDoc(); /* required */

&Sdoc.AddHeader(); /* optional */
&Sdoc.AddMethod("SOAPXml", 1); /* required */

&OK = &Sdoc.ValidateSOAPDoc();

/*Append to TEMP file*/
&Xstring = &Sdoc.GenXmlString();
&myfile = GetFile("cmsDoc.xml", "A", "UTF8");
&myfile.WriteLine(&Xstring);
&myfile.Close();

&METHOD = &Sdoc.MethodName;
&ParmCnt = &Sdoc.ParmCount;
&HdrNode= &Sdoc.HeaderNode; //returns SOAP-ENV:Header

&HdrName = &HdrNode.NodeName;

/* Echo out the Returned Outputs */
out_BI_results("SOAP Header test 1");
out_BI_results(" ");
out_BI_results("Validated: " | &OK);
out_BI_results("Method: " | &METHOD);
out_BI_results("Parm Count: " | &ParmCount);
out_BI_results("Header : " | &HdrName);

out_BI_results("End-of-Test");
```

Related Links

[AddHeader](#)

MethodName

Description

This property returns the name of the method of the SOAPDoc, as a string.

If you want a reference to the method that you can work with, as an XmlNode, use the MethodNode property.

This property is read-only.

MethodNode

Description

This property returns a reference to the method section of a SOAPDoc, as an XmlNode.

If you want only the name of the method returned, use the MethodName property.

This property is read-only.

Related Links

[Understanding XmlDoc Classes](#)

ParmCount

Description

This property returns the total number of parameters for the method section in a SOAP XML document as a number.

This property is read-only.

Example

```
For &I = 1 to &SOAPDoc.ParmCount
    &ParmName = &SOAPDoc.GetParmName(&I);
    &ParmValue = &SOAPDoc.GetParmValue(&I);
    /* do processing */
End-For;
```

XmlDoc

Description

This property transforms a SOAPDoc object to an XmlDoc object. This is necessary only when sending or receiving a response message. You do *not* need to do this conversion to use the XmlDoc or XmlNode methods and properties.

This property is read/write.

Example

The following is an example of sending a SOAP message and receiving the response:

```
Local XmlDoc &request, &response;
Local string &strXml;
Local SOAPDoc &soapReq, &soapRes;

/* create the SOAP XML Document */
&soapReq = CreateSOAPDoc();
&soapReq.AddMethod("GetPrice");
&soapReq.AddParm("Item", "Apples");

/* convert SOAP to XmlDoc */
&request = &soapReq.XmlDoc;

/* Send the Request */
&response = SyncRequestXmlDoc(&request, Message.QE_SOAP_REQ, Node.UNDERDOG);

/* Get the SOAP response from the XmlDoc response */
&soapRes = CreateSOAPDoc();
&soapRes.XmlDoc = &response;
&OK = &soapRes.ValidateSOAPDoc();
&strXml = &soapRes.GenXmlString();
```

SOAPDoc Class Examples

The following are typical example of how you would use a SOAPDoc object.

Creating a SOAP Document

The following is the minimal PeopleCode you need to create a SOAP XML document:

```
Local SOAPDoc &SOAPDoc;

&SOAPDoc = CreateSOAPDoc();
&SOAPDoc.AddMethod("GetPrice");
&SOAPDoc.AddParm("Item", "Apples");
```

The following is an example of creating a SOAP XML document with a simple method.

```
Local SOAPDoc &SOAPDoc;

&SOAPDoc = CreateSOAPDoc();

&SOAPDoc.AddEnvelope(0);
&SOAPDoc.AddBody();
&SOAPDoc.AddParm("symbols", "PSFT");
&SOAPDoc.AddParm("format", "l1c1d1t1");

&OK = &SOAPDoc.ValidateSOAPDoc();
```

Reading an Existing SOAP Document

The following code loads an SOAP XML document from a URL, then finds the method name and parameters to call that method.

```
Local SOAPDoc &SOAPDoc;
Local Number &ParmCount;
Local Boolean &Result;

&SOAPDoc = CreateSOAPDoc();
&SOAPDoc.ParseXmlFromURL("C:\ptdvl\840S2\files\inputSOAP.xml");

&ParmCount = &SOAPDoc.ParmCount;
For &I = 1 to &ParmCount

    &ParmName = &SOAPDoc.GetParmName(&I);
    &ParmValue = &SOAPDoc.GetParmValue(&I);

/* Do processing */
End-for;
```

Using SOAP XML Text

The following shows a SOAP XML Document text for the following pseudo-code:

```
Item = "Apples"
Price = GetPrice(Item);
```

Example of SOAP Request Header

Here's the HTTP Header for a SOAP message. This Host URL is the server where the method defined in the SOAP envelope is processed:

```
POST /GetPrice HTTP/1.1
Host: www.farmersmarket.com
Content-Type: text/xml; charset="utf-8"
Content-Length: nnnn
SOAPAction: "GetPrice"
```

This is a simple example of a SOAP XML Document, requesting the price of Apples. It uses the default SOAP schemas. The name of the method is GetPrice with the parameter Item which has a value of "Apples".

```
<SOAP-ENV:Envelope
  xmlns:SOAP-ENV="http://schemas.SOAP.org/soap/envelope/"
  xmlns:SOAP-ENC="http://schemas.SOAP.org/soap/encoding/"
>
  <SOAP-ENV:Body>
    <m:GetPrice xmlns:m="SomeURI">
      <Item>Apples</Item>
    </m:GetPrice>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

Example of SOAP HTML Reply Header

Here's the HTTP Header for a SOAP message Reply with a 200 return code that the message was processed OK.

```
HTTP/1.1 200 OK
Content-Type: text/xml; charset="utf-8"
Content-Length: nnnn
```

This simple example of a SOAP XML Document reply returns the price of Apples as 34. The SOAP reply always codes the name of the requested method with the Response tag attached to it, GetPriceResponse in this case.

```
<SOAP-ENV:Envelope
  xmlns:SOAP-ENV="http://schemas.SOAP.org/soap/envelope/"
  xmlns:SOAP-ENC="http://schemas.SOAP.org/soap/encoding/"
>
  <SOAP-ENV:Body>
    <m:GetPriceResponse xmlns:m="Some-URI">
      <Price>34</Price>
    </m:GetPriceResponse>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

Chapter 54

SQL Class

Understanding SQL Class

You can create SQL definitions in Application Designer. These can be entire SQL programs, or just fragments of SQL statements that you want to re-use. PeopleCode provides the SQL class for accessing these SQL definitions in your PeopleCode program at runtime.

The SQL class provides capability beyond that offered by SQLExec. Unlike SQLExec, which fetches just the first SELECTed row, operations for the SQL class allow iteration over all rows fetched. This can dramatically improve performance if you're doing a million operations and you've set the BulkMode property to True.

A list of input (bind) values, and a list of output variables are supported, as they are in SQLExec. The input and output variables are limited to the same PeopleCode types that can be used with SQLExec, with the addition of a new class called Record.

At runtime, you instantiate a record object from the Record class. A record object is a "one row" instantiation of a record definition.

- When used as an output from an SQL object, each next field in the record is populated with the next column returned.
- When used as an input, several fields in the record are used to replace a single bind marker in the SQL statement. The bind marker for a record describes the type of substitution to be done.

Both records and other PeopleCode types can be mixed in both the output and input.

At runtime, you instantiate a SQL object from the SQL class. The SQL object is loaded by either a constructor for the object, or an explicit Open method call. Optionally, a SQL constructor and the Open method support setting the SQL statement through a string parameter. This capability enables the creation and execution of ad-hoc SQL statements.

The SQL class has a Fetch method for iterating through the rows fetched by a select. A *cursor* is used to control this connection between the runtime SQL object and the database. The cursor is closed automatically when the object goes out of scope. The cursor can be closed before that by using the Close method. The status of the connection is available from the Boolean IsOpen property.

The general status of operations is available from function or method return values or properties. Detailed status is not available, as the operations are designed to terminate on unexpected errors or errors that cannot be reasonably recovered from by application level logic.

Considerations for Extra Spaces

On the DB2 for OS/390 and z/OS platform, when the **zparm** option is set to decimal equals comma (so comma is used as the database decimal separator), extra blanks are added after commas to ensure that they are not mistaken for decimal separators.

Considerations for Case Sensitivity

When processing a SQL statement, the system automatically casts all fieldnames and possibly record names to uppercase when processing a SQL statement. When processing records from a third party, fields that are lowercase get cast into uppercase, which can create a runtime issue on case sensitive platforms.

To prevent this, use the %NoUppercase meta-SQL statement at the beginning of the SQL statement.

"Understanding Data Buffer Access" (PeopleCode Developer's Guide)

"%NoUppercase" (PeopleCode Language Reference)

Using Record Class SQL

There are some SQL type operations that you can do with the Record class, such as INSERT, DELETE and UPDATE. The advantage of using the Record class methods is ease of use, re-use of code, and so on. However, if you're doing many iterations of the same operation (like a million UPDATES) you should use the SQL object with the BulkMode property set to True.

The SQL object maintains a state (that is, a cursor). Hence, if your database can take advantage of BulkMode, instead of a million operations, the commands are "bulked up" and committed only once. This can improve performance dramatically.

Creating a SQL Definition

You can create SQL definitions in Application Designer, using the SQL editor. These SQL statements can be entire SQL programs, or just fragments that you want to re-use. After you have created a SQL definition, you can use it to populate a SQL object (using FetchSQL, Open, or GetSQL)

You can also create a SQL statement in PeopleCode (using CreateSQL), save it as a SQL definition (StoreSQL), then access it in Application Designer.

Binding and Executing of SQL Statements

The processing of an SQL statement involves a series of steps.

1. The binding process is the replacement of (variable) input values in the statement, in places indicated by bind placeholders.

The input values are substituted into the SQL statement in place of the bind placeholders. These placeholders have the form ":*number*", or "%*bindop*(:*number* [, *parm*]. . .)" where the *number* indicates which input value is to be substituted, and the *bindop* and *parm* strings indicate what meta-SQL binding function is to be performed.

Note: There must be no spaces between the *bindop* and the left parenthesis.

The following binding meta-SQL functions are used with record objects to substitute various forms of fieldnames and values into the SQL statement. The goal of these binding functions is to enable the writing of SQL and PeopleCode that can manipulate records without dependencies on the exact fields in the records.

- %DTTM
- %InsertValues
- %KeyEqual
- %KeyEqualNoEffDt
- %List
- %OldKeyEqual
- %Table
- %UpdatePairs

2. The execution of an SQL statement is the carrying out of the operation of the statement by the database engine.

This view of SQL statement processing is actually simpler than what actually occurs. In actual practice, the binding occurs in two distinct phases. The database engine (or its supporting routines) is aware of only the latter phase. For some operations, some database engines are able to delay the second stage of binding and the execution of an SQL statement, so the statement can be rebound and re-executed (with different input values). The advantage of this is that these bindings and executions can be accumulated and transmitted across the network to the database server, with several database operations being done in one network operation. This is sometimes referred to as *bulk mode*. Because the network time consumes most database time operations, the performance advantages of bulk mode can be significant.

However, in bulk mode, individual operations might not be executed immediately by the database engine. The result is that the application might not see errors that arise until later operations are performed.

SQL SELECT statements are not bound multiple times, rather the retrieved rows are accumulated and sent across the network many rows at a time, also decreasing the effect of network delays.

"Understanding Meta-SQL" (PeopleCode Language Reference)

Fetching From a SELECT

Some operations fetch a row of data into a list of output variables. The values of the fields from the select row are assigned in order to the given output variables. If one of these is a reference to a PeopleCode record object, the fields in the record are assigned the successive values from the row of the select, until all the fields are assigned. Assignment then continues with the next output variable, if any. The number of output fields and variables must equal the number of fields in the row of the select.

Related Links

"Understanding Data Buffer Access" (PeopleCode Developer's Guide)

Using Array of Any for Bind Values or Fetch Results

You can use a parameter of type "Array of Any" in place of a list of bind values or in place of a list of fetch result variables for the Execute, Fetch, and Open methods. This is generally used when you don't know how many values are needed until the code runs.

For example, suppose that you had a SQL definition INSERT_TEST, that dynamically (that is, at runtime) generated the following SQL statement:

```
"INSERT INTO PS_TESTREC (TESTF1, TESTF2, TESTF3, TESTF4, . . . N) VALUES (:1, :2, %⇒
DateTimeIn(:3), %TextIn(:4)), . . . N";
```

Suppose you have placed the values to be inserted into an Array of Any, say &AAny:

```
&AAny = CreateArrayAny("a", 1, %DateTime, "abcdefg", . . . N);
```

You can execute the insert with the following:

```
&AAny = CreateArrayAny("a", 1, %DateTime, "abcdefg", . . . N);
&SQL = GetSQL(SQL.INSERT_TEST);
While /* Still something to do */
    &SQL.Execute (&AAny);
End-While;
&SQL.Close();
```

Because the Array of Any promotes to absorb any remaining select columns, it must be the last parameter for the SQL object Fetch method or (for results) SQLExec. For binding, it must be the only bind parameter, as it is expected to supply all the bind values needed.

Reusing a Cursor

Reusing a cursor means *compiling* a SQL statement just once, but *executing* it more than once. When a SQL statement is compiled, the database checks the syntax and chooses a query path. By doing this only once, but executing this statement several times, you can obtain an improvement in performance.

In PeopleCode, you can reuse a cursor either by using the `ReuseCursor` property or by following certain restrictions in your code.

Using the `ReuseCursor` Property

If you specify the `ReuseCursor` property as `True`, the cursor isn't closed until either the SQL object is explicitly closed or re-opened. This provides greater control over the cursor associated with your SQL object. However, when you set `ReuseCursor` to `True`, you're essentially pledging to do the right thing in your program. There are some considerations for how you use this property:

In a Application Engine program, if your program can be restarted, you *must* check for a restart after a checkpoint by testing to see if the SQL object is open after the checkpoint. If it isn't open, that means a restart has happened, and you must reopen the SQL object. In most cases, on checkpoints, your open SQL objects aren't closed, saving the overhead of re-establishing the SQL object after the checkpoint. If the SQL object is open on a select statement at a checkpoint it isn't restored to the open state because you cannot reliably establish the state of the execute-fetch sequence.

In the following example the SQL object is established on a select statement which is executed twice with different bind parameters but is compiled only once. Without the `ReuseCursor` property the SQL object would be closed after the first fetch cycle completes.

```
Local SQL &Sql;
Local String &Company1 = "CCB";
Local String &Company2 = "CCF";

&Sql = CreateSQL("SELECT A.COMPANY, %Timeout(A.EFFDT) FROM %Table(COMPANY_TBL) A WH⇒
ERE A.COMPANY=:1", &Company1);
/* commenting this out should make the subsequent Execute fail */
&Sql.ReuseCursor = True;

While &Sql.Fetch(&Company1, &Effdt)
    /* processing for the first Company */
End-While;

&Sql.Execute(&Company2);

While &Sql.Fetch(&Company1, &Effdt)
    /* processing for the second company */
End-While;

&Sql.Close();
```

Reusing a Cursor Without the `ReuseCursor` Property

If you want to reuse a cursor in your program, there are several conditions:

- You have to use the SQL object. Only SQL objects retain SQL cursor information.

- For INSERT, DELETE, and UPDATE statements, you automatically reuse the cursor as long as you don't change the SQL statement as part of the binding process. If the SQL statement is textually the same, so only the binds have changed, you get reuse. For example, you won't get reuse if you first bind one kind of record object to %Insert(), then bind another, different kind of record object.
- For SELECTs, you *must* use the meta-SQL shortcuts (%SelectAll, %SelectByKey, or %SelectByKeyEffDt), *and* the CreateSQL or GetSQL functions without supplying any bind or buffer parameters. The bind parameters are supplied in the Execute function. The Fetch parameter must be the fetch buffer, and be the same as the first Execute parameter. You can supply WHERE clauses, ORDER-BY, and so on, on the end of the SQL string containing the meta-SQL.

Note: BulkMode doesn't reuse the cursor in the same way as the SQL object. BulkMode requests that, when the system can reuse the cursor, it also holds all the changes so they can be communicated to the database in batches.

By using one of the forms of the Select meta-SQL, you're guaranteeing the resulting fetched values are all put into one record object (buffer). This means the implementation doesn't have to ask the database for the length and type of each column: the record buffer is already defined. So this sample code uses the SQL object to maintain the state of the connection with the database, and the record object, to maintain a series of fields suitable for database operations.

```
Local SQL &SQL;
Local Record &REC;

&REC = CreateRecord(Record.KP_KPI_DFN);

/* start with select statement, no bind refs, no */
/* bind parameters */

&SQL = CreateSQL("%Selectall(:1) Where SETID = :2 and KPI_ID = :3 and EFFDT = (SELE⇒
CT MAX(EFFDT) FROM PS_KP_KPI_DFN WHERE SETID = :4 AND KPI_ID = :5 AND EFFDT ≤= %Dat⇒
eIn(:6))");
```

Start Loop

```
/* bind and execute the statement */

&SQL.Execute(&REC, &SETID_KPI, &COMPID, &SETID_KPI, &COMPID, &EFFDT);

/* Note record parameter for Fetch statement must be
the same as the first Execute parameter
the results are in this record */

If &SQL.Fetch(&REC) Then

    /*process this record */

End-If;
```

End Loop

```
&SQL.Close(); /* there is no implicit close on a Fetch returning False */
```

The following example comes from a Application Engine program. Because the loop goes in and out of PeopleCode, you must declare the SQL object as Global. This example is in three parts.

1. Program called by Application Engine before the loop:

```
Global SQL &SQL;
```

```
&SQL = CreateSQL("INSERT INTO %Table(MY_WORK) (TRANS , REGISTERWRITE) VALUES (=>
:1, :2)");

&SQL.BulkMode = True; /* not required for reuse, but will get better performan=>
ce on platforms that support bulk insert */
```

2. Program called in the Application Engine loop on SELECT 'X' FROM PSRECDEFN WHERE RECNAME LIKE '%A':

```
Global SQL &SQL;

&var1 = "X";
&var2 = "Y";

&SQL.Execute(&var1, &var2);
```

3. Program called by Application Engine after the loop:

```
Global SQL &SQL;

&SQL.Close();
```

Understanding SQL Objects and Application Engine Programs

A global variable won't go out of scope until a Application Engine program finishes. However, all SQL objects are forced closed (that is, the cursor closed) sooner than that. *Any open SQL object is forced closed just before any checkpoint in an Application Engine program.* This is to ensure that the application can be restarted successfully from the checkpoint. After the SQL object is closed, you can reopen the SQL object, or query its properties, (such as Status, IsOpen). The simplest way to avoid unnecessary closing of the SQL object is to set the ReuseCursor property to True. A restartable program should always check that SQL objects are open before using them in steps where it's expected they're open. In the absence of an intervening checkpoint, an open SQL object remains open until the Application Engine program finishes.

Declaring a SQL Object

SQL objects are declared as type SQL. For example:

```
Local SQL &MYSQL;

Global SQL &MySql = CreateSQL(SQL.MySql);
```

Scope of an SQL Object

An SQL object can be instantiated only from PeopleCode.

This object can be used anywhere you have PeopleCode, that is, in an application class, Application Engine PeopleCode, record field PeopleCode, and so on.

Your SQL statements sometimes change the database. When your SQL changes the database, your code should be only in one of the following events:

- SavePreChange
- WorkFlow
- SavePostChange
- Message Subscription
- FieldChange
- Application Engine PeopleCode action

SQL Class Built-in Functions

"FetchSQL" (PeopleCode Language Reference)

"GetSQL" (PeopleCode Language Reference)

"StoreSQL" (PeopleCode Language Reference)

SQL Class Methods

In this section, we discuss the SQL class methods. The methods are discussed in alphabetical order.

Close

Syntax

```
Close ()
```

Description

The Close method closes the SQL object. This terminates any incomplete fetching of select result rows, completes any buffered operations (that is, using BulkMode), and disassociates the SQL object from any SQL statement that was open on it.

After BulkMode operations, the RowsAffected property is not valid.

Parameters

None

Returns

True on successful completion, False if there was a duplicate record error. Any errors associated with buffered operations (that is, using BulkMode), other than duplicate record errors, cause termination.

Example

```
&SQL = CreateSQL("%Delete(:1)");
While /* Still something to do */
  /* Set key field values of &ABS_HIST */
  &SQL.Execute (&ABS_HIST);
End-While;
&SQL.Close();
```

Related Links

[Open](#)

"CreateSQL" (PeopleCode Language Reference)

Execute

Syntax

Execute (*paramlist*)

Where *paramlist* is an arbitrary-length list of values in the form:

```
inval1 [, inval2] ...
```

Description

The Execute method executes the SQL statement of the SQL object. The SQL object must be open and unbound on a delete, insert, or update statement. That is, the CreateSQL, GetSQL, or Open preceding the Execute must have specified a delete, insert, or update statement with bind placeholders and must not have supplied any input values.

The values in *paramlist* are used to bind the SQL statement before it gets executed.

When using the optional BulkMode, the Execute operations may be buffered and are not guaranteed to have been presented to the database until a Close is done. Thus, in BulkMode, errors that arise may not be reported until later operations are done.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>paramlist</i>	Specify input values for the SQL string.

Returns

True on successful completion, False for "record not found" and "duplicate record" errors. Any other errors cause termination.

Example

The following example creates a SQL object for inserting. The statement isn't automatically executed when it's created because there aren't any bind variables. The Execute occurs after other processing is finished. The name of the record is passed in as the bind variable in the Execute method.

```
&SQL = CreateSQL("%Insert(:1)");
While /* Still something to do */
    /* Set all the field values of &ABS_HIST. */
    &SQL.Execute(&ABS_HIST);
End-While;
&SQL.Close();
```

The following example creates two SQL objects, one to be used for fetching, the other for updating the record. The first SQL object selects all the records in the &ABS_HIST record that match &EMPLID. The data is actually retrieved using the Fetch method. After values are set on the record, the update is performed by the Execute.

```
&SQL1 = CreateSQL("%Select(:1) where EMPLID = :2", &ABS_HIST, &EMPLID);
&SQL_UP = CreateSQL("%Update(:1)");
While &SQL1.Fetch(&ABS_HIST);
    /* Set some field values of &ABS_HIST. */
    &SQL_UP.Execute(&ABS_HIST);
End-While;
&SQL_UP.Close();
```

The following is an example of inserting an array of records:

```
Local SQL &SQL;
Local array of Record &RECS;

/* Set up the array of records. */
. . .

/* Create the SQL object open on an insert */
/* statement, and unbound */
&SQL = CreateSQL("%Insert(:1)");
/* While the array has something in it */
While &RECS.Len
    /* Insert the first record of the array, */
    /* and remove it from the array. */
    &SQL.Execute(&RECS.Shift());
End-While;
```

Related Links

[Close](#)

[BulkMode](#)

"CreateSQL" (PeopleCode Language Reference)

Fetch

Syntax

Fetch (*paramlist*)

Where *paramlist* is an arbitrary-length list of values in the form:

```
outvar1 [, outvar2] ...
```

Description

The Fetch method retrieves the next row of data from the SELECT that is open on the SQL object. Any errors result in termination of the PeopleCode program with an error message.

If there are no more rows to fetch, Fetch returns as False, the *outvars* are set to their default PeopleCode values, and the SQL object is automatically closed.

Using Fetch with a closed SQL object is processed the same as when there are no more rows to fetch.

Note: If you want to fetch only a single row, the SQLExec function can perform better, as it fetches only a single row from the server.

The return of Fetch is not optional, that is, you *must* check for the value of the fetch.

Setting Data Fields to Null

This method will *not* set Component Processor data buffer fields to NULL after a row not found fetching error. However, it does set fields that aren't part of the Component Processor data buffers to NULL. It does set work record fields to NULL.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>paramlist</i>	Specify output variables from the SQL Select statement.

Returns

The result of Fetch is True if a row was fetched. If there are no more rows to fetch, the result is False.

Example

In the following example, the Fetch method is used first to process a single row, then to process the ABS_HIST record.

```
Local SQL &SQL;
Local Record &ABS_HIST;

&ABS_HIST = CreateRecord(RECORD.ABSENCE_HIST);
&SQL = GetSQL(SQL.SEL27, 15, "Smith");
While &SQL.Fetch(&NAME1, &BIRTH_DT)
    /* Process NAME1, BIRTHDT from the selected row. */
End-While;

&SQL.Open(SQL.SEL_ABS_HIST, &NAME1, "Smith");
While &SQL.Fetch(&ABS_HIST)
    /* Process ABS_HIST record. */
```

The following is an example of reading in an array of record objects:

```
Local SQL &SQL;
Local Record &REC;
Local Array of Record &RECS;
```

```

/* Get the SQL object open and ready for fetches. */
&SQL = CreateSQL("%SelectAll(:1) where EMPLID = :2", RECORD.ABSENCE_HIST, &EMPLID);
/* Create the first record. */
&REC = CreateRecord(RECORD.ABSENCE_HIST);
/* Create an empty array of records. */
&RECS = CreateArrayRept(&REC, 0);
While &SQL.Fetch(&REC)
    /* We got a record, add it to the array */
    /* and create another.*/
    &RECS.Push(&REC);
    &REC = CreateRecord(RECORD.ABSENCE_HIST);
End-While;

```

[Open](#)

"GetSQL" (PeopleCode Language Reference)

"SQLExec" (PeopleCode Language Reference)

Open

Syntax

```
Open(sql [, paramlist])
```

Where *paramlist* is an arbitrary-length list of values in the form:

```
inval1 [, inval2] ...
```

Description

The Open method associates the *sql* statement with the SQL object. The *sql* parameter can be either:

- A string value giving the SQL statement.
- A reference to a SQL definition in the form **SQL.sqlname**.

If the SQL object was already open, it is first closed. This terminates any incomplete fetching of select result rows, completes any buffered operations (that is, using BulkMode), and disassociates the SQL object from any SQL statement that was open on it.

Opening and Processing sql

If *sql* is a SELECT statement, it is immediately bound with the *inval* input values and executed. The SQL object should subsequently be the subject of a series of Fetch method calls to retrieve the selected rows. If you want to fetch only a single row, use the SQLExec function instead. If you want to fetch a single row into a PeopleCode record object, use the record Select method.

If *sql* is not a SELECT statement, and either: there are some inval parameters, or there are no bind placeholders in the SQL statement, the statement is immediately bound and executed. This means that there is nothing further to be done with the SQL statement and the IsOpen property of the returned SQL object will be False. In this case, using the SQLExec function would generally be more effective. If you want to delete, insert, or update a record object, use the record Delete, Insert, or Update methods with the record object.

If *sql* is not a SELECT statement, there are no *inval* parameters, *and* there are bind placeholders in the SQL statement, the statement is neither bound nor executed. The resulting SQL object should subsequently be the subject of a series of Execute method calls to affect the desired rows.

Setting Data Fields to Null

This method will *not* set Component Processor data buffer fields to NULL after a row not found fetching error. However, it does set fields that aren't part of the Component Processor data buffers to NULL.

Parameters

Parameter	Description
<i>sql</i>	Specify either a SQL string or a reference to a SQL definition in the form SQL.sqlname .
<i>paramlist</i>	Specify input values for the SQL string.

Returns

None.

Example

Generally, you use the Open method only after you've already gotten a reference to another SQL object. SELECT and SEL_ABS_HIST are the names of the SQL definitions created in Application Designer.

```
Local SQL &SQL;
&SQL = GetSQL(SQL.SELECT);
/* do other processing */
/* get next SQL statement for additional processing */
/* The open automatically closes the previous */
/* SQL statement */

&SQL.Open(SQL.SEL_ABS_HIST, &NAME1, "Smith");
While &SQL.Fetch(&ABS_HIST)
  /* Process ABS_HIST record. */
End-While;
```

SQL Class Properties

In this section, we discuss the SQL class properties. The properties are discussed in alphabetical order.

BulkMode

Description

This property controls the use of bulk mode. Setting this property to True enables the use of bulk mode, and hence removes any guarantee of the synchronous presentation of error status.

Bulk mode is used only with those database connections and operations that support it. Bulk mode can be used with any SQL operation, that is, with INSERTs, DELETEs, or UPDATEs.

If you're using a Application Engine program, and have set this property to True, the rows inserted in BulkMode are committed at the next database commit in your program.

After BulkMode operations, the RowsAffected property is not valid.

The default value for BulkMode is False.

This property is read/write.

Example

The following code is an example of inserting an array of records using bulk mode:

```
Local SQL &SQL;
Local array of Record &RECS;

/* Set up the array of records. */
. . .
/* Create the SQL object open on an insert */
/* statement, and unbound.*/
&SQL = CreateSQL("%Insert(:1)");
/* Try for bulk mode. */
&SQL.BulkMode = True;
/* While the array has something in it&mldr; */
While &RECS.Len
  /* Insert the first record of the array, */
  /* and remove it from the array. */
  If not &SQL.Execute(&RECS.Shift) then
    /* A duplicate record found, possibly */
    /* in bulk mode. There is no way to */
    /* tell which record had the problem. */
    /* One approach to recovery is to fail*/
    /* the transaction and retry it with a*/
    /* process that does only one record */
    /* at a time, that is, doesn't use */
    /* bulk mode.*/
    . . . ;
  End-If;
End-While;
```

Related Links

[RowsAffected](#)

[Binding and Executing of SQL Statements](#)

IsOpen

Description

This property returns as True if the SQL object is open on some SQL statement.

This property is read-only.

Example

You might use the following in a Application Engine program, after a checkpoint. MYSELECT is the name of a SQL definition created in Application Designer:

```
If Not &MYSQL.IsOpen Then
    &MYSQL.Open(SQL.MYSELECT);
End-if;
```

LTrim

Description

This property specifies whether values read by the Fetch method are trimmed of blanks on the left, except in the following cases:

- For long columns.
- The record is directly used to buffer the incoming data. In the following example, the values aren't LTrimmed - regardless of the setting of the LTrim property.

```
Local Record &Rec = CreateRecord(Record.QA_TEST);
Local SQL &Sql = CreateSQL("%SelectAll(:1)");
&Sql.LTrim = True; /* the default */
&Sql.Execute(&Rec);
While &Sql.Fetch(&Rec)
    /* do processing */
End-While;
```

This property takes a Boolean value. The default value is True. If this property is set to False, the selected values are not trimmed of blanks on the left.

This property is read/write.

Note: The removal of blanks from the right end of fetched values (RTrimming) still occurs for non-long columns.

Example

```
Local Record &Rec = CreateRecord(Record.QA_TEST);
Local SQL &Sql = CreateSQL("%SelectAll(:1)", &Rec);
&Sql.LTrim = False;
While &Sql.Fetch(&Rec)
    /* do processing */
End-While;
```

ReuseCursor

Description

This property specifies whether the SQL object tries to reuse the open cursor. This property takes a Boolean value, True, to reuse the SQL cursor.

If specified as True, the SQL object won't be closed at checkpoints, and any non-SELECT SQL is restored. In addition the SQL object is not closed after a fetch cycle completes. It remains open ready to be executed, perhaps with different bind parameters.

If you use this property in your application program, you *must* close the SQL object explicitly or it is closed when the object goes out of scope (that is, when the program finishes.)

You must instantiate a SQL object first before you can reuse it.

This property is read/write.

Related Links

[Reusing a Cursor](#)

RowsAffected

Description

This property returns the number of rows affected by the last INSERT, UPDATE, or DELETE statement of the SQL object. After BulkMode operations, the RowsAffected property is not valid.

This property is read-only.

Example

The following code is an example that determines if a delete statement actually deleted anything:

```
Local SQL &SQL;

/* Create the SQL object and do the deletion. */
  &SQL = CreateSQL("Delete from %Table(:1) where EMPLID = :1", RECORD.ABSENCE_HIST⇒
, &EMPLID);
  If &SQL.RowsAffected = 0 Then
    /* We did not delete any rows. */
    .
    .
  End-If;
```

Related Links

[BulkMode](#)

Status

Description

This property returns the status of the last statement executed. You can use either the constant or the numeric value for this property. The values for this property are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
0	%SQLStatus_OK	No Errors.
1	%SQLStatus_NotFound	Record not found.
2	%SQLStatus_Duplicate	Duplicate Record Found

This property is read-only.

Example

The following example determines what went wrong after an update:

```
Local SQL &SQL;
Local Record &NEWREC, &OLDREC;

/* Create and initialize &OLDREC with the keys of the
record to be updated. Create and initialize &NEWREC
with the new field values for the record. */
...;

/* Create and execute the update. */
&SQL = CreateSQL("%Update(:1, :2)", &NEWREC, &OLDREC);
Evaluate &SQL.Status
When = %SQLStatus_OK
    /* It worked. */
When = %SQLStatus_NotFound
    /* The OLDREC keys were not found. */
When = %SQLStatus_Duplicate
    /* The NEWREC keys were already there. */
End-Evaluate;
```

TraceName

Description

This property enables you to assign a name to a SQL statement that has been created in PeopleCode using CreateSQL. This name is used in the Application Engine timings trace. This property takes a string value.

Note: You *cannot* associate the TraceName property with the execution of a simple SELECT statement created with CreateSQL. This is because the SELECT is executed when the SQL is created, before it has the TraceName assigned. To do this, create a SQL object instead.

If this property isn't set, it defaults to a substring of the SQL statement, indicating the operation and table, (for example, SELECT PS_VOUCHER_LINE.) It may be useful to set TraceName to indicate the origin of the SQL statement.

This property is read/write.

Example

```
&REC = CreateRecord(Record.VOUCHER_LINE);
&SQL = CreateSQL("%selectall(:1) WHERE BUSINESS_UNIT =:2 AND VOUCHER_ID =:3 AND VOU⇒
CHER_LINE_NUM = :4");
&SQL.TraceName = "AEPROG.SECT1.STEP1.SQL2";
&SQL.Execute(&REC, MATCHING_AET.BUSINESS_UNIT, MATCHING_AET.VOUCHER_ID, &count);
If &SQL.Fetch(&REC) Then
    &count2 = &count2 + 1;
End-If;
```

The previous example would produce the following in the timings trace.

SQL Statement	Count	Time	Count	Time	Count	Time	Time

PeopleCode							
AEPROG1.SECT1.STEP1.SQL1			169	5.371	169	3.083	4.000
AEPROG1.SECT1.STEP1.SQL2			100	5.371	100	3.083	4.454

							8.454

You can use this parameter with the Open statement also. The following is an example of how this works:

```
&Sql1 = CreateObject("SQL");
&Sql1.TraceName = "sql1";
&Sql1.Open("Select %FirstRows(1) 'x' FROM psstatus");
&Sql1.Fetch(&Temp);

&Sql2 = CreateObject("SQL");
&Sql2.TraceName = "sql2";
&Sql2.Open("Select 'x' FROM psstatus");
&Sql2.Fetch(&Temp);
```

Value

Description

This property returns the SQL statement associated with the SQL object as a string.

This property is read-only.

Example

To report an error in a SQL definition, including the actual SQL executed, use the Value property to get the text of the SQL statement:

```
Local SQL &SQL;

/* Execute some SQL. */
&SQL = CreateSQL(SQL.SOMESQL, &EMPLID);
```

```
If &SQL.Status = %SQLStatus.NotFound Then
  /* Get the SQL string used. */
  &SQLSTR = &SQL.Value;
  /* Report the error. */
  . . . ;
End-If;
```

Tile Wizard and Other Tile Classes

Understanding the Tile Wizard Classes

Oracle provides three Tile Wizard classes to help you create tile definitions and dynamic content for tiles:

- **Tile** — To define dynamic tile content using PeopleCode, implement a custom application class from the delivered PTGP_APPCLASS_TILE:Tiles:Tile base class. See [Implementing an Application Class for Tile Content](#) for more information. Then, associate your custom application class to a tile definition in Tile Wizard. See "Step 2: Data Source Information - Application Class" (Portal Technology) for more information.
- **ImageTile** Use the PTGP_APPCLASS_TILE:API:ImageTile class to create, publish, or update an image tile definition using PeopleCode.
- **FreeTextTile** Use the PTGP_APPCLASS_TILE:API:FreeTextTile class to create, publish, or update a free text tile definition using PeopleCode. Because the FreeTextTile class is a subclass of the ImageTile class, many of the methods and properties of the ImageTile class are inherited by and apply to the FreeTextTile class.

[Tile Class Methods](#)

[Tile Class Properties](#)

[ImageTile Class Methods](#)

[ImageTile Class Properties](#)

[FreeTextTile Class Methods](#)

[FreeTextTile Class Properties](#)

Understanding Other Tile Classes

Additional application classes support creating and managing tile definitions.

Write a custom application class that extends the PTGP_APPCLASS_TILE:API:TileAppFilter base class to control whether a tile is displayed or hidden on fluid homepages and dashboards based on application-specific business logic.

Related Links

[TileAppFilter Class Methods](#)

"Hiding or Displaying Tiles Using an Application Class" (Portal Technology)

Understanding Application Class Tile Content

When you specify an application class as the data type in Tile Wizard, in addition to specifying the application class ID, you also specify these options in Tile Wizard:

- Tile content type
- Live data (on/off)
- Badge data (on/off)

These options determine what dynamic content and data will appear in the tile. Your implementation of the application class in PeopleCode will determine the specifics of the dynamic content and data. However, your PeopleCode implementation can also override the options chosen in Tile Wizard.

The following diagram illustrates where these items appear within a tile and where these items are defined (Tile Wizard, PeopleCode, or both). These items are described in more detail in the sections that follow this diagram.

Tile Title

The tile's title appears in the title bar at the top of the tile. The title is defined at Step 1 in Tile Wizard, and cannot be overridden in PeopleCode.

Tile Content

The tile content consumes the majority of the face of the tile, beneath the title bar and above the live data and badge areas on the tile. While the tile content type is specified at Step 2 in Tile Wizard, it can be overridden in PeopleCode. The specific tile data for any tile content type must be defined in PeopleCode.

Related Links

[getTileLiveData](#)

Live Data

The live data region appears at the bottom of the tile. Whether live data is displayed on a tile is specified at Step 2 in Tile Wizard; this setting can be overridden in PeopleCode.

Live data consists of four elements, each of which is optional:

Live data value 1 + Trend image + Live data value 2 + Live data value 3

Related Links

[hasLiveDataDescr](#)

[TileLiveData_1](#)

[TileLiveData_2](#)

[TileLiveData_3](#)

[TrendImage](#)

Trend Image

A trend image, typically an up or down arrow, is an optional element of the live data region. The trend image depicts at a glance the direction of change of the second live data value, which is typically a metric or numerical value.

When a trend image is enabled with the `hasLivedataTrendImage` property, it can be displayed with a key performance indicator (KPI) instead when only a single KPI is displayed as tile content (either the 1 KPI or the chart and 1 KPI content types).

Note: Only one trend image can be displayed on a tile. The default location is in the live data area. Therefore, if you want to associate a trend image with KPI data, you should not enable the live data area for the tile. If you enable the live data area, the trend image will be displayed there and not with the KPI data.

Related Links

[hasLivedataTrendImage](#)

[TrendImage](#)

Badge Data

The badge data region appears at the bottom right of the tile, to the right of the live data region. A badge is a simple integer, typically a count of items (for example, new requisitions, open purchase orders, and so on).

Related Links

[setTileHasCount](#)

[hasLiveDataCount](#)

TileTransCount

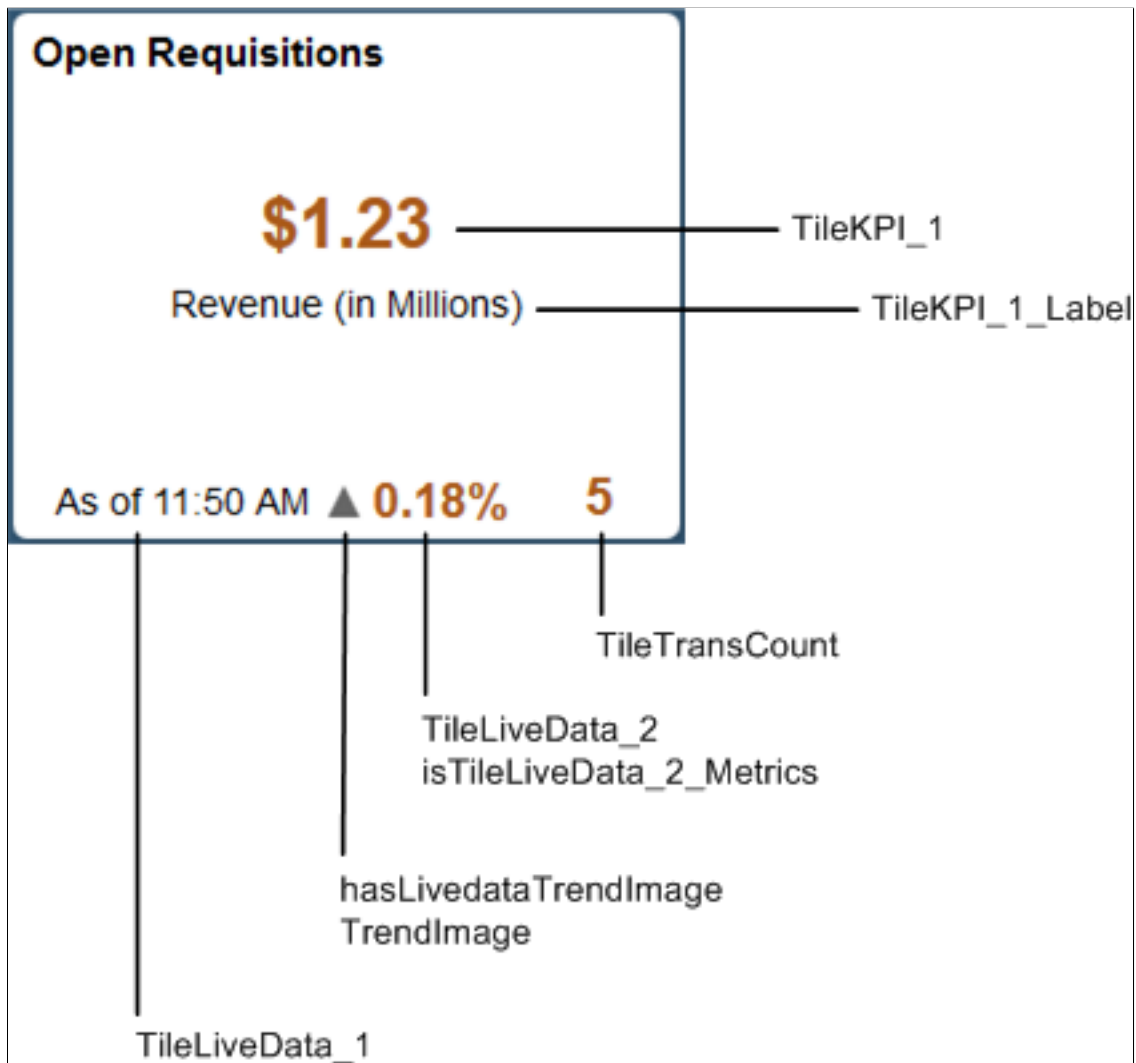

Example of Tile Content

The following example illustrates how tile content, live data, and badge data will appear together on a tile, and which properties were used to set which data values and formatting options. In Tile Wizard, the following options were set for this tile definition:

- Title: Open Requisitions
- Tile content: Data-1-KPI
- Live data: Enabled
- Badge data: Enabled

The following diagram illustrates example tile content:

- TileKPI_1 value: *\$1.23*
- TileKPI_1_Label value: *Revenue (in Millions)*
- TileLiveData_1 value: *As of 11:50 AM*
- TrendImage value: ▲
- TileLiveData_2 value: *0.18%*
- TileTransCount value: *5*

The following PeopleCode excerpt provides an example of how specific data values and formatting options were set for this tile:

```

/* 1 KPI tile content */
%This.TileKPI_1 = %This.getAmountFormattedValue(1.23456789, "USD");
%This.TileKPI_1_Label = "Revenue (in Millions)";

/* Live data */
%This.TileLiveData_1 = "As of " | DateTimeToLocalizedString(%Datetime, "h:mm a");
    
```

```

%This.hasLiveDataTrendImage = True;
%This.TrendImage = %This.k_strTrendUpImage;

%This.TileLiveData_2 = "0.18%";
%This.isTileLiveData_2_Metrics = True;

/* Tile badge */
%This.TileTransCount = &req_cnt;

```

Implementing an Application Class for Tile Content

To implement an application class for tile content, do the following in your application class definition:

1. Import the base class (also referred to as the superclass):

```
import PTGP_APPCLASS_TILE:Tiles:Tile;
```

2. In the class declaration, do the following:

- a. Indicate that your class (the subclass) extends the base class.
- b. Declare the constructor method for your class.
- c. Declare the required `getTileLiveData` method.
- d. (Optional) Declare any additional private methods and properties required by your implementation.

```

class My_Tile extends PTGP_APPCLASS_TILE:Tiles:Tile
  method My_Tile();
  method getTileLiveData();
end-class;

```

3. In the constructor method for your class, instantiate an object of the superclass:

```

method My_Tile
  %Super = create PTGP_APPCLASS_TILE:Tiles:Tile();
end-method;

```

4. In your implementation of the required `getTileLiveData` method, do the following:

- a. (Optional) Override the content type by invoking one of the optional `SetTileContentAs*` methods.
- b. (Optional) Override whether live data is displayed on the tile by invoking the `setTileLiveData` method or setting the `hasLiveDataDescr` property.
- c. (Optional) Override whether badge data is displayed on the tile by invoking the `setTileHasCount` method or setting the `hasLiveDataCount` property.
- d. For the tile content type selected, invoke any require methods and set all required properties for that content type. See [Properties and Methods Required by Tile Content Type](#) for more information.
- e. If live data is enabled for the tile, set all required properties for live data. See [Live Data](#) for more information.

- f. If badge data is enabled for the tile, set all required properties for badge data. See [Badge Data](#) for more information.
 - g. (Optional) Implement error handling by setting the `hasContent` property.
5. Create a tile definition in Tile Wizard. At Step 2, specify your custom application class. See "Step 2: Data Source Information - Application Class" (Portal Technology) for more information.

Properties and Methods Required by Tile Content Type

Each tile content type requires that you set required properties or invoke certain methods.

Chart

When you select the chart content type, use these properties and methods:

- [Tilechart](#)
- (Optional) [SetTitleContentAsChart](#)

Chart and 1 KPI

When you select the chart and 1 KPI content type, use these properties and methods:

- [Tilechart](#)
- [TileKPI_1](#)
- [TileKPI_1_Label](#)
- (Optional) [SetTitleContentAsChartAndKPI](#)
- (Optional) [hasLivedataTrendImage](#)
- (Optional) [TrendImage](#)

1 KPI

When you select the 1 KPI content type, use these properties and methods:

- [TileKPI_1](#)
- [TileKPI_1_Label](#)
- (Optional) [SetTitleContentAsOneKPI](#)
- (Optional) [hasLivedataTrendImage](#)
- (Optional) [TrendImage](#)

2 KPIs

When you select the 2 KPIs content type, use these properties and methods:

- [TileKPI_1](#)
- [TileKPI_1_Label](#)
- [TileKPI_2](#)
- [TileKPI_2_Label](#)
- (Optional) [TileKPI_2_Layout](#)
- (Optional) [SetTileContentAsOneKPI](#)
- (Optional) [SetTileContentAsTwoKPIsTopBottom](#)

HTML Area

When you select the HTML area content type, use these properties and methods:

- [TileHtmlArea](#)
- [TileHtmlAreaStyle](#)
- (Optional) [SetTileContentAsHTML](#)

Image

When you select the image content type, use these properties and methods:

- [ImageReferenceField](#) or [setTileImageRef](#)
- [TileImageReferenceLabel](#)
- (Optional) [SetTileContentAsImage](#)

Tile Class Methods

In this section, the Tile class methods are presented in alphabetical order.

getAmountFormattedValue

Syntax

```
getAmountFormattedValue(num_val, currency_cd)
```

Description

Invoke the `getAmountFormattedValue` method to return a String value that represents a numeric value that has been formatted with the currency symbol corresponding to the specified currency code.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>num_val</i>	Specifies the numeric value to be formatted as a Number value.
<i>currency_cd</i>	Specifies the currency code as a String value.

Returns

A String value.

Example

```
&total = &sub_tot1 + &sub_tot2;
%This.TileKPI_1 = %This.getAmountFormattedValue(&total, "USD");
```

Related Links

[ISO Country and Currency Codes](#)

getTileLiveData

Syntax

```
getTileLiveData ()
```

Description

This abstract method in the base class must be implemented in the subclass. In your implementation, you must set all properties required for the specified content type.

In addition, your implementation can include optional method invocations to dynamically override whether live data is displayed, whether a badge is displayed, or even the tile content type (by invoking one of the `SetTileContentAs*` methods).

Parameters

None.

Returns

None.

Example

```
method getTileLiveData
  /+ Extends/implements PTGP_APPCLASS_TILE:Tiles:Tile.getTileLiveData +/
  Local string &title, &img;
```

```

SQLExec("Select DESCR, PTGPLT_IMAGE FROM PS_PTPPB_GROUPLET Where PTPPB_GROUPLET_→
ID = :1", %This.TileID, &title, &img);

%This.ImageReferenceField.Value = @("Image." | &img);
%This.TileImageReferenceLabel = &title;

end-method;

```

Related Links

[Implementing an Application Class for Tile Content](#)

SetTileContentAsChart

Syntax

```
SetTileContentAsChart()
```

Description

Invoke the SetTileContentAsChart method within your implementation of the getTileLiveData method only if you wish to dynamically override the tile content type to display a chart at runtime.

If you invoke this method, then the Tilechart property is required.

Parameters

None.

Returns

None.

Related Links

[Tilechart](#)

SetTileContentAsChartAndKPI

Syntax

```
SetTileContentAsChartAndKPI()
```

Description

Invoke the SetTileContentAsChartAndKPI method within your implementation of the getTileLiveData method only if you wish to dynamically override the tile content type to display a chart and key performance indicator (KPI) at runtime.

If you invoke this method, then the Tilechart, TileKPI_1, and TileKPI_1_Label properties are required.

Parameters

None.

Returns

None.

Related Links

[Tilechart](#)

[TileKPI_1](#)

[TileKPI_1_Label](#)

SetTileContentAsHTML

Syntax

```
SetTileContentAsHTML ()
```

Description

Invoke the SetTileContentAsHTML method within your implementation of the getTileLiveData method only if you wish to dynamically override the tile content type to display an HTML area at runtime.

If you invoke this method, then the TileHtmlArea property is required; the TileHtmlAreaStyle property is optional.

Parameters

None

Returns

None.

Related Links

[TileHtmlArea](#)

[TileHtmlAreaStyle](#)

SetTileContentAsImage

Syntax

```
SetTileContentAsImage ()
```

Description

Invoke the `SetTileContentAsImage` method within your implementation of the `getTileLiveData` method only if you wish to dynamically override the tile content type to display an image at runtime. When the tile content is specified to be an image, either `setTileImageRef` method or the `ImageReferenceField` property is required.

Parameters

None.

Returns

None.

Related Links

[setTileImageRef](#)

[ImageReferenceField](#)

[TileImageReferenceLabel](#)

SetTileContentAsOneKPI

Syntax

```
SetTileContentAsOneKPI ()
```

Description

Invoke the `SetTileContentAsOneKPI` method within your implementation of the `getTileLiveData` method only if you wish to dynamically override the tile content type to display one KPI at runtime.

If you invoke this method, then the `TileKPI_1` and `TileKPI_1_Label` properties are required.

Parameters

None.

Returns

None.

Related Links

[TileKPI_1](#)

[TileKPI_1_Label](#)

SetTileContentAsTwoKPIs

Syntax

```
SetTileContentAsTwoKPIs ()
```

Description

Invoke the `SetTileContentAsTwoKPIs` method within your implementation of the `getTileLiveData` method only if you wish to dynamically override the tile content type to display two KPIs at runtime. With this method, the KPI data will be displayed side-by-side on the tile, rather than stacked. As an alternative, you can set the `TileKPI_2_Layout` property to change the orientation of the KPI data after invoking the `SetTileContentAsTwoKPIs` method.

If you invoke this method, then the `TileKPI_1`, `TileKPI_1_Label`, `TileKPI_2`, and `TileKPI_2_Label` properties are required.

Parameters

None.

Returns

None.

Related Links

[SetTileContentAsTwoKPIsTopBottom](#)

[TileKPI_1](#)

[TileKPI_1_Label](#)

[TileKPI_2](#)

[TileKPI_2_Label](#)

[TileKPI_2_Layout](#)

SetTileContentAsTwoKPIsTopBottom

Syntax

```
SetTileContentAsTwoKPIsTopBottom ()
```

Description

Invoke the `SetTileContentAsTwoKPIsTopBottom` method within your implementation of the `getTileLiveData` method only if you wish to dynamically override the tile content type to display two KPIs at runtime. With this method, the KPI data will be stacked on the tile, rather than side-by-side.

If you invoke this method, then the `TileKPI_1`, `TileKPI_1_Label`, `TileKPI_2`, and `TileKPI_2_Label` properties are required.

Parameters

None.

Returns

None.

[TileKPI_2_Label](#)

[TileKPI_2_Layout](#)

setTileContentOption

Description

Instead of `setTileContentOption`, use one of the `SetTileContentAs*` methods to set the tile content type.

setTileHasCount

Syntax

```
setTileHasCount (badge_display)
```

Description

Invoke the `setTileHasCount` method within your implementation only if you wish to dynamically override whether the badge area is enabled (that is, whether badge data is displayed). Invoking this method is equivalent to setting the `hasLiveDataCount` property. If the badge is enabled, you must also set the badge data with the `TileTransCount` property.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>badge_display</i>	Specify a String value: <ul style="list-style-type: none"> • Y - Indicates that the badge area is enabled for this tile. • N - Indicates that the badge area is disabled for this tile.

Returns

None.

Example

```
%This.setTileHasCount("Y"); /* Enables the badge area. */  
%This.TileTransCount = MY_REC.COUNT;
```

Related Links

[hasLiveDataCount](#)

[TileTransCount](#)

setTileID

Syntax

```
setTileID(Tile_ID)
```

Description

Invoke the setTileID method within your implementation only if you wish to dynamically override the ID specified for this tile at runtime.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Tile_ID</i>	Specifies the new tile ID as a String value.

Returns

None.

Related Links

[TileID](#)

setTileImageRef

Syntax

```
setTileImageRef(image_name)
```

Description

Invoke the setTileImageRef method to specify the image to be displayed when the tile's content type is specified as an image. Invoking this method is equivalent to specifying a value for the

ImageReferenceField property. When the tile content is specified to be an image, either this method or the ImageReferenceField property is required.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>image_name</i>	Specifies the image ID as a String value.

Returns

None.

Example

```
REM %This.ImageReferenceField.Value = Image.PTFP_DEFAULT_CLOUD; /* Property equiva⇒
lent */

setTileLiveData

Syntax

```
setTileLiveData (livedata_display)
```

Description

Invoke the setTileLiveData method within your implementation only if you wish to dynamically override whether the live data area is enabled (that is, whether live data is displayed). Invoking this method is equivalent to setting the hasLiveDataDescr property. If live data is enabled, you must also specify one or more live data values with the TileLiveData_1, TrendImage, TileLiveData_2, and TileLiveData_3 properties.

Parameters

Parameter	Description
<i>livedata_display</i>	Specify a String value: <ul style="list-style-type: none"> • Y - Indicates that the live data area is enabled for this tile. • N - Indicates that the live data area is disabled for this tile.

Returns

None.

Example

```
%This.setTileLiveData("Y"); /* Enables the live data area. */

%This.TileLiveData_1 = "Value 1";
%This.hasLiveDataTrendImage = True; /* Optional trend image */
%This.TrendImage = %This.k_strTrendUpImage;
%This.TileLiveData_2 = "Value 2";
%This.TileLiveData_3 = "Value 3";
```

Related Links

[hasLiveDataDescr](#)

[TileLiveData_2](#)

[TileLiveData_3](#)

[TrendImage](#)

Tile

Syntax

```
Tile()
```

Description

The Tile method is the constructor for the superclass. In your implementation, the constructor for your subclass must instantiate an object of the superclass using %Super.

Parameters

None

Returns

None.

Example

```
method My_Tile
    %Super = create PTGP_APPCLASS_TILE:Tiles:Tile();
end-method;
```

Related Links

"%Super" (PeopleCode Language Reference)

Tile Class Properties

In this section, the Tile class properties are presented in alphabetical order.

GroupletIDStyleClass

Description

Use the GroupletIDStyleClass property to specify a custom style class as a String value. The custom style class must be defined in a custom free-form style sheet that you have attached using the TileSpecificStyleSheet property.

This property is read/write.

Example

```
/* Custom free-form style sheet */
%This.TileSpecificStyleSheet = StyleSheet.MY_TILES_CSS;

/*Apply your custom style class to the tile content */
%This.GroupletIDStyleClass = "my_custom_style";
```

Related Links

[TileSpecificStyleSheet](#)

hasContent

Description

Use the hasContent property to set or return a Boolean value indicating whether the tile has content defined. This property provides you with an opportunity to perform alternate processing when an error condition has occurred.

When you set hasContent to False, you should define the following tile properties:

- An image in lieu of content (optional).
- PreferencesUrl (optional).
- PreferencesUrlLabel (required).

This property is read/write.

Example

```
If no_error_condition Then
    /* Normal processing of tile content */
Else
    %This.hasContent = False;
    %This.setTileImageRef("IMG_MISSING_DATA");
    %This.PreferencesUrlLabel = "No Data Available";
    %This.PreferencesUrl = "http://myserver.example.com/psc/my_site/EMPLOYEE/MY_NODE⇒
/c/MY_MENU.MY_COMPONENT.GBL";
End-If;
```

Related Links

[PreferencesUrl](#)

[PreferencesUrlLabel](#)

hasLiveDataCount

Description

Use the `hasLiveDataCount` property to set or return a Boolean value indicating whether the badge area is enabled. Set this property within your implementation only if you wish to dynamically override whether the badge area is enabled (that is, whether badge data is displayed). Setting this property is equivalent to invoking the `setTileHasCount` method. If the badge is enabled, you must also set the badge data with the `TileTransCount` property.

This property is read/write.

Example

```
%This.hasLiveDataCount = True; /* Enables the badge area. */
%This.TileTransCount = MY_REC.COUNT;
```

Related Links

[setTileHasCount](#)

[TileTransCount](#)

hasLiveDataDescr

Description

Use the `hasLiveDataDescr` property to set or return a Boolean value indicating whether the live data area is enabled. Set this property within your implementation only if you wish to dynamically override whether the live data area is enabled (that is, whether live data is displayed). Setting this property is equivalent to invoking the `setTileLiveData` method. If live data is enabled, you must also specify one or more live data values with the `TileLiveData_1`, `TrendImage`, `TileLiveData_2`, and `TileLiveData_3` properties.

This property is read/write.

Example

```
%This.hasLiveDataDescr = True; /* Enables the live data area. */

%This.TileLiveData_1 = "Value 1";
%This.hasLivedataTrendImage = True; /* Optional trend image */
%This.TrendImage = %This.k_strTrendUpImage;
%This.TileLiveData_2 = "Value 2";
%This.TileLiveData_3 = "Value 3";
```

Related Links

[setTileLiveData](#)

[TileLiveData_1](#)

[TileLiveData_2](#)

[TileLiveData_3](#)

[TrendImage](#)

hasLivedataTrendImage

Description

Use the hasLivedataTrendImage property to set a Boolean value indicating whether to display an optional trend image (up or down). When a trend image is enabled, it is displayed preceding the TileLiveData_2 element in the live data area or with the first KPI data value only when a single KPI is displayed (either the 1 KPI or the chart and 1 KPI content types).

Note: Only one trend image can be displayed on a tile. The default location is in the live data area. Therefore, if you want to associate a trend image with KPI data, you should not enable the live data area for the tile. If you enable the live data area, the trend image will be displayed there and not with the KPI data.

This property is read/write.

Example

```
%This.hasLiveDataDescr = True;
%This.TileLiveData_2 = NumberToString("%10.2v", &nMetric) | "%";
%This.isTileLiveData_2_Metrics = True;

/* A trend arrow is an optional element of live data. */
%This.hasLivedataTrendImage = True;
%This.TrendImage = %This.k_strTrendUpImage;
```

Related Links

[TileKPI_1](#)

[TileLiveData_2](#)

[TrendImage](#)

ImageReferenceField

Description

Use the ImageReferenceField property to specify the image to be displayed when the tile's content type is specified as an image. Setting a value for this property is equivalent to invoking the setTileImageRef method. When the tile content is specified to be an image, either this property or the setTileImageRef method is required.

Because ImageReferenceField is actually a Field object, you must set its Value property as follows:

```
%This.ImageReferenceField.Value  
= Image.IMAGE_ID;
```

This property is read/write.

Example

```
REM %This.setTileImageRef("MY_IMAGE"); /* Method equivalent */  
  
%This.ImageReferenceField.Value = Image.MY_IMAGE;  
%This.TileImageReferenceLabel("My tooltip");
```

Related Links

[SetTileContentAsImage](#)

[setTileImageRef](#)

[TileImageReferenceLabel](#)

isTileLiveData_1_Metrics

Description

Use the isTileLiveData_1_Metrics property to set a Boolean value indicating whether to format the TileLiveData_1 element as a metric similar to the badge metric (in tangerine orange and in bold).

Note: While this formatting style can also be used with the first live data element (TileLiveData_1), it is typically used with the second live data element only.

This property is read/write.

Related Links

[TileLiveData_1](#)

isTileLiveData_1_MetricsLabel

Description

Use the isTileLiveData_1_MetricsLabel property to set a Boolean value indicating whether to format the TileLiveData_1 element with a metrics label style.

Note: The `isTileLiveData_1_MetricsLabel` property and the metrics label style do not produce any visual formatting change for this live data element.

This property is read/write.

Related Links

[TileLiveData_1](#)

isTileLiveData_2_Metrics

Description

Use the `isTileLiveData_2_Metrics` property to set a Boolean value indicating whether to format the `TileLiveData_2` element as a metric similar to the badge metric (in tangerine orange and in bold). This is the recommended formatting for the second live data element.

This property is read/write.

Example

```
%This.hasLiveDataDescr = True;
%This.TileLiveData_2 = NumberToString("%10.2v", &nMetric) | "%";
%This.isTileLiveData_2_Metrics = True;
```

Related Links

[TileLiveData_2](#)

isTileLiveData_2_MetricsLabel

Description

Use the `isTileLiveData_2_MetricsLabel` property to set a Boolean value indicating whether to format the `TileLiveData_2` element with the metrics label style.

Note: The `isTileLiveData_2_MetricsLabel` property and the metrics label style do not produce any visual formatting change for this element.

This property is read/write.

Related Links

[TileLiveData_2](#)

isTileLiveData_3_Metrics

Description

Use the `isTileLiveData_3_Metrics` property to set a Boolean value indicating whether to format the `TileLiveData_3` element as a metric similar to the badge metric (in tangerine orange and in bold).

Note: While this formatting style can also be used with the third live data element (`TileLiveData_3`), it is typically used with the second live data element only.

This property is read/write.

Related Links

[TileLiveData_3](#)

isTileLiveData_3_MetricsLabel

Description

Use the `isTileLiveData_3_MetricsLabel` property to set a Boolean value indicating whether to format the `TileLiveData_3` element with the metrics label style.

Note: The `isTileLiveData_3_MetricsLabel` property and the metrics label style do not produce any visual formatting change for this element.

This property is read/write.

Related Links

[TileLiveData_3](#)

PreferencesUrl

Description

Use the `PreferencesUrl` property to set an alternate target content URL when an error condition exists—for example, when the tile content is invalid. Prior to setting the `PreferencesUrl` property, set the `hasContent` property to `False`.

Specify a String value that is a fully qualified URL that allows the *user* to correct the error condition.

This property is read/write.

Example

```
%This.hasContent = False;
%This.PreferencesUrl = "http://myserver.example.com/psc/my_site/EMPLOYEE/MY_NODE/c/⇒
MY_MENU.MY_COMPONENT.GBL";
```

Related Links[hasContent](#)[PreferencesUrlLabel](#)**PreferencesUrlLabel****Description**

Use the PreferencesUrlLabel property to set an alternate URL label when an error condition exists—for example, when the tile content is invalid. Prior to setting the PreferencesUrlLabel property, set the hasContent property to False.

If a custom URL label is not specified, the system default label is displayed instead.

This property is read/write.

Example

```
%This.hasContent = False;
%This.PreferencesUrlLabel = "No Data Available";
```

Related Links[hasContent](#)[PreferencesUrl](#)**Tilechart****Description**

Use the Tilechart property to instantiate a Chart object for this tile. Using this property is required when the tile content is set to either chart or chart plus one KPI. After associating a Chart object to this property, you can define additional properties and invoke methods on the Chart object to specify its characteristics.

This property is read/write.

Example

```
Local Chart &my_Chart;
Local Rowset &rowset;

&rowset = CreateRowset(Record.MY_CHART_DATA);
&rowset.Flush();
&rowset.Fill();

/* IMPORTANT: Instantiate your Chart object with this property.
&my_Chart = %This.Tilechart;
&my_Chart.SetData(&rowset);
/* Invoke other Chart class methods and set Chart class properties. */
```

Related Links[SetTitleContentAsChart](#)[SetTitleContentAsChartAndKPI](#)

Using the Chart Class

TileContentOption

Description

Instead of `TileContentOption`, use one of the `SetTileContentAs*` methods to set the tile content type.

This property is read/write.

Related Links

[Tile Class Methods](#)

TileHtmlArea

Description

Use the `TileHtmlArea` property to set the HTML text for this tile as a string value. Using this property is required when the tile content is set to an HTML area.

This property is read/write.

Example

```
/* Use an HTML definition as the HTML text. */
%This.TileHtmlArea = GetHTMLText(HTML.MY_HTML);

/* Alternatively, specify the HTML text inline. */
%This.TileHtmlArea = "<B>%UserId: </B>has exceeded quota.<BR><I>%Message(146,51): <=>
/I><BR>";
```

Related Links

[SetTileContentAsHTML](#)

[TileHtmlAreaStyle](#)

TileHtmlAreaStyle

Description

Use the `TileHtmlAreaStyle` property to specify a custom style class for the HTML area as a String value. The custom style class must be defined in a custom free-form style sheet that you have attached using the `TileSpecificStyleSheet` property.

This property is read/write.

Example

```
/* Custom free-form style sheet */
%This.TileSpecificStyleSheet = StyleSheet.MY_TILES_CSS;
```

```
/*Apply your custom style class to the HTML area */  
%This.TileHtmlAreaStyle = "my_custom_style";
```

Related Links

[TileHtmlArea](#)

[TileSpecificStyleSheet](#)

TileID

Description

Use this property to set or return the ID for this tile. Setting the ID for the tile is equivalent to invoking the `setTileID` method.

This property is read/write.

Related Links

[setTileID](#)

TileImageReferenceLabel

Description

Use the `TileImageReferenceLabel` property to set a tooltip (sometimes referred to as hover text) for image content as a String value. This tooltip can be read by screen readers and is also displayed as hover text.

This property is read/write.

Example

```
%This.setTileImageRef("MY_IMAGE");  
%This.TileImageReferenceLabel("My tooltip");
```

Related Links

[setTileImageRef](#)

[ImageReferenceField](#)

TileKPI_1

Description

Use the `TileKPI_1` property to set the first key performance indicator (KPI) data value as a String value. Setting this property is required when you have specified one of the KPI content types in Tile Wizard or you have invoked the one of the following methods: `SetTileContentAsChartAndKPI`, `SetTileContentAsOneKPI`, `SetTileContentAsTwoKPIs`, or `SetTileContentAsTwoKPIsTopBottom`.

Since KPIs are typically numeric values, you can use the `getAmountFormattedValue` method or several built-in functions (for example, `NumberToString` or `NumberToDisplayString`) to convert the numeric value to a `String` value.

Set a label for this data value using the `TileKPI_1_Label` property.

Optionally, you can use the `hasLivedataTrendImage` property to enable a trend image for display with the first KPI data value only when a single KPI is displayed (either the 1 KPI or the chart and 1 KPI content types).

This property is read/write.

Example

```
&rev = &total_rev / 1000000;  
%This.TileKPI_1 = %This.getAmountFormattedValue(&rev, "USD");  
%This.TileKPI_1_Label = "Revenue (in Millions)";
```

[SetTitleContentAsTwoKPIs](#)

[SetTitleContentAsTwoKPIsTopBottom](#)

TileLiveData_1

Description

Use the `TileLiveData_1` property to set the value for the first segment of live data as a String value. To display live data, the live data area must be enabled in the Tile Wizard definition, by invoking the `setTileLiveData` method, or by setting the `hasLiveDataDescr` property.

Typically, `TileLiveData_1` represents a label for the live data.

This property is read/write.

Example

```
%This.hasLiveDataDescr = True;  
%This.TileLiveData_1 = "Overall Profit Margin";
```

Related Links

[setTileLiveData](#)

[hasLiveDataDescr](#)

TileLiveData_2

Description

Use the `TileLiveData_2` property to set the value for the second segment of live data as a String value. To display live data, the live data area must be enabled in the Tile Wizard definition, by invoking the `setTileLiveData` method, or by setting the `hasLiveDataDescr` property.

Typically, `TileLiveData_2` is used to display a metric or other numeric value. Optionally, you can set the `isTileLiveData_2_Metrics` property to format this element as a metric similar to the badge metric (in tangerine orange and in bold). In addition, you can set the `TrendImage` property to display an up or down trend arrow preceding this metric.

This property is read/write.

Example

```

%This.hasLiveDataDescr = True;
%This.TileLiveData_2 = NumberToString("%10.2v", &nMetric) | "%";
%This.isTileLiveData_2_Metrics = True;

/* A trend arrow is an optional element of live data. */
%This.hasLiveDataTrendImage = True;
%This.TrendImage = %This.k_strTrendUpImage;

```

Related Links

[setTileLiveData](#)

[hasLiveDataDescr](#)

[isTileLiveData_2_Metrics](#)

[TrendImage](#)

TileLiveData_3

Description

Use the `TileLiveData_3` property to set the value for the third segment of live data as a String value. To display live data, the live data area must be enabled in the Tile Wizard definition, by invoking the `setTileLiveData` method, or by setting the `hasLiveDataDescr` property.

Typically, `TileLiveData_3` is used to display an additional description of the live data.

This property is read/write.

Example

```

%This.hasLiveDataDescr = True;
%This.TileLiveData_3 = "from Q3";

```

Related Links

[setTileLiveData](#)

[hasLiveDataDescr](#)

TileSpecificStyleSheet

Description

Use the `TileSpecificStyleSheet` to attach a custom free-form style sheet. Then, use either the `GroupletIDStyleClass` property or the `TileHtmlAreaStyle` property to specify a custom style class that is defined in the style sheet.

This property is read/write.

Example

```

/* Custom free-form style sheet */
%This.TileSpecificStyleSheet = StyleSheet.MY_TILES_CSS;

```

```
/*Apply your custom style class to the tile content */
%This.GroupletIDStyleClass = "my_custom_style";
```

Related Links

[GroupletIDStyleClass](#)

[TileHtmlAreaStyle](#)

TileTransCount

Description

Use the `TileTransCount` property to set the badge data as a `Number` value. To display badge data, the badge area must be enabled in the Tile Wizard definition, by invoking the `setTileHasCount` method, or by setting the `hasLiveDataCount` property.

This property is read/write.

Example

```
%This.hasLiveDataCount = True; /* Enables the badge area. */
%This.TileTransCount = MY_REC.COUNT;
```

Related Links

[setTileHasCount](#)

[hasLiveDataCount](#)

TrendImage

Description

Use the `TrendImage` property to set a `String` value indicating which optional trend arrow (up or down) to display.

Use either of these built-in constant values to set the trend image: `%This.k_strTrendUpImage` or `%This.k_strTrendDownImage`.

Alternatively, you can specify a custom trend image by specifying the image ID using the following syntax:

```
%This.TrendImage
= "MY_TREND_UP";
```

This property is read/write.

Example

```
%This.hasLiveDataDescr = True;
%This.TileLiveData_2 = NumberToString("%10.2v", &nMetric) | "%";
%This.isTileLiveData_2_Metrics = True;

/* A trend arrow is an optional element of live data. */
%This.hasLivedataTrendImage = True;
```

```
%This.TrendImage = %This.k_strTrendUpImage;
```

ImageTile Class Methods

In this section, the ImageTile class methods are presented in alphabetical order. Because the FreeTextTile class is an implementation of the ImageTile class, these methods are also inherited by and apply to the FreeTextTile class.

AddToHomePage

Syntax

```
AddToHomePage(HP_NAME, behavior)
```

Description

Use the AddToHomePage method to add the current tile to the specified fluid homepage or fluid dashboard.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>HP_NAME</i>	Specify the ID for the fluid homepage or fluid dashboard content reference definition as string value of up to 30 characters. Note: The ID cannot include spaces or special characters and must not begin with a number.
<i>behavior</i>	Specify the behavior for this tile as a four-character string value.

The *behavior* parameter can have these values:

<i>Value</i>	<i>Behavior</i>	<i>Description</i>
4OPT	Optional	The tile is available to all users for users that have permissions to the tile, but it is not visible by default; users can add, move, or delete the tile.

Value	Behavior	Description
3DEF	Optional default	<p>The tile is visible to all users by default for users that have permissions to the tile; users can move or delete the tile.</p> <hr/> <p>Note: You must specify 3DEF if you wish to publish additional tiles to users who have already personalized this homepage or dashboard. See "(Fluid only) Using the Tile Publish Page to Publish Additional Tiles" (Portal Technology) or "(Fluid only) Publishing Additional Tiles to Already Personalized Dashboards" (Portal Technology) for more information.</p>
2REQ	Required	The tile is visible to all users by default for users that have permissions to the tile; users can move the tile, however, they cannot delete it.
1FIX	Required-fixed	The tile is visible to all users by default for users that have permissions to the tile; however, users cannot move or delete it.

Returns

None.

Example

Note: DEFAULT_LP is the ID for the My Homepage content reference definition.

```
import PTGP_APPCLASS_TILE:API:ImageTile;

Local PTGP_APPCLASS_TILE:API:ImageTile &t1 = create PTGP_APPCLASS_TILE:API:ImageTile(
e("MY_TILE1");
&t1.AddToHomePage("DEFAULT_LP", "3DEF");
```

Delete

Syntax

Delete()

Description

Use the Delete method to delete this tile definition. This method deletes the tile from any fluid homepages and dashboards, deletes the content reference link definition for the tile, and deletes the tile's Tile Wizard definition.

Parameters

None.

Returns

None.

Example

```
import PTGP_APPCLASS_TILE:API:ImageTile;

Local PTGP_APPCLASS_TILE:API:ImageTile &t1 = create PTGP_APPCLASS_TILE:API:ImageTile(
e("MY_TILE1"));
&t1.Delete();
```

ImageTile

Syntax

ImageTile (*TILE_NAME*)

Description

The ImageTile constructor is automatically invoked when you instantiate an object of the ImageTile class. It is also invoked as a superclass when you instantiate an object of the FreeTextTile class. The ImageTile method initializes the ImageTile object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TILE_NAME</i>	Specifies the ID for the tile as string value of up to 30 characters. This represents the Tile Name of the tile definition in Tile Wizard. Note: The ID cannot include spaces or special characters and must not begin with a number.

Returns

An ImageTile object.

Example

```
import PTGP_APPCLASS_TILE:API:ImageTile;

Local PTGP_APPCLASS_TILE:API:ImageTile &t1 = create PTGP_APPCLASS_TILE:API:ImageTile("MY_TILE1");
```

Related Links

Name

Publish

Syntax

```
Publish()
```

Description

Use the Publish method to publish a new tile definition and to re-publish any modifications made to an existing tile definition. The initial publication of a tile definition creates the content reference link definition in the portal registry.

Important! You must always save a new tile definition prior to publishing it.

Important! This method will fail if any of these properties are undefined: ImageName, TargetCrefName, or Title. However, for a FreeTextTile, the Content property is required instead of the ImageName property.

Parameters

None.

Returns

None.

Example

```
import PTGP_APPCLASS_TILE:API:ImageTile;

Local PTGP_APPCLASS_TILE:API:ImageTile &t1 = create PTGP_APPCLASS_TILE:API:ImageTile("MY_TILE1");

/* Set required properties. */
&t1.Title = "My Image Tile";
&t1.TargetCrefName = "PT_SC_PERS_DICT_FL_GBL"; /* My Dictionary */
&t1.ImageName = "PS_PREFERENCES_L_FL"; /* My Preferences image */

&t1.Save(); /* For a new tile definition, a save is required. */
&t1.Publish();
```

Related Links

[ImageName](#)

[TargetCrefName](#)

[Title](#)

[Content](#)

Save

Syntax

```
Save ()
```

Description

Use the Save method to perform an intermediate save of the tile definition in Tile Wizard. Invoking this method is required when you create a new tile definition. You must invoke the Publish method to make the tile definition available or to update an already published definition with modifications.

Important! This method will fail if any of these properties are undefined: ImageName, TargetCrefName, or Title. However, for a FreeTextTile, the Content property is required instead of the ImageName property.

Parameters

None.

Returns

None.

Example

```
&t1.Save ();
```

ImageTile Class Properties

In this section, the ImageTile class properties are presented in alphabetical order. Because the FreeTextTile class is an implementation of the ImageTile class, these properties are also inherited by and apply to the FreeTextTile class.

Some of these properties are set on or derived from properties of the target page content reference definition—for example, the Height and Width properties correspond to the tile size, which is defined on the Fluid Attributes page of the target page content reference definition. Other properties are set on the content reference link definition that is created to represent the tile in the tile repository—for example, the Description property sets the long description of the content reference link definition.

- "Setting Fluid Attributes for Content References" (Portal Technology)

AlternateHeight

Description

Use the AlternateHeight property to set or return a number value representing the alternate height for a resizable tile. The default value is 0.

This property corresponds to the Alternate Height field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

Example

```
If &t1.IsResizable Then
    &t1.AlternateHeight = 2;
    &t1.AlternateWidth = 2;
End-If;
```

Related Links

[AlternateWidth](#)

[IsResizable](#)

AlternateWidth

Description

Use the AlternateWidth property to set or return a number value representing the alternate width for a resizable tile. The default value is 0.

This property corresponds to the Alternate Width field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

Related Links

[AlternateHeight](#)

[IsResizable](#)

Description

Description

Use the Description property to set or return a string value of up to 254 characters representing the long description of the content reference link that is created in the tile repository.

This property corresponds to the Long Description field, which is defined on the General page of the content reference link definition, and in Step 3 in Tile Wizard.

This property is read/write.

DisableHotspot

Description

Use the DisableHotspot property to set or return a boolean value indicating whether to disable displaying the target content defined for the tile when the tile is tapped. Note that any links displayed dynamically within the tile are not disabled. The default value is False.

This property corresponds to the Disable Main Hotspot field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

DisplayMode

Description

Use the DisplayMode property to set or return a number value representing how the target transaction or content appears once a user taps the tile. The default value is 0.

This property corresponds to the Display In field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

Options are:

<i>Numeric Value</i>	<i>Description</i>
0	Target content appears in the current browser window. <hr/> Note: This is the default value. <hr/>

<i>Numeric Value</i>	<i>Description</i>
1	Target content appears in a new tab in the browser.
2	Target content appears in a modal window.
3	Target content appears in the NavBar.

EventName

Description

Use the EventName property to set or return a string value representing the event name to subscribe to a push notification event defined on the server. Subscribing to an event allows the tile content to be updated by the event.

This property corresponds to the Event Name field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

Related Links

"Understanding the Push Notification Framework" (Fluid User Interface Developer's Guide)

"Defining Events" (Fluid User Interface Developer's Guide)

Height

Description

Use the Height property to set or return a number value representing the height of the tile. The default dimensions of a tile are 1 tile unit by 1 tile unit. Tiles up to 8x8 are supported. The default value is 1.

This property corresponds to the Height field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

ImageName

Description

Use the ImageName property to set or return a string value representing the image name of an SVG image from the image catalog. This SVG image is displayed on the tile.

Important! For an instantiation of the ImageTile class only, if this property is undefined, then the Save and Publish methods will fail.

This property corresponds to the Image Name field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

Related Links

[Publish](#)

[Save](#)

IsAuthorAccess

Description

Use the IsAuthorAccess property to return a boolean value indicating whether the creator of the content reference definition has access to the page regardless of other permissions assigned.

This property corresponds to the Author Access field, which is defined on the Security page of the target page content reference definition, and in Step 3 in Tile Wizard.

This property is effectively read-only.

IsAutosize

Description

Use the IsAutosize property to set or return a boolean value indicating whether to allow the fluid content to dynamically resize itself based on the size of the content. The default value is False.

This property corresponds to the Autosize field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

IsInteractive

Description

Use the IsInteractive property to set or return a boolean value indicating whether to display the fluid content as interactive, which allows users to enter data or click buttons within the fluid content. Since interactive fluid content require more resources than non-interactive ones, select this option only as needed. The default value is False.

This property corresponds to the Interactive field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

IsPublic

Description

Use the IsPublic property to return a boolean value indicating whether all users have access to the page regardless of other permissions assigned.

This property corresponds to the Public field, which is defined on the Security page of the target page content reference definition, and in Step 3 in Tile Wizard.

This property is effectively read-only.

IsPublished

Description

Use the IsPublished property to return a boolean value indicating whether this tile definition has been published.

This property is read-only.

Related Links

[ImageTile Class Methods](#)

IsResizable

Description

Use the IsResizable property to set or return a boolean value indicating whether to allow the tile to be redisplayed at the specified alternate dimensions. The default value is False.

This property corresponds to the Resizable field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

Example

```
If &t1.IsResizable Then
    &t1.AlternateHeight = 2;
    &t1.AlternateWidth = 2;
End-If;
```

Related Links

[AlternateHeight](#)

[AlternateWidth](#)

ModalParameters

Description

Use the ModalParameters property to set or return the custom modal options as a string value.

This property corresponds to the Modal Parameters field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

Related Links

"Modal Options" (Fluid User Interface Developer's Guide)

Name

Description

Use the Name property to return a string value representing the ID for this tile definition, which is specified when the ImageTile object is instantiated.

This property corresponds to the Tile Name field in Step 1 in Tile Wizard; it is not used in the content reference link definition.

This property is read-only.

Related Links

[ImageTile](#)

Owner

Description

Use the Owner property to set or return a string value representing the owner ID for the content reference link definition. The default value is "PPT" (PeopleTools).

This property corresponds to the Owner ID field, which is defined on the General page of the content reference link definition, and in Step 1 in Tile Wizard.

This property is read/write.

ParentFolder

Description

Use the ParentFolder property to set or return a string value of up to 30 characters representing the ID of the parent folder for the content reference link definition in the tile repository. This parent folder must be a subfolder of the Fluid Pages (PORTAL_GROUPLETS) folder. The default value is "PTFL_PEOPLETOOLS" (PeopleSoft Applications).

This property corresponds to the Parent Folder field, which is defined on the General page of the content reference link definition, and in Step 3 in Tile Wizard.

This property is read/write.

Related Links

"Understanding Tile Definitions and the Tile Repository" (Portal Technology)

Permissions

Description

Use the Permissions property to return an ApiObject representing a collection the permission lists from the target page content reference definition.

These permission lists are visible on the Security page of the target content reference definition and the Security page of the content reference link definition, and are displayed in Step 3 in Tile Wizard.

This property is read-only.

RefreshFrequency

Description

Use the RefreshFrequency property to set or return a number value representing the time in seconds to set as an automatic refresh period for dynamic content on a tile. When the timer limit has been reached, the system re-draws the tile so that it displays the current data, such as in the case with chart.

This property corresponds to the Refresh Timer field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

Roles

Description

Use the Roles property to return an ApiObject representing a collection the roles from the target page content reference definition.

These roles are visible on the Security page of the target content reference definition and the Security page of the content reference link definition, and are displayed in Step 3 in Tile Wizard.

This property is read-only.

ShowingSequence

Description

Use the ShowingSequence property to set or return a number value representing the sequence number for the content reference link. The default value is 9999.

This property corresponds to the Sequence number field, which is defined on the General page of the content reference link definition, and in Step 3 in Tile Wizard.

This property is read/write.

TargetCrefName

Description

Use the TargetCrefName property to set or return a string value representing the portal object name of the target page definition.

Important! If this property is undefined, then the Save and Publish methods will fail.

This property corresponds to the Name field of the Target Information group box, which is defined on the General page of the content reference link definition, and in Step 3 in Tile Wizard.

This property is read/write.

Example

```
&t1.TargetCrefName = "PT_CHANGE_PASSWORD_GBL";
```

Related Links

UseInDashboard

Description

Use the UseInDashboard property to set or return a boolean value specifying whether this tile is listed when the Add Tile dialog box is accessed from dashboards. The default value is True.

This property corresponds to the Dashboard check box, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

UseInHomePage

Description

Use the UseInHomePage property to set or return a boolean value specifying whether this tile is listed when the Add Tile dialog box is accessed from homepages. The default value is True.

This property corresponds to the Homepage check box, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

UseInNavBar

Description

Use the UseInNavBar property to set or return a boolean value specifying whether this tile is listed when the Add Tile dialog box is accessed from the NavBar. The default value is True.

This property corresponds to the NavBar check box, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

Width

Description

Use the Width property to set or return a number value representing the width of the tile. The default dimensions of a tile are 1 tile unit by 1 tile unit. Tiles up to 8x8 are supported. The default value is 1.

This property corresponds to the Width field, which is defined on the Fluid Attributes page of the target page content reference definition, and in Step 4 in Tile Wizard.

This property is read/write.

FreeTextTile Class Methods

In this section, the FreeTextTile constructor method is described. Because the FreeTextTile class is an implementation of the ImageTile class, the methods and properties of the ImageTile class are inherited by and apply to the FreeTextTile class. In particular, refer to the documentation on these methods of the ImageTile class:

- [AddToHomePage](#)
- [Delete](#)
- [Publish](#)
- [Save](#)

[ImageTile Class Properties](#)

FreeTextTile

Syntax

```
FreeTextTile(TILE_NAME)
```

Description

The FreeTextTile constructor is automatically invoked when you instantiate an object of the FreeTextTile class. Because the FreeTextTile class is a subclass of the ImageTextTile class, this method also instantiates an object of the superclass before initializing the FreeTextTile object.

Parameters

Parameter	Description
<i>TILE_NAME</i>	<p>Specifies the ID for the tile as string value of up to 30 characters. This represents the Tile Name of the tile definition in Tile Wizard.</p> <hr/> <p>Note: The ID cannot include spaces or special characters and must not begin with a number.</p> <hr/>

Returns

An ImageTile object.

Example

```
import PTGP_APPCLASS_TILE:API:FreeTextTile;

Local PTGP_APPCLASS_TILE:API:FreeTextTile &t2 = create PTGP_APPCLASS_TILE:API:FreeT⇒
extTile("MY_TILE2");

/* Set required properties */
&t2.Title = "My Text Tile";
&t2.TargetCrefName = "PT_SC_PERS_DICT_FL_GBL"; /* My Dictionary */
&t2.Content = "My tile <i>content.</i>";

/* Invoke methods defined in the base class. */
&t2.Save(); /* For a new tile definition, a sav⇒
e is required. */
&t2.Publish();
```

[ImageTile Class Properties](#)

Content

Description

Use the Content property to set or return a string value representing the HTML-formatted text to be displayed on the tile.

You can use the following HTML tags only: <h1>, <h2>, <h3>, <h4>, <h5>, <h6>,
, <p>, , <i>, and . Within the tag, src, width, height, and alt are allowable attributes. Use the %Image meta-HTML element to identify an image to include within the HTML:

```

```

Important! If this property is undefined, then the Save and Publish methods will fail.

This property is read/write.

Example

```
&t2.Content = "My tile <i>content.</i>";
```

TileAppFilter Class Methods

In this section, the TileAppFilter class methods are presented in alphabetical order.

IsTileVisible

Syntax

```
IsTileVisible(&CREF)
```

Description

Implement the IsTileVisible method to define application business logic that determines whether a tile is displayed or hidden on a fluid homepage or fluid dashboard.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&CREF</i>	Specifies the portal object for the tile definition as an already instantiated ApiObject object.

Returns

A boolean value:

- True if the tile is to be displayed.
- False if the tile is hidden and not to be displayed.

Example

```
method IsTileVisible
    /+ &cref as ApiObject +/
    /+ Returns Boolean +/
    /+ Extends/implements PTGP_APPCLASS_TILE:API:TileAppFilter.IsTileVisible +/

    /* Application-specific logic to hide or show a tile. */
    If IsUserInPermissionList("PTPT1000", "PTPT1600") And
        &cref.Name <> "PORTAL_ROOT_OBJECT" Then
        Return True;
    Else
        Return False;
    End-If;
end-method;
```

TransformData Class

Understanding the TransformData Class

When Integration Broker invokes a Application Engine transform program, it inserts the message content into a PeopleCode system variable, %TransformData, which remains in scope throughout the Application Engine program. Each program step can access the variable in turn and modify its content, which then becomes available to the next step.

In the Application Engine program, XSLT steps and PeopleCode steps access %TransformData differently:

- In XSLT, the data is automatically made available to your program. The XSLT program is literally a presentation of the output structure and data, which includes XSL tags that reference, process, and incorporate the input data into the output structure. There's no need to explicitly refer to %TransformData, which automatically receives the interpreted result of the XSLT step.
- In PeopleCode, use the PeopleCode %TransformData system variable to access the TransformData object. You access the XML data as the XmlDoc property of the TransformData object, which you then assign to an XmlDoc object and process normally. Because the XmlDoc object is a reference to the data portion of %TransformData, your modifications are automatically passed back to the system variable.

Related Links

"Understanding Filtering, Transformation, and Translation" (Integration Broker)

"%TransformData" (PeopleCode Language Reference)

Creating a TransformData Object

A TransformData object is returned from the system variable %TransformData. You cannot create a TransformData object directly.

When Integration Broker invokes a Application Engine transform program, it inserts the message content into the %TransformData system variable.

TransformData Class Properties

In this section, the TransformData class properties are presented in alphabetical order.

DestMsgName

Description

This property returns the name of the message at the receiving node as a string.

This property is read-only.

DestMsgVersion

Description

This property returns the name of the message version at the receiving node as a string.

This property is read-only.

DestNode

Description

This property returns the name of the node receiving the message as a string.

This property is read-only.

RejectTransform

Description

Use this property to terminate asynchronous transactions (asynchronous physical transformations only).

Use the following system constant to set this property: %IB_Transform_Rejected.

If this property is set within a transform program for an inbound asynchronous transaction, the result will be that no subscription contract is created. On the Service Operation Monitor Details page for the transaction, an informational message will be part of the error message link indicating that the transaction was terminated.

If this property is set within a transform program for an outbound asynchronous transaction, the publication contract status will be updated to done. The outbound message will not be sent. In addition, on the Service Operation Monitor Details page for the transaction, an informational message will be part of the error message link indicating that the transaction was terminated.

This property is read/write.

RoutingDefnName

Description

This property returns the routing definition name as a string. You can use this property to retrieve the connector's routing properties.

This property is read-only.

Related Links

[LoadConnectorPropFromRouting](#)

SourceMsgName

Description

This property returns the name of the message at the sending node as a string.

This property is read-only.

SourceMsgVersion

Description

This property returns the name of the message version at the sending node as a string.

This property is read-only.

SourceNode

Description

This property returns the name of the node sending the message as a string.

This property is read-only.

Status

Description

Use this property to communicate the success or failure of the transform program step to Integration Broker. Use the following values to set this property:

<i>Integer Value</i>	<i>System Constant</i>	<i>Description</i>
0 (default)	—	Indicates success.

<i>Integer Value</i>	<i>System Constant</i>	<i>Description</i>
1	—	Indicates that the message failed a filtering step.
2	%IB_Transform_Error	Indicates that an error occurred.

This property is read/write.

Related Links

"Understanding Filtering, Transformation, and Translation" (Integration Broker)

XmlDoc

Description

This property contains the XML message data.

You can assign this to an XmlDoc object and process the data using the XmlDoc class methods and properties.

This property is read/write.

Related Links

[Understanding XmlDoc Classes](#)

Tree Classes

Understanding Tree Classes

Using the tree classes in your PeopleCode, you have access to all the functionality of PeopleSoft Tree Manager. Your application should instantiate the appropriate tree objects when it must work with the tree system database data, call the appropriate methods and properties, then close the objects when it is finished.

Creating or deleting a tree *object* does not create or delete tree system database information. You must call the method for that tree object directly to create or delete database information, that is, the Create or Delete method.

One instance of a tree or tree structure object can be created to work on multiple database entities. However, only one tree or tree structure can be open at a time. If you open a Tree before closing the one that's currently open, you receive an error. You must explicitly close a tree or tree structure (using the Close method) before you try to open a second one.

All of the classes, and most of the properties and methods that make up the Tree Classes have a GUI representation in PeopleSoft Tree Manager. This document assumes that the reader is familiar with PeopleSoft Tree Manager.

The following classes make up the tree classes:

- Branch Collection
- Leaf
- Level
- Level Collection
- Node
- Tree
- Tree Structure

With most of the classes of objects in PeopleTools, when you use a *Getxxx* method, you are fully instantiating an object. However, for the tree class, when you use *GetTree* (from the Session object), you get a closed tree. A closed tree is a tree object with just the key fields filled in. The rest of the data is not present. To open the tree, you must use the Open method. Working with closed trees can improve your performance. The same applies to a tree structure: it's closed when you get it from the Session object, and you must open it before you can access its properties or change it.

There aren't any built-in functions for the tree classes: objects are instantiated from identifiers, from other objects, or from a Session object.

Using the `GenerateTree` function, you can produce a GUI representation of a tree in the PeopleSoft Pure Internet Architecture.

Related Links

"`TreeDetailInNode`" (PeopleCode Language Reference)

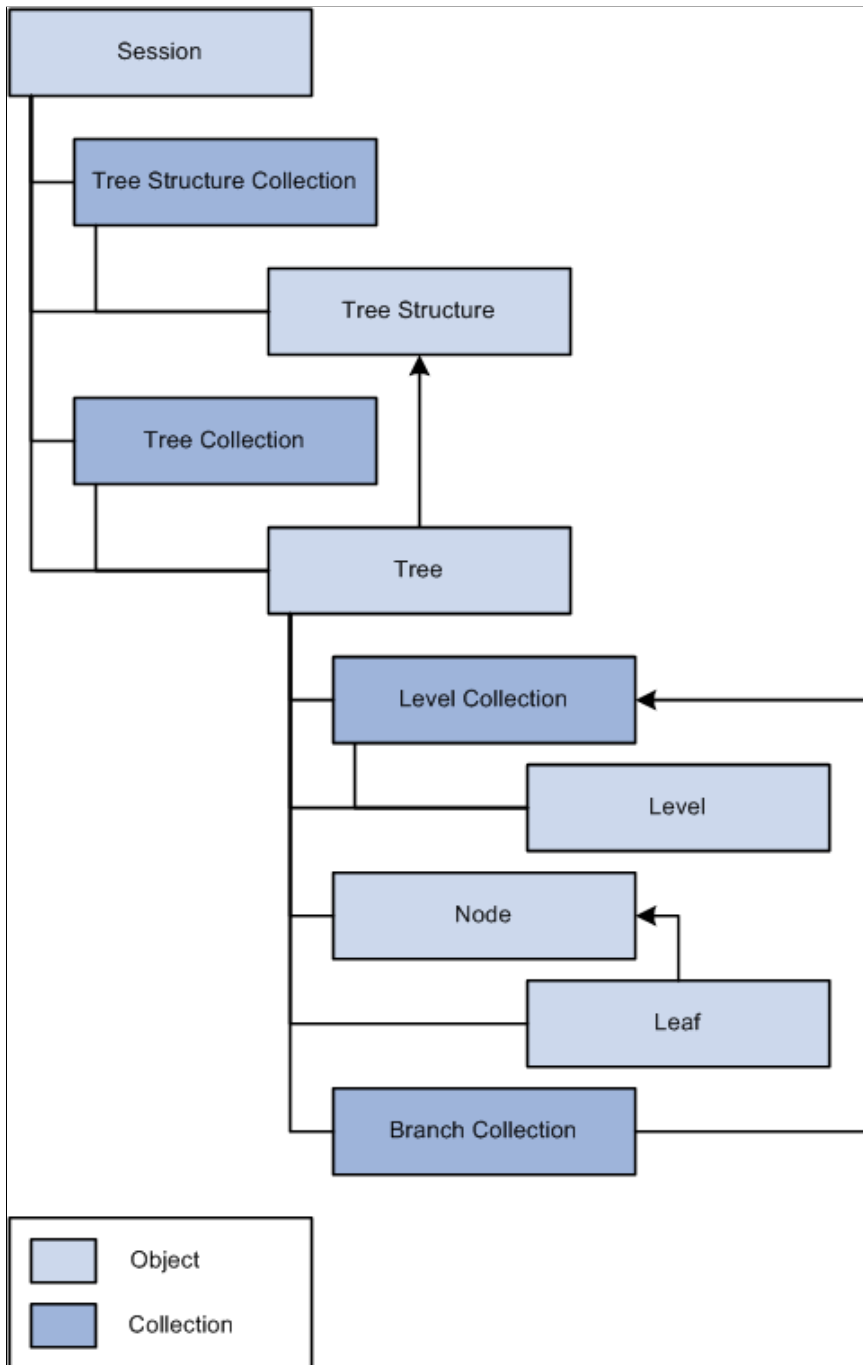

[Understanding Session Class](#)

"Using the `GenerateTree` Function" (PeopleCode Developer's Guide)

"Understanding Types of Trees" (Tree Manager)

Relationships Between Different Tree Classes

The following diagram shows the tree classes and their relationships. Objects at the tip of the arrowhead are accessed or created from the object at the left of the arrowhead. Squares indicate objects. Ovals indicate collections.

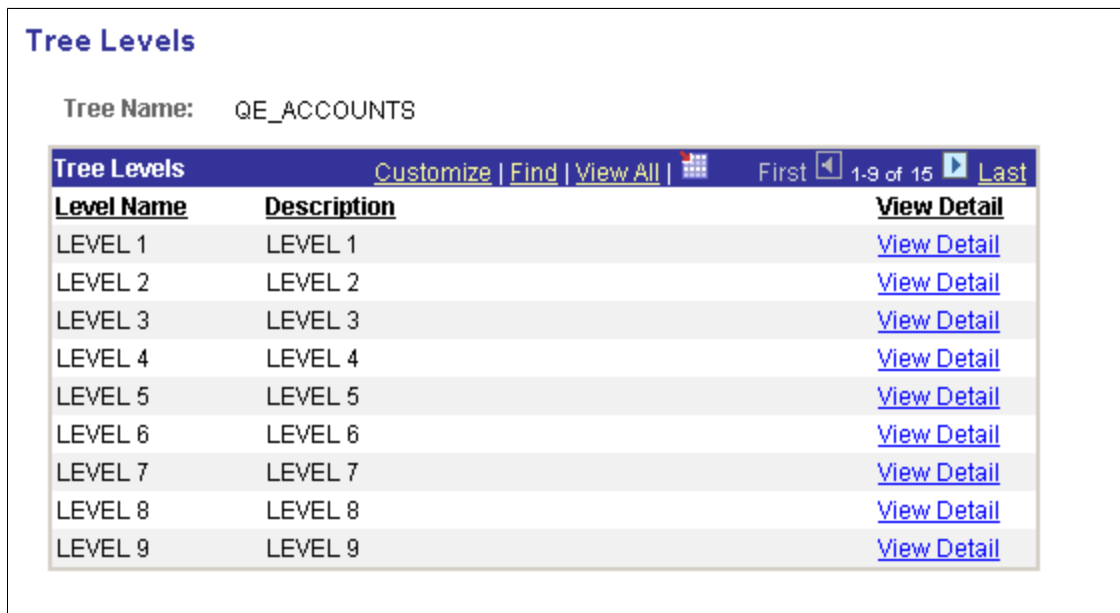

- From the session object, you can get identifiers for a tree or a tree structure.
- From the tree object, you can instantiate a tree, a tree structure, a branch collection, a leaf, a node, and a level collection.

- From the level collection object, you can instantiate a level object.
- From the branch collection object, you can get an identifier for a branch.
- From the node object, you can instantiate a leaf object or a node object.
- From the leaf object, you can instantiate a leaf object or a node object.

Collections in the Tree Classes

A *collection* is a set of similar things, like a group of already existing branches or levels. Like everything else in the tree classes, collections have a GUI representation. For example, when you find an existing branch from PeopleSoft Tree Manager, you get a dialog that lets you select the branches you want.

The following screen image is an example of different levels of collections in the Tree classes. And the dialog box data is represented in PeopleCode as the *tree level collection*.

Tree Levels

Tree Name: QE_ACCOUNTS

Level Name	Description	View Detail
LEVEL 1	LEVEL 1	View Detail
LEVEL 2	LEVEL 2	View Detail
LEVEL 3	LEVEL 3	View Detail
LEVEL 4	LEVEL 4	View Detail
LEVEL 5	LEVEL 5	View Detail
LEVEL 6	LEVEL 6	View Detail
LEVEL 7	LEVEL 7	View Detail
LEVEL 8	LEVEL 8	View Detail
LEVEL 9	LEVEL 9	View Detail

The following collections are part of the tree classes:

- Branch collection
- Level collection

Error Handling With Trees

The tree classes log descriptive information regarding errors and warnings to the PSMessages collection, instantiated from a session object.

In your program, use the PSMessages collection to identify and report to the user any errors that are encountered during processing.

The tree classes log errors "interactively", that is, as they happen. For example, suppose you had created a new tree, and were setting the effective date using the effective date property (EffDt). If you used an invalid value for the effective date, the error would be logged in the PSMessages collection as soon as you set the value, not when you saved the tree.

When you want to check for errors depends on your application. However, if you check for errors after every assignment, you may see a performance degradation.

One way to check for errors is to check the number of messages in the PSMessages collection, using the Count property. If the Count is 0, no error or warning messages have been logged to the PSMessages collection.

```
Local ApiObject &MYSESSION;
Local ApiObject &ERRORCOL;
Local ApiObject &TREE, TREELIST;

&MYSESSION = %Session;

If &MYSESSION Then
  /* connection is good */

  &MyTree = &Session.GetTree();
  /* open a tree */
  &TreeReturn = &MyTree.Open("", "", "PERSONAL_DATA", "1999-06-01", "", true);
  /* Do error checking */

  &ERRORCOL = &MYSESSION.PSMessages;
  If (&ERRORCOL.Count <> 0) Then
    /* errors occurred - do processing */
  Else
    /* no errors */
  End-If;
  Else
    /* do processing for no connection */
  End-If;
```

You can also do an error check based on the return value of your API calls

```
If ALL(&TreeReturn) then
  /* processing errors */
End-if:
```

Related Links

[Error Handling](#)

Leaves and Nodes Insert Verification

InsertChildLeaf, InsertSibNode, InsertChildNode, and so on, can return False or a Null object reference, depending upon the type of error encountered. You may want to declare references to new leaves or nodes as type ANY until after you verify they were actually created. You can do this by using the None or All PeopleCode functions to determine whether a valid Leaf or Node Object was created. If a Leaf or Node object was created ALL() returns True and None() returns False.

```
&NewLeaf = &RootNode.InsertChildLeaf("8000", "8999");
If NONE(&NewLeaf) Then
  /* Leaf not inserted, do error processing */
  &Messages = &Session.PSMessages;
  If &Messages.WarningPending Then
    /* do error processing */
```

```
End-if;
End-if;
```

"All" (PeopleCode Language Reference)

Restrictions on Trees When Used as a SmartNavigation Data Source

Note: SmartNavigation has been deprecated. This information has been retained for backward compatibility only.

When a tree is used as a SmartNavigation data source, the values of several tree-specific properties are passed to the SmartNavigation application via URL. Certain characters are inappropriate for use in a URL and must be avoided. When using a tree as a SmartNavigation data source, do not use any of the following characters in the tree name, setID, user key value, and tree branch values:

pound (#)	percent (%)	dollar (\$)
ampersand (&)	plus (+)	comma (,)
forward slash/virgule (/)	colon (:)	semi-colon (;)
equals (=)	question mark (?)	at symbol (@)
space ()	quotation marks(")	less than symbol (<)
greater than symbol (>)	left curly brace ({)	right curly brace (})
vertical bar/pipe ()	backslash (\)	caret (^)
tilde (~)	left square bracket ([)	right square bracket (])
grave accent (`)		

When using Tree class methods such as Copy, Create, Rename, SaveAs, SaveAsDraft, and others, take care to avoid using these invalid characters in the values for the tree name, setID, user key value, and tree branch.

Data Types for Tree Objects

All tree objects, that is, trees, tree structures, nodes, levels, and so on, are declared as type `ApiObject`. For example:

```
Local ApiObject &MYTREE;

Global ApiObject &MYNODE;
```

All tree objects can be declared as Local, Component or Global.

Scope of the Tree Objects

All tree objects, that is, trees, tree structures, nodes, leaves, and so on, can *only* be instantiated from `PeopleCode`.

This object can be used anywhere you have `PeopleCode`, that is, in an application class, Application Engine `PeopleCode`, record field `PeopleCode`, and so on.

You can instantiate a tree or tree structure object only from a session object. You have to instantiate the session object, and connect to the database, before you can instantiate a tree or tree structure.

```
Local ApiObject &TREELIST;
Local ApiObject &MYSESSION;

&MYSESSION = %Session;

If &MYSESSION Then
    /* connection is good */
Else
    /* do error processing */
End-if;
```

Note: Tree Classes are accessible only through `PeopleCode`.

Tree Classes Implementation

You will often want to create a new tree. The following procedure discusses this action in more detail.

The `TreeMover` Application Engine program uses the Tree API (and File Layouts) for importing a tree from a flat file or exporting a tree to a flat file.

To create a new tree:

In this example, you are creating a new tree based on an existing tree structure. The following is the complete code sample: the steps explain each line.

```
Local ApiObject &Session;
Local ApiObject &TreeList, &MyTree;
Local ApiObject &LvlColl;

&Session = %Session;

&MyTree = &Session.GetTree();
```

```

/* create new tree */

If All(&MyTree) Then
  &TreeReturn = &MyTree.Create("", "", "PERSONAL_DATA2", "1999-06-01", "PERSONAL_DA→
TA");

  If &TreeReturn <> 0 then
    /* check PSMessages collection */
  End-if;

  &MyTree.description = "test tree";

  /* add level */
  &LvlColl = &MyTree.levels;
  &Level = &LvlColl.add("FIRST LVL");
  &Level.description = "First Level";

  /* add root node */
  &RootNode= &MyTree.insertroot("00001");

If ALL(&RootNode) Then
  /* insert a leaf */
  &NewLeaf = &RootNode.InsertChildLeaf("8000", "8999");

  /* save new tree */
  &RSLT = &MyTree.Save();

  /* Do error checking */
  If &RSLT <> 0 Then
    /* errors occurred = do error checking */
    &ERRORCOL = &Session.PSMessages;
    For &I = 1 To &ERRORCOL.count
      /* do error processing */
    End-For;
  Else
    /* no errors - saved correctly - do other processing */
  End-If;
End-if;

End-if;

```

1. Get a session object.

Before you can get a tree, you have to get a session object. The session controls access to the tree, provides error tracing, enables you to set the runtime environment, and so on. Use the %Session system variable to return a reference to the current PeopleSoft session.

```
&Session = %Session;
```

2. Get a tree object.

Use the GetTree method specifying a null value (" ") to return a closed tree object.

```
&MyTree = &Session.GetTree();
```

3. Create the Tree.

The Create method creates a new tree with the name PERSONAL_DATA2. To ensure that you have a valid tree, use the All built-in function. Description is a required property (if you don't specify something for Description you cannot save the tree.)

```

&TreeReturn = &MyTree.Create("", "", "PERSONAL_DATA2", "1999-06-01", "PERSONAL→
_DATA");

&MyTree.description = "test tree";

```

4. Add a level.

To add a level, you have to instantiate a level collection. Although there aren't any levels in the tree, you can still access this collection. Use the Add method with the level collection to add a new level. Remember, the level name must be 8 characters or less. Description is a required property (if you don't specify something for Description you cannot save the tree.)

```
&LvlColl = &MyTree.levels;
&Level = &LvlColl.add("FIRST LVL");
&Level.description = "First Level";
```

5. Add the root node.

Because this is a new tree, you must first add the root node.

```
&RootNode = &MyTree.insertroot("00001");
```

6. Add a leaf.

To add a new leaf, you must have a reference to the parent node object. Using the All built-in function ensures that there is a root node before you try to insert the leaf with the InsertChildLeaf method.

```
If ALL(&RootNode) Then
    &NewLeaf = &RootNode.InsertChildLeaf("8000", "8999");
```

7. Save the tree.

When you execute the Save method, the new tree is saved to the database.

```
&RSLT = &MyTree.Save();
```

Note: If you're running the tree API from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a COMMIT.

8. Check for errors.

You can check if there were any errors using the PSMessages property on the session object.

```
If All (&RSLT) Then
    /* errors occurred = do error checking */
    &ERRORCOL = &Session.PSMessages;
    For &I = 1 To &ERRORCOL.count
        /* do error processing */
    End-For;
Else
    /* no errors - saved correctly - do other processing */
End-If;
```

If there are multiple errors, all errors are logged to the PSMessages collection, not just the first occurrence of an error.

Note: If you've called the Tree API from an Application Engine program, all errors are also logged in the application engine error log tables.

"Understanding TreeMover" (Tree Manager)

Tree Classes Reference

This section provides a reference to the following topics:

- Session class methods in the tree API.
- Branch collection.
- Leaf class.
- Level collection.
- Level class.
- Node class.
- Tree class.
- Tree structure class.

Session Class Methods

Tree Classes don't have any built-in functions. Instead, they're instantiated from the Session Class.

In this section, we discuss the Session class methods. The methods are discussed in alphabetical order.

GetTree

Syntax

```
GetTree ()
```

Description

The GetTree method returns a closed tree object. Before you can use some of the methods or any of the properties, you must use the Open method to open a tree object.

Parameters

None.

Returns

A reference to a closed tree object.

Example

To create a new tree, use the following:

```
&MYTREE = %Session.GetTree();
&MYTREE.Create("", "", "PERSONAL_NEW", "05-05-1997", "PERSONAL_DATA");
```

To determine if a tree already exists in the database, use the following code:

```
&MYTREE = %Session.GetTree();
If &MYTREE.Exists("", "", "PERSONAL_OLD", "05-05-1997", "PERSONAL_DATA") = 0 then
    /* Do processing */
End-If;
```

To open an existing tree, use the following code:

```
&MYTREE = %Session.GetTree();
&MYTREE.Open("", "", "PERSONAL_OLD", "05-05-1997", "PERSONAL_DATA", True);
```

GetTreeStructure

Syntax

```
GetTreeStructure ()
```

Description

The GetTreeStructure method returns a closed tree structure object. Before you can use some of the methods or any of the properties, you must use the Open method to open the tree structure object.

Branch Collection

A branch collection is returned from the Branches property, used with an open tree object.

```
&MYBRANCHCOLL = &MYTREE.Branches;
```

&MYTREE must be a branched tree. To verify whether a tree is branched, you can check the value of the IsBranched property of a tree object (Boolean value: True or False.)

See [Branches](#).

Branch Collection Property

In this section, we discuss the Branch collection properties. The properties are discussed in alphabetical order.

Count

Description

Returns the number of branches for the branch collection object.

Leaf Class

Leaf objects are instantiated from other tree classes as follows:

- From a tree object with the `FindLeaf` method.
- From a node object with the `FirstChildLeaf` property.
- From another leaf object with the `NextSib` and `PrevSib` properties.

See [FindLeaf](#), [FirstChildLeaf](#), [NextSib](#), [PrevSib](#).

Leaf Class Methods

In this section, we discuss the Leaf class methods. The methods are discussed in alphabetical order.

Cut

Syntax

```
cut ()
```

Description

The Cut method cuts the leaf and puts it into a buffer (the clipboard.) You can then use the PasteSib method to add the leaf back as a sibling of a different leaf. You can also use the PasteChild node method to add the leaf back as a child of a different node.

You can only have one object at a time on the clipboard. If you cut another leaf or node, the leaf in the clipboard is overwritten.

Parameters

None.

Returns

A number; 0 if the cut is successful.

Related Links

[Cut](#)

[PasteSib](#)

[PasteChild](#)

Delete

Syntax

```
Delete()
```

Description

The Delete method deletes the leaf object executing the method *from the database*.

Returns

A number; 0 if the delete is successful.

Example

```
&MYLEAF = &MYTREE.FindLeaf("8200", "8300");
&MYLEAF.Delete();
```

DeleteByRange

Syntax

```
DeleteByRange (RangeFrom, RangeTo)
```

Description

The DeleteByRange method deletes the specified leaf object from the database. The leaf specified by the parameters does *not* have to match the leaf executing the method. That is, if &MYLEAF is associated with a range 8200-8300, you can specify a different range with the DeleteByRange method. For example:

```
&MYLEAF = &MYTREE.FindLeaf("8200", "8300");
/* some processing */
&RET_VALUE = &MYLEAF.DeleteByRange("8400", "8500");
```

Parameters

Parameter	Description
<i>RangeFrom</i>	Specify the starting range of the leaf to be deleted. This parameter takes a string value.
<i>RangeTo</i>	Specify the ending range of the leaf to be deleted. This parameter takes a string value.

Returns

A number; 0 if the delete is successful.

Example

```
&RET_VALUE= &MYLEAF.DeleteByRange("8400", "8500");
```

GenABNMenuElement

Syntax

```
GenABNMenuElement()
```

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Use this method to generate a single element for this tree leaf.

The element from this leaf and the elements from its sibling leaves and nodes are concatenated to form an HTML code fragment to be consumed by the portal.

Parameters

None.

Returns

A string representing the element for this tree leaf.

GenABNMenuElementWithImage

Syntax

```
GenABNMenuElementWithImage(CREF_img_class_ID)
```

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Use this method to generate a single element for this tree leaf using the specified custom CREF icon.

The element from this leaf and the elements from its sibling leaves and nodes are concatenated to form an HTML code fragment to be consumed by the portal.

Parameters

Parameter	Description
<i>CREF_img_class_ID</i>	<p>Specifies the class ID for a custom CREF icon as a string. This class must be defined in a style sheet, and the style sheet must be assigned to the SmartNavigation folder.</p> <p>This is an optional parameter. To use the default CREF icon, you can omit this parameter or specify the null string "". However, to ensure forward compatibility, you must specify the null string.</p>

Returns

A string representing the element for this tree leaf.

InsertDynSib

Syntax

```
InsertDynSib()
```

Description

The InsertDynSib method inserts a dynamic leaf as a sibling leaf to the leaf object executing the method. The leaf is a *new* node.

A leaf object associated with the new leaf is returned. The new leaf is inserted as the next sibling leaf. If the new leaf isn't inserted successfully, the method returns Null.

Note: To insert a sibling leaf with a specific range, use the InsertSib method.

Parameters

None.

Returns

A reference to the new leaf. If this method fails, it returns either False or a Null object reference, depending upon the type of error encountered. The best way to test whether the object was inserted is to test the result using either the All or None functions.

Example

```
&NEWLEAF = &MYLEAF.InsertDynSib();
```

Related Links

[InsertSib](#)

"All" (PeopleCode Language Reference)

"None" (PeopleCode Language Reference)

InsertSib

Syntax

```
InsertSib(RangeFrom, RangeTo)
```

Description

The InsertSib method inserts a new leaf as a sibling leaf under the leaf currently executing the method. The leaf specified by the range parameters must be a *new* leaf. You receive an error if the leaf already exists.

A leaf object associated with the new leaf is returned. The new leaf is inserted as the next sibling leaf, although there is no explicit ordering of leaves: leaves take the order of the alphanumeric database sort on their range fields.

Note: To insert a dynamic sibling leaf (that is, without specifying a range) use the InsertDynSib method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RangeFrom</i>	Specify the starting range of the new leaf. This parameter takes a string value.
<i>RangeTo</i>	Specify the ending range of the new leaf. This parameter takes a string value.

Returns

A leaf object associated with the new leaf. If this method fails, it returns either False or a Null object reference, depending upon the type of error encountered. The best way to test whether the object was inserted is to test the result using either the All or None functions.

Example

```
&NEWLEAF = &MYLEAF.InsertSib("10090", "10100");
```

Related Links

[InsertDynSib](#)

"All" (PeopleCode Language Reference)

"None" (PeopleCode Language Reference)

LoadABNChart

Syntax

```
LoadABNChart(&chart_rowset, &relations_rowset)
```

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Use this method to load a child leaf of the current tree node into the SmartNavigation chart rowset and the component buffer.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&chart_rowset</i>	Specifies the SmartNavigation chart rowset. Typically, this is the rowset returned by the GetABNChartRowSet function.
<i>&relations_rowset</i>	Specifies the related actions rowset. Typically, this is the rowset returned by the GetABNRelActnRowSet function.

Returns

None.

LoadABNChartOrdered

Syntax

```
LoadABNChartOrdered(&chart_rowset, &relations_rowset, order)
```

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Use this method to load a child leaf of the current tree node into the SmartNavigation chart rowset and the component buffer. The order for the leaf within its chart level is specified by this method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&chart_rowset</i>	Specifies the SmartNavigation chart rowset. Typically, this is the rowset returned by the GetABNChartRowSet function.

Parameter	Description
<i>&relations_rowset</i>	Specifies the related actions rowset. Typically, this is the rowset returned by the GetABNRelActnRowSet function.
<i>order</i>	Specify the order for the leaf as a number. <hr/> Note: For a given chart level, all chart leaves must have a display order greater than zero. <hr/>

Returns

None.

MoveAsChild

Syntax

MoveAsChild (*Node*)

Description

The MoveAsChild method moves the leaf executing the method to a different node in the tree. The leaf becomes the first child leaf under the node, even though there is no explicit ordering of leaves: leaves take the order of the alphanumeric database sort on their range fields. The specified node becomes the new parent to the leaf.

Parameters

Parameter	Description
<i>Node</i>	Specify a node object. This parameter value must be an object, not a string or a name.

Note: To specify a node name, not a node object, use the MoveAsChildByName method.

Returns

A number; 0 if the move is successful.

Example

The following example moves leaf 8001 from node 10100 (old parent) to node 00001 (new parent)

```
&MY_LEAF = &MY_TREE.FindLeaf("8001", "8001");
&NEW_PARENT = &MY_TREE.FindNode("00001", "");
If &NEW_PARENT <> Null Then
```

```

    &RET_VALUE = &MY_LEAF.MoveAsChild(&NEW_PARENT);
End-If;

```

Related Links

[MoveAsChildByName](#)

MoveAsChildByName

Syntax

MoveAsChildByName (*NodeName*)

Description

The MoveAsChildByName method moves the leaf executing the method to a different node in the tree. The leaf becomes the first child leaf under the node, although there is no explicit ordering of leaves: leaves take the order of the alphanumeric database sort on their range fields. The specified node becomes the new parent to the leaf. The node specified by *NodeName* must be a valid node name.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of a node. <i>NodeName</i> must be a valid node for the existing tree. This parameter takes a string value.

Note: To specify a node object, not a node name, use the MoveAsChild method.

Returns

A number; 0 if the move is successful.

Example

The following example moves leaf 8001 from node 10100 (old parent) to node 00001 (new parent)

```

&MY_LEAF = &MY_TREE.FindLeaf("8001", "8001");
If &MY_LEAF <> Null Then
    &RET_VALUE = &MY_LEAF.MoveAsChildByName("00001");
End-If;

```

Related Links

[MoveAsChild](#)

MoveAsSib

Syntax

MoveAsSib (*Leaf*)

Description

The MoveAsSib method moves the leaf executing the method to a new place in the tree. The current leaf becomes the next sibling leaf under the specified leaf object, although there is no explicit ordering of leaves: leaves take the order of the alphanumeric database sort on their range fields.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Leaf</i>	Specify a leaf object. This parameter value must be an object, not a string or a name.

Note: To specify a range, not a leaf object, use the MoveAsSibByRange method.

Returns

A number; 0 if the move is successful.

Example

```
&MYLEAF = &MYTREE.FindLeaf("8000", "8000");
&MYLEAF2 = &MYTREE.FindLeaf("9000", "9000");
&RET_VALUE = &MYLEAF.MoveAsSib(&MYLEAF2);
```

Related Links

[MoveAsSibByRange](#)

MoveAsSibByRange

Syntax

MoveAsSibByRange (*RangeFrom*, *RangeTo*)

Description

The MoveAsSibByRange method moves the leaf executing the method to a new place in the tree. The current leaf becomes the next sibling leaf under the specified leaf object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RangeFrom</i>	Specify the starting range of the leaf that you want as the parent of the leaf executing the method. This parameter takes a string value.
<i>RangeTo</i>	Specify the ending range of the leaf that you want as the parent of the leaf executing the method. This parameter takes a string value.

Note: To specify a leaf object, not a range, use the `MoveAsSib` method.

Returns

A number; 0 if the move is successful.

Example

```
&MYLEAF = &MYTREE.FindLeaf("8000", "8000");
&RET_VALUE = &MYLEAF.MoveAsSibByRange("9000", "9000");
```

Related Links

[MoveAsSib](#)

PasteSib

Syntax

```
PasteSib()
```

Description

The `PasteSib` method makes the leaf from the buffer (clipboard) a sibling to the leaf executing the method. You must use the `Cut` leaf method before you can paste a leaf.

You can have only one object at a time on the clipboard. If you cut another leaf or node, the leaf in the clipboard is overwritten.

Parameters

None.

Returns

A number; 0 if the paste is successful.

RefreshDescription

Syntax

`RefreshDescription` (*expand_range*)

Description

Use this method to reload the tree leaf's description from the database.

Note: This method is currently supported for what is known as a single detail leaf. Do not use this method with ranged or dynamic leaves.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>expand_range</i>	Specify a Boolean value; however, this parameter is currently ignored. <hr/> Note: This parameter is reserved for future use.

Returns

A number: 0 if the refresh was successful.

Related Links

[Description](#)

UpdateRanges

Syntax

`UpdateRanges` (*RangeFrom*, *RangeTo*)

Description

The UpdateRanges method performs validation of edited ranges, updating as necessary.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RangeFrom</i>	Specify the starting range of the leaf that you updated. This parameter takes a string value.

Parameter	Description
<i>RangeTo</i>	Specify the ending range of the leaf you want updated. This parameter takes a string value.

Returns

A number; 0 if the update is successful.

Leaf Class Properties

In this section, we discuss the Leaf class properties. The properties are discussed in alphabetical order.

Description

Description

Use this property to return the tree leaf's description as a string.

Note: This property is currently supported for what is known as a single detail leaf. Do not use this property with ranged or dynamic leaves.

This property is read-only.

Related Links

[RefreshDescription](#)

DisplayLevelNumber

Description

When using the Tree API to create a graphic representation of the tree (such as for HTML Tree Manager or other application pages) use this property to indicate the *display* level, that is, tell the user how many levels deep the leaf is. This is generally used for trees where levels aren't used and the LevelNumber property always returns 0. This property always returns a number.

This property is read-only.

Related Links

[LevelNumber](#)

Dynamic

Description

This property specifies whether the leaf has a dynamic range or a specified range. If you set this property to True, the leaf has a dynamic range. If this is a new leaf, and you do not set this property, the value is automatically set is False.

This property is read/write.

Related Links

"Understanding Steps to Create Trees" (Tree Manager)

HasNextSib

Description

This property returns True if the leaf has a next sibling, that is, it isn't the last leaf listed under the parent node.

This property is read-only.

HasPrevSib

Description

This property returns True if the leaf has a previous sibling, that is, it isn't the first leaf listed under the parent node.

This property is read-only.

ImageName

Description

This property sets the which image is used to display the leaf. This property takes a string value for the image name of the leaf.

This property is read/write.

IsChanged

Description

This property returns True if the leaf has been edited or changed.

This property is read-only.

Example

```
If &MYLEAF.IsChanged Then
    &MYTREE.Save ();
End-If;
```

IsCut

Description

This property returns True if the leaf has been cut from the displayed tree. This property is generally used with the HTML Tree Manager.

This property is read-only.

IsDeleted

Description

This property returns True if the leaf has been deleted from the tree but the tree hasn't been saved.

This property is read-only.

IsInserted

Description

This property returns True if the leaf has been inserted as a new leaf in the tree but the tree hasn't been saved.

This property is read-only.

NextSib

Description

This property returns a leaf object associated with the next sibling leaf. The next sibling of a leaf is the leaf appearing under the current leaf. If there is no next sibling and you try to assign it to a variable, you receive a runtime error.

This property is read-only.

Example

The following code traversed the leaves from top to bottom.

```
While &MYLEAF.HasNextSib
    &MYLEAF = &MYLEAF.NextSib;
    /* do some processing */
End-While;
```

Parent

Description

This property returns a node object associated with the parent node for the leaf.

This property is read-only.

Example

```
&PARENTNODE = &MYLEAF.Parent;  
/* do node processing with node object */
```

PrevSib

Description

This property returns a leaf object associated with the previous sibling leaf. The previous sibling of a leaf is the leaf appearing above the current leaf. If there is no previous sibling and you try to assign it to a variable, you receive a runtime error.

This property is read-only.

Example

The following code traverses the leaves from bottom to top.

```
While &MYLEAF.HasPrevSib  
    &MYLEAF = &MYLEAF.PrevSib;  
    /* do some processing */  
End-While;
```

RangeFrom

Description

This property returns the starting range, as a string, of the leaf.

This property is read/write.

RangeTo

Description

This property returns the ending range, as a string, of the leaf.

This property is read/write.

TreeBranchName

Description

This property returns the branch name of the tree as a string if the tree is branched. If not branched, this property returns a blank string.

This property is read-only.

TreeEffDt

Description

This property returns the effective date of the tree as a string if the tree is effective-dated. If not effective-dated, this property returns a blank string.

This property is read-only.

TreeName

Description

This property returns the name of the tree as a string.

This property is read-only.

TreeSetId

Description

This property returns the SetID of the tree as a string if the tree has a SetID. If the tree doesn't have a SetID, this property returns a blank string.

This property is read-only.

TreeUserKeyValue

Description

This property returns the UserKeyValue of the tree as a string if the tree has a UserKeyValue. If the tree doesn't have a UserKeyValue, this property returns a blank string.

This property is read-only.

Level Collection

Level collection is instantiated from a tree object with the Levels property.

See [Levels](#).

Level Collection Methods

In this section, we discuss the Level Collection methods. The methods are discussed in alphabetical order.

Add

Syntax

```
Add(LevelName)
```

Description

The Add method adds a new level called *LevelName* to the database. The specified level must be a new level, that is, it cannot exist in the database. *LevelName* takes a string value.

Note: *LevelName* must be 8 characters or less.

If no levels currently exist in the tree, the level is added at the top level. If levels already exist in the tree, the new level is added as the last level. You can change the level number of a level using the Number property.

If the new level is the first level, the AllValuesAudit property is automatically set to True.

The new level is not added to the database until the tree is explicitly saved.

This method returns a reference to the new level object.

Related Links

[Number](#), [AllValuesAudit](#)

Item

Syntax

```
Item(LevelName, LevelNumber)
```

Description

The Item method returns a reference to the specified level in the level collection executing the method as an object. The *LevelName* parameter specifies the name of the level to access. This parameter takes a string value. The *LevelNumber* parameter specifies the number at which the level exists. This parameter takes a number value. For example, suppose your level collection contains the following levels, in this order:

1. CORPORATE

2. COMPANY
3. DIVISION
4. DEPARTMENT
5. BRANCH

You want to access the fourth level, DEPARTMENT. You would use the following code:

```
&MYLEVEL = &LVLCOLLECTION.Item("DEPARTMENT", 4);
```

Remove

Syntax

Remove ()

Description

The Remove method deletes the current level from the database. You can use this method only after you have used the First, Next, or Item properties: otherwise the system doesn't know which level to delete from the tree. If no level has been indicated yet system tries to remove the last level. If the level to remove has nodes associated with it, the system doesn't remove the level. The rest of the levels in the collection after the deleted level are moved up in the list and renumbered so that the levels remain consecutively numbered.

Returns

A number; 0 if the level is successfully removed.

Level Collection Properties

In this section, we discuss the Level collection properties. The properties are discussed in alphabetical order.

Count

Description

Returns the number of levels for the level collection object.

First

Description

The First property returns a reference to the first level in the level collection executing the method as an open object.

Last

Description

The Last property returns a reference to the last level in the level collection executing the method as an open object.

Next

Description

The Next property returns a reference to the next level in the level collection executing the method as an open object. You can use this method only after you have used either the First or Item properties: otherwise the system doesn't know where to start in the tree.

Level Class

Level objects are instantiated from the level class collection object with the Item method or one of the following properties:

- First
- Last
- Next

See [Item](#), [First](#), [Last](#), [Next](#).

Level Class Methods

In this section, we discuss the Leaf class properties. The properties are discussed in alphabetical order.

Create

Syntax

```
Create (LevelName, LevelNumber)
```

Description

Note: This method has been deprecated. If you create a level using this method, there is no way of saving the level to the database. Use the Add level collection method instead.

Level Class Properties

In this section, we discuss the Level class properties. The properties are discussed in alphabetical order.

AllValuesAudit

Description

This property specifies whether PeopleSoft Tree Manager permits nodes to skip over this level. To allow nodes to skip this level, specify this parameter as True. If you are creating a new level, and this level is the first level in a tree, this property is automatically set to True. If the level isn't the first level, this property is set to False by default..

This property is read/write.

Related Links

"Modifying Tree Definitions" (Tree Manager)

Description

Description

This property returns the description of the level.

This property is read/write.

Name

Description

This property returns the name of the level.

This property is read/write.

Number

Description

This property returns the number of the level.

Note: Though you can use this property to set the level of the number, you should not do so, as level numbers are automatically assigned when the level is inserted to the level collection using the Add method.

This property is read/write.

TreeBranchName

Description

This property returns the branch name of the tree as a string if the tree is branched. If not branched, this property returns a blank string.

This property is read-only.

TreeEffDt

Description

This property returns the effective date of the tree as a string if the tree is effective-dated. If not-effective dated, this property returns a blank string.

This property is read-only.

TreeName

Description

This property returns the name of the tree as a string.

This property is read-only.

TreeSetId

Description

This property returns the SetID of the tree as a string if the tree has a SetID. If the tree doesn't have a SetID, this property returns a blank string.

This property is read-only.

TreeUserKeyValue

Description

This property returns the UserKeyValue of the tree as a string if the tree has a UserKeyValue. If the tree doesn't have a UserKeyValue, this property returns a blank string.

Node Class

Node objects are instantiated from other tree classes, as follows:

- From a tree object with the FindNode method.

- From a leaf object with the Parent property.
- From another node object with the FirstChildNode, NextSib, PrevSib, and Parent properties.

See [FindNode](#), [FirstChildNode](#), [NextSib](#), [PrevSib](#).

See [Parent](#).

See [Parent](#).

Node Class Methods

In this section, we discuss the Node class methods. The methods are discussed in alphabetical order.

Branch

Syntax

```
Branch ()
```

Description

The Branch method branches the node executing this method, identifying all of its child nodes and leaves as part of that branch. *Branching* means taking a limb of a tree and creating another subtree to hold that limb. (Technically is it not creating a real tree.) The subtree is accessed through the Branches collection.

After you use the Branch method, you can no longer access the child nodes and leaves of the node that executed the method until you close the current tree, open the new branched tree, and find the node again. To unbranch the tree, use the Unbranch method.

Returns

A number; 0 if method is successful.

Example

```
&MYNODE = &MYTREE.FindNode("10900", "");  
&MYNODE.Branch();
```

Related Links

"Working with Tree Branches" (Tree Manager)

Cut

Syntax

```
Cut ()
```

Description

The Cut method cuts the node executing the method and puts it into a buffer (the clipboard). You can then use the PasteSib method to add the node back as a sibling of a different node. You can also use the PasteChild node method to add the node back as a child of a different node.

You can have only one object at a time on the clipboard. If you cut another leaf or node, the node on the clipboard is overwritten.

Parameters

None.

Returns

A number; 0 if method is successful.

Delete

Syntax

```
Delete()
```

Description

The Delete method deletes the node object executing the method *from the database*.

Returns

A number; 0 if method is successful.

DeleteByName

Syntax

```
DeleteByName(NodeName)
```

Description

The DeleteByName method deletes the specified node from the database. The *NodeName* parameter takes a string value. The node specified by *NodeName* does not have to match the node executing the method. That is, if &MYNODE is associated with node 100200, you can specify a different node with the DeleteByName method. For example:

```
&MYNODE = &MYTREE.FindNode("100200", "");  
/* some processing */  
&MYNODE.DeleteByName("100300");
```

The node name specified by *NodeName* must be a valid node in the existing open tree object. If *NodeName* doesn't exist, you receive a runtime error.

Returns

A number; 0 if method is successful.

Expand

Syntax

Expand (*ExpandType*)

Description

The Expand method gets the next level of nodes or leaves into memory from the selected node. What leaves or nodes get expanded depends on the *ExpandType*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ExpandType</i>	Specifies which leaves or nodes get expanded. Values are:

<i>Value</i>	<i>Description</i>
0	Expand only nodes
1	Expand nodes and leaves
2	Expand only one level

Returns

A number; 0 if method is successful.

Example

```
If (&MYNODE.State = 2 AND &MYNODE.HasChildren);
    /* if node is collapsed */
    &MYNODE.Expand(2);
End-if;
```

GenABNMenuElement

Syntax

GenABNMenuElement (*initial_node*)

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Use this method to generate a single element for this tree node.

The element from this node and any sibling nodes and leaves are concatenated to form an HTML code fragment to be consumed by the portal.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>initial_node</i>	Specifies the initial chart node. Typically, this is returned directly by calling the GetABNInitialNode function.

Returns

A string representing the element for this tree node.

GenABNMenuElementWithImage

Syntax

```
GenABNMenuElementWithImage(initial_node, fldr_img_class_ID, CREF_img_class_ID)
```

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Use this method to generate a single element for this tree node using the specified custom folder and CREF icons.

The element from this node and any sibling nodes and leaves are concatenated to form an HTML code fragment to be consumed by the portal.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>initial_node</i>	Specifies the initial chart node. Typically, this is returned directly by calling the GetABNInitialNode function.

Parameter	Description
<i>fldr_img_class_ID</i>	<p>Specifies the class ID for a custom folder icon as a string. This class must be defined in a style sheet, and the style sheet must be assigned to the SmartNavigation folder.</p> <p>This is an optional parameter. To use the default folder icon, you can omit this parameter or specify the null string "". However, to ensure forward compatibility, you must specify the null string.</p>
<i>CREF_img_class_ID</i>	<p>Specifies the class ID for a custom CREF icon as a string. This class must be defined in a style sheet, and the style sheet must be assigned to the SmartNavigation folder.</p> <p>This is an optional parameter. To use the default CREF icon, you can omit this parameter or specify the null string "". However, to ensure forward compatibility, you must specify the null string.</p>

Returns

A string representing the element for this tree node.

GenBreadCrumbs

Syntax

`GenBreadCrumbs (list)`

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Call the GenBreadCrumbs method from the requested node to generate an HTML code fragment that will be rendered in the browser as breadcrumbs.

The elements in the input string are created by the GenRelatedActions and GenABNMenuItem methods of the Node class, and the GenABNMenuItem method of the Leaf class.

Parameters

Parameter	Description
<i>list</i>	Specifies the list of elements as a string.

Returns

A string with the elements for the bread crumbs for this tree node appended.

GenRelatedActions

Syntax

```
GenRelatedActions ()
```

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Use this method to generate the list of elements for the related actions menu for the current tree node. Call this function before calling GenABNMenuElement for the same node. The elements from this function, from this node, from any child nodes and leaves traversed, and from the parent tree nodes are concatenated to form an HTML code fragment to be consumed by the portal.

Parameters

None.

Returns

A string representing the elements for the related actions for this tree node.

InsertChildLeaf

Syntax

```
InsertChildLeaf (RangeFrom, RangeTo)
```

Description

The InsertChildLeaf method inserts a new leaf (as specified by the range parameters) under the node object executing the method.

A leaf object associated with the new leaf is returned.

The new leaf is inserted as the child of the current node, although there is no explicit ordering of leaves: leaves take the order of the alphanumeric database sort on their range fields.

Note: You must specify a range with this method. To insert a dynamic range leaf (that is, one with no range) use the InsertDynChildLeaf method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RangeFrom</i>	Specify the starting range of the new leaf. This parameter takes a string value.

Parameter	Description
<i>RangeTo</i>	Specify the ending range of the new leaf. This parameter takes a string value.

Returns

A leaf object associated with the new leaf. If this method fails, it returns either `False` or a `Null` object reference, depending upon the type of error encountered. The best way to test whether the object was inserted is to test the result using either the `All` or `None` functions.

Example

```
&NEWLEAF = &MYLNODE.InsertChildLeaf("10090", "10100");

If None(&NEWLEAF) Then
    /* Error Processing */
End-If;
```

Related Links

[InsertDynChildLeaf](#)

InsertChildNode

Syntax

```
InsertChildNode (NodeName)
```

Description

The `InsertChildNode` method inserts a new node (as specified by *NodeName*) as a child node under the node object executing the method. The node specified by *NodeName* must be a new node. You receive an error if the node already exists.

A node object associated with the new node is returned. If the new node isn't inserted successfully, the method returns `False` or `Null`.

Parameters

Parameter	Description
<i>NodeName</i>	Specify a name for the new node. This parameter takes a string value. <i>NodeName</i> must not already exist.

Returns

A reference to the new node. If this method fails, it returns either `False` or a `Null` object reference, depending upon the type of error encountered. The best way to test whether the object was inserted is to test the result using either the `All` or `None` functions.

Example

```
&NEWMODE = &MYNODE.InsertChildNode("100500");

If None(&NEWMODE) Then
    /* Do error processing */
End-If;
```

Related Links

"All" (PeopleCode Language Reference)

"None" (PeopleCode Language Reference)

InsertChildRecord

Syntax

```
InsertChildRecord (NodeName)
```

Description

The `InsertChildRecord` method inserts a new record (as specified by *NodeName*) as a node under the parent node executing this method. This method works only on trees that are Query Access Trees.

A node object associated with the new node is returned, otherwise this method returns `False` or `Null`.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify an existing record name. This parameter takes a string value. This record must not already be a node under the parent node (that is, a parent node can't have the same record as a child node more than once.)

Returns

A reference to the new node. If this method fails, it returns either `False` or a `Null` object reference, depending upon the type of error encountered. The best way to test whether the object was inserted is to test the result using either the `All` or `None` functions.

Example

```
&NEWMODE = &MYNODE.InsertChildRecord("PERSONAL_DATA");

If None(&NEWMODE) Then
    /* Do error processing */
End-if;
```

InsertDynChildLeaf

Syntax

```
InsertDynChildLeaf()
```

Description

The InsertDynChildLeaf method inserts a dynamic leaf under the node object executing the method.

A leaf object associated with the new leaf is returned.

The new leaf is inserted as the child of the current node, although there is no explicit ordering of leaves.

Note: To insert a leaf with a specific range, use the InsertChildLeaf method.

Parameters

None.

Returns

A leaf object associated with the new leaf. If this method fails, it returns either False or a Null object reference, depending upon the type of error encountered. The best way to test whether the object was inserted is to test the result using either the All or None functions.

Example

```
&NEWLEAF = &MYLNODE.InsertDynChildLeaf();

If None(&NEWLEAF) Then
    /* Do error processing */
End-If;
```

InsertSib

Syntax

InsertSib (*NodeName*)

Description

The InsertSib method inserts a new node (as specified by *NodeName*) as a sibling node to the node object executing the method. The node specified by *NodeName* must be a *new* node. You receive an error if the node already exists.

A node object associated with the new node is returned. If the new node isn't inserted successfully, the method returns Null.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify a name for the new node. This parameter takes a string value. <i>NodeName</i> must not already exist.

Returns

A reference to the new node. If this method fails, it returns False.

Example

```
&NEWMODE = &MYNODE.InsertSib("100500");
```

InsertSibRecord

Syntax

InsertSibRecord (*NodeName*)

Description

The InsertSibRecord method inserts a new record (as specified by *NodeName*) as a sibling node of the parent node executing this method. This method works only on trees that are Query Access Trees.

A node object associated with the new node is returned, otherwise this method returns Null.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>nodeName</i>	Specify an existing record name. This parameter takes a string value. This record must not already be a sibling node for the node executing the object (that is, a node can't have the same record as a node more than once.)

Returns

A reference to the new node. If this method fails, it returns False.

Example

```
&NEWNODE = &MYNODE.InsertSibRecord("PERSONAL_DATA");
```

LoadABNChart

Syntax

```
LoadABNChart(&chart_rowset, &relations_rowset, requested_node, initial_node)
```

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Use this method to load the requested tree node into the SmartNavigation chart rowset and the component buffer.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&chart_rowset</i>	Specifies the SmartNavigation chart rowset. Typically, this is the rowset returned by the GetABNChartRowSet function.
<i>&relations_rowset</i>	Specifies the related actions rowset. Typically, this is the rowset returned by the GetABNRelActnRowSet function.
<i>requested_node</i>	Specifies as a Boolean value whether the calling node is the requested node.
<i>initial_node</i>	Specifies the initial chart node. Typically, this is returned directly by calling the GetABNInitialNode function.

Returns

None.

LoadABNChartOrdered

Syntax

```
LoadABNChartOrdered(&chart_rowset, &relactions_rowset, requested_node, initial_node⇒
, order)
```

Description

Note: SmartNavigation has been deprecated. This method remains for backward compatibility only.

Use this method to load the requested tree node into the SmartNavigation chart rowset and the component buffer. The order for this node within its chart level is specified by this method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&chart_rowset</i>	Specifies the SmartNavigation chart rowset. Typically, this is the rowset returned by the GetABNChartRowSet function.
<i>&relactions_rowset</i>	Specifies the related actions rowset. Typically, this is the rowset returned by the GetABNRelActnRowSet function.
<i>requested_node</i>	Specifies as a Boolean value whether the calling node is the requested node.
<i>initial_node</i>	Specifies the initial chart node. Typically, this is returned directly by calling the GetABNInitialNode function.
<i>order</i>	Specify the order for the node as a number. <hr/> Note: For a given chart level, all chart leaves must have a display order greater than zero. <hr/>

Returns

None.

MoveAsChild

Syntax

MoveAsChild (*Node*)

Description

The MoveAsChild method moves the node executing the method to a different node in the tree. The node becomes the first child node under the named node. The specified node becomes the new parent to the child node. The node specified by *Node* must be an existing node in the current tree. All child nodes and details are also moved with the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Node</i>	Specify a node object. This parameter value must be an object, not a string or a name.

Note: To specify a node name, not a node object, use the MoveAsChildByName method.

Returns

A number; 0 if method is successful.

Example

The following example moves node 10200 from node 10100 (old parent) to node 00001 (new parent).

```
&MY_NODE = &MY_TREE.FindNode("10200", "");
&NEW_PARENT = &MY_TREE.FindNode("00001", "");
If &NEW_PARENT <> Null Then
    &MY_NODE.MoveAsChild(&NEW_PARENT);
End-If;
```

Related Links

[MoveAsChildByName](#)

MoveAsChildByName

Syntax

MoveAsChildByName (*NodeName*)

Description

The MoveAsChildByName method moves the node executing the method to a different node in the tree. The node becomes the first child node under the parent node. The specified node becomes the new parent

to the node. The node specified by *NodeName* must be a valid node name. All child nodes and details are also moved with the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of a node. This parameter takes a string value. <i>NodeName</i> must be a valid node for the existing tree.

Note: To specify a node object, not a node name, use the `MoveAsChild` method.

Returns

A number; 0 if method is successful.

Example

The following moves node 10200 from node 10100 (old parent) to node 00001 (new parent)

```
&MY_NODE = &MY_TREE.FindNode("10200", "");
If &MY_NODE <> Null Then
    &MY_NODE.MoveAsChildByName("00001");
End-If;
```

Related Links

[MoveAsChild](#)

MoveAsSib

Syntax

MoveAsSib (*Node*)

Description

The `MoveAsSib` method moves the node executing the method to a new place in the tree. The current node becomes the next sibling node under the specified node. All child nodes and details are also moved with the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Node</i>	Specify a node object. This parameter value must be an object, not a string or a name.

Note: To specify a node name, not a node object, use the `MoveAsSibByName` method.

Returns

A number; 0 if method is successful.

Example

```
&MYNODE = &MYTREE.FindNode("20000", "");
&MYNODE2 = &MYTREE.FindNode("20100", "");
&MYNODE.MoveAsSib(&MYNODE2);
```

Related Links

[MoveAsSibByName](#)

MoveAsSibByName

Syntax

MoveAsSibByName (*NodeName*)

Description

The `MoveAsSibByName` method moves the node executing the method to a new place in the tree. The current node becomes the next sibling node under the specified node. All child nodes and details are also moved with the node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of a node. This parameter takes a string value. <i>NodeName</i> must be a valid node for the existing tree.

Note: To specify a node object, not a node name, use the `MoveAsSib` method.

Returns

A number; 0 if method is successful.

Example

```
&MYNODE = &MYTREE.FindNode("20000", "");
&MYNODE.MoveAsSibByName("10100");
```

Related Links

[MoveAsSib](#)

PasteChild

Syntax

```
PasteChild()
```

Description

The PasteChild method makes the node or leaf from the buffer (clipboard) a child to the node executing the method. You must use the Cut node or leaf method before you can paste a node or leaf.

You can have only one object at a time on the clipboard. If you cut another node or leaf, the node or leaf on the clipboard is overwritten.

Parameters

None.

Returns

A number; 0 if method is successful.

PasteSib

Syntax

```
PasteSib()
```

Description

The PasteSib method makes the node from the buffer (clipboard) a sibling to the node executing the method. You must use the Cut node method before you can paste a node.

You can have only one object at a time on the clipboard. If you cut another leaf or node, the node on the clipboard is overwritten.

Parameters

None.

Returns

A number; 0 if method is successful.

RefreshDescription

Syntax

```
RefreshDescription()
```

Description

The RefreshDescription method enables you to change the description of a node on a page and have the update be displayed immediately. If you don't use RefreshDescription, you must save the tree and reopen it for the change to be displayed.

Parameters

None.

Returns

A zero (0) if description is refreshed successfully, a different error number otherwise.

Example

```
&result= &NodeObj.refreshdescription();
```

Rename

Syntax

Rename (*NodeName*)

Description

The Rename method renames the node object executing the method without changing any other properties. The parameter *NodeName* takes a string value. The node specified by *NodeName* must be a new node. You receive an error if the node already exists.

Note: The Rename method does not rename the node in a user node component. Your application needs to do that.

Returns

A number; 0 if method is successful.

Example

```
&MYNODE = &MYTREE.FindNode("10900", "");  
&MYNODE.Rename("10200");
```

SwitchLevel

Syntax

SwitchLevel (*NewLevelNumber*)

Description

The SwitchLevel methods enables you to move a node down from one level to another.

NewLevelNumber must specify a valid level number. For trees in which the Level Use parameter is set to Strictly Enforce Levels, the new level must be at least one level lower than the node's parent level.

If the level specified by *NewLevelNumber* doesn't exist, it's automatically generated and added to the tree.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NewLevelNumber</i>	Specify the level number to where you want the node moved.

Returns

A zero (0) if node is moved successfully, a different error number otherwise.

Unbranch

Syntax

```
Unbranch ()
```

Description

The Unbranch method is the opposite of the Branch method: that is, it unbranches the node executing the method if it is branched. All of the child node and leaves of the node become part of the current open tree and accessible in that tree. You can't unbranch the Root Node in a branched tree.

If the node executing the method isn't branched, you receive a runtime error. Use the IsBranched property to make sure a node is branched.

Returns

A number; 0 if method is successful.

Example

```
&MYNODE = &MYTREE.FindNode("10900", "");
&MYNODE.Unbranch();
```

Node Class Properties

In this section, we discuss the Node class properties. The properties are discussed in alphabetical order.

AllChildCount

Description

This property returns the number of all the child nodes and leaves of the node, that is, all the nodes and leaves below this node.

This property is read-only.

AllChildNodeCount

Description

This property returns the number of child nodes of the node, that is, all the nodes below this node.

To determine all the leaves below a node, subtract the AllChildNodeCount from the AllChildCount

This property is read-only.

Example

To determine all the leaves below a node, use the AllChildNodeCount with the AllChildCount property.

```
&AllCount = (&MyNode.AllChildCount - &MyNode.AllChildNodeCount);
```

ChildLeafCount

Description

This property returns the number of immediate child leaves below this node.

This property is read-only.

ChildNodeCount

Description

This property returns the number of immediate child nodes below this node.

This property is read-only.

CollImageName

Description

This property enables you to specify the image name for a collapsed node.

This property is read/write.

Description

Description

This property returns the description of the node.

This property is read-only.

DisplayLevelNumber

Description

When using the Tree API to create a graphic representation of the tree (such as for HTML Tree Manager or other application pages) use this property to indicate the display level, that is, tell the user how many levels deep the node is. This is generally used for trees where levels aren't used and the LevelNumber property always returns 0.

This property is read-only.

Related Links

[LevelNumber](#)

ExpImageName

Description

This property enables you to specify the expanded image name for a node.

This property is read/write.

FirstChildLeaf

Description

This property returns a reference to the first child leaf of the node. This is the leaf that appears highest in the list of children of the node in PeopleSoft Tree Manager.

This property is read-only.

Example

```
&NEWLEAF = &MYNODE.FirstChildLeaf;
```

FirstChildNode

Description

This property returns a reference to the first child node of the node. This is the node that appears highest in the list of children of the node in PeopleSoft Tree Manager.

This property is read-only.

Example

```
&CHILDNODE = &MYNODE.FirstChildNode;
```

HasChildLeaves

Description

This property returns True if the node has immediate child leaves, False otherwise.

This property is read-only.

HasChildNodes

Description

This property returns True if the node has immediate child nodes, False otherwise.

This property is read-only.

HasChildren

Description

This property returns True if the node has either child leaves or child nodes anywhere in the subtree, not just immediately under the node.

This property is read-only.

HasNextSib

Description

This property returns True if the node has a next sibling, that is, if it isn't the last node.

This property is read-only.

Example

```
While &MYNODE.HasNextSib
    &MYNODE = &MYNODE.NextSib;
    /* do some processing */
End-While;
```

HasPrevSib

Description

This property returns True if the node has a previous sibling, that is, if it isn't the first node.

This property is read-only.

IsBranched

Description

This property returns True if the node is branched, False otherwise.

This property is read-only.

IsChanged

Description

This property returns True if the node has been edited or changed but the current tree hasn't been saved.

This property is read-only.

IsCut

Description

This property returns True if the node has been cut from the displayed tree. This property is generally used with the HTML Tree Manager.

This property is read-only.

IsDeleted

Description

This property returns True if the node has been deleted but the current tree hasn't been saved.

This property is read-only.

IsInserted

Description

This property returns True if the node was inserted as a new node into the tree but the tree hasn't been saved.

This property is read-only.

Example

```
If &MYNODE.IsInserted Then  
    &MYTREE.Save();  
End-if;
```

IsRoot

Description

This property returns True for both of the following:

- the node is the root node of an unbranched tree.
- the node is the top node of an opened tree branch.

Otherwise, the property returns False.

This property is read-only.

LastChildLeaf

Description

This property returns a reference to the last child leaf of the node. This is the leaf that appears lowest in the list of children of the node in PeopleSoft Tree Manager.

This property is read-only.

Example

```
&NEWLEAF = &MYNODE.LastChildLeaf;
```

LastChildNode

Description

This property returns a reference to the last child node of the node. This is the node that appears lowest in the list of children of the node in PeopleSoft Tree Manager.

This property is read-only.

Example

```
&CHILDNODE = &MYNODE.LastChildNode;
```

LevelNumber

Description

This property returns the level number of the node. Values are 1-99 for Strict or Loose level trees. This property returns 0 for trees that don't have levels.

Note: PeopleSoft does not recommend using this property to set the level of the node. Instead, use the `SwitchLevel` method.

This property is read/write.

Related Links

[SwitchLevel](#)

Name

Description

This property returns the name of the node (as a string.) You must set this property to a valid value if you are creating a new node.

Note: Do not use this property to change the name of an existing node. The change will not be reflected in the database. You must use the `Rename` method to change the name of an existing node.

This property is read/write.

Related Links

[Rename](#)

NextSib

Description

This property returns a reference to the next sibling node. If there isn't a next sibling node, Null is returned.

This property is read-only.

Example

```
While &MYNODE.HasNextSib  
    &MYNODE = &MYNODE.NextSib;  
    /* do some processing */  
End-While;
```

Parent

Description

This property returns a reference to the node that is the parent of the node executing the property. If the current node has no parent (is a root node) `False` is returned.

This property is read-only.

Example

```
&PARENT = &MYNODE.Parent;
```

PrevSib

Description

This property returns a reference to the node that is the previous sibling node to the node executing the property. If there isn't a previous sibling, `Null` is returned.

This property is read-only.

Example

```
If &MYNODE.PrevSib Then
  /* do processing */
End-if;
```

State

Description

This property returns the *state* of the node, that is, does it have children, and are they expanded or collapsed.

See [Expand](#).

The values for this property are:

Value	Description
0	Node has no children
1	Children are expanded
2	Children are collapsed
3	Leaves are collapsed

This property is read-only.

Example

```
&VALUE = &MYNODE.State;  
If &VALUE = 2 Then  
    &MYNODE.Expand(0);  
End-if;
```

TreeBranchName

Description

This property returns the branch name of the tree as a string if the tree is branched. If not branched, this property returns a blank string.

This property is read-only.

TreeEffDt

Description

This property returns the effective date of the tree as a string if the tree is effective-dated. If not effective-dated, this property returns a blank string.

This property is read-only.

TreeName

Description

This property returns the name of the tree as a string.

This property is read-only.

TreeSetId

Description

This property returns the SetID of the tree as a string if the tree has a SetID. If the tree doesn't have a SetID, this property returns a blank string.

This property is read-only.

TreeUserKeyValue

Description

This property returns the UserKeyValue of the tree as a string if the tree has a UserKeyValue. If the tree doesn't have a UserKeyValue, this property returns a blank string.

Type

Description

This property returns the type of the node. This property takes a string value. Values are:

- "G" (Group): normal unbranched node or record group
- "B" (Branched nodes)
- "R" (Query Record): used for Query Access Trees only

This property is read-only.

Tree Class

Tree objects are instantiated from a session object with the GetTree method.

The following code sample gets a tree, then opens the tree structure associated with that tree:

```
Local string &TREE_NAME;
Local string &TREE_DT;
Local ApiObject &MYSESSION, &VC_TREE, &STRUCT;

/* Get and Open the Tree using the Tree API */
&MYSESSION = %Session;

/* Get the Tree Name and Effective Date from the level 0 record */
&TREE_NAME = "CUSTOMER";
&TREE_DT = "1900-01-01";

/* Get and Open the Tree */
&VC_TREE = &MYSESSION.GetTree();

/* open the tree with read access only */
&VC_TREE.OPEN("BKINV", "", &TREE_NAME, &TREE_DT, "", False);

/* Get and Open Tree Structure */
&STRUCT = VC_TREE.Structure;
```

See [GetTree](#).

Tree Class Methods

In this section, we discuss the Tree class methods. The methods are discussed in alphabetical order.

Audit

Syntax

```
Audit ()
```

Description

The Audit method audits the tree object executing the method to determine its validity.

The Audit method can be used only on an open tree, not on a closed tree. This means you must have opened the tree with the Open method before you can audit it.

Returns

A number: 0 if the tree passes all audits. If Audit returns a value not equal to 0, an error is logged.

Related Links

[Open](#)

"Understanding the Auditing and Repairing of Trees" (Tree Manager)

AuditByName

Syntax

```
AuditByName (SetID, UserKeyValue, TreeName, EffDt, BranchName)
```

Description

The AuditByName method audits the tree specified by the parameters passed to it. The AuditByName method can be used only with a tree identifier, it cannot be used on a fully instantiated, open tree. Before you use the AuditByName method, you must explicitly close any open tree objects (with the Close method.) You receive an error if there are any open trees.

Parameters

Parameter	Description
<i>SetID</i>	<p>Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>UserKeyValue</i>	<p>Specify the User Key Value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>TreeName</i>	Specify the name for this tree. This parameter takes a string value.
<i>EffDt</i>	Specify the effective date for this tree. This parameter takes a string value.
<i>BranchName</i>	This parameter is required, but it is unused in this release. You must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.

Returns

A number: 0 if the tree passes all audits. If this method returns a value not equal to 0, an error is logged.

Example

```
&ISVALID = &MYTREE.AuditByName("", "", "PERSONAL_DATA", "05-05-1997", "");
```

Related Links

[Close](#)

[IndirectionMethod](#)

"Understanding the Auditing and Repairing of Trees" (Tree Manager)

Close

Syntax

```
Close ()
```

Description

The Close method closes the tree, freeing the memory associated with that object, and discarding any changes made to the tree since the last save. The Close method can be used only on an open tree, not a closed tree. This means you must have opened the tree with the Open method before you can close it. To save any changes, you must use the Save method before using Close.

Returns

A number: 0 if the method completed successfully.

Copy

Syntax

```
Copy (FromSetId, FromUserKeyValue, FromTreeName, FromEffDt, FromBranchName, ToSetId,⇒  
ToUserKeyValue, ToTreeName, ToEffDt, ToBranchName)
```

Description

The Copy method copies from the tree identified by the *From* parameters and copies it to the tree identified with the *To* parameters. The tree specified by the *To* parameters must be a *new* tree. You receive an error if the tree already exists. The tree specified by the *From* parameters does *not* have to match the tree identifier executing the method.

The Copy method can be used only with a *closed* tree, it cannot be used on an open tree. Before you use the Copy method, you must explicitly close any open tree objects (with the Close method.) You receive an error if there are any open trees.

To access the new tree, you must use the Open method.

Parameters

Parameter	Description
<i>FromSetId</i>	<p>Specify the table indirection key for the tree to be copied from. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>FromUserKeyValue</i>	<p>Specify the User Key Value for the tree to be copied from. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>FromTreeName</i>	<p>Specify the name for the tree to be copied from. This parameter takes a string value.</p>
<i>FromEffDt</i>	<p>Specify the effective date for the tree to be copied from. This parameter takes a string value.</p>
<i>FromBranchName</i>	<p>This parameter is required, but it is unused in this release. You must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>ToSetId</i>	<p>Specify the table indirection key for the tree to be copied to. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>ToUserKeyValue</i>	<p>Specify the User Key Value for the tree to be copied to. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "U" or "B" you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>

Parameter	Description
<i>ToTreeName</i>	Specify the name for the tree to be copied to. This parameter takes a string value.
<i>ToEffDt</i>	Specify the effective date for the tree to be copied to. This parameter takes a string value.
<i>ToBranchName</i>	This parameter is required, but it is unused in this release. You must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.

Returns

An integer: 0 if copied successfully.

Example

```
&MYTREE.Copy("", "", "PERSONAL_DATA", "05-05-1997", "", "", "", "PERSONAL_EDIT1", "05-05-1997", "");
```

Related Links

[Close](#)

[IndirectionMethod](#)

Create

Syntax

```
Create(SetID, UserKeyValue, TreeName, EffDt, StructureName)
```

Description

The Create method creates a new tree, based on the parameters passed with the method. The specified tree must be a new tree. You receive an error if the tree already exists.

The Create method can be used only with a closed tree, it cannot be used on an open tree. Before you use the Create method, you must explicitly close any open tree objects (with the Close method.) You receive an error if there are any open trees.

After you create a new tree, you don't have to open it with the Open method. The existing tree object points to the new tree.

The tree structure specified with *StructureName* determines what database fields the new tree is based on, what pages you can use to create tree nodes and detail values, and what record definitions PeopleSoft Tree Manager saves tree-related data in. The tree structure must already exist.

The new tree must be saved (Save, SaveAs, and so on) for this tree to be saved to the database.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SetID</i>	Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID. If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>UserKeyValue</i>	Specify the User Key Value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value. If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>TreeName</i>	Specify the name for this tree. This parameter takes a string value.
<i>EffDt</i>	Specify the effective date for this tree. This parameter takes a string value.
<i>StructureID</i>	Specify the name of the tree structure to use for this tree. This parameter takes a string value.

Returns

An integer: 0 if created successfully.

Example

```
&MYTREE.Create("", "", "PERSONAL_NEW", "05-05-1997", "PERSONAL_DATA");
```

Related Links

[IndirectionMethod](#)

["Understanding Steps to Create Trees" \(Tree Manager\)](#)

Delete

Syntax

`Delete` (*SetID*, *UserKeyValue*, *TreeName*, *EffDt*, *BranchName*)

Description

The Delete method deletes the specified tree from the database. The Delete method can be used only with a closed tree, it cannot be used on an open tree. Before you use the Delete method, you must explicitly close any open tree objects (with the Close method.) You receive an error if there are any open trees.

The specified tree does not have to match the tree identifier executing the method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SetID</i>	Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID. If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>UserKeyValue</i>	Specify the User Key Value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value. If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>TreeName</i>	Specify the name for this tree. This parameter takes a string value.
<i>EffDt</i>	Specify the effective date for this tree. This parameter takes a string value.
<i>BranchName</i>	Specify the name of the branch for the tree. This parameter takes a string value. If the tree is unbranched, you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.

Returns

An integer: 0 if deleted successfully.

Example

```
&MYTREE=&Session.GetTree();

If ALL(&MYTREE) Then
    &RETVALUE = &MYTREE.Delete("", "", "PERSONAL_REN2", "05-05-1997", "");
End-If;
```

Related Links

[Close](#)

[IndirectionMethod](#)

Exists

Syntax

```
Exists(SetID, UserKeyValue, TreeName, EffDt, BranchName)
```

Description

The Exists method finds an existing tree, as specified by the parameters. The parameters must specify a unique tree. If a tree matching the parameters is found, the method returns 0. This method works with either open or closed trees.

Parameters

Parameter	Description
<i>SetID</i>	Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID. If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>UserKeyValue</i>	Specify the User Key Value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value. If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>TreeName</i>	Specify the name for this tree. This parameter takes a string value.

Parameter	Description
<i>EffDt</i>	Specify the effective date for this tree. This parameter takes a string value.
<i>BranchName</i>	This parameter is required, but it is unused in this release. You must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.

Returns

An integer: 0 if tree exists.

Example

```
&RSLT = &MYTREE.Exists("", "", "VENDOR_PER_DATA", "05-03-1998", "");

If &RSLT = 0 Then
    /* tree exists, do processing */
Else
    /* tree doesn't exist, do error processing */
End-if;
```

Related Links

[IndirectionMethod](#)

FindLeaf

Syntax

```
FindLeaf(RangeFrom, RangeTo)
```

Description

The FindLeaf method finds an existing leaf (specified by the *range* parameters) in the tree executing this method. If the leaf is found, a leaf object is returned. If the leaf isn't found, a Null is returned.

You can use wildcards with the *range* parameters. Use an asterisk (*) in place of a number of characters. Use a question mark (?) in place of one character. You can also provide one of the ranges, and specify a Null string for the other.

Suppose you wanted to find the leaf with the range 81005 to 82000. The following would be valid:

```
&MyLeaf = &MyTree.FindLeaf("81*", "82000");
```

This would also be valid:

```
&MyLeaf = &MyTree.FindLeaf("8100?", "82000");
```

You could also specify this:

```
&MYLEAF = &MYTREE.FindLeaf("81000", "");
```

If you specify the exact same value for both *RangeFrom* and *RangeTo*, the *RangeTo* parameter is ignored.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RangeFrom</i>	Specify the starting range of the leaf to be found. This parameter takes a string value.
<i>RangeTo</i>	Specify the ending range of the leaf to be found. This parameter takes a string value.

Returns

A reference to a leaf object.

Example

```
&MYLEAF = &MYTREE.FindLeaf("81000", "");
```

FindNode

Syntax

```
FindNode(NodeName, Description)
```

Description

The FindNode method returns a reference to the node object specified by the parameters passed to the method. If the node is found, a node object is returned. If the node isn't found, a Null is returned.

Note: If you've only specified a node name, and the node you're searching for is in an unexpanded portion of the tree, this method expands the tree down to that node. If you've only specified a node description the search, occurs only in the memory. If the node isn't found, the tree is not expanded.

You should specify either the node name other description, not both. You should specify a Null string for the other. If both are provided, only the node name is used and the description is ignored.

You can use wildcards with the parameters. Use an asterisk (*) in place of a number of characters. Use a question mark (?) in place of one character.

Suppose you wanted to find the node called 10200, with a description of "Human Resources". The following would be valid:

```
&MyNode = &MyTree.FindNode("", "Human*");
```

This would also be valid:

```
&MyNode = &MyTree.FindNode("1020?", "");
```

You could also use the following:

```
&MYNODE = &MYTREE.FindNode("10200", "");
```

Note: If you're searching using wildcard characters and more than one node matches the search conditions, only the first occurrence of the node is returned

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of the node that you want to find. This parameter takes a string value. Specify either the node name or the description.
<i>Description</i>	Specify the description of the node that you want to find. This parameter takes a string value. Specify either the node name or the description.

Returns

A reference to a node object.

Example

```
&MYNODE = &MYTREE.FindNode("10200", "");
```

FindRoot

Syntax

```
FindRoot()
```

Description

The FindRoot method returns a reference to the root node object of the tree object executing the method. This method can be used only on an open tree, not on a closed tree. This means you must have opened the tree with the Open method before you can find the root node.

This method returns an error if the tree has no nodes associated with it.

Returns

A reference to a node object.

Example

```
&MYNODE = &MYTREE.FindRoot();
```

Related Links

[Open](#)

InsertRoot

Syntax

```
InsertRoot (NodeName)
```

Description

The InsertRoot method inserts a node at the top of the tree object executing the method. *NodeName* is the name of the node you are creating. This parameter takes a string value. The InsertRoot method can be used only on an open tree, not on a closed tree. This means you must have opened the tree with the Open method before you can insert any nodes.

You can insert the root node only in a new tree, that is, a tree that was just created with the Create method. Also, after you create a new tree, you must insert the root node before you can insert any other nodes.

In a strict level tree, the first level must be defined before you can insert the root node.

This method returns an error if the tree already has nodes in it.

Returns

A reference to a node object.

Example

```
&MyRootNode = &MYTREE.InsertRoot("000001");
```

Related Links

[Open](#)

LeafExists

Syntax

```
LeafExists (RangeFrom, RangeTo)
```

Description

The LeafExists method enables you to verify if the leaf specified by the parameters exists in the current tree.

Suppose you wanted to check the leaf with the range 81005 to 82000 exists. The following would be valid:

```
&MyResult = &MyTree.LeafExists("81005", "82000");
```

This would also be valid, and would check on leaves up to 82000:

```
&MyResult = &MyTree.LeafExists("", "82000");
```

If you specify the exact same value for both *RangeFrom* and *RangeTo*, the *RangeTo* parameter is ignored.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>RangeFrom</i>	Specify the starting range of the leaf you're verifying. This parameter takes a string value.
<i>RangeTo</i>	Specify the ending range of the leaf you're verifying. This parameter takes a string value.

Returns

An integer: 0 if the leaf exists.

[FindLeaf](#)

LockTree

Syntax

```
LockTree ()
```

Description

Use the LockTree method to check out a tree for editing. Use this method to prevent saving conflicts when you have multiple users accessing the same tree, using both the Tree API and PeopleSoft Tree Manager. To release a tree, use the UnlockTree method.

Note: In order to use this method, you must have Tree multi-user environment enabled. You can check if it is enabled by using UseUpdateReservation Tree property.

To verify if a tree is already locked, use the LockStatus property.

This method can be used only on an open tree, not on a closed tree. This means you must have opened the tree with the Open method.

Parameters

None.

Returns

An integer: 0 if locked successfully.

Related Links

[TreeLocksNumber](#)

[UnlockTree](#)

[HasLockedBranches](#)

[LockStatus](#)

[UseUpdateReservation](#)

Open

Syntax

```
Open (SetID, UserKeyValue, TreeName, EffDt, BranchName, Update)
```

Description

The Open method opens the tree object specified by the parameters. The Open method can be used only with a closed tree, it cannot be used on an open tree. You cannot read or set any properties of a tree until after you open it. When you open a tree, you can specify whether you want to open it for update, or in read-only mode, with the *Update* parameter. If you try updating or writing to a tree opened in read-only mode, you receive an error.

Note: Because EFFDT is a key field for a tree definition, an exact match is required to open a tree with the Open method. A less restrictive method, OpenAsOfDate, provides an alternative to Open by specifying an *AsOfDate* parameter instead of the *EffDt* parameter.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SetID</i>	<p>Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>

Parameter	Description
<i>UserKeyValue</i>	<p>Specify the User Key value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>TreeName</i>	Specify the name for the tree. This parameter takes a string value.
<i>EffDt</i>	Specify the effective date for the tree. This parameter takes a string value. The format must be in the correct format for the database platform the code is executing on.
<i>BranchName</i>	This parameter is required, but it is unused in this release. You must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>Update</i>	<p>Specify if you want to open the tree for update or in read-only mode. This parameter takes a Boolean value. Values for <i>Update</i> are:</p> <ul style="list-style-type: none"> • True: open tree structure in update mode (read/write). • False: open tree structure in read-only mode. <p>If you try updating or writing to a tree structure opened in read-only mode, you receive an error.</p>

Returns

An integer: 0 if opened successfully.

Example

The following example opens a tree object, then tests to see if the tree was actually opened:

```
&RSLT = &MYTREE.Open("", "", "PERSONAL_DATA", "05-05-1997", "", True);

If &RSLT = 0 Then
    /* normal processing */
Else
    /* error processing tree isn't open */
End-if;
```

Related Links

[Close](#)

[OpenAsOfDate](#)

IndirectionMethod**OpenAsOfDate****Syntax**

```
OpenAsOfDate (SetID, UserKeyValue, TreeName, AsOfDate, BranchName, Update)
```

Description

The `OpenAsOfDate` method operates similarly to the `Open` method and uses the same parameters except that instead of requiring the *EffDt* parameter, `OpenAsOfDate` uses a less restrictive *AsOfDate* parameter. The `OpenAsOfDate` method opens the most recent tree based on *AsOfDate*. If *AsOfDate* is not supplied, the current date is used.

Note: Because EFFDT is a key field for a tree definition, an exact match is required to open a tree with the `Open` method.

The `OpenAsOfDate` method can be used only with a closed tree; it cannot be used on an open tree. You cannot read or set any properties of a tree until after you open it. When you open a tree, you can specify whether you want to open it for update, or in read-only mode, with the `Update` parameter. If you try updating or writing to a tree opened in read-only mode, you receive an error.

Parameters

Parameter	Description
<i>SetID</i>	Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its <code>IndirectionMethod</code> specified as "S", you must specify a <code>SetID</code> . If the tree structure doesn't have its <code>IndirectionMethod</code> specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>UserKeyValue</i>	Specify the User Key value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its <code>IndirectionMethod</code> specified as "U" or "B", you must specify a User Key Value. If the tree structure doesn't have its <code>IndirectionMethod</code> specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>TreeName</i>	Specify the name for the tree. This parameter takes a string value.

Parameter	Description
<i>AsOfDate</i>	<p>Specify the “as-of-date” for the tree as a string. The format must be in the correct format for the database platform the code is executing on.</p> <p>If this parameter is not supplied, then the current date is used.</p> <p>If more than one tree matches the <i>SetID</i>, <i>UserKeyValue</i>, <i>TreeName</i>, and <i>BranchName</i> parameters, the tree with most recent effective date less than or equal to the as-of-date is opened.</p>
<i>BranchName</i>	<p>This parameter is required, but it is unused in this release. You must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>Update</i>	<p>Specify if you want to open the tree for update or in read-only mode. This parameter takes a Boolean value. Values for <i>Update</i> are:</p> <ul style="list-style-type: none"> • True: open tree structure in update mode (read/write). • False: open tree structure in read-only mode. <p>If you try updating or writing to a tree structure opened in read-only mode, you receive an error.</p>

Returns

An integer: 0 if opened successfully.

Example

The following example opens a tree object with most recent effective date matching the other tree criteria. Then, the program tests to see if the tree was actually opened:

```
&ret = &MyTree.OpenAsOfDate("QEDM1", "", "PERSONAL_DATA", "", "", True);

If &ret = 0 Then
    /* normal processing */
Else
    /* error processing tree isn't open */
End-if;
```

Related Links

[Open](#)

OpenForExport

Syntax

```
OpenForExport(SetID, UserKeyValue, TreeNameEffDt)
```

Description

Use the `OpenForExport` method to open a tree for export processes (using `TreeMover`.)

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SetID</i>	Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its <code>IndirectionMethod</code> specified as "S", you must specify a <code>SetID</code> . If the tree structure doesn't have its <code>IndirectionMethod</code> specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>UserKeyValue</i>	Specify the User Key value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its <code>IndirectionMethod</code> specified as "U" or "B", you must specify a User Key Value. If the tree structure doesn't have its <code>IndirectionMethod</code> specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>TreeName</i>	Specify the name for the tree. This parameter takes a string value.
<i>EffDt</i>	Specify the effective date for the tree. This parameter takes a string value. The format must be in the correct format for the database platform the code is executing on.

Returns

An integer: 0 if opened successfully.

Example

```
If &TREE.OpenForExport(&SETID, &USERKEYVALUE, &TREE_NAME, &TREE_EFFDT) <> 0 Then
/* processing */
End-if;
```

Related Links

"File Layout Details" (Tree Manager)

OpenWholeTree

Syntax

```
OpenWholeTree(SetID, UserKeyValue, TreeName, EffDt)
```

Description

The `OpenWholeTree` method enables you to open a tree as if it were an unbranched tree. With this kind of tree, branched nodes cannot be distinguished from unbranched nodes. This means you can traverse the entire tree. It also means that branches have a node icon, not a branch icon. This method can be used only with a closed tree, it cannot be used on an open tree. You cannot read any properties of a tree until after you open it. This tree is always opened as read-only.

Note: You can't open a tree using this method and update it. The tree is opened in read-only mode.

Parameters

Parameter	Description
<i>SetID</i>	Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its <code>IndirectionMethod</code> specified as "S", you must specify a <code>SetID</code> . If the tree structure doesn't have its <code>IndirectionMethod</code> specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>UserKeyValue</i>	Specify the User Key value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its <code>IndirectionMethod</code> specified as "U" or "B", you must specify a User Key Value. If the tree structure doesn't have its <code>IndirectionMethod</code> specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>TreeName</i>	Specify the name for the tree. This parameter takes a string value.
<i>EffDt</i>	Specify the effective date for the tree. This parameter takes a string value. The format must be in the correct format for the database platform the code is executing on.

Returns

An integer: 0 if opened successfully.

Example

```
&pSession = %Session;

&pTreeObj = &pSession.GetTree();
&status = &pTreeObj.OpenWholeTree(&Setid, &SetCntrlValue, &TreeName, String(&EffDt)⇒
);
```

NodeExists

Syntax

NodeExists (*NodeName*)

Description

The NodeExists method enables you to verify if the node specified by *NodeName* exists in the current tree.

Note: If the node you're searching for is in an unexpanded portion of the tree, this method expands the tree down to that node.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NodeName</i>	Specify the name of the node that you want to find. This parameter takes a string value.

Returns

An integer: 0 if the node exists.

[FindLeaf](#)

[FindNode](#)

[LeafExists](#)

Rename

Syntax

Rename (*FromSetId, FromUserKeyValue, FromTreeName, FromEffDt, FromBranchName, ToTree⇒*

Name)

Description

The Rename method renames a tree specified with the *From* parameters to the tree specified with *ToTreeName*. The tree specified by *ToTreeName* must be a new tree. You receive an error if the tree already exists. The tree specified by the *From* parameters does not have to match the tree executing the method.

The Rename method can be used only with a closed tree, it cannot be used on an open tree. Before you use the Rename method, you must explicitly close any open tree objects (with the Close method.) You receive an error if there are any open trees.

To access the new tree, you must use the Open method.

Parameters

Parameter	Description
<i>FromSetId</i>	Specify the table indirection key for the tree to be copied from. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID. If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>FromUserKeyValue</i>	Specify the User Key Value for the tree to be copied from. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value. If the tree structure doesn't have its IndirectionMethod specified as "U" or "B" you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>FromTreeName</i>	Specify the name for the tree to be copied from. This parameter takes a string value.
<i>FromEffDt</i>	Specify the effective date for the tree to be copied from. This parameter takes a string value.
<i>FromBranchName</i>	This parameter is required, but it is unused in this release. You must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>ToTreeName</i>	Specify the new name of the tree. This parameter takes a string value.

Returns

An integer: 0 if renamed successfully.

Example

```
&MYTREE.Rename ("", "", "PERSONAL_DATA3", "05-05-1997", "", "PERSONAL_REN2");
```

Save

Syntax

```
Save ()
```

Description

The Save method writes any changes to the tree executing the method to the database. It also performs audits.

The Save method can be used only on an open tree, not on a closed tree. This means you must have opened the tree with the Open method before you can save it.

The tree object remains open after executing Save. You must execute the Close method on the object before it is closed and the memory freed.

This method returns an optional Boolean value: True if the tree was saved with no errors, False if there are one or more errors.

Note: If you're calling the Tree API from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a COMMIT.

Related Links

"Understanding the Auditing and Repairing of Trees" (Tree Manager)

Parameters

None.

Returns

An integer: 0 if save successfully.

SaveAs

Syntax

```
SaveAs (SetID, UserKeyValue, TreeName, EffDt, BranchName)
```

Description

The SaveAs method writes any changes to the tree executing the method to the new tree specified with the parameters. It also performs audits.

The tree specified with the parameters must be a new tree. You receive an error if the tree already exists. The new tree must have at least one different key field from the original tree.

The SaveAs method automatically closes the tree that is associated with the tree object executing the method, and associates that tree object with the new tree. Any changes made to the original tree since the last time the tree was saved are discarded. For example, suppose you opened a tree named DEPENDENT_BENEF and associated it with the variable &MYTREE. If you executed the SaveAs method with &MYTREE, changing the name to DEPENDENT_BENEF2, &MYTREE would now be associated with DEPENDENT_BENEF2, and the original tree, DEPENDENT_BENEF, would be closed.

```
&MYTREE.Open("", "", "DEPENDENT_BENEF", "02-02-1999", "", False);
/* do some processing */
&MYTREE.SaveAs("", "", "DEPENDENT_BENEF2", "02-05-1999", "");
```

&MYTREE is now associated with DEPENDENT_BENEF2, not with the original open tree.

Note: If you're calling the Tree API from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a COMMIT.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SetID</i>	<p>Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>UserKeyValue</i>	<p>Specify the User Key Value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>

Parameter	Description
<i>TreeName</i>	Specify the name for this tree. This parameter takes a string value.
<i>EffDt</i>	Specify the effective date for this tree. This parameter takes a string value.
<i>BranchName</i>	This parameter is required, but it is unused in this release. You must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.

Returns

This method returns an integer: 0 if saved successfully, a number greater than 0 otherwise.

Example

```
&MYTREE.SaveAs("", "", "DEPENDENT_BENEF2", "02-05-1999", "");
```

Related Links

"Understanding the Auditing and Repairing of Trees" (Tree Manager)

SaveAsDraft

Syntax

```
SaveAsDraft(SetID, UserKeyValue, TreeName, EffDt, Branch`Name)
```

Description

The SaveAsDraft method writes any changes to the tree executing the method to the new tree specified with the parameters. However, it does not perform audits. Trees that are saved in this way are marked as "draft" and will not be valid (that is, cannot be used with other PeopleTools) until the tree audit is passed during Save, SaveAs, or the Tree Audits Application Engine Tree Utility program..

The tree specified with the parameters must be a new tree. You receive an error if the tree already exists. The new tree must have at least one different key field from the original tree.

The SaveAsDraft method automatically closes the tree that is associated with the tree object executing the method, and associates that tree object with the new tree. Any changes made to the original tree since the last time the tree was saved are discarded.

See SaveAs for more details.

Note: If you're calling the Tree API from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a Commit.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>SetID</i>	<p>Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>UserKeyValue</i>	<p>Specify the User Key Value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>
<i>TreeName</i>	Specify the name for this tree. This parameter takes a string value.
<i>EffDt</i>	Specify the effective date for this tree. This parameter takes a string value.
<i>BranchName</i>	This parameter is required, but it is unused in this release. You must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.

Returns

This method returns an integer: 0 if saved successfully, a number greater than 0 otherwise.

Example

```
&MYTREE. SaveAsDraft("", "", "PERSONAL_EDIT2", "05-05-1997", "");
```

Related Links

"Understanding the Auditing and Repairing of Trees" (Tree Manager)

SaveDraft

Syntax

```
SaveDraft()
```

Description

The SaveDraft method writes any changes to the tree executing the method to the database. However, it does not perform audits. Trees that are saved in this way are marked as "draft" and will not be valid (that is, cannot be used with other PeopleTools) until the tree audit is passed.

The SaveDraft method can be used only on an open tree, not on a closed tree. This means you must have opened the tree with the Open method before you can save it.

The tree object remains open after executing SaveDraft. You must execute the Close method on the object before it is closed and the memory freed.

Note: If you're calling the Tree API from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a Commit.

Parameters

None.

Returns

This method returns an integer: 0 if saved successfully, a number greater than 0 otherwise.

"Understanding the Auditing and Repairing of Trees" (Tree Manager)

SetImportMode

Syntax

```
SetImportMode (Nodes_NumberLeaves_Number)
```

Description

Use the SetImportMode method to set up special memory allocation and simplified processing rules when running Tree Import.

This special mode also cuts back on the number of SQL calls by not getting node descriptions. This mode also blocks internal validation while inserting new node or leaf from an input file. All validation occurs during saving.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Nodes_Number</i>	Specify the number of nodes.

Parameter	Description
<i>Leaves_Number</i>	Specify the number of leaves.

Returns

An integer: 0 if set successfully.

Related Links

"File Layout Details" (Tree Manager)

TreeLocksNumber

Syntax

```
TreeLocksNumber (setID, UserKeyValue, TreeName, EffDt)
```

Description

Use the TreeLocksNumber method to determine how many users have checked out any branches of a current tree. This method should be used to check if a tree definition could be changed without affecting other users working in different branches of a tree.

Note: In order to use this method, you must have Tree multi-user environment enabled. You can check if it is enabled by using UseUpdateReservation Tree property.

You can use the TreeLocksNumber method with a both an open as well as a closed tree.

Parameters

Parameter	Description
<i>SetID</i>	<p>Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a SetID.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>

Parameter	Description
<i>UserKeyValue</i>	Specify the User Key Value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value. If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.
<i>TreeName</i>	Specify the name for this tree. This parameter takes a string value.
<i>EffDt</i>	Specify the effective date for this tree. This parameter takes a string value.

Returns

The number of locked branches. If the tree is not branched, but is checked out, the return value is 1.

Related Links

[LockTree](#)

[UnlockTree](#)

[UnlockTree](#)

[UseUpdateReservation](#)

UnlockTree

Syntax

```
UnlockTree ()
```

Description

Use the UnlockTree method to release a tree after editing. Use this method to prevent saving conflicts when you have multiple users accessing the same tree, using both the Tree API and PeopleSoft Tree Manager. To checkout a tree, use the LockTree method.

Note: In order to use this method, you must have Tree multi-user environment enabled. You can check if it is enabled by using UseUpdateReservation Tree property.

To verify if a tree is checked out, use the LockStatus property.

This method can be used only on an open tree, not on a closed tree. This means you must have opened the tree with the Open method.

Parameters

None.

Returns

An integer: 0 if the tree is released successfully.

Related Links

[LockTree](#)

[LockStatus](#)

[UseUpdateReservation](#)

UpdateLock

Syntax

```
UpdateLock ( )
```

Description

Use the UpdateLock method to update the timestamp representing time when the user who has the tree checked out performed the last action on a tree.

Note: In order to use this method, you must have Tree multi-user environment enabled. You can check if it is enabled by using UseUpdateReservation Tree property.

Use this method to indicate that user who has the tree checked out is still working with it. The tree won't be released unless the **Tree Inactivity Period** specified on the People Tools Options page is expired.

This method should be called from PeopleCode in a response to any user action happened on a Tree Manager page.

This method can be used only on an open tree, not on a closed tree. This means you must have opened the tree with the Open method.

Parameters

None.

Returns

An integer: 0 if activity time was updated successfully.

Tree Class Properties

In this section, we discuss the Tree class properties. The properties are discussed in alphabetical order.

AllValues

Description

When the tree is audited, the AllValues property specifies whether the audit should verify that the tree includes all user data detail values. This property returns a Boolean value: True, check all values, False, do not check all values.

If this is a new tree, and you do not set this property, a default value of False is automatically set.

This property can be used only with an open tree, that is, you must use the Open method on the tree before you can use this property.

This property is read/write.

Example

```
&MyTree.AllValues = False;
```

AuditDetails

Description

Set this property to False in cases when you do not want to perform Detail Audit. It could happen if you are reusing existing structure that contains Detail information for tree that does not use details('Winter' tree).

The default value for this property is True.

This property is read/write.

Branches

Description

This property returns a reference to a branch collection object. This property is used only with branched trees: it returns Null for trees that aren't branched.

This property can be used only with an open tree, that is, you must use the open the tree using the Open method before you can use this property.

This property is read-only.

BranchImageName

Description

Use this property to specify the image used to display branches on a page. This property takes a string value.

This property is read/write.

BranchLevel

Description

This property returns the level number (as a number) where this branch occurs in the tree. This property is used only with trees with levels: it returns zero for trees that don't have levels.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

Example

```
&LevelNumber = &MyTree.BranchLevel;
```

BranchName

Description

This property returns the name of the specific branch for the tree, as a string. This property is used only with branched trees: it returns an empty string for trees that aren't branched.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

Example

```
&BranchName = &MyTree.BranchName;
```

Category

Description

This property returns the category name for the tree, as a string. The category is a high-level grouping under which you can organize your tree structures and tree definitions. If you are creating a new tree, this property is required.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Example

```
&MyTree.Category = "PurchaseOrders";
```

Description

Description

This property returns the description of the tree, as a string. If you are creating a new tree, this property is required.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Example

```
&MyTree.Description = "Departmental Security";
```

DuplicateLeaves

Description

In most trees, you want each detail value to appear only once in the tree. To permit duplicate values, set this property to True.

If this is a new tree, and you do not set this property, a default value of False is automatically set.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

EffDt

Description

This property returns the effective date of the tree, as a date.

Note: PeopleSoft does not recommend using this property to change data, as changes are not stored in the database.

If this is a new tree, and you do not set this property, a default value of the current date is automatically set.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Example

```
&TreeEffDt = &MYTREE.EffDt;
```

HasDetailRanges

Description

This property returns True if the tree has any detail ranges.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

HasLockedBranches

Description

This property indicates whether any user other than current one has checked out any branch in a tree. This property returns a Boolean value: true if the tree has checked out branches, false otherwise.

Note: In order to use this method, you must have Tree multi-user environment enabled. You can check if it is enabled by using UseUpdateReservation Tree property.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

IsBranched

Description

This property indicates whether the tree is branched. Possible values for this property are True and False: True if the tree is branched, False if it isn't.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

Example

```
If &MyTree.IsBranched Then  
    /* Do branched processing */
```

```

Else
    /*Do unbranched processing */
End-If;

```

IsChanged

Description

This property returns True if the tree has been changed but not saved, False if the tree is unchanged.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

Example

```

If &MyTree.IsChanged Then
    &MyTree.Save();
End-if;
&MyTree.Close();

```

IsOpen

Description

This property returns True if the tree is open, False if the tree is closed.

This property is read-only.

Example

```

If Not &MyTree.IsOpen Then
    &MyTree.Open("", "", "PERSONAL_DATA", &Date, "", True);
End-If;

```

IsQueryTree

Description

This property returns True if the tree is a Query access tree. It returns False if the tree is not a Query Access Tree.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

IsValid

Description

This property returns True if the tree is a valid tree that has passed all audits. It returns False otherwise.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

Related Links

"Understanding the Auditing and Repairing of Trees" (Tree Manager)

IsVersionChanged

Description

This property indicates if a tree version has been changed in the database. This property returns a Boolean value, true if the version was changed, false otherwise.

Use this function in a multi-user environment to check if a tree loaded in a read-only mode by User1 should be reloaded. A possible reason why it needs to be reloaded could be triggered by tree version change after User2, who had this tree checked out, released it.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

IsWholeTree

Description

This property indicates whether the entire tree is accessible. This property is set to True if a tree was opened using OpenWholeTree method. The OpenWholeTree method opens a tree in read-only mode without paying attention to the existing tree branches.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

Example

```
If &MyTree.IsWholeTree Then
    /* Do processing */
Else
    /* close tree and reopen using OpenWholeTree method */
End-If;
```

KeyBranchName

Description

This property returns the branch name of the tree as a string if the tree is branched. If not branched, this property returns a blank string.

This property can be used with a closed tree, that is, before you use the Open method.

If the tree has already been opened, you can use the KeyBranchName property to get the tree branch name

This property is read-only.

KeyEffDt

Description

This property returns the effective date of the tree as a string if the tree is effective-dated. If not effective-dated, this property returns a blank string.

This property can be used with a closed tree, that is, before you use the Open method.

If the tree has already been opened, you can use the KeyEffDt property to get the tree effective date

This property is read-only.

KeyName

Description

This property returns the name of the tree as a string.

This property can be used with a closed tree, that is, before you use the Open method.

If the tree has already been opened, you can use the Name property to get the tree name.

This property is read-only.

KeySetId

Description

This property returns the SetID of the tree as a string if the tree has a SetID. If the tree doesn't have a SetID, this property returns a blank string.

This property can be used with a closed tree, that is, before you use the Open method.

If the tree has already been opened, you can use the KeySetId to get the tree Set Id.

This property is read-only.

KeyUserKeyValue

Description

This property returns the UserKeyValue of the tree as a string if the tree has a UserKeyValue. If the tree doesn't have a UserKeyValue, this property returns a blank string.

This property can be used with a closed tree, that is, before you use the Open method.

If the tree has already been opened, you can use the KeyUserKeyValue to get the tree UserKeyValue.

This property is read-only.

LeafCount

Description

This property returns the number of leaves in the tree.

This property can be used only with an open tree, that is, you must use the Open method on the tree before you can use this property.

This property is read-only.

LeafImageName

Description

Use this property to specify the image used to display leaves on a page. This property takes a string name.

This property is read/write.

LeafOnClipboard

Description

Use this property to determine if a leaf has been cut and is available to be 'pasted' into tree. This property returns a Boolean value: True if a leaf object exists on the clipboard, False otherwise.

This property is read-only.

LevelCount

Description

This property returns the number of levels defined for the tree. If the tree doesn't have any levels, this property returns zero (0).

See the LevelUse property.

Valid value range is a number between 0 and 99.

This property can only be used with an open tree, that is, you must use the Open method on the tree before you can use this property.

This property is read-only.

Related Links

[LevelUse](#)

Levels

Description

This property returns a reference to a level collection object. This property is used only with trees that have levels: it returns Null for trees that don't have levels.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

Related Links

[Level Collection Methods](#)

LevelUse

Description

This property returns the level use of the tree. The values are:

<i>Value</i>	<i>Description</i>
"S"	Strict levels
"L"	Loose levels
"N"	No levels

If this is a new tree, and you do not set this property, the default value is Strict Levels.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Example

```
If &MyTree.LevelUse = "S" Then
/* add levels */
End-If;
```

LockOwner

Description

This property returns the user ID of the user who has checked out a specific tree or a tree branch, as a string.

Note: In order to use this method, you must have Tree multi-user environment enabled. You can check if it is enabled by using UseUpdateReservation Tree property.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

LockStatus

Description

This property indicates if an opened tree is checked out.

Note: In order to use this method, you must have Tree multi-user environment enabled. You can check if it is enabled by using UseUpdateReservation Tree property.

Possible values are:

<i>Value</i>	<i>Description</i>
0	Tree is not checked out by any user.
1	Tree is checked out by another user.
2	Tree is checked out by the current user and is editable.

This property is read-only.

Related Links

[LockTree](#)

[TreeLocksNumber](#)

[UnlockTree](#)

[LockOwner](#)

Name

Description

This property returns the name of the tree, as a string.

Note: Do not use this property to change the name of an existing tree. The change will not be reflected in the database. You must use the `Rename` method to change the name of an existing tree.

This property can be used only with an open tree, that is, you must open the tree using the `Open` method before you can use this property.

This property is read/write.

Example

```
&TreeName = &MyTree.Name;
```

Related Links

[Rename](#)

NodeCollImageName

Description

Use this property to specify the image displayed for a collapsed node. This property takes a string value.

This property is read/write.

NodeCount

Description

This property returns the number of nodes for the tree. A valid tree must have at least one node.

This property can be used only with an open tree, that is, you must open the tree using the `Open` method before you can use this property.

This property is read-only.

NodeExplImageName

Description

Use this property to specify the displayed image of an expanded node. This property takes a string value.

This property is read/write.

NodeOnClipboard

Description

Use this property to determine if a node has been cut and is available to be 'pasted' into a tree. This property returns a Boolean value: True if a node object exists on the clipboard, False otherwise.

This property is read-only.

ParentLevel

Description

This property returns the number of the parent branch level in a branched tree. If the tree does not have levels or is an unbranched tree, zero (0) is returned. Valid value range is a number between 0 and 100.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

ParentName

Description

This property returns the name of the parent branch in a branched tree, as a string. If the tree does not have levels, is an unbranched tree, or if the tree is the root level, Null is returned.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

PerformanceMethod

Description

This property sets the method to use for select and join statements used to generate SQL with the tree. This property is used with nVision layouts and Query.

The values for this property are:

<i>Value</i>	<i>Description</i>
"L"	Suppress Join: Use Literal Values.
"S"	Sub-SELECT Tree Selector.

Value	Description
"J"	Join to Tree Selector.
"D"	User Application Defaults.

If this is a new tree, and you do not set this property, the default value "D" is automatically set.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Related Links

"Understanding Types of Trees" (Tree Manager)

"PS/nVision Overview" (PS/nVision)

PerformanceSelector

Description

This property selects the tree selectors for nVision for the tree. This property is used with nVision layouts and Query.

The values for this property are:

Value	Description
"D"	Dynamic Selectors
"S"	Static Selectors

If this is a new tree, and you do not set this property, the default value "S" is automatically set.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Related Links

"PS/nVision Overview" (PS/nVision)

PerformanceSelectorOption

Description

This property selects the tree selector options for nVision for the tree. This property is used with nVision layouts and Query.

The values for this property are:

<i>Value</i>	<i>Description</i>
"S"	Single values
"R"	Ranges of values (>=...<=).
"B"	Range of values (BETWEEN).

If this is a new tree, and you do not set this property, the default value "R" is automatically set.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Related Links

"PS/nVision Overview" (PS/nVision)

SetID

Description

This property returns the SetID for the tree, as a string. This property is used only when the IndirectionMethod property for the tree structure the tree is based on has been set to "S". Otherwise, this property returns Null.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Note: PeopleSoft does not recommend setting the SetID for a tree, as there is no way to save this value to the database.

Related Links

[IndirectionMethod](#)

Status

Description

This property returns the effective status of the tree. The values are:

<i>Value</i>	<i>Description</i>
"A"	Active
"I"	Inactive

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Structure

Description

This property returns a reference to the tree structure of the tree. Before you can use some of the methods or any of the properties of a tree structure, you must use the Open method to open the tree structure.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read-only.

StructureName

Description

This property returns the name (*structure ID*) of the tree structure the tree is based on, as a string. This property can be set only with a new tree.

Note: Even though this is a writable property, you will receive an error if you try to change the tree structure for an existing tree.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

Related Links

[SetID](#)

TreeImageName

Description

Use this property to specify the displayed image for a tree. This property takes a string value.

This property is read/write.

UserKeyValue

Description

Use this property to read the key field value for the Node User Key Field specified from the NodeRecord on the associated tree structure.

This property is used only when the IndirectionMethod property for the tree structure has been set to "U" or "B". Otherwise, this property returns Null.

This property is read/write.

Note: PeopleSoft does not recommend setting the UserKeyValue for a tree, as there is no way to save this value to the database.

Related Links

[NodeRecord](#)

[IndirectionMethod](#)

UseUpdateReservation

Description

This property indicates if multi-user environment features are used. This property returns a Boolean value, true if multi-user environments features are used, false otherwise.

This property can be used with either an open or a closed tree.

This property is read-only.

Tree Structure Class

Tree structure objects are instantiated from the following:

- From a session object with the GetTreeStructure method.
- From a tree object with the Structure property.

See [GetTreeStructure](#), [Structure](#).

Tree Structure Class Methods

In this section, we discuss the Tree Structure class methods. The methods are discussed in alphabetical order.

Close

Syntax

```
Close ()
```

Description

The Close method closes the tree structure object executing the method, freeing the memory associated with that object, and discarding any changes made to the tree structure. The Close method can be used only on an open tree structure, not on a closed tree structure. This means you must have opened the tree structure with the Open method before you can save it. To save any changes, you must use the Save method before using Close.

Returns

A number; 0 if the method completed successfully.

Copy

Syntax

```
Copy (FromStructId, ToStructId)
```

Description

The Copy method copies the tree structure specified with *FromStructId* to the tree structure specified with *ToStructId*. Both parameters take string values. The tree structure specified by *ToStructId* must be a *new* tree structure. You receive an error if the tree structure already exists.

The Copy method can only be used with a closed tree structure, it cannot be used on an open tree structure. Before you use the Copy method, you must explicitly close any open tree structure objects (with the Close method.) You receive an error if there are any open tree structures.

To access the new tree structure, you must use the Open method.

Returns

A number; 0 if the method completed successfully.

Example

```
&MyTreeStruct = &MySession.GetTreeStructure ();  
&RetVal = &MyTreeStruct.Copy (PERSONAL_DATA, PERSONAL_DATA2);
```

Create

Syntax

`Create` (*StructId*, *Type*)

Description

The Create method creates a tree structure with the name *StructId*, and of the type *Type*. Both parameters take a string value.

Note: If the tree structure already exists, it is overwritten with the newly created tree structure.

The Create method can be used only with a closed tree structure, it cannot be used on an open tree structure. Before you use the Create method, you must explicitly close any open tree structure objects (with the Close method.) You receive an error if there are any open tree structures.

The new tree structure must be saved (using the Save method) for this structure to be saved to the database.

After you create a new tree structure, you can open it with the Open method.

The values for *Type* are:

- "D": create a detail tree structure.
- "S": create a summary tree structure.

Currently, only the value of "D" is supported for the *Type* parameter. You can specify an empty string for *Type*. If you need to create a summary structure follow the example below:

```
&MYSTRUCT=&SESSION.GETSTRUCTURE();
IF ALL( &MYSTRUCT) THEN
  &RETVALUE=&MYSTRUCT.CREATE('DEPARTMENT_SUM', ' ');
  IF NONE(&RETVALUE) THEN
    &MYSTRUCT.TYPE = 'S';
  END-IF;
  &RETVALUE=&MYSTRUCT.SAVE();
  &RETVALUE=&MYSTRUCT.CLOSE();
END-IF;
```

Delete

Syntax

`Delete` (*StructId*)

Description

The Delete method deletes the tree structure specified by *StructId* from the database. The Delete method can be used only with a tree structure identifier, it cannot be used on a fully instantiated, open tree structure. Before you use the Delete method, you must explicitly close any open tree structure objects (with the Close method.) You receive an error if there are any open tree structures.

The tree structure specified by *StructId* does not have to match the tree structure identifier executing the method.

Returns

A number: 0 if the method completed successfully.

Open

Syntax

```
Open (StructId, Update)
```

Description

The Open method opens the tree structure specified by *StructId*. *StructId* takes a string value. You cannot read or set any properties of a tree structure until after you open it.

When you open a tree structure, you can specify whether you want to open it for update, or in read-only mode, with the *Update* parameter. *Update* takes a Boolean value. Values for *Update* are:

- "True": open tree structure in update mode (read/write).
- "False": open tree structure in read-only mode.

If you try updating or writing to a tree structure opened in read-only mode, your changes are ignored.

Returns

A number: 0 if the method completes successfully.

Example

```
&MyTreeStruct = &MySession.GetTreeStructure();  
&RetVal = &MyTreeStruct.Open("ACCESS_GROUP", True);
```

Rename

Syntax

```
Rename (FromStructId, ToStructId)
```

Description

The Rename method renames the tree structure specified with *FromStructId* to the new name specified by *ToStructId*. Both parameters take a string value. The tree structure specified by *ToStructId* must be a *new* tree structure. You receive an error if the tree structure already exists. The change is automatically reflected in the database.

The Rename method can only be used with a closed tree structure, it cannot be used on an open tree structure. Before you use the Rename method, you must explicitly close any open tree structure objects (with the Close method.) You receive an error if there are any open tree structures.

Returns

A number: 0 if the method completes successfully.

Save

Syntax

```
Save ()
```

Description

The Save method writes any changes to the tree structure executing the method to the database.

The Save method can be used only on an open tree structure, not on a closed tree structure. This means you must have opened the tree structure with the Open method before you can save it.

The tree structure object remains open after executing Save. You must execute the Close method on the object before it is closed and the memory freed.

Note: If you're calling the Tree API from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a Commit.

Returns

A number: 0 if the method completes successfully.

Tree Structure Class Properties

In this section, we discuss the Tree Structure class properties. The properties are discussed in alphabetical order.

Description

Description

This property returns the description for the tree structure, as a string. The description is the text that displays in list boxes or reports.

This property can be used only with an open tree structure, that is, you must use the Open method on the tree structure before you can use this property.

This property is read/write.

Example

```
&MYTREESTRUCT.Description = "Department Security Chart";
```

DetailComponent

Description

This property returns the name of the detail component for the tree structure as a string.

This property can be used only with an open tree structure, that is, you must use the Open method on the tree structure before you can use this property.

This property is read/write.

DetailField

Description

This property returns the name of the detail field for the tree structure, as a string. This property is valid only if you define a detail tree structure. If you create a node-oriented tree structure, this property is not required. This field must exist on the specified DetailRecord.

This property can be used only with an open tree structure, that is, you must use the Open method on the tree structure before you can use this property.

This property is read/write.

Example

The following example sets the DetailPage, DetailRecord, and DetailField properties for a tree structure. Note that the names of the page, record, and field are all capitalized: this is required for all PeopleSoft page, record, and field names.

```
&MYTREESTRUCT.DetailPage = "BUS_UNIT_TREE_INV";  
&MYTREESTRUCT.DetailRecord = "BUS_UNIT_TBL_IN";  
&MYTREESTRUCT.DetailField = "BUSINESS_UNIT";
```

Related Links

[DetailRecord](#)

DetailMenu

Description

This property returns the name of the detail menu for the tree structure, as a string. If the page you use for detail values (DetailPage property) is part of a component, and you want to have access to the other pages in that group when you edit a node value, enter the name of the menu and menu bar for the component in the DetailMenu and DetailMenuBar properties.

This property is valid only if you define a detail tree structure. If you create a node-oriented tree structure, this property isn't required.

This property can be used only with an open tree structure, that is, you must use the Open method on the tree structure before you can use this property.

This property is read/write.

DetailMenuBar

Description

This property returns the name of the detail menu bar for the tree structure, as a string. If the page you use for detail values (DetailPage property) is part of a component, and you want to have access to the other pages in that group when you edit a node value, enter the name of the menu and menu bar for the component in the DetailMenu and DetailMenuBar properties.

This property is valid only if you're define a detail tree structure. If you create a node-oriented tree structure, this property isn't required.

This property can be used only with an open tree structure, that is, you must use the Open method on the tree structure before you can use this property.

This property is read/write.

DetailMenuItem

Description

This property returns the name of the detail menu item for the tree structure as a string.

This property can be used only with an open tree, that is, you must open the tree using the Open method before you can use this property.

This property is read/write.

DetailMultiNavigate

Description

This property sets or returns a Boolean value indicating whether the detail multi-navigation tree structure navigation option has been selected or not: True, the Detail Multi-Navigation check box has been selected, False otherwise.

This property is read/write.

Related Links

[NodeMultiNavigate](#)

"Using Multinavigation Paths" (Tree Manager)

DetailPage

Description

This property returns the name of the detail page for the tree structure as a string. If the page you use for detail values (DetailPage property) is part of a component, and you want to have access to the other pages in that group when you edit a node value, enter the name of the menu and menu bar for the component in the DetailMenu and DetailMenuBar properties.

This property is valid only if you're defining a detail tree structure. If you're creating a node-oriented tree structure, this property isn't required.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

Example

The following example sets the DetailPage, DetailRecord, and DetailField properties for a tree structure. Note that the names of the page, record, and field are all capitalized: this is required for all PeopleSoft page, record, and field names.

```
&MYTREESTRUCT.DetailPage = "BUS_UNIT_TREE_INV";  
&MYTREESTRUCT.DetailRecord = "BUS_UNIT_TBL_IN";  
&MYTREESTRUCT.DetailField = "BUSINESS_UNIT";
```

DetailRecord

Description

This property returns the name of the detail record for the tree structure as a string. This property is valid only if you define a detail tree structure. If you create a node-oriented tree structure, this property isn't required.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

Example

The following example sets the DetailPage, DetailRecord, and DetailField properties for a tree structure. Note that the names of the page, record, and field are all capitalized: this is required for all PeopleSoft page, record, and field names.

```
&MYTREESTRUCT.DetailPage = "BUS_UNIT_TREE_INV";  
&MYTREESTRUCT.DetailRecord = "BUS_UNIT_TBL_IN";  
&MYTREESTRUCT.DetailField = "BUSINESS_UNIT";
```

IndirectionMethod

Description

The following screen image is an example of Structure tab for Tree Structure setup. When you set up a tree structure, you can set the indirection at the bottom of the Structure tab, with the radio buttons in the Additional Key Field.

The screenshot shows a software interface with four tabs: Structure, Levels, Nodes, and Details. The 'Structure' tab is active. Below the tabs, there are three labeled fields: '*Structure ID:' with the value 'BU_PROJ_DATA', '*Description:' with a text input containing 'Test Tree Keyed by BU', and '*Type:' with a dropdown menu showing 'Detail'. Below these fields is a section titled 'Additional Key Field' containing four radio button options: 'SetId Indirection', 'Business Unit' (which is selected), 'User Defined', and 'None'.

In the Tree Classes API, you set these same values with the `IndirectionMethod` property. The values are:

- "S": SetID Indirection.
- "B": Business Unit.
- "U": User Defined Node Key.
- "N": None.

Both the *User Defined Node Key* and the *Business Unit* are the key field set with the `NodeRecord` property for this tree structure. If *Business Unit* is set, the key field set with the `NodeRecord` property is a business unit.

If you are creating a new tree structure, and you do not explicitly set this property, None ("N") is the default value, and is automatically set.

This property can be used only with an open tree structure, that is, you must open the tree structure with the `Open` method before you can use this property.

This property is read/write.

[IndirectionMethod](#)

[NodeRecord](#)

KeyName

Description

This property returns the name of the tree structure as a string.

This property can be used with a closed tree structure.

This property is read-only.

LevelComponent

Description

This property returns the name of the level component for the tree structure as a string.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

LevelMenu

Description

This property returns the name of the level menu for the tree structure as a string. If the page you use for level values (LevelPage property) is part of a component, and you want to have access to the other pages in that group when you edit a node value, enter the name of the menu and menu bar for the component in the LevelMenu and LevelMenuBar properties.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

LevelMenuBar

Description

This property returns the name of the level menu bar for the tree structure as a string. If the page you use for level values (LevelPage property) is part of a component, and you want to have access to the other pages in that group when you edit a node value, enter the name of the menu and menu bar for the component in the LevelMenu and LevelMenuBar properties.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

LevelMenuItem

Description

This property returns the name of the level menu item for the tree structure as a string.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

LevelPage

Description

This property returns the name of the level page for the tree structure object as a string. If you create a new tree structure, and you do not explicitly set this property, TREE_LEVEL is the default value, and is automatically set.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

LevelRecord

Description

This property returns the name of the level record for the tree structure object as a string. If you create a new tree structure, and you do not explicitly set this property, TREE_LEVEL_TBL is the default value, and is automatically set.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

Name

Description

This property returns the name of the tree structure as a string. This is also called the *structure ID*. Use this property to set the name (structure ID) of a tree structure. This property is required if you are creating a new tree structure.

Note: Do not use this property to change the name of an existing tree structure. The change will not be reflected in the database. You must use the Rename method to change the name of an existing tree structure.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

Example

```
&Name = &MYTREESTRUCT.Name;
```

[Rename](#)

NodeComponent

Description

This property returns the name of the node component for the tree structure as a string.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

NodeField

Description

This returns the name of the field used for storing information about nodes for the tree structure as a string. If you create a new tree structure, and you do not explicitly set this property, TREE_NODE is the default value, and is automatically set. This field must exist on the specified NodeRecord.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

Example

```
&MYTREESTRUCT.NodeField = "DEPT_ID";
```

NodeMenu

Description

This property returns the name of the node menu for the tree structure as a string. If the page you use for node values (NodePage property) is part of a component, and you want to have access to the other pages in that group when you edit a node value, enter the name of the menu and menu bar for the component in the NodeMenu and NodeMenuBar properties.

If you create a new tree structure, and you do not explicitly set this property, TREE_MANAGER is the default value, and is automatically set.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

NodeMenuBar

Description

This property returns the name of the node menu bar for the tree structure as a string. If the page you use for node values (NodePage property) is part of a component, and you want to have access to the other pages in that group when you edit a node value, enter the name of the menu and menu bar for the component in the NodeMenu and NodeMenuBar properties.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

NodeMenuItem

Description

This property returns the name of the node menu item for the tree structure as a string.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

NodeMultiNavigate

Description

This property sets or returns a Boolean value indicating whether the node multi-navigation tree structure navigation option has been selected: True, the Node Multi-Navigation check box has been selected, False otherwise.

This property is read/write.

[DetailMultiNavigate](#)

"Using Multinavigation Paths" (Tree Manager)

NodePage

Description

This returns the name of the page used for storing information about nodes for the tree structure as a string. If you create a new tree structure, and you do not explicitly set this property, TREE_NODE is the default value, and is automatically set.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

NodeRecord

Description

This returns the name of the record used for storing information about nodes for the tree structure as a string. If you create a new tree structure, and you do not explicitly set this property, TREE_NODE_TBL is the default value, and is automatically set.

If the IndirectionMethod property of this tree structure has been set to "U" or "B", use this property to specify the record that the NodeUserKeyField property will use.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

Related Links

[IndirectionMethod](#)

NodeUserKeyField

Description

Use this property to set the key field from the record specified with NodeRecord for use with the IndirectionMethod. This property is identical to the UserKeyValue property for a tree.

This property is used only when the IndirectionMethod property for the tree structure has been set to "U" or "B". Otherwise, this property returns Null.

This property can be used only with an open tree structure, that is, you must open the tree structure with the `Open` method before you can use this property.

This property is read/write.

[IndirectionMethod](#)

[UserKeyValue](#)

SummarySetId

Description

This property returns the SetID for the detail tree whose detail values the summary tree structure as a string summarizes. This property is valid only for Summary tree structures. Otherwise, this property returns Null.

This property can be used only with an open tree structure, that is, you must open the tree structure with the `Open` method before you can use this property.

This property is read/write.

SummaryLevelNumber

Description

This property returns the level number for the detail tree whose detail values the summary tree structure summarizes. The level number indicates the level in the detail tree whose nodes the summary tree will use as detail values. The top level in the detail tree is 1, the next is level two, and so on. Valid values are numbers between 1 and 99.

This property is only valid for Summary tree structures. Otherwise, this property returns Null.

This property can be used only with an open tree structure, that is, you must open the tree structure with the `Open` method before you can use this property.

This property is read/write.

SummaryTreeName

Description

This property returns the name of the detail tree whose detail values the summary tree structure summarizes, as a string. This property is valid only for Summary tree structures. Otherwise, this property returns Null.

This property can be used only with an open tree structure, that is, you must open the tree structure with the `Open` method before you can use this property.

This property is read/write.

SummaryUserKeyValue

Description

This property returns the name of the tree that the node records the tree structure is summarized to, as a string. This property is valid only for Summary tree structures. This property is used only when the IndirectionMethod property for the tree structure has been set to "U" for *User Defined Keys* or "B" for *Business Unit*. Otherwise, this property returns Null.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

Related Links

[IndirectionMethod](#)

Type

Description

This property returns the type of the tree structure as a string, whether it is a detail or summary tree structure. The values are:

- "D": detail tree structure.
- "S": summary tree structure.

This property can be used only with an open tree structure, that is, you must open the tree structure with the Open method before you can use this property.

This property is read/write.

Traverse Tree Hierarchy Example

The following is an example to transverse a tree hierarchy and write the information to a file.

```
Local ApiObject &TreeObj, &RootNodeObj;
Local number &Res;
Local string &sSetId, &sSetCntrlValue, &sTreeName, &sBranchName;
Local File &MyFile;

Function ProcessNodeChildren(&ParentNodeObj As ApiObject)

    Local ApiObject &ChildNodeObj, &ChildLeafObj;
    Local boolean &First;

    If &ParentNodeObj.HasChildren Then

        &ChildLeafObj = &ParentNodeObj.FirstChildLeaf;
        While All(&ChildLeafObj)
            &MyFile.WriteLine("Process Leaf Range From : " | &ChildLeafObj.RangeFrom);=>
```

```

        &ChildLeafObj = &ChildLeafObj.NextSib;
    End-While;

    If &ParentNodeObj.HasChildNodes Then
        &First = True;
        &ChildNodeObj = &ParentNodeObj.FirstChildNode;
        While &First Or
            &ChildNodeObj.HasNextSib

            If &First Then
                &First = False;
            Else
                &ChildNodeObj = &ChildNodeObj.NextSib;
            End-If;
            &MyFile.WriteLine("Process Node : " | &ChildNodeObj.Name);
            ProcessNodeChildren(&ChildNodeObj);

        End-While;
    End-If;
End-Function;

&TreeObj = %Session.GetTree();

If None(&TreeObj) then
    Error("Cannot get a tree");
End-if;

&sSetId = "";
&sSetCntrlValue = "";
&sTreeName = "QE_JOB_CODES";
&TreeEffDt = Date("1999-01-01");
&sBranchName = "";

&Res = &TreeObj.OPEN(&sSetId, &sSetCntrlValue, &sTreeName, &TreeEffDt, &sBranchName=>
, False);
If All(&Res) Then
    Error("Cannot open a tree");
End-If;

&MyFile = GetFile("TreeDump.txt", "A", "UTF8");
&RootNodeObj = &TreeObj.FindRoot();

&MyFile.WriteLine("Process Root Node : " | &RootNodeObj.Name);

ProcessNodeChildren(&RootNodeObj);
&MyFile.Close();

```

Universal Queue Classes

Understanding Universal Queue Classes

The universal queue classes provide the means by which applications can inspect objects that are processed by the queue server, such as tasks, agents, and queues. The classes also enable tasks to reenter the queue with their original task ID, as well as keep task times based on its original entry into the system.

All of the classes, and most of the properties and methods that make up the universal queue classes have a GUI representation in the PeopleSoft Multi-Channel Framework. This document assumes that the reader is familiar with PeopleSoft Multi-Channel Framework.

Related Links

"PeopleSoft MultiChannel Framework" (MultiChannel Framework)

Scope of the Universal Queue Classes

The universal queue classes can be instantiated only from PeopleCode.

The universal queue classes can be called from a component, an internet script, or an Application Engine program.

Universal queue classes can be of Local, Global, or Component scope.

Data Types of the Universal Queue Classes

Every universal queue class is its own data type, that is, Agent objects are declared as data type Agent, LogicalQueue objects are declared as type LogicalQueue, and so on.

The following are the data types of the universal queue classes:

- Agent
- AgentPhysQueueProps
- AgentPhysQueueTasks
- Broadcast
- LogicalQueue
- MCFFactory

- PhysicalQueue
- Task
- TaskList
- Util

How to Import Universal Queue Classes

The universal queue classes are *not* built-in classes, like rowset, field, record, and so on. They are application classes. You must import the universal queue application package before you can use the classes in your PeopleCode program.

An import statement names either all the classes in a package or one particular application class. For importing the universal queue classes, PeopleSoft recommends that you import all the classes in the application package.

The application package PT_MCF_UQAPI contains the following sub-packages:

- Agent
- AgentPhysQueueProps
- AgentPhysQueueTasks
- Broadcast
- LogicalQueue
- MCFFactory
- PhysicalQueue
- Task
- TaskList
- Util

The import statements you should use are as follows:

```
import PT_MCF_UQAPI:Agent:*;  
import PT_MCF_UQAPI:AgentPhysQueueProps:*;  
import PT_MCF_UQAPI:AgentPhysQueueTasks:*;  
import PT_MCF_UQAPI:Broadcast:*;  
import PT_MCF_UQAPI:LogicalQueue:*;  
import PT_MCF_UQAPI:MCFFactory:*;  
import PT_MCF_UQAPI:PhysicalQueue:*;  
import PT_MCF_UQAPI:Task:*;  
import PT_MCF_UQAPI:TaskList:*;  
import PT_MCF_UQAPI:Util:*;
```

Using the asterisks after the package name makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are *not* made available.

[Understanding Application Classes](#)

How to Create a Universal Queue Object

After you've imported the universal queue classes, you instantiate an object of one of those classes using the constructor for the class and the *Create* function.

The following example creates a new instance of the MCFFactory class, as the variable `&MyMCFFactory`, with local scope:

```
Local MCFFactory &myMCFFactory = Create MCFFactory ();
```

"NotifyQ" (PeopleCode Language Reference)

Universal Queue Classes Constructors

You must use the constructor for each class to instantiate an instance of that class. The following are the constructors for the universal queue Classes.

Agent

Syntax

```
Agent (AgentID)
```

Description

Use the Agent constructor to instantiate an Agent object.

All objects encapsulated by this object are created when the constructor is called.

Note: When an MCFFactory object is created, Agent objects are automatically created. In this case, the number of tasks in the list is limited by the *MAX_TASKLIST_ITEMS* parameter used when creating the MCFFactory object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>AgentID</i>	Specify a valid AgentID as a string.

Returns

An Agent object.

Example

```
Create Agent (&AgentID);
```

Related Links

[Agent Class](#)

AgentPhysQueueProps

Syntax

```
AgentPhysQueueProps (AgentID, PhysicalQueueID)
```

Description

Use the AgentPhysQueueProps constructor to instantiate an agent physical queue properties object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>AgentId</i>	Specify as valid AgentId as a string.
<i>PhysicalQueueId</i>	Specify a PhysicalQueueId as a string.

Returns

An agent physical queue properties object.

Related Links

[AgentPhysQueueProps Class](#)

AgentPhysQueueTasks

Syntax

```
AgentPhysQueueTasks(AgentID, PhysicalQueueID)
```

Description

Use the AgentPhysQueueTasks constructor to instantiate an agent physical queue task object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>AgentID</i>	Specify an agent ID as a string.
<i>PhysicalQueueID</i>	Specify a PhysicalQueueID as a string.

Returns

An agent physical queue task object.

Related Links

[AgentPhysQueueTasks Class](#)

Broadcast

Syntax

```
Broadcast( )
```

Description

Use the Broadcast constructor to instantiate a Broadcast object.

Parameters

None.

Returns

A Broadcast object.

Related Links

[Broadcast Class](#)

LogicalQueue

Syntax

`LogicalQueue (LogicalQueueID)`

Description

Use the LogicalQueue constructor to instantiate a LogicalQueue object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>LogicalQueueID</i>	Specify the ID of a logical queue as a string.

Returns

A LogicalQueue object.

Example

```
Local LogicalQueue &MyLogQueue = Create LogicalQueue (&LogicalQueueID);
```

Related Links

[LogicalQueue Class](#)

MCFFactory

Syntax

`MCFFactory ([MAX_TASKLIST_ITEMS])`

Description

Use the MCFFactory constructor to instantiate an MCFFactory object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>MAX_TASKLIST_ITEMS</i>	Specify the maximum number of tasks loaded on a TaskList.

Returns

An MCFFactory object.

Example

```
Local MCFFactory &myMCFFactory = Create MCFFactory(MAX_TASKLIST_ITEMS);
```

Related Links

[MCFFactory Class](#)

PhysicalQueue

Syntax

```
PhysicalQueue (PhysicalQueueID)
```

Description

Use the PhysicalQueue constructor to instantiate a PhysicalQueue object. All objects encapsulated by this object are created when the constructor is called.

Note: When an MCFFactory object is created, the PhysicalQueue objects are automatically created. In this case, the number of tasks in the list is limited by the *MAX_TASKLIST_ITEMS* parameter used when creating the MCFFactory object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PhysicalQueueID</i>	Specify a physical queue ID as a string.

Returns

A PhysicalQueue object.

Example

```
Local PhysicalQueue &myPhysicalQueue = Create PhysicalQueue(&PhysicalQueueID);
```

[PhysicalQueue Class](#)

Task

Syntax

Task (*TaskNumber*)

Description

Use the Task constructor to instantiate a task object.

Only persistent tasks (email and generic tasks) are available for introspection. Each persistent task goes through a lifecycle that is recorded by the following statuses:

State	Indicated Action	Status of Task Object
Enqueued by the universal queue server	Enqueued	ENQ
Universal queue assigns to physical queue	Assigned	ASGN
Agent accepts task	Accepted	ACPT
Agent completes task	Done	DONE
Task is not accepted within the overflow (action) time period	Overflowed	OVFL
Agent does not complete task or task not assigned within the escalation (complete) time period	Escalated	ESCL
Indeterminate Task (task not found in system)	Indeterminate	IND

Parameters

Parameter	Description
<i>TaskNumber</i>	Specify a task number.

Returns

A task object if the task exists, or an error message if the task number is not in the expected format. If the task number is properly formatted, but the task is not found, the task object is returned with a task status of IND.

Example

```
Local string &tasknumber, &status;
Local Task &myTask = Create Task(&tasknumber);
&status = &myTask.Status;
```

Related Links

[Task Class](#)

TaskList

Syntax

```
TaskList(Status, TaskType, PhysicalQueueID, AgentID)
```

Description

Use the TaskList constructor to instantiate a task list.

If the queue is not provided, a list of tasks for all physical queues for that *TaskType* and *Status* is returned. To get all tasks on all queues do not specify any of the optional parameters.

Parameters

Parameter	Description
<i>Status</i>	Specify a task status, as an uppercase string. If you do not specify a valid status, an empty tasklist is returned. Valid values are:

Value	Description
ACPT	Accepted
ASGN	Assigned
ENQ	Enqueued
ESCL	Escalated
OVFL	Overflowed

Parameter	Description
<i>TaskType</i>	Specify a task type as a lowercase string. Valid values are:

Value	Description
chat	Chat tasks.
email	Email tasks.
generic	Generic type tasks.
voice	Voice type tasks.

Parameter	Description
<i>PhysicalQueueID</i>	Specify a physical queue ID as a string.
<i>AgentID</i>	Specify an agent ID as a string.

Returns

A task list object.

Example

```
Local string &sStatus;

/* get all enqueued task on the UQ server*/

&sStatus = "ENQ";
Local TaskList &myTaskList = Create TaskList (&sStatus, "", "", "");
```

[TaskList Class](#)

Util

Syntax

```
Util()
```

Description

Use the Util constructor to instantiate a util object.

Parameters

None.

Returns

A Util object.

Example

```
Create Util();  
Local &myUtil = create Util();
```

[Util Class](#)

Agent Class

Use the agent class to refresh or view the properties, such as the agent ID or buddy list associated with a particular agent.

Related Links

"Defining Agents" (MultiChannel Framework)

Agent Methods

In this section, we discuss the agent class methods. The methods are discussed in alphabetical order.

Delete

Syntax

```
Delete()
```

Description

Use the Delete method to delete an agent from the database. You cannot delete an agent that has still has open tasks.

Parameters

None.

Returns

A number. The values are:

Value	Description
0	Agent deleted successfully.
1	Invalid agent ID.
2	Agent has accepted task and cannot be deleted.
3	Other SQL error in executing deletion. Possibly there are errors in the child tables.

Example

```
import PT_MCF_UQAPI:*;

    &testAgent = create PT_MCF_UQAPI:Agent("QEMGR");

    /* Delete an UQ Agent definition */
    &retCode = &testAgent.Delete();
```

Refresh

Syntax

Refresh()

Description

Use the Refresh method to refresh the properties of the agent.

An agent on a queue is processing tasks as they are assigned to them. Use this method to see real-time statistics on how much load an agent has, or possibly before running any metrics.

If you're interested in how tasklists have changed, use the RefreshQTaskList method instead.

Parameters

None.

Returns

None.

Example

The following refreshes all the properties of the agent:

```
&MyAgent.Refresh();
```

Related Links

[RefreshQTaskList](#)

RefreshQTaskList

Syntax

```
RefreshQTaskList (PhysQ)
```

Description

Use the RefreshQTaskList method to refresh the task list properties for the specified physical queue.

You might use this method if you're interested in seeing the real-time statistics for a particular tasklist. If you are only interested in an agent's work, use the Refresh method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>PhysQ</i>	Specify a physical queue ID as a string.

Returns

None.

Example

The following refreshes all task lists on the first physical queue of the agent:

```
&MyAgent.RefreshQTaskList (&myAgent.PhysicalQueueID [1]);
```

Related Links

[Refresh](#)

Agent Properties

In this section, we discuss the agent class properties. The properties are discussed in alphabetical order.

AgentID

Description

This property returns the agent ID as a string.

This property is read-only.

AgentProps

Description

This property returns the agent properties associated with this agent as an array of AgentPhysQueueProps objects.

This property is read-only.

Example

The following example returns the workload for physical queue SALES of agent properties object:

```
Local number &i = 1;

While &i < &myAgent.TotalPhysicalQueues
  If &myAgent.AgentProps[&i].PhysicalQueueID = "SALES" Then
    &AgentWorkLoad = &myAgent.AgentProps[&i].WorkLoad
    break;
  End-If;
End-While;
```

Related Links

[AgentPhysQueueProps Class](#)

AgentTasks

Description

This property returns the agent tasks associated with this agent as an array of AgentPhysQueueTasks objects.

This property is read-only.

Example

The following example returns the task number for the second task on physical queue SALES in the accepted task list:

```
Local Number &i = 1;

While &i < &myAgent.TotalPhysicalQueues
  If &myAgent.AgentProps[&i].PhysicalQueueID = "SALES" then
    &Tasknumber = &myAgent.AgentsTasks [&i].AcceptedTaskList.Task[2].TaskNumber
    break;
```

```
End-If;  
End-While;
```

Related Links

[AgentPhysQueueTasks Class](#)

Buddy

Description

This property returns a list of buddies for this agent, as an array of string.

This property is read-only.

Example

The following example returns the total number of buddies on the list:

```
&BuddyTotal = &myAgent.Buddy.Len;
```

Language

Description

This property returns the list of languages associated with the agent as an array of string.

This property is read-only.

Example

The following code example returns the first language code in the list of languages associated with the agent:

```
&Language = &myAgent.Language[1];
```

Name

Description

This property returns the name of the agent as a string.

This property is read-only.

NickName

Description

This property returns the nick name of the agent as a string.

This property

PhysicalQueueID

Description

This property returns the physical queues to which this agent is assigned as an array of string.

This property is read-only.

Example

The following example returns the first physical queue of agent.

```
&PhysicalQueueID = &myAgent.PhysicalQueueID[1];
```

Related Links

[PhysicalQueue Class](#)

TotalPhysicalQueues

Description

This property returns the total number of physical queues to which this agent is assigned as a number.

This property is read-only.

Example

```
&TotalPhysicalQueues = &myAgent.TotalPhysicalQueues;
```

Related Links

AgentPhysQueueProps Properties

In this section, we discuss the agent physical queue properties class properties. The properties are discussed in alphabetical order.

AgentID

Description

This property returns the agent ID as a string.

This property is read-only.

PhysicalQueueID

Description

This property returns the physical queue ID as a string.

This property is read-only.

Example

The following code example returns the physical queue ID for the physical queue of agent.

```
&PhysicalQueueID = &myAgentPhysQueueProps.PhysicalQueueID;
```

Related Links

[PhysicalQueue Class](#)

SkillLevel

Description

This property returns the skill level as a number.

This property is read-only.

Example

The following code example returns the skill level on physical queue.

```
&SkillLevel = &myAgentPhysQueueProps.SkillLevel;
```

WorkLoad

Description

This property returns the maximum work load that can be assigned to the agent, as an integer.

This property is read-only.

AgentPhysQueueTasks Class

Use the AgentPhysQueueTasks class to refresh or view the tasks associated with the physical queue assigned to the agent.

AgentPhysQueueTasks Method

In this section, we discuss the agent physical queue tasks class method Refresh.

Refresh

Syntax

```
Refresh (TaskList)
```

Description

Use the Refresh method to refresh the specified task list.

Parameters

Parameter	Description
<i>TaskList</i>	Specify the task list you want refreshed. You must specify a task list for this parameter.

Returns

None.

Example

The following code example refreshes the accepted task list of the physical queue (&MyAgentPhysQueueTasks) for the agent.

```
&myAgentPhysQueueTasks.Refresh (&myAgentPhysQueueTasks.AcceptedTaskList);
```

AgentPhysQueueTasks Properties

In this section, we discuss the agent physical queue tasks class properties. The properties are discussed in alphabetical order.

AcceptedTaskList

Description

This property returns the accepted task list as a task list object.

This property is read-only.

Example

The following code example returns the task number of the first accepted task:

```
&TaskNumber = &myAgentPhysQueueTasks.AcceptedTaskList.Task[1].TaskNumber;
```

AssignedTaskList

Description

This property returns the assigned task list as a task list object.

This property is read-only.

AgentID

Description

This property returns the agent ID as a string.

This property is read-only.

PhysicalQueueID

Description

This property returns the physical queue ID as a string.

This property is read-only.

Example

The following code example returns the physical queue ID for the physical queue of agent.

```
&PhysicalQueueID = &myAgentPhysQueueTasks.PhysicalQueueID;
```

[PhysicalQueue Class](#)

Broadcast Class

The Broadcast class has a single method, Broadcast. Use the Broadcast method to broadcast a notification message. You can specify whether to send the message to agents, to a queue, or even system wide.

Broadcast Class Method

The following is the description of the Broadcast class method Broadcast.

Broadcast

Syntax

```
Broadcast(ClusterID, QueueID, ChannelID, AgentState, AgentPresence, Message, MessageSetNumber, MessageNumber, DefaultMessage, SecurityLevel, ImportanceLevel, SenderId, NameValueString)
```

Description

Use the Broadcast function to broadcast a notification message. You can specify whether to send the message to agents, to a queue, or even system wide.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>ClusterID</i>	Specify the name of the cluster that you want to broadcast the message to, such as, RENCLSTR_001, as a string.
<i>QueueID</i>	Specify the name of the physical or logical queue that you want to broadcast the message to, such as, SALES, as a string.
<i>ChannelID</i>	Specify the name of the channel, or task, for the broadcast, such as Email, Chat, Voice or Generic, as a string.
<i>AgentState</i>	Specify the state of the agents you want to broadcast the message to, such as Available, as a string.
<i>AgentPresence</i>	Specify the presence of the agents you want to broadcast the message to, such as Active, as a string.

Parameter	Description
<i>Message</i>	Specify the text of the message you want to broadcast, as a string.
<i>MessageSetNumber</i>	Specify the message set number of a message from the message catalog if you want to broadcast a message from the message catalog. You must also specify values for the <i>MessageNumber</i> and <i>DefaultMessageText</i> parameters if you want to broadcast this type of message. Specify the message set number as a number.
<i>MessageNumber</i>	Specify the message number of a message from the message catalog if you want to broadcast a message from the message catalog. You must also specify values for the <i>MessageSetNumber</i> and <i>DefaultMessageText</i> parameters if you want to broadcast this type of message. Specify the message number as a number.
<i>DefaultMessageText</i>	Specify the text to be used if the specified message catalog message isn't found. Use the <i>MessageSetNumber</i> and <i>MessageNumber</i> parameters to specify the catalog message. Specify the default message text as a string.
<i>SecurityLevel</i>	Specify the security level for the broadcast message, as a string.
<i>ImportanceLevel</i>	Specify the importance level of the broadcast message, as a string.
<i>SenderID</i>	Specify the ID of the sender of the broadcast message, as a string.
<i>NameValueString</i>	Specify a string containing name-value pairs specific to your application.

Returns

None.

Example

The following example would broadcast a message to a specific logical queue:

```
import PT_MCF UQAPI:Broadcast:*;
Local PT_MCF_UQAPI:Broadcast &BC;

&BC.Broadcast("", "SALES", "", "", "Best of Luck!", "", "", "Default Message", "PRI⇒
V1", "URGENT", "Admin", "EffDate, 2005-10-25:12:00:45");
```

"MCFBroadcast" (PeopleCode Language Reference)

LogicalQueue Class

A logical queue is an application level queue that receives work requests (tasks) relating to an application area, such as chat requests regarding sales information, and routes them to agents capable of handling the work. Use the LogicalQueue class to view the properties for a logical queue.

LogicalQueue Properties

In this section, we discuss the logical queue class properties. The properties are discussed in alphabetical order.

LogicalQueueID

Description

This property returns the logical queue ID as a string.

This property is read-only.

PhysicalQueueID

Description

This property returns all the physical queues associated with this logical queue as an array of PhysicalQueue objects.

This property is read-only.

Example

The following code example returns the physical queue ID for the fourth physical queue.

```
&PhysicalQueueID = &myLogicalQueue.PhysicalQueue[4].PhysicalQueueID;
```

MCFFactory Class

The MCFFactory class is the base class of the universal queue classes. Instantiating an object in this class automatically instantiates all the associated universal queue classes. The MCFFactory contains all the logical queues operating on the MCF universal queue. The logical queues are comprised of physical queues. Agents log onto these physical queues. Tasks are queued to physical queues, and later, assigned and accepted by agents. If agents aren't available on a physical queue to accept the tasks on that queue, the tasks are either escalated or put into overflow.

MCFFactory Property

In this section, we discuss the MCFFactory class property LogicalQueue.

LogicalQueue

Description

This property returns all the logical queues with which this MCFFactory object is associated, as an array of LogicalQueue objects.

This property is read-only.

Example

The following code example returns the physical queue ID for the first physical queue on the logical queue, as well as the total of overflowed tasks on the first physical queue on the logical queue.

```
Local number &TotalTasks;  
Local MCFFactory &myMCFFactory = Create MCFFactory ();  
&PhysicalQueueID = &myMCFFactory.LogicalQueue [1].PhysicalQueue [1].PhysicalQueueID;  
&TotalTasks = &myMCFFactory.LogicalQueue [1].PhysicalQueue [1].OverflowedTaskList.⇒  
Total;
```

PhysicalQueue Class

Logical queues can be partitioned into physical queues for scalability. Use the PhysicalQueue class to refresh and view the properties of a physical queue.

PhysicalQueue Methods

In this section, we discuss the physical queue class methods. The methods are discussed in alphabetical order.

Refresh

Syntax

```
Refresh ()
```

Description

Use the Refresh method to refresh all the objects in the physical queue.

Parameters

None.

Returns

None.

Example

```
&myPhysicalQueue.Refresh();
```

RefreshTaskList

Syntax

```
RefreshTaskList (TaskList)
```

Description

Use the RefreshTaskList method to refresh the specified task list.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TaskList</i>	Specify the task list you want refreshed. You must specify a task list for this parameter.

Returns

None.

Example

The following code example refreshes the accepted task list for the physical queue.

```
&myPhysicalQueue.RefreshTaskList (&myPhysicalQueue.AcceptedTaskList);
```

PhysicalQueue Properties

In this section, we discuss the physical queue class properties. The properties are discussed in alphabetical order.

AcceptedTaskList

Description

This property returns the accepted task list as a task list object.

This property is read-only.

Example

The following code example returns the task number of the first accepted task:

```
&TaskNumber = &myPhysicalQueue.AcceptedTaskList.Task[1].TaskNumber;
```

Related Links

[TaskList Class](#)

AssignedTaskList

Description

This property returns the assigned task list as a task list object.

This property is read-only.

Related Links

[TaskList Class](#)

Agent

Description

This property returns all the agents assigned to the physical queue as an array of agent objects.

This property is read-only.

Example

The following example returns the name of the third agent.

```
&AgentName = &MyPhysicalQueue.Agent[3].Name;
```

BrowserURL

Description

This property returns the URL of the browser as a string. The format is that of an absolute URL.

The URL for the REN server that serves this MCF cluster for external clients and for agent chat. The Browser URL may be different from the InternalURL, which should not have to go through any firewall, reverse proxy server or other outward-facing security barrier.

This property is read-only.

Related Links

[InternalURL](#)

EnqueuedTaskList

Description

This property returns the enqueued task list as a task list object.

This property is read-only.

Related Links

[TaskList Class](#)

EscalatedTaskList

Description

This property returns the escalated task list as a task list object.

This property is read-only.

Related Links

[TaskList Class](#)

InternalURL

Description

This property returns the internal URL as a string. The format is that of an absolute URL.

This property is read-only.

Related Links

[BrowserURL](#)

IsActive

Description

This property returns true if the physical queue is active, false otherwise.

This property is read-only.

Example

```
Local LogicalQueue &myLogicalQueue = Create LogicalQueue (&LogicalQueueID);
For &I = 1 to &myLogicalQueue.PhysicalQueue.Len
    &PhysicalQueueID = &myLogicalQueue.PhysicalQueue[&I].PhysicalQueueID;
    &myPhysicalQueue = Create PhysicalQueue (&PhysicalQueueID);

    If &myPhysicalQueue.IsActive Then
        /* do work */
    Else
        /* return error */
    End-If;
End-For;
```

LogicalQueueID

Description

This property returns the logical queue ID associated with the physical queue as a string.

This property is read-only.

Example

```
&LogicalQueueID = &myPhysicalQueue.LogicalQueueID;
```

OverflowedTaskList

Description

This property returns the overflowed task list as a task list object.

This property is read-only.

Related Links

[TaskList Class](#)

PhysicalQueueID

Description

This property returns the physical queue ID of this physical queue.

This property is read-only.

RENURLID

Description

This property returns the ID of the REN server for the MCFFactory as a string.

This property is read-only.

TotalAgents

Description

This property returns the total number of agents belonging to this physical queue as a number. They may or may not be logged to the queue at that time.

This property is read-only.

Task Class

Use the task class to manipulate tasks or to view the properties of a specific task.

Task Methods

In this section, we discuss the task class methods. The methods are discussed in alphabetical order.

Close

Syntax

```
close (Comment)
```

Description

Use the Close method to close the task. Only use this method with overflowed or escalated tasks.

Note: This method does *not* resubmit the task. Use the Enqueue method to resubmit the task, then use this method to close it.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Comments</i>	Specify any comments you want associated with this closed task. You can specify a null value ("") for this parameter.

Returns

None.

Related Links

[Enqueue](#)

Enqueue

Syntax

```
Enqueue(LogicalQueueID, AgentID, Timeout, ResponseTime, Cost, Priority, MinSkill)
```

Description

Use the Enqueue method to add a task to the logical queue that the task was first assigned to. Every task enters the universal queue by being assigned to a logical queue.

Considerations Specifying Time

If no value (zero) is provided for the time parameters (such as *Timeout* or *ResponseTime*) the Timeout or ResponseTime properties from the task are used, respectively. This may cause the time to never occur as it creates a moving deadline. To avoid such a problem the time can be calculated for each task prior to enqueue as shown below.

Note: This logic is not included in the task's enqueue function, so as to allow you the choice for how you want your application to handle this situation.

```
&Utilobj = create Util();
&CurrentTask = create Task(&Task_Number);
&TimeDelta = &Utilobj.GetTimeDiff(&currenttime, &CurrentTask.EscalationTime) / 60;
&AgentAcceptTime = &Utilobj.GetTimeDiff(&CurrentTask.EnqueueTime, &CurrentTask.Over⇒
FlowTime) / 60;
  If AddToDateTime(&currenttime, 0, 0, 0, 0, &AgentAcceptTime, 0) >= &CurrentTask⇒
.EscalationTime Then
  If &TimeDelta > 0 Then
    &AgentAcceptTime = &TimeDelta;
  Else
/* The current time already exceeds the Escalationn time*/
  End-If;
End-If;
```

Parameters

Parameter	Description
<i>LogicalQueueId</i>	Specify the logical queue that you want to add this task to, as a string. You can specify a null value ("") for this parameter. If no value is provided , the logicalQueueID that is a property of task is used.
<i>AgentID</i>	Specify the agent ID for this task, as a string. You can specify a null value ("") for this parameter. If you specify a null value, the task is given to any available agent. You might expect to use a null for this parameter generally, as most tasks are to be reassigned for random agent allocation. However, there may be cases where a particular agent (such as one who previously worked on this task) might be required to take this task. In this case an agentID is provided
<i>Timeout</i>	Specify the time out period for this task as a number of minutes. You can specify a zero for this parameter. If no value is provided, the Timeout property of the task is used. The acceptance timeout is the period of time that an agent has to accept an assigned task (click on the flashing icon on the MultiChannel console). If the task is not accepted within this time, the task is re-enqueued.
<i>ResponseTime</i>	Specify the response time for this task as a number of minutes. You can specify a zero for this parameter. If no value is provided, the ResponseTime property of the task is used. The response time refers to the when a task should be completed by in order to satisfy customer contracts (such as, a platinum customer who requires a response in one day for a email. If by the end of 24 hours the task is not completed, it is escalated or the response time is exceeded.)
<i>Cost</i>	Specify the cost of this task as a number. You can specify a zero for this parameter. This is the cost of the task as set by the application when the task was enqueued. If no cost is set at that time, then the default cost is used.
<i>Priority</i>	Specify the priority of the task as a number. One is the lowest possible priority. Higher numbers indicate high priorities. If no priority is set, the default priority for the task is used.
<i>MinSkill</i>	Specify the minimum skill level required to do this task, as a number. You can specify a zero for this parameter.

Returns

None.

Example

```
&CurrentTask = create Task(&Task_Number);  
&CurrentTask.Enqueue(&CurrentTask.PhysicalQueueID, "", &AgentAcceptTime, &TaskCompl=  
eteTime, &CurrentTask.Cost, &CurrentTask.Priority, &CurrentTask.SkillLevel);
```

Refresh

Syntax

```
Refresh()
```

Description

Use the Refresh method to refresh the task properties. If you only want to refresh the status, use the RefreshStatus method.

Parameters

None.

Returns

None.

Example

The following refreshes all the properties of the task:

```
&MyTask.Refresh();
```

Related Links

[RefreshStatus](#)

RefreshStatus

Syntax

```
RefreshStatus()
```

Description

Use the RefreshStatus method to refresh only the status of the task. If you want to refresh all the task properties, use the Refresh method.

Parameters

None.

Returns

None.

Example

The following refreshes the status of the task:

```
&MyTask.RefreshStatus();
```

Related Links

[Refresh](#)

Task Properties

In this section, we discuss the task class properties. The properties are discussed in alphabetical order.

AgentID

Description

This property returns the agent ID as a string.

This property is read-only.

ApplicationData

Description

This property returns a string in which data relevant to the task is passed. Typically, for a task, it contains the URL to show when an agent access this task, the subject, and so on. This data is not really useful to the end-user, but only for administrators and for test purposes.

This property is read-only.

Comments

Description

Use this property to either set or return the comments associated with this task, as a string.

This property is read/write.

EnqueueTime

Description

This property returns the date and time when the task was submitted to the universal queue as a `DateTime` value.

This property is read-only.

EscalationTime

Description

This property returns the date and time when the task will be removed from the queue and placed in the escalated pool as a `DateTime` value.

This property is read-only.

Language

Description

This property returns the language associated with the task as a string.

This property is read-only.

OriginalTime

Description

This property returns the date and time when the task was first submitted to the universal queue as a `DateTime` value. This value is maintained for a task through its various stages and cannot change.

This property is read-only.

OverFlowTime

Description

This property returns a `DateTime` value representing the date and time when the task has reached the stipulated time during which the universal queue server could not find an agent to accept the task.

This property is read-only.

PhysicalQueueID

Description

This property returns the physical queue associated with the task as a string.

This property is read-only.

TiedAgentID

Description

This property returns the agent ID of the agent this task is enqueued for as a string.

This property is read-only.

TaskList Class

Use the task list class to refresh or view a task list.

TaskList Method

This section discusses the task list method Refresh.

Refresh

Syntax

```
Refresh ()
```

Description

Use the Refresh method to refresh the task list properties.

Parameters

None.

Returns

None.

Example

The following refreshes all the properties of the task list:

```
&MyTaskList.Refresh();
```

TaskList Properties

This sections discusses all the properties for the task list class. The properties are discussed in alphabetical order.

AgentID

Description

This property returns the agent ID as a string.

This property is read-only.

PhysicalQueueID

Description

This property returns the physical queue associated with the task list as a string.

This property is read-only.

Task

Description

This property returns all of the tasks in the task list as an array of task objects.

This property is read-only.

Example

```
For &I = 1 to &MyTaskList.Total
    &MyTask = &MyTaskList[&I];
    /* do work on every task in list */
End-For;
```

TaskType

Description

This property returns the task type as a string. A tasklist only contains tasks of a single type. The following are the valid task types for a tasklist:

Value	Description
ACPT	Accepted
ASGN	Assigned
ENQ	Enqueued
ESCL	Escalated
OVFL	Overflowed

This property is read-only.

Total

Description

This property returns the total number of tasks in the list as a number.

This property is read-only.

Util Class

The Util class is used to perform certain useful tasks, such as calculating times (so a task will timeout).

Util Methods

This section discusses the Util class methods. The methods are discussed in alphabetical order.

GetLogicalQueue

Syntax

```
GetLogicalQueue (PhysicalQueueID)
```

Description

Use the `GetLogicalQueue` to get the logical queue ID for the specified physical queue.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>physicalQueueID</i>	Specify the physical queue ID that you want to find the logical queue for, as a string.

Returns

A string containing the logical queue ID.

Example

The following code example returns the logical queue ID for a given physical queue ID .

```
&LogicalQueueID = &testUtil.GetLogicalQueue(&PhysicalQueueID);
```

GetTimeDiff

Syntax

```
GetTimeDiff(DateTime1, DateTime2)
```

Description

Use the `GetTimeDiff` method to determine the difference between two `DateTime` values.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>DateTime1</i>	Specify the starting date and time as a <code>DateTime</code> value.
<i>DateTime2</i>	Specify the ending date and time as a <code>DateTime</code> value.

Returns

A number specifying the difference between the two `DateTime` values (in seconds.)

Example

In the following example, `&nPeriod` is 15 minutes.

```
&DTM1 = DateTimeValue("10/09/97 10:35:36");
&DTM2 = DateTimeValue("10/09/97 10:50:36");

Local number &nPeriod = &myUtil.GetTimeDiff(&DTM1, &DTM2) / 60;
```

MCFFactory Example

The following is an example of creating an MCFFactory, then traversing the branches to reach elements from different points. It is the loops that are important—any code within the loops is just an example of retrieval.

```
&testMCFFactory = create MCFFactory(100); /* set a maximum number of tasks in a tas→
k list to 100 */

Local integer &i, &j, &k;
&i = 1;
&j = 1;
&k = 1;
&l = 1;
&m = 1;
&n = 1;

While &j < &testMCFFactory.LogicalQueue.Len + 1
  /*looping through the logical queues*/
  While &i < &testMCFFactory.LogicalQueue [&j].PhysicalQueue.Len + 1
    /*looping through the physical queues*/

    /* e.g. Tasklists by physical queues*/
    &PhysQID = &testMCFFactory.LogicalQueue [&j].PhysicalQueue [&i].PhysicalQueue⇒
ID;

    &nOvflTaskTotal = &testMCFFactory.LogicalQueue [&j].PhysicalQueue [&i].OverFl⇒
owedTaskList.Total;

    While &k < &testMCFFactory.LogicalQueue [&j].PhysicalQueue [&i].OverFlowedTas⇒
kList.Total + 1
      /*looping through the Tasklist on physical queues*/

      /* e.g. Tasks by physical queues*/
      &tasknum = &testMCFFactory.LogicalQueue [&j].PhysicalQueue [&i].OverFlowed⇒
TaskList.Task [&k].TaskNumber;

      &k = &k + 1;
    End-While; /* &k loop */
    /*Task List by Agents on a Physical Queue */
    While &l < &testMCFFactory.LogicalQueue [&j].PhysicalQueue [&i].TotalAgents +⇒
1
      While &m < &testMCFFactory.LogicalQueue [&j].PhysicalQueue [&i].Agent [&l]⇒
.TotalPhysicalQueues + 1
        /* e.g. Workload of agents on physical queues. NOTE: &m and &i are n⇒
ot the same value for the same physical queue.*/
        &AgentMaxWorkload = &testMCFFactory.LogicalQueue [&j].PhysicalQueue [&i]⇒
```

```

].Agent [&l].AgentProps [&m].Workload;
    While &n < &testMCFFactory.LogicalQueue [&j].PhysicalQueue [&i].Agent [=>
&l].AgentsTasks [&m].AcceptedTaskList.Total + 1
    /* e.g. tasks on Agent's accepted list NOTE: &m and &i are not the=>
same value for the same physical queue.*/
    &tasknum = &testMCFFactory.LogicalQueue [&j].PhysicalQueue [&i].Agen=>
t [&l].AgentsTasks [&m].AcceptedTaskList.Task [&n];
    &n = &n + 1;
    End-While; /* &n Loop - tasks on Phys Q of Agents */
    &n = 1;
    &m = &m + 1;
    End-While; /* &m loop - Phys Q of Agents - convoluted*/
    &m = 1;
    &l = &l + 1;
    End-While; /* &l loop - Agents on Phys Q */
    &i = &i + 1;
    &k = 1;
    End-While; /* &i loop- Physical Queues*/
    &j = &j + 1;
    &i = 1;
End-While; /* &j loop - Logical Queues*/

```

Workflow Notification Classes

Understanding Notification Classes

The Notification classes are used for ad-hoc notification. These classes enable you to create and send a notification to someone. The notifications can either be a PeopleSoft Worklist item or an SMTP email message. The Notification class also stores notifications in a table.

You can also use web services to create Worklist entries, then send notifications of completion using application messages.

The Notification classes can be called from a component, an internet script, or an Application Engine program. The WSWorklistEntry class can be used incase you are developing your own PT_WORKLIST notification handler.

Most of the classes, as well as most of the properties and methods that make up the Notification classes have a GUI representation in PeopleSoft Workflow. This document assumes that the reader is familiar with PeopleSoft Workflow.

Related Links

"Understanding PeopleSoft Workflow" (Workflow Technology)

Scope of the Notification Classes

The Notification classes can be called from a component, an internet script, Integration Broker, or an Application Engine program.

Notification classes can be of Local, Global, or Component scope.

Data Types of the Notification Classes

Every Notification class is its own data type, that is, Notifications are declared as data type Notification, Notification addresses are declared as type NotificationAddress, and so on.

The following are the data types of the Notification classes:

- Notification
- NotificationAddress
- NotificationTemplate
- WorklistEntry

- Worklist
- WSWorkListEntry

How to Import the Notification Classes

The Notification classes are *not* built-in classes, like Rowset, Field, Record, and so on. They are application classes. Before you can use these classes in your PeopleCode program, you must import them to your program.

An import statement names either all the classes in a package or one particular application class. For importing the Notification classes, PeopleSoft recommends that you import all the classes in the application package.

The application package PT_WF_NOTIFICATION contains the following classes:

- Notification
- NotificationAddress
- NotificationTemplate

The application package PT_WF_WORKLIST contains the following classes:

- Worklist
- WorklistEntry
- WSWorkListEntry

The import statements you should use are as follows:

```
import PT_WF_NOTIFICATION:*;  
import PT_WF_WORKLIST:*;
```

Using the asterisks after the package name makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are *not* made available.

Related Links

[Understanding Application Classes](#)

How to Create a Notification Object

After you've imported the Notification classes, you instantiate an object of one of those classes using the constructor for the class and the Create function.

The following example creates a new instance of the WorklistEntry class, as the variable &MyWE, with local scope:

```
Local WorklistEntry &MyWE = Create WorklistEntry();
```

Related Links

[Notification Classes Constructors](#)

Notification Classes Constructors

You must use the constructor for each class to instantiate an instance of that class. The following are the constructors for the Notification classes.

Notification

Syntax

```
Notification(NotifyFrom, dtmCreated, language_cd)
```

Description

Use Notification to instantiate a notification object.

Parameters

Parameter	Description
<i>NotifyFrom</i>	Specify the entity the notification is being sent from, as a string. Avoid overusing generic entities with this parameter, as this value, along with the value for <i>dtmCreated</i> are the key to understanding where notifications originated from.
<i>dtmCreated</i>	Specify the date and time the notification is being sent, as a DateTime value. Important! To ensure a unique timestamp for each notification that is sent, you must pass a DateTime value that includes milliseconds. Because the %Datetime system variable always returns 0 for the milliseconds value, use the combination of %Date+%PerfTime instead.
<i>language_cd</i>	Specify the 3-character language code of the current user, as a string.

Returns

A Notification object.

Example

To ensure a unique timestamp for each notification that is sent, you must pass a `DateTime` value that includes milliseconds to the `dtmCreated` parameter. Because the `%Datetime` system variable always returns 0 for the milliseconds value, use the combination of `%Date+%PerfTime` instead.

```
import PT_WF_NOTIFICATION:*;
import PT_WF_WORKLIST:*;

Local PT_WF_NOTIFICATION:Notification &MyNotify;

&MyNotify = create PT_WF_NOTIFICATION:Notification("Workflow_Admin", %Date + %PerfTime, %Language);
```

Related Links

[Notification Class](#)

NotificationAddress

Syntax

```
NotificationAddress(Oprid, Description, Language, EmailId, Channel)
```

Description

Use `NotificationAddress` to instantiate a notification address.

This address is used to build a notification using the `Notification` class. This class is required if you want to use the `Notification` data type.

Parameters

Parameter	Description
<i>Oprid</i>	Specify the user ID of the person receiving the notification, as a string.
<i>Description</i>	Specify the description of the entity receiving the notification (distribution group names, people's names, and so on) as a string.
<i>Language</i>	Specify the language code of the entity to be notified as a string.
<i>EmailId</i>	Specify the email address as a string.
<i>Channel</i>	Specify the 'channel' used for the notification, as a string. The values are:

Value	Description
Email	Notification is sent as email
Worklist	Notification is sent as a worklist

Returns

None.

Example

```
import PT_WF_NOTIFICATION:*;
import PT_WF_WORKLIST:*;

Local NotificationAddress &MyNotify_Addy;

&MyNotify_Addy = Create NotificationAddress(%UserID, &Description, %Language, &EmailID, &Channel);
```

Related Links

[NotificationAddress Class](#)

NotificationTemplate

Syntax

```
NotificationTemplate(ComponentId, Market, TemplateId, TemplateType)
```

Description

Use NotificationTemplate to instantiate a notification template.

If you're specifying a generic template, the first two parameters do not have to have values, that is, you must specify a Null string ("") instead.

Parameters

Parameter	Description
<i>ComponentId</i>	Specify the name of the component the notification is coming from as a string. To specify a generic template, you must specify a Null string ("") for this value instead.

Parameter	Description
<i>Market</i>	Specify the name of the market of the component the notification is coming from as a string. To specify a generic template, you must specify a Null string ("") for this value instead.
<i>TemplateId</i>	Specify the template ID as a string.
<i>TemplateType</i>	Specify the type of template as a string. Values are: <ul style="list-style-type: none"> • G: generic template • C: component template

Returns

An instance of the NotificationTemplate class.

Example

```
import PT_WF_NOTIFICATION:*;
import PT_WF_WORKLIST:*;
Local NotificationTemplate &Notify_Temp;
/* create a generic template */
&Notify_Temp = Create NotificationTemplate("", "", "MyTemplate", "G");
```

Related Links

[Worklist Class](#)

Worklist

Syntax

```
Worklist()
```

Description

Use the Worklist method to instantiate a Worklist object.

Parameters

None.

Returns

An instance of the `Worklist` class.

Example

The following example code creates a worklist.

```
import PT_WF_WORKLIST:*;  
  
Local Worklist &theWorklist = Create Worklist();
```

Related Links

[Worklist Class](#)

WorklistEntry

Syntax

```
WorklistEntry()
```

Description

Use `WorklistEntry` to instantiate a `WorklistEntry` object.

Parameters

None.

Returns

An instance of the `WorklistEntry` class.

Example

```
import PT_WF_NOTIFICATION:*;  
  
import PT_WF_WORKLIST:*;  
  
Local WorklistEntry &MyWorklistEntry = Create WorklistEntry();
```

Related Links

[WorklistEntry Class](#)

WSWorklistEntry

Syntax

```
WSWorklistEntry()
```

Description

Use the `WSWorklistEntry` constructor to instantiate a `WSWorklistEntry` object.

The `WSWorklistEntry` class is primarily used with web services.

Parameters

None.

Returns

A reference to a `WSWorklistEntry` object.

Related Links

[WSWorklistEntry Class](#)

Notification Class

This class is used to send a notification to people or people entities, as channel independent as possible. This enables functionality such as letting a user determine how to receive workflow notifications as a preference. It does not necessarily limit a person or entity to one channel.

See [Notification Classes Examples](#).

See "Understanding Notification Templates" (Workflow Technology).

Notification Class Import Statements

The `Notification` class imports the following classes:

- `NotificationAddress`
- `WorklistEntry`

Here are the import statements:

```
import PT_WF_NOTIFICATION:NotificationAddress;  
import PT_WF_WORKLIST:WorklistEntry;
```

Notification Class Method

In this section, we discuss the `Notification` class method `Send`.

Send

Syntax

`Send ()`

Description

Use the Send method to send a notification to the entities defined in the NotifyTo, NotifyCC, and NotifyBCC, using the Subject and Message properties.

Parameters

None.

Returns

None.

Related Links

"Understanding PeopleSoft Workflow" (Workflow Technology)

Notification Class Properties

In this section, we discuss the Notification class properties. The properties are discussed in alphabetical order.

ContentType

Description

This property returns the content type of the value specified by the Message property, as a string. This property is used only with email Notifications, that is, with SMTP email.

This property is read/write.

Related Links

[Message](#)

dtmCreated

Description

This property returns the date and time the notification was created as a DateTime value. Together with NotifyFrom this makes a notification unique.

Related Links

[NotifyFrom](#)

EmailReplyTo

Description

If an email is sent as a result of the Send method, this property returns the email reply that should be used, as a string. This property can have a different value from NotifyFrom. This property is valid only with notifications that have "email" specified as the channel.

This property is read/write.

Related Links

[Send](#)

[NotifyFrom](#)

FileNames

Description

This property returns an array of string, populated with the names of any file attachments sent with the notification. This property is valid only with notifications that have "email" specified as the channel.

This property is read/write.

FileTitles

Description

This property returns an array of string, populated with descriptions of any file attachments. The array order *must* be respective to the array order for FileNames, that is, file description matches file name one by using the same array index value. This property is valid only with notifications that have "email" specified as the channel.

This property is read/write.

Related Links

[FileNames](#)

language_cd

Description

This property returns the 3-character language code used for the notification, as a string. This is used for tracking purposes.

This property is read/write.

Message

Description

This property returns the text of the message sent with the notification as a string.

This property is read/write.

NotifyBCC

Description

This property returns an array of `NotificationAddress` objects, populated with the email addresses or worklist users of the people the notification is sent to. This list is used for notification information only, that is, the people on this list are generally not responsible for taking action specified by the notification. In addition, when you use the `Notification Send` method, other recipients cannot see the email addresses and or users that make up this array.

If you want to send a regular `CC` list, that is, one where the members of the list can see each other, use the `NotifyCC` property instead.

Related Links

[NotifyCC](#)

NotifyCC

Description

This property returns an array of `NotificationAddress` objects, populated with the email addresses of the people the notification is sent to. This list is used for notification information only, that is, the people on this list are generally not responsible for taking action specified by the notification. When using the `Notification Send` method, the email address or worklist users of this array are exposed to the recipients of the notification.

If you want to send a blind-`CC` list, that is, where the members of the list cannot see each other, use the `NotifyBCC` property instead.

Related Links

[NotifyBCC](#)

NotifyFrom

Description

This property returns the ID of the entity sending the notification as a string. For example, ad-hoc workflow uses the current user ID.

This property is read/write.

NotifyGuid

Description

This property returns the GUID of the notification. This is a unique identifier used for tracking purposes only.

This property is read/write.

NotifyTo

Description

This property returns an array of NotificationAddress objects, populated with the email addresses of the people the notification is sent to, and who are responsible for taking action if necessary.

To send the list to additional people, use the NotifyCC or NotifyBCC properties.

Related Links

[NotifyBCC](#)

[NotifyCC](#)

Rte

Description

Use this property to set or return a Boolean value indicating whether to use Rich Text formatting in the notification.

This property is read/write.

SourceComponent

Description

This property returns the name of the source component, that is, that initiated the notification process. This property is used for transaction tracking purposes only. This property is not required.

This property is read/write.

SourceMarket

Description

This property returns the name of the market of the source component, that is, that initiated the notification process. This property is used for transaction tracking purposes only. This property is not required.

This property is read/write.

SourceMenu

Description

This property returns the name of the menu of the source component, that is, that initiated the notification process. This property is used for transaction tracking purposes only. This property is not required.

This property is read/write.

Subject

Description

This property returns the subject used in the email notification as a string.

This property is read/write.

Template

Description

If the notification message originated from a template, this property returns the name of that template, as a string. This property is used for transaction tracking purposes only. This property is not required.

This property is read/write.

NotificationAddress Class

The main purpose of the NotificationAddress is to define an entity to a 'channel', it is concerned at a high level only that a notification was sent.

See [Notification Classes Examples](#).

See "Understanding Notification Templates" (Workflow Technology).

NotificationAddress Class Properties

In this section, we discuss the NotificationAddress class properties. The properties are discussed in alphabetical order.

Channel

Description

This property returns the 'channel' used for the notification, as a string. The values are:

<i>Value</i>	<i>Description</i>
Email	Notification is sent as email.
Worklist	Notification is sent as a worklist.

This property is read/write.

Description

Description

This property returns the description of the entity as a string. Entity descriptions include distribution group names or people's names.

This property is read/write.

EmailId

Description

This property returns the Email Address of the entity to be notified.

This property is read/write.

Language

Description

This property returns the language code of the entity to be notified.

This property is read/write.

Oprid

Description

This property returns the user ID of the person receiving the notification as a string.

This property is read/write.

NotificationTemplate Class

This class is useful for populating the message property of the Notification class.

See "Understanding Notification Templates" (Workflow Technology).

NotificationTemplate Class Methods

In this section, we discuss the NotificationTemplate class methods. The methods are discussed in alphabetical order.

GetAndExpandTemplate

Syntax

```
GetAndExpandTemplate(Language, Vars)
```

Description

Use the GetAndExpandTemplate method to expand and map the variables into the Text property of the template.

If this is a component template, you must use the SetupCompVarsAndRepts method first, before you use this method.

If this is a generic template, you must use the SetupGenericVars method first, before you use this method.

The value returned by the Setup methods must be used as the second parameter for this method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Language</i>	Specify the 3-character language code used with the notification.

Parameter	Description
<i>Vars</i>	Specify the variable representing the XML string returned by either the SetupCompVarsAndRcpts method or the SetupGenericVars method.

Returns

Returns a Boolean value: True if the template expanded properly, False otherwise.

Example

```
import PT_WF_NOTIFICATION:NotificationTemplate;
Local NotificationTemplate & mynotifytemplate;
&mynotifytemplate = create NotificationTemplate(%Component, %Market, &templateName,⇒
  "C");
&xmlVars = &mynotifytemplate.SetupCompVarsAndRcpts(GetLevel0());
&mynotifytemplate.GetAndExpandTemplate(%Language, &xmlVars);
```

Related Links

[SetupCompVarsAndRcptsLevel1](#)

[SetupGenericVars](#)

SetupCompVarsAndRcpts

Syntax

```
SetupCompVarsAndRcpts (&Rowset_Context)
```

Description

Use the SetupCompVarsAndRcpts method to set up variables for the component from the provided rowset. This method also sets up any additional recipients defined in the component.

The rowset corresponds to the component that the notification template was instantiated with. For example, if you created a notification template for JOB, the rowset used with this method should be based on the JOB component.

If you want to expand a component template, you must use this method first, before expanding the template.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Rowset_Context</i>	Specify an already instantiated and populated rowset containing the necessary variables.

Returns

A string containing XML that is used by the `GetAndExpandTemplate` method.

Example

```
import PT_WF_NOTIFICATION:NotificationTemplate;
Local NotificationTemplate & mynotifytemplate;
&mynotifytemplate = create NotificationTemplate(%Component, %Market, &templateName,⇒
  "C");
&xmlVars = &mynotifytemplate.SetupCompVarsAndRcpts(GetLevel0());
&mynotifytemplate.GetAndExpandTemplate(%Language, &xmlVars);
```

Related Links

[GetAndExpandTemplate](#)

SetupCompVarsAndRcptsLevel1

Syntax

```
SetupCompVarsAndRcptsLevel1(&Rowset_Context, row_num)
```

Description

Use the `SetupCompVarsAndRcpts` method to set up variables for the component from the provided rowset. This method also sets up any additional recipients defined in the component.

The rowset corresponds to the component that the notification template was instantiated with. For example, if you created a notification template for `JOB`, the rowset used with this method should be based on the `JOB` component.

If you want to expand a component template, you must use this method first, before expanding the template.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Rowset_Context</i>	Specify an already instantiated and populated Rowset object containing the necessary variables.
<i>row_num</i>	Specify the row number as a number value.

Returns

A string containing XML that is used by the GetAndExpandTemplate method.

Related Links

[GetAndExpandTemplate](#)

SetupGenericVars

Syntax

```
SetupGenericVars (&AryValues)
```

Description

Use the SetupGenericVars method to pass values to a generic template.

To expand a generic template, you must use this method first, before expanding the template.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&AryValues</i>	Specify an array of string containing values used with the expanded template.

Returns

A string containing XML that is used by the GetAndExpandTemplate method.

Example

```
import PT_WF_NOTIFICATION:NotificationTemplate;
. . .
&mynotifytemplate = create NotificationTemplate("", "", "MYTEMPLATE", "G");
/* Populate an array to contain the values needed by */
```

```
/* the template */
&aryValues = CreateArrayRept("", 0);
&aryValues.Push("FIRST VALUE");
&aryValues.Push("SECOND VALUE");
&xmlVars = &mynotifytemplate.SetupGenericVars(&aryValues);
&mynotifytemplate.GetAndExpandTemplate(%Language, &xmlVars);
```

Related Links

[GetAndExpandTemplate](#)

NotificationTemplate Class Properties

In this section, we discuss the NotificationTemplate class properties. The properties are discussed in alphabetical order.

ComponentId

Description

This property returns a component for the component type notification template as a string. This is not required for generic templates.

This property is read/write.

Instruction

Description

This property returns the notification instructions as a string.

This property is read/write.

Language

Description

This property returns the language used to retrieve template descriptions, as a string.

This property is read/write.

Market

Description

This property returns the market for component type notification templates as a string. This is not required for generic templates.

This property is read/write.

Priority

Description

This property returns the priority of the notification template as a string.

This property is read/write.

Responses

Description

This property is populated only if there are any RIMM responses.

This property is read/write.

Subject

Description

This property returns the subject of the notification template as a string.

This property is read/write.

TemplateId

Description

This property returns the template ID as a string. If you are creating a notification template, this property is always required.

This property is read/write.

TemplateType

Description

This property returns the template type as a string. Values are:

<i>Value</i>	<i>Description</i>
C	Component
G	Generic

If you are creating a notification template, this property is always required.

This property is read/write.

Text

Description

This property returns the Template Text as a string.

This property is read/write.

Worklist Class

The Worklist class is used to make mass modifications to worklist instances. Modifications to one worklist instance should be performed through the WorklistEntry class.

See [Worklist](#).

Worklist Class Method

In this section, we discuss the Worklist class method Reassign.

Reassign

Syntax

Reassign (*FromOperid*, *ToOperid*)

Description

Use the Reassign method to reassign all worklist items with a state less than “Worked” from one user to another.

If you only want to reassign a single worklist entry, use the Reassign WorklistEntry class method.

Parameters

Parameter	Description
<i>FromOperid</i>	Specify the user ID of the user from which you want to assign a worklist, as a string.
<i>ToOperid</i>	Specify the user ID of the user to which you want to assign a worklist, as a string.

Returns

A Boolean value: true if worklist was assigned successfully, false otherwise.

Related Links

[Reassign](#)

WorklistEntry Class

This class is used to create and or update a worklist entry.

See [Creating a WorklistEntry](#).

See [Updating a WorklistEntry](#).

See "Understanding PeopleSoft Workflow" (Workflow Technology).

WorklistEntry Class Methods

In this section, we discuss the WorklistEntry class methods. The methods are discussed in alphabetical order.

Create

Syntax

```
Create ()
```

Description

Use the Create method to create a new WorklistEntry object.

This method is *not* the same as the Create *constructor*. The Create constructor only creates an instance of the WorklistEntry class. To add the entry to the database, you must use this method.

The following properties must be set before calling this method:

- busactivity
- buseventname
- busprocname
- worklist

If this method completes successfully, the following properties are populated:

- instanceid

- transactionid

Parameters

None.

Returns

This method returns a numeric value: 0 if there is an error, nonzero if entry created successfully.

Example

```
import PT_WF_WORKLIST:*;

Local WorklistEntry &worklist;
Local Number &Rslt;

&worklist = create WorklistEntry();

&worklist.busprocname = "Administer Workflow";
&worklist.busactivity = "Send Note";
&worklist.buseventname = "Worklist Note";
&worklist.worklistname = "Worklist Note";

&Rslt = &worklist.Create();
```

Related Links

[busactivity](#)

[buseventname](#)

[busprocname](#)

[instanceid](#)

[transactionid](#)

GetResponseStatus

Syntax

```
GetResponseStatus ()
```

Description

Use the GetResponseStatus method to return the response status of the callback method. This is useful only for entries that are created by web services.

The following properties must be set before calling this method:

- busactivity
- buseventname
- busprocname
- requestmessageid

- worklistname

Parameters

None.

Returns

A number. Valid values are:

<i>Value</i>	<i>Description</i>
0	CreateWorklistEntry message not received yet or this entry was not created by any web service.
1	Message received but not processed yet.
2	Message processed and sent to message queue.
3	Error while sending message to the caller of create worklist entry.
4	Message was sent to the originating web server and was received successfully.

Reassign

Syntax

Reassign (*Operid*)

Description

The Reassign method assigns the worklist in the data buffers to the user specified by *Operid*. This method commits the version of the worklist entry in the data buffer to the database using the Save method.

If you want to reassign an entire worklist, use the Reassign Worklist class method.

Note: You must use the SelectByKey method to populate data buffers with the worklist entry.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Operid</i>	Specify the user ID to which you want to assign the worklist entry, as a string.

Returns

A Boolean value: true if the reassignment was successful, false otherwise.

Example

```
import PT_WF_WORKLIST:WorklistEntry;

Local WorklistEntry &wl = create WorklistEntry();
&wl.busprocname = WF_WORKLIST_VW2.BUSPROCNAME;
&wl.busactivity = WF_WORKLIST_VW2.ACTIVITYNAME;
&wl.buseventname = WF_WORKLIST_VW2.EVENTNAME;
&wl.worklistname = WF_WORKLIST_VW2.WORKLISTNAME;
&wl.instanceid = WF_WORKLIST_VW2.INSTANCEID;

If (&wl.SelectByKey()) Then
  If Not (&wl.Reassign("TOPSUSER2")) Then
    /* Reassign error */
  End-If;
Else
  /* SelectByKey error */
End-If;
```

Related Links

[Reassign](#)

Save

Syntax

```
Save()
```

Description

Use the Save method to save a WorklistEntry to the database.

PeopleCode Event Considerations

You must include this method within events that allow database updates. This includes the following PeopleCode events:

- SavePreChange (Page)
- SavePostChange (Page)
- Workflow
- FieldChange

If this method results in a failure, all database updates are rolled back. All information the user entered into the component is lost, as if the user pressed ESC.

Considerations Using Web Services

This method saves the instance of the worklist to the database. If the worklist entry is marked as worked, (that is, if inststatus property is set to 2) and the worklist entry was originally created by a web service,

the originating requestor is sent a response when this method is executed. If the requestor is expecting additional data, use the `SaveWithCustomData` method instead.

Parameters

None.

Returns

A numeric value: 0 if save didn't complete successfully, nonzero if save completed successfully.

Example

```
If (&worklist.Save() <> 0) Then
    /* success */
Else
    /* handle error */
End-If;
```

Related Links

[Update](#)

[SaveWithCustomData](#)

[inststatus](#)

SaveWithCustomData

Syntax

```
SaveWithCustomData(&Message, &FieldNameArray, &FieldValueArray)
```

Description

Use the `SaveWithCustomData` method to save the worklist entry to the database, as well as to pass additional data back to the requestor that created this worklist entry. You should only use this method with worklist entries that are created by web service. If you want to save a worklist entry without additional data, or a worklist entry that was not created using a web service, use the `Save` method instead.

If the worklist entry was not created by a web service, or if the worklist entry is not marked as worked (that is, if the `inststatus` property is not set to 2,) the additional data is ignored.

PeopleCode Event Considerations

You must include this method within events that allow database updates. This includes the following PeopleCode events:

- `SavePreChange` (Page)
- `SavePostChange` (Page)
- `Workflow`
- `Message Subscription` (the Integration Broker `INotificationHandler` interface)

- `FieldChange`

If this method results in a failure, all database updates are rolled back. All information the user entered into the component is lost, as if the user pressed **ESC**.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Message</i>	Specify an already instantiated and populated response message containing the custom data to be sent back to the originating web service.
<i>&FieldNameArray</i>	Specify an already instantiated and populated array of string containing the field names to be used by the web service that created the worklist entry.
<i>&FieldValueArray</i>	Specify an already instantiated and populated array of string containing matching field values to be used by the web service that created the worklist entry.

Returns

A message object containing the final message that was sent to the web service if successful, a null object otherwise.

[Save](#)

[inststatus](#)

SelectByKey

Syntax

```
SelectByKey ()
```

Description

The `SelectByKey` method uses the key field values that have been assigned to build and execute a Select SQL statement. The field values are then fetched from the database SQL table into the worklist entry and the Select statement is closed.

If you don't specify all the key fields, those you exclude are added to the Where clause with the condition equal to a blank value. If not all keys are set and more than one row is retrieved, you won't receive an error and `SelectByKey` won't fetch any data.

For worklist entries that were created by web services, use the `SelectByMessageId` method instead.

Parameters

None.

Returns

A Boolean value: true if the properties are set based on the database values, false otherwise.

Related Links

[SelectByMessageId](#)

SelectByMessageId

Syntax

```
SelectByMessageId ()
```

Description

Use the SelectByMessageId method to select a worklist entry by the message id. This is useful only for entries that are created by web services.

The following properties must be set before calling this method:

- busactivity
- buseventname
- busprocname
- requestmessageid
- worklistname

Parameters

None.

Returns

A Boolean value: true if this method completes successfully, false otherwise.

Related Links

[SelectByKey](#)

Update

Syntax

```
Update ()
```

Description

Use the Update method to update the worklist entry with any property values that have changed, and assign values to the associated record in the database. However, this method does not commit the changes to the record in the database. You must use the Save method to update the database.

Parameters

None.

Returns

A numeric value: 0 if update didn't complete successfully, nonzero if update completed successfully.

Example

```
If (&worklist.Update() <> 0) Then
    &worklist.inststatus = "2" /* mark entry worked */
    /* additional processing */
End-if;
```

WorklistEntry Class Properties

In this section, we discuss the WorklistEntry class properties. The properties are discussed in alphabetical order.

actiondtm

Description

This property returns the Worklist action date and time as a DateTime value.

This property is read/write.

busactivity

Description

This property returns the source activity name of the source business process as a string.

This property is read/write.

buseventname

Description

This property returns the source event name of the source activity as a string.

This property is read/write.

busprocname

Description

This property returns the source business process name as a string.

This property is read/write.

commentshort

Description

This property returns the short comment the previous user ID gave when reassigning a worklist as a string.

This property is read/write.

do_replicate_flag

Description

This property returns a flag that indicates if the worklist entry must be replicated. Values are:

<i>Value</i>	<i>Description</i>
Y	Worklist entry needs to be replicated
N	Worklist entry does not need to be replicated

This property is read/write.

instanceid

Description

This property returns the Instance Id. This property is used with the following properties to make the worklist entry a unique number:

- busprocname

- busactivity
- buseventname
- worklistname

This property is read/write.

instselecteddtm

Description

This property returns the date and time that the worklist was selected to be worked as a DateTime value.

This property is read/write.

inststatus

Description

This property returns the Worklist Entry status as a string. The values are:

<i>Value</i>	<i>Description</i>
0	new worklist entry
1	selected worklist entry
2	worked worklist entry
3	cancel string

This property is read/write.

insttimeoutddtm

Description

This property returns the date and time the worklist entry timed out as a DateTime value. Only some worklist types use this property.

This property is read/write.

instworkeddtm

Description

This property returns the date and time the worklist was worked as a DateTime value.

This property is read/write.

IsCreatedViaWebService

Description

This property returns a Boolean value: true if the WorklistEntry object was created from a web service, false otherwise.

This property is read-only.

oprid

Description

This property returns the user ID that is assigned the worklist as a string.

This property is read/write.

originatorid

Description

This property returns the user ID that caused the worklist to be created as a string.

This property is read-only.

prevoprid

Description

This property returns the previous user ID who used this worklist entry as a string.

This property is read/write.

requestmessageid

Description

This property is used with worklist entries that are created by web services. It contains the original message ID from the requesting party.

This property is read/write.

ResponseStatus

Description

This property returns the status of the response sent to the originating web service.

Valid values are:

<i>Value</i>	<i>Description</i>
0	CreateWorklistEntry message not received yet or this entry was not created by any web service.
1	Message received but not processed yet.
2	Message processed and sent to message queue.
3	Error while sending message to the caller of create worklist entry.
4	Message was sent to the originating web server and was received successfully.

This property is read/write.

syncid

Description

This property is reserved for future use.

This property is read/write.

timeout

Description

This property returns the status flag if the worklist has timed out. Values are:

<i>Value</i>	<i>Description</i>
Y	Worklist has timed out

Value	Description
N	Worklist has not timed out

This property is read/write.

transactionid

Description

This property returns the transaction Id as a number, which represents the unit of work. This can be useful for pooled worklists.

This property is read/write.

url

Description

This property returns the URL to work for the worklist as a string. This is used only for replicating worklist entries across PeopleSoft databases.

This property is read/write.

wl_priority

Description

This property returns the priority of the worklist as a string. The values are:

Value	Description
low	Worklist has low priority.
medium	Worklist has medium priority.
high	Worklist has high priority.

This property is read/write.

wldaystoselect

Description

This property returns the number of days to select worklist as a number.

This property is read/write.

wldaystowork

Description

This property returns the number of days to work the worklist as a number.

This property is read/write.

worklistname

Description

This property returns the source worklist name for the source event string as a string.

This property is read/write.

WSWorklistEntry Class

This class is used by web services to create Worklist entries.

This class implements the Integration Broker class IRequestHandler.

Related Links

"Understanding Sending and Receiving Messages" (Integration Broker)

WSWorklistEntry Class Methods

The following are the WSWorklistEntry class methods, in alphabetical order.

OnError

Syntax

```
OnError ( &Message)
```

Description

Use the OnError method to do error handling. This method implements the Integration Broker IRequestHandler interface OnError method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Message</i>	Specify an already instantiated and populated message object. This would normally be the message that was used to generate the worklist entry from the web service.

Returns

Depends on implementation.

Related Links

[Understanding Message Classes](#)

[Understanding theSOAPDoc Class](#)

"Understanding Sending and Receiving Messages" (Integration Broker)

OnNotify

Syntax

```
OnNotify (&Message)
```

Description

Use the OnNotify method to creates the worklist entry and the application worklist record.

This method implements the Integration Broker INotificationHandler interface OnNotify method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&Message</i>	Specify an already instantiated and populated message object. Generally this would be the originating message that created the worklist entry.

Returns

None.

Related Links

"Understanding Sending and Receiving Messages" (Integration Broker)

WSWorklistEntry Class Properties

The following describes the WSWorklistEntry class properties, in alphabetical order.

InstanceID

Description

This property returns the instance ID for the worklist entry, as a string.

This property is read-only.

TransactionID

Description

This property returns the transaction ID for the worklist entry, as a string.

This property is read-only.

Notification Classes Examples

The following are example of typical actions you perform using the notification classes.

See "Understanding Notification Templates" (Workflow Technology).

Creating a WorklistEntry

The following example creates a WorklistEntry.

The following is the complete code sample: the steps explain each line.

```
import PT_WF_WORKLIST:*;

Local WorklistEntry &worklist;

&worklist = create WorklistEntry();

&worklist.busprocname = "Administer Workflow";
&worklist.busactivity = "Send Note";
&worklist.buseventname = "Worklist Note";
&worklist.worklistname = "Worklist Note";

If (&worklist.Create() <> 0) Then
    &worklist.oprid = %UserId;
Else
    /* handle error */
End-If;

If (&worklist.Save() <> 0) Then
    /* success, create a corresponding row in */
    /* application worklist record... */
Else
```

```

    /* handle error */
End-If;

```

To create a WorklistEntry:

1. Import the WorklistEntry class.

You must import the WorklistEntry class before you can use it in your PeopleCode program. In addition, the second line declares the variable `&worklist` as type WorklistEntry.

```

import PT_WF_WORKLIST:*;

Local WorklistEntry &worklist;

```

2. Instantiate a WorklistEntry object.

Using the constructor, create an instance of the WorklistEntry class. This does *not* create a WorklistEntry. This creates a WorklistEntry object only. You must use the Create method to actually create the WorklistEntry in the system.

```

&worklist = create WorklistEntry();

```

3. Set the required parameters.

Some of the WorklistEntry class properties are required for every WorklistEntry. You must set a value for these properties before you can update or save the WorklistEntry.

```

&worklist.busprocname = "Administer Workflow";
&worklist.busactivity = "Send Note";
&worklist.buseventname = "Worklist Note";
&worklist.worklistname = "Worklist Note";

```

4. Create the WorklistEntry.

After you've set the required values, you need to create the WorklistEntry in the system. This does *not* update the database. This does, however, add values to the notification tables.

If this method completes successfully, the following properties are populated: instanceid and transactionid.

- instanceid
- transactionid

```

If (&worklist.Create() <> 0) Then
    &worklist.oprid = %userid;
Else
    /* handle error */
End-If;

```

5. Save the WorklistEntry.

After you've created the WorklistEntry, save it. The Save method actually updates the database, and so can be used only in events that allow database updates.

```

If (&worklist.Save() <> 0) Then
    /* success, create a corresponding row in */
    /* application worklist record... */
Else
    /* handle error */

```

```
End-If;
```

Updating a WorklistEntry

The following example updates a WorklistEntry so that it is considered worked.

The following is the complete code sample: the steps explain each line.

```
import PT_WF_WORKLIST:*;

Local WorklistEntry &worklist;

&worklist = create WorklistEntry();
&worklist.busprocname = "Administer Workflow";
&worklist.busactivity = "Send Note";
&worklist.buseventname = "Worklist Note";
&worklist.worklistname = "Worklist Note";
&worklist.instanceid = 2;

&ret = &worklist.SelectByKey();

&worklist.inststatus = "2"; /* mark entry worked */
If (&worklist.Update() <> 0) Then
  If (&worklist.Save() <> 0) Then
    /* success */
  Else
    /* handle error */
  End-If;
Else
  /* handle error */
End-If;
```

To update a WorklistEntry:

1. Import the WorklistEntry class.

You must import the WorklistEntry class before you can use it in your PeopleCode program. In addition, the second line declares the variable &worklist as type WorklistEntry.

```
import PT_WF_WORKLIST:*;

Local WorklistEntry &worklist;
```

2. Instantiate a WorklistEntry object.

Using the constructor, create an instance of the WorklistEntry class. This does *not* create a WorklistEntry. This creates a WorklistEntry object only. You must use the Create method to actually create the WorklistEntry in the database tables, and the Save method to update the tables.

```
&worklist = create WorklistEntry();
```

3. Set the required parameters.

Some of the WorklistEntry class properties are required for every WorklistEntry. You must set a value for these properties before you can update or save the WorklistEntry. The instanceid property, combined with the other properties, indicates a unique WorklistEntry. This value is populated after a WorklistEntry has already been created.

```
&worklist.busprocname = "Administer Workflow";
&worklist.busactivity = "Send Note";
&worklist.buseventname = "Worklist Note";
&worklist.worklistname = "Worklist Note";
&worklist.instanceid = 2;
```

4. Populate the worklist entry with data.

After you've set the keys, populate the worklist entry based on those keys using the `SelectByKey` method.

```
&ret = &worklist.SelectByKey();
```

5. Update and save the `WorklistEntry`.

After you've set the required parameters, try to update the `WorklistEntry`. If that is successful, mark the `WorklistEntry` as 'worked', and try to save the `WorklistEntry`. The `Save` method actually updates the database, and so can be used only in events that allow database updates.

```
If (&worklist.Update() <> 0) Then
    &worklist.inststatus = "2" /* mark entry worked */
    If (&worklist.Save() <> 0) Then
        /* success */
    Else
        /* handle error */
    End-If;
Else
    /* handle error */
End-if;
```

XmlDoc Classes

Understanding XmlDoc Classes

The Extended Markup Language (XML) describes a class of data objects called XML documents. It also partially describes the behavior of computer programs which process them. The `XmlDoc` class is used to create and manipulate XML data.

The Extended Markup Language (XML) is a method for putting structured data in a text file. Like HTML, XML uses tags, that is, text delimited by brackets (< and >). However, HTML specifies what each tag is, and how it's supposed to be displayed in a browser. XML uses tags only to delimit data. The interpretation of that data is entirely up to the application.

For example, in HTML specifies an unordered (bulleted) list. However, with XML, it could specify an underlined link.

Each XML document has both a physical and a logical structure:

- Physically, the XML document is composed of units called *entities*. A document begins in a "root" or document entity.
- Logically, the XML document is composed of declarations, elements, comments, character references, and processing instructions

The `CreateXmlDoc` function creates an `XmlDoc` object. An `XmlDoc` is composed of `XmlNode` objects. Each `XmlNode` represents an XML document *entity*. You can use `PeopleCode` to create the following types of entities:

- Attribute (specified both by a name and a `NamespaceURI`)
- CDATA Section
- Comment
- Element
- Entity References
- Process Instruction
- Text

When to Use an XmlDoc Object

You can use the `XmlDoc` class to access inbound messages. You can also use the `XmlDoc` class to create XML messages to be sent out, either synchronously or asynchronously.

All messages must be associated with a message definition. An XmlDoc message must be associated with an *unstructured* or nonrowset-based message, that is, a message definition that's created without any record definitions.

Use the XmlDoc object if any of the following is true:

- Your message structure doesn't fit the rowset model.
- Your message data doesn't come from database records.
- Your third-party source or target node requires non-XML messages.
- Your message uses the SOAP protocol.

Do *not* use the XmlDoc object if your message contains cookies.

XmlDoc Object Creation

Use the CreateXmlDoc function to create an XmlDoc object. You can create either an empty object, and populate it with data, or you can specify an XML string that is then transformed into an XmlDoc object that you can then manipulate with PeopleCode.

If you're creating an empty XmlDoc object, and you also want to specify a particular document type declaration (DTD) to be used to validate your XML, immediately after you use the CreateXmlDoc function, you should use the CreateDocumentType method to specify the DTD, followed by the CreateDocumentElement method to associate the DTD with the root entity.

For example:

```
Local XmlDoc &inXMLDoc;  
Local XmlNode &docTypeNode;  
Local XmlNode &rootNode;  
  
&inXMLDoc = CreateXmlDoc("");  
&docTypeNode = &inXMLDoc.CreateDocumentType("Personal", "", "Personal.dtd");  
&rootNode = &inXMLDoc.CreateDocumentElement("root", "", &docTypeNode);
```

The preceding PeopleCode program produces the following XML:

```
<?xml version="1.0"?>  
<!DOCTYPE Personal SYSTEM "Personal.dtd">  
</root>
```

After you've created your XmlDoc object, use the GenXmlString method to create an XML string. You can then use an Internet Script (iScript) Response object method to send the string as an XML response.

Related Links

[Understanding Internet Script Classes](#)

Considerations Using a Unique Namespace

In the root tag, the attribute **xmlns** stands for the XML namespace. This allows you to define namespaces for tag names so that collisions can be avoided and validation logic can be run.

If you do not give a prefix for an XML namespace, but instead define it with the tag (`xmlns`) followed by a colon (`:`) and then a unique namespace, for example,

```
xmlns:psft
```

For example, this sort of functionality allows you to have two nodes named "Transaction", but one can be referenced by a "psft" namespace and another not, allowing for two nodes with the same name to exist, but each containing different data.

```
<?xml version="1.0"?>
<root xmlns:psft="http://www.example.com">
  <psft:Transaction>Value</psft:Transaction>
  <Transaction>Another</Transaction>
</root>
```

Incorrect results can be returned when you have a namespace as in the above example, which belongs to the namespace defined in `http://www.people.com`. When the system tries to find the path of "root/Transaction", it may return multiple nodes when in fact the end user might only want to return one.

To avoid this, do one of the following:

- Do not use `FindNode`. Use `GetElementByTagName` instead. This does not use XPath to resolve entries in the DOM. Instead, it works at a node by node basis, for example, by getting the root node, then getting the transactions node. This code may be a bit more complex to write, but you lose the richness of XPath.
- Give every `xmlns` attribute a prefix. The system will use XPath correctly and find the node.

Considerations Using Rowsets

Unstructured XML should be transformed to structured if you want to use the full rowset abilities. PeopleSoft recommends transforming the data into a rowset-based message.

If you do not want to transform the data, you need to break it up using the Transaction tag around the equivalent of each level zero rowset, as shown in the example.

```
<?xml version="1.0" ?>
- <SAMPLE_MSG>
  - <Transaction>
    - <QE_SALES_ORDER class="R">
      <QE_ACCT_ID>26</QE_ACCT_ID>
      <QE_ACCOUNT_NAME>APG-65</QE_ACCOUNT_NAME>
      <QE_ADDRESS>F18 HORNET WAY</QE_ADDRESS>
      <QE_PHONE>(206) 544-1264</QE_PHONE>
      <QE_FROMROWSET />
      <QE_TOROWSET />
      <QE_SEND_SOA_BTN />
      <QE_SEND_SOS_BTN />
      <QE_TRAN_SOA_BTN />
      <QE_SEND_SO_BTN />
      <QE_TRAN_SOS_BTN />
      <QE_TRAN_APCODE_BTN />
      <QE_TRAN_SPCODE_BTN />
      <QE_PUBXMLDOC_BTN />
      <QE_CLEAR_BTN />
      <DESCRLONG />
    </QE_SALES_ORDER>
  </Transaction>
  - <Transaction>
    - <QE_SALES_ORDER class="R">
      <QE_ACCT_ID>27</QE_ACCT_ID>
      <QE_ACCOUNT_NAME>JASON ACCOUNT</QE_ACCOUNT_NAME>
```

```

    <QE_ADDRESS>THE ADDRESS</QE_ADDRESS>
    <QE_PHONE>(PHONE NUMBER</QE_PHONE>
    <QE_FROMROWSET />
    <QE_TOROWSET />
    <QE_SEND_SOA_BTN />
    <QE_SEND_SOS_BTN />
    <QE_TRAN_SOA_BTN />
    <QE_SEND_SQ_BTN />
    <QE_TRAN_SOS_BTN />
    <QE_TRAN_APCODE_BTN />
    <QE_TRAN_SPCODE_BTN />
    <QE_PUBXMLDOC_BTN />
    <QE_CLEAR_BTN />
    <DESCRLONG />
  </QE_SALES_ORDER>
</Transaction>
</SAMPLE_MSG>

```

XmlNode Class Considerations

In general, the XmlNode Class methods and properties can be broken up into the following categories:

Category	Description
Add	The Addxxx methods add an entity of the specified type to the end of the list of child nodes, and returns a reference to the newly created node.
Insert	The Insertxxx methods insert an entity of the specified type at the specific location and returns a reference to the newly created node.
Get	The Getxxx methods return a reference to the specified entity. The Getxxx methods may return a single reference or an array of references.
Other	The other methods enable you to find a particular entity in an XmlDocument (FindNode), copy data from one node into another, and remove nodes.

Accessing and Traversing an XmlNode Object

If you're creating an XmlDocument object, use the CreateDocumentElement, as well as the different Add and Insert methods to create XmlNode objects. These methods return a reference to the newly created node if successful.

Use the XmlNode properties for traversing the data structure (ParentNode, PreviousSibling, NextSibling, and so on.)

You can also use the ChildNodeCount property for looping through all the child nodes of a node.

Use the NodeType property to get the type of the node (element, processing instruction, comment, and so on).

Error Handling

Use the `IsNull` property to verify if the `XmlNode` returned by a method is a valid node. In the following example, a particular node is checked to see if it has another node after it. If it doesn't, a node is added.

```
Local XmlNode &usernode;
Local string &userName;

&usernode = &inXMLDoc.DocumentElement.FindNode("/Request/Company/Location/User");

If Not (&MyNode.IsNull) Then
    &userName = &usernode.NodeValue;
Else
    /* Do error processing */
End-If;
```

SOAPDoc Object Considerations

A SOAP Message is an ordinary XML document that consists of the following parts:

- A mandatory SOAP envelope
- An optional SOAP header
- A mandatory SOAP body

The `SOAPDoc` class is a separate class in `PeopleCode` that works similarly to the `XmlDoc` and `XmlNode` classes. Many of the same methods and properties that work with an `XmlDoc` or `XmlNode` object also work with a `SOAPDoc` object. However, there are also methods and properties that don't apply to a `SOAPDoc` object.

The following `XmlDoc` and `XmlNode` methods do *not* apply to a `SOAPDoc` object:

- `AddCDATASection`
- `AddProcessInstruction`
- `CopyToPSFTMessage`
- `CreateDocumentType`
- `InsertCDATASection`
- `InsertProcessInstruction`
- `LoadIBContent`

Related Links

[Understanding the SOAPDoc Class](#)

Scope of XmlDocument and XmlNode Objects

XmlDoc and XmlNode objects can be instantiated only from PeopleCode.

This object can be used anywhere you have PeopleCode, that is, in Application Engine PeopleCode, record field PeopleCode, and so on.

Data Type of an XmlDocument or XmlNode Object

XmlDoc objects are declared type XmlDocument.

XmlNode objects are declared type XmlNode.

For example:

```
Component XmlDocument &MyDoc;  
Local XmlNode &MyNode;
```

Note: XmlNode objects can be declared only as type Local.

XmlDoc Classes Built-in Functions

"TransformEx" (PeopleCode Language Reference)

"TransformExCache" (PeopleCode Language Reference)

"UpdateXmlDoc" (PeopleCode Language Reference)

XmlDoc Class Methods

In this section, we discuss the XmlDocument methods. The methods are discussed in alphabetical order.

CopyRowset

Syntax

```
CopyRowset(&InRowset[, MessageName ][, MessageVersion])
```

Description

Use the CopyRowset method to copy rowset data to an XmlDoc object.

Warning! If the XmlDoc is *not* empty, the existing structure and data are replaced with the data and structure from *InRowset* . If *MessageName* is not specified, this function makes the best possible XML structure given the passed rowset. Not passing the message name should only occur when using a nonrowset-based message or when using a standalone rowset. For best performance, PeopleSoft recommends to always specify the message name.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&InRowset</i>	Specify the variable of an already instantiated and populated rowset to copy data from.
<i>MessageName</i>	Specify the name of the message that the rowset belongs to, as a string. If the message name is not specified, the best possible XML structure is created.
<i>MessageVersion</i>	Specify the message version, as a string. If you do not specify a message version, the default message version is used.

Returns

A Boolean value: True, the rowset data copied successfully, False otherwise.

Example

```
Local XmlDoc &inXMLDoc;
Local boolean &ret;

&inXMLDoc = CreateXmlDoc("");
&ret = &inXMLDoc.CopyRowset(&rs, "<insert message name>", "<insert message version">
);
```

Related Links

[CopyToRowset](#)

[Understanding Rowset Class](#)

CopyToPSFTMessage

Syntax

`CopyToPSFTMessage(targetDoc, srcPath, targetPath)`

Description

Use the CopyToPSFTMessage method to copy an XmlDocument to a PeopleSoft message. The *srcPath* and *targetPath* parameters enable you to map the data of the XmlDocument (using the XmlDocument structure) to the message (following the message structure.)

The XmlDocument object generally has the following structure:

```
<?xml version="1.0"?>
<MESSAGE_NAME>
  <FieldTypes>
    ...
  </FieldTypes>
  <MsgData>
    <Transaction>
      ...
    </Transaction>
  </MsgData>
</MESSAGE_NAME>
```

Parameters

Parameter	Description
<i>targetDoc</i>	Specify the XmlDocument that contains the message structure.
<i>srcPath</i>	Specify an array of string that contains the mapping path information.
<i>targetPath</i>	Specify an array of string that contains the mapping path information.

Returns

A number. The values are:

Value	Description
0	Ok
1	Missing PSCAMA structure
2	Missing FieldType structure

Value	Description
3	General Error

Example

```
Local XmlDoc &srcDoc, &targetDoc;
Local array of string &srcPath, &targetPath;

&srcPath = CreateArrayRept("", 0);
&targetPath = CreateArrayRept("", 0);

&srcDoc = CreateXmlDoc("");
&targetDoc = CreateXmlDoc("");
&ret = &srcDoc.ParseXmlFromURL("c:/temp/source.xml");
&ret = &targetDoc.ParseXmlFromURL("c:/temp/target.xml");

&srcPath.Push("QE_EMPLOYEE");
&srcPath.Push("QE_EMPLOYEE/QE_ACCOUNT_TBL");
&srcPath.Push("QE_EMPLOYEE/QE_JOBCODE");
&srcPath.Push("QE_EMPLOYEE/DEPTID");
&srcPath.Push("EMAIL_MSG_RCD");
&srcPath.Push("EMAIL_MSG_RCD/EMAIL_FILE_RCD");

&targetPath.Push("QE_EMPLOYEE_TG");
&targetPath.Push("QE_EMPLOYEE_TG/QE_ACCOUNT_TBL_TG");
&targetPath.Push("QE_EMPLOYEE_TG/QE_JOBCODE_TG");
&targetPath.Push("QE_EMPLOYEE_TG/DEPTID_TG");
&targetPath.Push("EMAIL_MSG_RCD_TG");
&targetPath.Push("EMAIL_MSG_RCD/EMAIL_FILE_RCD_TG");

&ret = &srcDoc.CopyToPSFTMessage(&targetDoc, &srcPath, &targetPath);
```

[CopyRowset](#)

[CopyToRowset](#)

[Understanding Arrays](#)

[Understanding Message Classes](#)

CopyToRowset

Syntax

```
CopyToRowset(&Rowset, Message_Name, [Message_Version])
```

Description

Use the CopyToRowset method to copy data from the XmlDoc to an already instantiated rowset.

The rowset must be based on a message object that has the same *structure* as the XmlDoc. That is, if you have a record at level two in your message and you want that data, you must have the same level zero and level one records in your message as in your XmlDoc.

For example, suppose your XmlDoc had the following structure:

```
<?xml version="1.0"?>
<QE_SALES_ORDER>
  <QE_ACCT_ID/>
  <QE_ACCOUNT_NAME/>
  <QE_ADDRESS/>
  <QE_PHONE/>
  <QE_FROMROWSET/>
  <QE_TOROWSET/>
  <QE_SEND_SOA_BTN/>
  <QE_SEND_SOS_BTN/>
  <QE_TRAN_SOA_BTN/>
  <QE_SEND_SO_BTN/>
  <QE_TRAN_SOS_BTN/>
  <QE_TRAN_APCODE_BTN/>
  <QE_TRAN_SPCODE_BTN/>
  <QE_PUBXMLDOC_BTN/>
  <QE_CLEAR_BTN/>
  <DESCRLONG/>
</QE_SALES_ORDER>
```

If you wanted to include the information in the QE_SALES_ORDER record, you would have to have *at least* the following record structure in your message:

```
QE_SALES_ORDER
```

Any records or fields that are in the XmlDoc that aren't in the message (and vice-versa) are ignored.

Rowsets should be created using the following pseudo code:

```
Local Message &msg;
Local Rowset &rs;
Local XmlDoc &inXMLDoc;
Local boolean &ret;

&msg = CreateMessage(OPERATION.<insert message name>);
&rs = &msg.GetRowset();
&inXMLDoc = CreateXmlDoc("<insert XML structure here>");
&ret = &inXMLDoc.CopyToRowset(&rs, "<insert message name>", "<insert message versio→
n>");
```

XmlDoc objects have to follow the PeopleSoft message format:

```
<?xml version="1.0"?>
<PSmessage>
  <MsgData>
    <Transaction>
      <Record1 class="R">
        <Field1>xxx</Field1>
        <Field2>yyy</Field2>
        ...
        <Fieldn>nnn</Fieldn>
      <Record2>
        ...
      </Record2>
    </Record1>
  </Transaction>
</MsgData>
</PSmessage>
```

Warning! If *MessageName* is not specified, this function makes the best possible flat structure. Not passing the message name should only occur when using a nonrowset-based message or when using a standalone rowset. For best performance, PeopleSoft recommends to always specify the message name.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&InRowset</i>	Specify the variable of an already instantiated rowset to copy data to.
<i>Message_Name</i>	Specify the message name of the message. If the message name is not specified, the best possible flat structure is created.
<i>Message_Version</i>	Specify the message version, as a string. If the message version is not specified, the default message version is used.

Returns

This function always returns a True value, regardless of the success of the operation.

CreateDocumentElement

Syntax

```
CreateDocumentElement(TagName [, NamespaceURI ] [, &DocType])
```

where *NamespaceURI* can have *one* of the following forms:

URL.*URLname*

OR a string URL, such as

```
http://www.example.com/
```

Description

Use the CreateDocumentElement method to create the root element of the document.

For *&DocType* you must specify an already instantiated document type node using CreateDocumentType.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TagName</i>	Specify the name of the tag to be used for the document element.

Parameter	Description
<i>NamespaceURI</i>	Specify the URI that contains the Namespaces for the XmlDoc, as a string.
<i>&DocType</i>	Specify the document type node. This must already be instantiated using <code>CreateDocumentType</code> .

Returns

A reference to an XmlNode object representing the root element.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &docTypeNode;
Local XmlNode &rootNode;

&inXMLDoc = CreateXmlDoc("");
&docTypeNode = &inXMLDoc.CreateDocumentType("Personal", "", "Personal.dtd");
&rootNode = &inXMLDoc.CreateDocumentElement("root", "", &docTypeNode);
```

The preceding PeopleCode program produces the following XML:

```
<?xml version="1.0"?>
<!DOCTYPE Personal SYSTEM "Personal.dtd">
<root/>
```

Related Links

[CreateDocumentType](#)

CreateDocumentType

Syntax

```
CreateDocumentType(Name, PublicID, SystemID)
```

Description

Use the `CreateDocumentType` method to create the document type declaration (a document type node) in the XmlDoc.

You can specify only *one* document type node for an XmlDoc.

You need to create a document type node only if you have a document type definition (DTD). You don't need to specify a document type declaration in your XML. Generally, the DTD file is used for validating the XML.

If you do specify this type of node when creating an XmlDoc in PeopleCode, you *must* specify it immediately following the creation statement. Then, you must specify the document type when you create

the root node. This means your code should start with the `CreateXmlDoc` function, creating the `XmlDoc` object, then use the `CreateDocumentType` method, followed by the `CreateDocumentElement` method, creating the root node.

Considerations Using Public and System IDs

You can specify both a public and a system ID. However, if you want to use a system ID *only*, you must specify a Null string ("") for the public ID. To use a public ID *only*, you must specify a Null string ("") for the system ID. If the system ID and public ID are both Null (""), then the document type is considered as system.

To use the `Personal.dtd` as a system ID, you must use the following code:

```
&DocType = &MyDoc.CreateDocumentType("Personal", "", "Personal.dtd");
```

This produces the XML:

```
<!DOCTYPE Personal SYSTEM "Personal.dtd">
```

To use the `Personal.dtd` as a public ID, you must use the following code:

```
&DocType = &MyDoc.CreateDocumentType("Personal", "Personal.dtd", "");
```

This produces the XML:

```
<!DOCTYPE Personal PUBLIC "Personal.dtd">
```

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the document type declaration as a string.
<i>PublicID</i>	Specify the public ID of the document type declaration as a string.
<i>SystemID</i>	Specify the system ID of the document type declaration as a string.

Returns

A reference to an `XmlNode` object representing the document type element.

Example

The following example creates a document type declaration using the DTD named "Personal".

```
Local XmlDoc &inXMLDoc;
Local XmlNode &docTypeNode;
Local XmlNode &rootNode;

&inXMLDoc = CreateXmlDoc("");
&docTypeNode = &inXMLDoc.CreateDocumentType("Personal", "", "Personal.dtd");
&rootNode = &inXMLDoc.CreateDocumentElement("root", "", &docTypeNode);
```

This produces the following XML:

```
<?xml version="1.0"?>
<!DOCTYPE Personal SYSTEM "Personal.dtd">
<root/>
```

[CreateDocumentElement](#)

"CreateXmlDoc" (PeopleCode Language Reference)

GenFormattedXmlString

Syntax

```
GenFormattedXmlString()
```

Description

Use the GenFormattedXmlString method to return an XML string representing the XmlDoc object.

The GenFormattedXmlString method produces an XML string with new line characters and indents. If you want an unformatted XML string, that is, with all the data on a single line, use the GenXmlString method instead.

Parameters

None.

Returns

A formatted XML string.

Example

```
Local XmlDoc &inXMLDoc;
Local string &outStr;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><PSMessage/>");
&outStr = &inXMLDoc.GenFormattedXmlString();
```

Related Links

[GenXmlString](#)

GenXmlFile

Syntax

```
GenXmlFile(path)
```

Description

Use the `GenXmlFile` method to write the content of the `XmlDoc` object to a file. The XML output file will be in UTF-8 format, and its elements will be formatted and named exactly the same as the XML output from the `GenXmlString` method.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>path</i>	Specifies the absolute system path of the destination file.

Returns

A Boolean value: True, if the XML file was saved successfully, False otherwise.

Example

```
Local XmlDoc &xmldocRoot = CreateXmlDoc(" ");
Local XmlNode &nodeRoot = &xmldocRoot.CreateDocumentElement("root");
.
.
.
&result = &xmldocRoot.GenXmlFile("c:\data.xml");
```

Related Links

[GenFormattedXmlString](#)

GenXmlString

Syntax

```
GenXmlString()
```

Description

Use the `GenXmlString` method to return an XML string representing the `XmlDoc` object.

The `GenXmlString` method produces an XML string with all the data on a single line. If you want a formatted XML string, that is, with new line characters and indents, use the `GenFormattedXmlString` method instead.

Parameters

None.

Returns

An XML string.

Example

```
Local XmlDoc &inXMLDoc;
Local string &outStr;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><PSMessage/>");
&outStr = &inXMLDoc.GenXmlString();
```

Related Links

[GenFormattedXmlString](#)

GetElementsByTagName

Syntax

```
GetElementsByTagName (TagName)
```

Description

Use the `GetElementsByTagName` method to return an array of `XmlNode` objects that match the specified tag name.

If you specify an invalid tag name, an array is still returned, however, it has 0 elements in it.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TagName</i>	Specify the tag name that you want to look for.

Returns

An array of `XmlNode` objects.

Example

Using the following Xml structure:

```
<?xml version="1.0"?>
<PSmessage>
  <MsgData>
    <Transaction>
      <Record1 class="R">
        <Field1>one</Field1>
        <Field1>two</Field1>
        <Field1>three</Field1>
      </Record1>
    </Transaction>
  </MsgData>
</PSmessage>
```

The following code finds all of the *Field1* elements:

```
Local array of XmlNode &field1List;
```

```

&field1List = &inXMLDoc.GetElementsByTagName("Field1");

If &field1List.Len = 0 Then
    /* do error processing */
Else
    /* do processing */
End-If;

```

Related Links

[Understanding Arrays](#)

LoadIBContent

Syntax

```
LoadIBContent(Content[, RootTagName])
```

Description

Use LoadIBContent to load data into an XmlDoc object. This function is primarily used for display purposes, the main use is found in the Integration Broker Monitor for viewing message structures.

When *Content* is an XML string, the XmlDoc contains the DOM representation of the XML.

When *Content* is not an XML string, LoadIBContents generates a DOM wrapper.

Parameters

Parameter	Description
<i>Content</i>	Specify the content of the XmlDoc.
<i>RootTagName</i>	Specify the root tag name to be used in the XmlDoc object used as the wrapper, if the data is non-Xml. If a root tag name is not specified, and the data is non-Xml, the contents are not wrapped with the default of root tag name of PSMMessage.

Returns

This method returns a Boolean value that is always True.

Example

Using the following data:

```

John Q. Public,1234 West Eastland,925-987-0909
Jane Doe,423 Someplace,234-992-9383

```

The following PeopleCode program specifies a root name:

```
Local XmlDoc &inXMLDoc;
```

```

Local boolean &ret;
Local string &inStr;

&inStr = "John Q. Public,1234 West Eastland,925-987-0909" | Char(13) | "Jane Doe,42⇒
3 Someplace,234-992-9383";

&inXMLDoc = CreateXmlDoc("");
&ret = &inXMLDoc.LoadIBContent(&inStr, "Root");

```

This produces the following:

```

<?xml version="1.0"?>
<Root>
  <data PsNonXml="Yes">
    <![CDATA[John Q. Public,1234 West Eastland,925-987-0909
Jane Doe,423 Someplace,234-992-9383]]>
  </data>
</Root>

```

The following PeopleCode program does not specify a root name:

```

Local XmlDoc &inXMLDoc;
Local boolean &ret;
Local string &inStr;

&inStr = "John Q. Public,1234 West Eastland,925-987-0909" | Char(13) | "Jane Doe,42⇒
3 Someplace,234-992-9383";

&inXMLDoc = CreateXmlDoc("");
&ret = &inXMLDoc.LoadIBContent(&inStr);

```

This produces the following:

```

<?xml version="1.0"?>
<PSMessage>
  <data PsNonXml="Yes">
    <![CDATA[John Q. Public,1234 West Eastland,925-987-0909
Jane Doe,423 Someplace,234-992-9383]]>
  </data>
</PSMessage>

```

The following is an example of a valid XML document:

```

Local XmlDoc &inXMLDoc;
Local boolean &ret;
Local string &inStr;

&inStr = "<?xml version='1.0'?><root/>";

&inXMLDoc = CreateXmlDoc("");
&ret = &inXMLDoc.LoadIBContent(&inStr);

```

This produces the following:

```

<?xml version="1.0"?>
<root/>

```

ParseXmlFromURL

Syntax

```
ParseXmlFromURL(path [, DTDValidation])
```

Where *path* can have *one* of the following forms—a string URL, containing the filename and extension:

```
http://www.example.com/filename.ext
```

Or an absolute file path, including the filename and extension:

```
c:\directory\filename.ext
```

Note: HTTPS is not a supported protocol for *path*.

Description

Use the ParseXmlFromURL method to convert the XML file located at *path* into an XmlDoc object that you can then manipulate using PeopleCode. The XmlDoc object executing the method is populated with the XML string after it's been converted. Any data already existing in the XmlDoc object is overwritten.

Using this method also does basic validation of the XML string, comparing it to the document type declaration (DTD) if the DOCTYPE for the DTD is provided in the XML string.

Note: PeopleSoft only supports UTF-8 encoding. Therefore, if the input file is encoded, it must be encoded in UTF-8.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>path</i>	<p>Specify the URL or file path to the XML that file you want to manipulate. If you specify a string URL, the URL must be contained in quotation marks.</p> <hr/> <p>Note: HTTPS is not a supported protocol for <i>path</i>.</p> <hr/>
<i>DTDValidation</i>	<p>Specify whether to validate a document type definition (DTD.) This parameter takes a Boolean value. If you specify true, the DTD validation occurs if a DTD is provided. If you specify false, and if a DTD is provided, it is ignored and the XML isn't validated against the DTD. The default value for this parameter is false.</p> <p>In the case of application messaging, if a DTD is provided, it's always ignored and the XML isn't validated against the DTD.</p> <p>If the XML cannot be validated against a DTD, an error is thrown saying that there was an XML parse error.</p>

Returns

A Boolean value: True, the XML file converted successfully and was validated, False otherwise. (If the XML file is not valid, the PeopleCode program terminates.)

Example

The following PeopleCode program loads a file from a file path:

```
Local XmlDoc &inXMLDoc;
Local boolean &ret;

&inXMLDoc = CreateXmlDoc("");
&ret = &inXMLDoc.ParseXmlFromURL("c:\temp\in.xml");
```

The following PeopleCode program loads a file from a URL:

```
Local XmlDoc &inXMLDoc;
Local boolean &ret;

&inXMLDoc = CreateXmlDoc("");
&ret = &inXMLDoc.ParseXmlFromURL("http://www.example.com/xmlfile.xml");
```

Related Links

[ParseXmlString](#)

ParseXmlString

Syntax

```
ParseXmlString (XmlString)
```

Description

Use the ParseXmlString method to convert the XML string into an XmlDoc object that you can then manipulate using PeopleCode. The XmlDoc object executing the method is populated with the XML string after it's been converted. Any data already existing in the XmlDoc object is overwritten.

Using this method also does basic validation of the XML string, comparing it to the document type declaration (DTD) if the DOCTYPE for the DTD is provided in the XML string.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>XmlString</i>	Specify an XML string that you want to be able to manipulate using PeopleCode.

Returns

A Boolean value: True, the XML string converted successfully and was validated, False otherwise. (If the XML is not valid, the PeopleCode program terminates.)

Example

```
Local XmlDoc &inXMLDoc;
Local boolean &ret;
Local string &str;
```

```
&str = "<?xml version='1.0'?><root/>";

&inXMLDoc = CreateXmlDoc("");
&ret = &inXMLDoc.ParseXmlString(&str);

If &ret Then
    /* do processing */
Else
    /* do error processing */
End-If;
```

XmlDoc Properties

In this section, we discuss the XmlDoc properties. The properties are discussed in alphabetical order.

DocumentElement

Description

This property returns a reference to the root element of the document as an XmlNode.

This property is read-only.

Related Links

[XmlNode Class](#)

IsNull

Description

This property returns a Boolean value, indicating whether the doc is a valid object. This property returns True if the XmlDoc object is valid, False otherwise.

This property is read-only.

XmlNode Class

Unlike C++ and Java programming model, PeopleCode interface uses the root object XmlNode to represent all 11 different derived objects. An XmlNode object can be defined only as local.

XmlNode Class Methods

Add methods create a new node of the specific type, append this new node to the child list, and return this newly created node, while Insert methods add the node to the specified position.

In this section, we discuss the XmlNode methods. The methods are discussed in alphabetical order.

AddAttribute

Syntax

```
AddAttribute(Name, Value);
```

Description

Use the AddAttribute method to add an attribute to an XmlNode. A reference to the newly created attribute is returned.

If you specify an attribute name that already exists, the new value you use *replaces* the existing value, and a reference to the attribute is returned.

Attributes added by the AddAttribute method appear in an arbitrary order in the generated XML.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the Attribute that you want to create, as a string.
<i>Value</i>	Specify the value of the Attribute that you want to create, as a string.

Returns

None.

Example

Here is a set of XML response code.

```
<?xml version="1.0"?>
<myroot>
  <postreqresponse>
    <candidate>
      <user>
        <location scenery="great" density="low" blank="eh?" />
      </user>
    </candidate>
  </postreqresponse>
```

```
</myroot>
```

Here's the PeopleCode that builds it.

```
Local XmlDoc &inXMLDoc;
Local XmlNode &postReqNode;
Local XmlNode &candidatesNode;
Local XmlNode &userNode;
Local XmlNode &locationNode;
Local XmlNode &sceneryAtt;
Local XmlNode &densityAtt;
Local XmlNode &blankAtt;
Local boolean &ret;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><myroot/>");

&postReqNode = &inXMLDoc.DocumentElement.AddElement("postresponse");
&candidatesNode = &postReqNode.AddElement("candidates");
&userNode = &candidatesNode.AddElement("user");
&locationNode = &userNode.AddElement("location");

&locationNode.AddAttribute("scenery", "great");
&locationNode.AddAttribute("density", "low");
&locationNode.AddAttribute("blank", "eh?");
```

AddAttributeNS

Syntax

```
AddAttributeNS(NamespaceURI, AttributeName, Value)
```

where *NamespaceURI* can have *one* of the following forms:

```
URL.URLname
```

OR a string URL, such as

```
http://www.example.com/
```

Description

Use the AddAttributeNS method to add a namespace attribute to an XmlNode. The new attribute is appended to the list of child nodes.

A reference to the newly created attribute is returned.

If you specify an attribute name that already exists, the new value you use *replaces* the existing value, and a reference to the attribute is returned.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NamespaceURI</i>	Specify the URI that contains the Namespaces for the XmlDoc, as a string.
<i>AttributeName</i>	Specify the name of the Attribute that you want to create, as a string.
<i>Value</i>	Specify the value of the Attribute that you want to create, as a string.

Returns

None.

Example

```
Local XmlDoc &inXMLDoc;
Local XmlNode &childNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><myroot/>");
&childNode = &inXMLDoc.DocumentElement.AddElement("child");
&childNode.AddAttributeNS("http://www.example.com", "scenery", "great");
```

[IsNull](#)

AddCDATASection

Syntax

```
AddCDATASection (Data)
```

Description

Use the AddCDATASection to add a CDATA section to an XmlNode.

CDATA sections may occur anywhere character data may occur; they are used to escape blocks of text containing characters which would otherwise be recognized as markup.

To insert a CDATA section at a particular place in the list of nodes, use the InsertCDATASection method instead.

A reference to the newly created CDATA section is returned.

Note: You cannot use this method with a SoapDoc object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Data</i>	Specify the data to be included in the CDATA section as a string.

Returns

A reference to the newly created CDATA section.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &childNode;
Local XmlNode &cdataNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><myroot/>");
&childNode = &inXMLDoc.DocumentElement.AddElement("child");
&cdataNode = &childNode.AddCDATASection("testing...");
```

The preceding PeopleCode program produces the following:

```
<?xml version="1.0"?>
<myroot>
  <child>
    <![CDATA[testing...]]>
  </child>
</myroot>
```

Related Links

[InsertCDATASection](#)

AddComment

Syntax

```
AddComment (Text)
```

Description

Use the AddComment method to add a comment to an XmlNode. The new attribute is appended to the list of child nodes.

To insert a comment at a particular place in the list of nodes, use the InsertComment method instead.

A reference to the newly created comment is returned.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Text</i>	Specify the text to be used as the comment, as a string.

Returns

A reference to the newly created comment.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &childNode;
Local XmlNode &commentNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><myroot/>");
&childNode = &inXMLDoc.DocumentElement.AddElement("child");
&commentNode = &childNode.AddComment("This is an example of a comment.");
```

The preceding PeopleCode program produces the following XML:

```
<?xml version="1.0"?>
<myroot>
  <child>
    <!--This is an example of a comment.-->
  </child>
</myroot>
```

Related Links

[InsertComment](#)

AddElement

Syntax

```
AddElement (TagName)
```

Description

Use the AddElement method to add an element to the XmlNode. The new element is appended to the list of child nodes.

To insert an element at a particular place in the list of nodes, use the InsertElement method instead.

A reference to the newly created element is returned.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TagName</i>	Specify the tag for the new element that you are adding, as a string.

Returns

A reference to the newly created element.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &childNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><myroot/>");
&childNode = &inXMLDoc.DocumentElement.AddElement("child");
```

The preceding PeopleCode program produces the following XML:

```
<?xml version="1.0"?>
<myroot>
  <child/>
</myroot>
```

[InsertElement](#)

[GetElement](#)

[GetElementsByTagName](#)

AddElementNS

Syntax

```
AddElementNS(NamespaceURI, TagName)
```

Where *NamespaceURI* can have *one* of the following forms:

```
URL.URLName
```

Or a string URL, such as:

```
http://www.example.com/
```

Description

Use AddElementNS to add a namespace element to an XmlNode. The new element is appended to the list of child nodes.

To insert a Namespace element at a particular place in the list of nodes, use the `InsertElementNS` method instead. A reference to the newly created element is returned. If you specify an element name that already exists, the new value you use replaces the existing value, and a reference to the element is returned.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NamespaceURI</i>	Specify the URI that contains the Namespaces for the XmlDoc, as a string.
<i>TagName</i>	Specify the name of the Element that you want to create, as a string.

Returns

A reference to the newly created element if successful. If not successful, the `IsNull` property is set to `True`.

Example

```
Local XmlDoc &inXMLDoc;
Local XmlNode &childNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><myroot/>");
&childNode = &inXMLDoc.DocumentElement.AddElementNS("http://www.example.com", "child");
```

AddEntityReference

Syntax

AddEntityReference (*Name*)

Description

Use the `AddEntityReference` method to add an entity reference. An entity reference refers to the content of the named entity. The new entity reference is appended to the list of child nodes. In the generated XML, the entity reference is automatically prefaced with the `&` character and suffixed with a semi-colon.

The named entity must exist in the document type declaration (DTD).

To insert an entity reference at a particular place in the list of nodes, use the `InsertEntityReference` method instead.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the entity to which this reference refers to.

Returns

A reference to the newly created entity reference.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &childNode;
Local XmlNode &entityRef;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><myroot/>");
&childNode = &inXMLDoc.DocumentElement.AddElement("child");
&entityRef = &childNode.AddEntityReference("MyURL");
```

The preceding PeopleCode program produces the following XML:

```
<?xml version="1.0"?>
<myroot>
  <child>
    &MyURL; </child>
</myroot>
```

[InsertEntityReference](#)

AddNode

Syntax

```
AddNode (&XmlNode)
```

Description

Use the AddNode method to add an XmlNode to the XmlDoc. The new node is appended to the list of child nodes.

To insert a node at a particular place in the list of nodes, use the InsertNode method instead.

A reference to the newly created node is returned.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&XmlNode</i>	Specify an already instantiated XmlNode that you want to add.

Returns

None.

Example

```
Local XmlDoc &inXMLDoc, &firstDoc;
Local XmlNode &childNode;

&firstDoc = CreateXmlDoc("<?xml version='1.0'?><myroot><child><subchild/></child></=>
myroot>");
&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&childNode = &firstDoc.DocumentElement.FindNode("/child");
&inXMLDoc.DocumentElement.AddNode(&childNode);
```

AddProcessInstruction

Syntax

```
AddProcessInstruction(Target, Data)
```

Description

Use the AddProcessInstruction method to add a processing instruction to an XmlNode. The new process instruction is appended to the end of the child list.

To insert a processing instruction at a particular place, use the InsertProcessInstruction method instead.

A reference to the newly created processing instruction is returned.

Note: You cannot use this method with a SoapDoc object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Target</i>	Specify the application to which the instruction is directed, as a string.

Parameter	Description
<i>Data</i>	Specify the data used with the processing instruction.

Returns

A reference to the newly created processing instruction.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &procInst;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><myroot/>");
&procInst = &inXMLDoc.DocumentElement.AddProcessInstruction("xml-stylesheet", "href=>
=""book.css"" type=""text/css""");
```

The preceding PeopleCode program produces the following XML :

```
<?xml version="1.0"?>
<myroot>
  <?xml-stylesheet href="book.css" type="text/css"?>
</myroot>
```

[InsertProcessInstruction](#)

AddText

Syntax

AddText (*Data*)

Description

Use the AddText method to add a text node to an XmlNode.

Note: A text node is *not* the same as a text declaration. The text declaration is added automatically with the CreateXmlDoc function. A text node just contains text within an XmlDoc.

To insert a text node at a particular place, use the InsertText method instead.

A reference to the newly created text node is returned.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Data</i>	Specify the data to be used as the text node, as a string.

Returns

A reference to the newly created text node.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &childNode;
Local XmlNode &textNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><myroot/>");
&childNode = &inXMLDoc.DocumentElement.AddElement("child");
&textNode = &childNode.AddText("This is text");
```

The preceding PeopleCode program produces the following XML:

```
<?xml version="1.0"?>
<myroot>
  <child>This is text</child>
</myroot>
```

Related Links

[InsertText](#)

CopyNode

Syntax

```
CopyNode (&Node)
```

Description

Use the CopyNode method to copy a node specified by *&Node* and *all* of its child nodes into the current node, as a child node. The new node is appended to the end of the list of child nodes. The specified node can belong to a different XmlDoc.

If you just want to copy a top-level node, without copying its children, you can just create a new node with the name of the node you want.

Parameters

Parameter	Description
<i>&Node</i>	Specify an already instantiated node that you want to copy.

Returns

None.

Example

Suppose that your XmlDoc has the following structure:

```
<?xml version="1.0"?>
<myroot>
  <child>
    <subchild/>
  </child>
</myroot>
```

The following PeopleCode copies the node *child* and copies it into another doc.

```
Local XmlDoc &inXMLDoc, &firstDoc;
Local XmlNode &childNode;

&firstDoc = CreateXmlDoc("<?xml version='1.0'?><myroot><child><subchild/></child></=>
myroot>");
&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&childNode = &firstDoc.DocumentElement.FindNode("/child");
&inXMLDoc.DocumentElement.CopyNode (&childNode);
```

The following is the new structure:

```
<?xml version="1.0"?>
<root>
  <child>
    <subchild/>
  </child>
</root>
```

[FindNode](#)

[FindNodes](#)

FindNode

Syntax

FindNode (*Path*)

Description

Use the FindNode method to return a reference to an XmlNode.

The path is specified as the list of tag names, to the node that you want to find, each separated by a slash (/).

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Path</i>	Specify the tag names up to and including the name of the node that you want returned, starting with a slash and each separated by a slash (/). This is known as the XPath query language. See XML Path Language (XPath) Version 1.0 .

Returns

An XmlNode matching the path if successful. If not successful, the IsNull property on the XmlNode is set to True.

Example

Suppose your XmlDocument has the following structure:

```
<?xml version="1.0"?>
<myroot>
  <postreqresponse>
    <candidate>
      <user>
        <location scenery="great" density="low" blank="eh?" />
      </user>
    </candidate>
  </postreqresponse>
</myroot>
```

You want to return a reference to the location attribute. Use the following *Path* to do it:

```
&XmlNode = &MyDoc.FindNode("/myroot/postreqresponse/candidate/user/location");
```

Related Links

[GetChildNode](#)

[FindNodes](#)

FindNodes

Syntax

```
FindNodes (Path)
```

Description

Use the FindNodes method to return a reference to an array containing all the XmlNode objects that match the path.

The path is specified as the list of tag names, to the node that you want to find, each separated by a slash (/) when a namespace is not specified.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Path</i>	Specify the tag names up to and including the name of the node that you want returned, each separated by a slash (/). This is known as the XPath query language. See XML Path Language (XPath) Version 1.0 .

Returns

An array of XmlNode objects. If there is no match for the specified path, an array with 0 elements is returned.

Example

Using the following input:

```
<?xml version="1.0"?>
<PSmessage>
  <MsgData>
    <Transaction>
      <Record1 class="R">
        <Field1>one</Field1>
        <Field1>two</Field1>
        <Field1>three</Field1>
      </Record1>
    </Transaction>
  </MsgData>
</PSmessage>
```

The following PeopleCode program finds all of the *Field1* nodes:

```
Local array of XmlNode &field1List;

&field1List = &inXMLDoc.DocumentElement.FindNodes("MsgData/Transaction/Record1/Field1");

If &field1List.Len = 0 Then
  /* do error processing, no nodes returned */
Else
  /* do regular processing */
End-If;
```

[FindNode](#)

Understanding Arrays

GenXmlString

Syntax

```
GenXmlString()
```

Description

Use the GenXmlString method to generate an XML string of the XmlNode.

Parameters

None.

Returns

An XML String.

Example

```
&MyXML = &MyNode.GenXmlString();
```

GetAttributeName

Syntax

```
GetAttributeName (Index)
```

Description

Use the GetAttributeName method to return the specified attribute.

Parameters

Parameter	Description
<i>Index</i>	Specify an integer representing the attribute you want to access.

Returns

A string.

Example

```
Local XmlDoc &inXMLDoc;
```

```

Local string &attName;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&inXMLDoc.DocumentElement.AddAttribute("name", "Joe");
&inXMLDoc.DocumentElement.AddAttribute("address", "1234 West Eastland");

&attName = &inXMLDoc.DocumentElement.GetAttributeName(2);

```

GetAttributeValue

Syntax

```
GetAttributeValue({Name | Index})
```

Description

Use the GetAttributeValue method to return the specific attribute value, given an attribute name. The attribute name is case-sensitive, so you must specify the exact name.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i> <i>Index</i>	Specify the name or index of the attribute whose value you want to access.

Returns

A string containing the value of the specified attribute.

Example

```

Local XmlDoc &inXMLDoc;
Local string &attName;
Local string &attValue;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&inXMLDoc.DocumentElement.AddAttribute("name", "Joe");
&inXMLDoc.DocumentElement.AddAttribute("address", "1234 West Eastland");

&attName = &inXMLDoc.DocumentElement.GetAttributeName(2);
&attValue = &inXMLDoc.DocumentElement.GetAttributeValue(&attName);

```

GetCDATAValue

Syntax

```
GetCDATAValue()
```

Description

Use the GetCDATAValue method to return the *value* of the first CDATA section in an XmlNode.

Parameters

None.

Returns

A reference to the value of the first CDATA section as a string.

Example

```
Local XmlDoc &inXMLDoc;  
Local XmlNode &dataNode;  
Local XmlNode &cdataNode;  
Local string &theData;  
  
&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");  
&dataNode = &inXMLDoc.DocumentElement.AddElement("data");  
&cdataNode = &dataNode.AddCDATASection("this is a bunch of text");  
  
&theData = &dataNode.GetCDATAValue();
```

GetCDATAValues

Syntax

```
GetCDATAValues()
```

Description

Use the GetCDATAValues method to return an array of string containing the *values* of the CDATA section in an XmlNode.

Parameters

None.

Returns

An array of string.

Example

```
Local XmlDoc &inXMLDoc;  
Local XmlNode &dataNode;  
Local XmlNode &cdataNode;  
Local array of string &theData;  
  
&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
```

```

&dataNode = &inXMLDoc.DocumentElement.AddElement("data");
&cdataNode = &dataNode.AddCDataSection("this is a bunch of text");
&cdataNode = &dataNode.AddCDataSection("more text");
&cdataNode = &dataNode.AddCDataSection("still more text");

&theData = &dataNode.GetCDataValues();

```

GetChildNode

Syntax

```
GetChildNode(index)
```

Description

Use the GetChildNode method to return the specified child node of an XmlNode.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Index</i>	Specify an integer representing the child node that you want to access.

Returns

A reference to an XmlNode. If the specified XmlNode isn't found, the IsNull property for the XmlNode is set to True.

Example

```

Local XmlDoc &inXMLDoc;
Local XmlNode &dataNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&dataNode = &inXMLDoc.DocumentElement.AddElement("data");
&dataNode = &inXMLDoc.DocumentElement.AddElement("data2");

&dataNode = &inXMLDoc.DocumentElement.GetChildNode(2);

```

GetElement

Syntax

```
GetElement()
```

Description

Use the GetElement method to return the first child element node in the list of child nodes.

Parameters

None.

Returns

A reference to an element.

Example

```
Local XmlDoc &inXMLDoc;  
Local XmlNode &dataNode;  
  
&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");  
&dataNode = &inXMLDoc.DocumentElement.AddElement("data");  
&dataNode = &inXMLDoc.DocumentElement.AddElement("data2");  
  
&dataNode = &inXMLDoc.DocumentElement.GetElement();
```

GetElements

Syntax

```
GetElements()
```

Description

Use the GetElements method to return an array of all the XmlNode objects that are elements.

Parameters

None.

Returns

An array of XmlNode of all the element nodes. If there are no element nodes, an array with 0 elements is returned.

Example

```
Local XmlDoc &inXMLDoc;
Local XmlNode &dataNode;
Local array of XmlNode &dataList;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&dataNode = &inXMLDoc.DocumentElement.AddElement("data");
&dataNode = &inXMLDoc.DocumentElement.AddElement("data2");

&dataList = &inXMLDoc.DocumentElement.GetElements();

If &dataList.Len = 0 Then
    /* do error processing, no nodes returned */
Else
    /* do regular processing */
End-If;
```

[GetElementsByTagName](#)

[Understanding Arrays](#)

GetElementsByTagName

Syntax

```
GetElementsByTagName (TagName)
```

Description

Use the GetElementsByTagName method to return an array of XmlNode objects that match the specified tag name.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TagName</i>	Specify the tag name that you want to look for.

Returns

An array of XmlNode. If you specify an invalid tag name, the returned array has 0 elements.

Example

Using the following input:

```
<?xml version="1.0"?>
<PSmessage>
  <MsgData>
    <Transaction>
      <Record1 class="R">
        <Field1>one</Field1>
        <Field1>two</Field1>
        <Field1>three</Field1>
      </Record1>
    </Transaction>
  </MsgData>
</PSmessage>
```

The following PeopleCode program finds all *Field1* nodes:

```
Local array of XmlNode &field1List;

&field1List = &inXMLDoc.DocumentElement.GetElementsByTagName("Field1");

If &field1List.Len = 0 Then
  /* do error processing, no nodes returned */
Else
  /* do regular processing */
End-If;
```

GetElementsByTagNameNS

Syntax

GetElementsByTagNameNS(*NamespaceURI*, *TagName*)

Where *NamespaceURI* can have *one* of the following forms:

URL.*URLName*

Or a string URL, such as:

`http://www.example.com/`

Description

Use the `GetElementsByTagNameNS` method to return an array of `XmlNode` objects that match the specified namespace and qualified name.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>NamespaceURI</i>	Specify the URI that contains the Namespace for the XmlDocument, as a string.
<i>TagName</i>	Specify the name of the element that you want to retrieve.

Returns

An array of XmlNode. If you specify an invalid NamespaceURI, the returned array has 0 elements.

Example

Using the following input:

```
<?xml version="1.0"?>
<Psmessage xmlns="http://www.example.com">
  <MsgData>
    <Transaction>
      <Record1 class="R">
        <Field1>one</Field1>
        <Field1>two</Field1>
        <Field1>three</Field1>
      </Record1>
    </Transaction>
  </MsgData>
</Psmessage>
```

The following PeopleCode program finds all *Field1* nodes:

```
Local array of XmlNode &field1List;

&field1List = &inXMLDoc.DocumentElement.GetElementsByTagNameNS("http://www.example.⇒
com", "Field1");

If &field1List.Len = 0 Then
  /* do error processing, no nodes returned */
Else
  /* do regular processing */
End-If;
```

InsertCDATASection

Syntax

```
InsertCDATASection(Data, Position)
```

Description

Use the InsertCDATASection method to insert a CDATA section in an XmlNode, at the location specified by *Position*.

Note: You cannot use this method with a SoapDoc object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Data</i>	Specify the data for the CDATA section as a string.
<i>Position</i>	Specify where you want to insert the CDATA Section, as a number.

Returns

A reference to the newly created CDATA section.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &dataNode;
Local XmlNode &cdataNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&dataNode = &inXMLDoc.DocumentElement.AddElement("data");
&cdataNode = &dataNode.AddCDATASection("this is a bunch of text");
&cdataNode = &dataNode.AddCDATASection("still more text");

&cdataNode = &dataNode.InsertCDATASection("more text", 2);
```

This is the XML document before the insert:

```
<?xml version="1.0"?>
<root>
  <data>
    <![CDATA[this is a bunch of text]]>
    <![CDATA[still more text]]>
  </data>
</root>
```

This is the XML document after the insert:

```
<?xml version="1.0"?>
<root>
  <data>
    <![CDATA[this is a bunch of text]]>
    <![CDATA[more text]]>
    <![CDATA[still more text]]>
  </data>
</root>
```

InsertComment

Syntax

```
InsertComment(Data, Position)
```

Description

Use the `InsertComment` method to insert a comment in an `XmlNode` at the location specified by *Position*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Data</i>	Specify the data for the comment as a string.
<i>Position</i>	Specify where you want to insert the comment, as a number.

Returns

A reference to the newly created comment.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &dataNode;
Local XmlNode &commentNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&dataNode = &inXMLDoc.DocumentElement.AddElement("data");
&commentNode = &dataNode.AddComment("this is a comment");
&commentNode = &dataNode.AddComment("still another comment");

&commentNode = &dataNode.InsertComment("more comments", 2);
```

This is the XML document before the insert:

```
<?xml version="1.0"?>
<root>
  <data>
    <!--this is a comment-->
    <!--still another comment-->
  </data>
</root>
```

This is the XML document after the insert:

```
<?xml version="1.0"?>
<root>
  <data>
    <!--this is a comment-->
    <!--more comments-->
    <!--still another comment-->
  </data>
```

```
</root>
```

InsertElement

Syntax

```
InsertElement(TagName, Position)
```

Description

Use the InsertElement method to insert an element in an XmlNode at the location specified by *Position*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>TagName</i>	Specify the tagname for the element as a string.
<i>Position</i>	Specify where you want to insert the element, as a number.

Returns

A reference to the newly created element.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &dataNode;
Local XmlNode &elementNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&dataNode = &inXMLDoc.DocumentElement.AddElement("data");
&elementNode = &dataNode.AddElement("first");
&elementNode = &dataNode.AddElement("second");

&commentNode = &dataNode.InsertElement("third", 2);
```

This is the XML document before the insert:

```
<?xml version="1.0"?>
<root>
  <data>
    <first/>
    <second/>
  </data>
</root>
```

This is the XML document after the insert:

```
<?xml version="1.0"?>
<root>
  <data>
    <first/>
    <third/>
    <second/>
  </data>
</root>
```

InsertElementNS

Syntax

InsertElementNS (*NamespaceURI*, *TagName*, *Position*)

where *NamespaceURI* can have *one* of the following forms:

URL. *URLname*

OR a string URL, such as

`http://www.example.com/`

Description

Use `InsertElementNS` to insert a new element in an `XmlNode`, at the location specified by *Position*.

Parameters

Parameter	Description
<i>NamespaceURI</i>	Specify the URI that contains the Namespaces for the <code>XmlDoc</code> .
<i>TagName</i>	Specify the name of the element that you want to create, as a string.
<i>Position</i>	Specify where you want to insert the element, as a number.

Returns

A reference to the newly created element.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &dataNode;
Local XmlNode &elementNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root xmlns='http://www.example.com'=>
/>");
&dataNode = &inXMLDoc.DocumentElement.AddElement("data");
&elementNode = &dataNode.AddElement("first");
&elementNode = &dataNode.AddElement("second");

&elementNode = &dataNode.InsertElementNS("http://www.example.com", "third", 2);
```

This is the XML document before the insert:

```
<?xml version="1.0"?>
<root xmlns="http://www.example.com">
  <data>
    <first/>
    <second/>
  </data>
</root>
```

This is the XML document after the insert:

```
<?xml version="1.0"?>
<root xmlns="http://www.example.com">
  <data>
    <first/>
    <third/>
    <second/>
  </data>
</root>
```

InsertEntityReference

Syntax

InsertEntityReference (*Name*, *Position*)

Description

Use the InsertEntityReference method to add an entity reference. An entity reference refers to the content of the named entity.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Name</i>	Specify the name of the entity to which this reference refers to.
<i>Position</i>	Specify where you want to insert the entity reference, as a number.

Returns

A reference to the newly created entity reference.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &dataNode;
Local XmlNode &entityRef;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&dataNode = &inXMLDoc.DocumentElement.AddElement("data");
&entityRef = &dataNode.AddEntityReference("first");
&entityRef = &dataNode.AddEntityReference("second");

&entityRef = &dataNode.InsertEntityReference("third", 2);
```

This is the XML document before the insert:

```
<?xml version="1.0"?>
<root>
  <data>
    &first;&second;  </data>
</root>
```

This is the XML document after the insert:

```
<?xml version="1.0"?>
<root>
  <data>
    &first;&third;&second;  </data>
</root>
```

Related Links

[AddEntityReference](#)

InsertNode

Syntax

```
InsertNode (&NewNode, {&RefNode | Position})
```

Description

Use the `InsertNode` method to insert a new node. The node is inserted either before the node specified by *&RefNode*, or at the location specified by *Position*.

&NewNode refers to an already instantiated `XmlNode` object. You must create the node before you can insert it.

&RefNode refers to an already instantiated `XmlNode` object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>&NewNode</i>	Specify the name of an already instantiated XmlNode that you want to insert.
<i>&RefNode Position</i>	Specify either the name of an existing node or the location where you want the node to be inserted.

Returns

A reference to the newly inserted node.

Example

The following PeopleCode program inserts a node using a position:

```
Local XmlDoc &inXMLDoc, &firstDoc;
Local XmlNode &childNode;

&firstDoc = CreateXmlDoc("<?xml version='1.0'?><myroot><third><child/></third></myr⇒
oot>");
&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root><first/><second/></root>");
&childNode = &firstDoc.DocumentElement.FindNode("third");

&inXMLDoc.DocumentElement.InsertNode(&childNode, 2);
```

The following PeopleCode program inserts a node using a reference node:

```
Local XmlDoc &inXMLDoc, &firstDoc;
Local XmlNode &childNode, &secondNode;

&firstDoc = CreateXmlDoc("<?xml version='1.0'?><myroot><third><child/></third></myr⇒
oot>");
&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root><first/><second/></root>");
&childNode = &firstDoc.DocumentElement.FindNode("third");
&secondNode = &inXMLDoc.DocumentElement.FindNode("second");

&inXMLDoc.DocumentElement.InsertNode(&childNode, &secondNode);
```

The following is the XML document before the insert:

```
<?xml version="1.0"?>
<root>
  <first/>
  <second/>
</root>
```

The following is the XML document after the insert:

```
<?xml version="1.0"?>
<root>
  <first/>
  <third>
    <child/>
  </third>
  <second/>
```

```
</root>
```

InsertProcessInstruction

Syntax

```
InsertProcessInstruction(Target, Data, Position)
```

Description

Use the `InsertProcessInstruction` method to insert a processing instruction to an `XmlNode` at the location specified by *Position*.

Note: You cannot use this method with a `SoapDoc` object.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Target</i>	Specify the application to which the instruction is directed, as a string.
<i>Data</i>	Specify the data to be used with the instruction.
<i>Position</i>	Specify where you want to insert the process instruction, as a number.

Returns

A reference to the newly created processing instruction.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &procInst;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&procInst = &inXMLDoc.DocumentElement.AddProcessInstruction("first", "firstvalue");
&procInst = &inXMLDoc.DocumentElement.AddProcessInstruction("second", "secondvalue" =>
);

&procInst = &inXMLDoc.DocumentElement.InsertProcessInstruction("third", "thirdvalue =>
", 2);
```

This is the XML document before the insert:

```
<?xml version="1.0"?>
<root>
  <?first firstvalue?>
  <?second secondvalue?>
</root>
```

This is the XML document after the insert:

```
<?xml version="1.0"?>
<root>
  <?first firstvalue?>
  <?third thirdvalue?>
  <?second secondvalue?>
</root>
```

Related Links

[AddProcessInstruction](#)

InsertText

Syntax

```
InsertText(Data, Position)
```

Description

Use the InsertText method to insert a text node. The node is inserted at the location indicated by *Position*.

Note: A text node is *not* the same as a text declaration. The text declaration is added automatically with the CreateXmlDoc function. A text node just contains text within an XmlDoc.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Data</i>	Specify the data to be used for the text node, as a string.
<i>Position</i>	Specify where you want to insert the text node, as a number.

Returns

A reference to the newly created text node.

Example

For example:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &textNode;
```

```

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&textNode = &inXMLDoc.DocumentElement.AddText("first text");
&textNode = &inXMLDoc.DocumentElement.AddText("second text");

&textNode = &inXMLDoc.DocumentElement.InsertText("third text", 2);

```

This is the XML document before the insert:

```

<?xml version="1.0"?>
<root>
first textsecond text</root>

```

This is the XML document after the insert:

```

<?xml version="1.0"?>
<root>
first textthird textsecond text</root>

```

RemoveAllChildNode

Syntax

```
RemoveAllChildNode ()
```

Description

Use the `RemoveAllChildNode` method to remove all child nodes for an `XmlNode`.

Parameters

None.

Returns

None.

Example

For example:

```

Local XmlDoc &inXMLDoc;
Local XmlNode &elementNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&elementNode = &inXMLDoc.DocumentElement.AddElement("first");
&elementNode = &inXMLDoc.DocumentElement.AddElement("second");
&elementNode = &inXMLDoc.DocumentElement.AddElement("third");

&inXMLDoc.DocumentElement.RemoveAllChildNode ();

```

This is the XML document before the removal:

```

<?xml version="1.0"?>
<root>

```

```
<first/>
<second/>
<third/>
</root>
```

This is the XML document after the removal:

```
<?xml version="1.0"?>
<root/>
```

RemoveChildNode

Syntax

```
RemoveChildNode ({Position | Node})
```

Description

Use the RemoveChildNode method to remove the child node in an XmlNode specified by *Node*, or located at *Position*.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>Position Node</i>	Specify the child node that you want to delete, either using its position number or its name.

Returns

A reference to the removed XmlNode.

Example

The following PeopleCode program uses a position:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &elementNode, &removedNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&elementNode = &inXMLDoc.DocumentElement.AddElement("first");
&elementNode = &inXMLDoc.DocumentElement.AddElement("second");
&elementNode = &inXMLDoc.DocumentElement.AddElement("third");
```

```
&removedNode = &inXMLDoc.DocumentElement.RemoveChildNode(2);
```

The following PeopleCode program uses a reference node:

```
Local XmlDoc &inXMLDoc;
Local XmlNode &elementNode, &removedNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&elementNode = &inXMLDoc.DocumentElement.AddElement("first");
&elementNode = &inXMLDoc.DocumentElement.AddElement("second");
&elementNode = &inXMLDoc.DocumentElement.AddElement("third");

&elementNode = &inXMLDoc.DocumentElement.FindNode("/second");
&removedNode = &inXMLDoc.DocumentElement.RemoveChildNode(&elementNode);
```

This is the XML document before the removal:

```
<?xml version="1.0"?>
<root>
  <first/>
  <second/>
  <third/>
</root>
```

This is XML document after the removal:

```
<?xml version="1.0"?>
<root>
  <first/>
  <third/>
</root>
```

XmlNode Class Properties

The following are the XmlNode properties.

AttributesCount

Description

This property returns the number of attributes for an XmlNode, as a number.

This property is read-only.

Example

```
Local XmlDoc &inXMLDoc;
```

```

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&inXMLDoc.DocumentElement.AddAttribute("first", "John");
&inXMLDoc.DocumentElement.AddAttribute("last", "Public");
&inXMLDoc.DocumentElement.AddAttribute("address", "1234 West Eastland");

For &i = 1 To &inXMLDoc.DocumentElement.AttributesCount
    /* do some processing of the attributes here */
End-For;

```

ChildNodeCount

Description

This property returns the number of child nodes for an XmlNode, as a number.

This property is read-only.

Index

Description

This property returns the location (or position) of a node in the parent's child list, as a number. The root node always returns a 1.

This property is read-only.

IsNull

Description

This property returns a Boolean value, indicating whether the node is a valid node. Use this property to verify the value of the add or insert XmlNode methods.

This property is read-only.

Example

```

Local XmlDoc &inXMLDoc;
Local XmlNode &elementNode;

&inXMLDoc = CreateXmlDoc("<?xml version='1.0'?><root/>");
&elementNode = &inXMLDoc.DocumentElement.AddElement("first");

&elementNode = &inXMLDoc.DocumentElement.FindNode("/second");

If &elementNode.IsNull Then
    /* do some error processing here, will not find "second" */
End-If;

```

LocalName

Description

This property returns the local part of a namespace as a string. The local part is the second part of the namespace entry. If you want access to the first part of a namespace, use the Prefix property.

This property is read-only.

Related Links

[Prefix](#)

NamespaceURI

Description

This property returns a reference to the namespace URI as a string.

This property is read-only.

NextSibling

Description

This property returns the next child node in an XmlNode, as an XmlNode.

Use the IsNull property to verify that the XmlNode that is returned is valid.

This property is read-only.

Related Links

[IsNull](#)

NodeName

Description

This property returns the name of the XmlNode as a string. You can use this property to rename an XmlNode.

This property is read/write.

NodePath

Description

This property returns the path of the XmlNode, from the root.

This property is read-only.

NodeType

Description

This property returns the type of the XmlNode. You can use either a numeric value or a constant. The values are:

<i>Numeric Value</i>	<i>Constant Value</i>	<i>Description</i>
1	%ElementNode	Element node
2	%AttributeNode	Attribute node
3	%TextNode	Text node
4	%CDataSectionNode	CData section node
5	%EntityReferenceNode	Entity reference node
6	%EntityNode	Entity node
7	%ProcessingInstructionNode	Processing instruction node
8	%CommentNode	Comment node
9	%DocumentNode	Document node
10	%DocumentTypeNode	Document type node
11	%NotationNode	Notation node
12	%XmlDeclNode	XML DECL node

NodeValue

Description

This property returns the value of the XmlNode, as a string.

This property is read/write.

ParentNode

Description

This property returns a reference to the parent node for the XmlNode, as an XmlNode object.

Use the IsNull property to verify that the XmlNode that is returned is valid.

This property is read-only.

Related Links

[IsNull](#)

Prefix

Description

This property returns the prefix part of a namespace as a string. The prefix is the first part of the namespace entry. If you want access to the second part of a namespace, use the LocalName property.

This property is read-only.

Related Links

[LocalName](#)

PreviousSibling

Description

This property returns a reference to the previous node in the XmlNode, as an XmlNode object.

Use the IsNull property to verify that the XmlNode that is returned is valid.

This property is read-only.

[IsNull](#)

Using the XmlDocumentFactory Class

The XmlDocumentFactory class allows the processing of basic XML text strings that are otherwise too large to be loaded into a single XmlDocument instance.

The programmer sets specific node names to be searched for. The XmlDocumentFactory parses the input string looking for nodes that match said pattern. Once found, an XmlDocument object is created from that string using the found node as the root node of the new document.

Typical usage would be to traverse the entire input string looking for all such occurrences of the target string, creating new XmlDoc objects until no more can be created. In PeopleCode, that would look similar to this:

```
Local XmlDocFactory &theXmlDocFactory;
Local XmlDoc &theXmlDoc;
Local string &findString = "Transaction";

&theXmlDocFactory = CreateXmlDocFactory();

&returnbool = &theXmlDocFactory.SetStringToParse(&inputXmlString);

&theXmlDoc = &theXmlDocFactory.GetNextXmlDoc(&findString);

While ( Not &theXmlDoc.IsNull)

    rem do something with the XmlDoc;

    &theXmlDoc = &theXmlDocFactory.GetNextXmlDoc(&findString);

End-While;
```

In the preceding example, the `GetNextXmlDoc` method is called repeatedly until a null `XmlDoc` object is returned; this signifies that the `XmlDocFactory` object has reached the end of the input string.

There are two caveats when using the `XmlDocfactory` class:

- The input string must remain in scope for the duration of processing. Because such strings are typically large, the factory does not make a local copy of the string. It uses the original string passed to it. If the original string goes out of scope or becomes null, the factory processing will fail.
- The `XmlDocFactory` object must be declared as a local variable only. Component and global scope are not supported.

Related Links

"`CreateXmlDocFactory`" (PeopleCode Language Reference)

XmlDocFactory Class Methods

In this section, the `XmlDocFactory` class methods are presented in alphabetical order.

GetNextXmlDoc

Syntax

```
GetNextXmlDoc (nodeName)
```

Description

Use the `GetNextXmlDoc` method to retrieve the next XML subtree matching the given *nodeName* parameter.

The node name can be a single name, or a list of names separated by a forward slash. For example:

- "Transaction" returns an XML subtree with Transaction as the root.
- "Transaction/Date" returns an XML subtree in which Date has a parent node Transaction.

Matching occurs when a node name in the input string matches all of the characters in the *nodeName* parameter. For example:

- "Trans" matches nodes in the XML string with those leading characters. For example: Transaction, Transparent, and Transport.
- "Trans/Date" matches all Date nodes in the input string that have a parent like Transaction, Transparent, or Transport.

Finally, the wildcard * matches any node. Therefore, "Trans/Date/*" matches any node that has a parent matching Date, which in turn has a parent matching Trans.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>nodeName</i>	A case-sensitive string containing the identifier for the nodes to find

Returns

An XmlDoc object containing a matching XML subtree, in which case, the IsNull property of the XmlDoc object is set to False.

Otherwise, when nothing is found, the IsNull property of the XmlDoc object is set to True.

Example

```

Local XmlDocFactory &theXmlDocFactory;
Local XmlDoc &theXmlDoc;
Local string &findString = "Transaction";

&theXmlDocFactory = CreateXmlDocFactory();

&returnbool = &theXmlDocFactory.SetStringToParse(&inputXmlString);

&theXmlDoc = &theXmlDocFactory.GetNextXmlDoc(&findString);

While ( Not &theXmlDoc.IsNull)
    rem do something with the XmlDoc;
    &theXmlDoc = &theXmlDocFactory.GetNextXmlDoc(&findString);
End-While;

```

[IsNull](#)

SetNamespaceString

Syntax

`SetNamespaceString(namespaceString)`

Description

For certain XML structures, namespace declarations are separate from nodes using those namespaces. The `SetNamespaceString` method allows a namespace string to be inserted back into the output document. If this operation is not performed, there can be parsing errors when the output `XmlDoc` is created.

For example, the following is the input XML to the `XmlDocFactory` object:

```
<?xml version="1.0"?>
<ns1:transaction xmlns:qed="http://www.blue.com" xmlns:ns1="http://www.transaction.⇒
com">
  <purchaseOrder>
    <qed:electronics>
      <item>TV</item>
    </qed:electronics>
  </purchaseOrder>
</ns1:transaction>
```

The `GetNextXmlDoc` method is used to extract the electronics subtree:

```
<?xml version="1.0"?>
<qed:elecronics>
  <item>TV</item>
</qed:elecronics>
```

The resulting XML is actually invalid, as the namespace information for the prefix `qed` has been lost.

The following invocation of the `SetNamespaceString` method results in the namespace info being re-added:

```
&theXmlDocFactory.SetNamespaceString(" xmlns:qed='http://www.blue.com' ")
```

Important! There should be leading and trailing spaces in the namespace parameter being set.

The resulting XML document can be parsed:

```
<?xml version="1.0"?>
<qed:elecronics xmlns:qed="http://www.blue.com">
  <item>TV</item>
</qed:elecronics>
```

Parameters

<i>Parameter</i>	<i>Description</i>
<i>namespaceString</i>	<p>The namespace string to be added back into the XML document.</p> <hr/> <p>Important! There should be leading and trailing spaces in the namespace parameter being set.</p> <hr/>

Returns

A Boolean value: True if the namespace string is set, False otherwise.

Example

```

Local XmlDocFactory &theXmlDocFactory;
&theXmlDocFactory = CreateXmlDocFactory();
&returnbool = &theXmlDocFactory.SetStringToParse(&inputXmlString);
&returnbool = &theXmlDocFactory.SetNamespaceString(" xmlns:qed='http://www.blue.com⇒
' ");
Local XmlDoc &theXmlDoc;
&theXmlDoc = &theXmlDocFactory.GetNextXmlDoc("qed:elec");
While ( Not &theXmlDoc.IsNull)
    rem do something with the XmlDoc;
    &theXmlDoc = &theXmlDocFactory.GetNextXmlDoc(&findString);
End-While;

```

SetStringToParse

Syntax

```
SetStringToParse (xmlstring)
```

Description

Use the SetStringToParse method to set the XML string to be parsed by the XmlDocFactory object.

The XmlDocFactory class is not a full-featured XML parser. Strings to be parsed must be well-formed XML; otherwise the parsing will not work. In addition, the XmlDocFactory does not make a copy of the string to be parsed; as a result the string must remain in scope for the duration of processing.

Parameters

<i>Parameter</i>	<i>Description</i>
<i>xmlstring</i>	A string containing well-formed XML.

Returns

A Boolean value: True if the XML string is set, False otherwise.

Example

```
Local XmlDocFactory &theXmlDocFactory;  
&theXmlDocFactory = CreateXmlDocFactory();  
&returnbool = &theXmlDocFactory.SetStringToParse(&inputXmlString);  
Local XmlDoc &theXmlDoc;  
&theXmlDoc = &theXmlDocFactory.GetNextXmlDoc("Transaction");
```

Quick Reference for PeopleCode Classes

Deprecated Items and PeopleCode No Longer Supported

This section discusses deprecated items and PeopleCode that is no longer supported.

Deprecated Products and Classes

The following products and their supporting classes have been deprecated:

- BPEL support
 - AsyncFFSend class
 - BPELUtil class
 - IBUtil class
- Instant Messaging (MCF)
 - MCFIMInfo class and methods
 - MCFIMSingleButton class, methods, and properties
- Mobile Application Platform
 - Map class, methods, and properties
 - MapPage class, methods, and properties
 - MapElement class, methods, and properties
 - MapFluid class and methods

For a complete list of deprecated methods and properties, see [Deprecated Mobile Application Platform Items](#).

- Oracle Policy Automation
 - ProcessRequest class
 - ProcessRequest method
- PeopleSoft Business Interlinks
 - Business Interlinks class
 - BIDocs class
- PeopleSoft Mobile Agent
 - Mobile class
 - PropertyInfo collection
 - CI collection
 - Data collection
 - ListViewAttrs class

- PropertyAttrs class
- PeerDefaultAttributes class
- SyncServer class

- Verity search classes
 - SearchQuery class.
 - ParseResult collection.
 - ParseResult class.
 - SearchResult collection.
 - SearchResult class.
 - SearchField collection.
 - SearchField class.
 - SearchIndex collection.
 - SearchIndex class.
 - SearchRecord Options class.
 - SearchRecordField collection.
 - SearchRecordField class.
 - Search Language collection.
 - Search Language class.
 - Search Schedule collection.
 - Search Schedule class.
 - Search HTTP Options class.
 - Search FS Options class.
 - Search Start Options collection.
 - Search Start Options class.

Deprecated Functions, Methods, and Properties

The following are the built-in functions, methods, properties that have been deprecated.

Method or Property	Use Instead

Chart Items No Longer Supported

In PeopleTools 8.57, the DialGauge class including its methods and properties is not supported.

Deprecated BI Publisher Items

As of PeopleTools 8.50, a number of BI Publisher (formerly XML Publisher) classes, methods and properties have been deprecated. These items remain in PeopleTools for backward compatibility only.

Deprecated BI Publisher Methods

<i>Deprecated Method</i>	<i>Use Instead</i>
ReportDefn class, SetRuntimeDataRowset method <hr/> Note: The rowset data source has been deprecated.	Convert the rowset to an XML file—for example, using the file layout capabilities of the File class is one way to accomplish this. Then, use the SetRuntimeDataXMLFile method of the ReportDefn class to process the XML file as a data source.
ReportDefn class, SetRuntimeDataXMLDoc method <hr/> Note: The XmlDoc data source has been deprecated.	Convert the XmlDoc object to an XML file—for example, using the genXmlFile method of the XmlDoc class is one way to accomplish. Then, use the SetRuntimeDataXMLFile method of the ReportDefn class to process the XML file as a data source.
<hr/> Note: The rowset data source has been deprecated. <hr/> RowsetDS class: <ul style="list-style-type: none"> • AddXMLData method • AddXSDSchema method • GetXMLData method • GetXSDSchema method • RowsetDS method 	Convert the rowset to an XML file—for example, using the file layout capabilities of the File class is one way to accomplish this. Then, use the SetRuntimeDataXMLFile method of the ReportDefn class to process the XML file as a data source.

Deprecated BI Publisher Properties

<i>Deprecated Property</i>	<i>Use Instead</i>
OutputEditable	Use the Report Definition-Definition page (PSXPRPTPROP) to set report properties to override global properties.

BI Publisher Items No Longer Supported

As of PeopleTools 8.50, a number of BI Publisher (formerly XML Publisher) classes, methods and properties are no longer supported. These items remain in PeopleTools for PeopleSoft internal use only and should not be implemented in PeopleCode programs.

- All methods and properties of the DataSourceDefn class.
- Certain methods and properties of the ReportDefn class.
- All methods and properties of the TemplateDefn class.

- All methods and properties of the TemplateFile class.
- All methods and properties of the TranslationFile class.
- All methods of the XMLPManager class.
- All methods of the QueryDS class.
- All methods and properties of the EFTPProcessor class.
- All methods and properties of the FOProcessor class.
- All methods and properties of the FormProcessor class.
- All methods and properties of the FOUtility class.
- All methods and properties of the PDFMapTool class.
- All methods and properties of the RTFProcessor class.

DataSourceDefn Class Methods

Method	Use Instead
DataSourceDefn(<i>DataSourceID, DataSourceType, Public</i>)	NA

Deprecated Messaging PeopleCode Functions, Methods and Properties

In PeopleTools 8.48, messaging changed significantly. Many of the messaging PeopleCode functions, methods and properties are either deprecated or no longer supported, or their syntax changed.

See [Understanding Message Classes](#).

See "PeopleSoft Integration Broker Metadata" (Integration Broker).

Changed Messaging PeopleCode

The following are still valid, however, their syntax changed significantly.

- CreateMessage built-in function
- IntBroker class, GetMessageErrors method
- IntBroker class, SetMessageError method

Deprecated Messaging PeopleCode Built-in Functions

The following table lists the deprecated messaging PeopleCode built-in functions, as well as the method that should be used instead.

<i>Deprecated Function</i>	<i>Replacement Method</i>
CancelPubHeaderXmlDoc	IntBroker class method Cancel, specifying a message type of %IntBroker_BRK
CancelPubXmlDoc	IntBroker class method Cancel, specifying a message type of %IntBroker_PUB
CancelSubXmlDoc	IntBroker class method Cancel, specifying a message type of %IntBroker_SUB
ConnectorRequest	IntBroker class method ConnectorRequest
ConnectorRequestURL	IntBroker class method ConnectorRequestURL
GetMessage	IntBroker class method GetMessage
GetMessageXmlDoc	Message class method GetXmlDoc
GetPubHeaderXmlDoc	IntBroker class method GetMessage specifying a message type of %IntBroker_BRK
GetPubXmlDoc	IntBroker class method GetMessage specifying a message type of %IntBroker_PUB
GetSubXmlDoc	IntBroker class method GetMessage specifying a message type of %IntBroker_SUB

<i>Deprecated Function</i>	<i>Replacement Method</i>
GetSyncLogData	IntBroker class method GetSyncLogData
InBoundPublishXmlDoc	IntBroker class method InboundPublish
IsMessageActive	IntBroker class method IsOperationActive
PublishXmlDoc	IntBroker class method Publish
ReSubmitPubHeaderXmlDoc	IntBroker class method Resubmit specifying a message type of %IntBroker_BRK
ReSubmitPubXmlDoc	IntBroker class method Resubmit specifying a message type of %IntBroker_PUB
ReSubmitSubXmlDoc	IntBroker class method Resubmit specifying a message type of %IntBroker_SUB
SetChannelStatue	IntBroker class method SetQueueStatus
SyncRequestXmlDoc	IntBroker class method SyncRequest
UpdateXmlDoc	IntBroker class method UpdateXmlDoc

The following built-in functions are no longer supported. You will receive an error if you try to use them in a PeopleCode program.

- CreateWSDLMessage
- GetArchPubHeaderXmlDoc
- GetArchPubXmlDoc
- GetArchSubXmlDoc
- GetArchSubXmlDoc
- GetArchSyncLogData
- GetSyncLogData

Note: ReturnToServer is a special case of a built-in function that's no longer supported. The deprecated handler for OnRequest subscriptions cannot be upgraded. ReturnToServer can only be used in an OnRequest event fired using the deprecated handler. This means that ReturnToServer no longer works and is not valid in any case other than when the code has already been written and used in a deprecated handler.

Deprecated Message Class Methods and Properties

The following are the Message class methods and properties that have been deprecated.

<i>Deprecated Method</i>	<i>Replacement Method</i>
GetQueryString	IBConnectorInfo collection GetQueryStringArgName method
InBoundPublish	IntBroker class InBoundPublish method
Publish	IntBroker class Publish method
SetQueryString	IBConnectorInfo collection AddQueryStringArg method
SetStatus	IntBroker class SetStatus method
SyncRequest	IntBroker class SyncRequest method
Update	IntBroker class Update method

The following are the Message class properties that have been deprecated.

<i>Deprecated Property</i>	<i>Replacement Property</i>
ChannelName	Message class QueueName property
Cookies	IBConnectorInfo collection Cookies property
DefaultMessageVersion	Message class OperationVersion property
GUID	Message class TransactionId property
IsActive	Message class IsOperationActive property
PubId	Message class QueueSeqId property

<i>Deprecated Property</i>	<i>Replacement Property</i>
SubName	Message class ActionName property
SubscriptionProcessId	Message class TransactionId property
MessageChannel	IBInfo class MessageQueue property
MessageType	IBInfo class OperationType property

The following Message class properties are no longer supported. You will receive an error if you try to use them in your PeopleCode program.

- MessageDetail
- PublicationId

Additional Messaging Deprecated Methods and Properties

The following additional methods and properties are either deprecated or no longer supported:

- The IBInfo class method LoadConnectorPropFromTrx is no longer supported.
- The IBInfo class MessageChannel property has been deprecated. Use the IBInfo class MessageQueue property instead.
- The IBInfo class PublicationID property is no longer supported.

Integration Broker Web Service Discovery Class No Longer Supported

The Integration Broker Web Service Discovery class is no longer supported. The following methods are empty and should not be used.

- FindCIWebServices
- FindMsgWebServices
- FindWebServices
- GetCIWebServiceWSDL
- GetMsgWebServiceWSDL
- GetWSDL

Functions No Longer Supported

The following functions no longer work. You will receive an error if you try to use them in your PeopleCode program.

Function	Description
%MessageAgent	Used with Message Agent activities
ChDir	Used only on the client with DOS
ChDrive	Used only on the client with DOS
CheckMenuItem	Used with menu items
Codeb	Used before true Unicode integration
DBCSTrim	Used before true Unicode integration
Findb	Used before true Unicode integration
GetControl	Used with ActiveX controls
GetControlOccurence	Used with ActiveX controls
GetCwd	Used only on the client with DOS
GetMessageInstance	Used with messaging
GetPubContractInstance	Used with messaging
GetSelectedTreeNode	Used with dynamic trees
GetSubContractInstance	Used with messaging
GetTreeNodeParent	Used with dynamic trees
GetTreeNodeRecordName	Used with dynamic trees
IsDisconnectedClient	Used with PeopleSoft Mobile Agent.
MSFGetNextNumber	Used with PeopleSoft Mobile Agent.
Lenb	Used before true Unicode integration
RefreshTree	Used with dynamic trees

Function	Description
ScheduleProcess	Used with PeopleSoft Process Scheduler
Substringb	Used before true Unicode integration
UnCheckMenuItem	Used with menu items
WinEscape	Used only on client
WinExec	Used only on client

Deprecated Built-in Functions from Prior to PeopleTools 8.0

The first column in the following table lists built-in PeopleCode functions that existed prior to PeopleTools 8.0. The second column lists the new method or property that should be used instead of the deprecated function. The existing functions still work in PeopleTools 8.0, however, they are being retained for backward compatibility only. New applications should be created using the new classes, methods, and properties.

Deprecated Function	Use Instead
ActiveRowCount	Rowset class, ActiveRowCount property
ClearSearchDefault	Field class, SearchDefault property
ClearSearchEdit	Field class, SearchEdit property
CompareLikeFields	Record class, CompareFields method
CopyFields	Record class, CopyFieldsTo method or CopyChangedFieldsTo method
CopyRow	Row class, CopyTo method
CurrEffDt	Rowset class, DeleteEnabled property
CurrEffRowNum	Row class, RowNumber property in combination with Rowset class, GetCurrEffRow method
CurrEffSeq	Rowset class, EffSeq property
CurrentRowNumber	Row class, RowNumber property

<i>Deprecated Function</i>	<i>Use Instead</i>
DeleteRecord	Record class, Delete method
DeleteRow	Rowset class, DeleteRow method
FetchValue	Field class, Value property
FieldChanged	Field class, IsChanged property
GetRelField	Field class, GetRelated method
GetStoredFormat	Field class, StoredFormat property
Gray	Field class, Enabled property
Hide	Field class, Visible property
HideRow	Row class, Visible property
HideScroll	Rowset class, HideAllRows method
InsertRow	Rowset class, InsertRow method
IsHidden	Row class, Visible property
NextEffDt	GetNextEffRow().REC.FIELD.Value
NextRelEffDt	GetNextEffRow().REC.FIELD.GetRelated(rec.field).value
PriorEffDt	GetPriorEffRow().REC.Field.Value
PriorRelEffDt	GetPriorEffRow().REC.FIELD.GetRelated(rec.field).value
RecordChanged	Record class, IsChanged property
RecordDeleted	Record class, IsDeleted property
RecordNew	Row class, IsNew property
RemoteCall for Application Engine	CallAppEngine function

<i>Deprecated Function</i>	<i>Use Instead</i>
RowFlush	Rowset class, FlushRow method
RowScrollSelect	Rowset class, Select method
RowScrollSelectNew	Rowset class, SelectNew method
ScrollFlush	Rowset class, Flush method
ScrollSelect	Rowset class, Select method
ScrollSelectNew	Rowset class, SelectNew method
SetDefault	Field class, SearchDefault property
SetDefaultAll	Rowset class, SetDefault method
SetDefaultNext	GetNextEffRow().REC.FIELD.SetDefault()
SetDefaultNextRel	GetNextEffRow().REC.Field.GetRelated(REC.FIELD).SetDefault()
SetDefaultPrior	GetPriorEffRow().REC.FIELD.SetDefault()
SetDefaultPriorRel	GetPriorEffRow().REC.Field.GetRelated(REC.FIELD).SetDefault()
SetDisplayFormat	Field class, DisplayFormat property
SetLabel	Field class, Label property
SetSearchDefault	Field class SearchDefault property
SetSearchEdit	Field class, SearchEdit property
SetTracePC	If using API (Session object), use Trace Setting class properties.
SetTraceSQL	If using API (Session object), use Trace Setting class properties.
SortScroll	Rowset class, Sort method

<i>Deprecated Function</i>	<i>Use Instead</i>
TotalRowCount	Rowset class, RowCount property
Ungray	Field class, Enabled property
UnHide	Field class, Visible property
UnHideRow	Row class, Visible property
UnhideScroll	Rowset class, ShowAllRows method
UpdateValue	Field class, Value property

Mapping PeopleTools 8.1 Objects to New Objects

In PeopleTools 8.1, the names of some of the object definitions in Application Designer changed. The names of related built-in functions have changed accordingly.

The first table lists the old terms and new terms.

In the second table, the left column lists the old names of the functions, system variables, or reserved words. The right column lists the new names. The old functions, system variables, and reserved words in this table still work in PeopleTools; however, they have been deprecated and are being retained for backward compatibility only. New applications should be created using the new functions, system variables, and reserved words.

<i>Old Term</i>	<i>New Term</i>
Operator	User
Panel	Page
Panel Group	Component
Business Component	Component Interface

<i>Deprecated Function, System Variable or Reserved Word</i>	<i>New Function, System Variable or Reserved Word</i>
DoModalPanelGroup built-in function	DoModalComponent built-in function
GetNextNumberWithGaps	GetNextNumberWithGapsCommit built-in function

Deprecated Function, System Variable or Reserved Word	New Function, System Variable or Reserved Word
IsModalPanelGroup built-in function	IsModalComponent built-in function
IsOperatorInClass built-in function	IsUserInPermissionList built-in function
PanelGroupChanged built-in function	ComponentChanged built-in function
ScheduleProcess built-in function	CreateProcessRequest built-in function
SetNextPanel built-in function	SetNextPage built-in function
TransferPanel built-in function	TransferPage built-in function
%OperatorClass System Variable	%PrimaryPermissionList System Variable
%OperatorID System Variable	%UserId System Variable
%OperatorRowLevelSecurityClass System Variable	%RowSecurityPermissionList System Variable
%Panel System Variable	%Page System Variable
%PanelGroup System Variable	%Component System Variable
PANEL reserved word	PAGE reserved word
PANELGROUP reserved word	COMPONENT reserved word
PanelGroup variable declaration	Component variable declaration

Business Components are now named Component Interfaces. Therefore, for Component Interfaces, the old reserved word, methods, and system variables *are no longer valid*. You *must* use the new reserved word, methods, or system variables.

No Longer Valid	Use Instead
COMPONENT reserved word	COMPINTFC reserved word
GetComponent method	GetCompIntfc method
FindComponent method	FindCompIntfcs method

<i>No Longer Valid</i>	<i>Use Instead</i>
%Component system variable	%CompIntfc system variable
