January 2024

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software, software documentation, data (as defined in the Federal Acquisition Regulation), or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software," "commercial computer software documentation," or "limited rights data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle®, Java, MySQL, and NetSuite are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

## **Documentation Accessibility**

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <https://docs.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

## **Access to Oracle Support**

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit <https://docs.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <https://docs.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

# Preface

---

## Understanding the PeopleSoft Online Help and PeopleBooks

The PeopleSoft Online Help is a website that enables you to view all help content for PeopleSoft applications and PeopleTools. The help provides standard navigation and full-text searching, as well as context-sensitive online help for PeopleSoft users.

### Hosted PeopleSoft Online Help

You can access the hosted PeopleSoft Online Help on the [Oracle Help Center](#). The hosted PeopleSoft Online Help is updated on a regular schedule, ensuring that you have access to the most current documentation. This reduces the need to view separate documentation posts for application maintenance on My Oracle Support. The hosted PeopleSoft Online Help is available in English only.

To configure the context-sensitive help for your PeopleSoft applications to use the Oracle Help Center, see [Configuring Context-Sensitive Help Using the Hosted Online Help Website](#).

### Locally Installed PeopleSoft Online Help

If you're setting up an on-premises PeopleSoft environment, and your organization has firewall restrictions that prevent you from using the hosted PeopleSoft Online Help, you can install the online help locally. Installable PeopleSoft Online Help is made available with selected PeopleSoft Update Images and with PeopleTools releases for on-premises installations, through the [Oracle Software Delivery Cloud](#).

Your installation documentation includes a chapter with instructions for how to install the online help for your business environment, and the documentation zip file may contain a README.txt file with additional installation instructions. See *PeopleSoft 9.2 Application Installation* for your database platform, "Installing PeopleSoft Online Help."

To configure the context-sensitive help for your PeopleSoft applications to use a locally installed online help website, see [Configuring Context-Sensitive Help Using a Locally Installed Online Help Website](#).

### Downloadable PeopleBook PDF Files

You can access downloadable PDF versions of the help content in the traditional PeopleBook format on the [Oracle Help Center](#). The content in the PeopleBook PDFs is the same as the content in the PeopleSoft Online Help, but it has a different structure and it does not include the interactive navigation features that are available in the online help.

### Common Help Documentation

Common help documentation contains information that applies to multiple applications. The two main types of common help are:

- Application Fundamentals

- Using PeopleSoft Applications

Most product families provide a set of application fundamentals help topics that discuss essential information about the setup and design of your system. This information applies to many or all applications in the PeopleSoft product family. Whether you are implementing a single application, some combination of applications within the product family, or the entire product family, you should be familiar with the contents of the appropriate application fundamentals help. They provide the starting points for fundamental implementation tasks.

In addition, the *PeopleTools: Applications User's Guide* introduces you to the various elements of the PeopleSoft Pure Internet Architecture. It also explains how to use the navigational hierarchy, components, and pages to perform basic functions as you navigate through the system. While your application or implementation may differ, the topics in this user's guide provide general information about using PeopleSoft applications.

## Field and Control Definitions

PeopleSoft documentation includes definitions for most fields and controls that appear on application pages. These definitions describe how to use a field or control, where populated values come from, the effects of selecting certain values, and so on. If a field or control is not defined, then it either requires no additional explanation or is documented in a common elements section earlier in the documentation. For example, the Date field rarely requires additional explanation and may not be defined in the documentation for some pages.

## Typographical Conventions

The following table describes the typographical conventions that are used in the online help.

| <b><i>Typographical Convention</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                                   |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Key+Key</b>                         | Indicates a key combination action. For example, a plus sign (+) between keys means that you must hold down the first key while you press the second key. For <b>Alt+W</b> , hold down the <b>Alt</b> key while you press the <b>W</b> key. |
| <b>. . . (ellipses)</b>                | Indicate that the preceding item or series can be repeated any number of times in PeopleCode syntax.                                                                                                                                        |
| <b>{ } (curly braces)</b>              | Indicate a choice between two options in PeopleCode syntax. Options are separated by a pipe ( ).                                                                                                                                            |
| <b>[ ] (square brackets)</b>           | Indicate optional items in PeopleCode syntax.                                                                                                                                                                                               |
| <b>&amp; (ampersand)</b>               | When placed before a parameter in PeopleCode syntax, an ampersand indicates that the parameter is an already instantiated object.<br><br>Ampersands also precede all PeopleCode variables.                                                  |

| <b><i>Typographical Convention</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                          |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ⇒                                      | This continuation character has been inserted at the end of a line of code that has been wrapped at the page margin. The code should be viewed or entered as a single, continuous line of code without the continuation character. |

## ISO Country and Currency Codes

PeopleSoft Online Help topics use International Organization for Standardization (ISO) country and currency codes to identify country-specific information and monetary amounts.

ISO country codes may appear as country identifiers, and ISO currency codes may appear as currency identifiers in your PeopleSoft documentation. Reference to an ISO country code in your documentation does not imply that your application includes every ISO country code. The following example is a country-specific heading: "(FRA) Hiring an Employee."

The PeopleSoft Currency Code table (CURRENCY\_CD\_TBL) contains sample currency code data. The Currency Code table is based on ISO Standard 4217, "Codes for the representation of currencies," and also relies on ISO country codes in the Country table (COUNTRY\_TBL). The navigation to the pages where you maintain currency code and country information depends on which PeopleSoft applications you are using. To access the pages for maintaining the Currency Code and Country tables, consult the online help for your applications for more information.

## Region and Industry Identifiers

Information that applies only to a specific region or industry is preceded by a standard identifier in parentheses. This identifier typically appears at the beginning of a section heading, but it may also appear at the beginning of a note or other text.

Example of a region-specific heading: "(Latin America) Setting Up Depreciation"

### Region Identifiers

Regions are identified by the region name. The following region identifiers may appear in the PeopleSoft Online Help:

- Asia Pacific
- Europe
- Latin America
- North America

### Industry Identifiers

Industries are identified by the industry name or by an abbreviation for that industry. The following industry identifiers may appear in the PeopleSoft Online Help:

- USF (U.S. Federal)

- E&G (Education and Government)

## Translations and Embedded Help

PeopleSoft 9.2 software applications include translated embedded help. With the 9.2 release, PeopleSoft aligns with the other Oracle applications by focusing our translation efforts on embedded help. We are not planning to translate our traditional online help and PeopleBooks documentation. Instead we offer very direct translated help at crucial spots within our application through our embedded help widgets. Additionally, we have a one-to-one mapping of application and help translations, meaning that the software and embedded help translation footprint is identical—something we were never able to accomplish in the past.

---

## Using and Managing the PeopleSoft Online Help

Select About This Help in the left navigation panel on any page in the PeopleSoft Online Help to see information on the following topics:

- Using the PeopleSoft Online Help.
- Managing hosted Online Help.
- Managing locally installed PeopleSoft Online Help.

## Chapter 1

# Activity Guide Classes

---

## Understanding the Activity Guide Classes

Activity guides are a PeopleTools feature that allow you to define guided procedures for a user or group of users to complete. Users are presented with a list of actions, or tasks, that need to be completed to finish the procedure. The activity guide classes documented in these topics provide you with a programmatic interface to manage and manipulate activity guide templates, activity guide instances, action items, participants, and so on. In addition, some of these activity guide classes can be used to customize and extend your implementation of activity guides.

---

## Importing Activity Guide Classes

The activity guide classes are application classes, not built-in classes, like Rowset, Field, Record, and so on. Before you can use these classes in your PeopleCode program, you must import them into your program.

An import statement either names a particular application class or imports all the classes in a package.

Using the asterisks after the package name makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are not made available.

---

## Activity Guide Classes Reference

This reference section documents the following classes from the PTAI\_ACTION\_ITEMS application package:

- List class
- ActionItem class
- Member class
- ContextData class

---

## List Class

This section provides an overview of the List class and discusses:

- List class methods.
- List class properties.

The List class is used to manage an activity guide template or an activity guide instance.

Typically, activity guides are defined by the properties and characteristics of activity guide templates. An *activity guide template* provides a reusable definition of the important aspects of an activity guide: its properties, participants, contextual data, list of action items and to whom they are assigned, and so on. Then, at run time, an *activity guide instance* can be created from the definitions stored in the template. The instance will be generated with the contextual data that uniquely differentiates one instance from another. For example, for a benefits enrollment activity guide, the contextual data would likely include the employee ID, the country and locale (state, province, and so on) where the employee works, and any other key data required to initiate the benefits process.

## List Class Methods

In this section, the List class methods are presented in alphabetical order.

### createInstance

#### Syntax

```
createInstance(instance_ID, title, &context_data)
```

#### Description

Use this method to create an activity guide instance by cloning the current activity guide template including its action items, participants, and so on.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                     |
|-------------------------|---------------------------------------------------------------|
| <i>instance_ID</i>      | Specifies the ID for the activity guide instance as a string. |

| <b>Parameter</b>         | <b>Description</b>                                                                                                                                |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>title</i>             | Specifies the title for the activity guide instance as a string.<br><hr/> <b>Note:</b> The title is also referred to as the Label property. <hr/> |
| <i>&amp;context_data</i> | Specifies the contextual data for the activity guide instance as a PTAI_COLLECTION:Collection object.                                             |

## Returns

A List object.

## Example

This is a code example of the **CreateInstance** method:

```
method CreateInstFromCtxtData
    /* &Ctxt as PTAI_COLLECTION:Collection */
    /* Returns String */
    Local PTAI_ACTION_ITEMS:ContextData &ctxData;
    Local PTAI_ACTION_ITEMS:List &newList = create PTAI_ACTION_ITEMS:List();
    Local PTAI_COLLECTION:Collection &ctxDataColl = create PTAI_COLLECTION:Collectio⇒

n();
    Local integer &i, &nbr;
    Local string &label, &descr, &InstanceId;
    try
        For &i = 1 To &Ctxt.Count
            &ctxData = (&Ctxt.Item(&i) As PTAI_ACTION_ITEMS:ContextData);
            If &ctxData.ctxKey And
                &ctxData.keyValue = "" Then
                Return "";
            End-If;
            &ctxDataColl.InsertItem(&ctxData);
        End-For;

        &newList.open(&Template_Id);
        SQLExec(SQL.PTAI_GET_INSTANCES, &newList.ListId, &nbr);
        &nbr = &nbr + 1;
        &label = &newList.Label | "-" | &nbr;
        &InstanceId = &newList.createInstance(&label, &newList.DescrLong, &ctxDataCol⇒

1).ListId;
        Return &InstanceId;
    catch Exception &e
        Return "";
    end-try;
end-method;
```

## getActionItems

### Syntax

```
getActionItems()
```

### Description

Use this method to return an array of *all* action item IDs for the current activity guide. This method returns IDs for both summary and detail action items.

### Parameters

None.

### Returns

An array of string.

### Related Links

[getRootItems](#)

## GetContext

### Syntax

```
GetContext()
```

### Description

Use this method to get the contextual data for the current activity guide.

### Parameters

None.

### Returns

A PTAI\_COLLECTION:Collection object.

### Related Links

[ContextData Class](#)

## getMembers

### Syntax

```
getMembers()
```

### Description

Use this method to return a PTAI\_COLLECTION:Collection object representing participants for the current activity guide.

### Parameters

None.

### Returns

A PTAI\_COLLECTION:Collection object.

### Related Links

[Member Class](#)

## GetPgltBtn

### Syntax

```
GetPgltBtn()
```

### Description

Use this method to return a PTAI\_COLLECTION:Collection representing the definitions for custom navigation frame buttons for the current activity guide.

### Parameters

None.

### Returns

A PTAI\_COLLECTION:Collection object.

## getRootItems

### Syntax

```
getRootItems()
```

## Description

Use this method to return an array of action item IDs for summary action items for the current activity guide.

---

**Note:** This method does not return IDs for detail action items.

---

## Parameters

None.

## Returns

An array of string.

## Related Links

[getActionItems](#)

[ActionItem Class](#)

## new

## Syntax

```
new(ID, portal, title)
```

## Description

Use this method to generate a new activity guide.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ID</i>               | Specifies the ID for the new activity guide as a string.                                                                                 |
| <i>portal</i>           | Specifies a portal for the activity guide as a string.                                                                                   |
| <i>title</i>            | Specifies the title for the activity guide as a string.<br><hr/> <b>Note:</b> The title is also referred to as the Label property. <hr/> |

## Returns

None.

## Related Links

[Label](#)

[ListId](#)

## open

### Syntax

```
open ( ID )
```

### Description

Use this method to retrieve an activity guide definition from the database and sets all the properties.

### Parameters

| <i>Parameter</i> | <i>Description</i>                           |
|------------------|----------------------------------------------|
| <i>ID</i>        | Specifies the activity guide ID as a string. |

### Returns

None.

## Related Links

[ListId](#)

## save

### Syntax

```
save ()
```

### Description

Use this method to save the current activity guide definition to the database. If this is a new activity guide, then the definition is inserted into the database; otherwise, an existing definition is updated in the database.

### Parameters

None.

### Returns

A Boolean value: True if the save is successful, False otherwise.

## SaveContext

### Syntax

```
SaveContext(&context_data)
```

### Description

Use this method to save the contextual data for the current activity guide to the database. Any existing contextual data for this activity guide definition is deleted from the database first.

### Parameters

| <i><b>Parameter</b></i>  | <i><b>Description</b></i>                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------|
| <i>&amp;context_data</i> | Specifies the contextual data for the activity guide as a PTAI_COLLECTION:Collection object. |

### Returns

None.

### Related Links

[ContextData Class](#)

## saveMembers

### Syntax

```
saveMembers (&members)
```

### Description

Use this method to save the participants (members) for the current activity guide to the database. Any existing participants for this activity guide definition are deleted from the database first.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------|
| <i>&amp;members</i>     | Specifies the participants for the activity guide as a PTAI_COLLECTION:Collection object. |

### Returns

None.

Related Links

[Member Class](#)

SavePgltBtn

Syntax

```
SavePgltBtn (&pgltBtns)
```

Description

Use this method to save the definitions for the custom navigation frame buttons for the current activity guide to the database. Any existing custom button definitions for this activity guide are deleted from the database first.

Parameters

| Parameter            | Description                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------|
| <i>&amp;pgltBtns</i> | Specifies the custom navigation frame buttons for the activity guide as a PTAI_COLLECTION:Collection object. |

Returns

A PTAI\_COLLECTION:Collection object.

---

List Class Properties

In this section, the List class properties are presented in alphabetical order.

AppClassID

Description

Use this property to set or return a string value representing the name of the application class that contains the method to be invoked at activity guide instance creation.

---

**Note:** The full path to the method is constructed from four properties: PackageRoot, QualifyPath, AppClassID, and AppClassMethod

---

This property is read/write.

## Status

### Description

Use this property to set or return the status of the instance, which determines whether the activity guide is displayed in the Activity Guides - In Progress pagelet. The valid values are:

| <i><b>Value</b></i> | <i><b>Description</b></i> |
|---------------------|---------------------------|
| CA                  | Cancelled                 |
| CP                  | Complete                  |
| IP                  | In progress               |

This property is read/write.

### Example

In the following example, the method sets the activity guide status to complete:

```
method CompleteStatus
  /+ &list_id as String +/

  Local PTAI_ACTION_ITEMS:List &ObjList;

  &ObjList = create PTAI_ACTION_ITEMS:List();
  &ObjList.open(&list_id);

  Rem set the status of the template to Complete;

  &ObjList.Status = "CP";
  &return = &ObjList.save();

end-method;
```

---

## ActionItem Class

This section provides an overview of the ActionItem class and discusses:

- ActionItem class methods.

- `ActionItem` class properties.

The `ActionItem` class is used to manage action items.

Action items are the tasks that are assigned for completion within an activity guide. As an application developer, you will refer to these as action items. To users, they are presented as tasks or steps.

Action items can be created and maintained within activity guide templates or within activity guide instances. However, typically you will define action items and their details at the template level only. Once an activity guide instance is created, updates to the action items themselves occur programmatically or through actions of the user.

## Related Links

“Creating and Maintaining Action Items” (Portal Technology)

---

## ActionItem Class Methods

In this section, the `ActionItem` class methods are presented in alphabetical order.

### delete

#### Syntax

```
delete()
```

#### Description

Use this method to delete the current action item.

#### Parameters

None.

#### Returns

A Boolean value: True if the deletion was successful, False otherwise.

### getAssignments

#### Syntax

```
getAssignments()
```

#### Description

Use the `getAssignments` method to obtain the action item assignments (user/role) as a collection object.

**Note:** While you can specify any user ID or role, only a user or role that has also been assigned Contributor privileges on the template or instance Security page will be allowed to complete the action item. The system will not validate your selection against the users or roles defined on the Security page.

Parameters

None.

Returns

A PTAI\_COLLECTION:Collection object containing user or role assignments data for the action item.

Example

```
import PTAI_ACTION_ITEMS:ActionItem;
import PTAI_COLLECTION:Collection;

Local PTAI_ACTION_ITEMS:ActionItem &item;
Local PTAI_COLLECTION:Collection &oAssignmentColl = create PTAI_COLLECTION:Collecti⇒
on();

&item = create PTAI_ACTION_ITEMS:ActionItem();
/*Pass an action item id*/
&item.open(&item_id);
&oAssignmentColl = &item.getAssignments();
```

Related Links

[saveAssignments](#)

new

Syntax

```
new(item_ID, title, list_ID)
```

Description

Use this method to create and initialize a new action item.

Parameters

| Parameter | Description                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| item_ID   | Specifies the ID for the new action item as a string.                                                                         |
| title     | Specifies the title for the new action item as a string.<br><b>Note:</b> The title is also referred to as the Label property. |

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                  |
|-------------------------|----------------------------------------------------------------------------|
| <i>list_ID</i>          | Specifies the activity guide to which the action item belongs as a string. |

## Returns

None.

## Related Links

[ItemId](#)

[Label](#)

[ListId](#)

## nextAction

### Syntax

```
nextAction()
```

### Description

Use this method to return the next *detail* action item in the activity guide that is assigned and is not cancelled or on hold.

### Parameters

None.

### Returns

An ActionItem object.

## open

### Syntax

```
open(item_ID)
```

### Description

Use this method to retrieve the specified action item definition from the database and set the properties.

## Parameters

| <i>Parameter</i> | <i>Description</i>                        |
|------------------|-------------------------------------------|
| <i>item_ID</i>   | Specifies the action item ID as a string. |

## Returns

None.

[ItemId](#)

## prevAction

### Syntax

```
prevAction()
```

### Description

Use this method to return the previous *detail* action item in the activity guide that is assigned and is not cancelled or on hold.

### Parameters

None.

### Returns

An ActionItem object.

## save

### Syntax

```
save()
```

### Description

Use this method to save the current action item definition to the database. If this is a new activity guide, then the definition is inserted into the database; otherwise, an existing definition is updated in the database.

### Parameters

None.

## Returns

A Boolean value: True if the save is successful, False otherwise.

## saveAssignments

### Syntax

```
saveAssignments (&AssignmentColl)
```

### Description

Use the saveAssignments method to save or update action item assignments. If you are adding new user assignments to an action item, use the getAssignments method to get the existing assignments as a collection object, insert new assignments to the returned collection object, and call the saveAssignments method with the updated collection object as input.

---

**Note:** While you can specify any user ID or role, only a user or role that has also been assigned Contributor privileges on the template or instance Security page will be allowed to complete the action item. The system will not validate your selection against the users or roles defined on the Security page.

---

### Parameters

| <i><b>Parameter</b></i>    | <i><b>Description</b></i>                                                                              |
|----------------------------|--------------------------------------------------------------------------------------------------------|
| <i>&amp;AssignmentColl</i> | Specifies the user or role assignment data for the action item as a PTAI_COLLECTION:Collection object. |

### Returns

None.

### Example

```
import PTAI_ACTION_ITEMS:ActionItem;
import PTAI_COLLECTION:Collection;
import PTAI_ACTION_ITEMS:ActionItemAssignments;
import PTAI_COLLECTION:Collectable;

Local PTAI_ACTION_ITEMS:ActionItem &item;
Local PTAI_COLLECTION:Collection &oAssignmentColl = create PTAI_COLLECTION:Collecti⇒
on();
Local PTAI_ACTION_ITEMS:ActionItemAssignments &oAssignment = create PTAI_ACTION_ITE⇒
MS:ActionItemAssignments();
&oAssignment.AssignType = "USER";
&oAssignment.AssignValue = %OperatorId;

&oAssignmentColl.InsertItem(&oAssignment As PTAI_COLLECTION:Collectable);

&item = create PTAI_ACTION_ITEMS:ActionItem();
/*Pass an action item id*/
&item.open(&item_id);
```

```
&item.saveAssignments(&oAssignmentColl);
```

## ActionItem Class Properties

In this section, the ActionItem class properties are presented in alphabetical order.

### AppClassID

#### Description

Use this property to set or return a string value representing the name of the application class that contains the ItemPostProcess method to be invoked for post-processing of this action item.

---

**Note:** The full path to the ItemPostProcess method is constructed from three properties: PackageRoot, QualifyPath, and AppClassID

---

This property is read/write.

## ActionItemAssignments Class

This section provides an overview of the ActionItemAssignments class and discusses:

- ActionItemAssignments class methods.
- ActionItemAssignments class properties.

The ActionItemAssignments class is used to manage action item user/role assignments data for action items in an activity guide template and instance. You can use the ActionItemAssignments class properties to create action item assignment object and add/update the action item user or role assignment data.

If you are adding new user assignments to an action item, use the `getAssignments` method to get the existing assignments as a collection object, insert new assignments to the returned collection object, and call the `saveAssignments` method with the updated collection object as input.

---

## ActionItemAssignments Class Methods

In this section, the ActionItemAssignments class method is presented:

### IsEqual

#### Syntax

```
IsEqual (&object)
```

#### Description

Use this method to evaluate the equivalency of an object with the current ActionItemAssignments object. Equivalency is established based on the value of two properties: `&AssignType` and `&AssignValue`.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                    |
|-------------------------|------------------------------------------------------------------------------|
| <i>&amp;object</i>      | Specifies the object to be compared as a PTAI_COLLECTION:Collectable object. |

## Returns

A Boolean value: True if the objects are equivalent, False otherwise.

---

## ActionItemAssignments Class Properties

In this section, the ActionItemAssignments class properties are presented in alphabetic order

### AssignType

#### Description

Use the AssignType property to set or return the assignment as a String. The value can be either USER or ROLE.

This property is read/write.

### AssignValue

#### Description

Use the AssignValue property to set or return the user or role assignment value as a String.

This property is read/write.

---

## Member Class

This section provides an overview of the Member class and discusses:

- Member class methods.
- Member class properties.

The Member class is used to manage activity guide participants.

## Member Class Methods

In this section, the Member class methods are presented in alphabetical order.

### IsEqual

#### Syntax

```
IsEqual (&object)
```

#### Description

Use this method to evaluate the equivalency of an object with the current member. Equivalency is established based on the value of two properties: the object's Name and the Type.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                    |
|-------------------------|------------------------------------------------------------------------------|
| <i>&amp;object</i>      | Specifies the object to be compared as a PTAI_COLLECTION:Collectable object. |

#### Returns

A Boolean value: True if the objects are equivalent, False otherwise.

#### Related Links

[Name](#)

[Type](#)

### Member

#### Syntax

```
Member (name, type)
```

#### Description

Use this constructor method to initialize a Member object with the specified name and type.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                        |
|-------------------------|------------------------------------------------------------------|
| <i>name</i>             | Specifies the participant's name as a string value.              |
| <i>type</i>             | Specifies the participant type (role or user) as a string value. |

## Returns

None.

---

## Member Class Properties

In this section, the Member class properties are presented in alphabetical order.

### Name

#### Description

Use this property to return the participant's name as a string value.

This property is read-only.

### PrivilegeSetID

#### Description

Use this property to set or return the privilege level assigned to this participant as a string value.

This property is read/write.

#### Example

Set or return a value for the PrivilegeSetID property using the Constants class:

| <i><b>Constant Value</b></i>        | <i><b>Description</b></i> |
|-------------------------------------|---------------------------|
| &PTAI_CONSTANTS.PRIVSET_ADMIN       | Administrator             |
| &PTAI_CONSTANTS.PRIVSET_CONTRIBUTOR | Contributor               |
| &PTAI_CONSTANTS.PRIVSET_VIEWER      | Viewer                    |

For example:

```
import PTAI_ACTION_ITEMS:*;  
  
Local PTAI_ACTION_ITEMS:Constants &PTAI_CONSTANTS;  
Local PTAI_ACTION_ITEMS:Member &member;  
  
&PTAI_CONSTANTS = create PTAI_ACTION_ITEMS:Constants();  
&member = create PTAI_ACTION_ITEMS:Member(&name, &type);  
  
&member.PrivilegeSetID = &PTAI_CONSTANTS.PRIVSET_ADMIN;
```

## Type

### Description

Use this property to return the participant type (user or role) as a string value.

This property is read-only.

---

## ContextData Class

This section provides an overview of the ContextData class and discusses:

- ContextData class methods.
- ContextData class properties.

The ContextData class is used to manage contextual data for activity guide templates and instances.

You can define contextual data that will be passed to the activity guide instance when it is created. Contextual data defined as key fields will be used to uniquely identify each activity guide instance. For example, if the employee ID were defined as a key contextual field, then each activity guide instance will be created for a specific employee ID. Contextual data defined as non-key fields is not used to differentiate an instance, but can be passed to the instance nevertheless. For example, non-key data can be displayed in the activity guide pagelet by specifying the Context Visible option for the field. In this way, instead of displaying the employee ID, you could display the employee name in the pagelet.

---

## ContextData Class Methods

In this section, the ContextData class methods are presented in alphabetical order.

## ContextData

### Syntax

```
ContextData(rec_name, field_name, label, value, isKey, isVisible)
```

### Description

Use this constructor method to initialize one row of contextual data for an activity guide.

### Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>rec_name</i>         | Specifies the record name that is the source for the contextual field as a string value.                                                                                            |
| <i>field_name</i>       | Specifies the name of the source contextual field as a string value.                                                                                                                |
| <i>label</i>            | Specifies an optional label for the contextual field as a string value. This label can be displayed along with the data value in the activity guide pagelet on the WorkCenter page. |
| <i>value</i>            | Specifies the contextual data value as a string.                                                                                                                                    |
| <i>isKey</i>            | Specifies a Boolean value indicating whether the contextual field is a key field.                                                                                                   |
| <i>isVisible</i>        | Specifies a Boolean value indicating whether to display the contextual data and labels in the activity guide pagelet on the WorkCenter page.                                        |

### Returns

None.

## IsEqual

### Syntax

```
IsEqual(&object)
```

## Description

Use this method to evaluate the equivalency of an object with the current ContextData object. Equivalency is established based on the value of five properties: recname, fieldname, keyLabel, keyValue, and ctxKey.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                    |
|-------------------------|------------------------------------------------------------------------------|
| <i>&amp;object</i>      | Specifies the object to be compared as a PTAI_COLLECTION:Collectable object. |

## Returns

A Boolean value: True if the objects are equivalent, False otherwise.

---

## ContextData Class Properties

In this section, the ContextData class properties are presented in alphabetical order.

### ctxKey

#### Description

Use this property to set or return a Boolean value indicating whether the contextual field is a key field.

This property is read/write.

### ctxVisible

#### Description

Use this property to set or return a Boolean value indicating whether to display the contextual data and labels in the activity guide pagelet on the WorkCenter page.

This property is read/write.

### fieldname

#### Description

Use this property to set or return the name of the source contextual field as a string value.

This property is read/write.

## keyLabel

### Description

Use this property to set or return an optional label for the contextual field as a string value. This label can be displayed along with the data value in the activity guide pagelet on the WorkCenter page.

This property is read/write.

## keyValue

### Description

Use this property to set or return the contextual data value as a string.

This property is read/write.

## recname

### Description

Use this property to set or return the record name that is the source for the contextual field as a string value.

This property is read/write.

# AESession Class

---

## Understanding the AESession Class

Before PeopleTools 8, users could perform SQL directly on the Application Engine tables, thereby changing their SQL and Application Engine "flow" in a dynamic manner, prior to running their applications. Some applications, for example, let the user input their "rules" in a user-friendly application, then convert these rules, at save time, into Application Engine constructs.

With PeopleTools 8, Application Engine programs should not perform SQL directly on the Application Engine tables, as they are system tables, and are cached. SQL on the Application Engine tables may not be accurately reflected when the applications are executed, because of the caching mechanism.

To overcome this problem, developers have two basic operations that let them modify their Application Engine programs from their online pages:

- Ability to modify SQL definitions, which are referenced within Application Engine SQL using the PeopleCode SQL class and the meta-SQL function %SQL.
- Ability to dynamically change the execution flow of a given Application Engine section.

Use the AESession class to do the latter. This section object is used to modify the steps and SQL associated with a given section by using PeopleCode.

Before describing the specifics of the AESession class, the following are some general terms to understand:

- *base* section

The *base* section represents the Application Engine section you are working on. This is the section that you are changing in PeopleCode. In other words, it's the target section.

- *template* section

The *template* section represents the Application Engine section that is the source, or "model" for the section you're building. You copy *from* the template section *to* the base section.

The template must exist in the database before you can use it.

If the base section you specify doesn't exist, a *new* base section is created. This enables you to dynamically create sections as needed.

You can copy steps (and their attributes) from the template to the base. The only attribute of the step you can modify is the SQL statement that gets executed.

---

**Warning!** When you open or get an AESession object, (that is, the base section) any existing steps in the section are deleted. You must add a new step to the section before you can modify it.

---

The main assumption for this class is that your rules are dynamic primarily in the SQL that they execute, but that the structure of the rules are static, or at least defined well enough that a standard template can be applied.

Note that you can't update the Application Engine *actions* that are not SQL-related (that is, PeopleCode, Call Section, or Log Message). In other words, you can't change the PeopleCode associated with a PeopleCode action within a step. You can add a step containing a PeopleCode action to your new section, but you can't change the PeopleCode dynamically.

---

## How an AERSection is Accessed

When an AERSection is opened (or accessed), the system first checks if it exists with the given input parameters.

If the base section you specify doesn't exist, a *new* base section is created. This enables you to dynamically create sections as needed. In addition, if the target section doesn't exist, all section-level attributes are copied from the template to the target section. If the target exists, it retains its attribute settings.

If an effective date is specified (with EffDt), but there is no match using that effective date, the AERSection is opened using the base effective date of '1900-01-01'.

The market defined for the current component is used for the section to be open. If no section with this market exists, the default GBL is used.

If you open an AERSection object from within a running Application Engine program, the market value is set to the value of the current process.

The database platform you're currently running is used as the database platform for the section to be opened. If no section with this database platform exists, the default "none" is used.

To find the correct section to open, the precedence is:

1. Market
2. Database platform
3. Effective date

When a section is closed and its changes are saved, the market and database platform from the system that performed the changes is used as the market and database platform for the modified section.

Let's take an example. Assume that you're running on DB2 for OS/390 and z/OS, and your current market is set to 'MKT'. Assume that you want to open a section called Sect1 in an Application Engine program called TestAppl, and that your data looks something like this:

| <b>Number</b> | <b>Application<br/>Engine Program</b> | <b>Application<br/>Engine Section</b> | <b>Market</b> | <b>Platform</b> | <b>Effective Date</b> |
|---------------|---------------------------------------|---------------------------------------|---------------|-----------------|-----------------------|
| 1             | TestAppl                              | Sect1                                 | USA           | DB2             | 1990-01-01            |
| 2             | TestAppl                              | Sect1                                 | USA           | None            | 1900-01-01            |
| 3             | TestAppl                              | Sect1                                 | GBL           | None            | 1900-01-01            |

If you use:

```
&SECTION.Open("TestAppl", "Sect1", "1998-12-14");
```

Then the third section in the previous list is used, because the market takes highest precedence. When the section is saved, the values for market and platform are updated to the current system values.

---

**Warning!** When you open or get an AERSection object, (that is, any base section) any existing steps in the section are deleted. You must add a new step to the section before you can modify it.  
The other attributes of the section, however, are retained, with the exceptions noted previously.

---

## AERSection Example

Assume that you have a template section called TEMPLATE in the Application Engine program called MY\_APPL. The template looks like this:

| <b>Steps</b> | <b>Actions</b>              |
|--------------|-----------------------------|
| NewStep1     | DO When<br>DO Select<br>SQL |
| NewStep2     | DO Select<br>CallSection    |

Also, assume that you have a base section called DYN\_SECT in the Application Engine program called RULES. When you start, this section looks like this:

| <b>Steps</b> | <b>Actions</b>                       |
|--------------|--------------------------------------|
| Step1        | DO Select<br>Call Section<br>DO Unit |

| Steps | Actions      |
|-------|--------------|
| Step2 | Call Section |

Here's the PeopleCode:

```
Local AERSection &Section;
&Section = GetAERSection("RULES", "DYN_SECT");
/* Open the base section */
&Section.SetTemplate("MY_APPL", "TEMPLATE");
/* Set the template section */
&Section.AddStep("NewStep2");
/* Insert NewStep2 */
/* Do some SQL stuff here */
&Section.SetSQL("DO_SELECT", &MySql);
/* Modify the SQL in the added step */
&Section.Save();
&Section.Close();
/* Save and close */
```

The base section looks like this after execution:

| Steps    | Actions                   |
|----------|---------------------------|
| NewStep2 | DO Select<br>Call Section |

**Note:** The existing steps in the base section have been *overwritten* by the new step from the template section.

## Data Type of an AERSection Object

You should declare an AERSection object as type AERSection. For example:

```
Local AERSection &SECTION;
```

## Scope of an AERSection Object

An AERSection object can only be instantiated from PeopleCode.

The AERSection Object is designed for use within online pages. Typically, dynamic sections should be constructed in response to an end-user action.

**Note:** Do not call an AERSection object from an Application Engine PeopleCode Action. If you need to access another section, use CallSection Actions instead.

### AERSection Class Methods

In this section, we discuss each AERSection class method, in alphabetical order.

#### AddStep

##### Syntax

```
AddStep(ae_step_name [, NewStepName])
```

##### Description

The given step name from the template section is added as the next step into the base section, and named the existing step name.

---

**Note:** When you open or get a section, all the existing steps are deleted. The first time you execute AddStep, you add the first step. The second time you execute AddStep, you add the second step, and so on.

---

All attributes of the step are copied, including all of its actions. The only changeable attribute of a step are its SQL statements, which can be modified using the SetSQL method. SetSQL is run on the *current* step, that is, the step most recently added.

You can also change the name of the step by using the optional parameter *NewStepName*.

If the step named does not exist in the template, an error occurs. Likewise, if you have not opened or set the template for the section, you receive an error.

##### Parameters

| <i>Parameter</i>    | <i>Description</i>                                                                                                                    |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>ae_step_name</i> | Specify the step name from the template to be added as the <i>next</i> step in the base section. This parameter takes a string value. |
| <i>NewStepName</i>  | Specify a new name for the step to be added. This parameter is optional, and takes a string value.                                    |

##### Returns

None.

## Example

See [AERSection Example](#).

## Related Links

[SetSQL](#)

## Close

### Syntax

```
Close ()
```

### Description

Close closes the AERSection object. Any unsaved changes to the section are discarded.

### Parameters

None.

### Returns

None.

## Example

See [AERSection Example](#).

## Related Links

[Save](#)

[Open](#)

“GetAERSection” (PeopleCode Language Reference)

## Open

### Syntax

```
Open (ae_applid, ae_section, [effdt])
```

### Description

The Open method associates the AERSection object with the given Application Engine section, based on the *ae\_applid* and *ae\_section*. If the *effdt* is specified, this is also used to get the section object. In other words, the Open method sets the base section.

---

**Warning!** When you open or get an AERSection object, (that is, the base section) any existing steps in the section are deleted.

---

**Note:** If the base section you specify doesn't exist, a *new* base section is created. This enables you to dynamically create sections as needed. In addition, if the target section doesn't exist, all section-level attributes are copied from the template to the target section. If the target exists, it retains its attribute settings.

---

If the AERSection is still open when you issue the Open method, the previously opened object is discarded and none of the changes saved. To prevent accidentally discarding your changes, you can use the IsOpen property to verify if a section is already open.

The AERSection is open based on the Market and database type of your current system.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------|
| <i>ae_applid</i>        | Specify the application ID of the section you want to access. This parameter takes a string value.            |
| <i>ae_section</i>       | Specify the section name of the section you want to access. This parameter takes a string value.              |
| <i>effdt</i>            | Specify the effective date of the section you want to access (optional). This parameter takes a string value. |

## Returns

An AERSection object.

## Example

```
Local AERSection &SECTION;

&SECTION = GetAERSection("RULES1", "DYN_SECT");

/* do some processing */

&SECTION.Close();

&SECTION.Open("RULES2", "DYN_SECT");

/* do additional processing */
```

## Related Links

[IsOpen](#)

“GetAERSection” (PeopleCode Language Reference)

## Save

### Syntax

**Save** ()

### Description

The Save method saves the section to the database. The AERSection object remains open after you use this method. To close the object, you must use the Close method.

You must commit all database changes prior to using this method. This is to avoid locking critical Tools tables and hence freezing all other users. You receive a runtime error message if you try to use this method when there are pending database updates, and your PeopleCode program terminates. You need to commit any database updates prior to using this method. Use the CommitWork function to commit database updates.

### Parameters

None.

### Returns

None.

### Example

See [AERSection Example](#).

### Related Links

[Close](#)

[Open](#)

“CommitWork” (PeopleCode Language Reference)

## SetSQL

### Syntax

**SetSQL**(*action\_type\_string*, *string*)

### Description

The SetSQL method replaces the SQL associated with the given action type in the current step in the base section with the SQL in *string*. The *current* step is the latest step that was added using AddStep. The action types are:

- DO\_WHEN
- DO\_WHILE

- DO\_SELECT
- SQL
- DO\_UNTIL

---

**Note:** All action types must be passed in as strings with quotation marks.

---

If the action specified does not exist in the current step, an error occurs.

You can use a SQL object as *string*.

```
&SECTION.SetSQL("SQL", &SQL);
```

## Parameters

| <i>Parameter</i>   | <i>Description</i>                                                                                         |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <i>action_type</i> | Specifies the action type of the current step that should be changed. This parameter takes a string value. |
| <i>string</i>      | Specifies the SQL to be used to replace the SQL in the current step.                                       |

## Returns

None.

## Example

See [AERSection Example](#).

## Related Links

[AddStep](#)

[Understanding SQL Class](#)

## SetTemplate

### Syntax

```
SetTemplate(ae_applid, ae_section)
```

### Description

The SetTemplate method sets the template to be used with an AERSection object, as identified by *ae\_applid* and *ae\_section*.

The rules for assigning a template section are similar to the rules for selecting a base section. The selection of market and database platform are done exactly the same. However, the effective date of the template is always set based on the effective date of '1900-01-01'.

You must set the template before you can use any of the other methods.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------|
| <i>ae_applid</i>        | Specify the name of the Application Engine program that contains the section to be used as the template. |
| <i>ae_section</i>       | Specify the name of the Application Engine section in the program to be used as the section template.    |

## Returns

None.

## Example

See [AERSection Example](#).

# AERSection Class Property

In this section, we discuss the IsOpen AERSection property.

## IsOpen

### Description

If this property is True, the section object is already open. If you try to open a section object that is already open, the open section object is closed and all the changes that haven't been saved are discarded before the object is re-opened.

### Example

```
If Not(&MYSECTION.IsOpen) Then
    &MYSECTION.Open(MYAPPLID, SECTION2);
End-If;
```

# Analytic Calculation Engine Classes

---

## Understanding the Analytic Calculation Engine Classes

PeopleSoft Analytic Calculation Engine comprises a calculation engine plus several PeopleTools features which enable application developers to define both the calculation rules and the display of calculated data within PeopleSoft applications for the purposes of multi-dimensional reporting, data editing and analysis.

More specifically, developers create *analytic models* in order to define the rules which are used to calculate data. Developers also create PeopleSoft Pure Internet Architecture pages with *analytic grids* in order to display the data within PeopleSoft applications. End users view, analyze and make changes to this data. When end users save their changes, PeopleSoft Analytic Calculation Engine recalculates the data and saves the calculated data to the database.

PeopleCode enables developers to manipulate analytic calculation data as follows:

- Use the Analytic Calculation Engine classes to either retrieve or specify data in an instance of an analytic model loaded into the system, and also to calculate (or recalculate) cube values.
- Use the Analytic Calculation Engine metadata classes to manipulate an analytic model definition. For example, you can add cubes to a cube collection or rename an existing user function for a model.
- Use the Analytic Grid classes to manipulate the display of analytic calculation data on a page.
- Use the Analytic Type classes to manipulate an analytic type definition. For example, you can specify a new analytic model for an analytic type definition.

---

**Important!** The Analytic Calculation Engine classes are not supported on IBM z/OS and Linux for IBM System z platforms.

---

[AnalyticType Classes Example](#)

[Understanding the Analytic Calculation Engine Classes](#)

## Using the Analytic Calculation Engine Classes with Application Engine

All Application Engine programs run on the application engine server. This means your program runs on the application engine server, not the analytic server.

PeopleSoft recommends that you put each of the following methods into its own step when you're creating an analytic calculation using a Application Engine program:

- AnalyticInstance Load method

- AnalyticInstance Unload method
- AnalyticInstance Copy method
- AnalyticInstance Delete method (in case of any readable/writable records in the analytic type)
- AnalyticModel Recalculate method
- CubeCollection SetData method

Also, with the Recalculate method, you should use the **Commit after step** option.

---

## Running Synchronously

Some of the methods and functions associated with these classes have the option of being run asynchronously. When you run these asynchronously, and not from a Application Engine program, these methods and functions have additional functionality, that is, if the RenServer is configured, a window displays the PeopleSoft Analytic Calculation Engine execution status.

---

## Using Trees

PeopleSoft Analytic Calculation Engine uses trees to establish hierarchies of a dimension's parent-child relationships. PeopleSoft Analytic Calculation Engine uses these hierarchies to:

- Calculate and display aggregated data to end users.
- Enable end users to navigate through data by performing such actions as expanding and collapsing nodes.
- Enable end users to drill down and drill up through data.

It is important to understand that PeopleSoft trees and hierarchies differ in the following manner: You create one tree for each dimension that requires a hierarchy. The analytic model uses that tree to create one hierarchy for one dimension.

Use the AttachTree method to attach a tree to a dimension, and use the DetachTree method to detach the tree from the dimension.

You should be aware of the following restrictions:

- Because the AttachTree method attaches a specific tree to an analytic instance, the system throws an error if the tree's name, setID or effective date is incorrect.
- You can attach only one tree to one dimension at a time.
- If the analytic instance is already loaded into the analytic server, the tree isn't attached until the analytic model is loaded.
- No aggregate data is displayed to the user after you use the DetachTree method.

- If your application loads the analytic model after the tree has been detached, the analytic model doesn't create a hierarchy for the dimension.
- If the analytic instance is already loaded into the analytic server, the DetachTree method isn't applied to the tree until the next time your application loads the analytic instance.

You can only attach a tree to an analytic model before the analytic instance

No aggregate data displayed to user after detach tree.

### Related Links

“Understanding the Relationship of PeopleSoft Trees to Analytic Models” (Analytic Calculation Engine)

---

## Error Handling

All the Analytic Calculation Engine classes throw PeopleCode exceptions for any fatal error that occurs in the execution of the operation. PeopleSoft recommends enclosing your analytic model programs in try-catch statements. This way, if your program catches the exception, the message set and message number that are associated with the exception object indicate the error.

### Using the Messages Property

Use the Messages property to determine whether any errors occurred. The Messages property returns a multi-dimensional array. You can use the Len property of the array class to determine the length of the array. If the array has a length of 0, there are no errors.

---

## Data Types for Analytic Calculation Engine Classes

Every PeopleSoft Analytic Calculation Engine object is declared as its own data type, that is, AnalyticModel objects are declared as type AnalyticModel, CubeCollection objects are declared as type CubeCollection, and so on.

The following are the data types for the PeopleSoft Analytic Calculation Engine classes:

- AnalyticInstance
- AnalyticModel
- CubeCollection

---

## Scope of Analytic Calculation Engine Classes

The Analytic Calculation Engine objects can only be instantiated from PeopleCode.

These objects can be used anywhere you have PeopleCode, that is, in a Application Engine program, an application class, record field PeopleCode, and so on.

Analytic Calculation Engine objects can be of scope Local, Component, or Global.

---

## AnalyticInstance Class Methods

In this section, we discuss the AnalyticInstance methods. The methods are discussed in alphabetical order.

### CheckAsyncStatus

#### Syntax

**CheckAsyncStatus** (*OperationID*)

#### Description

Use the CheckAsyncStatus method to determine the current state of the asynchronous methods, as well as the Load method when executed asynchronously.

#### Parameters

| <b>Parameter</b>   | <b>Description</b>                                                                                                                            |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>OperationID</i> | Specify the operation ID of the asynchronous operation.<br>This operation ID is returned when one of the asynchronous operations is executed. |

#### Returns

This method returns one of the following values:

| <b>Value</b>   | <b>Description</b>                    |
|----------------|---------------------------------------|
| Less than 0    | The operation completed with errors.  |
| 0              | The operation has not completed yet.  |
| Greater than 0 | The operation completed successfully. |

[Unload](#)

## CheckStatus

### Syntax

```
CheckStatus()
```

### Description

Use the CheckStatus method to determine the current state of the analytic calculation engine.

### Parameters

None.

### Returns

This method returns one of the following values:

| <i><b>Value</b></i>            | <i><b>Description</b></i>                                              |
|--------------------------------|------------------------------------------------------------------------|
| %AnalyticInstance_NotLoaded    | The analytic instance has not been loaded into the application server. |
| %AnalyticInstance_Loading      | The analytic instance is being loaded.                                 |
| %AnalyticInstance_Idle         | The analytic instance is idle, that is, not currently running.         |
| %AnalyticInstance_Busy         | The analytic instance is currently running.                            |
| %AnalyticInstance_Inaccessible | The analytic instance is currently inaccessible.                       |
| %AnalyticInstance_Terminating  | The analytic instance is currently ending.                             |

## Related Links

[Load](#)

[Unload](#)

# Copy

## Syntax

**Copy** (*NewID*, *ForceDelete*&*Record*)

## Description

Use the Copy method to copy all the data and metadata to a new analytic instance from the current analytic instance.

If the specified *NewID* exists, or any data for *NewID* exists, the data is not copied unless *ForceDelete* has been specified as true.

If a tree is attached to the existing analytic instance, all tree data is also copied to the new analytic instance.

In addition, the analytic instance and the tree information are not copied unless the record specified with the &*Record* parameter is populated with the existing analytic instance ID.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                                                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>NewID</i>            | Specify the new analytic instance ID as a string.                                                                                                                                                                                                                                                                                   |
| <i>ForceDelete</i>      | <p>If the specified <i>NewID</i> exists, and <i>ForceDelete</i> is specified as false, the copy is cancelled.</p> <p>If the specified <i>NewID</i> exists, and <i>ForceDelete</i> is specified as true, the analytic instance specified by <i>NewID</i> is deleted, and a new analytic instance is created from the current ID.</p> |
| & <i>Record</i>         | Specify an already instantiated record object to pass in values to the Copy application package method that's defined with the specified analytic type definition.                                                                                                                                                                  |

## Returns

None.

## Example

```
&ai.Copy("MYTESTCOPY", True, &MyRecord);
```

## Related Links

[Delete](#)

[Load](#)

[Unload](#)

## “Understanding Analytic Type Definitions” (Optimization Framework)

### Delete

#### Syntax

```
Delete(ForceUnload, &RecordRef)
```

#### Description

Use the Delete method to remove all the metadata related to the given analytic instance.

Every analytic type definition is defined with an application package that contains three methods: Create, Delete, and Copy. The values in *&RecordRef* are passed to the Delete method.

This method does not delete the analytic instance if the analytic instance is currently loaded. Specify *ForceUnload* as true to unload the analytic instance before deleting it.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ForceUnload</i>      | Specify whether to force the deletion of the analytic instance. This parameter takes a Boolean value. If the analytic instance is currently loaded, specifying true for this parameter forces the analytic instance to be unloaded before it is deleted. |
| <i>&amp;RecordRef</i>   | Specify a record to pass in values to the application package Delete class that's associated with the analytic type definition.                                                                                                                          |

#### Returns

None.

#### Example

```
&ai.Delete(TRUE, &Record);
```

#### Related Links

[Unload](#)

“Understanding Analytic Type Definitions” (Optimization Framework)

### GetAnalyticModel

#### Syntax

```
GetAnalyticModel(AnalyticModel.ModelName)
```

## Description

Use the `GetAnalyticModel` method to return a reference to an `AnalyticModel` object.

## Parameters

| <i><b>Parameter</b></i>              | <i><b>Description</b></i>                                                                                                                         |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>AnalyticModel.ModelName</code> | Specify the name of the analytic model for which you want to return a reference. The model definition must already exist in Application Designer. |

## Returns

A reference to an `AnalyticModel` object or `Null`.

## Related Links

[AnalyticModel Class Methods](#)

## Load

### Syntax

```
Load(Sync, IdleTimeout, Message.messagename)
```

### Description

Use the `Load` method to load the `AnalyticInstance` object executing the method into the analytic server.

If this analytic instance is already loaded, this method fails.

When the analytic instance is loaded, if there are fields in the analytic type definition that haven't been selected but are mapped to a cube or dimension, an error message is logged to the analytic server log and the analytic instance load fails.

If there is a record in the analytic type definition that has none of its fields mapped to a cube or dimension, a warning message is logged to the analytic server log.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Sync</code>       | Specify whether the analytic instance should be run synchronously or asynchronously. This parameter takes a Boolean value: true if it should be run synchronously, false otherwise.<br><br>See <a href="#">Running Synchronously</a> . |

| <b>Parameter</b>                   | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>IdleTimeOut</i>                 | <p>Specify, in minutes, the idle time out value. A value of 0 is an infinite time out. A value of -1 indicates that it should use the value specified in the default configuration for the analytic server.</p> <hr/> <p><b>Note:</b> When loading an analytic grid, you should always specify a value of -1.</p> <hr/> <p>See “Loading and Unloading Analytic Instances” (Analytic Calculation Engine).</p> |
| <b>Message.</b> <i>MessageName</i> | <p>Specify an application message that should be sent if the analytic server crashes while the analytic instance is loaded.</p> <hr/> <p><b>Note:</b> The message is sent when the analytic server process restarts itself after crashing.</p> <hr/>                                                                                                                                                         |

## Returns

A string. For asynchronous loads, this string is passed to the CheckAsyncStatus method.

This method returns one of the following values:

| <b>Value</b>                   | <b>Description</b>                                                  |
|--------------------------------|---------------------------------------------------------------------|
| %AnalyticInstance_NotLoaded    | The analytic instance has not been loaded into the analytic server. |
| %AnalyticInstance_Loading      | The analytic instance is being loaded.                              |
| %AnalyticInstance_Idle         | The analytic instance is idle, that is, not currently running.      |
| %AnalyticInstance_Busy         | The analytic instance is currently running.                         |
| %AnalyticInstance_Inaccessible | The analytic instance is currently inaccessible.                    |
| %AnalyticInstance_Terminating  | The analytic instance is currently terminating.                     |

## Related Links

[CheckAsyncStatus](#)

[Unload](#)

## RunAsync

### Syntax

**RunAsync** ()

### Description

Use the RunAsync method to specify if the analytic instance executing the method should be run in an asynchronous manner.

This method is used only to define the transaction in the analytic type definition in optimization. PeopleSoft Analytic Calculation Engine programs uses the Load method for defining synchronous or asynchronous operation.

### Parameters

None.

### Returns

None.

### Related Links

“Creating Analytic Type Definitions” (Optimization Framework)

## RunSync

### Syntax

**RunSync** ()

### Description

Use the RunSync method to specify if the analytic instance executing the method should be run in a synchronous manner.

This method is used only to define the transaction in the analytic type definition in optimization. PeopleSoft Analytic Calculation Engine programs uses the Load method for defining synchronous or asynchronous operation.

### Parameters

None.

### Returns

None.

## Related Links

“Creating Analytic Type Definitions” (Optimization Framework)

## Terminate

### Syntax

```
Terminate()
```

### Description

Use the Terminate method to force the termination of an analytic instance loaded in an analytic server.

This method should only be used from PeopleCode running in a Application Engine program to cause an analytic instance loaded in an analytic server to be terminated.

Attempting to terminate an analytic instance that is not loaded or is loaded in a Application Engine process results in a PeopleCode exception.

Although the Terminate method returns instantly, it may take up to a minute before the analytic instance is actually terminated.

### Parameters

None.

### Returns

None.

## Related Links

[Load](#)

[Unload](#)

## Unload

### Syntax

```
Unload()
```

### Description

Use the Unload method to unload the analytic instance executing the method from the analytic server. After unloading the analytic instance, the analytic server process is restarted.

### Parameters

None.

## Returns

None.

## Example

```
&ai.UnLoad();
```

# AnalyticInstance Class Properties

In this section, we discuss the AnalyticInstance properties. The properties are discussed in alphabetical order.

## AnalyticType

### Description

This property returns the name of the analytic type definition for this AnalyticInstance object as a string.

This property is read-only.

## ID

### Description

This property returns the analytic instance ID of this AnalyticInstance object as an integer.

This property is read-only.

## Messages

### Description

This property returns a multi-dimensional array of any, containing the messages that occurred.

The first dimension contains the message set number. The second dimension contains the message number. The third dimension contains the number of parameters in that message. The subsequent dimensions contain the values for the parameters. The maximum number of possible dimensions is 8.

After you access this property, only new messages are returned, that is, messages are only returned once.

This property is read-only.

## AnalyticModel Class Methods

In this section, we discuss the AnalyticModel methods. The methods are discussed in alphabetical order.

### AddMember

#### Syntax

```
AddMember(DimName, MemberName)
```

#### Description

Use the AddMember method to add the specified dimension member to the specified dimension.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                       |
|-------------------------|---------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the dimension to which you want to add the member.                      |
| <i>MemberName</i>       | Specify the name of the member that you want to add to the specified dimension. |

#### Returns

None.

### AttachTree

#### Syntax

```
AttachTree(DimName, TreeName, setID, UserKeyValue, EffDt, NodeName, OverrideRecord,⇒  
DetailStartLvl, TreeDiscardLvl)
```

## Description

Use the AttachTree method to attach a tree to a dimension. Only one tree can be attached to a dimension at a time. You can only attach a tree before the analytic instance is loaded.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension that you want to attach a tree to.                                                                                                                                                                                                                                                                                                                                                                 |
| <i>TreeName</i>         | Specify the name of the tree that you want to attach to the dimension.                                                                                                                                                                                                                                                                                                                                                               |
| <i>setID</i>            | <p>Specify the table indirection key for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "S", you must specify a setID.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "S", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p>                 |
| <i>UserKeyValue</i>     | <p>Specify the User Key Value for the tree. This parameter takes a string value. If the tree structure the tree is based on has its IndirectionMethod specified as "U" or "B", you must specify a User Key Value.</p> <p>If the tree structure doesn't have its IndirectionMethod specified as "U" or "B", you must enter a Null string (that is, two quotation marks with no blank space between them ("")) for this parameter.</p> |
| <i>EffDt</i>            | Specify an effective date for this tree. This parameter takes a string value.                                                                                                                                                                                                                                                                                                                                                        |
| <i>NodeName</i>         | Specify the tree node used as the dimension hierarchy root. This can be different from the tree root, that is, you can pick a subtree.                                                                                                                                                                                                                                                                                               |
| <i>OverrideRecord</i>   | <p>Specify the name of a record to be used for overriding the aggregate.</p> <p>See “Working with Overrides” (Analytic Calculation Engine).</p>                                                                                                                                                                                                                                                                                      |

| <b>Parameter</b>      | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DetailStartLvl</i> | <p>Specify the tree level number (such as 1 for the node hierarchy root specified by the <i>NodeName</i> parameter) at which detail nodes start.</p> <p>If you specify a value other than 0, any nodes at this level or greater than this level are considered details node, and any nodes with levels less than the start level are considered aggregate nodes</p> <p>If you specify 0, detail nodes are nodes that don't have parents (a node can be a parent either by having children or by having child ranges).</p> |
| <i>TreeDiscardLvl</i> | <p>Specify the tree level number (such as 1 for the node hierarchy root specified by the <i>NodeName</i> parameter) at which to stop loading the tree. Nodes at this level or at levels greater are discarded. This parameter is only used if it has a value other than 0, and if it has a value greater than <i>DetailStartLvl</i>.</p>                                                                                                                                                                                  |

## Returns

None.

## CalculateCube

### Syntax

```
CalculateCube(CubeName[, Sync])
```

### Description

Use the CalculateCube method to calculate the named cube in synchronous mode.

### Parameters

| <b>Parameter</b> | <b>Description</b>                                       |
|------------------|----------------------------------------------------------|
| <i>CubeName</i>  | Specify the name of the cube that you want to calculate. |

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Sync</i>             | This parameter is optional and is not used. It is only being included for previous releases. This parameter takes a Boolean value. The value of this parameter is ignored. The cube is always calculated in synchronous mode. |

## Returns

None.

# DetachTree

## Syntax

**DetachTree** (*DimName*)

## Description

Use the DetachTree method to detach a tree from the specified dimension.

You can only attach a tree when the analytic instance is not loaded. This method fails if you try to detach a tree while the analytic instance is loaded.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                               |
|-------------------------|-------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension from which you want to detach a tree. |

## Returns

None.

## Related Links

[AttachTree](#)

## GetCubeCollection

### Syntax

**GetCubeCollection** (*CubeCollName*)

### Description

Use the GetCubeCollection method to return a reference to a CubeCollection object.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                              |
|-------------------------|------------------------------------------------------------------------|
| <i>CubeCollName</i>     | Specify the name of the cube collection to which you want a reference. |

### Returns

A CubeCollection object if successful.

### Related Links

[CubeCollection Class](#)

## GetCellProperties

### Syntax

**GetCellProperties** (*CubeName*, *&Node*)

### Description

Use the GetCellProperties method to get information about a cell.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>CubeName</i>         | Specify the name of the cube that contains the cell you want information about.                                                                                |
| <i>&amp;Node</i>        | Specify an already instantiated array of array of string (a two-dimensional array of string) containing name-value pairs of the node name and the node detail. |

## Returns

An array of string.

The four strings returned in the array are:

1. Cell type. Values are “Aggregate” or “Detail”
2. User function.
3. Dimension for aggregation, the dimension name.
4. Aggregation reason. Values are: “Dimension Level Override”, “Member Level Override”, “Cube Dimension Level Override”, “None.”

## Related Links

[Understanding Arrays](#)

## GetMembers

### Syntax

```
GetMembers (DimName, DimFilter)
```

### Description

Use the GetMembers method to return the names of the members in the specified dimension. You can specify a user function to be used as a filter for the dimension using *DimFilter*.

When filtering hierarchy nodes, if the parent member is filtered, all the child nodes are also filtered.

In order to filter the parent member if all of its children are filtered, the user function should be written such that for the parent node, apply the condition on all of its children, using the FORCHILDREN built-in function. If none of the children satisfy the condition, return zero from the user function, which filters the parent node.

### Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                 |
|-------------------------|---------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension from which you want to get the members. |
| <i>DimFilter</i>        | Specify a user function that you want to use to filter the dimension.     |

### Returns

A two-dimensional array of any.

The first dimension contains the member names. The second dimension contains the parent of the member. The members are sorted in the hierarchy order.

If the dimension does not have a hierarchy, all members are returned as level one.

For example, if the dimension has the following members:

```
ALLREGIONS
  NORTH AMERICA
    USA
    CANADA
    MEXICO
  EUROPE
    FRANCE
    GERMANY
    ENGLAND
  ASIA
    JAPAN
    CHINA
```

The GetMembers method returns the following:

| <i><b>Member Name</b></i> | <i><b>Level</b></i> |
|---------------------------|---------------------|
| ALLREGIONS                | Null                |
| NORTHAMERICA              | ALLREGIONS          |
| USA                       | NORTHAMERICA        |
| CANADA                    | NORTHAMERICA        |
| MEXICO                    | NORTHAMERICA        |
| EUROPE                    | ALLREGIONS          |
| FRANCE                    | EUROPE              |
| ENGLAND                   | EUROPE              |
| GERMANY                   | EUROPE              |
| ASIA                      | ALLREGIONS          |
| JAPAN                     | ASIA                |
| CHINA                     | ASIA                |

If the total member is present in the metadata, it is returned as level zero.

## GetTree

### Syntax

**GetTree** (*DimName*)

### Description

Use the GetTree method to return an array of string that contains information about the tree that is attached to the specified dimension.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                      |
|-------------------------|----------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension to which a tree is attached. |

### Returns

An array of string.

The array items have the following format:

1. TreeName
2. setID
3. UserKey Value
4. EffDt
5. BranchName
6. Override record name
7. DetailStartLvl
8. TreeDiscardLvl

## Recalculate

### Syntax

**Recalculate** (*Sync*)

### Description

Use the Recalculate method to recalculate the loaded analytic model. If *Sync* is true, the transaction is synchronous, else it is performed asynchronously.

The Recalculate method always writes any changes to readable, readable and writable, as well as writable records to the database as specified by the analytic type definition.

If you are running in asynchronous mode, this method returns an optional string that contains the operation ID to be used with the CheckAsyncStatus property.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Sync</i>             | Specify whether the recalculation should be run synchronously or asynchronously. This parameter takes a Boolean value: true if it should be run synchronously, false otherwise. |

### Returns

A string.

## RenameMember

### Syntax

**RenameMember** (*DimName, OrigMemberName, NewMemberName*)

### Description

Use the RenameMember method to rename a member in the specified dimension.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                |
|-------------------------|--------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the dimension that contains the member you want to rename.       |
| <i>OrigMemberName</i>   | Specify the name of the member that you want to rename.                  |
| <i>NewMemberName</i>    | Specify the new name for the member specified by <i>OrigMemberName</i> . |

## Returns

None.

## AnalyticModel Class Property

In this section, we discuss the AnalyticModel class property.

## Messages

### Description

This property returns a multi-dimensional array of any containing the messages that occurred during execution of the Recalculate method.

The first dimension contains the message set number. The second dimension contains the message number. The third dimension contains the number of parameters in that message. The subsequent dimensions contain the values for the parameters. The maximum number of possible dimensions is 8.

After you access this property, only new messages are returned, that is, messages are only returned once.

This property is read only.

# CubeCollection Class

Instantiate a CubeCollection object using the AnalyticModel class GetCubeCollection method.

In cube collections, the total member behaves just as the root of the hierarchy. If it's present, it's displayed first in the list.

Filtering of members in a dimension in the cube collection is similar to filtering members using the AnalyticModel class GetMembers method. If you filter the parent node, the children of that node are filtered as well.

See [GetCubeCollection](#).

## CubeCollection Class Methods

In this section we discuss the CubeCollection class methods. The methods are described in alphabetical order.

### CollapseNode

#### Syntax

**CollapseNode** (*DimName*, &*Node*)

#### Description

Use the CollapseNode method to collapse a node in the dimension specified by *DimName*.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension that contains the node you want to collapse.                                                                                                                                                               |
| <i>&amp;Node</i>        | <p>Specify an already instantiated array of array of string (a two-dimensional array of string) containing name-value pairs of the node name and the node detail. For example:</p> <div>PRODUCTS      Fax Modem<br/>REGION        East</div> |

#### Returns

None.

[ExpandNode](#)

## DrillIntoNode

### Syntax

```
DrillIntoNode (DimName, &Node)
```

### Description

Use the DrillIntoNode method to display more data for the specified node and dimension. This is very similar to expanding, except that when you expand a node, the top level (node) is still present. When you drill into a node, the top level or levels are no longer displayed.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension that contains the node that you want to drill into.                                                                                                                                                    |
| <i>&amp;Node</i>        | <p>Specify an already instantiated array of array of string (a two-dimensional array of string) containing name-value pairs of the node name and the node detail. For example:</p> <pre>PRODUCTS    Fax Modem<br/>REGION      East</pre> |

### Returns

None.

## Related Links

[DrillOutOfNode](#)

## DrillOutOfNode

### Syntax

```
DrillOutOfNode (DimName, &Node)
```

### Description

Use the DrillOutOfNode method to collapse the data that you just expanded.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension that contains the node you want to drill out of.                                                                                                                                                       |
| <i>&amp;Node</i>        | Specify an already instantiated array of array of string (a two-dimensional array of string) containing name-value pairs of the node name and the node detail. For example:<br><br><pre>PRODUCTS      Fax Modem REGION        East</pre> |

## Returns

None.

## ExpandNode

### Syntax

**ExpandNode** (*DimName*, *&Nodes*, *ExpandAll*)

### Description

Use the ExpandNode method to expand the nodes in the specified dimension.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension contains the node that you want to expand.                                                                                   |
| <i>&amp;Nodes</i>       | Specify an already instantiated array of array of string (a two-dimensional array of string) containing name-value pairs of the node name and the node detail. |
| <i>ExpandAll</i>        | Specify whether to expand the sub-nodes or not. This parameter takes a Boolean value; true to expand the nodes, false to not expand the nodes.                 |

Returns

None.

Example

In the following example, both the Accounts and Dept dimensions have hierarchies.

When the data is displayed, it will be as follows:

When you want to expand All Depts under Account 100 , use the following PeopleSoft Analytic Calculation Engine code:

```
BAMCoordinate coord;  
coord.SetValue( "Account", "100");  
coord.SetValue("Dept" , "All Depts")  
ExpandNode("Dept", coord, false)
```

The result of this will have the following:

GetData

Syntax

```
GetData(&DataRowset, StartRow, EndRow[, NetChanges])
```

## Description

Use the GetData method to populate a rowset with data from the cube collection.

*DataRowset* is the rowset into which is put the data. If you specify an already instantiated rowset, the given rowset is populated with the data. If you specify a rowset that has not been instantiated, a new rowset is created, with the record field definition of the desired cube collection.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;DataRowset</i>  | Specify the rowset into which to put the data. If you specify an already instantiated rowset, the given rowset is populated with the data. If you specify a rowset that has not been instantiated, a new rowset is created, with the record field definition of the desired cube collection. |
| <i>StartRow</i>         | Specify the first row of data to be retrieved, as an integer.                                                                                                                                                                                                                                |
| <i>EndRow</i>           | Specify the last row of data to be retrieved, as an integer. If you specify a zero for this parameter, all rows are retrieved.                                                                                                                                                               |
| <i>NetChanges</i>       | Specify whether all values within the range are returned, or whether just values changed since the last time the Recalculate method was used. This parameter takes a Boolean value: true, return all values, false, return just the changed values. The default value is false.              |

## Returns

None.

## GetDimFilter

### Syntax

**GetDimFilter** (*DimName*)

### Description

Use the GetDimFilter method to return the name of the current user function (filter) used with the specified dimension.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension for which you want the associated user function (filter). |

## Returns

A string containing the name of the user function. If there is no filter applied to the dimension, this method returns an empty string.

## Related Links

[SetDimFilter](#)

## GetDimSort

### Syntax

`GetDimSort (DimName)`

### Description

Use the GetDimSort to return the current sort settings on the specified dimension.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                 |
|-------------------------|---------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension for which you'd like the sort settings. |

## Returns

An array of any. The array contains the same structure as the signature for the SetDimSort method.

| <i><b>Value</b></i> | <i><b>Description</b></i> |
|---------------------|---------------------------|
| Array index 1       | IsAscending as Boolean    |
| Array index 2       | Key1 as string            |
| Array index 3       | IsAscending2 as Boolean   |

| <b><i>Value</i></b> | <b><i>Description</i></b> |
|---------------------|---------------------------|
| Array index 4       | Key2 as string            |
| Array index 5       | IsAscending3 as Boolean   |
| Array index 6       | Key3 as string            |

## Related Links

[SetDimSort](#)

## GetLayout

### Syntax

```
GetLayout(&SlicerArray, &RowAxisArray, &ColumnAxisArray)
```

### Description

Use the GetLayout method to return the current layout for the three axes, (slice, row, and column) on the specified dimension.

### Parameters

| <b><i>Parameter</i></b>     | <b><i>Description</i></b>                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------|
| <i>&amp;SlicerArray</i>     | Specify an already instantiated array of string containing the list of fields used on the slice axis.  |
| <i>&amp;RowAxisArray</i>    | Specify an already instantiated array of string containing the list of fields used on the row axis.    |
| <i>&amp;ColumnAxisArray</i> | Specify an already instantiated array of string containing the list of fields used on the column axis. |

### Returns

None.

## GetRowCount

### Syntax

```
GetRowCount ( )
```

## Description

Use the GetRowCount method to return the total number of rows in the cube collection.

The number of rows is a function of the hierarchy, that is, what is shown or not shown, and filtered values.

## Parameters

None.

## Returns

An integer.

## Related Links

[GetDimension](#)

## GetSlice

### Syntax

```
GetSlice (&SliceRecord)
```

### Description

Use the GetSlice method to return the current slice values of all the dimensions.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                              |
|-------------------------|----------------------------------------------------------------------------------------|
| <i>&amp;SliceRecord</i> | Specify an already instantiated record object to hold the values of the slicer record. |

### Returns

None.

### Related Links

[SetSlice](#)

## SetData

### Syntax

```
SetData (&DataRowset)
```

## Description

Use the `SetData` method to populate the data in the cube collection with the data in the specified rowset.

The system extracts only changed values from the rowset, that is, values marked as updated. .

`SetData` method also writes the changes to the database for any record marked as writable or readable and writable in the analytic type definition, and mapped to the specified cube collection.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                         |
|-------------------------|---------------------------------------------------------------------------------------------------|
| <i>&amp;DataRowset</i>  | Specify the rowset object that contains the data you want to use to populate the cube collection. |

## Returns

None.

# SetDimensionOrder

## Syntax

```
SetDimensionOrder (&FieldNames)
```

## Description

Use the `SetDimensionOrder` method to specify the order of dimensions for this cube collection.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;FieldNames</i>  | Specify an already instantiated array of string containing the field names that are the dimensions in the cube collection, in the order you want the dimensions. |

## Returns

None.

[SetDimSort](#)

## SetDimFilter

### Syntax

```
SetDimFilter(DimName, DimFilter)
```

### Description

Use the SetDimFilter method to set a dimension filter for the specified dimension in the cube collection.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension for which you want to specify a dimension filter.          |
| <i>DimFilter</i>        | Specify the name of the dimension filter (user function) that you want to use the dimension. |

### Returns

None.

## Related Links

“Understanding Dimensions” (Analytic Calculation Engine)

## SetDimSort

### Syntax

```
SetDimSort(DimName, IsAscending [, Key1, IsAscending2, Key2, IsAscending3, Key3])
```

### Description

Use the SetDimSort method to specify the sorting order for the cube collection.

*Key1*, *Key2* and *Key3* are optional parameters. If they are not specified, the sorting works as a name sort, that is, it sorts by the name of members in the given dimension, either in ascending or descending order.

If keys are specified, the keys values refer to the names of the cubes to be used as they key. The method orders the members of the dimension based on the value of the cubes for each member. The Boolean parameter *IsAscending* defines whether sorting should be in ascending or descending order. Up to three

sort keys may be specified. *Key1* is the primary sort key. *Key2* is used to sub-sort any members that have the same key value under *Key1*, and so on.

The scope of this method is the same as the scope of the *AnalyticModel* object created in *PeopleCode*, that is, if the *AnalyticModel* object was declared with scope *Global*, this method would have a global scope as well, if it was declared as *Local*, it would have *Local*, and so on.

Specifying a null string for *DimName* or for keys one through three removes the current value as a sort value.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                        |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the dimension name that you would like sorted.                                                                                                                                                                           |
| <i>IsAscending</i>      | Specify if the sort order is ascending or descending. This parameter takes a Boolean value: true if the sort is ascending, false if it's descending.                                                                             |
| <i>Key1</i>             | Specify the name of a key field by which the sort should be ordered. If you do not specify keys, the sort is ordered by the names of the members in the given dimensions. If you do specify keys, the sort is order by the keys. |
| <i>IsAscending2</i>     | Specify if the sort order for <i>Key1</i> is ascending or descending. This parameter takes a Boolean value: true if the sort is ascending, false if it's descending.                                                             |
| <i>Key2</i>             | Specify the name of a key field to be used to sub-sort the primary key field <i>Key1</i> .                                                                                                                                       |
| <i>IsAscending3</i>     | Specify if the sort order for <i>Key2</i> is ascending or descending. This parameter takes a Boolean value: true if the sort is ascending, false if it's descending.                                                             |
| <i>Key3</i>             | Specify the name of a key field to be used to sub-sort the primary key field <i>Key2</i> .                                                                                                                                       |

## Returns

None.

## SetSlice

### Syntax

**SetSlice** (&*SliceRecord*)

## Description

Use the SetSlice method to specify a slice record for this cube collection.

## Parameters

| <i>Parameter</i>        | <i>Description</i>                                                                                     |
|-------------------------|--------------------------------------------------------------------------------------------------------|
| <i>&amp;SliceRecord</i> | Specify an already instantiated record as the record to be used for the slice for the cube collection. |

## Returns

None.

## Related Links

[GetSlice](#)

## ShowHierarchy

### Syntax

**ShowHierarchy** (*DimName*, *Show*, *ExpandToLevel*)

### Description

Use the ShowHierarchy method to either hide or display the cube collection hierarchy.

If there is a tree attached to the dimension, and *Show* is false, only the detail level members are shown in the Analytic grid. If *Show* is true, all members including nodes are shown.

When the hierarchy is hidden, the GetData method returns only leaf values. When the hierarchy is displayed, GetData returns node values and leaf values.

The *ExpandToLevel* parameter expands the hierarchy to the level specified. Level indexes start from 0 , the root level.

For example, if you specify *ExpandToLevel* as 1, the grid displays the total (root member) and all the detail members in a dimension with no tree attached.

In the following example, if you specify *ExpandToLevel* as 2, the hierarchy would be displayed only to the quarter level, and not to the month level.

```
ALL_TIME
  2003
    Q1
      Jan
      Feb
      Mar
    Q2
      Apr
      May
```

Parameters

| Parameter     | Description                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------|
| DimName       | Specify the name of the dimension for which you want to either display or hide the hierarchy.                                            |
| Show          | Specify whether to display or hide the hierarchy. This parameter takes a Boolean value; true to display the hierarchy, false to hide it. |
| ExpandToLevel | Specify to what level to expand the hierarchy, as a number.                                                                              |

Returns

None.

UnsetDimFilter

Syntax

```
UnsetDimFilter (DimName)
```

Description

Use the UnsetDimFilter method to remove the filter on the specified dimension for the cube collection.

Parameters

| Parameter | Description                                                                 |
|-----------|-----------------------------------------------------------------------------|
| DimName   | Specify the name of the dimension from which you want to remove the filter. |

## Returns

None.

[SetDimFilter](#)

## UnsetDimSort

### Syntax

```
UnsetDimSort (DimName)
```

### Description

Use the UnsetDimSort method to remove the sorting on the specified dimension for a cube collection. After using this method, the members are returned in the global member order as specified in the analytic model definition.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                |
|-------------------------|--------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension from which you want to remove sorting. |

## Returns

None.

## CubeCollection Class Property

In this section we discuss the CubeCollection class property.

## Messages

### Description

This property returns a multi-dimensional array of any containing the messages that occurred during execution of the GetData, SetData, and CalculateCube methods.

The first dimension contains the message set number. The second dimension contains the message number. The third dimension contains the number of parameters in that message. The subsequent dimensions contain the values for the parameters. The maximum number of possible dimensions is 8.

After you access this property, only new messages are returned, that is, messages are only returned once.

This property is read-only.

# Analytic Calculation Engine Metadata Classes

---

## Understanding the PeopleSoft Analytic Calculation Engine Metadata Classes

PeopleSoft Analytic Calculation Engine comprises a calculation engine plus several PeopleTools features which enable application developers to define both the calculation rules and the display of calculated data within PeopleSoft applications for the purposes of multi-dimensional reporting, data editing and analysis.

More specifically, developers create *analytic models* in order to define the rules which are used to calculate data. Developers also create PeopleSoft Pure Internet Architecture pages with *analytic grids* in order to display the data within PeopleSoft applications. End users view, analyze and make changes to this data. When end users save their changes, PeopleSoft Analytic Calculation Engine recalculates the data and saves the calculated data to the database.

PeopleCode enables developers to manipulate analytic calculation data as follows:

- Use the Analytic Calculation Engine classes to either retrieve or specify data in an instance of an analytic model loaded into the system, and also to calculate (or recalculate) cube values.
- Use the Analytic Calculation Engine metadata classes to manipulate an analytic model definition. For example, you can add cubes to a cube collection or rename an existing user function for a model.
- Use the Analytic Grid classes to manipulate the display of analytic calculation data on a page.
- Use the Analytic Type classes to manipulate an analytic type definition. For example, you can specify a new analytic model for an analytic type definition.

---

**Important!** The Analytic Calculation Engine Metadata classes are not supported on IBM z/OS and Linux for IBM System z platforms.

---

[Understanding the Analytic Calculation Engine Classes](#)

[AnalyticGrid Class Methods](#)

[Using the Analytic Type Classes](#)

---

## Using the Analytic Calculation Engine Metadata Classes

You can create analytic model definitions using Application Designer. PeopleSoft provides the Analytic Calculation Engine Metadata classes for accessing these definitions at runtime.

You can also create an analytic model definition in PeopleCode, using the Create method, then saving it to the database using the Save method. After you save the definition, you can access it using Application Designer.

All of the primary objects (dimensions, cube collections, cubes, and so on) are instantiated from an analytic model object, so you only need to create an instance of the analytic model. You can also build a rule as an object instead of as a string.

## Inserting and Deleting Objects

If you insert or delete an object from a group of objects, any existing object references are no longer valid. For example, if you use the DeleteCube method, any existing references to cube objects are no longer valid. You need to create any object references after using any insert or delete method.

## Building a Rule as an Object

The RuleExpressions subpackage contains several classes. Each of these classes represents the different parts of the analytic calculation engine rule grammar. These objects are created using the Create built-in function and the constructor for that class, then added to the RuleDefn object with the AddRuleExpression method.

The following example creates a cube that uses the Analytic Calculation Engine built-in function AT.

```
Function AT_Cube
    /** AT Cube Rule */
    &Expected = "AT(GENERAL2, [GENERAL2:4], LOOKUPVALUES)";
    &CubeName = "AT";

    &Funcall = create PT_ANALYTICMODELDEFN:RuleExpressions:FunctionCall(&Constants.Funcall_Type_Builtin, &Constants.Funcall_Builtin_AT);

    &Constant = create PT_ANALYTICMODELDEFN:RuleExpressions:Constant(&Constants.Constant_Type_Literal, "GENERAL2");
    &Funcall.AddArgument(&Constant);

    &MemberRefArgument = create PT_ANALYTICMODELDEFN:RuleExpressions:MemberReference("GENERAL2", "4");
    &Funcall.AddArgument(&MemberRefArgument);

    &CubeArgument = create PT_ANALYTICMODELDEFN:RuleExpressions:Cube("LOOKUPVALUES");

    &Funcall.AddArgument(&CubeArgument);

    &RuleDefn = create PT_ANALYTICMODELDEFN:RuleDefn("");
    &CubeDefn = &Model.GetCube(&CubeName);
    &RuleDefn.AddRuleExpression(&Funcall);
    &RuleDefn.GenerateRule();
    &CubeDefn.SetRule(&RuleDefn);
    If (Not (Exact(&RuleDefn.RuleString, &Expected))) Then
        &Model.Save();
        Error ("Rule Expression API Failed [Cube " | &CubeName | " Rule]");
    End-If;
End-Function;
```

---

## Error Handling

All the Analytic Calculation Engine Metadata classes throw PeopleCode exceptions for any fatal error that occurs in the execution of the operation. PeopleSoft recommends enclosing your analytic model programs in try-catch statements. This way, if your program catches the exception, the message set and message number that are associated with the exception object indicate the error.

### Related Links

[Try-Catch Blocks](#)

---

## Data Types of the Analytic Calculation Engine Metadata Objects

Every PeopleSoft Analytic Calculation Engine metadata object is declared as its own data type, that is, `AnalyticModelDefn` objects are declared as type `AnalyticModelDefn`, `CubeDefn` objects are declared as type `CubeDefn`, and so on.

---

## Scope of Analytic Calculation Engine Metadata Objects

The Analytic Calculation Engine Metadata objects can only be instantiated from PeopleCode.

These objects can be used anywhere you have PeopleCode, that is, in a Application Engine program, an application class, record field PeopleCode, and so on.

Analytic Calculation Engine Metadata objects can be of scope Local, Component or Global.

---

## How to Import the Analytic Calculation Engine Metadata Classes

The Analytic Calculation Engine metadata classes are *not* built-in classes, like `Rowset`, `Field`, `Record`, and so on. They are application classes. Before you can use these classes in your PeopleCode program, you must import them to your program.

An import statement names either all the classes in a package or one particular application class. For importing the Analytic Calculation Engine metadata classes, PeopleSoft recommends that you import all the classes in the application package.

The application package `PT_ANALYTICMODELDEFN` contains the following subclasses:

- `AnalyticModelDefn`
- `CubeCollectionDefn`
- `CubeDefn`
- `DimensionDefn`
- `ExplicitDimSet`

- OrganizerDefn
- RuleDefn
- UserFunctionDefn

Additionally, there is a sub-application package, RuleExpressions, that contains classes used to build a rule as object instead of as a simple string. This package contains the following classes:

- Assignment
- Comparison
- Constant
- Constants
- Cube
- ExpressionBlock
- FunctionCall
- MemberReference
- Operation
- RuleExpression
- Variable

The import statements that you should use should be as follows:

```
import PT_ANALYTICMODELDEFN:*;  
import PT_ANALYTICMODELDEFN:RuleExpressions:*;
```

Using the asterisks after the package name makes all the application classes directly contained in the named package available.

# How to Create an Analytic Calculation Engine Metadata Class Object

After you've imported the Analytic Calculation Engine metadata classes, you need to instantiate an instance of the AnalyticModelDefn class, using the constructor for that class and the Create function. After you create the object, you must populate it using either the Get or Create method.

The following example creates an AnalyticModelDefn object from the QE\_ALLFUNCTION analytic model definition.

```
import PT_ANALYTICMODELDEFN:*;
```

```
Local AnalyticModelDefn &Model;  
  
&Model = create AnalyticModelDefn("QE_ALLFUNCTION");
```

**Related Links**

[Analytic Calculation Engine Metadata Classes Constructor](#)

---

# Analytic Calculation Engine Metadata Classes Constructor

You must use the constructor for the AnalyticModelDefn class to instantiate an instance of that class. All other metadata objects are instantiated from this class.

## AnalyticModelDefn

**Syntax**

```
AnalyticModelDefn (ModelName)
```

**Description**

Use the AnalyticModelDefn constructor to create an AnalyticModelDefn object.

Once the AnalyticModelDefn object is created, you can then execute either the Get or Create methods to ‘instantiate’ the model.

---

**Note:** The Delete and Rename methods can only be executed before a model is ‘instantiated’.

---

**Parameters**

| <i>Parameter</i> | <i>Description</i>                                |
|------------------|---------------------------------------------------|
| <i>ModelName</i> | Specify the name of an analytic model definition. |

**Returns**

An AnalyticModelDefn object.

**Example**

```
&Model = create AnalyticModelDefn("QE_ALLFUNCTION");
```

## AnalyticModelDefn Class Methods

The following section discusses the AnalyticModelDefn class methods. The methods are discussed in alphabetical order.

### AddCube

#### Syntax

**AddCube** (*CubeName*)

#### Description

Use the AddCube method to add a new cube to the analytic model definition. This method fails if the cube specified by *CubeName* already exists.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                  |
|-------------------------|----------------------------------------------------------------------------|
| <i>CubeName</i>         | Specify the name of a new cube that you want to add to the analytic model. |

#### Returns

A CubeDefn object.

## AddCubeCollection

### Syntax

**AddCubeCollection** (*CubeCollectionName*)

### Description

Use the AddCubeCollection method to add a new cube collection to the analytic model definition. This method fails if *CubeCollectionName* already exists.

### Parameters

| <i><b>Parameter</b></i>   | <i><b>Description</b></i>                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------|
| <i>CubeCollectionName</i> | Specify the name of a new cube collection that you want to add to the analytic model definition. |

### Returns

A CubeCollectionDefn object.

### Related Links

## AddDimension

### Syntax

**AddDimension** (*DimName*)

### Description

Use the AddDimension method to add a new dimension to the analytic model. This method fails if the specified dimension already exists.

When you add a dimension to a cube, the dimension is also automatically added to any cube collections that already contain the cube.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                        |
|-------------------------|----------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension you want to add. This must be a new dimension. |

## Returns

A DimensionDef object.

## AddExplicitDimensionSet

### Syntax

```
AddExplicitDimensionSet(ExplicitDimSetName)
```

### Description

Use the AddExplicitDimensionSet method to add a new explicit dimension set to the analytic model. This method fails if the specified explicit dimension set already exists.

## Parameters

| <i><b>Parameter</b></i>   | <i><b>Description</b></i>                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------|
| <i>ExplicitDimSetName</i> | Specify the name of the explicit dimension you want to add. This must be a new explicit dimension. |

## Returns

An ExplicitDimensionSet object.

## AddOrganizer

### Syntax

**AddOrganizer** (*OrganizerName*)

### Description

Use the AddOrganizer method to add a new organizer to the analytic model. This method fails if the organizer specified by *OrganizerName* already exists.

### Parameters

| <i>Parameter</i>     | <i>Description</i>                                 |
|----------------------|----------------------------------------------------|
| <i>OrganizerName</i> | Specify the name of the organizer you want to add. |

### Returns

An OrganizerDefn object.

## AddUserFunction

### Syntax

**AddUserFunction** (*UserFunctionName*)

### Description

Use the AddUserFunction method to add a new user function to the analytic model. This method fails if the user function specified by *UserFunction* already exists.

### Parameters

| <i>Parameter</i>        | <i>Description</i>                                              |
|-------------------------|-----------------------------------------------------------------|
| <i>UserFunctionName</i> | Specify the name of the new user function that you want to add. |

## CopyCube

### Syntax

**CopyCube** (*CubeName*, *NewCubeName*)

### Description

Use the CopyCube method to copy the specified cube to the new cube. This method fails if the cube specified by *CubeName* already exists.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                 |
|-------------------------|-----------------------------------------------------------|
| <i>CubeName</i>         | Specify the name of the cube that you want to copy.       |

## CopyCubeCollection

### Syntax

**CopyCubeCollection**(*CubeCollectionName*, *NewCubeCollectionName*)

### Description

Use the CopyCubeCollection method to copy the specified cube collection to a new collection. If the new cube collection specified by *NewCubeCollectionName* already exists, this method fails.

### Parameters

| <b>Parameter</b>             | <b>Description</b>                                             |
|------------------------------|----------------------------------------------------------------|
| <i>CubeCollectionName</i>    | Specify the name of the cube collection that you want to copy. |
| <i>NewCubeCollectionName</i> | Specify the name you want for the new cube collection.         |

## CopyDimension

### Syntax

**CopyDimension**(*DimName*, *NewDimName*)

### Description

Use the CopyDimension method to copy the dimension specified by *DimName* to a new dimension. If the dimension specified by *NewDimName* already exists, this method fails.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                               |
|-------------------------|-------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension that you want to copy.                |
| <i>NewDimName</i>       | Specify the name of the new dimension that you want the data copied to. |

## Delete

### Syntax

```
Delete()
```

### Description

Use the Delete method to delete the analytic model executing the method.

You can only use this method on a *closed* analytic model definition, that is, before you use a Get or Create method.

---

**Warning!** The delete occurs immediately, that is, the analytic model definition is removed from the database. Only use this method if you're certain you want to delete the definition.

---

If this model is used by any existing analytic type definition, this method fails.

### Parameters

None.

### Returns

None.

## DeleteCube

### Syntax

```
DeleteCube(CubeName, ForceDelete)
```

### Description

Use the DeleteCube method to delete the cube specified by *CubeName*.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>CubeName</i>         | Specify the name of the cube you want to delete from the analytic model.                                                                                                                                                                                                                                                        |
| <i>ForceDelete</i>      | Specify if the cube should always be deleted. This parameter takes a Boolean value. If you specify <i>ForceDelete</i> as false, and the cube is used by another part (such as a cube collection) this method fails. If you specify <i>ForceDelete</i> as true, and the cube is used by another part, the cube is still deleted. |

## Description

Use the RenameCubeCollection method to rename the cube collection specified by *CubeCollectionName* to the new name *NewCubeCollectionName*

## Parameters

| <b><i>Parameter</i></b>      | <b><i>Description</i></b>                                                                                                                                                                                                                                                                                                                                              |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>CubeCollectionName</i>    | Specify the name of the cube collection that you want to rename.                                                                                                                                                                                                                                                                                                       |
| <i>NewCubeCollectionName</i> | Specify the new name of the cube collection.                                                                                                                                                                                                                                                                                                                           |
| <i>ForceRename</i>           | Specify if the cube collection should always be renamed. This parameter takes a Boolean value. If you specify <i>ForceRename</i> as false, and the cube collection is used by another part (such as an organizer) this method fails. If you specify <i>ForceRename</i> as true, and the cube collection is used by another part, the cube collection is still renamed. |

## RenameDimension

### Syntax

**RenameDimension** (*DimName*, *NewDimName*, *ForceRename*)

### Description

Use the RenameDimension method to rename the dimension specified by *DimName* to the new name *NewDimName*.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                             |
|-------------------------|-------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension you want to rename. |
| <i>NewDimName</i>       | Specify the new name of the dimension.                |

| <b>Parameter</b>   | <b>Description</b>                                                                                                                                                                                                                                                                                                                       |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ForceRename</i> | Specify if the dimension should always be renamed. This parameter takes a Boolean value. If you specify <i>ForceRename</i> as false, and the dimension is used by another part (such as a cube) this method fails. If you specify <i>ForceRename</i> as true, and the dimension is used by another part, the dimension is still renamed. |

# RenameExplicitDimensionSet

## Syntax

```
RenameExplicitDimensionSet(ExplicitDimSetName, NewExplicitDimSetName, ForceRename)
```

## Description

Use the `RenameExplicitDimensionSet` method to rename the explicit dimension set specified by *ExplicitDimSetName* to the new name *NewExplicitDimSetName*.

## Parameters

| <b>Parameter</b>             | <b>Description</b>                                                 |
|------------------------------|--------------------------------------------------------------------|
| <i>ExplicitDimSetName</i>    | Specify the name of the explicit dimension set you want to rename. |
| <i>NewExplicitDimSetName</i> | Specify the new name of the explicit dimension set.                |
| <i>ForceRename</i>           | The value for this parameter is ignored in the current release.    |

## RenameOrganizer

### Syntax

```
RenameOrganizer(OrganizerName, NewOrganizerName, ForceRename)
```

### Description

Use the RenameOrganizer method to rename the organizer specified by *OrganizerName* to the new name *NewOrganizerName*.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                       |
|-------------------------|-----------------------------------------------------------------|
| <i>OrganizerName</i>    | Specify the name of the organizer you want to rename.           |
| <i>NewOrganizerName</i> | Specify the new name for the organizer.                         |
| <i>ForceRename</i>      | The value for this parameter is ignored in the current release. |

### Returns

## Save

### Syntax

**Save** ()

### Description

Use the `Save` method to save any changes to the analytic model definition to the database. If the saved model is valid, the value of the `IsValid` property is set to true, if it is not valid, it is set to false.

The `Messages` property is populated with messages from the validation that occurs with the save.

## Parameters

None.

## Returns

None.

# Validate

## Syntax

```
Validate()
```

## Description

Use the Validate method to validate the analytic model definition. This method returns true if the model successfully validates. If this method returns false, the detailed error messages are available through the Messages property.

The IsValid property is not set with this method. The Save method sets the IsValid property.

## Parameters

None.

## Returns

A Boolean value: true if the analytic model definition validates successfully, false otherwise.

# AnalyticModelDefn Properties

The following section discusses the AnalyticModelDefn class properties. The properties are discussed in alphabetical order.

## CircularFormulaWarn

### Description

Use this property to specify whether warnings occur when there are circular dependencies as rules are added. This property takes a Boolean value: true if warnings should occur, false otherwise. The default value for this property is false.

This property is read/write.

## Description

### Description

Use this property to specify the description of the analytic model. This property takes a string value.

This property is read/write.

## IsValid

### Description

This property indicates if the analytic model is valid, that is, if it would successfully load.

This property is read-only.

### Related Links

[Validate](#)

[Save](#)

“Validating Analytic Models” (Analytic Calculation Engine)

## LongDescription

### Description

Use this property to specify the long description of the analytic model definition. This property takes a string value.

This property is read/write.

## MaxDelta

### Description

This property specifies the maximum number of value changes for the analytic model

This property takes a float value. The default value is 0.

This property is read/write.

### Related Links

“Understanding the Analytic Model Definition Creation Process” (Analytic Calculation Engine)

## MaxIterations

### Description

Use this property to specify the maximum number of iterations for the analytic model.

This property take an integer value. The default value is 100.

This property is read/write.

### Related Links

[Understanding the Analytic Calculation Engine Classes](#)

## Messages

### Description

This property returns a multi-dimensional array of any that contains the messages that occurred during execution of the Validate or Save methods. This array is only populated after the Validate or Save method has completed successfully.

The first dimension contains the message set number. The second dimension contains the message number. The third dimension contains the number of parameters in that message. The subsequent dimensions contain the values for the parameters. The maximum number of possible dimensions is 8.

This property is read-only.

### Related Links

[Validate](#)

[Save](#)

## Name

### Description

This property indicates the name of the analytic model.

This property is read-only.

### Related Links

[Rename](#)

## ResolveCircularDeps

### Description

Use this property to specify if the analytic model should resolve circular dependencies through iteration. This property takes a Boolean value: true if the dependencies should be resolved, false otherwise. The default value is false.

This property is read/write.

---

## DimensionDefn Class

Use the DimensionDefn class to access a dimension that's associated with an analytic model. You instantiate an object of this class using the following AnalyticModelDefn methods:

- AddDimension
- CopyDimension
- GetDimension

---

## DimensionDefn Class Properties

The following section discusses the DimensionDefn class properties. The properties are discussed in alphabetical order.

## AggregateSequence

### Description

This property indicates the sequence number of this dimension used during aggregation of the analytic model

This property is read-only..

## AggregationUserFunction

### Description

Use this property to specify the name of a user function that can be used to override the default aggregation for this dimension.

This property is read/write.

## Comments

### Description

Use this property to specify additional notes about the dimension.

This property is read/write.

## Name

### Description

This property indicates the name of the dimension.

This property is read-only.

### Related Links

[GetDimensionNames](#)

[RenameDimension](#)

## TotalMemberName

### Description

Use this property to specify a field value that is used at runtime to host the total value for this dimension. If a total isn't applicable, this property has no value.

This property is read/write.

---

## ExplicitDimensionSet Class

Use the ExplicitDimensionSet class to access an explicit dimension set associated with an analytic model. You instantiate an object of this class using one of the following AnalyticModelDefn methods:

- AddExplicitDimensionSet
- CopyExplicitDimensionSet
- GetExplicitDimensionSet

You can also use the GetExplicitDimensionSetNames to return an array containing the names of all the explicit dimension sets associated with the analytic model.

---

## ExplicitDimensionSet Methods

The following section discusses the ExplicitDimensionSet class methods. The methods are discussed in alphabetical order.

### AttachDimension

#### Syntax

```
AttachDimension (DimName)
```

#### Description

Use the AttachDimension method to attach a dimension to an explicit dimension set.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                             |
|-------------------------|-------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension you want to attach. |

#### Returns

None.

#### Related Links

[DetachDimension](#)

### DetachDimension

#### Syntax

```
DetachDimension (DimName)
```

#### Description

Use the DetachDimension method to detach a dimension from an explicit dimension set.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                  |
|-------------------------|------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension that you want to detach. |

## Returns

None.

## Related Links

[AttachDimension](#)

# GetDimensionNames

## Syntax

```
GetDimensionNames()
```

## Description

Use the GetDimensionNames method to return an array of string that contains the names of all the dimensions associated with the ExplicitDimensionSet.

## Parameters

None.

## Returns

An array of string.

## Related Links

[AttachDimension](#)

[DetachDimension](#)

---

# ExplicitDimensionSet Properties

The following section discusses the ExplicitDimensionSet class properties. The properties are discussed in alphabetical order.

## Name

### Description

The Name property returns the name of the explicit dimension set as a string.

This property is read-only.

# SequenceNumber

## Description

This property returns the sequence number of the explicit dimension set.

This property is read-only.

---

# CubeDefn Class

Use the CubeDefn class to access a cube associated with an analytic model. You instantiate an object of this class using the following AnalyticModelDefn methods:

- AddCubeDefn
- CopyCubeDefn
- GetCubeDefn

---

# CubeDefn Class Methods

The following section discusses the CubeDefn class methods. The methods are discussed in alphabetical order.

## AttachDimension

### Syntax

`AttachDimension (DimName)`

### Description

Use the AttachDimension method to attach an existing dimension specified by *DimName* to the cube.

### Parameters

| Parameter      | Description                                             |
|----------------|---------------------------------------------------------|
| <i>DimName</i> | Specify the name of the dimension that you want to add. |

### Returns

None.

## GetCauses

### Syntax

```
GetCauses (CauseType)
```

### Description

Any cube that affects another cube is a *cause* of that cube. Use the GetCauses method to return a list of all the other cubes that are the causes for this cube.

The cube names are returned in an array of string.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                     |
|-------------------------|-----------------------------------------------|
| <i>CauseType</i>        | Specify the type of causes you want returned. |

| <i><b>Value</b></i>        | <i><b>Description</b></i>                                                 |
|----------------------------|---------------------------------------------------------------------------|
| AnalyticModel_DirectCauses | Only return direct causes.                                                |
| AnalyticModel_AllCauses    | Return all cubes that are causes for this cube, both direct and indirect. |
| AnalyticModel_AllInputs    | Return all cubes that have input to this cube.                            |

## Returns

An array of string.

## Related Links

## GetCircularDeps

### Syntax

**GetCircularDeps** (*DimName*)

### Description

Use the GetCircularDeps method to return all cubes that have circular dependencies based on the dimension specified by *DimName*.

The cube names are returned in an array of string.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                          |
|-------------------------|------------------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension that you want to find circular dependencies for. |

## Returns

An array of string.

## GetEffects

### Syntax

**GetEffects** (*EffectType*)

### Description

Any cube that is affected by another cube is an *effect* of that cube. Use the GetEffects method to return a list of all the cubes affected by this cube.

The list of cubes is returned as an array of string.

### Parameters

| <b>Parameter</b>  | <b>Description</b>                             |
|-------------------|------------------------------------------------|
| <i>EffectType</i> | Specify the type of effects you want returned. |

| <b>Value</b>                | <b>Description</b>                                       |
|-----------------------------|----------------------------------------------------------|
| AnalyticModel_DirectEffects | Only return cubes that are a direct effect on this cube. |
| AnalyticModel_AllEffects    | Return all cubes that are an effect on this cube.        |

### Returns

An array of string.

## GetRule

### Syntax

```
GetRule ()
```

### Description

Use the GetRule method to get a reference to a RuleDefn object that represents the rule for this cube.

### Parameters

None.

### Returns

A RuleDefn object.

### Related Links

[RuleDefn Class](#)

[SetRule](#)

## SetDimensionAggregate

### Syntax

```
SetDimensionAggregate (DimName, UserFunctionName)
```

### Description

Use the SetDimensionAggregate method to specify the user function to be used for the aggregate for the dimension *DimName*.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                   |
|-------------------------|-----------------------------------------------------------------------------|
| <i>DimName</i>          | Specify the name of the dimension for which you want to set the aggregate.  |
| <i>UserFunctionName</i> | Specify the name of the user function to be used as the aggregate function. |

## Returns

None.

## Related Links

[GetDimensionAggregate](#)

## SetRule

### Syntax

```
SetRule (&RuleDefn)
```

### Description

Use the SetRule method to specify a RuleDefn object to be used as the rule for this cube.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------|
| <i>&amp;RuleDefn</i>    | Specify an already instantiated RuleDefn object that you want to associate with this cube. |

## Returns

None.

## Related Links

[GetRule](#)

[RuleDefn Class](#)

## UsesDimension

### Syntax

`UsesDimension` (*DimName*)

### Description

Use the `UsesDimension` method to determine if the dimension specified by *DimName* is used by this cube.

### Parameters

| <i>Parameter</i> | <i>Description</i>                                            |
|------------------|---------------------------------------------------------------|
| <i>DimName</i>   | Specify the name of the dimension that you want to check for. |

### Returns

A Boolean value: true if the dimension is used, false otherwise.

## CubeDefn Class Properties

The following section discusses the `CubeDefn` class properties. The properties are discussed in alphabetical order.

## CalcAggregates

### Description

Use this property to specify if the aggregate is calculated for this cube. This property takes a Boolean value: true if the aggregate is calculated, false otherwise.

This property is read/write.

## Comments

### Description

Use this property to specify additional notes about the cube.

This property is read/write.

## DimensionCount

### Description

This property indicates the number of dimensions associated with this cube.

This property is read-only.

## FormatType

### Description

Use this property to specify the format of the cube. The values are:

| <b><i>Value</i></b>         | <b><i>Description</i></b>     |
|-----------------------------|-------------------------------|
| AnalyticModel_Format_Number | The format is of type number. |
| AnalyticModel_Format_Date   | The format is of type date.   |
| AnalyticModel_Format_Member | The format is of type member. |
| AnalyticModel_Format_Text   | The format is of type text.   |

This property is read/write.

## IsVirtual

### Description

Use this property to specify if the cube is a virtual cube, that is, if it doesn't store data. This property takes a Boolean value: true if the cube is a virtual cube, false otherwise.

This property is read/write.

## Name

### Description

This property specifies the name of the cube.

This property is read-only.

## ValueDimensionName

### Description

Use this property to specify the dimension name for cubes that have a format of member.

This property is only valid when a cube has a format of member.

This property is read/write.

Use the CubeCollectionDefn class to access cube collections associated with an analytic model. You instantiate an object of this class using the following AnalyticModelDefn class methods:

- AddCubeCollection
- CopyCubeCollection
- GetCubeCollection

---

## CubeCollectionDefn Class Methods

The following section discusses the CubeCollectionDefn class methods. The methods are discussed in alphabetical order.

### AttachCube

#### Syntax

**AttachCube** (*CubeName*)

#### Description

Use the AttachCube method to attach the existing cube specified by *CubeName* to the cube collection.

You should only specify cube collections comprised of derived/work records as the main record for a presentation cube collection.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                        |
|-------------------------|--------------------------------------------------|
| <i>CubeName</i>         | Specify the name of the cube you want to attach. |

## Returns

None.

## Related Links

[DetachCube](#)

[GetCubeNames](#)

[CubeDefn Class](#)

## DetachCube

### Syntax

**DetachCube** (*CubeName*)

### Description

Use the DetachCube to detach the cube specified by *CubeName* from the cube collection.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                             |
|-------------------------|-------------------------------------------------------|
| <i>CubeName</i>         | Specify the name of the cube that you want to detach. |

## Returns

None.

[CubeDefn Class](#)

## GetAggregateMapping

### Syntax

```
GetAggregateMapping(PartName, IsCube)
```

### Description

Use the GetAggregateMapping method to return the aggregate mapping field specified by the part *PartName*.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <i>PartName</i>         | Specify the part name for which you want the aggregate mapping field name.                                                    |
| <i>IsCube</i>           | Specify whether the part is a cube or not. This parameter takes a Boolean value, true if the part is a cube, false otherwise. |

### Returns

A string.

## GetCubeNames

### Syntax

```
GetCubeNames ()
```

### Description

Use the GetCubeNames method to return an array of strings containing all the names of the cubes associated with this cube collection.

### Parameters

None.

## Returns

An array of string.

## Related Links

# GetDimensionNames

## Syntax

```
GetDimensionNames ()
```

## Description

Use the GetDimensionNames method to return an array of string containing the names of all the dimensions associated with the cube collection.

The dimension names are returned in an array of string.

## Parameters

None.

## Returns

An array of string.

## Related Links

[AttachDimension](#)

[DetachDimension](#)

[DimensionDefn Class](#)

# GetDimSort

## Syntax

```
GetDimSort (DimensionName)
```

## Description

Use the `GetDimSort` method return the sorting keys used for the dimension.

The sorting keys are returned as an array of any.

The first string is either true or false. If the first string is true it indicates that the dimension is sorted by the names of the members in the dimension.

The second string then is either true or false, indicating whether the sort is ascending (or descending). If the first string is false it indicates that the dimension is sorted by keys, which are the specified by the other strings in the array. The keys are names of cubes. The strings are as follows:

- `Ascend1`
- `CubeName1`
- `Ascend2`
- `CubeName2`
- `Ascend3`
- `CubeName3`

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                              |
|-------------------------|------------------------------------------------------------------------|
| <i>DimensionName</i>    | Specify the name of the dimension for which you want the sorting keys. |

## Returns

An array of any.

## Related Links

[SetDimSort](#)

[GetDimSort](#)

[SetDimSort](#)

## GetFieldMapping

### Syntax

**GetFieldMapping**(*PartName*, *IsCube*)

## Description

Use the `GetFieldMapping` method to return the name of the mapped field name for the part specified by *PartName*.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>PartName</i>         | Specify the name of the part for which you want the mapped field name.                                                         |
| <i>IsCube</i>           | Specify whether this part is a cube or not. This parameter takes a Boolean value: true if the part is a cube, false otherwise. |

## Returns

A string.

## Related Links

[GetAggregateMapping](#)

[SetFieldMapping](#)

[SetAggregateMapping](#)

## GetFilter

### Syntax

**GetFilter** (*DimensionName*)

### Description

Use the `GetFilter` method to return the name of the user function used as a filter for the dimension specified by *DimensionName*.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                             |
|-------------------------|-----------------------------------------------------------------------|
| <i>DimensionName</i>    | Specify the name of the dimension for which you want the filter name. |

## Returns

A string.

## Related Links

[SetAggregateMapping](#)

“Filter User Functions” (Analytic Calculation Engine)

## GetPersistAggregate

### Syntax

```
GetPersistAggregate (DimensionName)
```

### Description

Use the GetPersistAggregate method to return the value for the persist aggregate for the dimension specified by *DimensionName*.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------|
| <i>DimensionName</i>    | Specify the name of the dimension for which you want to find the persist aggregate value. |

### Returns

An integer, which is one of the following values:

| <i><b>Value</b></i>         | <i><b>Description</b></i>                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------|
| AnalyticModel_AggrType_Root | The persist aggregate type is <i>Root</i> , that is, only the root node's data is saved to the database.                |
| AnalyticModel_AggrType_All  | The persist aggregate type is <i>All</i> , that is, save all of the dimension's aggregate data to the database.         |
| AnalyticModel_AggrType_None | The persist aggregate type is <i>None</i> , that is, do not save any of the dimension's aggregate data to the database. |

[SetFieldMapping](#)

[SetPersistAggregate](#)

## SetAggregateMapping

### Syntax

```
SetAggregateMapping(PartName, IsCube, AggregateFieldName)
```

### Description

Use the SetAggregateMapping method to specify an aggregate field for the part specified by *PartName*.

You can map a field to only one data cube or dimension within one cube collection.

### Parameters

| <i>Parameter</i>          | <i>Description</i>                                                                                                     |
|---------------------------|------------------------------------------------------------------------------------------------------------------------|
| <i>PartName</i>           | Specify the name of the part for which you want to add an aggregate field.                                             |
| <i>IsCube</i>             | Specify whether the part is a cube. This parameter takes a Boolean value, true if the part is a cube, false otherwise. |
| <i>AggregateFieldName</i> | Specify the name of the field to be used to hold the aggregate value.                                                  |

### Returns

A string containing the name of the field that contains the aggregate value.

[SetPersistAggregate](#)

## SetDimSort

### Syntax

```
SetDimSort(DimName, IsAscending [, CubeName1, IsAscending2, CubeName2,  
IsAscending3, CubeName3])
```

### Description

Use the SetDimSort method to specify the sorting order for the dimension.

If *CubeName1* is an empty string, the dimension is sorted by the names of the members of the dimension, and the other parameters are not used.

If *CubeName1* is not an empty string, the dimension is sorted by cubes, as specified by the other parameters.

The Boolean parameter *IsAscending* defines whether sorting should be in ascending or descending order. Up to three sort keys may be specified. *CubeName1* is the primary sort key. *CubeName2* is used to sub-sort any members that have the same key value under *CubeName1*, and so on.

## Parameters

| <b>Parameter</b>     | <b>Description</b>                                                                                                                                                                                                           |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DimensionName</i> | Specify the name of the dimension that you would like to specify a sort order for.                                                                                                                                           |
| <i>IsAscending</i>   | Specify if the dimension should be sorted in ascending or descending order. This parameter takes a Boolean value: true if the sort should be ascending, false if it should be descending.                                    |
| <i>CubeName1</i>     | Specify whether the dimension is to be sorted by members or by cubes. If the dimension is to be sorted by members, specify a null string for this parameter. If the dimension is to be sorted by cubes, specify a cube name. |
| <i>IsAscending2</i>  | Specify if the sort for <i>CubeName1</i> is in ascending or descending order. This parameter takes a Boolean value: true if the sort is ascending, false if its descending.                                                  |
| <i>CubeName2</i>     | Specify the name of a cube to be used to sub-sort the primary sort specified by <i>CubeName1</i> .                                                                                                                           |
| <i>IsAscending3</i>  | Specify if the sort for <i>CubeName2</i> is in ascending or descending order. This parameter takes a Boolean value: true if the sort is ascending, false if its descending.                                                  |
| <i>CubeName3</i>     | Specify the name of a cube to be used to sub-sort the primary sort specified by <i>CubeName2</i> .                                                                                                                           |

## Returns

None.

## SetFieldMapping

### Syntax

```
SetFieldMapping(PartName, FieldName, IsCube)
```

### Description

Use the SetFieldMapping method to specify the name of the main field used for mapping the part specified by *PartName*.

You can map a field to only one data cube or dimension within one cube collection.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <i>PartName</i>         | Specify the name of the part for which you want to assign a mapping field.                                                    |
| <i>FieldName</i>        | Specify the name of the field to be used for the field mapping.                                                               |
| <i>IsCube</i>           | Specify whether or not the part is a cube. This parameter takes a Boolean value: true if the part is a cube, false otherwise. |

### Returns

None.

## SetFilter

### Syntax

```
SetFilter(DimensionName, UserFunctionName)
```

### Description

Use the SetFilter method to specify the user function to be used as a filter for the dimension specified by *DimensionName*.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                      |
|-------------------------|--------------------------------------------------------------------------------|
| <i>DimensionName</i>    | Specify the name of the dimension for which you want to set a filter.          |
| <i>UserFunctionName</i> | Specify the name of a user function to be used as a filter for this dimension. |

## Returns

None.

## SetPersistAggregate

### Syntax

**SetPersistAggregate** (*DimensionName*, *AggregateType*)

### Description

Use the SetPersistAggregate to specify the value for the persist aggregate for the dimension specified by *DimensionName*.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                          |
|-------------------------|------------------------------------------------------------------------------------|
| <i>DimensionName</i>    | Specify the name of the dimension for which you want to set the persist aggregate. |
| <i>AggregateType</i>    | Specify the aggregate type. Values are:                                            |

| <b><i>Value</i></b>         | <b><i>Description</i></b>                                                                                       |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------|
| AnalyticModel_AggrType_Root | The persist aggregate type is <i>Root</i> , that is, only the root node's data is saved to the database.        |
| AnalyticModel_AggrType_All  | The persist aggregate type is <i>All</i> , that is, save all of the dimension's aggregate data to the database. |

| <b><i>Value</i></b>          | <b><i>Description</i></b>                                                                                               |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| AnalyticModel_AggrType_ None | The persist aggregate type is <i>None</i> , that is, do not save any of the dimension's aggregate data to the database. |

## Returns

None.

## UsesCube

### Syntax

**UsesCube** (*CubeName*)

### Description

Use the UsesCube method to determine if the cube collection uses the cube specified by *CubeName*.

### Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                             |
|-------------------------|-------------------------------------------------------|
| <i>CubeName</i>         | Specify the name of the cube that you want to verify. |

### Returns

A Boolean value, true if the specified cube is part of the cube collection, false otherwise.

## UsesDimension

### Syntax

`UsesDimension(DimensionName)`

### Description

Use the UsesDimension method to determine if the cube collection uses the dimension specified by *DimensionName*.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                  |
|-------------------------|------------------------------------------------------------|
| <i>DimensionName</i>    | Specify the name of the dimension that you want to verify. |

### Returns

A Boolean value: true if the dimension is part of the cube collection, false otherwise.

## CubeCollectionDefn Class Properties

The following section discusses the CubeCollectionDefn class properties. The properties are discussed in alphabetical order.

### AggregateRecName

#### Description

Use this property to specify the name of the aggregate record associated with this cube collection. This property takes a string value.

This property is read/write.

### Comments

#### Description

Use this property to specify additional notes about the cube collection.

This property is read/write.

## CubeCount

### Description

This property returns the number of cubes in the cube collection.

This property is read-only.

## DimensionCount

### Description

This property returns the number of dimensions associated with this cube collection.

This property is read-only.

## Name

### Description

This property returns the name of the cube collection as a string.

This property is read-only.

## RecordName

### Description

Use this property to specify the name of the main record associated with the cube collection. This property takes a string value.

This property is read/write.

---

## UserFunctionDefn Class

Use the UserFunctionDefn class to access the user functions that are associated with an analytic model. You instantiate an object of this class using the following AnalyticModelDefn class methods:

- AddUserFunction
- CopyUserFunction
- GetUserFunction

---

## UserFunctionDefn Class Methods

In this section we discuss the UserFunctionDefn class methods. They are described in alphabetical order.

### GetRule

#### Syntax

```
GetRule()
```

#### Description

Use the GetRule method to return a RuleDefn object that represents the rule associated with this user function.

#### Parameters

None.

#### Returns

A RuleDefn object.

#### Related Links

[RuleDefn Class](#)

### SetRule

#### Syntax

```
SetRule(&Rule)
```

#### Description

Use the SetRule method to specify a rule defined by a RuleDefn object to be the rule for this user function.

#### Parameters

| <i>Parameter</i> | <i>Description</i>                                                                                       |
|------------------|----------------------------------------------------------------------------------------------------------|
| <i>&amp;Rule</i> | Specify an already instantiated RuleDefn object that you want to use as the rule for this user function. |

## Returns

None.

---

## UserFunctionDefn Class Properties

The following section discusses the UserFunctionDefn class properties. The properties are discussed in alphabetical order.

### Comments

#### Description

Use this property to specify additional notes about the user function.

This property is read/write.

### Name

#### Description

This property specifies the name of the user function.

This property is read-only.

---

## OrganizerDefn Class

Use the OrganizerDefn class to access the organizers that are associated with an analytic model. You instantiate an object of this class using the following AnalyticModelDefn class methods:

- AddOrganizer
- CopyOrganizer
- GetOrganizer

---

## OrganizerDefn Class Methods

The following section discusses the OrganizerDefn class methods. The methods are discussed in alphabetical order.

## AttachPart

### Syntax

**AttachPart**(*PartName*, *PartType*)

### Description

Use the AttachPart method to attach the part specified by *PartName* to the organizer. The part must exist in the analytic model.

### Parameters

| <b>Parameter</b> | <b>Description</b>                                            |
|------------------|---------------------------------------------------------------|
| <i>PartName</i>  | Specify the name of the part that you want to attach.         |
| <i>PartType</i>  | Specify the type of part that you want to attach. Values are: |

| <b>Value</b>                 | <b>Description</b>        |
|------------------------------|---------------------------|
| AnalyticModel_Dimension      | Attach a dimension.       |
| AnalyticModel_Cube           | Attach a cube.            |
| AnalyticModel_CubeCollection | Attach a cube collection. |
| AnalyticModel_UserFunction   | Attach a user function.   |

### Returns

None.

### Related Links

[DetachPart](#)

[GetPartNames](#)

[UsesPart](#)

## DetachPart

### Syntax

**DetachPart**(*PartName*, *PartType*)

## Description

Use the DetachPart method to detach the part specified by *PartName* from the organizer.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                               |
|-------------------------|-------------------------------------------------------------------------|
| <i>PartName</i>         | Specify the name of the part that you want to detach.                   |
| <i>PartType</i>         | Specify the type of the part that you want to detach. Valid values are: |

| <b><i>Value</i></b>          | <b><i>Description</i></b> |
|------------------------------|---------------------------|
| AnalyticModel_Dimension      | Detach a dimension.       |
| AnalyticModel_Cube           | Detach a cube.            |
| AnalyticModel_CubeCollection | Detach a cube collection. |
| AnalyticModel_UserFunction   | Detach a user function.   |

## Returns

None.

## Related Links

[AttachPart](#)

[GetPartNames](#)

[UsesPart](#)

## GetPartNames

### Syntax

**GetPartNames** ( )

### Description

Use the GetPartNames method to return a list of the names of the parts used by the organizer. The names are returned as an array of string.

## Parameters

None.

## Returns

An array of string.

## Related Links

[AttachPart](#)

[DetachPart](#)

[UsesPart](#)

## UsesPart

### Syntax

**UsesPart** (*PartName*, *PartType*)

### Description

Use the UsesPart method to determine if the organizer uses the part specified by *PartName*.

### Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                               |
|-------------------------|-------------------------------------------------------------------------|
| <i>PartName</i>         | Specify the name of the part that you want to verify.                   |
| <i>PartType</i>         | Specify the type of the part that you want to verify. Valid values are: |

| <b><i>Value</i></b>          | <b><i>Description</i></b> |
|------------------------------|---------------------------|
| AnalyticModel_Dimension      | A dimension.              |
| AnalyticModel_Cube           | A cube.                   |
| AnalyticModel_CubeCollection | A cube collection.        |
| AnalyticModel_UserFunction   | A user function.          |

### Returns

A Boolean value: true if the part is associated with the organizer, false otherwise.

## OrganizerDefn Class Properties

The following section discusses the OrganizerDefn class properties. The properties are discussed in alphabetical order.

### Comments

#### Description

Use this property to specify additional notes about the organizer.

This property is read/write.

### Name

#### Description

This property specifies the name of the organizer.

This property is read-only.

---

## RuleDefn Class

Use the RuleDefn class to access a rule that is associated with an analytic model. You instantiate an object of this class using the GetRule method for both the CubeDefn and UserFunctionDefn classes.

---

## RuleDefn Class Methods

In this section, we discuss the RuleDefn class methods. The methods are described in alphabetical order.

### AddRuleExpression

#### Syntax

```
AddRuleExpression (&Expr)
```

## Description

Use the `AddRuleExpression` method to add a rule expression to the rule. Use the classes in the `RuleExpression` subpackage to create the expression specified by *&Expr*.

After you have finished adding rule expressions to the rule, you need to use the `GenerateRule` method to generate the rule.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                               |
|-------------------------|-------------------------------------------------------------------------|
| <i>&amp;Expr</i>        | Specify the rule expression that you want added to the rule definition. |

## Returns

None.

## Related Links

[GenerateRule](#)

[RuleExpressions Classes](#)

## GenerateRule

### Syntax

```
GenerateRule ( )
```

### Description

Use the `GenerateRule` method to create the rule string for the rule that represents the current rule expressions that have been added using `AddRuleExpression`.

### Parameters

None.

### Returns

None.

### Related Links

[AddRuleExpression](#)

[RuleExpressions Classes](#)

---

## RuleDefn Class Property

The following describes the RuleDefn class property.

### RuleString

#### Description

This property specifies a string representation of the rule.

After the rule is returned using the GetRule method, this string represents the existing rule cube or user function.

After AddRuleExpression and GenerateRule are called, this is the string representation of the rule.

This property is read-only.

---

## RuleExpressions Classes

The RuleExpressions classes represents the different parts of the analytic calculation engine rule grammar. These objects are created using the Create built-in function and the constructor for that class, then added to the RuleDefn object with the AddRuleExpression method.

The following are the RuleExpressions classes:

- Assignment
- Comparison
- Constant
- Constants
- Cube
- ExpressionBlock
- FunctionCall
- MemberReference
- Operation
- RuleExpression
- Variable

---

**Note:** The RuleExpression object is the object that the other objects are derived from. You should not create or use this object directly.

---

## Using the Constants Class

All of the constants used with the RuleExpression classes, such as FunctionCall, comparison, operation, and so on, are actually properties of the constants class. You must always instantiate an object of the constants class to use any constants in your program.

For example, the comparison class uses a constant to test whether two operands are equal. Use the following code to create a comparison testing this:

```
&Comparison = create Comparison(&Constants.Comparison_Type_Equal);
```

All of the properties for the constants class are listed with the classes that use them.

---

## Assignment Class

An assignment object represents an assignment statement in an analytic calculation rule.

Use the following to create an assignment object:

```
&Assignment = create Assignment();
```

---

## Assignment Class Method

The following is the method for the assignment class.

### GenerateRule

#### Syntax

```
GenerateRule()
```

#### Description

Use the GenerateRule method to return a string that contains the rule for this object.

Generally you wouldn't use this method on the individual RuleExpression objects, but instead would use the GenerateRule method on the RuleDefn object.

#### Parameters

None.

#### Returns

A string.

#### Related Links

[AddRuleExpression](#)

---

# Assignment Class Properties

In this section we discuss the assignment class properties. The properties are described in alphabetical order.

## Expression

### Description

Use the Expression property to specify the right-hand side of the assignment statement.

This property is read/write.

## Variable

### Description

Use the Variable property to specify the left-hand side of the assignment statement.

This property is read/write.

---

# Comparison Class

A comparison object represents a comparison statement in an analytic calculation rule.

Use the following to create a comparison class object:

```
&Comparison = create Comparison(&Constants.Comparison_Type);
```

Where *Comparison\_Type* is one of the following:

| <i><b>Value</b></i>       | <i><b>Description</b></i>                                                      |
|---------------------------|--------------------------------------------------------------------------------|
| Comparison_Type_Equal     | Compare if the value of Operand1 equals Operand2.                              |
| Comparison_Type_Greater   | Compare if the value of Operand1 is greater than the value of Operand2.        |
| Comparison_Type_Less      | Compare if the value of Operand1 is less than the value of Operand2.           |
| Comparison_Type_GreaterEq | Compare if the value of Operand1 is greater or equal to the value of Operand2. |

| <b>Value</b>           | <b>Description</b>                                                               |
|------------------------|----------------------------------------------------------------------------------|
| Comparison_Type_LessEq | Compare if the value of Operand1 is less than or equal to the value of Operand2. |
| Comparison_Type_NotEq  | Compare if the value of Operand1 is not equal to the value of Operand2.          |

Specify Operand1 and Operand2 with the Operand1 and Operand2 comparison class properties.

The following code example creates a rule that compares if the first operand is greater than or equal to the second operand, then adds the rule using the AddArgument method.

```
&Comparison = create Comparison(&Constants.Comparison_Type_GreaterEq);  
&Constant = create Constant(&Constants.Constant_Type_Literal, "1000");  
&Comparison.Operand1 = &Constant;  
&Constant = create Constant(&Constants.Constant_Type_Literal, "100");  
&Comparison.Operand2 = &Constant;  
&FunCall.AddArgument(&Comparison);
```

---

## Comparison Class Method

The following is the comparison class method.

### GenerateRule

#### Syntax

```
GenerateRule()
```

#### Description

Use the GenerateRule method to return a string that contains the rule for this object.

Generally you wouldn't use this method on the individual RuleExpression objects, but instead would use the GenerateRule method on the RuleDefn object.

#### Parameters

None.

#### Returns

A string.

#### Related Links

[AddRuleExpression](#)

[RuleExpressions Classes](#)

## Comparison Class Properties

In this section we discuss the comparison class properties. The properties are described in alphabetical order.

### Operand1

#### Description

Use this property to specify the RuleExpression object that is the first operand to be used in the comparison.

This property is read/write.

### Operand2

#### Description

Use this property to specify the RuleExpression object that is the second operand to be used in the comparison.

This property is read/write.

### Type

#### Description

This property returns the type of the comparison that was used to instantiate the comparison object.

The values are:

| <b>Value</b>              | <b>Description</b>                                                                  |
|---------------------------|-------------------------------------------------------------------------------------|
| Comparison_Type_Equal     | Compare if the value of Operand1 equals Operand2.                                   |
| Comparison_Type_Greater   | Compare if the value of Operand1 is greater than the value of Operand2.             |
| Comparison_Type_Less      | Compare if the value of Operand1 is less than the value of Operand2.                |
| Comparison_Type_GreaterEq | Compare if the value of Operand1 is greater than or equal to the value of Operand2. |
| Comparison_Type_LessEq    | Compare if the value of Operand1 is less than or equal to the value of Operand2.    |

| <b>Value</b>          | <b>Description</b>                                                      |
|-----------------------|-------------------------------------------------------------------------|
| Comparison_Type_NotEq | Compare if the value of Operand1 is not equal to the value of Operand1. |

This property is read-only.

---

## Constant Class

A constant object represents a constant statement in an analytic calculation rule.

---

**Note:** This is not the same as the constants class.

---

A constant object exposes all the constants that are passed to the constructors of the various RuleExpression objects.

Use the following to create a constant class object:

```
&Constant = create Constant(&Constants.Constant_Type, [&Constants.]Constant_Value);
```

where *Constant\_Type* is one of the following:

| <b>Value</b>          | <b>Description</b>                                                                                                                                                                                                  |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Constant_Type_Builtin | The <i>Constant_Value</i> is an analytic calculation engine built-in function. In this instance, the constant value must be prefaced with an already instantiated constants object. For possible values, see below. |
| Constant_Type_Number  | The <i>Constant_Value</i> is a number.                                                                                                                                                                              |
| Constant_Type_Literal | The <i>Constant_Value</i> is a string.                                                                                                                                                                              |

When the *Constant\_Type* is Constant\_Type\_Builtin, the *Constant\_Value* is one of the following:

- Constant\_Builtin\_ALL
- Constant\_Builtin\_BASE\_E
- Constant\_Builtin\_DEFAULT
- Constant\_Builtin\_DETAILS
- Constant\_Builtin\_DIRECT
- Constant\_Builtin\_FALSE
- Constant\_Builtin\_FORWARD
- Constant\_Builtin\_PI

- Constant\_Builtin\_REVERSE
- Constant\_Builtin\_TRUE

The following code creates a PeopleSoft Analytic Calculation Engine built-in function to be used as a constant:

```
&Constant = create Constant(&Constants.Constant_Type_Builtin, &Constants.Constan→
t_Builtin_REVERSE);
```

The following code creates a literal (string) constant:

```
&Constant = create Constant(&Constants.Constant_Type_Literal, "GENERAL");
```

The following code creates a number constant:

```
&Constant = create Constant(&Constants.Constant_Type_Number, "-1");
```

## Constant Class Method

The following is the constant class method.

### GenerateRule

#### Syntax

```
GenerateRule()
```

#### Description

Use the GenerateRule method to return a string that contains the rule for this object.

Generally you wouldn't use this method on the individual RuleExpression objects, but instead would use the GenerateRule method on the RuleDefn object.

#### Parameters

None.

#### Returns

A string.

## Constant Class Properties

In this section we discuss the constant class properties. The properties are described in alphabetical order.

## Type

### Description

This property returns the value of the *Constant Type* that was used to instantiate the constant class object.

This property is read-only.

### Related Links

[Constant Class](#)

## Value

### Description

This property returns the value of the *Constant Value* that was used to instantiate the constant class object.

This property is read-only.

### Related Links

[Constant Class](#)

---

## Constants Class

All of the constants used with the RuleExpression classes, such as FunctionCall, comparison, operation, and so on, are actually properties of the constants class. You must always instantiate an object of the constants class to use any constants in your program.

For example, the comparison class uses a constant to test whether two operands are equal. Use the following code to create a comparison testing this:

```
&Comparison = create Comparison(&Constants.Comparison_Type_Equal);
```

All of the properties for the constants class are listed with the classes that use them.

---

## Cube Class

A cube object represents a cube statement in an analytic calculate engine rule.

Use the following to create a cube object.

```
&Assignment = create Cube("CubeName");
```

---

## Cube Class Methods

In the following section, we discuss the cube class methods. The methods are described in alphabetical order.

### AddIndex

#### Syntax

```
AddIndex (&MemberReference)
```

#### Description

Use the AddIndex method to add a MemberReference object to the cube.

#### Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                       |
|-----------------------------|---------------------------------------------------------------------------------|
| <i>&amp;MemberReference</i> | Specify an already instantiated MemberReference object to be added to the cube. |

#### Returns

None.

#### Related Links

[MemberReference Class](#)

### GenerateRule

#### Syntax

```
GenerateRule ()
```

#### Description

Use the GenerateRule method to return a string that contains the rule for this object.

Generally you wouldn't use this method on the individual RuleExpression objects, but instead would use the GenerateRule method on the RuleDefn object.

#### Parameters

None.

## Returns

A string.

## GetIndexes

### Syntax

```
GetIndexes ()
```

### Description

Use the GetIndexes method to return an array of MemberReference's (indexes) for this cube. These MemberReferences are the MemberReferences that were added with the AddIndex method.

### Parameters

None.

### Returns

An array of MemberReference objects.

### Related Links

[MemberReference Class](#)

[AddIndex](#)

---

## Cube Class Property

The following is the cube class property.

### Name

#### Description

This property indicates the name of the cube that was used to instantiate the cube object.

This property is read-only.

---

## ExpressionBlock Class

For some function, you need multi-statement nested expressions. You need to use the ExpressionBlock class to group these expressions. For example, all the statements inside of a FOR statement should be included in an expression block.

```
FOR(&Index, 1, PERIOD,
```

```
        SET(&Value, &Value + 1);  
        SET(&countPl4, &countPl4 + 4);  
    );
```

Use the following code to create an ExpressionBlock object:

```
&ExpressionBlock = create ExpressionBlock();
```

---

# ExpressionBlock Methods

In the following section we discuss the ExpressionBlock class methods. The methods are described in alphabetical order.

## AddRuleExpression

### Syntax

```
AddRuleExpression (&Expr)
```

### Description

Use the AddRuleExpression method to add an expression to the expression block and the rule. Use the classes in the RuleExpression subpackage to create the expression specified by *&Expr*.

---

**Note:** As the rule string is generated, the system adds a ";" after each RuleExpression, except the last.

---

### Parameters

| Parameter        | Description                                                              |
|------------------|--------------------------------------------------------------------------|
| <i>&amp;Expr</i> | Specify the rule expression that you want added to the expression block. |

### Returns

None.

## GetRuleExpressions

### Syntax

```
GetRuleExpressions ()
```

### Description

Use the GetRuleExpressions to return an array of rule expression objects that have been added using the AddRuleExpression method.

Parameters

None.

Returns

An array of RuleExpression objects.

FunctionCall Class

A FunctionCall object represents a function call statement in an analytic calculation engine rule.

Use the following code to create a FunctionCall object:

```
&Assignment = create FunctionCall(&Constants.Function_Call_Type, [&Constants.]Function_Call_Name);
```

Where *Function\_Call\_Type* can be one of the following:

| Value                      | Description                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FunctionCall_Type_Builtin  | Specifies that the function call is a PeopleSoft Analytic Calculation Engine built-in functions. In this instance, the function name must be prefaced with an already instantiated constants object. For the built-in function values used with <i>Function_Call_Name</i> , see below. |
| FunctionCall_Type_UserFunc | Specifies that the function call is a user function. The value specified for <i>Function_Call_Name</i> must be an already created user function defined in this analytic model. Specify this value as a string.                                                                        |

When the *Function\_Call\_Type* is specified as *Function\_Call\_Type\_Builtin*, the *Function\_Call\_Name* must be one of the following:

- FunctionCall\_Builtin\_ABS
- FunctionCall\_Builtin\_ACOS
- FunctionCall\_Builtin\_ARGUMENTS
- FunctionCall\_Builtin\_ASC
- FunctionCall\_Builtin\_ASIN
- FunctionCall\_Builtin\_AT
- FunctionCall\_Builtin\_ATAN
- FunctionCall\_Builtin\_BREAK
- FunctionCall\_Builtin\_CASE

- FunctionCall\_Builtin\_CHANGE
- FunctionCall\_Builtin\_CHILDCOUNT
- FunctionCall\_Builtin\_CHR
- FunctionCall\_Builtin\_CONSOL
- FunctionCall\_Builtin\_COS
- FunctionCall\_Builtin\_CUBEID
- FunctionCall\_Builtin\_CUBSUM
- FunctionCall\_Builtin\_CUMAVG
- FunctionCall\_Builtin\_DAVG
- FunctionCall\_Builtin\_DAY
- FunctionCall\_Builtin\_DCOUNT
- FunctionCall\_Builtin\_DDB
- FunctionCall\_Builtin\_DEC
- FunctionCall\_Builtin\_DLOOKUP
- FunctionCall\_Builtin\_DMAX
- FunctionCall\_Builtin\_DMIN
- FunctionCall\_Builtin\_DSUM
- FunctionCall\_Builtin\_E
- FunctionCall\_Builtin\_FIRST
- FunctionCall\_Builtin\_FOR
- FunctionCall\_Builtin\_FORCHILDREN
- FunctionCall\_Builtin\_FORMEMBERS
- FunctionCall\_Builtin\_FV
- FunctionCall\_Builtin\_GROUPAVG
- FunctionCall\_Builtin\_GROUPBY
- FunctionCall\_Builtin\_GROUPMAX
- FunctionCall\_Builtin\_GROUPMIN
- FunctionCall\_Builtin\_GROUPSUM
- FunctionCall\_Builtin\_GROW

- FunctionCall\_Builtin\_IF
- FunctionCall\_Builtin\_IFNPV
- FunctionCall\_Builtin\_INC
- FunctionCall\_Builtin\_INDICATE
- FunctionCall\_Builtin\_INPUT
- FunctionCall\_Builtin\_INSUBTREE
- FunctionCall\_Builtin\_INTERCEPT
- FunctionCall\_Builtin\_IRR
- FunctionCall\_Builtin\_ISINPUT
- FunctionCall\_Builtin\_LEFT
- FunctionCall\_Builtin\_LEN
- FunctionCall\_Builtin\_LN
- FunctionCall\_Builtin\_LOWER
- FunctionCall\_Builtin\_MATCH
- FunctionCall\_Builtin\_MAX
- FunctionCall\_Builtin\_MBR2TEXT
- FunctionCall\_Builtin\_MEDIAN
- FunctionCall\_Builtin\_MEMBER
- FunctionCall\_Builtin\_MID
- FunctionCall\_Builtin\_MIN
- FunctionCall\_Builtin\_MOD
- FunctionCall\_Builtin\_MONTH
- FunctionCall\_Builtin\_NEXT
- FunctionCall\_Builtin\_NPER
- FunctionCall\_Builtin\_NUM2TEXT
- FunctionCall\_Builtin\_NUMMEMBERS
- FunctionCall\_Builtin\_NPV
- FunctionCall\_Builtin\_PARAMETER
- FunctionCall\_Builtin\_PARENT

- FunctionCall\_Builtin\_PCT
- FunctionCall\_Builtin\_PERCENTILE
- FunctionCall\_Builtin\_PI
- FunctionCall\_Builtin\_PMT
- FunctionCall\_Builtin\_PREV
- FunctionCall\_Builtin\_PREVSELF
- FunctionCall\_Builtin\_PV
- FunctionCall\_Builtin\_QUARTILE
- FunctionCall\_Builtin\_RAND
- FunctionCall\_Builtin\_RATE
- FunctionCall\_Builtin\_REPLACE
- FunctionCall\_Builtin\_RETURN
- FunctionCall\_Builtin\_RIGHT
- FunctionCall\_Builtin\_ROUND
- FunctionCall\_Builtin\_SELF
- FunctionCall\_Builtin\_SET
- FunctionCall\_Builtin\_SIN
- FunctionCall\_Builtin\_SLN
- FunctionCall\_Builtin\_SLOPE
- FunctionCall\_Builtin\_SQRT
- FunctionCall\_Builtin\_STDEV
- FunctionCall\_Builtin\_SYD
- FunctionCall\_Builtin\_TAN
- FunctionCall\_Builtin\_TEXT2MBR
- FunctionCall\_Builtin\_TEXT2NUM
- FunctionCall\_Builtin\_THIS
- FunctionCall\_Builtin\_THISCUBE
- FunctionCall\_Builtin\_TRUNC
- FunctionCall\_Builtin\_UPPER

- `FunctionCall_Builtin_VAR`
- `FunctionCall_Builtin_WHILE`
- `FunctionCall_Builtin_YEAR`

The following code creates a function call using a PeopleSoft Analytic Calculation Engine built-in function:

```
&FunCall = create FunctionCall (&Constants.FuncCall_Type_Builtin, &Constants.FuncCal⇒
l_Builtin_ABS);
```

## FunctionCall Class Methods

In this section we discuss the FunctionCall class methods. The methods are described in alphabetical order.

### AddArgument

#### Syntax

```
AddArgument (&RuleExpression)
```

#### Description

Use the AddArgument method to add an argument to this function call.

#### Parameters

| <i><b>Parameter</b></i>    | <i><b>Description</b></i>                                                      |
|----------------------------|--------------------------------------------------------------------------------|
| <i>&amp;RuleExpression</i> | Specify an already instantiated rule expression object, such as a cube object. |

#### Returns

None.

### GenerateRule

#### Syntax

```
GenerateRule ()
```

## Description

Use the `GenerateRule` method to return a string that contains the rule for this object.

Generally you wouldn't use this method on the individual `RuleExpression` objects, but instead would use the `GenerateRule` method on the `RuleDefn` object.

## Parameters

None.

## Returns

A string.

## GetArguments

### Syntax

```
GetArguments()
```

### Description

Use the `GetArguments` method to return an array of `RuleExpression` objects associated with this `FunctionCall`. These are the `RuleExpression` objects that were added using the `AddArgument` method.

### Parameters

None.

### Returns

An array of `RuleExpression` objects.

### Related Links

[AddArgument](#)

---

## FunctionCall Class Properties

In this section we discuss the `FunctionCall` class properties. The properties are described in alphabetical order.

### Name

#### Description

This property specifies the name of the function call used to instantiate the `FunctionCall` object.

This property is read-only.

## Type

### Description

This property specifies the type of the function call used to instantiate the FunctionCall object.

This property is read-only.

---

## MemberReference Class

A MemberReference object represents a member in an analytic calculation engine rule.

Use the following code to create a MemberReference object:

```
&Member = create MemberReference(DimensionName, MemberName);
```

---

## MemberReference Class Method

This section discusses the MemberReference class method.

## GenerateRule

### Syntax

```
GenerateRule()
```

### Description

Use the GenerateRule method to return a string that contains the rule for this object.

Generally you wouldn't use this method on the individual RuleExpression objects, but instead would use the GenerateRule method on the RuleDefn object.

### Parameters

None.

### Returns

A string.

---

## MemberReference Class Properties

In this section we discuss MemberReference class properties. The properties are described in alphabetical order.

### Dimension

#### Description

This property specifies the name of the dimension used to create the MemberReference object.

This property is read-only.

### Member

#### Description

This property specifies the name of the member used to create the MemberReference object.

This property is read-only.

---

## Operation Class

An operation object represents an operation in an analytic calculation engine rule. The operation is generally some type of mathematical function performed between two operands. Specify the operands for the operation using the Operand1 and Operand2 operation class properties.

Use the following code to create an operation object:

```
&Comparison = create Operation(&Constants.Operation_Type);
```

Where *Operation\_Type* has a value of one of the following:

| <b>Value</b>         | <b>Description</b>                    |
|----------------------|---------------------------------------|
| Operation_Type_Plus  | The operation is addition.            |
| Operation_Type_Minus | The operation is subtraction.         |
| Operation_Type_Mult  | The operation is multiplication.      |
| Operation_Type_Div   | The operation is division.            |
| Operation_Type_And   | Use a logical AND with the operation. |

| <b>Value</b>       | <b>Description</b>                              |
|--------------------|-------------------------------------------------|
| Operation_Type_Or  | Use a logical OR with the operation.            |
| Operation_Type_Not | Use a logical NOT with the operation.           |
| Operation_Type_Neg | Use a mathematical negate with the operation.   |
| Operation_Type_Exp | Use a mathematical exponent with the operation. |

The following code creates an operations that is a multiplication between two operands.

```
&operation = create Operation(&Constants.Operation_Type_Mult);
&Constant = create Constant(&Constants.Constant_Type_Literal, "PI");
&operation.Operand1 = &Constant;
&Constant = create Constant(&Constants.Constant_Type_Literal, "SLOPE");
&operation.Operand2 = &Constant;
&FunCall.AddArgument(&operation);
```

---

## Operation Class Method

The following is the operation class method.

### GenerateRule

#### Syntax

```
GenerateRule()
```

#### Description

Use the GenerateRule method to return a string that contains the rule for this object.

Generally you wouldn't use this method on the individual RuleExpression objects, but instead would use the GenerateRule method on the RuleDefn object.

#### Parameters

None.

#### Returns

A string.

---

## Operation Class Properties

In this section we discuss the operation class properties. The properties are described in alphabetical order.

### Operand1

#### Description

Use this property to specify the RuleExpression object that is the first operand to be used in the operation.

This property is read/write.

### Operand2

#### Description

Use this property to specify the RuleExpression object that is the second operand to be used in the operation.

This property is read/write.

### Type

#### Description

This property returns the type of the operation used to instantiate the operation object.

The values for this property are:

| <i><b>Value</b></i>  | <i><b>Description</b></i>            |
|----------------------|--------------------------------------|
| Operation_Type_Plus  | The operation is addition.           |
| Operation_Type_Minus | The operation is subtraction.        |
| Operation_Type_Mult  | The operation is multiplication.     |
| Operation_Type_Div   | The operation is division.           |
| Operation_Type_And   | Use a logical AND for the operation. |
| Operation_Type_OR    | Use a logical OR for the operation.  |

| <b>Value</b>       | <b>Description</b>                             |
|--------------------|------------------------------------------------|
| Operation_Type_Not | Use a logical NOT for the operation.           |
| Operation_Type_Neg | Use a mathematical negate for the operation.   |
| Operation_Type_Exp | Use a mathematical exponent for the operation. |

---

## Variable Class

A variable object represents a variable in an analytic calculation engine rule.

Use the following code to create a variable object:

```
&Variable = create Variable(&Constants.Variable_Type, "Variable_Name");
```

Where *Variable\_Type* is one of the following:

| <b>Value</b>             | <b>Description</b>                                                                                                      |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Variable_Type_Auto       | Use a local variable.                                                                                                   |
| Variable_Type_Expression | The variable is in an expression. Specify an already instantiated rule expression object for the <i>Variable_Name</i> . |
| Variable_Type_Dimension  | The variable is a dimension name. Specify a dimension name for the <i>Variable_Name</i> .                               |

The following code example creates a variable, then adds it to the rule.

```
&Variable = create Variable(&Constants.Variable_Type_Auto, "StartVal");
&FunCall.AddArgument(&Variable);
```

---

## Variable Class Method

The following is the variable class method.

### GenerateRule

#### Syntax

```
GenerateRule()
```

## Description

Use the `GenerateRule` method to return a string that contains the rule for this object.

Generally you wouldn't use this method on the individual `RuleExpression` objects, but instead would use the `GenerateRule` method on the `RuleDefn` object.

## Parameters

None.

## Returns

A string.

---

## Variable Class Properties

In this section we discuss the variable class properties. The properties are described in alphabetical order.

### Name

#### Description

This property specifies the name of the variable that was used to create the variable object, passed in the constructor.

This property is read-only.

### Type

#### Description

This property specifies the type of the variable, passed in the constructor. The possible values are:

| <b>Value</b>             | <b>Description</b>                                                                                                   |
|--------------------------|----------------------------------------------------------------------------------------------------------------------|
| Variable_Type_Auto       | A local variable.                                                                                                    |
| Variable_Type_Expression | The variable is an expression. Specify an already instantiated rule expression object for the <i>Variable_Name</i> . |
| Variable_Type_Dimension  | The variable is a dimension name. Specify a dimension name for the <i>Variable_Name</i> .                            |

This property is read-only.

## Analytic Model Metadata Classes Examples

The following are some examples of the most general cases of using the Analytic Model Metadata classes.

### Creating an Analytic Model Code Example

The following code creates an analytic model definition “from scratch” without retrieving an existing definition from the Application Designer, adds parts such as dimensions, cubes, and cube collections, then saves the definition.

```
import PT_ANALYTICMODELDEFN:*;

Function CreateGENXModel

    Local PT_ANALYTICMODELDEFN:AnalyticModelDefn &Model;
    Local PT_ANALYTICMODELDEFN:UserFunctionDefn &UserFunc;
    Local PT_ANALYTICMODELDEFN:DimensionDefn &Dim;
    Local PT_ANALYTICMODELDEFN:CubeDefn &Cube;
    Local PT_ANALYTICMODELDEFN:CubeCollectionDefn &CubeColl;
    Local array of string &arr;

    &ACEMODELID = QE_ACE_META_WK.QE_ACE_MODELID.Value;

    &Model = create PT_ANALYTICMODELDEFN:AnalyticModelDefn(&ACEMODELID);

    &Model.Create();

    /* Model Properties */

    &Model.Description = QE_ACE_META_WK.DESCR;
    &Model.LongDescription = QE_ACE_META_WK.DESCR200;
    &Model.MaxDelta = QE_ACE_META_WK.QE_ACE_MAXDELTA_FL;
    &Model.MaxIterations = QE_ACE_META_WK.QE_ACE_MAXITER_FLD;

    If (QE_ACE_META_WK.QE_ACE_CIRCWARN_FL.Value = 0) Then
        &Circ = True;
    Else
        &Circ = False;
    End-If;

    If (QE_ACE_META_WK.QE_ACE_RESOLVE_FLD.Value = 0) Then
        &Resolve = True;
    Else
        &Resolve = False;
    End-If;

    &Model.ResolveCircularDeps = &Resolve;
    &Model.CircularFormulaWarn = &Circ;

    /* Add User Functions */

    &UserFunction = &Model.AddUserFunction("FILTERPRODUCTS");
    &Rule = &UserFunction.GetRule();
    &Rule.RuleString = "IF( ((UNIT_COST = 0) .AND. (UNITS_SOLD = 0) .AND. (PROD_SALE⇒
S = 0 )) , RETURN(0), RETURN(1))";
    &UserFunction.SetRule(&Rule);

    /* Add the Dimensions */
    &Dim = &Model.AddDimension("MONTH");
```

```

&Dim = &Model.AddDimension("PRODUCTS");
&Dim.TotalMemberName = "TOTAL";

&Dim = &Model.AddDimension("PROD_CAT");

&Dim = &Model.AddDimension("REGION");

/* Add the cubes */
&Cube = &Model.AddCube("PROD_SALES");
&Cube.FormatType = &Cube.AnalyticModel_Format_Number;
&Cube.IsVirtual = False;
&Cube.CalcAggregates = False;
&Cube.Rule = "UNIT_COST * UNITS_SOLD";
&Cube.AttachDimension("MONTH");
&Cube.AttachDimension("PRODUCTS");
&Cube.AttachDimension("REGION");

&Cube = &Model.AddCube("SALES");
&Cube.FormatType = &Cube.AnalyticModel_Format_Number;
&Cube.IsVirtual = False;
&Cube.CalcAggregates = False;

&Cube = &Model.AddCube("TGT_COST");
&Cube.FormatType = &Cube.AnalyticModel_Format_Number;
&Cube.IsVirtual = False;
&Cube.CalcAggregates = False;
&Cube.AttachDimension("PRODUCTS");

&Cube = &Model.AddCube("UNITS_SOLD");
&Cube.FormatType = &Cube.AnalyticModel_Format_Number;
&Cube.IsVirtual = False;
&Cube.CalcAggregates = False;
&Cube.AttachDimension("MONTH");
&Cube.AttachDimension("PRODUCTS");
&Cube.AttachDimension("REGION");

&Cube = &Model.AddCube("UNIT_COST");
&Cube.FormatType = &Cube.AnalyticModel_Format_Number;
&Cube.IsVirtual = False;
&Cube.CalcAggregates = False;
&Cube.AttachDimension("MONTH");
&Cube.AttachDimension("PRODUCTS");
&Cube.AttachDimension("REGION");

/* Add Cube Collections */
&CubeColl = &Model.AddCubeCollection("REG_SALES_IN");
&CubeColl.RecordName = "QE_BAM_FACT_TBL";
&CubeColl.AttachCube("PROD_SALES");
&CubeColl.AttachCube("UNITS_SOLD");
&CubeColl.AttachCube("UNIT_COST");
&CubeColl.SetFieldMapping("MONTH", "QE_BAM_MONTH_FLD", False);
&CubeColl.SetPersistAggregate("MONTH", &CubeColl.AnalyticModel_AggrType_None);
&CubeColl.SetDimSort("MONTH", False, "", False, "", False, "");
&CubeColl.SetFieldMapping("PRODUCTS", "QE_BAM_PRODUCT_FLD", False);
&CubeColl.SetPersistAggregate("PRODUCTS", &CubeColl.AnalyticModel_AggrType_None)⇒
;

&CubeColl.SetDimSort("PRODUCTS", False, "", False, "", False, "");
&CubeColl.SetFieldMapping("REGION", "QE_BAM_REGION_FLD", False);
&CubeColl.SetPersistAggregate("REGION", &CubeColl.AnalyticModel_AggrType_None);
&CubeColl.SetDimSort("REGION", False, "", False, "", False, "");
&CubeColl.SetFieldMapping("PROD_SALES", "QE_BAM_PRDSALES_FL", True);
&CubeColl.SetFieldMapping("UNITS_SOLD", "QE_BAM_SALES_FLD", True);
&CubeColl.SetFieldMapping("UNIT_COST", "QE_BAM_UNIT_FLD", True);

&CubeColl = &Model.AddCubeCollection("REG_SALES_PROD");
&CubeColl.RecordName = "QE_BAM_CCSSMOKE";
&CubeColl.AttachCube("PROD_SALES");
&CubeColl.AttachCube("UNITS_SOLD");
&CubeColl.AttachCube("UNIT_COST");
&CubeColl.SetFieldMapping("MONTH", "QE_BAM_MONTH_FLD", False);

```

```

&CubeColl.SetPersistAggregate("MONTH", &CubeColl.AnalyticModel_AggrType_None);
&CubeColl.SetDimSort("MONTH", False, "", False, "", False, "");
&CubeColl.SetFieldMapping("PRODUCTS", "QE_BAM_PRODUCT_FLD", False);
&CubeColl.SetPersistAggregate("PRODUCTS", &CubeColl.AnalyticModel_AggrType_None)⇒

;
&CubeColl.SetFilter("PRODUCTS", "FILTERPRODUCTS");
&CubeColl.SetDimSort("PRODUCTS", False, "", False, "", False, "");
&CubeColl.SetFieldMapping("REGION", "QE_BAM_REGION_FLD", False);
&CubeColl.SetPersistAggregate("REGION", &CubeColl.AnalyticModel_AggrType_None);
&CubeColl.SetDimSort("REGION", False, "", False, "", False, "");
&CubeColl.SetFieldMapping("PROD SALES", "QE_BAM_PRDSALES_FL", True);
&CubeColl.SetFieldMapping("UNITS SOLD", "QE_BAM_SALES_FLD", True);
&CubeColl.SetFieldMapping("UNIT_COST", "QE_BAM_UNIT_FLD", True);

&CubeColl = &Model.AddCubeCollection("TGT_COST_PROD");
&CubeColl.RecordName = "QE_BAM_CC_TRGT";
&CubeColl.AttachCube("TGT_COST");
&CubeColl.SetFieldMapping("PRODUCTS", "QE_BAM_PRODUCT_FLD", False);
&CubeColl.SetPersistAggregate("PRODUCTS", &CubeColl.AnalyticModel_AggrType_None)⇒

;
&CubeColl.SetDimSort("PRODUCTS", False, "", False, "", False, "");
&CubeColl.SetFieldMapping("TGT_COST", "QE_BAM_TARGET_FLD", True);

&Model.Save();
/* &Valid = &Model.Validate(); */

QE_ACE_META_WK.QE_BAM_PCSTATUS = "The Model " | &ACEMODELID | " was created and ⇒
saved.";

End-Function;

```

# Analytic Grid Classes

---

## Understanding the Analytic Calculation Engine Classes

PeopleSoft Analytic Calculation Engine comprises a calculation engine plus several PeopleTools features which enable application developers to define both the calculation rules and the display of calculated data within PeopleSoft applications for the purposes of multi-dimensional reporting, data editing, and analysis.

More specifically, developers create *analytic models* in order to define the rules which are used to calculate data. Developers also create PeopleSoft Pure Internet Architecture pages with *analytic grids* in order to display the data within PeopleSoft applications. End users view, analyze, and make changes to this data. When end users save their changes, PeopleSoft Analytic Calculation Engine recalculates the data and saves the calculated data to the database.

PeopleCode enables developers to manipulate analytic calculation data as follows:

- Use the Analytic Calculation Engine classes to either retrieve or specify data in an instance of an analytic model loaded into the system, and also to calculate (or recalculate) cube values.
- Use the Analytic Calculation Engine metadata classes to manipulate an analytic model definition. For example, you can add cubes to a cube collection or rename an existing user function for a model.
- Use the Analytic Grid classes to manipulate the display of analytic calculation data on a page.
- Use the Analytic Type classes to manipulate an analytic type definition. For example, you can specify a new analytic model for an analytic type definition.

---

**Important!** The analytic grid classes are not supported on IBM z/OS and Linux for IBM System z platforms.

---

## Using the Analytic Grid in PeopleCode

The PeopleCode AnalyticGrid object is a reference to a page runtime object for the analytic grid. These particular page runtime objects aren't present until the component is started.

---

**Note:** PeopleSoft builds a page grid one row at a time. Because the AnalyticGrid class applies to a complete grid, you can't attach PeopleCode that uses the AnalyticGrid class to events that occur before the grid is built; the earliest event you can use is the page Activate Event.

---

If you're using the analytic grid within a secondary page, the runtime object for the grid isn't created until the secondary page is run. The grid object can't be obtained until then, which means that the earliest PeopleCode event you can use to activate a grid that's on a secondary page is the Activate event for the secondary page.

The attributes you set for displaying an analytic grid remain in effect only while the page is active. When you switch between pages in a component, you have to reapply those changes *every time* the page is displayed.

In addition, the Activate event associated with a page fires every time the page is displayed. Any PeopleCode associated with that Activate event runs, which may undo the changes you made when the page was last active. For example, if you hide a grid column in the Activate event, then display it as part of a user action, when the user tabs to another page in the component, then tabs back, the Activate event runs again, hiding the grid column again.

If a user at runtime hides a column of a grid, tabs to another page in the component, then tabs back to the first page, the page is refreshed and the grid column is displayed again.

You can use the rowset class methods and properties on analytic grid data. You can access the data loaded by the analytic grid by accessing a rowset object after the grid is populated.

Use the analytic grid classes to manipulate the display of an analytic grid—that is, one associated with PeopleSoft Analytic Calculation Engine data. If you want to manipulate a grid control, use the grid classes.

“GetRowset” (PeopleCode Language Reference)

“Activate Event” (PeopleCode Developer's Guide)

---

## Using Freeze Column Mode

If you specify Freeze Column Mode for an analytic grid in Application Designer, the analytic grid isn't populated from the component buffer by default. It is your responsibility to write your application code so that it populates the rowset bound to the analytic grid.

---

**Note:** You should not be adding and deleting data from the analytic grid when you are not in Freeze Column Mode; this is an unsupported feature and might cause unexpected behavior.

---

In addition, no layout information is available, and there is no slicer, row, or column axis.

The following is an example of populating the analytic grid with data from a normal grid in Freeze Column Mode.

```
Local Rowset &RSAGRID;
Local Rowset &RSGRID;
```

```
/* Get the rowset associated with normal grid whose primary record is */
/* QE_BAM_FACTTBL */
```

```

&RSGRID = GetLevel0() (1).GetRowset(Scroll.QE_BAM_FACTTBL);

/* Get the rowset associated with Analytic grid whose primary record is */
/* QE_BAM_CCSMOKE */
&RSAGRID = GetLevel0() (1).GetRowset(Scroll.QE_BAM_CCSMOKE);

/* Flush out existing Data from the Analytic Grid */
&RSAGRID.Flush();

/* Copy data from Normal Grid to Analytic Grid in Freeze Column Mode*/
&RSGRID.CopyTo(&RSAGRID, Record.QE_BAM_FACTTBL, Record.QE_BAM_CCSMOKE);

```

Do not use the following methods with an analytic grid that is in Freeze Column Mode:

- Analytic grid GetCubeCollection method
- Analytic grid LoadData method
- Analytic grid SetAnalyticInstance method
- Analytic grid SetLayout method
- Analytic grid SlicerVisible property

---

## Error Handling

All the analytic type classes throw PeopleCode exceptions for any fatal error that occurs in the execution of the operation. PeopleSoft recommends enclosing your analytic model programs in try-catch statements. This way, if your program catches the exception, the message set and message number that are associated with the exception object indicate the error.

### Related Links

[Try-Catch Blocks](#)

---

## Data Types of the Analytic Grid Objects

Analytic grids are declared using the AnalyticGrid data type. For example,

```
Local AnalyticGrid &MyAnalyticGrid;
```

Analytic grid columns are declared using the AnalyticGridColumn data type. For example:

```
Local AnalyticGridColumn &MYGRIDCOL;
```

---

## Scope of Analytic Grid Objects

Both the AnalyticGrid and AnalyticGridColumn objects can be instantiated from PeopleCode only.

An AnalyticGrid is a control on a page. You generally use these objects only in PeopleCode programs that are associated with an online process, not in an Application Engine program, a message notification, a Component Interface, and so on.

AnalyticGrid objects can be of scope local, component or global.

---

## AnalyticGrid Class Reference

This reference for the AnalyticGrid class includes:

- AnalyticGrid class built-in function.
- AnalyticGrid class methods.
- AnalyticGrid class properties.

---

## AnalyticGrid Class Built-in Function

“GetAnalyticGrid” (PeopleCode Language Reference)

---

## AnalyticGrid Class Methods

In this section, we discuss the AnalyticGrid class methods. The methods are described in alphabetic order.

### GetColumn

#### Syntax

`GetColumn (ColumnName)`

#### Description

Use the GetColumn method to instantiate an AnalyticGridColumn object.

---

**Note:** The properties for an AnalyticGridColumn and a GridColumn are the same. Any differences are indicated in the description for the GridColumn property.

---

Specify the grid column name in the page field properties for that field, consisting of any combination of uppercase letters, digits and "#", "\$", "@", and "\_".

To specify a grid column name:

1. Open the page in Application Designer, select the analytic grid and access the Analytic Grid control properties.
2. On the General tab, type the new grid name in **Page Field Name**.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                               |
|-------------------------|---------------------------------------------------------|
| <i>ColumnName</i>       | Specify the name of the column that you want to access. |

## Returns

An AnalyticGridColumn object.

---

**Note:** The properties for an AnalyticGridColumn and a GridColumn are the same. Any differences are indicated in the description for the GridColumn property.

---

## Related Links

[GridColumn Class](#)

## GetCubeCollection

### Syntax

```
GetCubeCollection()
```

### Description

Use the GetCubeCollection method to return a reference to the cube collection associated with the analytic grid.

---

**Note:** Do not use this method with an analytic grid that is in Freeze Column Mode.

---

## Parameters

None.

## Returns

A CubeCollection object.

## Related Links

[Understanding the Analytic Calculation Engine Classes](#)

[CubeCollection Class](#)

## LoadData

### Syntax

```
LoadData()
```

## Description

Use the LoadData method to cause the system to get fresh data for the grid from the analytic calculation engine. Generally, you would use this method after you perform some operation, such as SetLayout, that might change the value or layout of the data.

---

**Note:** Do not use this method with an analytic grid that is in Freeze Column Mode.

---

## Parameters

None.

## Returns

None.

## SetAnalyticInstance

### Syntax

**SetAnalyticInstance** (*ID*)

### Description

Use the SetAnalyticInstance method to specify the analytic instance to be associated with this analytic grid.

An AnalyticGrid object can be bound only once to an analytic instance. If the SetAnalyticInstance method is called after the analytic grid is bound to an instance, the method call has no effect.

---

**Note:** Do not use this method with an analytic grid that is in Freeze Column Mode.

---

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                     |
|-------------------------|-----------------------------------------------|
| <i>ID</i>               | Specify the analytic instance ID as a string. |

### Returns

None.

### Related Links

[Understanding the Analytic Calculation Engine Classes](#)

[Understanding the Analytic Calculation Engine Classes](#)

[AnalyticInstance Class Methods](#)

# SetLayout

## Syntax

```
SetLayout(&SlicerArray, &RowAxisArray, &ColumnAxisArray)
```

## Description

Use the SetLayout method to set the layout for the three axes, slice, row, and column.

**Note:** Do not use this method with an analytic grid that is in Freeze Column Mode.

If you specify No Drag drop mode for an analytic grid in Application Designer, the analytic grid has the column axis, row axis and slicer axis, but the end user isn't allowed to change the layout by dragging and dropping elements between axes. However, you can still change the layout using the SetLayout method.

**Note:** You can specify a null value ("" ) for all the required parameters for this method.

## Parameters

| Parameter        | Description                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| &SlicerArray     | Specify an already instantiated array of string containing the list of fields to be put on the slice axis.                                                                                                                      |
| &RowAxisArray    | Specify an already instantiated array of string containing the list of fields to be put on the row axis.                                                                                                                        |
| &ColumnAxisArray | <div>Specify an already instantiated array of string containing the list of fields to be put on the column axis.</div> <div><b>Note:</b> The maximum number of columns that can be displayed in an analytic grid is four.</div> |

## Returns

None.

# AnalyticGrid Class Properties

In this section we discuss the AnalyticGrid properties. The properties are described in alphabetic order.

## Inactive

### Description

Use this property to specify whether the analytic grid is inactive or active. This property takes a Boolean value, true if the grid is inactive, false otherwise.

If you specify this property as true, the analytic grid is not displayed to the user and no data is fetched from the database.

This property is read/write.

## Label

### Description

Use this property to specify the label that appears as the title of the grid.

---

**Note:** You can't use this property to set labels longer than 100 characters. If you try to set a label of more than 100 characters, the label is truncated to 100 characters. Always put any changes to labels in the Activate event for the page. This way the label is set every time the page is accessed.

---

This property is read/write.

## ShowGridLines

### Description

Use this property to specify whether grid lines are displayed with the analytic grid. This property takes a Boolean value, true to show the lines, false otherwise.

This property is read/write.

## SlicerVisible

### Description

Use this property to specify whether the slicer is displayed with the analytic grid. This property takes a Boolean value, true to show the slicer, false otherwise.

---

**Note:** Do not use this method with an analytic grid that is in Freeze Column Mode.

---

This property is read/write.

## SummaryText

### Description

Use this property to set or return a string representing the summary text for the analytic grid.

Summary text enables you to provide a brief description of the functionality and content of the grid area. This property is pertinent for users who access the application in screen reader mode.

This property is read/write.

### Example

```
&MyAnGrid = GetAnalyticGrid(Page.PSMYPAGE, "PSMYPAGE");  
&MyAnGrid.SummaryText = "This is the new summary text through PeopleCode";
```

## Understanding the Analytic Calculation Engine Classes

PeopleSoft Analytic Calculation Engine comprises a calculation engine plus several PeopleTools features which enable application developers to define both the calculation rules and the display of calculated data within PeopleSoft applications for the purposes of multi-dimensional reporting, data editing, and analysis.

More specifically, developers create *analytic models* in order to define the rules which are used to calculate data. Developers also create PeopleSoft Pure Internet Architecture pages with *analytic grids* in order to display the data within PeopleSoft applications. End users view, analyze and make changes to this data. When end users save their changes, PeopleSoft Analytic Calculation Engine recalculates the data and saves the calculated data to the database.

PeopleCode enables developers to manipulate analytic calculation data as follows:

- Use the Analytic Calculation Engine classes to either retrieve or specify data in an instance of an analytic model loaded into the system, and also to calculate (or recalculate) cube values.
- Use the Analytic Calculation Engine metadata classes to manipulate an analytic model definition. For example, you can add cubes to a cube collection or rename an existing user function for a model.
- Use the analytic grid classes to manipulate the display of analytic calculation data on a page.
- Use the analytic type metadata classes to manipulate an analytic type definition. For example, you can specify a new analytic model for an analytic type definition.

---

**Important!** The analytic type classes are not supported on IBM z/OS and Linux for IBM System z platforms.

---

---

## Using the Analytic Type Classes

You can create analytic type definitions using Application Designer. PeopleSoft provides the analytic type classes for accessing these definitions at runtime.

You can also create an analytic type definition in PeopleCode, using the Create method, then saving it to the database using the Save method. After you save the definition, you can access it using Application Designer.

You only need to create an instance of the analytic type. All other objects are instantiated from the analytic type object.

Once the `AnalyticTypeDefn` object is created, you can then execute either the `Get` or `Create` methods to “instantiate” the analytic type object.

---

## Error Handling

All the analytic type classes throw `PeopleCode` exceptions for any fatal error that occurs in the execution of the operation. PeopleSoft recommends enclosing your analytic model programs in try-catch statements. This way, if your program catches the exception, the message set and message number that are associated with the exception object indicate the error.

### Related Links

[Try-Catch Blocks](#)

---

## Data Types of the Analytic Type Objects

Every PeopleSoft analytic type object is declared as its own data type, that is, `AnalyticTypeDefn` objects are declared as type `AnalyticTypeDefn`, `AnalyticTypeModelDefn` objects are declared as type `AnalyticTypeModelDefn`, and so on.

The following are the data types for the PeopleSoft analytic type classes:

- `AnalyticTypeDefn`
- `AnalyticTypeModelDefn`
- `AnalyticTypeRecordDefn`

---

## Scope of Analytic Type Objects

The analytic type objects can only be instantiated from `PeopleCode`.

These objects can be used anywhere you have `PeopleCode`, that is, in a `Application Engine` program, an application class, record field `PeopleCode`, and so on.

Analytic type objects can be of scope `Local`, `Component` or `Global`.

---

## How to Import the Analytic Type Classes

The analytic type classes are *not* built-in classes, like `Rowset`, `Field`, `Record`, and so on. They are application classes. Before you can use these classes in your `PeopleCode` program, you must import them to your program.

An import statement names either all the classes in a package or one particular application class. For importing the analytic type classes, PeopleSoft recommends that you import all the classes in the application package.

The application package PT\_ANALYTICTYPEDEFN contains the following subclasses:

- AnalyticTypeDefn
- AnalyticTypeModelDefn
- AnalyticTypeRecordDefn

The import statement you should use should be as follows:

```
import PT_ANALYTICTYPEDEFN:*;
```

Using the asterisks after the package name makes all the application classes directly contained in the named package available.

[Understanding Application Classes](#)

## How to Create an Analytic Type Class Object

After you've imported the analytic type classes, you need to instantiate an instance of the AnalyticTypeDefn class, using the constructor for that class and the Create function. After you create the object, you must populate it using either the Get or Create method.

The following example creates an AnalyticTypeDefn object from the QE\_ACE\_ALLFUNCTION analytic type definition.

```
Local PT_ANALYTICTYPEDEFN:AnalyticTypeDefn &AnalyticType;
&AnalyticType = create PT_ANALYTICTYPEDEFN:AnalyticTypeDefn("QE_ACE_ALLFUNCTION");
```

[Analytic Calculation Engine Metadata Classes Constructor](#)

## Analytic Type Classes Constructor

You must use the constructor for the AnalyticTypeDefn class to instantiate an instance of that class. All other objects are instantiated from this class.

### AnalyticTypeDefn

#### Syntax

```
AnalyticTypeDefn (TypeName)
```

## Description

Use the `AnalyticTypeDefn` constructor to create an `AnalyticTypeDefn`.

Once the `AnalyticTypeDefn` object is created, you can then execute either the `Get` or `Create` methods to instantiate the model.

---

**Note:** The `Delete` and `Rename` methods can only be executed before a model is instantiated.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                        |
|-------------------------|--------------------------------------------------|
| <i>TypeName</i>         | Specify the name of an analytic type definition. |

## Returns

An `AnalyticTypeDefn` object.

## Example

```
&Model = create AnalyticTypeDefn("QE_ACE_ALLFUNCTION");
```

---

## AnalyticTypeDefn Class Methods

This section describes the analytic type definition class methods. The methods are discussed in alphabetical order.

## AddModel

### Syntax

```
AddModel (ModelName, ModelType)
```

### Description

Use the `AddModel` method to add either an analytic model or optimization model to the analytic type definition. If the model doesn't exist, this method fails.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>              |
|-------------------------|----------------------------------------|
| <i>ModelName</i>        | Specify the name of an existing model. |

| <b><i>Parameter</i></b> | <b><i>Description</i></b>           |
|-------------------------|-------------------------------------|
| <i>ModelType</i>        | Specify the model type. Values are: |

| <b><i>Value</i></b> | <b><i>Description</i></b>                    |
|---------------------|----------------------------------------------|
| %ModelType_ACE      | The model is an Analytic Calculation Engine. |
| %ModelType_OPT      | The model is an optimization.                |

## Returns

The new AnalyticTypeModelDefn object.

## Related Links

## AddRecord

### Syntax

**AddRecord** (*RecordName*)

### Description

Use the AddRecord method to add a record to the analytic type definition. If the record definition doesn't exist in Application Designer, or if the record already exists in this analytic type definition, this method fails.

### Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                            |
|-------------------------|------------------------------------------------------|
| <i>RecordName</i>       | Specify the name of the record that you want to add. |

## Returns

An AnalyticTypeRecordDefn object that represents the record.

## Related Links

[GetRecordNames](#)[AnalyticTypeRecordDefn Class Methods](#)

## Create

### Syntax

**Create** ()

### Description

Use the Create method to create, and instantiate, a new analytic type. If the analytic type already exists, an exception is thrown.

### Parameters

None.

### Returns

None.

### Related Links

[Save](#)[Try-Catch Blocks](#)

## CopyTo

### Syntax

**CopyTo** (*NewAnalyticTypeName*)

### Description

Use the CopyTo method to copy the current AnalyticTypeDefn object to the AnalyticTypeDefn object with the specified name. This method fails if the analytic type specified with *NewAnalyticTypeName* already exists.

### Parameters

| <i><b>Parameter</b></i>    | <i><b>Description</b></i>                                                     |
|----------------------------|-------------------------------------------------------------------------------|
| <i>NewAnalyticTypeName</i> | Specify the name of the new analytic type definition that you want to create. |

## Returns

The new `AnalyticTypeDefn` object.

## Related Links

[Save](#)

## Delete

### Syntax

```
Delete ()
```

### Description

Use the Delete method to delete the analytic type definition. You must use this method immediately after you create the `AnalyticType` object, before you instantiate it, that is, before you use either the Get or Create method.

---

**Note:** This method executes immediately, and deletes the definition from Application Designer.

---

### Parameters

None.

### Returns

None.

## DeleteModel

### Syntax

```
DeleteModel (ModelName)
```

### Description

Use the DeleteModel method to delete the specified model from the analytic type definition.

---

**Note:** The model is not deleted from the analytic type definition until you use the Save method.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                |
|-------------------------|--------------------------------------------------------------------------|
| <i>ModelName</i>        | Specify the name of a model that exists in the analytic type definition. |

## Returns

None.

## DeleteRecord

### Syntax

**DeleteRecord** (*RecordName*)

### Description

Use the DeleteRecord method to delete a record from the analytic type definition.

---

**Note:** The record deleted from the analytic type definition until you use the Save method.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------|
| <i>RecordName</i>       | Specify the name of the record that you want to remove from the analytic type definition. |

## Returns

None.

[Create](#)

[Save](#)

GetModel

Syntax

`GetModel(ModelName)`

Description

Use the GetModel method to return a reference to an AnalyticTypeModelDefn object.

This method fails if the model specified by *ModelName* doesn't exist.

Parameters

| <i>Parameter</i> | <i>Description</i>                                                              |
|------------------|---------------------------------------------------------------------------------|
| <i>ModelName</i> | Specify the name of the analytic type model definition that you want to access. |

Returns

An AnalyticTypeModelDefn object.

## Related Links

[AnalyticTypeModelDefn Class Properties](#)

## GetModelNames

### Syntax

```
GetModelNames ()
```

### Description

Use the GetModelNames method to return an array of string containing all the model names in this analytic type definition.

### Parameters

None.

### Returns

An array of string.

# Rename

## Syntax

```
Rename (NewAnalyticTypeName)
```

## Description

Use the `Rename` method to rename an existing analytic type definition to a new name. You must use this method immediately after you create the `AnalyticType` object, before you instantiate it, that is, before you use either the `Get` or `Create` method. The new name is not saved to the database until you use the `Save` method.

## Parameters

| <i>Parameter</i>           | <i>Description</i>                                     |
|----------------------------|--------------------------------------------------------|
| <i>NewAnalyticTypeName</i> | Specify the new name for the analytic type definition. |

## Returns

None.

## Related Links

[Save](#)

## Save

### Syntax

**Save** ( )

### Description

Use the Save method to save any changes that were made to the AnalyticTypeDefn object to the database.

### Parameters

None.

### Returns

None.

---

## AnalyticTypeDefn Class Properties

In this section we discuss the AnalyticTypeDefn class properties. The properties are described in alphabetic order.

### AppClassPath

#### Description

Use this property to specify the full name of the application package that contains the Create, Copy and Delete methods used with this analytic type definition.

This property is read/write.

## Comments

### Description

Use this property to specify comments for the analytic type.

This property is read/write.

## Description

### Description

Use this property to specify a description for the analytic type.

This property is read/write.

## Name

### Description

This property specifies the name of the AnalyticTypeDefn.

This property is read-only.

## OwnerID

### Description

This property specifies the owner ID for this AnalyticTypeDefn.

This property is read/write.

---

## AnalyticTypeModelDefn Class Properties

In this section we discuss the AnalyticTypeModelDefn class properties. The properties are described in alphabetic order.

## Name

### Description

This property specifies the name of the analytic type model.

This property is read-only.

## Type

### Description

This property specifies the type of the analytic type model. Values are:

| <b><i>Value</i></b> | <b><i>Description</i></b>                    |
|---------------------|----------------------------------------------|
| %ModelType_ACE      | The model is an Analytic Calculation Engine. |
| %ModelType_OPT      | The model is an optimization.                |

This property is read-only.

---

## AnalyticTypeRecordDefn Class Methods

In this section we describe the AnalyticTypeRecordDefn class methods. The methods are discussed in alphabetic order.

### GetSelectedField

#### Syntax

```
GetSelectedField()
```

#### Description

Use the GetSelectedField to return an array of string containing the names of the fields that are selected for this record.

#### Parameters

None.

#### Returns

An array of string.

#### Related Links

[SetSelectedField](#)

## SetSelectedField

### Syntax

```
SetSelectedFields(FieldName)
```

### Description

Use the SetSelectedField method to specify the name of the field that is selected for this record.

### Parameters

| <i>Parameter</i> | <i>Description</i>                                     |
|------------------|--------------------------------------------------------|
| <i>FieldName</i> | Specify the name of the field that you want to select. |

### Returns

None.

### Related Links

[GetSelectedField](#)

## UnsetSelectedField

### Syntax

```
UnsetSelectedField(FieldName)
```

### Description

Use the UnsetSelectedField method to deselect the selected field.

This method throws an exception if the field specified by *FieldName* isn't selected.

### Parameters

| <i>Parameter</i> | <i>Description</i>                                       |
|------------------|----------------------------------------------------------|
| <i>FieldName</i> | Specify the name of the field that you want to deselect. |

### Returns

None.

---

## AnalyticTypeRecordDefn Class Properties

In this section we discuss the AnalyticTypeRecordDefn class properties. The properties are described in alphabetic order.

All of the properties listed here can also be set for the analytic type definition using Application Designer.

### Related Links

“Understanding Analytic Model Properties” (Analytic Calculation Engine)

## Callback

### Description

Use this property to specify whether this record has a callback. This property takes a Boolean value, true if the record has a callback, false otherwise.

This property is read/write.

## Description

### Description

Use this property to specify a description for the record.

This property is read/write.

## Name

### Description

This property specifies the name of the record.

This property is read-only.

## Readable

### Description

Use this property to specify whether this record is readable. This property takes a Boolean value, true if the record is readable, false otherwise.

This record is read/write.

## ReadOnce

### Description

Use this property to specify whether this record is specified as read once. This property takes a Boolean value, true if the record is only read once, false otherwise.

This property is read/write.

## ScenarioManaged

### Description

Use this property to specify if the record is specified as scenario managed. This property takes a Boolean value, true if the record is scenario managed, false otherwise.

This property is read/write.

## SyncOrder

### Description

This property specifies the synchronization order for the record. It returns an integer value.

This property is read/write.

## Writeable

### Description

Use this property to specify if a record is specified as writeable. This property takes a Boolean value, true if the record is writeable, false otherwise.

This property is read/write.

---

## AnalyticType Classes Example

The following is a typical example of using the AnalyticType classes.

```
import PT_ANALYTICTYPEDEFN:*;

Local PT_ANALYTICTYPEDEFN:AnalyticTypeDefn &AnalyticType;

Local PT_ANALYTICTYPEDEFN:AnalyticTypeRecordDefn &AnalyticTypeRecordDefn;

&AnalyticType = create PT_ANALYTICTYPEDEFN:AnalyticTypeDefn("BB_TEST");

&AnalyticType.Create();

&AnalyticType.AddModel("QE_BAM_GENX", %ModelType_ACE);
```

```
&AnalyticTypeRecordDefn = &AnalyticType.AddRecord1("QE_BAM_CCSMOKE");  
&AnalyticTypeRecordDefn = &AnalyticType.AddRecord1("QE_BAM_FACTTBL");  
&AnalyticType.Save();
```

# Application Classes

---

## Understanding Application Classes

You can create Application Packages in Application Designer. These *packages* contain application classes (and may contain other packages also). An application class, at its base level, is just a PeopleCode program. However, using the Application Packages, you can create your own classes, and extend the functionality of the existing PeopleCode classes.

The application classes provide capability beyond that offered by the existing PeopleCode classes. Unlike the existing classes, a subclass can inherit all the properties and methods of the class it extends. This provides all the advantages of true object-oriented programming:

- easier to debug because all the pieces are separate
- easier to maintain because functionality is gathered into a single place
- extensible by subclass

In addition, the application classes provide more structure. Using the Application Packages, you have a clear definition of each class, as well as its listed properties and methods. This makes it easier to create a complex program that uses many functions.

### Related Links

“Creating Application Packages” (PeopleCode Developer’s Guide)

## When Would You Use Application Classes?

Use Application classes to help structure your existing PeopleCode functions. For example, prior to Application classes, most PeopleCode functions were put into FUNCLIB records. However, in larger, more complex programs, it is sometimes difficult to find (let alone maintain) a function. You could make every function a class in a package with very little reworking of your PeopleCode (as well as making the different fields in a record a package, and combining them into a single larger package.) This provides a better visual interface for grouping your functions.

In addition, use Application classes when you have to do generic processing, and just the details are different. For example, suppose one of the processes for your application is reading a file object and doing bulk insert. The process could all be contained in a single package, with the classes and subclasses providing all the details, different kinds of reading for different types of files, different inserts based on the record, and so on.

One of the main differences between a class and a function call is that the call to the class is dynamic, like a function variable, but more closely controlled. All the calls to the class (methods) must have the same signature.

For example, suppose you want to provide a more generic sort, with comparison function at the end of it. You want to use the array class Sort method, but your process has to be generic: you aren't certain if you're comparing two records or two strings. You could define a class that had as its main method a comparison, and return a -1, 0, or 1. Then write your personalized sort, extending the array class method Sort.

Another use is for business processing. Think in terms of core functionality, with vertical product solutions that extend the basic processing by providing specifics, in other words, by extending the general classes with subclasses. This could be appropriate for sales force automation or order entry.

Generally, use application classes where you can extract the common functionality.

---

**Note:** Do not extend a SOAPDoc with an application class. This is currently not supported.

---

---

## Application Classes General Structure

This section discusses the general form of an application class. All application classes are contained in application packages; and all application classes are composed of executable PeopleCode statements.

The division of application classes facilitates object-oriented programming and enables a separation of the following:

- What the class provides to other classes.
- What is applicable to the entire class.
- What is applicable to the definition of a method.

The data types used in an application class (for methods parameters, return values, and so on) can be any PeopleCode types, including application classes. Likewise, application classes can be used anywhere in a PeopleCode program where a general data type can be used.

### Related Links

“Data Types” (PeopleCode Developer’s Guide)

## Class Name

Application classes have a fully qualified name that is formed hierarchically by the name of the top-level package that contains them, the package that contains that package, and so on down to the short class name, that is, the one specified when the class was created in Application Designer, using a colon for the separator between names.

The fully qualified name of the class must be unique, as this is what identifies the class. The short name of the class does not have to be unique.

For example, suppose package CRM contains the application classes Address and Customer as well as the package Utilities, which in turn contains the application classes Address and Incident:

There are four distinct application classes in this example:

- CRM:Address
- CRM:Customer
- CRM:Utilities:Address
- CRM:Utilities:Incident

---

**Note:** If you change the name of a package or an application class, that name change is *not* automatically propagated through all your PeopleCode programs. You must make the change manually in your programs. If you specify an incorrect name for a package or application class, you receive a warning when you try to save the PeopleCode.

---

## Class Extension

Extension represents the "is-a" relationship. When a class extends another class, it's called a *subclass* of that class. Conversely, the class being extended is called a *superclass* of that subclass.

A subclass inherits all of the public methods and properties (collectively called *members*) of the class it extends. These members can be overridden by declarations of methods and properties in the subclass.

---

**Note:** Application classes have no multiple inheritance (that is, being able to extend more than one class.)

---

Type checking in PeopleCode (both at design time and runtime) does strong type checking of application classes, tracking each application class as a separate type. A subclass can be used as the class it extends, because it implements the public interfaces of its superclass. This is called *subtyping*.

In the following example, the class `Banana` extends the class `Fruit`. `Banana` is the *subclass* of `Fruit`. From `Fruit`, you can extend to `Bananas`. However, from `Bananas` you can't extend to `Fruit`. Another way to think about this is you can only extend from the general to the specific, not the other way around.

```
class Fruit
  method DoFruit();
  property number FruitNum instance;
end-class;

class Banana extends Fruit
  method DoBanana();
  property number BananaNum instance;
end-class;
```

The following code shows a correct way to assign a class object, because `Banana` is a *subtype* of `Fruit`.

```
local Fruit &Bref = create Banana();
```

The following is *not* correct. `Banana` is a subtype of `Fruit`. `Fruit` is *not* a subtype of `Banana`. This assignment causes an error at design time.

```
local Banana &Fref = create Fruit();
```

Before you can extend a class, you must first import it. You must import all class names you use in a PeopleCode program before you use them.

## Related Links

[Import Declarations](#)

## Declaration of Public External Interface

The names of the members (that is, all the methods and properties of a class) must be unique only within that class. Different classes can have members with the same name. As members are used only with objects, and each object knows its class, the member that's accessed is the one associated with that class.

For example, more than one class has the property `Name` which returns the name of the object executing the property. There isn't any confusion, because the field `Name` property returns the name of a field, while the record name property returns the name of a record. No class has more than one property called `Name`.

---

**Note:** Within a class, each member name *must* be unique.

---

The public part of a class declaration specifies the methods and properties that the class provides to other PeopleCode programs. These methods and properties are *dynamically bound*, that is, the actual method that is called depends on the actual class of the object, as it might be an overridden method or property from a subclass.

In the following code example, the text in bold indicates the public part of the class declaration.

```
/* generic building class */
class BuildingAsset
  method Acquire();
  method DisasterPrep();
end-class;
```

## Access Control and the Declaration of Protected Properties and Methods

Application class objects have private and public access control. Properties or methods that are declared outside the “private” declaration section have public access control. This means that they can be referenced and used by any PeopleCode. This access is of course subject to access controls such as “readonly”. Private properties and methods are private to the class, not instance, and can only be referenced by objects of this application class.

Between these two access control schemes of public and private, lies the concept of protected methods and properties. Protected methods and properties can be accessed only by objects of this application class and those derived from this application class. Use protected methods or properties when you want to hide them from outside use, but allow the flexibility of using them in derived classes.

The declarations of protected variables and methods are done within the class declaration, before the declaration of private variables and methods. You can use protected instance variables in interface classes. Protected methods and properties can be overridden by subclasses.

Most of the time your design can be implemented through the use of private methods and properties without resorting to the use of protected methods and properties. The following examples demonstrates the rules and some of the subtleties about when to use protected methods and properties.

```
class A;
    method A();
    property string Q;
protected
    method MP() Returns string;
    property string p;
end-class;

method A;
    &p = "Class A: property p";
end-method;

method MP
    /+ Returns String +/
    Return "Class A: method MP";
end-method;

=====

class B extends A;
    method B();
    method M(&X As C);
    method m2(&Aobj As A);
    /* property string P; */
protected
    property string Q;
    method MP() Returns string;
end-class;

method B;
    %Super = (create A());
    &Q = "Class B: property Q";
    /* &P = "Class B: property P"; */
end-method;

method M
    /+ &X as FOXTEST:C +/;

    MessageBox(0, "", 0, 0, "In B:M %This.P=" | %This.p);
    /* %This.p is class A property P */
    MessageBox(0, "", 0, 0, "In B:M %This.Q=" | %This.Q);
    /* %This.q is class B property Q */
    MessageBox(0, "", 0, 0, %This.MP());
```

```

/* %This.MP() calls class B method MP */

    if &X.p = "Error" then
        end-if;
/* error: cannot reference &X.p since class B is
not involved in the implementation of class C */
end-method;

method m2
    /+ &Aobj as FOXTEST:A +/
/* MessageBox(0, "", 0, 0, "In B:M2 &Aobj.P=" | &Aobj.p);
/* Error: cannot reference &Aobj.p from class B
since class B is not involved in its implementation */

end-method;

method MP
    /+ Returns String +/
    Return "Class B: method MP";
end-method;

=====

class C extends A;
    method C();
protected
    property string P;
end-class;

method C;
    %Super = (create A());
    &P = "Class C: property P";
end-method;
=====

/* AE program */
import FOXTEST:*;

Local A &A = (create A());

Local object &obj = &A;
MessageBox(0, "", 0, 0, "In AEMINITEST: &Obj.p=" | &obj.P);
/* run time error: anonymous access through type
object not allowed*/

```

The following example also illustrates some of the rules surrounding protected access control.

```

import FOXTEST:Point3d;

class Point
    method Point(&X1 As integer, &Y1 As integer);
    method Warp(&A As Point3d);
protected
    property integer x;
    property integer y;
end-class;

method Point
    /+ &X1 as Integer, +/
    /+ &Y1 as Integer +/;

    %This.x = &X1;
    %This.y = &Y1;
end-method;

method Warp
    /+ &A as FOXTEST:Point3d +/
    /* Local Integer &temp = &A.Z; ERROR cannot access &A.Z */
end-method;
=====
import FOXTEST:Point;

```

```

class Point3d extends Point
    method Point3d(&X1 As integer, &Y1 As integer, &Z1 As integer);
    method Delta(&P As Point);
    method Delta3d(&Q As Point3d);
protected
    property integer z;
end-class;

method Point3d
    /+ &X1 as Integer, +/
    /+ &Y1 as Integer, +/
    /+ &Z1 as Integer +/;
    %Super = (create Point(&X1, &Y1));
    %This.z = &Z1;
end-method;

method Delta
    /+ &P as FOXTEST:Point +/

    /* &P.x = %This.x;
    ERROR cannot access &P.x since while Point3d
    (the class in which references to fields x and y occur)
    is a subclass of Point (the class in which x and y are declared),
    it is not involved in the implementation of Point (the type of parameter p)*/

    /* &P.y = %This.y;
    ERROR cannot access &P.y. Same reason as above */
end-method;

method Delta3d
    /+ &Q as FOXTEST:Point3d +/

    /* The protected members of Q can be accessed because the class point3d is a subcla→
    ss of Point and is involved in the implementation of Point3d */
    &Q.x = %This.x;
    &Q.y = %This.y;
    &Q.z = %This.z;

end-method;

```

## Declaration of Private Instance Variables and Methods

The private part of a class declaration gives the declaration of any private methods, instance variables, and private class constants. Private methods *cannot* be overridden by subclasses, because they are completely private to the declaring class. Likewise, the instance variables can't be overridden.

The declarations of private variables and methods are done within the class declaration.

---

**Note:** You cannot have private methods or instance variables in an interface type of class.

---

In the following example, there are both public as well as private methods and properties. Any method that is declared before the keyword `Private` in the initial class declaration is public. Any method declared after the keyword `Private` is private. Properties are only declared in `Public`. Instances and Constants are only declared in `Private`

In the following example, the class `Example` extends the class `ExampleBase`. It has both public as well as private methods and properties. It also defines the private method in the definition of methods section of the code (the private definitions are marked **like this**.)

```

import PWWPACK:ExampleBase;

class Example extends ExampleBase

```

```

    method Example();
    method NumToStr(&Num As number) Returns string;
    method AppendSlash();
    property number SlashCount get;
    property number ImportantDayOfWeek get set;
    property string SlashString readonly;
    property date ImportantDate;
private
    method NextDayOfWeek(&Dow As number) Returns date;
    Constant &Sunday = 1;
    instance string &BaseString;
end-class;

Global string &CurrentBaseString;

/* Method definitions */
method NumToStr
    return String(&num);
end-method;

method AppendSlash
    &SlashString = &SlashString | "/";
end-method;

get SlashCount
    Return Len(&SlashString) - Len(&BaseString);
end-get;

get ImportantDayOfWeek
    Return Weekday(&ImportantDate);
end-get;

set ImportantDayOfWeek
    &importantdate = %This.nextdayofweek(&newvalue);
end-set;

/* Private method. */
method nextdayofweek
    Return &ImportantDate + (&dow - Weekday(&ImportantDate));
end-method;

/* Constructor. */
method Example
    &BaseString = &CurrentBaseString;
    &SlashString = &BaseString;
    &ImportantDate = Date(19970322);
end-method;

```

## Definition of Methods

After the declaration of any global or component variables and external functions needed by the methods, comes the actual definition of the methods. This section discusses some of the differences in how application programs are processed by the system, and how application class method parameters are processed.

- Application programs generally pass parameters by value, which is not the same as for existing functions.
- Parameter passing with object data types is by reference.
- Application programs use the out specifier to pass a parameter by reference.

## Passing Parameters in Application Class Methods

The parameters to a method are passed by value in the absence of an *out* specification in the parameter list. However, if a parameter list has an out specification, that argument (when used in the call of a method) must be a value that can be assigned something, and is passed by *reference*. In particular this means you cannot pass an object property to a method which requires the parameter to be an "out" parameter. Application class properties are always passed by value.

For example:

```
/* argument passed by reference */
method increment(&value as number out);
```

```
/* argument passed by value */
method increment(&value as number);
```

This is in contrast with existing PeopleCode functions that pass *all* parameters by reference when they can be assigned something. This means the method signature is a specification of which parameters can be updated by the method. This makes the code easier to debug and maintain because it's easy to see what can be updated and what can't.

The following is an example of code that increments a variable by one.

```
local Number &Mine;

&Mine = 1;

&obj.Increment(&Mine);
```

&Mine now has the value 2.

You cannot pass properties by reference. For example, suppose MyProp is a property of class Xan, a statement that requires a reference doesn't work if you supply the property. The following code will always fail because &Xan.MyProp is always passed by value and the MySQLExec method requires it to be passed by reference (so a value can be returned.)

```
MySQLExec("select from bar", &Xan.MyProp)
```

This makes sense because the semantics of an object require that you can only change a property with standard property references, not as a side affect of some other action.

## Passing Parameters with Object Data Types

Parameters with object data types are always passed by reference:

```
/* argument passed by reference */
method storeInfo(&f as File);
```

If you specify the out modifier for a method parameter with an object data type, it becomes a *reference parameter*. This means that the parameter variable is passed by reference instead of the object that it is pointing at when passed.

For example, if you pass an object parameter with the out modifier:

```
method myMethod(&arg as MyObjectClass);

local MyObjectClass &o1 = create MyObjectClass("A");
local MyOtherObjectClass &o2 = create MyOtherObjectClass();

&o2.myMethod(&o1);
```

And inside myMethod this occurs:

```
Method myMethod
    &arg = create MyObjectClass("B");
end-method;
```

Since the method argument is reassigned within the body of myMethod, &o1 does not point at the new instance of MyObjectClass (initialized with "B") after the method call completes. This is because &o1 still references the original instance of MyObjectClass.

However, if &o1 had been passed with the out modifier, after the method call completes, &o1 points at whatever the parameter was last assigned to; in this case, the new instance of MyObjectClass. The parameter, rather than the object, is passed by reference.

## Using the Out Specification for a Parameter

In the following example, a class, AddStuff, has a single public method, DoAdd. This adds two numbers together, then assigns them as different numbers. In the signature of the method declaration, the first parameter is *not* declared with an out statement, while the second one is.

```
class AddStuff
    method DoAdd(&P1 as number, &P2 as number out);
end-class;

method DoAdd
    &X = &P1 + &P2;
    &P1 = 1;
    &P2 = 2;
end-method;
```

In the following PeopleCode example, an object named &Aref is instantiated from the class AddStuff. Two parameters, &I and &J are also defined.

```
local AddStuff &Aref = create AddStuff();
local number &I = 10;
local number &J = 20;
```

The following code example is correct. &J is changed, because of the *out* statement in the method signature, and because the value is being passed by reference. The value of &I is *not* updated.

```
&Aref.DoAdd(&I, &J); /* changes &J but not &I */
```

The following code example causes a design time error. The second parameter must be passed *by reference*, not by value.

```
&Aref.DoAdd(10, 20); /* error - second argument not variable */
```

## Declaration of Abstract Methods and Properties

You can declare methods and properties as abstract, that is, a method or property that has a signature which specifies the parameters and results, but has no implementation in the class that defines it. The implementation may occur in one of the classes that extend the class where the method or property is initially defined.

Abstract methods and properties could be used, for example, when your application wants to provide a means for in-field customization. Your application might deliver a base class specifying the abstract methods and properties and you would allow the customization to complete those methods and properties by using a class that would extend the base class and provide implementations for some or all of the abstract methods and properties.

For a class that only contains abstract methods and properties, that is, a pure interface class, you would define a `PeopleCode` interface, instead of a class. You define a `PeopleCode` interface by using the keyword `Interface` instead of `Class`. In an interface, all the methods and properties are abstract by default.

The following example illustrates the use of abstract methods and properties. Class `MyInterface` is the base class which has mostly abstract methods and properties. However it is fully specified by the class `MyImplementation` which provides an implementation for all the methods and properties.

```
class MyInterface
    method MyMethod1() abstract;
    method MyMethod2() Returns string abstract;
    method MyMethod3();
    property string myproperty1 abstract readonly;
    property number myproperty2 abstract;
    property number myproperty3 abstract;
end-class;

method MyMethod3
end-method;

-----
import FOXTEST:MyInterface;

class MyImplementation extends MyInterface;
    method MyImplementation();
    method MyMethod1();
    method MyMethod2() Returns string;
    property string myproperty1 readonly;
    property number myproperty2;
    property number myproperty3;
end-class;

method MyImplementation
    %Super = create MyInterface();
end-method;

method MyMethod1
    /* dummy */
end-method;

method MyMethod2
    /* Returns String */
    Return "MyMethod2's implementation is this";
end-method;
```

## Considerations Using Abstract Methods and Properties

Be aware of the following considerations when using abstract methods or properties.

- You cannot have private abstract methods.
- You will receive an error if you try to provide a method body for an abstract method.
- The method signatures must be identical between the abstract method definition and the method implementation in the derived subclass.
- You will receive an error if you try to provide a Get or Set body with an abstract property.

- You will receive an error and your PeopleCode program will be terminated if you try to call an abstract method or property at runtime, unless caught in a try-catch block.
- The class that implements an interface must still assign %Super in its constructor.

## Interfaces

The concept of an interface class is purely a syntactic assist when you are defining an application class which is totally composed of abstract methods and properties. In this case by simply specifying the keyword **interface** you are indicating that all the methods and properties are abstract. The following two definitions are semantically equivalent.

```
class MyInterface
    method MyMethod1() abstract;
    method MyMethod2() Returns string abstract;
    property string myproperty1 abstract readonly;
    property number myproperty2 abstract;
    property number myproperty3 abstract;
end-class;

interface MyInterface
    method MyMethod1();
    method MyMethod2() Returns string;
    property string myproperty1 readonly;
    property number myproperty2;
    property number myproperty3;
end-interface;
```

When you provide an implementation for an interface you can also use the keyword **implements** instead of **extends**. While this is not mandatory, specifying **implements** describes more accurately what your application class is doing.

If your class implements an interface, you don't need to create an object reference to the superclass since the system does that automatically for you.

In addition if your constructor takes no parameters and simply exists to create an object reference to the superclass (that is, there is only one statement such as `%Super = create mySuper();`), then you don't need to define a constructor method at all.

## Constructors

The constructor for a class is the public method with the same name as the (short name of the) class. The statements contained in this method (if any) provide the initialization of the class.

This constructor is *always* executed when an object of the class is instantiated.

---

**Note:** Before a constructor runs, the instance variables for the class are set by default based on their declared types.

---

Instantiate new objects of an application class by using the create function. This function takes the name of the class, and any parameters needed for the constructor method.

If the short class name is unambiguous, that is, only one class by that short name has been imported, you can use just the short class name.

The following code instantiates an object of the class Fruit:

```
&Fref = create Fruit();
```

If there's a possibility that the name is ambiguous, you can use the full class name to instantiate the object.

The following code instantiates an object of the Invoice class:

```
&InvObj = create PT:examples:Invoice();
```

If the create function is used in the context of further object expressions, that is, with a reference to members by a dot operation, the function call must be enclosed in parentheses. This is to emphasize that the creation happens before the member reference. For example:

```
&InvCust = (create Invoice()).Cust();
```

If necessary, the constructor is supplied its parameters by the call-list after the class name in the create statement. For example:

```
&Example = create Example(&ConstructorParameter1, 2, "Third");
```

A class that does not extend some other class does not need any constructor.

A class that extends another class must have a constructor, and in the constructor, it must initialize its super class. This restriction is relaxed if the super class constructor takes no parameters, and all the constructor does is assign it to %Super. In this case, the runtime creates the super object and runs its constructor automatically. The benefit of this is two-fold: at design time you do not need to provide a constructor since the runtime automatically does the equivalent of %Super = create MySuperObject(); Also, at runtime, you may notice a performance increase since the super class object creation and construction are done without any PeopleCode. This latter benefit can be compounded in the case where there are multiple levels of inheritance.

To the general case, to initialize a superobject, an instance of the superclass is assigned to the keyword %Super in the constructor for the subclass. This assignment is allowed only in the constructor for the subclass.

The following example shows this type of assignment:

```
class Example extends ExampleBase
    method Example();
    ...
end-class;

Global string &CurrentBaseString;

method Example
    %Super = create ExampleBase();
    &BaseString = &CurrentBaseString;
    &SlashString = &BaseString;
    &ImportantDate = Date(19970322);
end-method
```

If your subclass' constructor only exists to create the superclass object and assign that to your %Super, you can dispense with providing a constructor completely as the following example illustrates.

```
class A
    ...
end-class;

Class B extends A
    ...
end-class;
```

```

Class C extends B
...
end-class;

...
Local C &c = create C();

...

```

Classes A, B and C have no constructors and the one call to `create C` creates objects of class C, B and A and run their constructors. PeopleSoft recommends that unless your constructors take parameters and need to do more than be assigned to their `%Super`, that you do not provide constructors since that simplifies design time as well as may improve runtime performance significantly.

The above example is semantically equivalent to the following, except that it may run much faster, since it does not have to run PeopleCode at each step of the construction process.

```

class A
...
end-class;

Class B extends A
    Method B();
...
end-class;

method B
    %Super = create A();
end-method;

Class C extends B
    Method C();
...
end-class;

method C
    %Super = create B();
end-method;

```

---

**Note:** Application classes don't have destructors, that is, a method called just before an object is destroyed. The PeopleCode runtime environment generally cleans up any held resources, so they're not as necessary as they are in other languages.

[“%Super” \(PeopleCode Language Reference\)](#)

## External Function Declarations

External function declarations are allowed in application classes, in the global and component variable declarations, after the class declaration (after the `end-class` statement), and before the method definitions. For example:

```

import SP:Record;

class Person extends SP:Record
    method Person(&pid As string);

    method getPerson() Returns Record;

```

```

        method getUser_name() Returns string;

private
    instance Record &recPerson;

end-class;

Declare Function getUser_name PeopleCode FUNCLIB_PP.STRING_FUNCTIONS FieldFormula;

method Person
    /+ &pid as String +/

    %Super = create SP:Record(Record.SPB_PERSON_TBL);
    &recPerson = %Super.getRecord();
    &recPerson.PERSON_ID.Value = &pid;

end-method;

method getPerson
    /+ Returns Record +/

    Return &recPerson;

end-method;

method getUser_name
    /+ Returns String +/
    Local string &formattedName;

    &formattedName = getUser_name(&recPerson.PERSON_ID);
    Return &formattedName;
end-method;

```

When application class properties and instance variables are used as the argument to functions or methods, they are always passed by value, never by reference. This means that the called function or method cannot change the value of the property or instance variable. If you want a function call to change a property or instance variable, use a local variable in the call and then assign the property or instance variable after the call.

Suppose you have the following class and you want to call Meth2 in the body of Meth1, passing it MyProp:

```

class MyClass
    property number MyProp;
    method Meth1();
    method Meth2(&i as number out);
end-class;

```

The following PeopleCode *fails* with a compile-time error:

```

method Meth1
    Meth2(%This.MyProp); /* error - field or temp name required. */
    Meth2(&MyProp); /* error - field or temp name required. */
end-method;

```

The following PeopleCode is valid:

```

method Meth1
    /* Assignment needed if &i is input as well as output in Meth2. */
    local number &Var = %This.MyProp;
    Meth2(&Var);
    %This.MyProp = &Var;
end-method;

```

---

**Note:** You call a Java program from an Application Class the same way you do using any other PeopleCode program, that is, by using one of the existing Java class built-in functions.

---

See [From Java to PeopleCode](#).

---

## Naming Standards

This section describes the naming standards these components of application classes: packages, classes, methods, and properties.

### Naming Packages

The naming standard for application packages is in the following format.

`CC_XXX[_YYY]`

Where CC is the company name (for example, PS is PeopleSoft), XXX is the product line, and YYY is the product code.

Examples are PS\_CRM and PS\_CRM\_RB.

### Naming Classes

Use a constructor to be the same name as the short name for the class. PeopleSoft recommends that you do not name classes to be GetXxx.

### Naming Methods

Make method names simple verb or verb object words, spelled out, first letter of each word capitalized. Examples: GetField, Save, SetDefault, WriteRecord

### Naming Properties

Make property names nouns, likewise spelled out, first letter of each word capitalized. Examples: Dimension, HTTPMethod, PathInfo, SubscriptionProcessId.

For Boolean read-only properties, sometimes IsXxx is appropriate. Examples: IsOpen, IsNewFieldID, IsChanged, IsDeleted

State Boolean properties positively, that is, IsChanged, as opposed to negatively, IsUnChanged. This avoids double negatives when testing (If Not &MyField.IsUnChanged Then. . .)

---

## Import Declarations

Before you can use a class name in a PeopleCode program (either a class definition program or an ordinary PeopleCode program), you must first import it using an import statement at the beginning of your program.

An import statement names either all the classes in a package or one particular application class.

If you're importing all the classes in a package, the syntax for the import statement ends with the following:

```
:*
```

This makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are *not* made available.

If you're importing one particular application class, the syntax of the import statement ends with the short name of the class. Only that class is made available.

For example, the following imports all the classes of the package named Fruit:

```
Import Fruit:.*;
```

The following imports only the application classes Banana and Kiwi. If the package named Fruit contains other classes, those are not made available to the PeopleCode program:

```
Import Fruit:Banana;
```

```
Import Fruit:Kiwi;
```

If you had a subpackage in Fruit named Drinks, you could access all the classes in that subpackage like this:

```
Import Fruit:Drinks:.*;
```

A PeopleCode program (either a separate program or one contained within a class definition) can use only application class names that have been imported. However, a class definition can use its own name without having to import it.

It's possible to import two packages which contain application classes with the same short name. For example, suppose my package Fruit contained classes Apple and Banana. Suppose a second package, Drinks, contained Apple and Cherry.

```
Import Fruit:.*;
```

```
Import Drinks:.*;
```

You could refer to the Banana and Cherry classes using just the short name of the class. However, you couldn't refer to the Apple class by the short name. You must always use the full name reference (that is, the name of the package and the name of the class) when referring to Apple.

```
Global Banana &MyBanana;
```

```
Local Cherry &CherryTree;
```

```
Component Fruit:Apple &GreenApple;
```

The following line produces an error, because the program doesn't know which Apple class you're referring to:

```
Component Apple &GreenApple;
```

---

**Note:** Single class imports (such as, Import Fruit:Banana) are checked for existence when you save your PeopleCode.

---

## Self-Reference

A method can refer to the current object using the %This system variable.

Due to subtyping, %This is an object of either the method's class or a subclass of the method's class.

In PeopleCode, the methods and properties of the class *cannot* be used without an object qualification.

In the following code example, the line in bold indicates an error. You can't call the class this way: you must use %This.

```
class FactorialClass
    method factorial(&I as number) returns number;
end-class;

method factorial
    if &I <= 1 then
        return 1;
    end-if;

    return &I * factorial(&I - 1); /* error - factorial undefined */

    return &I * %This.factorial(&I - 1); /* okay */
end-method;
```

One of the implications of this is that when you're writing a method, there isn't any way to guarantee you'll access your own class' version of a public method (rather than a subclass') as it might be overridden by a subclass. The only way to make sure that you can access your own method is to make it private.

If you have some action that you also want to make public, and you want guaranteed access to it, you can make the action a private method, then define a public method for it that calls the private one.

In the following example, factorial is the public method that can be used by other classes. myFactorial is the private action.

```
class FactorialClass
    method factorial(&I as number) returns number;
private
    method myFactorial(&I as number) returns number;
end-class;

method factorial
    return myFactorial(&I);
end-method;

method myFactorial
    if &I <= 1 then
        return 1;
    end-if;

    return &I * %This.myFactorial(&I - 1);
end-method;
```

If you declare an instance variable as private you can still access it as a private property in another instance of the same class. For example, given the following declaration:

```
class Example
    private
        instance number &Num;
end-class;
```

A method of Example could reference another Example instance's &Num instance variable as follows:

```
&X = &SomeOtherExample.Num;
```

## Related Links

“%This” (PeopleCode Language Reference)

## Using %This with Constructors

%This when used in application class constructor code refers to the object currently being constructed. It does not refer to the dynamic this pointer of some object under construction. Given these two application classes, the PeopleCode %This.Test() in the Base constructor *always* refers to the Test method in the Base class.

```
class Base
    method Base();
    method Test();
    method CallTest();
    property string sTestResult;
end-class;

method Base
    %This.Test();
end-method;

method Test
    &sTestResult = "BASE_METHOD_CALLED";
end-method;

method CallTest
    %This.Test();
end-method;

import PACKAGE:Base;

class Extend extends PACKAGE:Base;
    method Extend();

    method Test();
end-class;

method Extend
    %Super = create PACKAGE:Base();
end-method;

method Test
    /* Extends/implements PACKAGE:Base.Test */
    %This.sTestResult = "EXTENSION_METHOD_CALLED";
end-method;
```

Even though the Extend class method provides its own Test method which overrides Base's Test method, in PeopleCode create Extend() which ultimately runs Base's constructor, the %This.Test() call

in Base's constructor still references Base's Test method, not Extend's Test method, because %This always refers to the object under construction

---

## Properties and Constants

This section discusses the various ways to use properties and constants with application classes.

### Differentiating Between Properties and Methods

A method is a procedure or routine, associated with one or more classes, that acts on an object.

A property is an attribute of an object.

PeopleSoft recommends that you use read/write or read-only properties instead of creating methods named GetXxx and SetXxx. For example, instead of creating a method GetName, that takes no parameter, just to return the name of an object, create a read-only property Name.

If your properties simply set or return the value of an instance variable, it is far more efficient to declare the property that way than have a get and set method. The overhead of having a get and set method means that each time the property is reference some PeopleCode has to be run.

Application classes can have read-only properties, but no indexed properties.

### Considerations Creating Public Properties

There are two implementations of (public) properties:

- as instance variables.
- as get-set methods.

From outside the class, you cannot tell the difference between them (for example, both are dynamically bound). However, if you just want to expose an instance variable to users of the class, you can declare a property of that name and type, which declares the instance variable too:

```
class xxx
    property string StringProp;
end-class
```

If you want the property to be read-only outside the class, use the following code:

```
class xxx
    property string StringProp readonly;
end-class
```

Both of these code examples declare an instance variable called &StringProp and provide its value for getting and change its value for setting (if not readonly). You can think of this as shorthand for the usual implementation of get-set methods.

If you want to implement the same with code (perhaps deriving the property from other instance variables or other data), use the following sort of PeopleCode program:

```
class xxx
    property string StringProp get set;
```

```

private
    instance string &inst_str;

end-class;

get StringProp
    /* Returns String */
    Return &inst_str; /* Get the value from somewhere. */
end-get;

set StringProp
    /* &NewValue as String */
    /* Do something with &NewValue. */
    &inst_str = &NewValue;
end-set;

```

To specify a read-only property, omit the set portions of the code example.

## Overriding Properties

A property of a superclass can be overridden by a subclass by providing a different implementation.

The properties of a class are implemented by the keywords `Get` and `Set`, or by access to an otherwise private instance variable.

To access the property, you do not have to specify `Get` or `Set`: the context tells the processor which task you're doing. To create read-only properties, specify only a `Get` method, with no `Set` method, or for instance variable properties, specify `Readonly`.

For an instance variable property, there are two different ways for method code in the class itself to refer to the property:

- `%This.PropertyName`
- `&PropertyName`

The first way is dynamically bound, as it uses whatever (possibly overridden by a subclass) implementation of *PropertyName* that the current object provides.

The second way always accesses the private instance variable of the class that the method is declared in.

The following example returns strings, by converting the property. It also demonstrates overriding.

```

class A
    property number Anum;
    property string Astring get;
    property string Astring2 get;
end-class;

```

```

/* The following is a dynamic reference to the Anum property of the current object,⇒
   which might be a subclass of A, so this might not access the A class's implementat⇒
   ion of Anum as an instance variable. */

```

```

Get Astring
    return String(%This.Anum);
end-get;

```

```

/* The following is a static reference to our &Anum instance variable. Since it doe⇒
   s not use %This, it will not be overridden even if the current object is a subclass⇒
   of A. */

```

```

Get Astring2
    return String(&Anum);
end-get;

/* The following overrides the Anum property of our superclass,
in this case by providing another instance variable implementation.
This gives us our own &Anum instance variable. */
class B extends A
    property number Anum;
end-class;
. . .
/* Set the Anum property in B. Because of the above definitions, this sets
the &Anum instance variable in the B object, but not the &Anum instance
variable in its superobject. In the absence of other setting, the latter will
be defaulted to 0. */

local B &B = Create B();
&B.Anum = 2;

&MyValue = &B.Astring; /* &MyValue is "2" */
&MyValue = &B.Astring2; /* &MyValue is now "0" */

```

## Using Get and Set with Properties

PeopleSoft recommends against defining properties that are public and mutable in application classes (similar to public instance variables) because this allows external code to read and change the internal state of the object without any controls. Instead, modify the property declarations with the Get and Set keywords.

There is a slight performance advantage, and you write less code, if you use the Get and Set keywords over using get and set methods.

If you define a property with the Get and Set keywords, you also must define a get or set block in the same part of the code that contains the method bodies.

## Using Read-Only Properties

PeopleCode read-only properties are functionally similar to static variables, as long as the class that defines the properties initializes them and does not change them. The difference is that you need an instance of the class to access them.

For example, consider a Category object that has a CategoryType member that can have one of the following values:

- 'R' for Regular
- 'B' for Browse
- 'N' for News

You can define three read-only properties corresponding to each of these values, REGULAR, BROWSE, and NEWS, then initialize them to the appropriate values in the constructor of the class.

When you write code to evaluate the CategoryType of the Category object, perform a test like this:

```
If (&category.getCategoryType() = &constants.NEWS) then...
```

PeopleSoft recommends referring to the read-only properties, rather than their literal values, for the following reasons:

- If you spell a literal value incorrectly, the PeopleCode editor does not catch it; if you spell a read-only property wrong, it does.
- If you ever need to change the value of a read-only property, you only have to do it in one place.
- It makes the code more maintainable and reusable (because NEWS is more intelligible than 'N').

## Using Methods and Properties for Collections

Application classes can contain collections. Collections of objects generally have at least the following methods and properties.

- First()
- Item(*Index*)
- Next()
- Count (as a property)

All numeric indexes in PeopleCode are one-origin, that is, start all indexes at 1, not 0.

## Declaring Constants

PeopleSoft recommends that if constants are inextricably linked to a class, you should define them within that class. If the constants are more general, potentially used by multiple classes, consolidate the constants into a constants class at application-level or package-level.

Message catalog set and message numbers are good candidates to centralize into a single constants class. It can improve the readability of code and make it easier to maintain these values.

For example, you can define a constant MSG\_SET\_NBR, and then define constant values for each message that explain a little about what the message represents (like REQUIRED\_VALUE\_MISSING, UNIMPLEMENTED\_METHOD, or INSUFFICIENT\_PRIVILEGES).

---

## Using Variables in Application Classes

This section discusses how to use variables in application classes.

### Placement of Variable Declarations

Variables are declared after the class definition (the end-class statement) before anything else. After you have declared a variable, you can use it anywhere in your program.

```
class Example
    method Example_M1(&par As string);
end-class;
```

```
Global boolean &b;
```

```
method Example_M1
    /+ &par as String +/
    &b = False;
```

```
end-method;
```

## Declaring Private Instance Variables

A private instance variable is private to the class, not just to the object instance. For example, consider a linked-list class where one instance needs to update the pointer in another instance. Another example is the following class declaration:

```
class Example private instance number &Num; end-class;
```

A method of Example could reference another instance of the Example &Num instance variable as:

```
&X = &SomeOtherExample.Num;
```

Avoid making every instance-scoped variable a public property. You should consider each variable individually and decide if it belongs in the public interface or not. If it does, decide if the variable warrants get or set modifiers and therefore should be a public property. If the variable only serves internal purposes to the class, it should be declared as a private instance variable.

## Global Variables

PeopleSoft recommends avoiding global variables in application classes unless there is a situation where no other code works. Generally, an application class should not know about anything scoped outside of its instance. There are exceptions, since not all application classes should be standalone. For example, an application class that interacts with the Component Buffer must know about the Component Buffer objects.

## Overriding Variables and Properties

PeopleSoft recommends against overriding of variables and of properties.

Since instance variables are private in scope, you cannot access them in subclasses, but you can redeclare them in subclasses. The same is true of public properties; you can even explicitly access the overridden or overriding property. However, overriding is not recommended.

---

## Superclass Reference

A method can refer to a member of its superclass by using the %Super system variable. This construction is needed only to access superclass members that are hidden by overriding members in the current class.

In the following example, the classes that extend the general BuildingAsset class each have their own method DisasterPrep, that does the specific processing, then calls the superclass (generic) version of DisasterPrep.

```
/* generic building class */
class BuildingAsset
  method Acquire();
  method DisasterPrep();
end-class;

method Acquire
  %This.DisasterPrep();
end-method;method DisasterPrep
```

```

    PrepareForFire() ;
end-method;

/* building in Vancouver */
class VancouverBuilding extends BuildingAsset method DisasterPrep() ;
end-class;

method DisasterPrep
    PrepareForEarthquake(); %Super.DisasterPrep(); /* call superclass method */
end-method;

/* building in Edmonton */
class EdmontonBuilding extends BuildingAsset method DisasterPrep() ;
end-class;

method DisasterPrep
    PrepareForFreezing(); %Super.DisasterPrep(); /* call superclass method */
end-method;

local BuildingAsset &Building = Create VancouverBuilding();

&Building.Acquire(); /* calls PrepareForEarthquake then PrepareForFire */

&Building = Create EdmontonBuilding();

&Building.Acquire(); /* calls PrepareForFreezing then PrepareForFire */

```

## Downcasting

Downcasting is the process of determining if an object is of a particular subclass type. If the object has that subtype (either the object is of that subtype, or is a subtype of it), a reference to the subobject is returned, otherwise Null is returned. In either case, the type of the resulting value is compatible with the named subclass type.

This downcast inquiry into the actual type of an object can be used when the object has been passed to some general facility, then passed back to more specific code. For example, the general facility might be a dispatch mechanism, or a new storage structure such as a binary balanced tree. These general facilities won't know about specific types, but it might be necessary for the specific program using the general facility to recover the actual type of an object that is returned to it by the general facility.

A downcast should *not* be used when you could add members to a common base class to provide the same functionality. In other words, if you find yourself using the downcast to test whether the object is one or another of several related types, you should add members to the common base class to provide the operations or properties that you are trying to access, then provide separate implementations of those actions or properties in each specific class.

If the downcast operator is to be used in the context of further object expressions (such as references to other members using dot notation) then the downcast must be enclosed in parentheses to emphasize that the downcast happens before the member reference.

```

class Fruit
    property number FruitCount;
end-class;

class Banana extends Fruit
    property number BananaCount;

```

```
end-class;
```

In the following code example, first the variables are assigned. All the variable assignments are legal, for Banana is a subtype of Fruit.

```
local Banana &MyBanana = Create Banana();
local Fruit &MyFruit = &MyBanana; /* okay, Banana is a subtype of Fruit */
local number &Num = &MyBanana.BananaCount;
```

The next two lines of code don't produce an error, as &MyFruit is currently a Banana at runtime.

```
&MyBanana = &MyFruit As Banana;

&Num = (&MyFruit As Banana).BananaCount; /* same as &MyBanana.BananaCount */
```

In the next lines of code, we're reassigning &MyFruit to be of type Fruit, that is, of the superclass Fruit. When you try to reassign &MyFruit as Banana, &MyBanana is assigned as Null, because &MyFruit is no longer of type Banana.

```
&MyFruit = Create Fruit();

&MyBanana = &MyFruit As Banana; /* assigns Null - &MyFruit isn't a Banana */
```

---

## Exception Handling

Use the Exception class to do exception handling in your PeopleCode. This class provides a try, catch, and throw mechanism so you don't need to check after each operation for errors. Instead, by the structure of the try-catch blocks, you can declare when you are interested in handling exceptions, and how you want to handle them.

Exceptions are instances or subclasses of the PeopleCode Exception class. Oracle recommends that when applicable, application class methods should throw exceptions instead of communicating back to the calling code with return values. You can create exceptions by:

- Creating an Exception base class that encapsulates the built-in function call and handles its function parameters consistently. This is the preferred way.
- Calling the built-in function CreateException.

Since a method can throw exceptions for several different reasons, Oracle recommends that you:

- Create Exception subclasses often.
- Throw strongly typed exceptions.

This allows the calling code to make decisions based on the exception type.

For example, a method that retrieves customer data from a database might throw an exception named SQLException if a database error occurs, or an exception named PrivilegeException if the current user doesn't have the appropriate permissions to perform the operation. There could be different errors causing either of these exception types to be thrown in this method; if necessary, you can write the calling code to examine the specific message numbers and react accordingly.

Oracle recommends that you always catch an exception; if it is not caught, it causes a runtime error. Use a try-catch block.

Not catching an exception causes a runtime error and can cause PeopleTools to display a dialog box with the message catalog entry and information about the technical context of the exception. The reasons for avoiding this by using try-catch blocks are:

- Application code often continues some form of processing even in the event of an exception; you should not assume that the script stops all processing if an exception occurs.
- The error message that PeopleTools displays might not be appropriate for end-users because of its technical information.

# Commenting and Documenting Application Classes

This section contains guidelines for writing method header comments, class header comments, and tags inside the comments.

## Understanding Comments and Documentation

Documentation is important in all code, but even more so in application class code, which aims at, and incurs certain overhead in the name of, higher levels of reuse.

There are two types of inline comments:

- Internal comments, which start with `/*` and end with `*/`.
- Comments which can potentially be used to generate API documentation, which start with `/*` and end with `*/`. You can write method header and class header comments for application classes, and you can use the comment tags, with this type of comment.

---

**Warning!** In application classes you will see the use of `/+ +/` style comments. *Do not use these in your PeopleCode.* These annotations are generated by the compiler. If you use them, they will be removed the next time you validate, compile, or save your PeopleCode. They are used to provide signature information on application class methods and properties, and are regenerated each time the compiler compiles your application class PeopleCode. Instead, use the standard commenting mechanisms listed above.

---

PeopleSoft recommends keeping a running line of asterisks along one side of an extensive comment to help the readability of the code by making the entire comment stand out from the surrounding code.

## Method Header Comments

The following is an example of documentation conventions for method header comments, which are also suitable for PeopleCode. It contains comment tags, which are explained below the example.

```
/**
 * Description of what method does
```

```
*
* @param a optional description of param a
* @param b optional descriptions of param b
* @exception PrivilegeException thrown if etc, etc
* @exception SQLException thrown if etc., etc.
* @return String - description of potential values
*/
Method myMethod
...
End-method;
```

Method Comment Tags

The following are the suggested tags for commenting methods.

| Tag                    | Description                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| @param <i>N</i>        | Specify a description for each method parameter. The name of the parameter is specified after the keyword @param.                                                                                                                             |
| @exception <i>name</i> | Specify a description of each exception class. The name of the exception is specified after the keyword @exception. For example, the descriptions can explain what causes certain exceptions to be thrown.                                    |
| @return <i>Type</i>    | Specify a description of the return value. The type of data that is returned is specified after the keyword @return. For example, explain the potential values a method may return, whether it returns null in some circumstances, and so on. |

Not all methods require documentation. For example, some simple set or get methods have method signatures that are descriptive enough. In other cases, it may suffice to include a brief sentence in the header explaining what the method does.

As with methods, PeopleCode get or set blocks should also carry method header comments.

Class Header Comments

Header comments for the class should provide descriptive information about the class, and may optionally include additional tags, indicating version and author:

```
/**
* class description
*
* @version 1.0
* @author amachado
*/
```

Class Header Comment Tags

The following are the suggested tags for commenting class headers.

| <b>Tag</b>             | <b>Description</b>                    |
|------------------------|---------------------------------------|
| @version <i>number</i> | Specify a version number for a class. |
| @author <i>name</i>    | Specify an author for a class.        |

---

## Designing Base Classes

This section discusses some ways you can design application classes.

### Base Classes

Base classes contain a representation of data elements, such as documents, categories, users, and miscellaneous security-related entities.

To design the document data element to be integration-friendly, PeopleSoft recommends you start with a relatively basic base class. Then use more specialized types of documents to create a subclass from that base class, adding the necessary specialized attributes.

Even if you think of ways to use data to drive the business rules, PeopleSoft recommends that you do not place them into your data objects. Replicating business rules for every instance of a data element can be detrimental to performance.

### Abstract Base Classes

Abstract base classes contain reusable logic for PeopleCode classes; you do not instantiate them directly. Instead, you instantiate classes that are subclasses of the abstract base class. Abstract base classes use placeholder methods for specialized logic, and its subclasses override those methods to provide the specialized logic.

An example of a candidate for an abstract base class is a class that is used for administering a data entity, such as an invoice. Such a class has a Save method. A Save method can use normal methods to call generic validation routines, talk to the database, and handle errors; it can use the placeholder methods for specialized logic, such as mapping a given data class to a particular database table.

PeopleSoft recommends that you program an active validation check into your placeholder method that causes a runtime error, such as throwing an `UnimplementedMethodException`, if an abstract base class placeholder method hasn't been overridden.

### Generic Base Classes

Generic base classes contain reusable logic for PeopleCode classes; you write them to be self-contained, fully implemented, and capable of being instantiated directly. This differs from abstract base classes, which are not instantiated directly and need subclasses that override methods to provide specialized logic.

Some examples of classes that are good candidates for creating generic base classes are:

- Service classes, which typically extend a class that provides infrastructure services, such as configurable application logging.
- Data classes, which typically extend a class that enables you to plug in adapters to support sorting their instances with custom sort algorithms.

Even when a class does not seem generic because it only has a couple of subclasses, you can still define it in your design as a generic base class rather than cloning common code across different classes. The main reason is maintainability: it's easier to maintain a single class than trying to keep track of the same code scattered across your database.

## Utility Classes

Some reusable code is the kind you typically don't want to inherit, but you just want to use here and there. Utility classes can serve this purpose.

String parsing, data type conversion, and formatting routines are all good candidates for utility classes. PeopleSoft recommends that anytime you code something that's more than just a line or two, and that seems to be reusable, write it as a utility class.

---

## Declaration of Application Classes

This section provides instructions for declaring application classes.

### Declaring Application Classes

Application object references are declared in your PeopleCode programs by either the short name of the class (if the short name is unambiguous amongst all the imported classes), or by the full name of the class. Like all uses of class names, to use the name in a variable declaration, you must have imported the class. Application objects can be of Local, Global, or Component scope.

Every application class is a definition of a new data type in PeopleCode, like the record, rowset, or field data types. The application class includes both the definition of its external interface, its data (properties and instance variables), and its actions (methods), just like the PeopleSoft delivered classes.

### Importing Class Names

When you import a class name, fully-qualifying it is optional. The syntax is:

```
<package>:<subpackage>:<...>:<classname or wildcard>
```

PeopleSoft recommends that you individually import each class when you import multiple classes from the same package, instead of using wildcards.

### Referencing Superclasses

PeopleSoft recommends that you do not set %Super to a new instance of the current class you are defining because this would start an infinite loop.

```
/* Do not do this! */
```

```
%Super = %This;
```

## Declaring Private Methods

PeopleSoft recommends that you use private methods for succinct operations, even if they aren't reused, to improve the readability and maintainability of the code. You can also do this by using many inline comments.

---

## Scope of an Application Class

Application classes can be instantiated only from PeopleCode. These classes can be used anywhere you have PeopleCode, that is, in message notification PeopleCode, Component Interface PeopleCode, record field PeopleCode, and so on.

---

## Application Classes Built-in Functions and Language Constructs

In this section, we discuss the Application classes built-in functions and language constructs, in alphabetical order.

### class

#### Syntax

```
class ClassName [{extends | implements} SuperClassName]
    [Method_declarations]
    [Property_declarations]
    [protected
        [Method_declarations]
        [Instance_declarations]
        [Constant_declaration]]
    [private
        [Method_declarations]
        [Instance_declarations]
        [Constant_declaration]]
end-class
```

Where Method\_declarations are of the form:

```
method methodname([MethodParam1 [, MethodParam2...] [Returns Datatype]] [abstract])⇒
```

Where Property\_declarations are of the form:

```
property DataType PropertyName [{[get] | [set]} | [abstract] | [readonly]}]
```

Where Instance\_declarations are of the form:

```
instance DataType &Variable1 [, &Variable2...]
```

Where Constant\_declarations are of the form:

```
constant &Constant = {Number | String | True | False | Null }
```

## Description

Use the Class language construct to build application classes in an application package. All classes within a package must be uniquely named, however, classes contained in different packages do not have to be named uniquely.

External function declarations are allowed in application classes, in the global and component variable declarations, after the class declaration (after the end-class statement), and before the method definitions.

## Parameters

| <b>Parameter</b>                                         | <b>Description</b>                                                                                                                                                                                                                                             |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ClassName</i>                                         | Specify the name of the class that you are creating. All classes within a package must be uniquely named, however, classes contained in different packages do not have to be named uniquely.                                                                   |
| <b>extends</b>   <b>implements</b> <i>SuperClassName</i> | For a regular class, specify the name of the class that this class extends. If the class is an interface type of class, specify the name of the interface that this class implements.<br><hr/> <b>Important!</b> You must import the class to extend it. <hr/> |
| <i>Method_declarations</i>                               | Specify the methods (and their signature) as used in this class.                                                                                                                                                                                               |
| <i>Property_declarations</i>                             | Specify the properties, and their usage, in this class.                                                                                                                                                                                                        |
| <b>protected</b>                                         | Use this keyword to declare any methods, constants, or instance variables as protected to the class, that is, are only visible to the declaring class and subclasses.                                                                                          |
| <b>private</b>                                           | Use this keyword to declare any methods, constants, or instance variables as private to the class, that is, they can't be accessed by any other classes.                                                                                                       |
| <i>Instance_declarations</i>                             | Specify any variables that should be in any instance (object) of the class.                                                                                                                                                                                    |
| <i>Constant_declarations</i>                             | Specify any constants that should be used with this class.                                                                                                                                                                                                     |

## Returns

None.

## Example

```
class Example extends ExampleBase
    method NumToStr(&Num As number) Returns string;
```

```
method AppendSlash();
property number SlashCount get;
property number ImportantDayOfWeek get set;
property string SlashString readonly;
property date ImportantDate;
private
method NextDayOfWeek(&DoW As number) Returns date;
constant &Sunday = 1;
instance number &BaseString;
end-class;
```

## Related Links

[method](#)

[property](#)

[get](#)

[set](#)

## get

### Syntax

```
get PropertyName
    StatementList
end-get
```

### Description

Use the get language construct when defining properties in an application class that are implemented by methods rather than an instance variable. All properties within an application class must be uniquely named.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>PropertyName</i>     | Specify the name of the property that you're implementing.                                                                             |
| <i>StatementList</i>    | Returns the value of the property. In other words, this is a method which has no parameters and must return the value of the property. |

### Returns

Depends on the assignment within *StatementList*

### Example

```
get FruitCount
    Return &MyFruit.Number();
end-get;
```

## Related Links

[set](#)

“Return” (PeopleCode Language Reference)

## import

### Syntax

```
import PKG_NAME[:SubpackageName[:SubpackageName]]{:ClassName | *}
```

### Description

Before you can use a class name, you must first import it using an import declaration statement at the beginning of your program.

An import declaration statement names either all the classes in a package or a single application class.

### Parameters

| <i><b>Parameter</b></i>          | <i><b>Description</b></i>                                                                                                            |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>import</b> PKG_NAME           | Specify the name of the package that you want to import.                                                                             |
| :SubpackageName[:SubpackageName] | Specify the subpackage path to the class.                                                                                            |
| ClassName                        | Import only this class of the specified package. You won't have access to any other classes in the specified package, only this one. |
| *                                | Import all the classes of the specified package.                                                                                     |

### Returns

None.

### Example

The following gives you access to all the classes in the FRUIT package:

```
import FRUIT:*
```

The following gives you access to the Banana class only in the FRUIT package:

```
import FRUIT:Banana;
```

The following gives you access to the Apple class only from the Fruit subpackage of the DRINKS package:

```
import DRINKS:Fruit:Apple;
```

## Related Links

[class](#)

## interface

### Syntax

```
interface ClassName [{extends | implements} SuperClassName]
    [Method_declarations]
    [Property_declarations]
    [protected    [Method_declarations]
    [Instance_declarations]
    [Constant_declaration]]
end-interface
```

Where *Method\_declarations* are of the form:

```
method methodName ([MethodParam1 [, MethodParam2...]) [Returns Datatype] [abstract] =>
```

Where *Property\_declarations* are of the form:

```
property Datatype PropertyName {{[get] | [set]}} | [abstract] | [readonly]
```

Where *Instance\_declarations* are of the form:

```
instance Datatype &Variable1 [, &Variable2...]
```

Where *Constant\_declarations* are of the form:

```
constant &Constant = {Number | String | True | False | Null }
```

### Description

Use the Interface language construct to create classes of type interface in an application package. An interface class is a purely abstract class.

### Parameters

An interface does not have private methods or properties, but all the other parameters are identical to the class language construct.

### Returns

None.

[class](#)

## method

### Syntax

```
method MethodName  
    StatementList  
end-method
```

### Description

Use the method statement to define the methods of your application class.

### Parameters

| <i><b>Parameter</b></i>         | <i><b>Description</b></i>                             |
|---------------------------------|-------------------------------------------------------|
| <b>method</b> <i>MethodName</i> | Specify the name of the method that you are creating. |
| <i>StatementList</i>            | Specify the program of the method, what it does.      |

### Returns

Depends on the method.

### Example

```
method NumToStr  
    /* Returns String */  
    Return String(&Num);  
end-method;  
  
method AppendSlash  
    &SlashString = &SlashString | "/";  
end-method;
```

“Return” (PeopleCode Language Reference)

## property

While properties are declared, they do not have explicit definitions like methods. However, you can create definitions to set or get the value of a property. See [set](#) and [get](#).

## set

### Related Links

[get](#)

## Syntax

```
set PropertyName  
    StatementList  
end-set
```

## Description

Use the set language construct when implementing properties in an application class. All properties within an application class must be uniquely named. The new value for the property is available in the &NewValue parameter of the set definition.

---

**Note:** You cannot create a set-only property. You can create only get-set properties.

---

## Parameters

| <i>Parameter</i>        | <i>Description</i>                                         |
|-------------------------|------------------------------------------------------------|
| set <i>PropertyName</i> | Specify the name of the property that you're implementing. |
| <i>StatementList</i>    | Change the value of the property to be &NewValue.          |

## Returns

None.

## Example

```
set FruitCount  
    /+ &NewValue as String +/  
    &NewValue = &MyFruit.ActiveRowCount;  
    &FruitCount = &NewValue;  
end-set;
```

# Application Data Set Classes

---

## Understanding the Application Data Set Classes

The Data Migration Workbench is designed to manage the complexity of migrating configuration data across multiple PeopleSoft systems. Data Migration Workbench uses Application Data Sets (ADS) as its underlying infrastructure. There are five main parts to the Data Migration Workbench:

- The ADS definition designer is used to define ADS definitions, which define the data sets that can be migrated. Each ADS definition includes a record hierarchy. An ADS definition has associated validation PeopleCode specified by an application class, which is the main subject of these topics.
- The Project Editor allows you to interactively create projects containing ADS instance data (that is, the data defined by ADS definitions) and edit their content.
- The Project Manager allows ADS projects to be exported to a file, compared from a file, or copied from a file.
- The Project Reviewer is used to view the results of compares, including validation.
- The Project Approver invokes the approval framework to assure that the each project has been properly reviewed and approved before it is copied.

PeopleTools supplies the base class application class, PTADSDEFN:AdsValidationBase, that provides the basic validation described in the following sections.

Prescribed methods described in the following sections of the validation application class are automatically invoked when ADS projects are compared or copied. If you wish to provide additional validation, or to override the base validation, you can implement an application class derived from PTADSDEFN:AdsValidationBase and register that class in the ADS definition designer part of the Data Migration Workbench. The derived class should override one or more of the automatically invoked methods.

### Basic Validation

The DoADSValidations method provides basic validation by validating static prompts, translate values, Y/N values, and required fields. Because basic validation is always triggered for any copy or compare, you do not need to explicitly call DoADSValidations. Therefore, even when you do not define an extended application class for a specific ADS definition, basic validations are performed by this method. If a validation error is detected, DoADSValidations returns false and information about the error is written to the target database.

### Extended Validation

You can extend the AdsValidationBase base class to define specific validation logic for your data sets. To provide data set-specific validation or transformation logic, you can extend three methods from

the base class and define any additional methods and properties as necessary. The following three AdsValidationBase class methods can be extended in your custom application class:

- OnPreCopyCompare
- OnPreUpdate
- OnPostCopy

---

## Importing Application Data Set Classes

The Application Data Set classes are application classes, not built-in classes, like Rowset, Field, Record, and so on. Before you can use these classes in your PeopleCode program, you must import them into your program.

An import statement either names a particular application class or imports all the classes in a package.

Using the asterisks after the package name makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are not made available.

## AdsValidationBase Class

This section provides an overview of the AdsValidationBase class and discusses: AdsValidationBase class methods.

PeopleTools supplies the base class application class, PTADSDEFN:AdsValidationBase, that provides the basic validation described in the following sections. If you wish to provide additional validation, or to override the base validation, you can implement an application class derived from PTADSDEFN:AdsValidationBase and register that class in the ADS definition designer part of the Data Migration Workbench. The derived class should override one or more of the automatically invoked methods.

“Defining Extension” (Lifecycle Management Guide)

---

## AdsValidationBase Class Methods

In this section, the AdsValidationBase class methods are presented in alphabetical order.

### AdsValidationBase

#### Syntax

```
AdsValidationBase (project_name)
```

#### Description

This is the base class constructor supplied by Oracle. If the ADS definition does not specify an application class, this constructor will be automatically invoked when ADS projects are copied or compared. If the ADS definition *does* specify an application class, the constructor of the specified class will be automatically invoked when ADS projects are copied or compared. In the latter case, the derived class constructor must invoke this constructor as a %Super.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                              |
|-------------------------|--------------------------------------------------------|
| <i>project_name</i>     | Specifies the data migration project name as a string. |

#### Returns

None.

#### Example

Use this methodology to instantiate a subclass to perform extended validations:

```
import PTADSDEFN:AdsValidationBase;

class ADSValidations1 implements PTADSDEFN:AdsValidationBase;
    method ADSValidations1(&ProjectName As string);
end-class;

/* constructor */

method ADSValidations1
    /+ &ProjectName as String +/
    %Super = create PTADSDEFN:AdsValidationBase (&ProjectName);
end-method;
```

[Constructors](#)

## DoADSValidations

### Syntax

```
DoADSValidations (&ADS_rowset, ADS_name)
```

### Description

In the base class supplied by Oracle, this method provides basic validation of static prompts, translate values, Y/N values, and required fields.

The base class method will be automatically invoked for each ADS instance when ADS projects are copied or compared unless the method is overridden in the derived application class for the current ADS definition. If the method is overridden, then the overriding method from the derived class will be automatically invoked. During copy, this method is called for all objects in the project before any objects are copied so that a single validation error anywhere in the project will prevent any objects from being copied.

When this method encounters a validation error, it invokes the ReportErrorModified method to store the error in the database so that it can be reviewed later on the Validation page.

### Parameters

| <i>Parameter</i>       | <i>Description</i>                                                                                                       |
|------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;ADS_rowset</i> | Specifies the current ADS rowset instance as a rowset object. The rowset contains the data from the source project file. |
| <i>ADS_name</i>        | Specifies the name of the current ADS definition as a string.                                                            |

### Returns

A Boolean value: True if all basic validations succeeded, False if any errors were encountered.

### Example

```
import PTADSDEFN:AdsValidationBase;

class AdsValidationSample extends PTADSDEFN:AdsValidationBase
  method AdsValidationSample(&ProjectName As string);
  method DoADSValidations(&ADSRowset As Rowset, &ADSName As string,) Returns boole⇒
an;

end-class;

method AdsValidationSample
  /+ &ProjectName as String +/

  %Super = create PTADSDEFN:AdsValidationBase(&ProjectName);

end-method;

method DoADSValidations
```

```

/+ &ADSRowset as Rowset, +/
/+ &ADSName as String +/
/+ Returns Boolean +/

/* delegate to the base class DoADSValidations method */
Return %Super.DoADSValidations(&ADSRowset, &ADSName);

end-method;
```

**OnPreCopyCompare**

**Syntax**

```
OnPreCopyCompare(&ADS_rowset, ADS_name)
```

**Description**

This method will be automatically invoked for each ADS instance when ADS projects are copied or compared unless the method is overridden in the derived application class for the current ADS definition. If the method is overridden, then the overriding method from the derived class will be automatically invoked. During copy, this method is called for all objects in the project before any objects are copied so that a single validation error anywhere in the project will prevent any objects from being copied.

The definition of this method in the base class is an “empty implementation.”

If this method encounters a validation error, it should invoke the ReportErrorModified method to store the error in the database so that it can be reviewed later on the Validation page.

**Parameters**

| Parameter              | Description                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;ADS_rowset</i> | Specifies the current ADS rowset instance as a rowset object. The rowset contains the data from the source project file. |
| <i>ADS_name</i>        | Specifies the name of the current ADS definition as a string.                                                            |

**Returns**

A Boolean value: True if pre-copy compare validations succeeded, False if any errors were encountered.

**Example**

```
import PTADSDEFN:AdsValidationBase;
```

```
class AdsValidationSample extends PTADSDEFN:AdsValidationBase
  method AdsValidationSample(&ProjectName As string);
  method OnPreCopyCompare(&ADSRowset As Rowset, &ADSName As string,) Returns boole⇒
an;

end-class;

method AdsValidationSample
  /+ &ProjectName as String +/

  %Super = create PTADSDEFN:AdsValidationBase(&ProjectName);

end-method;

method OnPreCopyCompare
  /+ &ADSRowset as Rowset, +/
  /+ &ADSName as String +/
  /+ Returns Boolean +/

  /* place code to validate the input rowset here */

end-method;
```

**Related Links**

- [ReportErrorModified](#)
- [Understanding Rowset Class](#)
- “Defining Extension” (Lifecycle Management Guide)

**OnPreUpdate**

**Syntax**

```
OnPreUpdate (&ADS_rowset, ADS_name)
```

**Description**

This method will be automatically invoked after all data in each distinct ADS name in the project has been copied.

The definition of this method in the base class is an “empty implementation.”

If this method encounters a validation error, it should invoke the ReportErrorModified method to store the error in the database so that it can be reviewed later on the Validation page.

If errors are detected by this method, subsequent data will not be copied, but any data already copied to the database will not be rolled back.

**Parameters**

| Parameter   | Description                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------|
| &ADS_rowset | Specifies the current ADS rowset instance as a rowset object. The rowset contains the data from the source project file. |

| <b>Parameter</b> | <b>Description</b>                                            |
|------------------|---------------------------------------------------------------|
| <i>ADS_name</i>  | Specifies the name of the current ADS definition as a string. |

## Returns

A Boolean value: True if pre-copy compare validations succeeded, False if any errors were encountered.

## Example

```
import PTADSDEFN:AdsValidationBase;

class AdsValidationSample extends PTADSDEFN:AdsValidationBase
  method AdsValidationSample(&ProjectName As string);
  method OnPreUpdate(&ADSRowset As Rowset, &ADSName As string,) Returns boolean;
end-class;

method AdsValidationSample
  /+ &ProjectName as String +/

  %Super = create PTADSDEFN:AdsValidationBase(&ProjectName);

end-method;

method OnPreUpdate
  /+ &ADSRowset as Rowset, +/
  /+ &ADSName as String +/
  /+ Returns Boolean +/

  /* place code to validate the input rowset here */

end-method;
```

## Related Links

[ReportErrorModified](#)

[Understanding Rowset Class](#)

“Defining Extension” (Lifecycle Management Guide)

## OnPostCopy

### Syntax

```
OnPostCopy(ADS_name, &content_list)
```

### Description

This method will be automatically invoked for each ADS instance when ADS projects are copied or compared unless the method is overridden in the derived application class for the current ADS definition. If the method is overridden, then the overriding method from the derived class will be automatically invoked. During copy, this method is called for each object in the project immediately prior to copying the object to the database. This occurs only after OnPreCopyCompare has been called for all objects with no validation errors.

The definition of this method in the base class is an “empty implementation.”

This method should be used for validations that require SQL access to all the data that was in the project and in the target database simultaneously. If any errors are encountered and cleanup is required, updates can be performed by this method.

If this method encounters a validation error, it should invoke the `ReportErrorModified` method to store the error in the database so that it can be reviewed later on the Validation page.

In addition, the `OnPreUpdate` method can perform database updates. If severe errors are detected by this method, the current data set will not be copied and subsequent data sets will not be copied; however, any data sets already copied to the database will not be rolled back.

## Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                     |
|-------------------------|---------------------------------------------------------------|
| <i>ADS_name</i>         | Specifies the name of the current ADS definition as a string. |

| <b>Parameter</b>         | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;content_list</i> | <p>Specifies an array of integers that identify the keys of the objects in the current project for the current ADS name.</p> <p>To translate this array into the keys of objects, one can query the project definition tables in the target database as follows:</p> <pre>SELECT PTADSCONTENTID, SEQNBR, PTBINDSYM⇒ BOL, PTADSBINDEXPR FROM PSPROJBINDITEM WHERE PROJECTNAME = :1 AND PTADSNAM⇒ E = :2 AND PTADSCONTENTID IN (:3, :4, ..⇒ .) ORDER BY SEQNBR, PTADSCONTENTID");</pre> <p>The fields and bind variables are defined as follows:</p> <ul style="list-style-type: none"> <li>• :1 – The project name (which is stored in the AdsValidationBase property called strProjectName).</li> <li>• :2 – The ADS definition name.</li> <li>• :3, :4, ... – The integers in the <i>&amp;content_list</i> array.</li> <li>• PTBINDSYMBOL – The ADS key name.</li> <li>• PTADSBINDEXPR – The ADS key value.</li> <li>• SEQNBR – The key sequence number.</li> </ul> <p>The keys thus retrieved are the unique keys of the top-level record in the ADS definition. They are also keys, but generally not unique keys, of the child records in the ADS definition.</p> <p>Once the keys are retrieved, you can use the rowset API to validate the data. The records in the rowset can be determined from the ADS definition with the following query:</p> <pre>SELECT RECNAME, PTPARENTRECNAME FROM PSADSDEFNITEM WHERE PTADSNAME = :1</pre> <p>The fields and bind variables are defined as follows:</p> <ul style="list-style-type: none"> <li>• :1 – The ADS definition name.</li> <li>• RECNAME – The child record name.</li> <li>• PTPARENTRECNAME – The parent record name or blank when RECNAME is the root record.</li> </ul> |

## Returns

A Boolean value: True if post-copy compare validations succeeded, False if any errors were encountered.

Example

```
import PTADSDEFN:AdsValidationBase;

class AdsValidationSample extends PTADSDEFN:AdsValidationBase
  method AdsValidationSample(&ProjectName As string);
  method OnPostCopy(&AdsName As string, &ContentList As array of integer) Returns =>
boolean;

end-class;

method AdsValidationSample
  /+ &ProjectName as String +/
  %Super = create PTADSDEFN:AdsValidationBase(&ProjectName);
end-method;

method OnPostCopy
  /+ &AdsName As string +/
  /+ &ContentList As array of integer +/

  /* place code to validate the data just copied here */

end-method;
```

Related Links

- [ReportErrorModified](#)
- [Understanding Rowset Class](#)
- “Defining Extension” (Lifecycle Management Guide)

ReportErrorModified

Syntax

```
ReportErrorModified(&recReportKey, &recReportError)
```

Description

Invoke the ReportErrorModified method to write validation errors to the database to be reviewed later on the Validation page.

Invocation of the ReportErrorModified method is optional and can be skipped if error reporting in the validation report is not a requirement for your custom validation.

---

**Important!** ReportErrorModified is a protected method and *must not be* extended in your custom application class.

---

Parameters

| Parameter     | Description                                                     |
|---------------|-----------------------------------------------------------------|
| &recReportKey | Specifies a record based on the PSCOMPOBJKEY record definition. |

| <b>Parameter</b>           | <b>Description</b>                                              |
|----------------------------|-----------------------------------------------------------------|
| <i>&amp;recReportError</i> | Specifies a record based on the PSCompoBJERR record definition. |

## Returns

None.

## Example

### Example 1

The following pseudo-code excerpt demonstrates how to invoke the ReportErrorModified method:

```
Local Record &recReportKey, &recReportError, &recParent;

&recReportKey = CreateRecord(Record.PSCompoBJKEY);
&recReportError = CreateRecord(Record.PSCompoBJERR);

*** error processing ***

If * error type 1 *
/* Set error record field values */
  &recReportError.PTADSVALIDIDTYPE.Value = "";
  ***
Else
  If * error type 2 *
  /* Set error record field values */
    &recReportError.PTADSVALIDIDTYPE.Value = "";
    ***
  End-If;

# Application Services Framework Classes

---

## ServiceAPI Class

This section provides an overview of the ServiceAPI class and discusses:

- ServiceAPI class methods
- ServiceAPI class properties

For Application Services, create an application class extending the PTCBAPPLSVCDEFN:ApplicationServiceBase application class and then implement the invokeService() method to define your application logic.

Use the %This.ServiceAPI property to read and write parameters and other Application Services metadata.

## ServiceAPI Methods

In this section, the ServiceAPI class methods are presented in alphabetical order.

### getInputParameter

#### Syntax

**getInputParameter** (*parameter\_name*)

#### Description

Use this method to retrieve input value based on parameter defined on the application service.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                |
|-------------------------|----------------------------------------------------------|
| <i>parameter_name</i>   | Specifies the name of the input parameter (as a string). |

## Returns

Any.

Values can be the following:

- Boolean
- Date
- Document
- Integer
- JSON Object
- Number
- Number Array
- String
- String Array
- Time

## Example

```
&state = %This.ServiceAPI.getInputParameter("conditions");
```

## Related Links

[setInputParameter](#)

## getInputRow

### Syntax

```
getInputRow(index)
```

### Description

Use this method to retrieve the specified input message row based on the index.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                 |
|-------------------------|-----------------------------------------------------------|
| <i>index</i>            | Specifies the index (as a Number) of the row to retrieve. |

## Returns

The specified message row.

## Example

```
&jsNoteBook = %This.ServiceAPI.getInputRow (1).getParameter("notebook");
```

## getLocationURL

### Syntax

```
getLocationURL (URI_index)
```

### Description

Use this method to create the URL string based on the passed in URI index.

### Parameters

| <i>Parameter</i> | <i>Description</i>                                          |
|------------------|-------------------------------------------------------------|
| <i>URI_index</i> | Specifies the URI index defined on the application service. |

## Returns

A String; the URL.

## Example

```
%This.ServiceAPI.setLocationTemplateParameter("musicCode", &intValue, True);  
This.ServiceAPI.setResponseHeader("Location",%This.ServiceAPI.getLocationURL(1));
```

## getOutputContentData

### Syntax

```
getOutputContentData ()
```

### Description

Use the getOutputContentData method to retrieve the actual content data sent back from the third party for consumer REST call.

### Parameters

None.

## Returns

A String value.

## Example

```
&RawData = &ServiceAPI.getOuputContentData();
```

## getOutputParameter

### Syntax

```
getOutputParameter(parameter_name)
```

### Description

Use this method to retrieve output value based on parameter defined on the application service.

### Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                 |
|-------------------------|-----------------------------------------------------------|
| <i>parameter_name</i>   | Specifies the name of the output parameter (as a string). |

### Returns

Any.

Values can be the following:

- Boolean
- Date
- Document
- Integer
- JSON Object
- Number
- Number Array
- String
- String Array
- Time

## Example

```
&state = %This.ServiceAPI.getOutputParameter("conditions");
```

[setOutputParameter](#)

# getOutputRow

## Syntax

```
getOutputRow(index)
```

## Description

Use this method to retrieve the specified output message row based on the index.

## Parameters

| <i>Parameter</i> | <i>Description</i>                                        |
|------------------|-----------------------------------------------------------|
| <i>index</i>     | Specifies the index (as a Number) of the row to retrieve. |

## Returns

The specified message row.

## Example

```
%This.ServiceAPI.getOutputRow(1).setParameter("tools", &Inst);
```

[InsertOutputRow](#)

# getRequestHeaderValue

## Syntax

```
getRequestHeaderValue(header_name)
```

## Description

Use this method to retrieve request header value based on header defined on the application service.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                               |
|-------------------------|---------------------------------------------------------|
| <i>header_name</i>      | Specifies the name of the request header (as a String). |

## Returns

A String; the value of the request header.

## Example

```
&headervalue = %This.ServiceAPI.getRequestHeaderValue("Accept-Language");
```

## getTemplateParameter

### Syntax

```
getTemplateParameter(parameter_name)
```

### Description

Use this method to retrieve template value based on parameter defined on the application service.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                |
|-------------------------|----------------------------------------------------------|
| <i>parameter_name</i>   | Specifies the name of the input parameter (as a string). |

## Returns

Any.

Values can be the following:

- Boolean
- Date
- Decimal
- Integer
- String
- Time

- Array of Any

Example

```
&state = %This.ServiceAPI.getTemplateParameter("instrument");
```

InsertOutputRow

Syntax

```
InsertOutputRow()
```

Description

Use this method to insert an empty message row.

Parameters

None.

Returns

None.

Example

```
%This.ServiceAPI.InsertOutputRow();
%This.ServiceAPI.OutputRows [1].setParameter("numPlayers", 3);
%This.ServiceAPI.OutputRows [1].setParameter("instrument", &value);
```

setInputParameter

Syntax

```
setInputParameter(parameter_name,parameter_type)
```

Description

Use this method to set input value based on parameter defined on the application service.

Parameters

| Parameter             | Description                                              |
|-----------------------|----------------------------------------------------------|
| <i>parameter_name</i> | Specifies the name of the input parameter (as a string). |

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>parameter_type</i>   | <p>Specifies the type of the input parameter (as Any).</p> <p>Values can be the following:</p> <ul style="list-style-type: none"><li>• Boolean</li><li>• Date</li><li>• Document</li><li>• Integer</li><li>• JSON Object</li><li>• Number</li><li>• Number Array</li><li>• String</li><li>• String Array</li><li>• Time</li></ul> |

## Returns

None.

## Example

```
%This.ServiceAPI.setInputParameter("conditions", &state);
```

# setLocationTemplateParameter

## Syntax

```
setLocationTemplateParameter(template_name,template_type,template_collection)
```

## Description

Use this method to set the variable value defined on the base template defined on the application service.

## Parameters

| <i><b>Parameter</b></i>    | <i><b>Description</b></i>                                                                                                                                                                                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>template_name</i>       | Specifies the name of the template parameter (as a String).                                                                                                                                                                                                           |
| <i>template_type</i>       | <p>Specifies the type of the template parameter (as Any).</p> <p>Values can be the following:</p> <ul style="list-style-type: none"><li>• Boolean</li><li>• Date</li><li>• Decimal</li><li>• Integer</li><li>• String</li><li>• Time</li><li>• Array of Any</li></ul> |
| <i>template_collection</i> | Specifies whether the template parameter is a collection or not. True if the template parameter is a collection; false otherwise.                                                                                                                                     |

## Returns

None.

## Example

```
%This.ServiceAPI.setLocationTemplateParameter("instrument", "drums", False);  
%This.ServiceAPI.setLocationTemplateParameter("timein", %Time, False);
```

## setOutputParameter

### Syntax

```
setOutputParameter (parameter_name, parameter_type)
```

### Description

Use this method to set output value based on parameter defined on the application service.

Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>parameter_name</i> | Specifies the name of the output parameter (as a string).                                                                                                                                                                                                                                                              |
| <i>parameter_type</i> | <div>Specifies the type of the output parameter (as Any).</div> <div>Values can be the following:</div> <ul style="list-style-type: none"><li>Boolean</li><li>Date</li><li>Document</li><li>Integer</li><li>JSON Object</li><li>Number</li><li>Number Array</li><li>String</li><li>String Array</li><li>Time</li></ul> |

Returns

None.

Example

```
import PTCBAPPLSVCDEFN:ApplicationServiceBase;

class STUDENT extends PTCBAPPLSVCDEFN:ApplicationServiceBase
    method invokeService();

end-class;

method invokeService
    /+ Extends/implements PTCBAPPLSVCDEFN:ApplicationServiceBase.invokeService +/
    Local JsonArray &jsStudentArray;
    Local array of string &stud;
    &jsStudentArray = CreateJsonArray();
    &jsStudentArray.AddElement(&stud [1]);
    &jsStudentArray.AddElement(&stud [2]);
    %This.ServiceAPI.setOutputParameter("student", &jsStudentArray);
end-method;
```

Related Links

[getOutputParameter](#)

## setOverrideURL

### Syntax

```
setOverrideURL (&URL)
```

### Description

Use the setOverrideURL method to override the URL sent to the third party for consumer REST call.

### Parameters

| <i>Parameter</i> | <i>Description</i>             |
|------------------|--------------------------------|
| <i>&amp;URL</i>  | Specifies the URL as a String. |

### Returns

None.

### Example

```
&ServiceAPI.SetOverrideURL("URL");
```

## setResponseHeader

### Syntax

```
setResponseHeader (header_name, header_value)
```

### Description

Use this method to set the response header value based on header defined on the application service.

### Parameters

| <i>Parameter</i>    | <i>Description</i>                                        |
|---------------------|-----------------------------------------------------------|
| <i>header_name</i>  | Specifies the name of the response header (as a String).  |
| <i>header_value</i> | Specifies the value of the response header (as a String). |

### Returns

None.

## Example

```
%This.ServiceAPI.setResponseHeader("Language", "eng");
```

---

# ServiceAPI Properties

In this section, the ServiceAPI class properties are presented in alphabetical order.

## HttpMethod

### Description

Use the HttpMethod property to return the HTTP method that was invoked for the transaction.

### Example

```
If %This.ServiceAPI.HttpMethod = %AppService_HTTP_GET then  
    /* process a GET request */  
End-If;
```

## HttpResponseCode

### Description

The HttpResponseCode property returns the actual HTTP response code from the third party as an integer value.

Examples of response code are 200, 400.

This property is read-only.

### Example

```
&RespCode = &ServiceAPI.HttpResponseCode;
```

## InputRows

### Description

Use the InputRows property to get values on the specified row.

### Example

```
&Inst = %This.ServiceAPI.InputRows [1].getParameter("instrument");
```

### Related Links

[OutputRows](#)

## IsChatbot

### Description

Use the IsChatbot property to determine whether the request came from ODA.

### Example

```
if %This.ServiceAPI.IsChatbot then  
/* perform Chatbot specific update */  
End-if;
```

## OutputRows

### Description

Use the OutputRows property to set values on the specified row.

### Example

```
%This.ServiceAPI.OutputRows [1].setParameter("numPlayers", 3);
```

### Related Links

[InputRows](#)

## OverrideResultStateDesc

### Description

Use the OverrideResultStateDesc property to override the result state description.

### Example

```
%This.ServiceAPI.ResultState = "Failure";  
%This.ServiceAPI.OverrideResultStateDesc = "bad data";
```

## ResponseException

### Description

The ResponseException property returns a string of the actual exception (if any) that was sent back from the third party. Depending on the provider of the integration, the HTTP response code (if an error response code) includes additional information about the error.

This property is read-only.

## ResponseFailed

### Description

The ResponseFailed property specifies whether the response failed from the third party. This property takes a Boolean value: true, if the response failed; false otherwise.

This property is read-only.

### Example

```
If &ServiceAPI.ResponseFailed Then
    /* throw error */
Else
    /* process response */
End-If;
```

## ResultState

### Description

Use the ResultState property to set the result state to be returned for the request.

### Example

```
%This.ServiceAPI.ResultState = "SUCCESS - PLAY MUSIC";
```

## RootResource

### Description

The root resource of the URI that was used to invoke the application service request.

### Example

```
&RootResource = %This.ServiceAPI.RootResource;
```

## ServiceID

### Description

The service ID that is used to invoke the application service request.

### Example

```
&SrvID = %This.ServiceAPI.ServiceID;
```

## URIIndex

### Description

Use the URIIndex property to return the URI index that is invoked as defined on the application service.

### Example

```
If %This.ServiceAPI.HttpMethod = %AppService_HTTP_GET Then  
  If %This.ServiceAPI.URIIndex = 1 Then  
    /* process request */  
  End-if;  
End-if;
```

## UserException

### Description

Use the UserException property to specify whether a user handles any exception. This property takes a Boolean value: true, if the exception is handled by a user; false otherwise.

This property is read/write.

## Chapter 10

# API Repository

---

## Understanding the PeopleSoft API Repository

This section provides an overview of the PeopleSoft API Repository and discusses how to access the repository.

### The PeopleSoft API Repository

The PeopleSoft API Repository enables PeopleCode and third-party integrators to discover the internally available classes, methods, and properties that are provided by PeopleSoft for integration. The repository is useful to third-party integrators who integrate in a generic fashion: middleware providers, testing tool providers, and automated documentation providers.

The PeopleSoft API Repository is *nota* necessary interface for integrators who integrate at the business-rule level, such as integration with an expense report, and so on. Those integrators should use component interfaces.

The repository describes available PeopleSoft APIs and provides mechanisms to determine the classes that are available in the API, the properties of each class, the methods of a class (along with the required parameters), and information concerning which group a class belongs to (known as a namespace).

The process of determining information about the API is known as *discovery*. Third-party integrators use information found through discovery to drive generic integration tools.

The repository is divided into namespaces. Each namespace contains a collection of related classes. Example namespaces include "PeopleSoft," "ComponentInterface," "Trees," and "BusinessInterlinks".

A *class* defines a related set of methods and properties. Using the repository, you can determine the methods and properties that are available and that can be used on any object returned by a call to the PeopleSoft API. An instance of a class is known as an object.

A *property* is a data item of an object that has both a name and type (string, number, Boolean, and so on are examples of types). Some properties are used for inputting data to a class, some are used for getting data from a class, and some are used for both. Whether a property is used for input or output or both is known as usage.

A *method* is a function that you can call on an object. Methods have a name and a return type (string, number, Boolean, and so on). Methods also have a collection of arguments that must be set prior to invoking the method. Methods arguments have identical attributes to properties.

### Example of Accessing the Repository Using PeopleCode

This example gets information for the class ABS\_HIST from the Namespace component interface and writes it to the file BC.TXT:

This is the complete code sample, followed by the flat file. The next section presents steps that explain each line.

```

Local ApiObject &MYSESSION;
Local ApiObject &MYCI;
Local string &OutTEXT;
Local File &MYFILE;

&MYSESSION = %Session;

&MYFILE = GetFile("CI.txt", "A", "UTF8");

&NAMESPACES = &MYSESSION.Repository.Namespaces;
&NAMESPACE = &NAMESPACES.ItemByName("CompIntfc");

&OutTEXT = "Namespace = " | &NAMESPACE.Name;
&MYFILE.WriteLine(&OutTEXT);

&CLASSES = &NAMESPACE.classes;
&CLASS = &CLASSES.ItemByName("ABS_HIST");

&OutTEXT = "  Class: " | &CLASS.Name;
&MYFILE.WriteLine(&OutTEXT);

&OutTEXT = "      Methods";
&MYFILE.WriteLine(&OutTEXT);

&METHODS = &CLASS.methods;
For &K = 0 To &METHODS.Count - 1
    &METHOD = &METHODS.item(&K);
    &OutTEXT = "          " | &METHOD.name | ": " | &METHOD.Type

    &MYFILE.WriteLine(&OutTEXT);
    &ARGUMENTS = &METHOD.arguments;
    For &M = 0 To &ARGUMENTS.count - 1
        &ARGUMENT = &ARGUMENTS.item(&M);
        &OutTEXT = "              " | &ARGUMENT.name | ": " | &ARGUMENT.type;
        &MYFILE.WriteLine(&OutTEXT);
    End-For;
End-For;

&OutTEXT = "      Properties";
&MYFILE.WriteLine(&OutTEXT);

&PROPERTIES = &CLASS.properties;
For &I = 0 To &PROPERTIES.count - 1
    &PROPERTY = &PROPERTIES.item(&I);
    &OutTEXT = "          " | &PROPERTY.name | ": " | &PROPERTY.type;
    &MYFILE.WriteLine(&OutTEXT);
End-For;
&MYFILE.Close();

```

The previous code produces the following flat file:

```

Namespace = CompIntfc
Class: ABS_HIST
Methods
    Get: Boolean
    Save: Boolean
    Cancel: Boolean
    Find: ABS_HIST
    GetPropertyByName: Variant
    Name: String
    SetPropertyByName: Number
    Name: String
    Value: Variant
    GetPropertyInfoByName: CompIntfcPropertyInfo
    Name: String
Properties
    EMPLID: String

```

```

LAST_NAME_SRCH: String
NAME: String
ABSENCE_HIST: ABS_HIST_ABSENCE_HISTCollection
interactiveMode: Boolean
getHistoryItems: Boolean
componentName: String
compIntfcName: String
stopOnFirstError: Boolean
propertyInfoCollection: CompIntfcPropertyInfoCollection
createKeyInfoCollection: CompIntfcPropertyInfoCollection
getKeyInfoCollection: CompIntfcPropertyInfoCollection
findKeyInfoCollection: CompIntfcPropertyInfoCollection

```

## The PeopleCode Example Explanation

This procedure goes through the PeopleCode example line by line.

To retrieve information from the API Repository:

1. Get a session object.

Before you can access the PeopleSoft API Repository, you have to get a session object. The session controls access to PeopleSoft, provides error tracing, enables you to set the runtime environment, and so on.

```
&MYSESSION = %Session;
```

2. Open the file.

As this text will be written to a flat file, the next step is to open the file. If the file is already created, the new text is appended to the end of it. If the file hasn't been created, the GetFile built-in function creates the file.

```
&MYFILE = GetFile("CI.txt", "A", "UTF8");
```

3. Get the namespace you want.

Use the Namespaces property on the repository object to get a collection of available namespaces. We want to discover information about a component interface, so we specify CompIntfc in the ItemByName method to get that namespace. With ItemByName, you must specify a namespace that already exists. You'll receive a runtime error if you specify one that doesn't exist.

```

&NAMESPACES = &MYSESSION.Repository.Namespaces;
&NAMESPACE = &NAMESPACES.ItemByName("CompIntfc");

```

4. Write the text to the file.

Because all of the information discovered is being written to a file, the next step is to write text to the file. This code writes the string "Namespace", followed by the name of the namespace, to the file.

```

&OutTEXT = "Namespace = " | &NAMESPACE.Name;
&MYFILE.WriteLine(&OutTEXT);

```

5. Get the class that you want and write text to the file.

Use the Classes property on the Namespace object to get a collection of all the available classes. We want to discover information about the component interface named ABS\_HIST, so we specify that using ItemByName. Then we write that information to the file.

```

&CLASSES = &NAMESPACE.classes;
&CLASS = &CLASSES.ItemByName("ABS_HIST");

```

```
&OutTEXT = "   Class: " | &CLASS.Name;
&MYFILE.WriteLine(&OutTEXT);
```

## 6. Get the methods and arguments, and write the information to the file.

Use the `Methods` property on the `Class` object to get a collection of all the available methods. After you get each method and write the information to the file, loop through and find all of the arguments for the method, then write that information to the file.

```
&OutTEXT = "       Methods";
&MYFILE.WriteLine(&OutTEXT);

&METHODS = &CLASS.methods;
For &K = 0 To &METHODS.Count - 1
    &METHOD = &METHODS.item(&K);
    &OutTEXT = "           " | &METHOD.name | ": " | &METHOD.Type;
    &MYFILE.WriteLine(&OutTEXT);
    &ARGUMENTS = &METHOD.arguments;
    For &M = 0 To &ARGUMENTS.count - 1
        &ARGUMENT = &ARGUMENTS.item(&M);
        &OutTEXT = "           " | &ARGUMENT.name | ": " | &ARGUMENT.type;
        &MYFILE.WriteLine(&OutTEXT);
    End-For;
End-For;
```

## 7. Get the properties and write the information to the file.

Use the `Properties` property on the `Class` object to get a collection of all the available properties. Write each property, with its type, to the file. At the end of the program, close the file.

```
&OutTEXT = "       Properties";
&MYFILE.WriteLine(&OutTEXT);

&PROPERTIES = &CLASS.properties;
For &I = 0 To &PROPERTIES.count - 1
    &PROPERTY = &PROPERTIES.item(&I);
    &OutTEXT = "           " | &PROPERTY.name | ": " | &PROPERTY.type;
    &MYFILE.WriteLine(&OutTEXT);
End-For;
&MYFILE.Close();
```

# Example of Accessing the Repository by Using Visual Basic

This example gets information for the class `ABS_HIST` from the `Namespace` component interface.

## Repository Properties

This section discusses the Repository properties in alphabetical order.

### Bindings

#### Description

The Bindings property returns a reference to a Bindings collection.

This property is read-only.

### Namespaces

#### Description

The Namespaces property returns a reference to a Namespaces collection.

This property is read-only.

---

## Bindings Collection Properties

This section discusses the Bindings collection properties in alphabetical order.

### Count

#### Description

This property returns the number of Bindings Properties objects in the Bindings collection object.

---

**Note:** All repository counts begin at zero, not one.

---

This property is read-only.

#### Example

```
&COUNT = &BINDINGS.Count;
```

## Bindings Collection Methods

This section discusses the Bindings collection methods in alphabetical order.

## Item

### Syntax

**Item**(*number*)

### Description

The Item method returns a Bindings object that exists at the number position in the Bindings collection executing the method

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------|
| <i>number</i>           | Specify the position number in the collection of the Bindings object that you want returned. |

### Returns

A reference to a Bindings object or NULL.

### Example

```
For &N = 0 to &BINDINGS.Count - 1
    &BINDING = &BINDINGS.Item(&N);
    /* do processing */
End-For;
```

---

## Bindings Properties

This section discusses the Bindings properties in alphabetical order.

### Name

#### Description

This property returns the name of the object as a string.

This property is read-only.

---

## Bindings Methods

## Generate

### Syntax

`Generate()`

### Description

This method is a reserved internal function and shouldn't be used at this time.

---

## Namespaces Collection Properties

This section discusses the Namespaces collection properties in alphabetical order.

## Count

### Description

This property returns the number of Namespaces Properties objects in the Namespaces collection object.

---

**Note:** All repository counts begin at zero, not one.

---

This property is read-only.

### Example

```
&COUNT = &NameC.Count;
```

## Namespaces Collection Methods

This section discusses the Namespaces collection methods in alphabetical order.

## Item

### Syntax

`Item(number)`

### Description

The Item method returns a Namespaces object that exists at the *number* position in the Namespaces collection executing the method.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------|
| <i>number</i>           | Specify the position number in the collection of the Namespaces object that you want returned. |

## Returns

A reference to a Namespaces object or NULL.

## Example

```
For &N = 0 to &NAMESPACES.Count - 1
    &NAMESPACE = &NAMESPACES.Item(&N);
    /* do processing */
End-For;
```

## ItemByName

### Syntax

**ItemByName** (*name*)

### Description

The ItemByName method returns the item specified by *name*. *Name* is not case-sensitive.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------|
| <i>name</i>             | Specify the name of the Namespaces object that you want returned. This parameter takes a string value. |

## Returns

A reference to a Namespaces object or NULL.

## Example

```
&NAMESPACE = &NAMESPACES.ItemByName("BusinessComponent");
```

---

## Namespaces Properties

This section discusses the Namespaces properties in alphabetical order.

## Classes

### Description

This property returns a reference to a `ClassInfo` collection object.

This property is read-only.

### Example

```
&CLASSC = &NAME.Classes;
```

## Item

### Syntax

**Item** (*number*)

### Description

The Item method returns a ClassInfo object that exists at the *number* position in the ClassInfo collection executing the method.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------|
| <i>number</i>           | Specify the position number in the collection of the ClassInfo object that you want returned. |

### Returns

A reference to a ClassInfo object or NULL.

### Example

```
For &N = 0 to &CLASSES.Count - 1
```

```
&CLASS = &CLASSES.Item(&N);  
/* do processing */  
End-For;
```

## ItemByName

### Syntax

**ItemByName** (*name*)

### Description

The ItemByName method returns the item specified by *name*. *Name* is not case-sensitive.

### Parameters

| <i>Parameter</i> | <i>Description</i>                                                                                    |
|------------------|-------------------------------------------------------------------------------------------------------|
| <i>name</i>      | Specify the name of the ClassInfo object that you want returned. This parameter takes a string value. |

### Returns

A reference to a ClassInfo object or NULL.

### Example

```
&CLASS = &CLASSES.ItemByName("ABS_HIST");
```

---

## ClassInfo Properties

This section discusses the ClassInfo properties in alphabetical order.

## Documentation

### Description

This property doesn't actually return all the documentation for the class, just a brief description of the class as a string.

This property is read-only.

## Methods

### Description

This property returns a reference to a MethodInfo collection object.

This property is read-only.

## Item

### Syntax

```
Item(number)
```

### Description

The Item method returns a MethodInfo object that exists at the *number* position in the MethodInfo collection executing the method.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------|
| <i>number</i>           | Specify the position number in the collection of the MethodInfo object that you want returned. |

### Returns

A reference to a MethodInfo object or NULL.

## Example

```
For &K = 0 To &METHODS.Count - 1  
    &METHOD = &METHODS.item(&K);  
    &OutTEXT = "          " | &METHOD.name | ": " | &METHOD.Type;  
    &MYFILE.WriteLine(&OutTEXT);  
End-For;
```

## ItemByName

### Syntax

```
ItemByName(name)
```

## Description

The `ItemByName` method returns the item specified by *name*. *Name* is not case-sensitive.

## Parameters

| <i>Parameter</i> | <i>Description</i>                                                                                                  |
|------------------|---------------------------------------------------------------------------------------------------------------------|
| <i>name</i>      | Specify the name of the <code>MethodInfo</code> object that you want returned. This parameter takes a string value. |

## Returns

A reference to a `MethodInfo` object or `NULL`.

## Example

```
&METHOD = &METHODS.ItemByName ("Save");
```

---

## MethodInfo Properties

This section discusses the `MethodInfo` properties in alphabetical order.

## Arguments

### Description

This property returns a reference to a `PropertyInfo` collection object.

This property is read-only.

## Documentation

### Description

This property doesn't actually return all the documentation for the class, just a brief description of the class, as a string.

This property is read-only.

## Name

### Description

This property returns the name of the object as a string.

This property is read-only.

## Type

### Description

This property returns the type of the method. Values include:

- Bool (Boolean).
- Number.
- Float.
- String.
- Variant.
- Blob (binary large object).
- Any API class name.

This property is read-only.

---

## PropertyInfo Collection Properties

This section discusses the PropertyInfo collection properties in alphabetical order.

## Count

### Description

This property returns the number of PropertyInfo Properties objects in the PropertyInfo collection object.

---

**Note:** All repository counts begin at zero, not one.

---

This property is read-only.

### Example

```
&COUNT = &PropC.Count;
```

# PropertyInfo Collection Methods

This section discusses the PropertyInfo collection methods in alphabetical order.

## Item

### Syntax

**Item**(*number*)

### Description

The Item method returns a PropertyInfo object that exists at the *number* position in the PropertyInfo collection executing the method.

### Parameters

| <i>Parameter</i> | <i>Description</i>                                                                               |
|------------------|--------------------------------------------------------------------------------------------------|
| <i>number</i>    | Specify the position number in the collection of the PropertyInfo object that you want returned. |

### Returns

A reference to a PropertyInfo object or NULL.

### Example

```
For &K = 0 To &PROPERTIES.Count - 1
    &PROPERTY = &PROPERTIES.item(&K);
    &OutTEXT = "          " | &PROPERTY.name | ": " | &PROPERTY.Type;
    &MYFILE.WriteLine(&OutTEXT);
End-For;
```

## ItemByName

### Syntax

**ItemByName**(*name*)

### Description

The ItemByName method returns the item specified by *name*. *Name* is not case-sensitive.

## Parameters

| <i>Parameter</i> | <i>Description</i>                                                                                       |
|------------------|----------------------------------------------------------------------------------------------------------|
| <i>name</i>      | Specify the name of the PropertyInfo object that you want returned. This parameter takes a string value. |

## Returns

A reference to a PropertyInfo object or NULL.

## Example

```
&PROPERTY = &PROPERTIES.ItemByName(&ldquo;GetHistoryItems&rdquo;);
```

---

## PropertyInfo Properties

This section discusses the PropertyInfo properties in alphabetical order.

## Documentation

### Description

This property doesn't actually return all the documentation for the class, just a brief description of the class, as a string. This property is read-only.

## Name

### Description

This property returns the name of the object as a string.

This property is read-only.

## Type

### Description

This property returns the data type. Values are:

- Bool (Boolean).
- Number.
- Float.
- String.

- Variant.
- Blob (binary large object).
- Any API class name.

This property is read-only.

## Usage

### Description

This property returns a number that describes in which direction the specified property (or argument) can be passed. The following table describes the valid values.

| <i><b>Value</b></i> | <i><b>Description</b></i>                           |
|---------------------|-----------------------------------------------------|
| 0                   | Can be passed into PeopleSoft API.                  |
| 1                   | Can be passed out of PeopleSoft API.                |
| 2                   | Can be passed either into or out of PeopleSoft API. |

This property is read-only.

## Chapter 11

# Array Class

---

## Understanding Arrays

An array is a collection of data storage locations, each of which holds the same type of data. Each storage location is called an element of the array. When you create an array, you don't have to declare the size of the array at declaration time. Arrays grow and shrink dynamically as you add (or remove) data. The size of an array is limited by the available memory. You can't access past the end of an array, but you can assign outside the existing boundaries, thereby growing the array.

---

## Creating Arrays

Arrays are declared by using the Array type name, optionally followed by "of" and the type of the elements. If the element type is omitted, it is set by default to ANY.

```
Local Array of Number &MYARRAY;  
Local Array &ARRAYANY;
```

Arrays can be composed of any valid PeopleCode data type, such as string, record, number, date, and so on.

PeopleSoft recommends you declare every object you use in PeopleCode. This provides some syntax checking when you save PeopleCode. It's better to find out that you misspelled the name of a method or property at design time, rather than at runtime!

Arrays can be declared as Local, Global, or Component, just like any other PeopleTools object.

Arrays can be created with one or more dimensions. An array with more than one dimension is called an array of arrays. The *dimension* of an array is the number of Array type names in the declaration. This is also called the *depth* of an array. The maximum depth of a PeopleCode array is 15 dimensions.

In the following example, &MYARRAY has three dimensions, and &MYA2 has two dimensions.

```
Local Array of Array of Array of Number &MYARRAY;  
Local Array of Array &MYA2;
```

An array must always have a consistent dimension. This means that in a one-dimensional array *none* of the elements can be an array, in a two-dimensional array *all* of the elements must be one-dimensional arrays, and so on.

After you declare an array, use one of the built-in array functions to instantiate it and return an object reference to it. For example, the following creates an array containing one element of type &TEMP, whatever data type &TEMP may be.

```
&MYARRAY = CreateArray(&TEMP);
```

Or you can use the `CreateArrayRept` function to instantiate an array. The `Rept` stands for *repeat*. `CreateArrayRept` creates an array that contains the number of copies you specify of a particular value. The following code creates an array with three copies of the string `&MYSTRING`. This does *not* create a three-dimensional array, but rather creates an array that's already populated with three elements of data (`Len = 3`), each of which contain the same string (`&MYSTRING`).

```
&MYARRAY = CreateArrayRept(&MYSTRING, 3);
```

An array *object* can be assigned to an array *variable*. Array objects can be passed from and returned to any kind of `PeopleCode` function:

```
ANewFunc (&myarray);
MyFunc (&myarray);
&MyArray = YourFunc("something");
```

For example, the `ReturnToServer` function returns an array of nodes to which a message can be published.

Elements in an array are specified by providing a bracketed subscript after the array object reference:

```
&MyArray[1] = 123;
&temp = &memory[1][2][3];
&temp = &memory[1, 2, 3]; /* Same as preceding line. */
MyFunc(&MyArray[7]);
MyFunc(10)[15] = "a string";
```

To access data in a two-dimensional array, you must specify both indexes. The following accesses the second item in the first subarray:

```
&VALUE = &DOUBLE[1][2];
```

You receive an error if you use a zero or negative index in an array. Accessing an array element whose index is larger than the last array element is also an error, but storing to such an index extends the array. Any intervening elements between the former last element and the new last element are assigned a value based on the element type of the array. This is the same value as an unassigned variable of that type.

An array is an object, which means that assignments to an array are the same as for any other object. An array variable can be assigned the distinguished value `NULL`, which indicates the absence of any array value.

Array variables are supported for all scopes. This means that you can have local, global, and Component array variables.

---

## Populating an Array

There are several ways to populate an array. The example code following each of these methods creates the exact same array, with the same elements:

- Use `CreateArray` when you initially create the array:

```
Local Array of Number &MyArray;
```

```
&MyArray = CreateArray(100, 200, 300);
```

- Assign values to the elements of the array:

```
Local Array of Any &MYARRAY;

&MYARRAY = CreateArray();
&MYARRAY[1] = 100;
&MYARRAY[2] = 200;
&MYARRAY[3] = 300;
```

---

**Note:** Using CreateArray without any parameters creates an array of Any.

---

- Use the Push method to add items to the end of the array:

```
Local Array of Number &MYARRAY;
Local Number &MYNUM;

&MYARRAY = CreateArrayRept(&MYNUM, 0);
/* this creates an empty array of number */
&MYARRAY.Push(100);
&MYARRAY.Push(200);
&MYARRAY.Push(300);
```

- Use the Unshift method to add items to the beginning of the array:

```
Local Array of Number &MYARRAY;
Local Number &MYNUM;

&MYARRAY = CreateArrayRept(&MYNUM, 0);
/* this creates an empty array of number */
&MYARRAY.Unshift(300);
&MYARRAY.Unshift(200);
&MYARRAY.Unshift(100);
```

You can also use CreateArrayRept (repeat) when you initially create the array. The following example creates an array with three elements: all three elements have the same data, that is, 100:

```
Local Array of Number &MYARRAY;

&MYARRAY = CreateArrayRept(100, 3);
```

---

## Removing Items From an Array

You can remove elements from either the start or the end of the array:

- Use the POP method to select and remove an element from the end of an array

```
Local Array of Number &MYARRAY;

&MYARRAY = CreateArray();
&MYARRAY[1] = 100;
&MYARRAY[2] = 200;
&MYARRAY[3] = 300;

&ANSWER = &MYARRAY.Pop();
```

&ANSWER will equal 300.

- Use the SHIFT method to select and remove an element from the beginning of an array

```
Local Array of Number &MYARRAY;
```

```

&MYARRAY = CreateArray();
&MYARRAY[1] = 100;
&MYARRAY[2] = 200;
&MYARRAY[3] = 300;

&ANSWER = &MYARRAY.Shift();

```

&ANSWER equals 100.

## Creating Empty Arrays

If you create an array using `CreateArray` of any data type other than `ANY`, the new array is *not* empty: it contains one item. If you need to create a completely empty array that contains 0 elements, use one of the following:

```

Local Array of Number &AN;
Local Array of String &AS;
Local Array of Record &AR;
Local Array of Array of Number &AAN;
Local Record &REC;

&AN = CreateArrayRept(0,0); /* creates an empty array of number */
&AS = CreateArrayRept("", 0); /* creates an empty array of string */
&AR = CreateArrayRept(&REC, 0); /*create empty array of records */
&AAN = CreateArrayRept(&AN, 0); /*creates empty array of array of number */
&BOTH = CreateArray(CreateArrayRept("", 0), CreateArrayRept("", 0)); /* creates an =>
empty array of array of string */

```

## Creating and Populating Multi-Dimensional Arrays

You can create arrays with more than one dimension. Each element in a multi-dimensional array is itself an array. For example, a two-dimensional array is really an array of arrays. Each subarray has to be created and populated as an array.

Each subarray in a multi-dimensional array must be of the same type. For example, you can't create a two dimensional array that has one subarray of type string and a second subarray of type number.

The following example creates an array of array of string, then reads two files, one into each "column" of the array. The `CreateArrayRept` function call creates an empty array of string (that is, the `Len` property is 0) but with two dimensions (that is, with two subarrays, `Dimension` is 2). The first `Push` method adds elements into the first subarray, so at the end of that `WHILE` loop in the example, `&BOTH` has `Len` larger than 0. The other `Push` methods add elements to the second subarray.

```

Local array of array of string &BOTH;
Local File &MYFILE;
Local string &HOLDER;

/* Create empty &BOTH array */
&BOTH = CreateArrayRept(CreateArrayRept("", 0), 0);

/* Read first file into first column */

&MYFILE = GetFile("names.txt", "R", "UTF8");
While &MYFILE.ReadLine(&HOLDER);
    &BOTH.Push(&HOLDER);
End-While;

```

```

/* read second file into second column */

&MYFILE = GetFile("numbers.txt", "R", "UTF8");
&LINENO = 1;
While &MYFILE.ReadLine(&HOLDER);
    If &LINENO > &BOTH.Len Then
        /* more number lines than names, use a null name */
        &BOTH.Push(CreateArray("", &HOLDER));
    Else
        &BOTH[&LINENO].Push(&HOLDER);
    End-If;
    &LINENO = &LINENO + 1;
End-While;

/* if more names than numbers, add null numbers */
for &LINENO = &LINENO to &BOTH.Len
    &BOTH[&LINENO].Push("");
End-For;

```

This example illustrates the fields and controls on the &BOTH array expanded in PeopleCode debugger at program end. You can find definitions for the fields and controls later on this page.

| Local Name  | Local Value |
|-------------|-------------|
| &BOTH       | Array       |
| └ Dimension | 2           |
| └ Len       | 3           |
| [1]         |             |
| └ Dimension | 1           |
| └ Len       | 2           |
| └ [1]       | Pete        |
| └ [2]       | 100         |
| [2]         |             |
| └ Dimension | 1           |
| └ Len       | 2           |
| └ [1]       | Sue         |
| └ [2]       | 200         |
| [3]         |             |
| └ Dimension | 1           |
| └ Len       | 2           |
| └ [1]       | Laszlo      |
| └ [2]       | 400         |
| &MYFILE     | File        |
| &HOLDER     | 400         |
| &LINENO     | 4           |

The following code reads from a two-dimensional array and writes the data from the each subarray into a separate file.

```

Local File &MYFILE1, &MYFILE2;
Local string &STRING1, &STRING2;
Local array of array of string &BOTH;

/* code to load data into array would be here */

/* open files to be written to */

&MYFILE1 = GetFile("names.txt", "A", "UTF8");
&MYFILE2 = GetFile("numbers.txt", "A", "UTF8");

/* loop through array and write to files */

For &I = 1 To &BOTH.Len
    &J = 1;
    &STRING1 = &BOTH[&I][&J];
    &MYFILE1.writeline(&STRING1);
    &J = &J + 1;
    &STRING2 = &BOTH[&I][&J];

```

```

        &MYFILE2.writeline(&STRING2);
End-For;

&MYFILE1.Close();
&MYFILE2.Close();

```

The following example populates a multi-dimensional string array using SQL. This could be used for reading small tables.

```

Component array of array of string &ArrRunStatus;

&ArrRunStatus = CreateArrayRept(CreateArrayRept("", 0), 0);
&ArrRunStatusDescr = CreateArrayRept("", 0);

&SQL = CreateSQL("SELECT FIELDVALUE, XLATSHORTNAME FROM XLATTABLE WHERE FIELDNAME =>
'RUNSTATUS'");

&LineNo = 1;
While &SQL.Fetch(&FieldValue, &XlatShortName)
    &ArrRunStatus.Push(&FieldValue);
    &ArrRunStatus[&LineNo].Push(&XlatShortName);
    &LineNo = &LineNo + 1;
End-While;

```

To search for a particular element in this array, use the following:

```

&iIndex = &ArrRunStatus.Find(&RunStatusToGet);

&RunStatusDescr = &ArrRunStatus[&iIndex][2];

```

The following example shows how to create a two-dimension array using `CreateArrayRept` and `Push`. In addition, it shows how to randomly assigns values to the cells in a two-dimension array.

```

Local array of array of string &ValueArray;

&Dim1 = 10;
&Dim2 = 5;
&ValueArray = CreateArrayRept(CreateArrayRept("", 0), 0);
For &I = 1 To &Dim1
    &ValueArray.Push(CreateArrayRept("", &Dim2));
End-For;

&ValueArray[1][1] = "V11";
&ValueArray[2][1] = "V21";

WinMessage("&ValueArray[1][1] = " | &ValueArray[1][1] | " " | "&ValueArray[2][1] = =>
" | &ValueArray[2][1], 0);

```

---

## Using Flattening and Promotion

Several of the functions and methods that support arrays in PeopleCode use flattening and promotion to convert their operands to the correct dimension for the array.

*Flattening* converts an array into its elements. For example, the `CreateArray` built-in function constructs an array from its parameters. If it is constructing a one-dimensional array and is given an array as a parameter, then it flattens that array into its elements and adds each of them to the array that it is building, rather than adding a reference to the array (which would be a dimension error) or reporting an error.

Likewise, for functions that operate on multiple-dimension arrays, if they are given a non-array parameter, they use *promotion* to convert it into an array of suitable dimension. For example, the `Push`

method appends elements onto the end of an array. If it is operating with a two-dimensional array of Array of Number, and is given a numeric argument, it will convert the argument into a one-dimensional array of Number with the given number as its only element, and then append that to the two-dimensional array.

An array value can only be assigned to an array variable if the value and variable have both the same dimension and base type. This means you cannot assign an Array of Any to an Array of Number variable or vice-versa. You can, however, assign an Array of Number to an Any variable, as long as you do not break the rule that the base element of an array cannot be an array reference value.

---

## Declaring Array Objects

Arrays are declared by using the Array type name, optionally followed by "of" and the type of the elements. If the element type is omitted, it is set by default to ANY.

```
Local Array of Number &MYARRAY;  
Local Array &ARRAYANY;
```

Arrays can be composed of any valid PeopleCode data type, such as string, record, number, date, and so on.

---

## Understanding the Scope of an Array Object

An array object can only be instantiated from PeopleCode. This object can be used anywhere you have PeopleCode, that is, in an application class, Component Interface PeopleCode, record field PeopleCode, and so on.

---

## Array Class Built-in Functions

“CreateArray” (PeopleCode Language Reference)

“CreateArrayAny” (PeopleCode Language Reference)

“CreateArrayRept” (PeopleCode Language Reference)

“Split” (PeopleCode Language Reference)

---

## Array Class Methods

In this section, we discuss the array class methods.

## Clone

### Syntax

`Clone()`

### Description

The Clone method returns a reference to a new array, which is a copy of the given array. It copies all levels of the array, meaning, if the array contains elements which are themselves arrays (actually references to arrays), then the copy contains references to copies of the subarrays. Furthermore, if the array contains elements that are references to the same subarray, then the copy contains references to *different* subarrays (which of course have the same value).

### Parameters

None. The array object that the clone method is executed against is the array to be cloned. Assigning the result of this method assigns a reference to the new array.

### Returns

An array object copied from the original.

### Example

In the following example, &AAN2 contains the three elements like &AAN, but they are distinct arrays. The last line changes only &AAN2[1][1], *not* &AAN[1][1].

```
Local Array of Array of String &AAN, &AAN2;

&AAN = CreateArray(CreateArray("A", "B"), CreateArray("C", "D"), "E");
&AAN2 = &AAN.Clone();
&AAN2[1][1] = "Z";
```

After the following example, &AAN contains three elements: two references to the subarray that was &AAN[2] (with elements C and D), and a reference to a subarray with element E.

```
&AAN[1] = &AAN[2];
```

After the following example, &AAN2 contains three elements: references to two different subarrays both with elements C and D, and a subarray with element E.

```
&AAN2 = &AAN.Clone();
```

### Related Links

[Subarray](#)

## Find

### Syntax

`Find(value)`

## Description

For a one-dimensional array, the Find method returns the lowest index of an element in the array that is equal to the given value. If the value is not found in the array, it returns zero.

For a two-dimensional array, the Find method returns the lowest index of a subarray which has its first element equal to the given value. If such a subarray is not found in the array, it returns zero.

---

**Note:** This method works with arrays that have only one or two dimensions. You receive a runtime error if you try to use this method with an array that has more than two dimensions.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>             |
|-------------------------|---------------------------------------|
| <i>value</i>            | The string or subarray to search for. |

## Returns

An index of an element or zero.

## Example

Given an array &AS containing (A, B, C, D, E), the following code sets &IND to the index of D, that is, &IND has the value 4:

```
Local array of string &AS;  
  
&AS = CreateArrayRept("", 0);  
&AS.Push("A");  
&AS.Push("B");  
&AS.Push("C");  
&AS.Push("D");  
&AS.Push("E");  
&IND = &AS.Find("D");
```

Given an array of array of string &AABYNAME containing (("John", "July"), ("Jane", "June"), ("Norm", "November")), the following code sets &IND to the index of the subarray starting with "Jane", that is, &IND has the value 2:

```
&NAME = "Jane";  
&IND = &AABYNAME.Find(&NAME);
```

## Related Links

[Replace](#)

[Substitute](#)

## Get

### Syntax

**Get** (*index*)

## Description

Use the Get method to return the *index* element of an array. This method is used with the Java PeopleCode functions, instead of using subscripts (which aren't available in Java.)

Using this method is the same as using a subscript to return an item of an array. In the following example, the two lines of code are identical:

```
&Value = &MyArray[8];  
&value = &MyArray.Get(8);
```

## Parameters

| <i>Parameter</i> | <i>Description</i>                |
|------------------|-----------------------------------|
| <i>index</i>     | The array element to be accessed. |

## Returns

An element in an array.

## Related Links

[Set](#)

[Understanding Application Classes](#)

# Join

## Syntax

```
Join([separator [, arraystart, arrayend [,stringsizehint]])
```

## Description

The Join method *converts* the array that is executing the method into a string by converting each element into a string and *joining* these strings together, separated by *separator*.

---

**Note:** Join does *not* join two arrays together.

---

Each array or subarray to be joined is preceded by the string given by *arraystart* and followed by the string given by *arrayend*. If the given array is multi-dimensional, then (logically) each subarray is first joined, then the resulting strings are joined together.

## Parameters

| <b>Parameter</b>      | <b>Description</b>                                                                                                                                                                                   |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>separator</i>      | Specifies what the elements in the resulting string should be separated with in the resulting string. <i>Separator</i> is set by default to a comma (",").                                           |
| <i>arraystart</i>     | Specifies what each array or subarray to be joined should be preceded with in the resulting string. <i>arraystart</i> is set by default to a left parenthesis ("(").                                 |
| <i>arrayend</i>       | Specifies what each array or subarray to be joined should be followed by in the resulting string. <i>arrayend</i> is set by default to a right parenthesis (")").                                    |
| <i>stringsizehint</i> | Specify a hint to the Join method about the resulting size of the string. This can improve performance if your application is concatenating a large number of string. See the Example section below. |

## Returns

A string containing the converted elements of the array.

## Example

The following example:

```
Local array of array of number &AAN;

&AAN = CreateArray(CreateArray(1, 2), CreateArray(3, 4), 5);
&STR = &AAN.Join(", ");
```

produces in &STR the string:

```
((1, 2), (3, 4), 5)
```

The following example makes use of the *stringsizehint* parameter. The following application class passes the resulting string size hint in the Value property.

```
class StringBuffer
  method StringBuffer(&InitialValue As string, &MaxSize As integer);
  method Append(&New As string);
  method Reset();
  property string Value get set;
  property integer Length readonly;
private
  instance array of string &Pieces;
  instance integer &MaxLength;
end-class;

method StringBuffer
  /+ &InitialValue as String, +/
  /+ &MaxSize as Integer +/
  &Pieces = CreateArray(&InitialValue);
  &MaxLength = &MaxSize;
```

```

        &Length = 0;
    end-method;

    method Reset
        &Pieces = CreateArrayRept("", 0);
        &Length = 0;
    end-method;

    method Append
        /+ &New as String +/
        Local integer &TempLength = &Length + Len(&New);
        If &Length > &MaxLength Then
            throw CreateException(0, 0, "Maximum size of StringBuffer exceeded(" | &MaxLe⇒
            ngth | ")");
        End-If;
        &Length = &TempLength;
        &Pieces.Push(&New);
    end-method;

    get Value
        /+ Returns String +/
        Local string &Temp = &Pieces.Join("", "", "", &Length);
        /* collapse array now */
        &Pieces = CreateArrayRept("", 0);
        &Pieces.Push(&Temp); /* start out with this combo string */
        Return &Temp;
    end-get;

    set Value
        /+ &NewValue as String +/
        /* Ditch our current value */
        %This.Reset();
        &Pieces.Push(&NewValue);
    end-set;

```

The following code concatenates strings.

```

While &file.ReadLine(&line)
    &S.Append(&line);
    &S.Append(&separator);

```

## Next

### Syntax

**Next** (&index)

### Description

The Next method increments the given index variable. It returns true if and only if the resulting index variable refers to an existing element of the array. Next is typically used in the condition of a WHILE clause to process a series of array elements up to the end of the array.

&index must be a variable of type integer, or of type Any initialized to an integer, as Next attempts to update it.

If you want to start from the first element of the array, start `Next` with an index variable with the value zero. The first thing `Next` does is to increment the value by one.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;index</i>       | The array element where processing should start. <i>&amp;index</i> must be a variable of type integer, or of type Any initialized to an integer, as <code>Next</code> attempts to update it. |

## Returns

True if the resulting index refers to an existing element of the array, False otherwise.

## Example

`Next` can be used in a `While` loop to iterate through an array in the following manner:

```
&INDEX = 0;
While &A.Next(&INDEX)
    /* Process &A[&INDEX] */
End-While;
```

In the following code example, `&BOTH` is a two-dimensional array. This example writes the data from each subarray in `&BOTH` into a different file.

```
&I = 0;
While &BOTH.Next(&I)
    &J = 1;
    &STRING1 = &BOTH[&I][&J];
    &MYFILE1.writeline(&STRING1);
    &J = &J + 1;
    &STRING2 = &BOTH[&I][&J];
    &MYFILE2.writeline(&STRING2);
End-While;
```

[Len](#)

## Pop

### Syntax

```
Pop()
```

### Description

The `Pop` method removes the last element from the array and returns its value.

## Parameters

None.

## Returns

The value of the last element of the array. If the last element is a subarray, the subarray is returned.

## Example

The Pop method can be used with the Push method to use an array as a stack. To put values on the end of the array, use Push. To take the values back off the end of the array, use Pop.

Suppose we have a two-dimensional array &SUBPARTS which gives the subparts of each part of some assemblies. Each row (subarray) of &SUBPARTS starts with the name of the part, and then has the names of the subparts. Assuming there are no "loops" in this data, the following code puts all the subparts, subsubparts, and so on, of the part given by &PNAME into the array &ALLSUBPARTS, in "depth first order" (that is, subpart1, subparts of subpart1, ..., subpart2, subparts of subpart2, ...). We stack the indexes into &SUBPARTS when we want to go down to the subsubparts of the current subpart.

```
Local array of array of string &SUBPARTS;
Local array of string &ALLSUBPARTS;
Local array of array of number &STACK;
Local array of number &CUR;
Local string &SUBNAME;

/* Set the ALLSUBPARTS array to an empty array of string. */
&ALLSUBPARTS = CreateArrayRept("dummy", 0);

/* Start with the part name. */
&STACK = CreateArray(CreateArray(&SUBPARTS.Find(&PNAME), 2));
While &STACK.Len > 0
    &CUR = &STACK.Pop();
    If &CUR[1] <> 0 And
        &CUR[2] <= &SUBPARTS[&CUR[1]].Len Then

        /* There is a subpart here. Add it. */
        &SUBNAME = &SUBPARTS[&CUR[1], &CUR[2]];
        &ALLSUBPARTS.Push(&SUBNAME);

        /* Tour its fellow subparts later. */
        &STACK.Push(CreateArray(&CUR[1], &CUR[2] + 1));

        /* Now tour its subsubparts. */
        &STACK.Push(CreateArray(&SUBPARTS.Find(&SUBNAME), 2));

    End-If;
End-While;
```

## Related Links

[Push](#)

[Replace](#)

[Shift](#)

[Unshift](#)

## Push

### Syntax

```
Push(paramlist)
```

Where *paramlist* is an arbitrary-length list of values in the form:

```
value1 [, value2] ...
```

### Description

The Push method adds the values in *paramlist* onto the end of the array executing the method. If a value is not the correct dimension, it is flattened or promoted to the correct dimension first, then the resulting values are added to the end of the array.

### Considerations Using Arrays With Object References

This method only adds an element to the end of an array. It does not clone or otherwise deep-copy the parameters. For example, if you are adding a reference to an object, Push just adds a reference to the object at the end of the array. This is similar to an assignment. It is *not* making a copy of the object. The following code snippet only puts a reference to the same record onto the end of the array.

```
While &SQL.Fetch(&Rec);  
&MYARRAY.Push(&Rec);  
...  
End-While;
```

Even though the array is growing, all the elements point to the same record. You have only as many standalone record objects as you create. The following code snippet creates new standalone records, so each element in the array points to a new object:

```
local Record &FetchedRec = CreateRecord(Record.PERSONAL_DATA);  
  
While &SQL.Fetch(&FetchedRec)  
    &MYARRAY.Push(&FetchedRec);  
    &FetchedRec = CreateRecord(Record.PERSONAL_DATA);  
End-While;
```

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                |
|-------------------------|----------------------------------------------------------|
| <i>paramlist</i>        | An arbitrary-length list of values, separated by commas. |

### Returns

None.

### Example

The following example loads an array with data from a database table.

```
Local array of record &MYARRAY;
```

```

Local SQL &SQL;

&I = 1;
&SQL = CreateSQL("Select(:1) from %Table(:1) where EMPLID like &lsquo;8%&rsquo;", &⇒
REC);
While &SQL.Fetch(&REC);
    &MYARRAY.Push(CreateRecord(RECORD.PERSONAL_DATA));
    &I = &I + 1;
    &REC.CopyFieldsTo(&MYARRAY[&I]);
End-While;

```

## Related Links

[Pop](#)

[Replace](#)

[Shift](#)

[Unshift](#)

[Using Flattening and Promotion](#)

“Assigning Objects” (PeopleCode Developer’s Guide)

## Replace

### Syntax

```
Replace(start, length[, paramlist])
```

Where *paramlist* is an arbitrary-length list of values in the form:

```
value1 [, value2] ...
```

### Description

Replace replaces the *length* elements starting at *start* with the given values, if any. If *length* is zero, the insertion takes place *before* the element indicated by *start*. Otherwise, the replacement starts with *start* and continues up to and including *length*, replacing the existing values with *paramlist*.

If a negative number is used for *start*, it indicates the starting position relative to the last element in the array, such that  $-1$  indicates the position just *after* the end of the array. To insert at the end of the array (equivalent to the Push method), use a *start* of  $-1$  and a *length* of 0.

If a negative number is used for *length*, it indicates a length measuring downward to lower indexes. Both flattening and promotion can be applied to change the dimension of the supplied parameters to match the elements of the given array.

Similar to how the built-in function Replace is used to update a string, the Replace method is a general way to update an array, and can cause the array to grow or shrink.

See [Using Flattening and Promotion](#).

### Using Replace to Remove an Element

You can use the Replace method to remove an element from an array. Just specify the item you want replaces, with *length* equal to one.

The following example removes the item from `&Index`:

```
&Array.Replace(&Index, 1);
```

## Parameters

| <b>Parameter</b> | <b>Description</b>                                                                                                                                                                                |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>start</i>     | Specifies where to start replacing the given elements in the array. If a negative number is used for <i>start</i> , it indicates the starting position relative to the last element in the array. |
| <i>length</i>    | Specifies the number of elements in the array to be replaced.                                                                                                                                     |
| <i>paramlist</i> | Specifies values to be used to replace existing values in the array. This parameter is optional.                                                                                                  |

## Returns

None.

## Example

For example, given the following array:

```
Local array of string &AS;
```

```
&AS = CreateArray("AA", "BB", "CC");
```

After executing the next code, the array `&AN` will contain four elements, ZZ, YY, BB, CC:

```
&AS.Replace(1, 1, "ZZ", "YY");
```

After executing the next code, the array `&AN` will contain three elements, ZZ, MM, CC:

```
&AS.Replace(2, 2, "MM");
```

After executing the next code, the array `&AN` will contain three elements, ZZ, OO, CC.

```
&AS.Replace(- 2, - 1, "OO");
```

The following image is an example of `&AS` expanded in PeopleCode debugger.

| Local Name                         | Local Value |
|------------------------------------|-------------|
| <input type="checkbox"/> &AS       | Array       |
| <input type="checkbox"/> Dimension | 1           |
| <input type="checkbox"/> Len       | 3           |
| <input type="checkbox"/> [1]       | ZZ          |
| <input type="checkbox"/> [2]       | OO          |
| <input type="checkbox"/> [3]       | CC          |

## Related Links

[Substitute](#)

## Find

# Reverse

## Syntax

**Reverse**()

## Description

The Reverse method reverses the order of the elements in the array.

If the array is composed of subarrays, the Reverse method reverses only the elements in the super-array, it doesn't reverse all the elements in the subarrays. For example, the following:

```
&AN = CreateArray(CreateArray(1, 2), CreateArray(3, 4), CreateArray(5, 6)).reverse(⇒  
);
```

results in &AN containing:

```
((5,6), (3,4), (1,2))
```

## Parameters

None.

## Returns

None.

## Example

Suppose you had the following array.

```
Local Array of Sting &AS;  
&AS = CreateArray("R", "O", "S", "E");
```

If you executed the Reverse method on this array, the elements would be ESOR.

## Related Links

[Sort](#)

# Set

## Syntax

**Set**(*index*)

## Description

Use the Set method to set the value of the *index* element of an array. This method is used with the Java PeopleCode functions, instead of using subscripts (which aren't available in Java.)

Using this method is the same as using a subscript to reference an item of an array. In the following example, the two lines of code are identical:

```
&MyArray[8] = &MyValue;  
&MyArray.Set(8) = &MyValue;
```

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>         |
|-------------------------|-----------------------------------|
| <i>index</i>            | The array element to be accessed. |

## Returns

None.

## Related Links

[Get](#)

[Understanding Java Class](#)

# Shift

## Syntax

```
Shift()
```

## Description

Use the Shift method to remove the first element from the array and return it. Any following elements are "shifted" to an index of one less than they had.

## Parameters

None.

## Returns

Returns the value of the first element of the array. If the first element is a subarray, the subarray is returned.

## Example

```
For &i = 1 to &ARRAY.Len;
```

```

        &ITEM = &ARRAY.Shift();
        /* do processing */
    End-For;

```

## Related Links

[Pop](#)

[Push](#)

[Replace](#)

[Unshift](#)

# Sort

## Syntax

```
Sort(order)
```

## Description

The Sort method rearranges the elements of the array executing the method into an order.

The type of sort done by this function, that is, whether it is a linguistic or binary sort, is determined by the **Sort Order Option** on the PeopleTools Options page.

If the array is one-dimensional, the elements are arranged in either ascending or descending order.

The type of the first element is used to determine the kind of comparison to be made. Any attempt to sort an array whose elements are not all of the same type results in an error.

If *order* is "A", the order is ascending; if it is "D", the order is descending. The comparison between elements is the same one as if done using the PeopleCode comparison operators (<, >, =, and so on.)

---

**Note:** If you execute this method on a server, the string sorting order is determined by the character set and localization of the server.

---

If the array is two-dimensional, the subarrays are arranged in order by the first element of each subarray. Sorting an array whose subarrays have different types of first elements will result in an error. The comparison is done by using the PeopleCode comparison operators (<, >, =, and so on.)

---

**Note:** This method works with arrays that have only one or two dimensions. You receive a runtime error if you try to use this method with an array that has more than two dimensions.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------|
| <i>order</i>            | Specifies whether the array should be sorted in ascending or descending order. Values for <i>order</i> are: |

| <i><b>Value</b></i> | <i><b>Description</b></i> |
|---------------------|---------------------------|
| A                   | Ascending                 |
| D                   | Descending                |

Returns

None.

Example

The following example changes the order of the elements in array &A to be ("Frank", "Harry", "John").

```
&A = CreateArray("John", "Frank", "Harry");

&A.Sort();

&A = CreateArray(CreateArray("John", 1952), CreateArray("Frank", 1957), CreateArray⇒
("Harry", 1928));
```

The following example changes the order of the elements in array &A to be (("Frank", 1957), ("Harry", 1928), ("John", 1952)).

| Local Name                                                                                    | Local Value |
|-----------------------------------------------------------------------------------------------|-------------|
|  &A        | Array       |
|  Dimension | 2           |
|  Len       | 3           |
|  [1]       |             |
|  Dimension | 1           |
|  Len       | 2           |
|  [1]       | John        |
|  [2]       | 1952        |
|  [2]       |             |
|  Dimension | 1           |
|  Len       | 2           |
|  [1]       | Frank       |
|  [2]       | 1957        |
|  [3]       |             |
|  Dimension | 1           |
|  Len       | 2           |
|  [1]       | Harry       |
|  [2]       | 1928        |

```
&A.Sort("A");
```

The following image is an example of &A expanded in PeopleCode debugger, showing code results.

| Local Name   | Local Value |
|--------------|-------------|
| ⊞ &A         | Array       |
| └─ Dimension | 2           |
| └─ Len       | 3           |
| ⊞ [1]        |             |
| └─ Dimension | 1           |
| └─ Len       | 2           |
| └─ [1]       | Frank       |
| └─ [2]       | 1957        |
| ⊞ [2]        |             |
| └─ Dimension | 1           |
| └─ Len       | 2           |
| └─ [1]       | Harry       |
| └─ [2]       | 1928        |
| ⊞ [3]        |             |
| └─ Dimension | 1           |
| └─ Len       | 2           |

[Reverse](#)  
“Using Administration Utilities” (System and Server Administration)

Subarray

Syntax

```
Subarray(start, length)
```

Description

The Subarray method creates a new array from an existing one, taking the elements from *start* for a total of *length*. If *length* is omitted, all elements from *start* to the end of the array are used.

If the array is multi-dimensional, the subarrays of the created array are *references* to the same subarrays from the existing array. This means if you make changes to the original subarrays, the referenced subarrays are also changed. To make distinct subarrays, use the Clone method.

Parameters

| Parameter     | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| <i>start</i>  | Specifies where in the array to begin the subarray.                       |
| <i>length</i> | Specifies the number of elements in the array to be part of the subarray. |

## Returns

An array object.

## Example

To make a distinct array from a multi-dimensional array, use the following:

```
&A = &AAN.Subarray(1, 2).Clone();
```

## Related Links

[Clone](#)

# Substitute

## Syntax

```
Substitute(old_val, new_val)
```

## Description

The Substitute method replaces every occurrence of a value found in an array with a new value. To replace an element that occurs in a specific location in an array, use Replace.

If the array is one-dimensional, Substitute replaces every occurrence of the *old\_val* in the array with *new\_val*.

If the array is two-dimensional, Substitute replaces every subarray whose first element is equal to *old\_val*, with the subarray given by *new\_val*.

---

**Note:** This method works with arrays that have only one or two dimensions. You receive a runtime error if you try to use this method with an array that has more than two dimensions.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                 |
|-------------------------|---------------------------------------------------------------------------|
| <i>old_val</i>          | Specifies the existing value in the array to be replaced.                 |
| <i>new_val</i>          | Specifies the value with which to replace occurrences of <i>old_val</i> . |

## Returns

None

## Example

The following example changes the array &A to be ("John", "Jane", "Hamilton").

```
&A = CreateArray();
&A[1] = "John";
&A[2] = "Jane";
&A[3] = "Henry";
&A.Substitute("Henry", "Hamilton");
```

The following example changes the array &A to be (("John", 1952), ("Jane", 1957), ("Hamilton", 1971), ("Frank", 1961)).

```
&A = CreateArray(CreateArray("John", 1952), CreateArray("Jane", 1957), CreateArray(⇒
"Henry", 1928), CreateArray("Frank", 1961));
&A.Substitute("Henry", CreateArray("Hamilton", 1971));
```

## Unshift

### Syntax

**Unshift**(*paramlist*)

Where *paramlist* is an arbitrary-length list of values in the form:

```
value1 [, value2] ...
```

### Description

The Unshift method adds the given elements to the *start* of the array. Any following elements are moved up to indexes that are larger by the number of values moved. Flattening and Promotion are used to change the dimension of the supplied parameters to be one less than that of the given array.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                               |
|-------------------------|---------------------------------------------------------|
| <i>paramlist</i>        | Specifies values to be added to the start of the array. |

### Returns

None.

## Example

The following code changes &A to be ("x", "Y", "a", "B", "c").

```
&A = CreateArray("a", "B", "c");  
&A.Unshift("x", "Y");
```

# Array Class Properties

In this section, we discuss the array class properties.

## Dimension

### Description

The Dimension property is the number of "Array" type names from the declaration of the array, also called subarrays. This property returns a number.

This property is read-only.

### Example

The following example sets &DIM to 2.

```
Local Array of Array of Number &AAN;  
&DIM = &AAN.Dimension;
```

## Len

### Description

The Len property is the current number of elements in the array. This property can be updated. Setting it to a negative value results in an error.

If this property is set to a smaller (nonnegative) number than its current value, the array is truncated to that length, discarding any elements whose indexes are larger than the given new length.

If this property is set to a number larger than its current value, the array is extended to the new length. Any new elements are set to a default value based on the element type of the array.

This property is read/write.

## Example

The following is a test of whether an array is empty:

```
If &ARR.Len = 0 then  
  /* &ARR is empty. */  
End-If;
```

# BannerTile Class

---

## BannerTile Class

Contextual fluid dashboards allow application developers to design a fluid dashboard in which user-specified or fixed context values determine the content of the tiles displayed on the dashboard. As part of the development process of creating a contextual fluid dashboard, you must create a custom application class that implements this PTNUI:Banner:BannerTile base class.

### Related Links

“Creating Contextual Fluid Dashboards” (Portal Technology)

---

## BannerTile Class Methods

In this section, the BannerTile class methods are presented in alphabetical order.

### ApplyVisuals

#### Syntax

```
ApplyVisuals ()
```

#### Description

You must invoke the ApplyVisuals method in the page Activate program for the dashboard header page to ensure that dashboard header component is displayed properly on all form factors.

---

**Important!** Usage of this method is required.

---

#### Parameters

None.

#### Returns

None.

### Related Links

“Adding PeopleCode to the Dashboard Header Page and Component” (Portal Technology)

## BannerTile

### Syntax

```
BannerTile (&homepage_ID)
```

### Description

Use the BannerTile constructor method to instantiate an object of the superclass. In your implementation, the constructor method for your custom application class must invoke this method to instantiate an object of the superclass.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;homepage_ID</i> | Specifies the homepage ID for the fluid dashboard definition. This value, returned by the Request object, is used to instantiate an object of your custom application class, and then is passed to the superclass. |

### Returns

A BannerTile object.

### Example

In the following example, the constructor method of the MyBannerComp class instantiates an object of the BannerTile superclass:

```
method MyBannerComp
  /+ &hp_ID as String +/
  %Super = create PTNUI:Banner:BannerTile(&hp_ID);
  %This.AnnounceText = "One or more tiles has been updated.";
  rem %This.IsPersistContext = False;
end-method;
```

### Related Links

“Creating a Custom Application Class” (Portal Technology)

## ClearContextString

### Syntax

```
ClearContextString ()
```

## Description

---

**Note:** This method has been deprecated. Use the `DeleteContext`, `DeleteContextAndUpdate`, or `DeleteKey` methods instead.

---

## Parameters

None.

## Returns

None.

## Related Links

[DeleteContext](#)

[DeleteContextAndUpdate](#)

[DeleteKey](#)

## DeleteContext

### Syntax

```
DeleteContext()
```

### Description

Use the `DeleteContext` method to delete all context keys and context values from memory. Only invoke this method if `IsPersistContext` is `True`.

---

**Note:** You must separately and explicitly update both the context for the tiles on the dashboard as well as the context fields displayed to the user.

---

### Parameters

None.

### Returns

None.

### Related Links

[IsPersistContext](#)

[DeleteContextAndUpdate](#)

[DeleteKey](#)

[UpdateContext](#)

## DeleteContextAndUpdate

### Syntax

`DeleteContextAndUpdate()`

### Description

Use the `DeleteContextAndUpdate` method to delete all context keys and context values from memory and then update the tiles on the dashboard to reflect this change. Only invoke this method if `IsPersistContext` is `True`. For example, invoke `DeleteContextAndUpdate` in a `FieldChange` program associated with a `Clear` button to clear the context and update the dashboard and its tiles.

---

**Note:** You must separately and explicitly update the context fields displayed to the user.

---

### Parameters

None.

### Returns

None.

### Example

```
import MYPKG:MyBannerComp;

Component MYPKG:MyBannerComp &oBanner;

/* Clears the context keys and values and updates the tiles. */
&oBanner.DeleteContextAndUpdate();

/* Clears the values displayed to the user. */
MY_REC.SETID.Value = "";
MY_REC.DESCR.Value = "";
```

### Related Links

[IsPersistContext](#)

[DeleteContext](#)

[DeleteKey](#)

## DeleteKey

### Syntax

`DeleteKey (KEYNAME)`

### Description

Use the `DeleteKey` method to delete an individual context key and value from memory by specifying the key's name. Only invoke this method if `IsPersistContext` is `True`.

## Parameters

| <i>Parameter</i> | <i>Description</i>                               |
|------------------|--------------------------------------------------|
| <i>KEYNAME</i>   | Specifies the name of the key as a string value. |

## Returns

None.

## Example

```
If &oBanner.IsKeyExist("SETID") Then  
    &oBanner.DeleteKey("SETID");  
End-If;
```

## Related Links

[IsPersistContext](#)

[DeleteContext](#)

[DeleteContextAndUpdate](#)

[UpdateContext](#)

## GetBannerLabel

### Syntax

```
GetBannerLabel ()
```

### Description

Override the GetBannerLabel method to set and return a label for the dashboard header component. Because this label is used for accessibility purposes, never set the label to an empty string.

---

**Note:** The default label is: Dashboard Header.

---

---

**Important!** Do not explicitly invoke this method. It will be invoked by the PeopleSoft system as necessary.

---

### Parameters

None.

### Returns

A string value.

## Example

The following implementation of `GetBannerLabel` overrides the base class implementation.

```
method GetBannerLabel
    /+ Returns String +/
    /+ Extends/implements PTNUI:Banner:BannerTile.GetBannerLabel +/
    Return "My Dashboard: Contextual Data Area";
end-method;
```

## GetContextString

### Syntax

```
GetContextString()
```

### Description

Use the `GetContextString` method to return the context string as query string parameters. The following example demonstrates the string returned when two context keys are defined:

```
SETID=DFLTSET&CURRENCY=USD
```

### Parameters

None.

### Returns

A string value.

### Example

```
&cxt_str = &oBanner.GetContextString();
```

### Related Links

[SetKeyValue](#)

[KeyVals](#)

## GetGroupletURL

### Syntax

```
GetGroupletURL()
```

### Description

You must provide an implementation of the `GetGroupletURL` abstract method. In your implementation, return the URL to the dashboard header component as a string value.

---

**Important!** Do not explicitly invoke this method. It will be invoked by the PeopleSoft system as necessary.

---

## Parameters

None.

## Returns

A string value.

## Example

The following example shows an implementation of `GetGroupletURL` that uses the `GenerateComponentContentURL` built-in PeopleCode function to generate the URL string.

```
method GetGroupletURL
    /* Returns String */
    /* Extends/implements PTNUI:Banner:BannerTile.GetGroupletURL */
    Local string &url = GenerateComponentContentURL(%Portal, %Node, MenuName.MY_MENU⇒
, "GBL", Component.MY_DRIVERCOMP, "", "");
    Return &url;
end-method;
```

## Related Links

“`GenerateComponentContentURL`” (PeopleCode Language Reference)

# GetKeyValue

## Syntax

**GetKeyValue** (*KEYNAME*)

## Description

Use the `GetKeyValue` method to return a string value representing the key value associated with the specified key.

## Parameters

| <i>Parameter</i> | <i>Description</i>                               |
|------------------|--------------------------------------------------|
| <i>KEYNAME</i>   | Specifies the name of the key as a string value. |

## Returns

A string value.

## Related Links

[GetContextString](#)

[SetKeyValue](#)

## IsKeyExist

### Syntax

```
IsKeyExist (KEYNAME)
```

### Description

Use the IsKeyExist method to return a boolean value indicating whether the specified key name exists.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                        |
|-------------------------|--------------------------------------------------|
| <i>KEYNAME</i>          | Specifies the name of the key as a string value. |

### Returns

A boolean value.

### Example

```
If &oBanner.IsKeyExist("SETID") Then  
    &oBanner.DeleteKey("SETID");  
End-If;
```

## OverrideDefaultProperties

### Syntax

```
OverrideDefaultProperties ()
```

### Description

Implement the OverrideDefaultProperties method in your custom application class to override the default setting for certain properties—for example, setting the IsExpanded property to False.

---

**Important!** Do not explicitly invoke this method. It will be invoked by the PeopleSoft system as necessary.

---

### Parameters

None.

## Returns

None.

## Example

```
method OverrideDefaultProperties
    /* Extends/implements PTNUI:Banner:BannerTile.OverrideDefaultProperties */
    Local number &count;
    SQLExec("Select count(*) FROM PS_TL_ESS_JOB_VW3 WHERE EMPLID=:1", %EmployeeId, &⇒
count);
    If &count = 1 Then
        %This.IsExpanded = False;
    End-If;
end-method;
```

## Related Links

[IsExpanded](#)

“Creating a Custom Application Class” (Portal Technology)

## SetDefaultContext

### Syntax

```
SetDefaultContext()
```

### Description

Override the SetDefaultContext method to set the initial context keys and values for the dashboard header component.

---

**Note:** If the IsPersistContext property is set to False in the constructor method of your custom application class, the default context keys and values are still propagated to the tiles on the dashboard. However, these keys and values are not retained in memory.

---

---

**Important!** Do not explicitly invoke this method. It will be invoked by the PeopleSoft system as necessary.

---

### Parameters

None.

### Returns

None.

## Example

The following example demonstrates how to override the `SetDefaultContext` method within your custom application class.

```
method SetDefaultContext
    /+ Extends/implements PTNUI:Banner:BannerTile.SetDefaultContext +/
    %This.SetKeyValue("SETID", "AUS01");
    %This.SetKeyValue("DESCR", "Default description");
end-method;
```

## Related Links

“Creating a Custom Application Class” (Portal Technology)

[SetKeyValue](#)

[IsPersistContext](#)

## SetKeyValue

### Syntax

```
SetKeyValue(KEYNAME, KEYVALUE)
```

### Description

Use the `SetKeyValue` method to set a context key name and value pair.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                |
|-------------------------|----------------------------------------------------------|
| <i>KEYNAME</i>          | Specifies the name of the context key as a string value. |
| <i>KEYVALUE</i>         | Specifies the context value as a string value.           |

### Returns

None.

## Example

```
%This.SetKeyValue("SETID", "DFLTSET");
```

## Related Links

[GetKeyValue](#)

[SetDefaultContext](#)

## UpdateContext

### Syntax

```
UpdateContext()
```

### Description

Use the UpdateContext method to pass the defined context keys and values from the dashboard header component to the tiles on the fluid dashboard. For example, invoke UpdateContext in a FieldChange program to pass user-supplied values to the tiles.

### Parameters

None.

### Returns

None.

### Example

```
import MYPKG:MyBannerComp;

Component MYPKG:MyBannerComp &oBanner;

&oBanner.SetKeyValue("SETID", GetField(MY_REC.SETID).Value);
&oBanner.SetKeyValue("DESCR", GetField(MY_REC.DESCR).Value);

&oBanner.UpdateContext()
```

### Related Links

“Adding PeopleCode to the Dashboard Header Page and Component” (Portal Technology)

---

## BannerTile Class Properties

In this section, the BannerTile class properties are presented in alphabetical order.

## AnnounceText

### Description

Use the AnnounceText property to set or return a string value representing an announcement to be posted to an ARIA (Accessible Rich Internet Applications) live region of the page when the tiles have been updated with new context values—for example, after UpdateContext has been invoked. This announcement is available to be read by screen readers and other assistive technologies.

Set this property in the constructor method of your custom application class.

---

**Note:** There is no default value; you must specify the announcement text.

---

This property is read/write.

### Example

```
%This.AnnounceText = "One or more tiles has been updated.";
```

### Related Links

[DeleteContextAndUpdate](#)

[UpdateContext](#)

“Creating a Custom Application Class” (Portal Technology)

## HomepageId

### Description

Use the `HomepageId` property to return a string value representing the concatenation of the following values: *NODE\_NAME.PORTAL\_NAME.HOMEPAGE\_NAME* For example:

```
QEDMO.EMPLOYEE.MY_CONTEXT_DB
```

This property is read-only.

### Related Links

[HomepageName](#)

[NodeName](#)

[PortalName](#)

## HomepageName

### Description

Use the `HomepageName` property to return a string value representing the homepage ID that was specified by the *&homepage\_ID* parameter when an object of your custom application class was instantiated in the dashboard header page’s Activate event. This value, returned by the Request object, represents the content reference name for the fluid dashboard definition. For example:

```
MY_CONTEXT_DB
```

This property is read-only.

### Related Links

[BannerTile](#)

## IsExpanded

### Description

Use the IsExpanded property to set or return a boolean value indicating whether the dashboard header page is expanded or not displayed at all. When IsExpanded is set to False, the dashboard header is hidden for all users affected by this change; otherwise users have the option whether to hide or display the dashboard header. To override the default value of this property, set it in the OverrideDefaultProperties method only.

---

**Note:** The default value is True.

---

While this property is read/write, you must set it using the OverrideDefaultProperties method in your custom application class implementation only.

### Example

```
%This.IsExpanded = False;
```

### Related Links

[OverrideDefaultProperties](#)

## IsPersistContext

### Description

Use the IsPersistContext property to set or return a boolean value indicating whether the context keys and values are persisted in memory throughout the user's session. Set this property in the constructor method of your custom application class. If IsPersistContext is set to False, the default context keys and values as specified by SetDefaultContext are still propagated to the tiles on the dashboard. However, these keys and values are not retained in memory.

---

**Note:** The default value is True.

---

This property is read/write.

### Example

```
%This.IsPersistContext = False;
```

### Related Links

[SetDefaultContext](#)

“Creating a Custom Application Class” (Portal Technology)

## KeyVals

### Description

Use the KeyVals property to return an array of array of string representing the current context keys and key values. For example, KeyVals [1][1] represents the first context key, and KeyVals [1][2] represents the corresponding key value.

This property is read-only.

### Example

For example, the GetContextString method returns the following context string:

```
SETID=DFLTSET
```

Then, KeyVals [1][1] equals SETID, and KeyVals [1][2] equals DFLTSET.

### Related Links

[GetContextString](#)

[GetKeyValue](#)

[SetKeyValue](#)

## NodeName

### Description

Use the NodeName property to return a string value representing the node name for the current node.

This property is read-only.

## PortalName

### Description

Use the PortalName property to return a string value representing the node name for the current node.

This property is read-only.

# BI Publisher Classes

---

## Understanding BI Publisher and the BI Publisher Classes

Oracle Business Intelligence Publisher (BI Publisher, formerly XML Publisher) enables you to separate the data, layout, and translation layers of a report from each other. This can improve flexibility, as well as reduce maintenance. You need to create report definitions, define templates, and so on, using BI Publisher. The BI Publisher classes enable you to access the runtime portions of the XML publishing process programmatically—that is, after the templates and reports have been created.

The BI Publisher classes are divided into the following categories:

- Report manager definition classes
- Report manager search classes
- Engine classes

### BI Publisher Report Manager Definition Classes

To create a report with BI Publisher, you first create a report definition using the Report Definition page. The report definition includes report properties, output formats, templates to be used, report security, and so on. At run time, the `ReportDefn` class uses these attributes to process the report. The `ReportDefn` class itself can be invoked from a batch process or a page `PeopleCode`. For example, the report can be scheduled from the Query Report Scheduler page, or viewed from Query Report Viewer page.

See [ReportDefn Class](#).

### BI Publisher Report Manager Search Classes

After you've published a report, it is stored in the report repository. Using the report manager search classes, you can search for a report based on defined search keys, or even add additional search keys for searching.

See [Report Class](#).

See [ReportManager Class](#).

See [SearchAttribute Class](#).

### BI Publisher Engine Classes

Use the BI Publisher engine classes to combine PDF files into a single PDF file, and to specify page numbers and watermarks on merged PDF reports.

See [PageNumber Class](#).

See [PDFMerger Class](#).

See [Properties Class](#).

See [Watermark Class](#).

---

## BI Publisher Terms

The following is a list of general BI Publisher terms and their definitions.

| <i><b>Field or Control</b></i> | <i><b>Description</b></i>                                                                                                         |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| EFT                            | Electronic Funds Transfer, a format used by the banking industry.                                                                 |
| eText                          | Electronic text, specifically, files in ASCII text format.                                                                        |
| FO                             | Formatting objects, an XML markup language for document formatting.                                                               |
| HTML                           | Hyper Text Markup Language, a markup language designed for the creation of web pages.                                             |
| PDF                            | Portable Document Format, a file format developed by Adobe Systems for representing documents in an independent format.           |
| RTF                            | Rich Text Format, a document file format used for cross-platform document interchange.                                            |
| XML                            | Extendable Markup Language, a general purpose markup language for many types of data.                                             |
| SMS                            | Short messaging service, a short alphanumeric (160 characters) that is generally sent to a mobile device, such as a mobile phone. |

---

## BI Publisher Flow Diagram

The following diagram presents the general flow of an XML report showing how and when certain BI Publisher classes are used in the publishing process.

BI Publisher prepares the report data from the data source: a PS Query, a connected query, or an XML file. Then, BI Publisher uses the PSXP\_RPTDEFNMANAGER report definition classes to generate and route the report. Optionally, BI Publisher uses the PSXP\_REPORTMGR search classes to search for a report in the reports repository.

---

## Error Handling

Different BI Publisher classes handle errors differently.

Use of report manager definition and report manager search classes should be wrapped in a try-catch statement to handle any errors. The BI Publisher engine class methods typically contain an error parameter as part of their signature that you can check for any errors. Other BI Publisher classes generally return a populated object that can be checked for a null value to determine any errors.

### Related Links

“try” (PeopleCode Language Reference)

---

## Data Type and Scope of BI Publisher Objects

Each BI Publisher class is its own data type—that is, report definitions are declared as the ReportDefn data type, a report manager is declared as the ReportManager type, and so on.

An BI Publisher object can be declared of type local, component, or global and instantiated from PeopleCode only.

---

## Instantiating BI Publisher Objects

The BI Publisher classes are not built-in classes, like Rowset, Field, Record, and so on. They are application classes. Before you can use these classes in your PeopleCode program, you must import them into your program.

Your import statements should look similar to the following:

```
import PSXP_RPTDEFNMANAGER.*;
```

---

**Note:** Using the asterisks after the package name makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are not made available.

---

After you've imported the appropriate BI Publisher classes, you instantiate an object of one of those classes using the constructor for the class and the create method.

The following example declares the variable `&rptDefn` and creates a new instance of the `ReportDefn` class:

```
Local PSXP_RPTDEFNMANAGER:ReportDefn &rptDefn = create PSXP_RPTDEFNMANAGER:ReportDe→  
fn(&rptDefnId);
```

[Import Declarations](#)

---

## Search Operator Values

Methods in the report manager definition and report search manager classes enable you to search for existing definitions. Many of the parameters for these methods should be specified in pairs, that is, a value specified with a search operator. All the search operator parameters use the same values.

| <b>Value</b>        | <b>Description</b>                                         |
|---------------------|------------------------------------------------------------|
| %PSXP_SrchBegins    | The name to search for begins with the specified value.    |
| %PSXP_SrchContains  | The name to search for contains the specified value.       |
| %PSXP_SrchEquals    | The name to search for equals the specified value.         |
| %PSXP_SrchNotEquals | The name to search for does not equal the specified value. |
| %PSXP_SrchLessThan  | The name to search for is less than the specified value.   |

| <b>Value</b>            | <b>Description</b>                                                                                                                              |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| %PSXP_SrchLessEquals    | The name to search for is less than or equal to the specified value.                                                                            |
| %PSXP_SrchGreaterThan   | The name to search for is greater than the specified value.                                                                                     |
| %PSXP_SrchGreaterEquals | The name to search for is greater than or equal to the specified value.                                                                         |
| %PSXP_SrchBetween       | The name to search for is between two values. Separate the values by a comma. Do not use quotation marks. For example, ACCT1, ACCT9.            |
| %PSXP_SrchIn            | The name to search for is in the specified list. Separate the values with commas. Do not use quotation marks. For example, ACCT1, ACCT2, ACCT3. |

---

## BI Publisher Classes Reference

The BI Publisher classes reference includes the *public* subset of BI Publisher classes divided into the following sections:

- BI Publisher report manager definition classes.
- BI Publisher report manager search classes.
- BI Publisher engine classes.

---

## BI Publisher Report Manager Definition Classes

The following report manager definition classes are described in this chapter: ReportDefn class.

---

### ReportDefn Class

This section provides an overview of the ReportDefn class and discusses:

- ReportDefn class constructor
- ReportDefn class methods
- ReportDefn class properties

Use the ReportDefn class to process a report definition created through the Report Definition component. Use this class to generate and publish report output.

---

## ReportDefn Class Constructor

This section describes the constructor for the ReportDefn class.

### ReportDefn

#### Syntax

```
ReportDefn (ReportId)
```

#### Description

Use the ReportDefn constructor to instantiate a ReportDefn object. You must then use the Get method to initialize the object.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                        |
|-------------------------|------------------------------------------------------------------|
| <i>ReportId</i>         | Specify a unique ID to be associated with the report definition. |

#### Returns

A reference to a ReportDefn object.

#### Example

```
import PSXP_RPTDEFNMANAGER:ReportDefn;  
  
Local PSXP_RPTDEFNMANAGER:ReportDefn &rptDefn = create PSXP_RPTDEFNMANAGER:ReportDe⇒  
  
fn (&rptDefnId);  
&rptDefn.Get ();
```

---

## ReportDefn Class Methods

In this section, the ReportDefn class methods are presented in alphabetical order.

### Close

#### Syntax

```
Close ()
```

## Description

Use this method when there is an exception or error calling the ProcessReport method or any other output method (Publish, PrintOutout or DisplayOutput) of the ReportDefn class. Calling this method cleans up all temporary files, folders, and resources.

## Parameters

None.

## Returns

None.

## Related Links

[DisplayOutput](#)

[PrintOutput](#)

[ProcessReport](#)

[Publish](#)

# DisplayOutput

## Syntax

```
DisplayOutput()
```

## Description

Use the DisplayOutput method to display the report generated by the ProcessReport method in a separate browser window.

You must successfully call the ProcessReport method prior to calling this method.

This method displays a single report. Therefore, the report definition must not be set for bursting.

## Parameters

None.

## Returns

None.

## Related Links

[Close](#)

[ProcessReport](#)

## EmailOutput

### Syntax

**EmailOutput**(*ProcessInstanceID*)

### Description

Use the EmailOutput method to email the report generated by the ProcessReport method. This method can be used for bursted and non-burstured reports. You must successfully call the ProcessReport method prior to calling this method.

The report is distributed as an email attachment to the report viewers defined in the report definition, to users defined by the Distribution link during run-time report scheduling, or to external users when the IPT\_BIP\_EXT\_EMAIL\_INT:BIP\_EMAIL\_DATA interface class is implemented.

### Parameters

| <i><b>Parameter</b></i>  | <i><b>Description</b></i>                                                                                                                                                                                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ProcessInstanceID</i> | <p>Specify the process instance of the calling process, such as the calling Application Engine program.</p> <hr/> <p><b>Note:</b> Invoking this method with a process instance ID of 0 is invalid; the EmailOutput method can only be used for scheduled reports.</p> <hr/> |

### Returns

A Boolean value: True if the report was sent (email) successfully; otherwise, False.

[Understanding the BIP\\_EMAIL\\_DATA Interface Class](#)

## Get

### Syntax

**Get** ()

### Description

Use the Get method to return a reference to the existing ReportDefn object.

### Parameters

None.

Returns

A reference to the newly instantiated and populated ReportDefn object.

GetOutDestFormatString

Syntax

```
GetOutDestFormatString(OutDestFormat)
```

Description

Use the GetOutDestFormatString method to convert the output format returned from system variable %OutDestFormat to a BI Publisher output format string that can be passed to the output type parameter of the ProcessReport method. This method is useful when processing reports generated by application engine programs that are run process scheduler.

Parameters

| Parameter            | Description                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>OutDestFormat</i> | Specify the output destination format as a number. If you specify something other than a valid value, the method throws an exception. Valid values are: |

| Value | Description |
|-------|-------------|
| 2     | PDF format  |
| 5     | HTM format  |
| 8     | XLS format  |
| 12    | RTF format  |

Returns

A string if successful. Valid values are:

- PDF
- HTM
- XLS
- RTF

[ProcessReport](#)

# GetPSQueryPromptRecord

## Syntax

```
GetPSQueryPromptRecord()
```

## Description

Use the GetPSQueryPromptRecord method to return the runtime prompts of a query as a record object. This method should only be used when the data source type associated with the report definition is a PeopleSoft query or a Composite Query. This method returns a null when the data source type isn't a PeopleSoft Query or a Composite Query.

## Parameters

None.

## Returns

A record object populated with the query prompts if the data source definition is a PeopleSoft query or a Composite Query, null otherwise.

## Related Links

[SetPSQueryPromptRecord](#)

# PrintOutput

## Syntax

```
PrintOutput(DestPrinter)
```

## Description

Use the PrintOutput method to print the report definition object executing the method. The ProcessReport method must be called successfully before you use this method.

---

**Note:** If you don't set the printer type with the SetPrinterType method before invoking PrintOutput, the default value of *PDF* is used.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                 |
|-------------------------|---------------------------------------------------------------------------|
| <i>DestPrinter</i>      | Specify the printer you want to use for printing the report, as a String. |

## Returns

None.

## Related Links

[Close](#)

[SetPrinterType](#)

## ProcessReport

### Syntax

```
ProcessReport(TemplateId, LanguageCD, AsOfDate, OutputFormat)
```

### Description

Use the ProcessReport method to generate a report and store the information.

Before you generate the report, you must:

- Set the report output destination with the OutDestination property if the output type is a file.
- Specify the data source using the SetRuntimeDataXMLFile method if you are using a data source other than a PeopleSoft query.

After you use the ProcessReport method, you can use the Publish method to post the report, the DisplayOutput method to display the report in a browser window, or the PrintOutput method to print the report.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>TemplateId</i>       | Specify the template to be used for processing this report, as a string. You can specify a null value for this parameter, that is, (""). When you specify a null value, the default template associated with the report definition is used. |

| <b>Parameter</b>    | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>LanguageCD</i>   | <p>Specify the three-letter language code for the report definition, such as ENG, FRA, ESP and so on.</p> <p>This parameter controls both the translation and the language specific output details such as font selection and right-to-left page orientation for Arabic/Hebrew.</p> <p>You can specify a null value for this parameter, that is, (""). If you specify a null value, the current language of the session is used.</p> |
| <i>AsOfDate</i>     | Specify the as of date for the report, as a date.                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>OutputFormat</i> | <p>Specify the output format, as a string.</p> <p>See <a href="#">GetOutDestFormatString</a>.</p> <p>You can specify a null value for this parameter, that is, (""). When you specify a null value, the default output format associated with the report definition is used.</p>                                                                                                                                                     |

## Returns

## Publish

### Syntax

```
Publish(ServerName, ReportPath, FolderName, ProcessInstanceID)
```

### Description

Use the Publish method to publish the current report definition

You must have successfully completed a call to the ProcessReport method before you can use this method.

The Publish method was intended to be used primarily for reports running on the Process Scheduler server, but can also be used when running the report on the application server as well. In the latter case, even though the report is run on the application server, the report distribution must occur on an active Process Scheduler server that is configured with a running Distribution Agent service and a properly configured report node.

- When the Publish method is called while running a report using the Process Scheduler server, the *ServerName* parameter must be specified as a blank string (""), and the *ProcessInstanceID* parameter must be set to the process instance of the calling process.
- When the Publish is called while running a report on the application server, the *ServerName* parameter must be specified with an active Process Scheduler server that will post the report. The specified server must also have access to the report output destination folder in order to successfully post the report. If the application server and the Process Scheduler server share the same physical host machine, this will not be a concern. If not, you may specify an alternate output destination folder for the report (for example, a network share location) using the report definition's *OutDestination* property to ensure that the Process Scheduler server is able to access it for posting the report.

Parameters

| <i>Parameter</i>         | <i>Description</i>                                                                                                                                                                                                                      |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ServerName</i>        | Specify the server to use for publishing the report, as a string. You can specify a null value for this parameter—that is, ("").                                                                                                        |
| <i>ReportPath</i>        | Always specify a null value only for this parameter—that is, ("").                                                                                                                                                                      |
| <i>FolderName</i>        | Specify the name of the report folder that the report should be posted to. You can specify a null value for this parameter—that is, (""). If you do not provide a value for this parameter, the default folder is used to post reports. |
| <i>ProcessInstanceID</i> | Specify the process instance of the calling process, such as the calling Application Engine program. If you specify a 0, a new process instance is generated to track the report posting process.                                       |

Returns

None.

## setPDFConversionFiles

### Syntax

```
setPDFConversionFiles (&inputFiles)
```

### Description

Use the setPDFConversionFiles method to specify the paths to external documents to be converted to PDF and merged with the main report. You must call this method before invoking the ProcessReport method.

BI Publisher for PeopleSoft enables you to include attachments from external sources with a PDF report. The source attachments are converted to PDF format and then merged with the main report. The report is then displayed to the end users or delivered to Report Manager.

### Parameters

| <i>Parameter</i>       | <i>Description</i>                                                                                                                      |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;inputFiles</i> | Specify an already instantiated array of String representing the paths to the external documents to include in the report as PDF files. |

### Returns

None.

### Example

```
Local number &oitTimeOut = 15;  
&oRptDefn.setPDFConversionFiles (&inputFiles);  
&oRptDefn.setPDFConversionTimeOut (&oitTimeOut);
```

### Related Links

“Including External Attachments with BI Publisher Reports” (BI Publisher for PeopleSoft)

## setPDFConversionPageNumbering

### Syntax

```
setPDFConversionPageNumbering (x_pos, y_pos)
```

### Description

Use the setPDFConversionPageNumbering method to specify the position of the page numbering across merged attachments and the main report. If this method is not invoked, no page numbers will be added to the pages in the report.

---

**Note:** Double page numbering will occur if you invoke this method when the report itself or any of the attachments include their own internal page numbering.

---

You must use this method before using the ProcessReport method.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------|
| <i>x_pos</i>            | Specify an integer value representing the position in 72 dpi pixels from the left edge of the page.   |
| <i>y_pos</i>            | Specify an integer value representing the position in 72 dpi pixels from the bottom edge of the page. |

## Returns

None.

## Example

```
&oRptDefn.setPDFConversionPageNumbering(550, 15);
```

## Related Links

“Including External Attachments with BI Publisher Reports” (BI Publisher for PeopleSoft)

# setPDFConversionTimeOut

## Syntax

```
setPDFConversionTimeOut (seconds)
```

## Description

Use the setPDFConversionTimeOut method to specify a time-out interval for PDF conversion for this report that overrides the value of the psxp\_pdfconversion\_timeout global property.

You must use this method before using the ProcessReport method.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                             |
|-------------------------|-----------------------------------------------------------------------|
| <i>seconds</i>          | Specify a Number value representing the time-out interval in seconds. |

## Returns

None.

## Example

```
Local number &oitTimeOut = 15;
&oRptDefn.setPDFConversionFiles(&inputFiles);
&oRptDefn.setPDFConversionTimeOut(&oitTimeOut);
```

## Related Links

“Including External Attachments with BI Publisher Reports” (BI Publisher for PeopleSoft)

# SetPrinterType

## Syntax

```
SetPrinterType(OutDestFormat)
```

## Description

Use the SetPrinterType method to set the printer type when using the PrintOutput method. If you don't set the printer type before invoking PrintOutput, the default value of *PDF* is used.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>OutDestFormat</i>    | Specify the printer type as a String value: <ul style="list-style-type: none"> <li>• "PDF"</li> <li>• "PCL"</li> <li>• "PS"</li> </ul> |

## Returns

None.

## Related Links

[PrintOutput](#)

# SetPSQueryPromptRecord

## Syntax

```
SetPSQueryPromptRecord(&Record)
```

Description

Use the SetPSQueryPromptRecord method to specify an already instantiated record object that contains the prompt values for the query to be used to populate the report.

This method can only be used with reports that have a PeopleSoft query or a Composite Query defined as the data source.

You must use this method before using the ProcessReport method.

Parameters

| Parameter          | Description                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Record</i> | Specify an already instantiated and populated record object that contains the values for the query to be used to populate the report. |

Returns

None.

Related Links

- [ProcessReport](#)
- [GetPSQueryPromptRecord](#)
- [Understanding Query Classes](#)

SetRuntimeDataXMLFile

Syntax

```
SetRuntimeDataXMLFile (FilePath)
```

Description

Use the SetRuntimeDataXMLFile method to specify an existing XML file as the data source for the report.

---

**Note:** Because the SetRuntimeDataRowset and SetRuntimeDataXMLDoc methods have been deprecated, use this SetRuntimeDataXMLFile method instead.

---

Report definitions that use a data source other than a PeopleSoft query must set that data source before generating the report using the ProcessReport method.

Forward or back slashes are used in the path according to the operating system of the application server or process scheduler server—that is, on Unix servers, the directory separator is a forward slash, while Windows servers use back slashes.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>FilePath</i>         | <p>Specify an absolute path to the file that you want to use. You must include the file name and file extension in the parameter.</p> <p>Forward or back slashes are used in the path according to the operating system of the application server or process scheduler server. That is, on Unix servers, the directory separator is a forward slash, while a Windows server use a path with back slashes.</p> |

## Returns

None.

## Related Links

## SetRuntimeProperties

### Syntax

```
SetRuntimeProperties (&NameArray, &ValueArray)
```

### Description

Use the SetRuntimeProperties method to set additional runtime values and properties required for generating this report.

---

**Note:** BI Publisher's properties are defined at three different levels. Global properties are defined on the Global Properties page, and system properties are defined in the xdo.cfg file. At the report definition level, properties are defined on the Report Definition - Properties page. The runtime properties defined using this method override both global and report definition properties. However, system properties defined in the xdo.cfg file cannot be overridden using this method.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;NameArray</i>   | <p>Specify an already instantiated and populated array of string containing the names of the additional properties or variables that you need for this report.</p> |

| <b>Parameter</b>       | <b>Description</b>                                                                                                                                                                                                                                 |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;ValueArray</i> | Specify an already instantiated and populated array of string containing the values of the additional properties or variables that you need for this report. The values should be in the same order as the names listed in <i>&amp;NameArray</i> . |

## Returns

None.

## Example

The following example sets extra parameters for securing a document.

```
&asPropName = CreateArrayRept("", 0);
&asPropValue = CreateArrayRept("", 0);
&asPropName.Push("pdf-compression");
&asPropValue.Push("false");
&asPropName.Push("pdf-hide-menubar");
&asPropValue.Push("true");
&oRptDefn.SetRuntimeProperties(&asPropName, &asPropValue);
```

## Setting Custom Runtime Parameters

The `SetRuntimeProperties` method can also be used to set custom runtime parameters. When setting custom runtime parameters with the `SetRuntimeProperties` method, the parameter names need to be prefixed with *xslt*, and the values need to be surrounded by single quotes (for example, 'xyz'). For example, the following code creates a custom runtime parameter named `xslt.ReportOwner`:

```
&asPropName = CreateArrayRept("", 0);
&asPropValue = CreateArrayRept("", 0);
&asPropName.Push("xslt.ReportOwner");

/* Note the single quotes around the parameter value */
&asPropValue.Push(" 'John Smith' ");

&oRptDefn.SetRuntimeProperties(&asPropName, &asPropValue);
```

The custom parameter may now be used in the template via the tag `<?$ReportOwner?>`. Before using it, it does need to be declared in a form field on the report template using the following tag:

```
<xsl:param name="ReportOwner" xdofo:ctx="begin"/>
```

## ReportDefn Class Properties

In this section, the ReportDefn class properties are presented in alphabetical order.

### Description

#### Description

Use the Description property to return a description for the report definition.

This property is effectively read-only.

### DestinationPrinter

#### Description

Use the DestinationPrinter property to specify a printer for the generated report.

This property is read/write.

### FolderName

#### Description

Use the FolderName property to specify a folder name for the generated report to be posted to.

This property is read/write.

### OutDestination

#### Description

This property sets the report output destination as a string. This property must be set before calling the ProcessReport method. When ProcessReport is called, it places the generated report files in the directory specified by this property.

If this property is not set prior to calling the ProcessReport method, the report processing directory and the value returned by the OutDestination property depends on the setting of the psxp\_usedefaultoutdestination property. The psxp\_usedefaultoutdestination property, which is set on the Report Definition - Properties page, is used to set a compatibility mode with pre-8.50 PeopleTools versions.

See “Setting Report Properties” (BI Publisher for PeopleSoft).

This property is effectively write-only.

---

**Important!** While this property is read/write, your PeopleCode program should read this property only if the program set the property first. Reading the property before it has been explicitly set produces unexpected results.

---

## Related Links

[ProcessReport](#)

# OutDestinationType

## Description

This property returns the type of device specified for the output of the report definition, as a string.

This property returns the output destination value set on the Report Definition-Output page; it is not used internally to determine the output type. It can be used in a PeopleCode program to determine how to process and produce report output (for example, whether to call Publish, how to set OutDestination).

This property is effectively read-only.

# ProcessInstance

## Description

Use this property to specify a number representing a process instance for running the report.

In certain circumstances—for example, when running report using a Process Scheduler server—a process instance number is required for setting drilling URLs in the report output. In these cases, you must set the ProcessInstance property prior to calling the ProcessReport method.

This property is read/write.

## Example

```
&ProcessInstance=PSXPQRYRPT_AET.PROCESS_INSTANCE;  
&oRptDefn.ProcessInstance = &ProcessInstance;  
&oRptDefn.ProcessReport("", "", %Date, "");
```

# ReportFileName

## Description

Use the ReportFileName property to specify the file name for the generated report as a string. When this property is set, it overrides the setting of the UseBurstValueAsOutputFileName property.

This property is read/write.

## Related Links

[UseBurstValueAsOutputFileName](#)

## Status

### Description

This property returns the status of the report definition as a string. Valid values are:

| <b>Value</b> | <b>Description</b>                                                                 |
|--------------|------------------------------------------------------------------------------------|
| A            | The report definition is active and can be run.                                    |
| I            | The report definition is inactive and cannot be run.                               |
| P            | The report definition is in progress and cannot be run. This is the default value. |

This property is read-only.

## UseBurstValueAsOutputFileName

### Description

Use the UseBurstValueAsOutputFileName property to specify different names for all the files that result from bursting. This property takes a Boolean value: true, the report output files are named *BurstValue.Extention*. False is the default value.

---

**Note:** If the ReportFileName property is set, it overrides the setting of this property.

---

This property is read/write.

## BI Publisher Report Manager Search Classes

The following report manager search classes are described in this chapter:

- Report class
- ReportManager class
- SearchAttribute class

---

## Report Class

This section provides an overview of the Report class and discusses:

- Report class constructor
- Report class properties

The Report class is one of the report manager search classes. Use the Report class to access individual reports that have already been published to the report repository.

## Report Class Constructor

This section describes the constructor for the Report class.

### Report

#### Syntax

```
Report(RptId, Prcsinstance, Contentid, Dbname, RptName, RptDescr, RptURL, RptCreate⇒  
Dttm,  
RptExpireDt, FldrName)
```

#### Description

Use the Report constructor to instantiate and populate a Report object with the data of an already published report.

#### Parameters

| Parameter           | Description                                                                  |
|---------------------|------------------------------------------------------------------------------|
| <i>RptId</i>        | Specify the report ID of the report you want to access, as a string.         |
| <i>Prcsinstance</i> | Specify the process instance of the report you want to access, as a number.  |
| <i>Contentid</i>    | Specify the content ID number of the report you want to access, as a number. |
| <i>Dbname</i>       | Specify the data base name, as a string.                                     |
| <i>RptName</i>      | Specify the name of the report you want to access, as a string.              |
| <i>RptDescr</i>     | Specify the description of the report you want to access, as a string.       |
| <i>RptURL</i>       | Specify the URL to the report details page, as a string.                     |

| <b>Parameter</b>     | <b>Description</b>                                                                                                                                                                                                                                |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RptCreateDttm</i> | Specify the date and time of the report you want to access, as a date time value.                                                                                                                                                                 |
| <i>RptExpireDt</i>   | Specify the date when the report will be archived, and no longer considered active, as a date.                                                                                                                                                    |
| <i>FldName</i>       | <p>Specify the name of the folder the report was published to, as a string.</p> <p>You must specify an absolute path name, using forward and back slashes as required by the operating system of the application server or process scheduler.</p> |

## Returns

A reference to a Report object.

## Example

```
import PSXP_REPORTMGR:Report;

Local PSXP_REPORTMGR:Report &oRpt = create PSXP_REPORTMGR:Report(String(&nRptId), &⇒
prcsinstance, &contentid, &sdbname, &sRptName, &sRptDescr, &sRptURL, &sFileURL, &dR⇒
ptCreateDttm, &dRptExpireDt, &sFldrName);
```

---

## Report Class Properties

In this section, the Report class properties are presented in alphabetical order.

### contentId

#### Description

This property returns the content ID of the report, as a number.

This property is read-only.

### CreatedDateTime

#### Description

This property returns the date time when the report was created, as a date time.

This property is read-only.

## DatabaseName

### Description

This property returns the data base name associated with the report, as a string.

This property is read-only.

## Description

### Description

This property returns the description of the report definition, as a string.

This property is read-only.

## ExpireDate

### Description

This property returns the date when the report will be archived, as a date value.

This property is read-only.

## FileURL

### Description

This property returns a URL to the actual report file in the report repository.

Use the ReportURL property to access the report detail page instead.

This property is read-only.

### Related Links

[ReportURL](#)

## FolderName

### Description

This property returns the full path name of the folder where the report is stored, as a string.

This property is read-only.

## ProcessInstanceID

### Description

This property returns the process instance ID associated with the report when it was posted, as a number.

This property is read-only.

### Related Links

[ReportInstanceID](#)

## ReportInstanceID

### Description

This property returns the report instance ID, that was populated when the report was run, as a number.

This property is read-only.

### Related Links

[ProcessInstanceID](#)

## ReportName

### Description

This property returns the name of the report, as a string.

This property is read-only.

## ReportURL

### Description

This property returns a URL as a string, that points to the report detail page.

Use the FileURL to access a URL to the actual file containing the report in the report repository.

This property is read-only.

### Related Links

[FileURL](#)

---

## ReportManager Class

This section provides an overview of the ReportManager class and discusses:

- ReportManager class constructor
- ReportManager class methods

The ReportManager class is one of the report manager search classes. Use the ReportManager class to set the search criteria for reports that have already been published to the report repository.

---

## ReportManager Class Constructor

This section describes the constructor for the ReportManager class.

### ReportManager

#### Syntax

```
ReportManager()
```

#### Description

Use the ReportManager constructor to instantiate an instance of the ReportManager class.

#### Parameters

None.

#### Returns

A ReportManager object.

#### Example

```
import PSXP_REPORTMGR:ReportManager;  
  
Local REPORTMGR:ReportManager &rptMgr = create REPORTMGR:ReportManager();
```

---

## ReportManager Class Methods

In this section, the ReportManager class methods are presented in alphabetical order.

### AddSearchFieldCriteria

#### Syntax

```
AddSearchFieldCriteria(&SearchAttribute)
```

## Description

Use the AddSearchFieldCriteria method to add an already instantiated and populated SearchAttribute object to the search.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                             |
|-----------------------------|-----------------------------------------------------------------------|
| <i>&amp;SearchAttribute</i> | Specify an already instantiated and populated SearchAttribute object. |

## Returns

A Boolean, true if the criteria was added successfully, false otherwise.

## Example

```
Local PSXP_REPORTMGR:SearchAttribute &oSearch;  
Local integer &compOpSrch;  
  
&CompOpSrch = oRptMgr.PSXP_SrchBegins;  
  
&oSearch = create PSXP_REPORTMGR:SearchAttribute(&sAttrname, &sAttrVal, &compOpSrch→  
) ;  
  
&bResult = &oRptMgr.addSearchFieldCriteria(&oSearch);
```

## Related Links

[SearchAttribute Class](#)

# GetReportList

## Syntax

```
GetReportList()
```

## Description

Use the GetReportList method to return a list of the report objects that satisfy all the criteria you specified with the other methods associated with the ReportManager object.

## Parameters

None.

## Returns

An array of Report objects.

## Related Links

[Report Class](#)

## SetBurstFieldCriteria

### Syntax

```
SetBurstFieldCriteria(BurstFld, BurstOp, BurstValue)
```

### Description

Use the SetBurstFieldCriteria method to specify the burst criteria to be used with searching report definitions.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>BurstField</i>       | Specify the name of the burst field used to generate the report, as a string.                                           |
| <i>BurstOp</i>          | Specify the search operator to be used <i>BurstField</i> , as a string.<br>See <a href="#">Search Operator Values</a> . |
| <i>BurstValue</i>       | Specify the pattern string to be matched with burst field value using <i>BurstOp</i> .                                  |

### Returns

A Boolean value, true if the method completes successfully, false otherwise.

## SetCaseSensitive

### Syntax

```
SetCaseSensitive(IsCaseSensitive)
```

### Description

Use the SetCaseSensitive method to specify the case sensitivity flag applicable to search field and bursting criteria for searching reports.

## Parameters

| <b>Parameter</b>       | <b>Description</b>                                                                                  |
|------------------------|-----------------------------------------------------------------------------------------------------|
| <i>IsCaseSensitive</i> | Specify a Boolean value: true to make the search case sensitive, false to make it case insensitive. |

## Returns

None.

## SetDateCriteria

### Syntax

```
SetDateCriteria(createdDate, createdLastVal, createdUnit)
```

### Description

Use the SetDateCriteria method to specify the creation date criteria for searching reports.

## Parameters

| <b>Parameter</b>      | <b>Description</b>                                                                                                                                                                                                                                                                                                 |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>createdDate</i>    | Specify a date used to search for reports generated on and after this date. You should specify a null value (" ") for this parameter if using <i>createdLastVal</i> and <i>createdUnit</i> .                                                                                                                       |
| <i>createdLastVal</i> | Specify a value to be used in conjunction with <i>createdUnit</i> , as a number. If you specify a value, it is used and any value given for <i>createdDate</i> is ignored. If you are not using this search criteria, you should specify a null value (" ") for this parameter.                                    |
| <i>createdUnit</i>    | Specify a value to be used for reports generated during last <i>n</i> number of periodic units. This value is used with <i>createdLastVal</i> . For example, if <i>createdLastVal</i> is set to 10, and <i>createdUnit</i> is set to 1, the reports generated in the last ten days are returned. Valid values are: |

| <b>Value</b> | <b>Description</b> |
|--------------|--------------------|
| 1            | Days               |
| 2            | Hours              |

| <i><b>Value</b></i> | <i><b>Description</b></i> |
|---------------------|---------------------------|
| 3                   | Minutes                   |

## Returns

None.

## SetFolderCriteria

### Syntax

```
SetFolderCriteria (FolderName)
```

### Description

Use the SetFolderCriteria method to specify the folder criteria for searching reports.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                            |
|-------------------------|----------------------------------------------------------------------|
| <i>FolderName</i>       | Specify the name of the folder the report is posted in, as a string. |

## Returns

A Boolean value, true if the search criteria is added successfully, false otherwise.

## SetProcessInstanceCriteria

### Syntax

```
SetProcessInstanceCriteria (FromPID, ToPID)
```

### Description

Use the SetProcessInstanceCriteria method to specify the process instance range criteria for searching reports.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>FromPID</i>          | Specify a process instance ID to be used as the starting range from which to search, as a number. This value must be less than or equal to <i>ToPID</i> . You can specify a null value for this parameter, that is, (" ").    |
| <i>ToPID</i>            | Specify a process instance ID to be used as the ending range from which to search, as a number. This value must be greater than or equal to <i>FromPID</i> . You can specify a null value for this parameter, that is, (" "). |

## Returns

A Boolean value: true if the search criteria is added successfully, false otherwise.

## SetReportIDCriteria

### Syntax

```
SetReportIDCriteria (ReportId)
```

### Description

Use the SetReportIDCriteria method to specify a report ID for searching reports.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                            |
|-------------------------|----------------------------------------------------------------------|
| <i>ReportId</i>         | Specify a report ID to be used for searching for report definitions. |

## Returns

A Boolean value: true if the search criteria was set successfully, false otherwise.

## SetUserIdCriteria

### Syntax

```
SetUserIdCriteria (UserId)
```

## Description

Use the `SetUserIdCriteria` method to specify a user ID to be used for searching reports intended to be accessed by that recipient.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                    |
|-------------------------|------------------------------------------------------------------------------|
| <i>UserId</i>           | Specify the user ID to be matched with the intended recipient of the report. |

## Returns

A Boolean: true if the search criteria is set successfully, false otherwise.

---

## SearchAttribute Class

This section provides an overview of the `SearchAttribute` class and discusses:

- `SearchAttribute` class constructor
- `SearchAttribute` class properties

The `SearchAttribute` class is one of the report manager search classes. Use the `SearchAttribute` class to discover name-value pairs for the search criteria for reports that have already been published to the report repository. In addition, you can also specify a comparison operator to be used with the name-value pairs.

---

## SearchAttribute Class Constructor

This section describes the constructor for the `SearchAttribute` class.

## SearchAttribute

### Syntax

```
SearchAttribute (AttrName, AttrValue, CompareOperator)
```

### Description

Use the `SearchAttribute` constructor to instantiate an instance of a `SearchAttribute` object.

## Parameters

| <i>Parameter</i>       | <i>Description</i>                                                                 |
|------------------------|------------------------------------------------------------------------------------|
| <i>AttrName</i>        | Specify the attribute name, as a string.                                           |
| <i>AttrValue</i>       | Specify the attribute value, as a string.                                          |
| <i>CompareOperator</i> | Specify a comparison operator.<br><br>See <a href="#">Search Operator Values</a> . |

## Returns

A SearchAttribute object.

## Example

```
import PSXP_REPORTMGR:SearchAttribute;  
  
Local PSXP_REPORTMGR:SearchAttribute &oSearch = create PSXP_REPORTMGR:SearchAttribu→  
te(&sAttrname, &sAttrVal, &compOpSrch);
```

---

## SearchAttribute Class Properties

In this section, the SearchAttribute class properties are presented in alphabetical order.

### attrName

#### Description

This property returns the attribute name used with search.

This property is read-only.

### attrValue

#### Description

This property returns the attribute value used with search???

This property is read-only.

## compareOp

### Description

This property returns the comparison operator used with search.

This property is read-only.

---

## BI Publisher Engine Classes

The following engine classes are described in this chapter:

- PageNumber class
- PDFMerger class
- Properties class
- Watermark class

---

## PageNumber Class

This section provides an overview of the PageNumber class and discusses:

- PageNumber class constructor
- PageNumber class properties

Use the PageNumber class to set the page number for a merged PDF file. Objects in this class are used with the PageNumber property of the PDFMerger class.

### Related Links

[PageNumber](#)

---

## PageNumber Class Constructor

This section describes the constructor for the PageNumber class.

## PageNumber

### Syntax

**PageNumber** ( )

## Description

Use the PageNumber constructor to instantiate a PageNumber object.

## Parameters

None.

## Returns

A PageNumber object.

## Example

```
import PSXP_ENGINE:PageNumber;  
  
Local PSXP_ENGINE:PageNumber &pNum = create PSXP_ENGINE:PageNumber();
```

---

# PageNumber Class Properties

In this section, the PageNumber class properties are presented in alphabetical order.

## BackgroundFile

### Description

Use the BackgroundFile property to specify a file to be used for the page number, as a string.

You must specify an absolute file name.

This property is read/write.

### Considerations Using the BackgroundFile Property

You should either use the BackgroundFile property, or you should use the other properties associated with this class, like position or font. You cannot use both.

The file you specify must be a PDF file. The page size of the background PDF must be the same as the target PDF document, otherwise the page numbering doesn't work properly. All page numbering starts on the first page of the target document.

## FontName

### Description

Use the FontName property to specify the name of the font to be used for the page number, as a string. Valid values are:

- Courier

- Courier-Bold
- Courier-BoldOblique
- Helvetica (this is the default value)
- Helvetica-Bold
- Helvetica-BoldOblique
- Helvetica-Oblique
- Symbol
- Times-Bold
- Time-BoldItalic
- Time-Italic
- Time-Roman
- ZapfDingbats

If you specify an invalid font name, the default (Helvetica) is used.

This property is read/write.

## Related Links

[FontSize](#)

## FontSize

### Description

Use the FontSize property to specify the size of the page number, as a number.

The default value is 8.

This property is read/write.

## Related Links

[FontName](#)

## PositionX

### Description

Use the PositionX property to specify the X axis position of the text page number in the merged document.

This property is read/write.

**Related Links**[PositionY](#)**PositionY****Description**

Use the PositionY property to specify the Yaxis position of the text page number in the merged document.

This property is read/write.

**Related Links**[PositionX](#)**StartFromPageNum****Description**

Use the StartFromPageNum property to specify the page index from which you'd like to start the page numbering.

For example, if you have a PDF document which has two cover pages, and you want to start printing page numbers on the document from the third page, specify a three for this property.

This property is read/write.

**Related Links**[StartNum](#)**StartNum****Description**

Use the StartNum property to specify the page number to use as the first page number in the merged document. If you don't specify a starting number, the pages are numbered starting from 1.

This property is read/write.

**Related Links**[StartFromPageNum](#)

---

**PDFMerger Class**

This section provides an overview of the PDFMerger class and discusses:

- PDFMerger class constructor

- PDFMerger class method
- PDFMerger class properties

Use the PDFMerger class to combine two or more PDF files into a single PDF file.

---

## PDFMerger Class Constructor

This section describes the constructor for the PDFMerger class.

### PDFMerger

#### Syntax

```
PDFMerger()
```

#### Description

Use the PDFMerger constructor to instantiate a PDFMerger object.

#### Parameters

None.

#### Returns

A reference to a PDFMerger object.

#### Example

```
import PSXP_ENGINE:PDFMerger;  
  
Local PSXP_ENGINE:PDFMerger &oMerger = create PSXP_ENGINE:PDFMerger();
```

---

## PDFMerger Class Methods

In this section, the PDFMerger class methods are described in alphabetic order.

### isPDFValid

#### Syntax

```
isPDFValid(PDFInputFile, Error)
```

## Description

Use the `isPDFValid` method to test whether a PDF file has a valid structure and whether it can be expected to merge successfully when supplied as an input file to the `MergePDFs` method.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>PDFInputFile</i>     | <p>Specify the full path name of the PDF file you want to validate.</p> <p>Forward or back slashes are used in the path according to the operating system of the application server or Process Scheduler server. That is, on Unix servers, the directory separator is a forward slash, while a Windows server requires a path with back slashes.</p> |
| <i>Error</i>            | <p>If any errors occur during processing, this parameter is populated with the text of the error message.</p>                                                                                                                                                                                                                                        |

## Returns

A Boolean: true if the PDF file is validated successfully, false otherwise. If this method returns false, the Error parameter is populated with the text of the error message that occurred.

## Example

```
import PSXP_ENGINE:PDFMerger;

Local PSXP_ENGINE:PDFMerger &oMerger = create PSXP_ENGINE:PDFMerger();
Local boolean &bResult;
Local string &sErr;
Local string &sInputFile = "c:\temp\PDF_input_files\file_to_be_merged.pdf";
&bResult = &oMerger.isPDFValid(&sInputFile, &sErr);

If Not &bResult Then
    WriteToLog(%ApplicationLogFence_Error, "File " | &sInputFile | " will not merge =>
successfully due to error: " | &sErr);
Else
    WriteToLog(%ApplicationLogFence_Error, "File " | &sInputFile | " will merge succ=>
essfully");
End-If;
```

## MergePDFs

### Syntax

```
MergePDFs(PDFFileArray, PDFOutputFile, Error)
```

## Description

Use the MergePDFs method to merge the specified PDF files into a single output file.

The order of the files specified in the array are the order in which the files are merged.

## Parameters

| <i>Parameter</i>     | <i>Description</i>                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>PDFFileArray</i>  | Specify an already instantiated and populated array of string containing the names of the PDF files that you want to merge together.                                                                                                                                                                                                                                   |
| <i>PDFOutputFile</i> | <p>Specify the full path name of the file you want populated with the merged PDF file.</p> <p>Forward or back slashes are used in the path according to the operating system of the application server or process scheduler server. That is, on Unix servers, the directory separator is a forward slash, while a Windows server returns a path with back slashes.</p> |
| <i>Error</i>         | If any errors occur during processing, this parameter is populated with the text of the error message after processing.                                                                                                                                                                                                                                                |

## Returns

A Boolean: true if the method completed successfully, false otherwise. If this method returns false, the *Error* parameter is populated with the text of the error message that occurred.

## Example

```
Local PSXP_ENGINE:PDFMerger &oMerger;  
  
&sErr = "";  
&asNames = CreateArray(&sPdfFile1);  
&asNames.Push(&sPdfFile2);  
&bResult = &oMerger.mergePDFs(&asNames, &sOutputPdfFile, &sErr);
```

---

## PDFMerger Class Properties

In this section, the PDFMerger class properties are presented in alphabetical order.

## ConfProp

### Description

Use the ConfProp property to specify an already instantiated and populated Properties object that contains the configuration to be used for processing the document. This property enables you to accommodate different system configurations.

### Related Links

[Properties Class](#)

## Locale

### Description

Use the Locale property to specify the locale for the processing. If no value is specified for this property, the default system locale will be used.

The locale is specified using a two character ISO language code and a two character ISO country code (LC-CC). When you don't need to reflect country specific formatting, the locale code is made up of just the language code.

This property is read/write.

## PageNumber

### Description

Use this property to specify an already instantiated and populated PageNumber object to be used with the merged document.

This property is read/write.

### Example

```
Local PSXP_ENGINE:PDFMerger &oMerger;
Local PSXP_ENGINE:PageNumber &oPageNumber;

&oMerger = create PSXP_ENGINE:PDFMerger();
&oPageNumber = create PSXP_ENGINE:PageNumber();

&oPageNumber.FontName = "Symbol";
&oPageNumber.FontSize = 16;
&oPageNumber.PositionX = 300;
&oPageNumber.PositionY = 20;
&oMerger.oPageNumber = &oPageNumber;

&sErr = "";
&asNames = CreateArray(&sPdfFile1);
&asNames.Push(&sPdfFile2);
&bResult = &oMerger.mergePDFs(&asNames, &sOutputPdfFile, &sErr);
```

## Related Links

[PageNumber Class](#)

## Watermark

### Description

Use this property to specify an already instantiated and populated Watermark object to be used with the merged object.

This property is read/write.

### Example

```
Local PSXP_ENGINE:PDFMerger &oMerger;  
Local PSXP_ENGINE:Watermark &oWatermark;  
  
&oMerger = create PSXP_ENGINE:PDFMerger();  
&oWatermark = create PSXP_ENGINE:Watermark();  
  
&oWatermark.Text = "DEMO";  
&oWatermark.TextStartPosX = 200;  
&oWatermark.TextStartPosY = 400;  
&oMerger.oWatermark = &oWatermark;  
  
&sErr = "";  
&asNames = CreateArray(&sPdfFile1);  
&bResult = &oMerger.mergePDFs(&asNames, &sOutputPdfFile, &sErr);
```

## Properties Class

This section provides an overview of the Properties class and discusses:

- Properties class constructor
- Properties class methods

Use the Properties class to specify the properties for setting up the processor configuration. This class is used with the PDFMerger class.

## Related Links

[ConfProp](#)

---

## Properties Class Constructor

This section describes the constructor for the Properties class.

## Properties

### Syntax

```
Properties()
```

### Description

Use the Properties constructor to instantiate a Properties object.

### Parameters

None.

### Returns

A Properties object.

### Example

```
import PSXP_ENGINE:Properties;  
  
Local PSXP_ENGINE:Properties &rProps = create PSXP_ENGINE:Properties();
```

---

## Properties Class Methods

In this section, the Properties class methods are presented in alphabetical order.

## GetProperty

### Syntax

```
GetProperty(Name, OutValue)
```

### Description

Use the GetProperty method to return the value of the specified property.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                 |
|-------------------------|---------------------------------------------------------------------------|
| <i>Name</i>             | Specify the name of the property that you want to access the value.       |
| <i>OutValue</i>         | Specify a string to contain the value of the property you want to access. |

## Returns

A Boolean: true if the method completed successfully, false otherwise. If this method returns false, the *Error* parameter is populated with the text of the error message that occurred.

## Example

```
Local PSXP_ENGINE:Properties &oProp;  
  
&oProp = create PSXP_ENGINE:Properties();  
%sValue = "";  
&bResult = &oProp.getProperty("pdf-security", %sValue);
```

## SetProperty

### Syntax

**SetProperty**(*Name*, *Value*)

### Description

Use the SetProperty method to specify the value of the specified property.

### Parameters

| <i>Parameter</i> | <i>Description</i>                                      |
|------------------|---------------------------------------------------------|
| <i>Name</i>      | Specify the name of the property that you want to set.  |
| <i>Value</i>     | Specify the value of the property that you want to set. |

## Returns

A Boolean: true if the method completed successfully, false otherwise. If this method returns false, the *Error* parameter is populated with the text of the error message that occurred.

## Example

```
Local PSXP_ENGINE:Properties &oProp;  
  
&oProp = create PSXP_ENGINE:Properties();  
&bResult = &oProp.setProperty("pdf-security", "true");
```

---

## Watermark Class

This section provides an overview of the Watermark class and discusses:

- Watermark class constructor

- Watermark class properties

Use the Watermark class to specify a watermark for a merged PDF file. Objects in this class are used with the Watermark property of the PDFMerger class. You can generate a watermark either using text or an image. You can either use the text properties or the image properties. You cannot use both.

The following are the image properties of the Watermark class:

- ImageFile
- ImageLowerLeftX
- ImageLowerLeftY
- ImageUpperRightX
- ImageUpperRightY

The following are the text properties of the Watermark class:

- Text
- TextAngle
- TextFontName
- TextFontSize
- TextStartPosX
- TextStartPosY

## Watermark Class Constructor

This section describes the constructor for the Watermark class.

### Watermark

#### Syntax

```
Watermark ( )
```

#### Description

Use the Watermark constructor to instantiate a Watermark object.

## Parameters

None.

## Returns

A Watermark object.

## Example

```
import PSXP_ENGINE:Watermark;  
  
Local PSXP_ENGINE:Watermark &rProps = create PSXP_ENGINE:Watermark();
```

---

# Watermark Class Properties

In this section, the Watermark class properties are presented in alphabetical order.

## ImageFile

### Description

Use the ImageFile property to specify the full path name of an image file to be used for the watermark.

Forward or back slashes are used in the path according to the operating system of the application server or process scheduler server. That is, on Unix servers, the directory separator is a forward slash, while a Windows server returns a path with back slashes.

This property is read/write.

## ImageFileLowerLeftX

### Description

Use the ImageFileLowerLeftX property to specify the lower left, X-axis position for the watermark, as a number.

This property is read/write.

## ImageFileLowerLeftY

### Description

Use the ImageFileLowerLeftY property to specify the lower left, Y-axis position for the watermark, as a number.

This property is read/write.

## ImageFileUpperRightX

### Description

Use the ImageFileUpperRightX property to specify the upper right, X-axis position for the watermark, as a number.

This property is read/write.

## ImageFileUpperRightY

### Description

Use the ImageFileUpperRightY property to specify the upper right, Y-axis position for the watermark, as a number.

This property is read/write.

## PageIndex

### Description

Use the PageIndex property to specify the page where the watermark begins. For example, you might not want a watermark to display on a cover page. The default value is 0, which sets the watermark on all pages (page index starts at 1.)

This property is read/write.

## Text

### Description

Use the Text property to specify the text for the watermark, as a string.

This property is read/write.

## TextAngle

### Description

Use the TextAngle property to specify the angle of the watermark text across the page. You must specify a number between 1 and 360.

This property is read/write.

## TextFontName

### Description

Use the TextFontName property to specify the name of the font to be used for the text for the watermark.

This property is read/write.

## TextFontSize

### Description

Use the TextFontSize property to specify the size of the text font. The default value is 8.

This property is read/write.

## TextStartPosX

### Description

Use the TextStartPosX property to specify the starting position, X-axis location for the text to be used as the watermark.

This property is read/write.

## TextStartPosY

### Description

Use the TextStartPosY property to specify the starting position, Y-axis location for the text to be used as the watermark.

This property is read/write.

---

## Understanding the DigitalCertStore Class

The DigitalCertStore class defines the available methods that can be invoked by a custom implementation of the IPT\_PDFSIGNATURE\_INT:IPDFSignature interface class to retrieve digital certificates and passwords for PDF reports produced with BI Publisher for PeopleSoft. The DigitalCertStore class is also used internally by BI Publisher for PeopleSoft for similar purposes.

### Related Links

[Understanding the IPDFSignature Interface Class](#)

“Using the External Digital Certificates Page” (Security Administration)

“Understanding Digital Signature in BI Publisher Reports” (BI Publisher for PeopleSoft)

---

## DigitalCertStore Class Methods

The methods in this section are described in alphabetical order.

### DigitalCertStore

#### Syntax

```
DigitalCertStore()
```

#### Description

Use the DigitalCertStore constructor method to instantiate a DigitalCertStore object.

#### Parameters

None.

#### Returns

A DigitalCertStore object.

#### Example

Use the create built-in function to instantiate a DigitalCertStore object:

```
import PT_SECURITY_DIGITALCERTSTORE:DigitalCertStore;

&oStore = create PT_SECURITY_DIGITALCERTSTORE:DigitalCertStore();
```

### ExtractCertificateByAuthorizedRole

#### Syntax

```
ExtractCertificateByAuthorizedRole(digital_ID, auth_role, dest_location, &keystore ⇒  
pwd)
```

#### Description

Use the ExtractCertificateByAuthorizedRole method to retrieve a digital certificate file to the specified location on the application server based on the specified digital ID and whether the current user has the specified role. This method also returns the encrypted password for the certificate file.

---

**Important!** Do not use this method in an implementation of the IPT\_PDFSIGNATURE\_INT:IPDFSignature interface class. Oracle reserves the right to modify this method in the future.

---

## Parameters

| <b>Parameter</b>         | <b>Description</b>                                                                                    |
|--------------------------|-------------------------------------------------------------------------------------------------------|
| <i>digital_ID</i>        | Specifies the digital ID for the certificate as a string value.                                       |
| <i>auth_role</i>         | Specifies a role name as a string value.                                                              |
| <i>dest_location</i>     | Specifies the absolute URL to store the certificate file on the application server as a string value. |
| <i>&amp;keystore_pwd</i> | Specifies an already instantiated string variable to store the returned encrypted password.           |

## Returns

A return code as a numeric value:

| <b>Numeric Value</b> | <b>Description</b>                                                                                           |
|----------------------|--------------------------------------------------------------------------------------------------------------|
| 0                    | The method executed successfully.                                                                            |
| 58                   | The digital ID, role name, or the destination location is invalid due to being specified as an empty string. |
| 59                   | There is no certificate file or password available to the specified role name.                               |
| 60                   | The role name is not authorized or cannot be found.                                                          |
| 61                   | There was an error downloading the certificate file from the database.                                       |
| 79                   | The current user does not have the specified role.                                                           |

## ExtractCertificateByAuthorizedUser

### Syntax

```
ExtractCertificateByAuthorizedUser(digital_ID, auth_user, dest_location, &keystore_⇒  
pwd)
```

## Description

Use the `ExtractCertificateByAuthorizedUser` method to retrieve a digital certificate file to the specified location on the application server based on the specified digital ID and whether the current user is the specified user. This method also returns the encrypted password for the certificate file.

---

**Important!** Do not use this method in an implementation of the `IPT_PDFSIGNATURE_INT:IPDFSignature` interface class. Oracle reserves the right to modify this method in the future.

---

## Parameters

| <i><b>Parameter</b></i>  | <i><b>Description</b></i>                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------|
| <i>digital_ID</i>        | Specifies the digital ID for the certificate as a string value.                                       |
| <i>auth_user</i>         | Specifies a user ID as a string value.                                                                |
| <i>dest_location</i>     | Specifies the absolute URL to store the certificate file on the application server as a string value. |
| <i>&amp;keystore_pwd</i> | Specifies an already instantiated string variable to store the returned encrypted password.           |

## Returns

A return code as a numeric value:

| <i><b>Numeric Value</b></i> | <i><b>Description</b></i>                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------|
| 0                           | The method executed successfully.                                                                          |
| 54                          | The digital ID, user ID, or the destination location is invalid due to being specified as an empty string. |
| 55                          | There is no certificate file or password available to the specified user ID.                               |
| 56                          | The specified user ID is not authorized or cannot be found.                                                |
| 57                          | There was an error downloading the certificate file from the database.                                     |
| 78                          | The specified user ID is not the current user.                                                             |

## ExtractCertificateByDigitalID

### Syntax

```
ExtractCertificateByDigitalID(digital_ID, dest_location, &keystore_pwd)
```

### Description

Use the ExtractCertificateByDigitalID method to retrieve a digital certificate file to the specified location on the application server based on the specified digital ID. This method also returns the encrypted password for the certificate file.

---

**Important!** Do not use this method in an implementation of the IPT\_PDFSIGNATURE\_INT:IPDFSignature interface class. Oracle reserves the right to modify this method in the future.

---

### Parameters

| <i><b>Parameter</b></i>  | <i><b>Description</b></i>                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------|
| <i>digital_ID</i>        | Specifies the digital ID for the certificate as a string value.                                       |
| <i>dest_location</i>     | Specifies the absolute URL to store the certificate file on the application server as a string value. |
| <i>&amp;keystore_pwd</i> | Specifies an already instantiated string variable to store the returned encrypted password.           |

### Returns

A return code as a numeric value:

| <i><b>Numeric Value</b></i> | <i><b>Description</b></i>                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------|
| 0                           | The method executed successfully.                                                                |
| 50                          | The digital ID or the destination location is invalid due to being specified as an empty string. |
| 51                          | There is no certificate file or password for the specified digital ID                            |
| 52                          | The digital ID is inactive or cannot be found.                                                   |
| 53                          | There was an error downloading the certificate file from the database.                           |

| <b><i>Numeric Value</i></b> | <b><i>Description</i></b>                                   |
|-----------------------------|-------------------------------------------------------------|
| 56                          | The specified user ID is not authorized or cannot be found. |
| 79                          | The current user does not have the specified role.          |

## Example

```
&errCode = &oStore.ExtractCertificateByDigitalID(&digitalID, &sOutDestination, &psw⇒  
);  
&keystorePswd = &psw;  
  
If &errCode > 0 Then  
    &m_sError = &oStore.ErrorMessageDetail;  
End-If;
```

## getDigitalCertFileNameByDigitalID

### Syntax

```
getDigitalCertFileNameByDigitalID(digital_ID, &file_name)
```

### Description

Use the getDigitalCertFileNameByDigitalID method to return the name of the digital certificate file based on the specified digital ID.

---

**Important!** Do not use this method in an implementation of the IPT\_PDFSIGNATURE\_INT:IPDFSignature interface class. Oracle reserves the right to modify this method in the future.

---

### Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------|
| <i>digital_ID</i>       | Specifies the digital ID for the certificate as a string value.                                |
| & <i>file_name</i>      | Specifies an already instantiated string variable to store the returned certificate file name. |

### Returns

A return code as a numeric value:

| <b>Numeric Value</b> | <b>Description</b>                                |
|----------------------|---------------------------------------------------|
| 0                    | The method executed successfully.                 |
| 65                   | The digital ID was specified as the empty string. |
| 70                   | No file name is defined for this digital ID.      |

## Example

```

&errCode = &oStore.getDigitalCertFileNameByDigitalID(&digitalID, &tmpStr);
If &errCode > 0 Then /* failure */
    &m_sError = &oStore.ErrorMessageDetail;
Else /* success */
    ...
End-If;

```

## getDigitalIdBySigner

### Syntax

```
getDigitalIdBySigner(signer, &array_digitalIDs)
```

### Description

Use the getDigitalIdBySigner method to return a list of digital IDs that are available to the specified signer.

### Parameters

| <b>Parameter</b>          | <b>Description</b>                                                                           |
|---------------------------|----------------------------------------------------------------------------------------------|
| <i>signer</i>             | Specifies the ID of the signer as a string value.                                            |
| & <i>array_digitalIDs</i> | Specifies an already instantiated array of string to store the returned list of digital IDs. |

### Returns

A return code as a numeric value:

| <b>Numeric Value</b> | <b>Description</b>                |
|----------------------|-----------------------------------|
| 0                    | The method executed successfully. |

| <b><i>Numeric Value</i></b> | <b><i>Description</i></b>                     |
|-----------------------------|-----------------------------------------------|
| 62                          | The signer was specified as the empty string. |
| 63                          | No digital IDs are defined for this signer.   |

## getEncPassword

### Syntax

```
getEncPassword(digital_ID, &keystore_pwd )
```

### Description

Use the getEncPassword method to return the encrypted password for the specified digital ID.

---

**Important!** Do not use this method in an implementation of the IPT\_PDFSIGNATURE\_INT:IPDFSignature interface class. Oracle reserves the right to modify this method in the future.

---

### Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------|
| <i>digital_ID</i>       | Specifies the digital ID of the certificate as a string value.                              |
| & <i>keystore_pwd</i>   | Specifies an already instantiated string variable to store the returned encrypted password. |

### Returns

A return code as a numeric value:

| <b><i>Numeric Value</i></b> | <b><i>Description</i></b>                         |
|-----------------------------|---------------------------------------------------|
| 0                           | The method executed successfully.                 |
| 65                          | The digital ID was specified as the empty string. |
| 73                          | No password is defined for this digital ID.       |

## getListOfAuthorizedRoleNames

### Syntax

```
getListOfAuthorizedRoleNames(digital_ID, &array_auth_roles)
```

### Description

Use the `getListOfAuthorizedRoleNames` method to return the list of authorized roles for the specified digital ID.

### Parameters

| <i><b>Parameter</b></i>      | <i><b>Description</b></i>                                                                               |
|------------------------------|---------------------------------------------------------------------------------------------------------|
| <i>digital_ID</i>            | Specifies the digital ID for the certificate as a string value.                                         |
| <i>&amp;array_auth_roles</i> | Specifies an already instantiated array of string to store the returned list of authorized roles names. |

### Returns

A return code as a numeric value:

| <i><b>Numeric Value</b></i> | <i><b>Description</b></i>                                                                           |
|-----------------------------|-----------------------------------------------------------------------------------------------------|
| 0                           | The method executed successfully.                                                                   |
| 65                          | The digital ID was specified as the empty string.                                                   |
| 68                          | No authorized roles are defined for this digital ID.                                                |
| 69                          | The method executed successfully. There are <i>n</i> authorized roles for the specified digital ID. |

## getListOfAuthorizedUsers

### Syntax

```
getListOfAuthorizedUsers(digital_ID, &array_auth_users)
```

### Description

Use the `getListOfAuthorizedUsers` method to return the list of authorized users for the specified digital ID.

## Parameters

| <i><b>Parameter</b></i>      | <i><b>Description</b></i>                                                                            |
|------------------------------|------------------------------------------------------------------------------------------------------|
| <i>digital_ID</i>            | Specifies the digital ID for the certificate as a string value.                                      |
| <i>&amp;array_auth_users</i> | Specifies an already instantiated array of string to store the returned list of authorized user IDs. |

## Returns

A return code as a numeric value:

| <i><b>Numeric Value</b></i> | <i><b>Description</b></i>                                                                           |
|-----------------------------|-----------------------------------------------------------------------------------------------------|
| 0                           | The method executed successfully.                                                                   |
| 65                          | The digital ID was specified as the empty string.                                                   |
| 66                          | No authorized users are defined for this digital ID.                                                |
| 67                          | The method executed successfully. There are <i>n</i> authorized users for the specified digital ID. |

## getListOfDigitalId

### Syntax

```
getListOfDigitalId(&array_digitalIDs)
```

### Description

Use the getListOfDigitalId method to return the list of all digital IDs defined in the certification store.

## Parameters

| <i><b>Parameter</b></i>      | <i><b>Description</b></i>                                                                    |
|------------------------------|----------------------------------------------------------------------------------------------|
| <i>&amp;array_digitalIDs</i> | Specifies an already instantiated array of string to store the returned list of digital IDs. |

## Returns

A return code as a numeric value:

| <b><i>Numeric Value</i></b> | <b><i>Description</i></b>                              |
|-----------------------------|--------------------------------------------------------|
| 0                           | The method executed successfully.                      |
| 64                          | No digital IDs are defined in the certification store. |

## Example

```
&arrIds = CreateArrayRept("", 0);
&errCode = &secStore.getListOfDigitalId(&arrIds);
```

## getListOfSigner

### Syntax

```
getListOfSigner(&array_signers)
```

### Description

Use the getListOfSigner method to return the list of all signers defined in the certification store.

### Parameters

| <b><i>Parameter</i></b>   | <b><i>Description</i></b>                                                                |
|---------------------------|------------------------------------------------------------------------------------------|
| <i>&amp;array_signers</i> | Specifies an already instantiated array of string to store the returned list of signers. |

### Returns

A return code as a numeric value:

| <b><i>Numeric Value</i></b> | <b><i>Description</i></b>                          |
|-----------------------------|----------------------------------------------------|
| 0                           | The method executed successfully.                  |
| 72                          | No signers are defined in the certification store. |

## getSignerByDigitalId

### Syntax

```
getSignerByDigitalId(digital_ID, &signer)
```

## Description

Use the `getSignerByDigitalId` method to return the ID of the signer for the specified digital ID.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                            |
|-------------------------|--------------------------------------------------------------------------------------|
| <i>digital_ID</i>       | Specifies the digital ID for the certificate as a string value.                      |
| <i>&amp;signer</i>      | Specifies an already instantiated string variable to store the returned signer's ID. |

## Returns

A return code as a numeric value:

| <i><b>Numeric Value</b></i> | <i><b>Description</b></i>                         |
|-----------------------------|---------------------------------------------------|
| 0                           | The method executed successfully.                 |
| 65                          | The digital ID was specified as the empty string. |
| 71                          | No signer is defined for this digital ID.         |

## isDigitalCertValid

### Syntax

```
isDigitalCertValid(digital_ID)
```

### Description

Use the `isDigitalCertValid` to determine whether the digital ID is valid.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                   |
|-------------------------|---------------------------------------------|
| <i>digital_ID</i>       | Specifies the digital ID as a string value. |

### Returns

A Boolean value.

## DigitalCertStore Class Properties

The properties in this section are described in alphabetical order.

### ErrorMessageDetail

#### Description

Use this property to return the detailed error message as a string.

---

**Note:** This property is effectively read-only.

---

### ErrorMessageSet

#### Description

Use this property to return the defined message set number as a number value. This property should always return the value: 136.

---

**Note:** This property is effectively read-only.

---

## Understanding the IPDFSignature Interface Class

If the signer of the report needs to be determined dynamically at report run time (for example, the signer is to be determined based on the report data), then a custom application class based on the `IPT_PDFSIGNATURE_INT:IPDFSignature` interface must be used. However, if the report signer and digital certificate are known at report design time, then the certificate ID (referred to as the digital ID or signature ID) can be specified in the `psxp_signature_digitalID` property in the report definition. In this case, there is no need to implement a custom application class.

Consider these situations when determining whether to create a custom implementation of the `IPT_PDFSIGNATURE_INT:IPDFSignature` interface class:

- If the `psxp_signature_digitalID` property has a value, BI Publisher for PeopleSoft can use this value as the digital ID; therefore, you do not need to implement a custom application class.
- If a digital signature will be applied to the PDF report and the `psxp_signature_digitalID` property has no value, you must specify a custom implementation of the `IPT_PDFSIGNATURE_INT:IPDFSignature` interface class in the `psxp_signature_appclass` property.
- If you specify a value for both `psxp_signature_digitalID` and `psxp_signature_appclass`, the value of `psxp_signature_digitalID` is ignored and your application class will be used to determine the digital ID.

When you create an implementation of the `IPT_PDFSIGNATURE_INT:IPDFSignature` interface, you need your application class to return which digital ID is to be used for signing a specific report. When you implement this interface:

1. You must not set any of the four properties that are set for you by BI Publisher for PeopleSoft. These are: `OperatorId`, `ProcessInstance`, `ReportId`, and `secStore`.
2. In addition, you must not set two other properties that BI Publisher for PeopleSoft may set for you: `KeyFieldNames` and `KeyFieldValues`.

Those properties are populated from XML report file data as arrays of string when the report's `psxp_signature_mapfields` property has a value. Use those arrays to determine the signer for the specified report or report instance. In the case of a bursted report with a different signer for each instance, BI Publisher for PeopleSoft will call your application class separately for each report instance with these properties set to values specific to the report instance.

3. You must complete implementations of the interface's two abstract methods:
  - Implement `getSignatureId` to return the digital ID for the certificate that is to be used to sign a specific report.

See `getSignatureId` for an example implementation.

- Implement `getErrorString` to return a detailed error message to BI Publisher for PeopleSoft.

See `getErrorString` for more information and an example.

4. You must provide a value for the `UseSameSignatureForBursting` read-only property to indicate whether to use the same signer for bursted instances of this report.

See `UseSameSignatureForBursting` for an example of a technique to implement this.

5. You must provide the full path to your application class by specifying the `psxp_signature_appclass` property on the Global Properties page—for example:

```
MY_CUSTOM_PACKAGE:MY_SignedPDF
```

---

**Important!** If both the `psxp_signature_appclass` property and the `psxp_signature_digitalID` property are set, the `psxp_signature_digitalID` property is ignored.

---

The following example shows just the class definition block of an example implementation of an application class named `My_SignedPDF`:

```
class My_SignedPDF implements IPT_PDFSIGNATURE_INT:IPDFSignature
/* inputs */
property string ReportId; /* report Id that requires digital signature */
property string OperatorId; /* operator ID who runs a report */
property number ProcessInstance; /* Process Scheduler Process Instance */
property array of string KeyFieldNames; /* an array of field names that contain =>
key data */
property array of string KeyFieldValues; /* an array of field values that contain=>
n key data */
property PT_SECURITY_DIGITALCERTSTORE:DigitalCertStore secStore; /* Security App=>
class used to get Digital Certificates info from Security storage */

/* outputs */
property boolean UseSameSignatureForBursting get; /* If true the same signature =>
will be reused for all bursted instances */
method My_SignedPDF(); /* Constructor */
```

```

        method getSignatureId() Returns string; /* Signature Authority ID to be used for⇒
        signing a report */
        method getErrorString() Returns string; /* An error string, if any */

private
    instance string &m_errorStr;
    instance number &m_ErrorMessageSet;
    instance Boolean &mb_ReuseSignature;
end-class;

```

## IPDFSignature Class Methods

The methods in this section are described in alphabetical order.

### getErrorString

#### Syntax

```
getErrorString()
```

#### Description

Implement the `getErrorString` method to return a detailed error message to BI Publisher for PeopleSoft. A detailed error message can be internal to your implementation of the `getSignatureId` method or one that is passed back from an invocation of a `PT_SECURITY_DIGITALCERTSTORE:DigitalCertStore` method.

---

**Note:** This is an abstract method.

---

#### Parameters

None.

#### Returns

A String value.

#### Example

During execution of the `getSignatureId` method, the `&m_errorStr` instance variable is set to the message catalog entry corresponding to any error returned from invocations of `DigitalCertStore` methods. For example:

```

If ... Then
    &m_errorStr = MsgGet(&m_ErrorMessageSet, 64, "### Not able to retrieve a list of⇒

```

```
    digital IDs.");
End-If;
```

Then, this `&m_errorStr` instance variable is set as the return value for the `getErrorString` method:

```
method getErrorString
    /+ Returns String +/
    /+ Extends/implements IPT_PDFSIGNATURE_INT:IPDFSignature.getErrorString +/
    Return &m_errorStr;
end-method;
```

## getSignatureId

### Syntax

```
getSignatureId()
```

### Description

Implement the `getSignatureId` method to return the digital ID for the certificate that is to be used to sign a specific report. In this context, the certificate's digital ID is also referred to as the *signature ID*.

---

**Note:** This is an abstract method.

---

Use the six input properties set by BI Publisher for PeopleSoft to determine who is the signer of the specific report instance. In particular, the `KeyFieldNames` and `KeyFieldValues` arrays contain values that pertain to the specific report instance. Use methods of `PT_SECURITY_DIGITALCERTSTORE:DigitalCertStore` (accessed through the `secStore` property) to obtain information on certificates, signers, digital IDs, and authorized users defined in the certification store.

For example, use the following methods to determine digital IDs and signers:

- `getDigitalIdBySigner`
- `getListOfDigitalId`
- `getListOfSigner`

Use the `OperatorId` property and the following methods to determine whether the current user (the operator) is authorized to produce a report signed by this signer:

- `getListOfAuthorizedUsers`
- `getListOfAuthorizedRoleNames`

Finally, use the `isDigitalCertValid` method to determine whether a specific certificate in the certification store is valid.

## Parameters

None.

## Returns

A String value.

## Example

The following example implementation is incomplete in that it does not include the application logic that would determine the actual report signer, the digital IDs that can be used by that signer, or which of those digital IDs to use to sign this report. These determinations depend on specific business rules and requirements. However, once the signer and a digital ID are determined, this example invokes the `getListOfDigitalId` method to determine whether the specified digital ID exists in the certification store. If that check is successful, then this digital ID is returned as the ID for the certificate to be used to sign the report.

```
method getSignatureId
    /* Returns String */
    /* Extends/implements IPT_PDFSIGNATURE_INT:IPDFSignature.getSignatureId */

    /* DigitalCertStore instance (&secStore) is provided by BI Publisher, so this par⇒
t
is not required */
    If &secStore = Null Then
        &secStore = create PT_SECURITY_DIGITALCERTSTORE:DigitalCertStore();
        If &secStore = Null Then
            &m_errorStr = "Cannot create an instance of PT_SECURITY_DIGITALCERTSTORE:
DigitalCertStore.";
            Return "";
        End-If;
    End-If;
    &m_ErrorMessageSet = &secStore.ErrorMessageSet;

    Local string &psw, &digitalID, &retrievedID, &sOutDestination, &certPath;
    Local array of string &arrIds;
    Local number &errCode, &i;

    &digitalID = "";

    /* Insert the application logic to determine the report signer and his or her *⇒
/
    /* certificate IDs (digital IDs) here. For this example, the signer is assumed *⇒
/
    /* to be Joe Doe, and the digital ID retrieved for this user is "JoeDoe".      *⇒
/

    &retrievedID = "JoeDoe";

    /* Determine whether this digital ID is in the digital certification store. */
    &arrIds = CreateArrayRept("", 0);
    &errCode = &secStore.getListOfDigitalId(&arrIds);
    If &errCode > 0 Then
        &m_errorStr = &secStore.ErrorMessageDetail;
        Return "";
    End-If;

    If &arrIds.Len = 0 Then
        &m_errorStr = MsgGet(&m_ErrorMessageSet, 64, "### Not able to retrieve a list⇒
```

```

of digital IDs.");
    Return "";
End-If;

For &i = 1 To &arrIds.Len
    If &arrIds [&i] = &retrievedID Then
        &digitalID = &retrievedID;
        Return &digitalID;
    End-If;
End-For;

&m_errorStr = MsgGet(&m_ErrorMessageSet, 71, "### Not able to retrieve signer fo⇒
r
this digital ID", &retrievedID);
    Return "";
end-method;

```

# IPDFSignature Class Properties

The properties in this section are described in alphabetical order.

## KeyFieldNames

### Description

Use this property to retrieve an array of string representing key field names to be used to determine the signing authority for the report. These key field names are set by BI Publisher for PeopleSoft.

---

**Note:** This property is effectively read-only.

---

### Example

```

For &i = 1 To &KeyFieldNames.Len
    WriteToLog(%ApplicationLogFence_Level1, "&KeyFieldNames[ " | String(&i) | "]: " ⇒
    | &KeyFieldNames [&i]);
End-For;
For &i = 1 To &KeyFieldValues.Len
    WriteToLog(%ApplicationLogFence_Level1, "&KeyFieldValues[ " | String(&i) | "]: "⇒
    | &KeyFieldValues [&i]);
End-For;

```

## KeyFieldValues

### Description

Use this property to retrieve an array of string representing key field values to be used to determine the signing authority for the report. These key field values are set by BI Publisher for PeopleSoft.

---

**Note:** This property is effectively read-only.

---

### Example

```
For &i = 1 To &KeyFieldNames.Len
    WriteToLog(%ApplicationLogFence_Level1, "&KeyFieldNames[ " | String(&i) | "]: " =>
    | &KeyFieldNames [&i]);
End-For;
For &i = 1 To &KeyFieldValues.Len
    WriteToLog(%ApplicationLogFence_Level1, "&KeyFieldValues[ " | String(&i) | "]: "=>
    | &KeyFieldValues [&i]);
End-For;
```

## OperatorId

### Description

Use this property to retrieve a string representing the current user ID as set by BI Publisher for PeopleSoft.

---

**Note:** This property is effectively read-only.

---

## ProcessInstance

### Description

Use this property to retrieve a number representing the process ID as set by BI Publisher for PeopleSoft.

---

**Note:** This property is effectively read-only.

---

## ReportId

### Description

Use this property to retrieve a string representing the report ID as set by BI Publisher for PeopleSoft.

---

**Note:** This property is effectively read-only.

---

## secStore

### Description

Use this property to retrieve the DigitalCertStore object instantiated by BI Publisher for PeopleSoft.

---

**Note:** This property is effectively read-only.

---

## UseSameSignatureForBursting

### Description

Use this property to return a Boolean value indicating whether to use the same signature if this is a bursted report.

---

**Important!** This property has been identified as one of the values to be output by your implementation of the interface. However, the property is also defined as read-only, and therefore cannot be set or assigned directly. See the following code excerpt on how to set the value of a private instance variable to be returned as the value of this property.

---

### Example

UseSameSignatureForBursting is defined as read-only, and therefor cannot be set directly. However, as demonstrated in the following code excerpt, you can define a private instance variable. In the following example, `&mb_ReuseSignature` is set to True or False as needed within the application logic. Then, a `get` definition is used to return the value of `&mb_ReuseSignature` as the value for the UseSameSignatureForBursting property.

```
class My_SignedPDF implements IPT_PDFSIGNATURE_INT:IPDFSignature
...

    property boolean UseSameSignatureForBursting get; /* If true the same signature =>
will be reused for all bursted instances */
...

private
...

    instance Boolean &mb_ReuseSignature;
end-class;
...

/***** Application logic *****/
Rem if signer is the same for all bursted instances;
If <some_condition> Then
    &mb_ReuseSignature = True;
Else
    Rem if signer is different and depends on some bursted reports values;
    &mb_ReuseSignature = False;
End-If;
/***** Application logic *****/
...

get UseSameSignatureForBursting
/+ Returns Boolean +/
/+ Extends/implements IPT_PDFSIGNATURE_INT:IPDFSignature.UseSameSignatureForBurs=>
```

```

ting +/
    Return &mb_ReuseSignature;
end-get;

```

## Understanding the BIP\_EMAIL\_DATA Interface Class

There may be situations where you want to distribute reports using email to recipients that do not have PeopleSoft user profiles. PeopleTools enables you to distribute bursted and non-bursted BI Publisher reports to external users whose email addresses are stored in the database, file server, or another location.

You create an implementation of the IPT\_BIP\_EXT\_EMAIL\_INT:BIP\_EMAIL\_DATA interface class to retrieve the stored distribution lists. Then, your implemented application class is specified in the psxp\_ext\_email\_appclass property of the report definition.

When you create an implementation of the IPT\_BIP\_EXT\_EMAIL\_INT:BIP\_EMAIL\_DATA interface, you need your application class to return an array of email addresses. When you implement this interface:

1. You must not set any of the three properties that are set for you by BI Publisher for PeopleSoft. These are: ReportName, BurstFieldName, and BurstFieldValue.
2. Implement the BIP\_EMAIL\_DATA constructor method to initialize the error message set to your custom implementation.

See [BIP\\_EMAIL\\_DATA](#) for an example implementation.

3. You must complete implementations of the interface's two abstract methods:

- Implement getEmailAddressArray to return the array of external email addresses.

See [getEmailAddressArray](#) for an example implementation.

- Implement getErrorString to return a detailed error message to BI Publisher for PeopleSoft.

See [getErrorString](#) for more information and an example.

4. You must provide the full path to your application class by specifying the psxp\_ext\_email\_appclass property on the Global Properties page—for example:

```
MY_CUSTOM_PACKAGE:MY_BIP_EMAIL_DATA
```

The following example shows just the class definition block of an example implementation of an application class named MY\_BIP\_EMAIL\_DATA:

```

import IPT_BIP_EXT_EMAIL_INT:BIP_EMAIL_DATA;

class MY_BIP_EMAIL_DATA implements IPT_BIP_EXT_EMAIL_INT:BIP_EMAIL_DATA
/* inputs */
    property string ReportName; /* Report Name */
    property string BurstFieldName; /* burst field name */
    property string BurstFieldValue; /* burst field value */

/* outputs */
    method MY_BIP_EMAIL_DATA(); /*Class constructor */
    method getEmailAddressArray() Returns array of string; /* String array of email =>
recipient addresses */
    method getErrorString() Returns string; /* An error string, if any */

```

```
private
    /* those instance variables could be used for data retrieval and validation */
    instance string &m_errorStr;
    instance number &m_ErrorMessageSet;

end-class;
```

## BIP\_EMAIL\_DATA Class Methods

The methods in this section are described in alphabetical order.

### Related Links

[Understanding the BIP\\_EMAIL\\_DATA Interface Class](#)

## BIP\_EMAIL\_DATA

### Syntax

```
BIP_EMAIL_DATA()
```

### Description

Implement the BIP\_EMAIL\_DATA class constructor to initialize the BIP\_EMAIL\_DATA object with a custom message set number.

### Parameters

None.

### Returns

None.

### Example

```
method BIP_EMAIL_DATA
    &m_errorStr = "";
    &m_ErrorMessageSet = 235;
end-method;
```

## getEmailAddressArray

### Syntax

```
getEmailAddressArray()
```

### Description

Implement the getEmailAddressArray method return an array of external email addresses to BI Publisher for PeopleSoft.

---

**Note:** This is an abstract method.

---

### Parameters

None.

### Returns

An array of String.

### Example

In the following example, DEPTID is used as the burst field. The email addresses corresponding to the specified DEPTID burst value are retrieved from the PS\_EMPL\_MD\_EMAIL table and returned in the array.

```
method getEmailAddressArray
    /* Returns Array of String */
    /* Extends/implements IPT_BIP_EXT_EMAIL_INT:BIP_EMAIL_DATA.getEmailAddressArray =>
+
    Local array of string &aEmailAddressArray = CreateArrayRept("", 0);
    Local string &sql;
    Local string &sEmail;
    Local string &sDeptId;
    Local SQL &SQLObj;
    Local number &i;

    If &ReportName = "" Or
        &ReportName = " " Then
        &m_errorStr = "No Report Name is specified";
        Return Null;
    End-If;
    try

        Evaluate Upper(LTrim(RTrim(&ReportName)))
        When "CQ_EMAILS_MD"
        When "CQEMAILNB_MD"

        When-Other
            &m_errorStr = "Incorrect user email data application class is used for the=>
report - " | &ReportName;
        Return Null;
    End-Evaluate;
```

```

        If &BurstFieldName <> "" Then
            WriteToLog(%ApplicationLogFence_Level1, "App Plugin - BurstFieldName: " | =>
&BurstFieldName);
            WriteToLog(%ApplicationLogFence_Level1, "App Plugin - BurstFieldValue: " | =>
&BurstFieldValue);
        End-If;

        If &BurstFieldName <> "" Then
            If Not (Upper(&BurstFieldName) = "DEPTID" Or
                Upper(&BurstFieldName) = "A.DEPTID") Then
                &m_errorStr = "&BurstFieldName is not equal to DEPTID (A.DEPTID)";
                Return Null;
            End-If;
        End-If;
        &sDeptId = &BurstFieldValue;

        If &BurstFieldName <> "" Then
            &sql = "SELECT A.EMAILID FROM PS_EMPL_MD_EMAIL A WHERE A.EFFDT = ( SELECT =>
MAX(B.EFFDT) FROM PS_EMPL_MD_EMAIL B WHERE A.EMPLID = B.EMPLID AND A.DEPTID = B.DEP=>
TID AND B.EFFDT <=%CurrentDateIn) AND A.DEPTID =  ' ' | &sDeptId | ' '";
        Else
            &sql = "SELECT A.EMAILID FROM PS_EMPL_MD_EMAIL A  WHERE A.EFFDT = ( SELECT=>
MAX(B.EFFDT) FROM PS_EMPL_MD_EMAIL B WHERE A.EMPLID = B.EMPLID AND A.DEPTID = B.DE=>
PTID AND B.EFFDT <=%CurrentDateIn)";
        End-If;

        &SQLObj = CreateSQL();
        &SQLObj.Open(&sql);
        &SQLObj.ReuseCursor = True;
        While &SQLObj.Fetch(&sEmail)
            If All(&sEmail) Then
                &aEmailAddressArray.Push(&sEmail);
            End-If;
        End-While;

        If &SQLObj.IsOpen Then
            &SQLObj.Close();
        End-If;
        Return &aEmailAddressArray;

    catch Exception &Err
        Local string &sSub1, &sSub2, &sSub3, &sSub4, &sSub5;
        Evaluate &Err.SubstitutionCount
        When > 4
            &sSub5 = &Err.GetSubstitution(5);
        When > 3
            &sSub4 = &Err.GetSubstitution(4);
        When > 2
            &sSub3 = &Err.GetSubstitution(3);
        When > 1
            &sSub2 = &Err.GetSubstitution(2);
        When > 0
            &sSub1 = &Err.GetSubstitution(1);
        End-Evaluate;
        &m_errorStr = MsgGet(&Err.MessageSetNumber, &Err.MessageNumber, &Err.ToString=>
(), &sSub1, &sSub2, &sSub3, &sSub4, &sSub5);
        Return Null;
    end-try;

end-method;

```

## getErrorString

### Syntax

```
getErrorString()
```

### Description

Implement the `getErrorString` method to return a detailed error message to BI Publisher for PeopleSoft. The detailed error message should be internal to your implementation of the `getEmailAddressArray` method.

---

**Note:** This is an abstract method.

---

### Parameters

None.

### Returns

A String value.

### Example

During execution of the `getEmailAddressArray` method, the `&m_errorStr` instance variable is set to a literal string in some cases or to the message catalog entry. For example:

```
&m_errorStr = MsgGet(&Err.MessageSetNumber, &Err.MessageNumber, &Err.ToString(), =>
&sSub1, &sSub2, &sSub3, &sSub4, &sSub5);
```

Then, this `&m_errorStr` instance variable is set as the return value for the `getErrorString` method:

```
method getErrorString
    /+ Returns String +/
    /+ Extends/implements IPT_BIP_EXT_EMAIL_INT:BIP_EMAIL_DATA.getErrorString +/

    Return &m_errorStr;
end-method;
```

---

## BIP\_EMAIL\_DATA Class Properties

The properties in this section are described in alphabetical order.

### Related Links

[Understanding the BIP\\_EMAIL\\_DATA Interface Class](#)

## BurstFieldName

### Description

Use this property to retrieve a string set by BI Publisher for PeopleSoft representing the name of the burst field used to generate the report.

---

**Note:** This property is effectively read-only.

---

## BurstFieldValue

### Description

Use this property to retrieve a string set by BI Publisher for PeopleSoft representing the burst value used to generate the report.

---

**Note:** This property is effectively read-only.

---

## ReportName

### Description

Use this property to retrieve a string representing the report ID as set by BI Publisher for PeopleSoft.

---

**Note:** This property is effectively read-only.

---

---

## BI Publisher Classes Example

The following example provides a complete example of the code first, then goes through the program line by line.

## Generating and Publishing a Report

In the following example, a report is created from an existing report definition. It is populated with an already instantiated and populated XmlDocument object, then published.

The following is the complete code sample: the steps explain each line.

```
import PSXP_RPTDEFNMANAGER:ReportDefn;

Local string &sFileName = "c:\path\filename.xml";
Local string &rptDefnId = "Financial";
Local string &LanguageCode = "ENG";
Local date &effdt = Date(20090821);
Local string &outputfmt = "HTM";

Local string &folderName = "General";
Local string &serverName = "PSNT";
Local PSXP_RPTDEFNMANAGER:ReportDefn &rptDefn;
```

```

&rptDefn = create PSXP_RPTDEFNMANAGER:ReportDefn(&rptDefnId);
&rptDefn.Get();
&rptDefn.SetRuntimeDataXMLFile(&sFileName);
&rptDefn.ProcessReport("", &languageCd, &effdt, &outputfmt);

&rptDefn.Publish(&serverName, "", &folderName, &PID);

```

To generate and publish a report:

1. Import the appropriate application class.

Because this program generates and publishes a report, you need to import the report manager definition class.

```
import PSXP_RPTDEFNMANAGER:ReportDefn;
```

2. Initialize variables.

The variable declaration strings not only specify values for the variables, but give them type and scope as well. This can be very useful when debugging.

```

Local string &sFileName = "c:\path\filename.xml";
Local string &rptDefnId = "Financial";
Local string &LanguageCode = "ENG";
Local date &effdt = Date(20090821);
Local string &outputfmt = "HTM";

Local string &folderName = "General";
Local string &serverName = "PSNT";
Local PSXP_RPTDEFNMANAGER:ReportDefn &rptDefn;

```

3. Instantiate the report definition object and initialize it.

After you instantiate a report definition object, you must initialize it and populate it using the Get method.

```

&rptDefn = create PSXP_RPTDEFNMANAGER:ReportDefn(&rptDefnId);
&rptDefn.Get();

```

4. Specify the data for the report.

This report uses an XML file as the data source, so you must specify the runtime data source for the report before you process it.

```
&rptDefn.SetRuntimeDataXMLFile(&sFileName);
```

5. Process the report.

You must process the report, generate a version of it for the report repository, before you can distribute the report.

```
&rptDefn.ProcessReport("", &languageCd, &effdt, &outputfmt);
```

6. Publish the report.

After you've generated the report, you may want to publish it to another location.

```
&rptDefn.Publish(&serverName, "", &folderName, &PID);
```

# Business Interlink Class

---

## Understanding Business Interlink Class

The PeopleSoft Business Interlink framework provides a gateway for PeopleSoft applications to the services of any external system. This framework enables any PeopleSoft component (that is, a page, an Application Engine program, and so on) to integrate with any external system in near real-time and batch modes.

This framework enables a PeopleCode program to map the input and outputs of a Business Interlink definition to PeopleCode variables and record fields, then, using an Interlink object, call the Interlink plug-in, which in turn calls the external system, passes the information to the external system, and returns values to the PeopleCode program.

This documentation describes only the Interlink object portion of the PeopleSoft Business Interlink framework.

Each Interlink object is based on a Business Interlink definition, which is created in Application Designer. An Interlink object can be based on only a single Business Interlink definition.

---

**Note:** PeopleSoft Business Interlinks is a deprecated product. The Business Interlinks class currently exists for backward compatibility only. For new integrations, use Integration Broker instead.

---

### Related Links

[Understanding Message Classes](#)

---

## Using the Interlink Object

After you instantiate an Interlink object, use the Interlink object to:

- Populate the input buffer
- Send the data to the Interlink plug-in (by using the Execute method)
- Fetch the outputs from the buffer
- Check for status and error messages

After the Business Interlink object is instantiated, you can assign values from constants, PeopleSoft variables, or record fields to the inputs of that Business Interlink object.

When you execute the Business Interlink object, it loads the appropriate Business Interlink Plug-in and passes itself to that Business Interlink Plug-in. The Business Interlink Plug-in processes the input data,

passing the input values of the Business Interlink object to the external system and then fills the output values of the Business Interlink object (if there are outputs).

---

## Deciding Which Methods to Use

After you create your Business Interlink definition, you must use PeopleCode to instantiate an Interlink object and execute the Business Interlink plug-in. This PeopleCode can be long and complex. Rather than write it directly, you can drag and drop the Business Interlink definition from the Application Designer Project View into an open PeopleCode edit pane. Application Designer analyzes the definition and generates initial PeopleCode as a template, which you can modify.

### Related Links

[Understanding Business Interlink Class](#)

## Executing the Business Interlink Object

In most cases, you must use the Execute method to execute the Business Interlink object. However, for bulk input, you can use the BulkExecute method instead.

The Execute and BulkExecute methods return a value you can use for status and error checking.

## Supporting Batch Input and Output

The methods discussed in this section, except for BulkExecute, add input values to the Business Interlink object one set, or row, at a time. The call to the Business Interlink Plug-in occurs only once. All the input data is passed with the single Execute. All output is returned as batch as well. The methods then get the output values one set, or row, at a time.

If you're sending a large amount of data to the input buffers, instead of adding one input row at a time, you might write the data to a staging table, then use the BulkExecute method. This method automatically executes; that is, you don't have to use the Execute method. It also automatically fills the output record specified with the method with all the output values in every row in the output buffer if you've specified an output record.

## Supporting Rowsets

If your data is mapped into rowsets, you may want to use the InputRowset method. This method takes a standard rowset object to populate the inputs for the Business Interlink object. You can use the FetchIntoRowset method to repopulate the rowset with new data.

## Using the Flat Table Methods

If your data is in a flat table structure, you can use the flat table methods. AddInputRow adds rows of input to the Business Interlink object; FetchNextRow fetches rows of output from the Business Interlink object.

## Supporting Dynamic Output

A Business Interlink can have dynamic output, meaning that the outputs for a Business Interlink object are changeable in data type or number of outputs.

Business Interlinks supplies a set of methods to support dynamic output. These methods enable you to interrogate the output buffer programmatically to determine the number of fields (columns), their types, and their values.

The following methods support dynamic output:

- `GetFieldCount`
- `GetFieldType`
- `GetFieldValue`
- `MoveFirst`
- `MoveNext`

Use the `MoveFirst` method to move to the first column, first row of the output buffer, and within a loop, use the `MoveNext` method to move to each row on the output buffer.

Within a `MoveFirst` (or `MoveNext`) loop, use the `GetFieldCount` method to get the number of columns in the output buffer, which is also the number of outputs for this Business Interlink object. Then you can extract the outputs from the buffer in a loop.

Within the `GetFieldCount` loop, use `GetFieldName` to get the name of the output, `GetFieldValue` to get the value of the output (which will be returned as a string), and `GetFieldType` to get the type of the output (if the output is not a string type, you will convert it to this type).

See [`GetFieldCount`](#), [`GetFieldType`](#), [`GetFieldValue`](#), [`MoveFirst`](#), [`MoveNext`](#).

## Using Hierarchical Data (BIDocs)

A Business Interlink can have hierarchical data. Think of the structure as a tree, with a root doc, node docs, and values. The hierarchical data methods and objects are also referred to as BIDocs.

### Input Structures

The following shows an example of an input structure:

This example illustrates the fields and controls on the Example input structure. You can find definitions for the fields and controls later on this page.

The *root doc* is Calculate Cost(Domestic). A root doc can contain both values and node docs.

The *node docs* are From, To, Package\_Info and Account\_Info\_List. Each node can contain both values and child nodes. Node docs can be further described as either:

- *Simple node docs* have only one set of values for a single instance of a root doc. From, To, Package\_Info are all simple node docs.
- *List node docs* can contain more than one set of values for a single instance of a root doc. Account\_Info\_List is a list node doc.

The values in the From node are OriginCountry, OriginPostal\_Code, and Ship\_Date. The value within the root node is input\_param1. Notice that there are values both within the root doc and within node docs.

Business Interlinks support hierarchical input structures with the following methods:

- GetInputDocs
- AddDoc
- AddValue
- AddNextDoc

The GetInputDocs method returns a reference to the root doc of an input structure. From the previous example, it returns a reference to Calculate Cost(Domestic).

Use the AddDoc method to access the node docs. From the previous example, you would use AddDoc to access the From, To, Package\_Info, and Account\_Info\_List node docs. If any of these nodes contained nodes, you could use AddDoc to access those as well.

Use the AddValue method to set values. From the previous example, you would use AddValue to set the value for input\_param1, OriginCountry, OriginPostal\_Code, and Ship\_date. You must call AddDoc on a node before you can call AddValue for its values.

Use the AddNextDoc method to access the following:

- If a node doc is a list, that is, it can contain more than one set of values, use AddNextDoc to reference the next set of values.

- To add another copy of the entire input structure, use `AddNextDoc` to return a reference to the next root doc.

The following code example sets values for the node doc `From`, which is a simple node doc. It also sets the values for `Account_Info_List`, which is a list node doc.

```
&Calc_Input = &QE_COST.GetInputDocs("");

&FromDoc = &Calc_Input.AddDoc("From");
&ret = &FromDoc.AddValue("OriginCountry", "United States");
&ret = &FromDoc.AddValue("OriginPostal_Code", &ORIGIN);
&ret = &FromDoc.AddValue("Ship_Date", &SHIPDATE);

&Account_Doc = &Calc_Input.AddDoc("Account_Info_List");
&ret = &Account_Doc.AddValue("Account_Number", "CT-8001");
&ret = &Account_Doc.AddValue("Meter_Number", &METER);
&ret = &Account_Doc.AddValue("Service_Type", &MODE);

/* add next set of values in list */

&ret = &Calc_Input.AddNextDoc();
&ret = &Account_Doc.AddValue("Account_Number", "CT-8002");
&ret = &Account_Doc.AddValue("Meter_Number", &METER);
&ret = &Account_Doc.AddValue("Service_Type", &MODE);
```

## Output Structures

The following shows an example of an output structure:

This example illustrates the fields and controls on the Example output structure. You can find definitions for the fields and controls later on this page.

The *root doc* is `Calculate Cost(Domestic)`.

The *node docs* are `Service_Rate` and `output_param2_List`. Each node can contain both values and child nodes. Node docs can be further described as either:

- *Simple node docs* have only one set of values for a single instance of a root doc. `Service_Rate` is a simple node doc.
- *List node docs* can contain more than one set of values for a single instance of a root doc. `output_param2_List` is a list node doc.

The values in the `Service_Rate` node are `Service_Type`, `Rate`, and in the `output_param2_List` node, `output_member1` and `output_member2`, and within the root node, `output_param1`.

Business Interlinks support hierarchical output structures with the following methods:

- `GetOutputDocs`

- GetDoc
- GetNextDoc
- GetPreviousDoc
- GetStatus
- GetValue
- GetCount
- MoveToDoc

The GetOutputDocs method returns a reference to the root doc of an output structure. From the previous example, it returns a reference to Calculate Cost(Domestic).

Use the GetDoc method to access node docs. From the previous example, you would use GetDoc to access the Service\_Rate or output\_param2\_List node docs. If any of these nodes contain nodes, you use GetDoc to access those as well.

Use the GetValue method to retrieve the values. From the previous example, you would use GetValue to retrieve the values for output\_param1, and for the Service\_Rate node, to get the values Service\_Type, Rate, output\_member1, and output\_member2. You must call GetDoc on a node before you can call GetValue for its values.

Use the GetNextDoc (or GetPreviousDoc) method to access the following:

- A reference to the next (or previous, respectively) root doc.
- If a node doc is a list, that is, can contain more than one set of values, use GetNextDoc to reference the next node doc in the list (or GetPreviousDoc to access the previous node doc in the list.)

Use the GetCount method to return either the number of docs in a list node doc, or the number of root docs. In the example, you can count the number of Calculate Cost(Domestic) nodes or the number of output\_param2\_list nodes.

Use the MoveToDoc method to move to a particular doc at the root level or to a list node doc. In the example, you can move to a Calculate Cost(Domestic) node or to an output\_param2\_list\_node.

The following code example gets values for the node docs Service Rate, which is a simple node doc. It also sets the values for output\_param2\_List, which is a list node doc.

```
&Calc_Input = &QE_COST.GetOutputDocs("");

&Service_Rate_Doc = &Calc_Input.GetDoc("Service_Rate");
&ret = &Service_Rate_Doc.GetValue("Service_Type", "Overnight");
&ret = &Service_Rate_Doc.GetValue("Rate", "50.00");

&Out_Param_Doc = &Calc_Input.GetDoc("output_param2_List");
&ret = &Out_Param_Doc.GetValue("output_member1", "value1");
&ret = &Out_Param_Doc.GetValue("output_member2", "value2");

/* get next set of values in list */

&Account_Doc = &Out_Param_Doc.AddNextDoc();
&ret = &Out_Param_Doc.GetValue("output_member1", "value3");
&ret = &Out_Param_Doc.GetValue("output_member2", "value4");
```

---

## Using the Incoming Business Interlink Methods and Properties

The incoming Business Interlink methods enable you to parse an XML request and build an XML response.

The incoming Business Interlink uses a set of methods and functions.

The `GetContentBody` Request object method converts the request content into an XML string. You can then use this string with the `GetBiDoc` function to create a BiDocs structure from it that is the same shape and contains the same data as the XML document contained in the XML string.

After you have the BiDocs structure containing the XML request, you can:

- Use the `GetNode` method to get one of the XML elements.
- Use the `NodeType` method to get the type of the node (element, processing instruction, comment).
- Use the `NodeName` property to get the name of the element.
- Use the `NodeValue` property to get the value of the element.

You can also use the standard BiDocs methods (such as `GetDoc`, `GetValue`) to retrieve information from this BiDocs object.

When an XML element contains attributes, the `AttributeCount` property gets the number of attributes, the `GetAttributeName` method gets the name of an attribute, and the `GetAttributeValue` method gets the value of an attribute.

To build an XML response, you can use the `GetBiDocs` function to create a blank BiDocs structure. To create the XML structure within that BiDocs, use `CreateElement` to create an XML tag, `AddComment` to add an XML comment, `AddAttribute` to add an attribute to an XML tag, and `AddProcessInstruction` to add a processing instruction (the first tag of the XML response).

Use the `GenXMLString` method to create an XML string from the BiDocs structure. Then you can use the `Write Response` method to write the response to the HTTP response string.

## Understanding the State of an Interlink Object

PeopleSoft Business Interlink API that are run on the application server should be stateless, that is, if you want to save information from one call of the Interlink object to the next, you have to do it yourself by writing the relevant information to the database. If you use the `Execute` method more than once within a single PeopleCode event (that is, if you have the `Execute` method in some sort of loop) the state is preserved. After you leave the event, any state associated with the Interlink object is lost.

You should create only one Business Interlink object, that is, you should only use the `GetInterlink` function once. After that, you can load it with data, pass the data to the Interlink plug-in (using `Execute`) and fetch output data as many times as you need.

---

## Using Business Interlink with Application Engine

In a regular PeopleCode program, you can only declare a Business Interlink object as local. However, in an Application Engine program, you can declare a Business Interlink object as global. Instantiating a Business Interlink object once as a global saves on the significant overhead of reinstantiating a local object for every iteration of PeopleCode called in a loop.

- Global Business Interlink objects can only be used in Application Engine PeopleCode programs because PeopleCode that runs on an application server must be stateless.
- When a restartable Application Engine program abends, global Business Interlink objects that were instantiated before the last checkpoint are automatically reinstantiated at restart. So the object will be available, even though no call has been made to `GetInterlink` in the restarted process. However, the associated Business Interlink data buffers are *not* recovered, so the Application Engine program must be written such that these buffers are empty whenever a checkpoint is taken.
- Business Interlink objects should *not* be declared as global unless they are used in several PeopleCode actions, or in a PeopleCode action that is called in a loop. Only in these instances is the overhead of doing a checkpoint worthwhile.

---

## Using the Data Type of a Business Interlink Object

You should declare a Business Interlink object using the data type `Interlink`. For example,

```
Local Interlink &MYBI;
```

Declare hierarchical data as type `BIDocs`. For example:

```
Local BIDocs &OutlistDoc;
```

---

**Note:** `BIDocs` and `Interlink` objects used in PeopleCode programs run on the application server can be declared only as type `Local`. You can declare `Interlinks` as `Global` only in an Application Engine program.

---

---

## Understanding the Scope of a Business Interlink Object

A Business Interlink object can be instantiated from PeopleCode.

This object can be used anywhere you have PeopleCode, that is, in an application class, Application Engine PeopleCode, record field PeopleCode, and so on.

# Business Interlink Class Methods

In this section, we discuss the Business Interlink class methods. The methods are discussed in alphabetical order.

## AddDoc

### Syntax

```
AddDoc (docname)
```

### Description

The AddDoc method adds a document to an input structure. The added document is an input parameter for a Business Interlink object that is not of simple type (such as integer or string). You must add the document to the input structure before you can add values to its members with AddValue.

### Parameters

| Parameter | Description                                                 |
|-----------|-------------------------------------------------------------|
| docname   | The name of the document that AddDoc adds to the structure. |

### Returns

The document added to the BIDocs input document.

### Example

In the following example, the input structure for Calculate Cost, or the root level document, is created with the GetInputDocs method. (To create, or add, more input structures, use AddNextDoc.) The Calculate Cost input parameter From is a document, so the AddDoc method adds it to the input document.

```
Local Interlink &QE_COST;
Local BIDocs &CalcCostIn;
Local BIDocs &FromDoc, &ToDoc, &PackageDoc, &AccountDoc;
Local number &ret, &retinput;

&QE_COST = GetInterlink(Interlink.QE_COST_EX);

&CalcCostIn = &QE_COST.GetInputDocs("");

&ret = &CalcCostIn.AddValue("input_param1","value");
&FromDoc = &CalcCostIn.AddDoc("From");
&ret = &FromDoc.AddValue("OriginCountry", "United States");
&ret = &FromDoc.AddValue("OriginPostal_Code", &ORIGIN);
&ret = &FromDoc.AddValue("Ship_Date", &SHIPDATE);

/* Call AddDoc and AddValue for To, Package_Info, and Account_Info_List (code not shown) */
```

The following shows the input structure for this example. It contains five input parameters: `input_param1`, `From`, `To`, `Package_Info`, and `Account_Info_List`. This is a version of the Federal Express plug-in that was modified for this example (`input_param1` was added, `Account_Info` was modified to be a list).

[AddNextDoc](#)

## AddInputRow

### Syntax

```
AddInputRow(inputname, value)
```

where *inputname* and *value* are in matched pairs, in the form:

```
inputname1, value1 [, inputname2, value2] . . .
```

### Description

The `AddInputRow` method adds a row of input data (*value*) from PeopleCode variables or record fields for the Business Interlink object executing the method. These must be entered in matched pairs, that is, every input name must be followed by its matching value.

---

**Note:** The input *name*, not the input path, of the interface definition is used for this method.

---

There must be an input name for every input parameter defined in the interface definition used to instantiate the Business Interlink object.

If you specify a record field that is not part of the record the PeopleCode program is associated with, you must use *recname.fieldname* for that value.

You can specify default values for every input name in the interface definition (created in Application Designer.) These values are used if you create a PeopleCode "template" by dragging the interface definition from the Project window in Application Designer to an open PeopleCode editor window.

## Parameters

| <i>Parameter</i> | <i>Description</i>                                                                                                                                                     |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| inputname        | Specify the input name. There must be one <i>inputname</i> for every input name defined in the interface definition used to instantiate the Business Interlink object. |
| value            | Specify the value for the input name. This can be a constant, a variable, or a record field. Each <i>value</i> must be paired with an <i>inputname</i> .               |

## Returns

A Boolean value: True if the input values were successfully added. Otherwise, it returns False.

## Example

In the following example, the Business Interlink object name is SRA\_ALL\_1, and the input name, such as ship\_site\_name, are being bound to record fields, such as QE\_RP\_SITENAME or VENDOR\_INFO.QE\_RP\_PROMISEDATE, to variables like &PARTNAME, or to literals, like 10 for quantity.

```
&SRA_ALL_1.AddInputRow("ship_site_name", QE_RP_SITENAME,
    "promise_date", VENDOR_INFO.QE_RP_PROMISEDATE,
    "request_date", QE_RP_ORDERREQDATE,
    "subline_site_name", QE_RP_SITENAME,
    "quantity", 10,
    "part_name", &PARTNAME,
    "site_name", INV_LOCATIONS.QE_RP_SITENAME);
```

## Related Links

[Execute](#)

“GetInterlink” (PeopleCode Language Reference)

## AddNextDoc

### Syntax

```
AddNextDoc()
```

### Description

The AddNextDoc method adds a document to one of the following levels:

- The root level of the input structure for a Business Interlink object. You create a reference to this level with the GetInputDocs method.
- When a document within the input structure is a list, AddNextDoc adds another document to the list. If you use AddNextDoc on a document that is not a list, AddNextDoc fails and returns an error.

## Parameters

None.

## Returns

This method returns an integer. The values are:

| <b>Value</b> | <b>Description</b>                                                                                                                                                                                                                                                                   |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | eNoError. The method succeeded.                                                                                                                                                                                                                                                      |
| 1            | eNO_DOCUMENT. The document referenced by this method does not exist.                                                                                                                                                                                                                 |
| 2            | eDOCLIST_OUT_RANGE. You tried to access a document in a list, but the document list is out of range. For example, if a document list contains five documents, and then you call GetDoc/GetOutputDocs once, you can call GetNextDoc four times; the fifth time results in this error. |
| 3            | eDOCUMENT_UNINITIALIZED. Internal error.                                                                                                                                                                                                                                             |
| 4            | eNOT_DOCUMENTTYPE. You tried to perform an operation upon a parameter that is not a document type.                                                                                                                                                                                   |
| 5            | eNOT_LISTTYPE. You tried to perform a GetNextDoc or AddNextDoc upon a document that is not a list.                                                                                                                                                                                   |
| 7            | eNOT_BASICTYPE. You tried to perform a GetValue or AddValue upon a parameter that is not of basic type: Integer, Float, String, Time, Date, DateTime.                                                                                                                                |
| 8            | eNO_DATA. You tried to retrieve data from a document that contained no data.                                                                                                                                                                                                         |

## Example

In this example, the input structure for Calculate Cost, or the root level document, is accessed with the GetInputDocs method. The AddNextDoc method adds another BIDocs input document. The Calculate Cost input parameter Account\_Info\_List is a document, so the AddDoc method adds it to the BIDocs input document. Account\_Info\_List is also a document list, so AddNextDoc method adds another Account\_Info\_List document.

```
Local Interlink &QE_COST;
Local BIDocs &CalcCostIn;
Local BIDocs &FromDoc, &ToDoc, &PackageDoc, &AccountDoc;
Local number &ret, &retinput;
```

```
&QE_COST = GetInterlink(Interlink.QE_COST_EX);
```

```

&CalcCostIn = &QE_COST.GetInputDocs("");

For &n = 1 to &number_of_input_sets
/* Get values for inputs, such as &ORIGIN (code not shown) */

    &ret = &CalcCostIn.AddValue("input_param1", "value");
    &FromDoc = &CalcCostIn.AddDoc("From");
    &ret = &FromDoc.AddValue("OriginCountry", "United States");
    &ret = &FromDoc.AddValue("OriginPostal_Code", &ORIGIN);
    &ret = &FromDoc.AddValue("Ship_Date", &SHIPDATE);

/* Call AddDoc and AddValue for To and Package_Info
   (code not shown) */

/* Call AddDoc and AddNextDoc for the AccountDoc document list */
&AccountDoc = &CalcCostIn.AddDoc("Account_Info_List");
For &m = 1 to &number_of_AccountDocs
    &ret = &AccountDoc.AddValue("Account_Number", &ACCOUNT);
    &ret = &AccountDoc.AddValue("Meter_Number", &METER);
    &ret = &AccountDoc.AddValue("Service_Type", &SVCTYPE);
    &retinput = &AccountDoc.AddNextDoc();
End-For; &retinput = &CalcCostIn.AddNextDoc();

End-For;

&retinput = &To.AddNextDoc();

```

The following shows the input structure for this example. It contains five input parameters: input\_param1, From, To, Package\_Info, and Account\_Info\_List.

From, To, and Package\_Info are not lists, so if you try to use AddNextDoc with these parameters, such as the following line of code, AddNextDoc will fail and return an error message.

## AddValue

### Syntax

**AddValue** (*paramname*, *value*)

## Description

The AddValue method adds a value to a member of a document within the input structure for a Business Interlink object.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>paramname</i>        | The name of the member of the document that is having a value added to it.                                                                                    |
| <i>value</i>            | The value that is added. This can be a constant, a variable, or a record field. The data type can be String, Integer, Double, Float, Time, Date, or DateTime. |

## Returns

This method returns an integer. The values are:

| <i><b>Value</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                   | eNoError. The method succeeded.                                                                                                                                                                                                                                                      |
| 1                   | eNO_DOCUMENT. The document referenced by this method does not exist.                                                                                                                                                                                                                 |
| 2                   | eDOCLIST_OUT_RANGE. You tried to access a document in a list, but the document list is out of range. For example, if a document list contains five documents, and then you call GetDoc/GetOutputDocs once, you can call GetNextDoc four times; the fifth time results in this error. |
| 3                   | eDOCUMENT_UNINITIALIZED. Internal error.                                                                                                                                                                                                                                             |
| 4                   | eNOT_DOCUMENTTYPE. You tried to perform an operation upon a parameter that is not a document type.                                                                                                                                                                                   |
| 5                   | eNOT_LISTTYPE. You tried to perform a GetNextDoc or AddNextDoc upon a document that is not a list.                                                                                                                                                                                   |
| 7                   | eNOT_BASICTYPE. You tried to perform a GetValue or AddValue upon a parameter that is not of basic type: Integer, Float, String, Time, Date, DateTime.                                                                                                                                |
| 8                   | eNO_DATA. You tried to retrieve data from a document that contained no data.                                                                                                                                                                                                         |

## Example

In the following example, the Business Interlink object name is QE\_COST.

In the following example, the input structure for Calculate Cost, or the root level document, is accessed with the GetInputDocs method. (To create, or add, more input structures, use AddNextDoc.) The Calculate Cost input parameter From is a document, so the AddDoc method adds it to the input structure. Then the AddValue method adds values to each of the From document members.

```
Local Interlink &QE_COST;
Local BIDocs &CalcCostIn;
Local BIDocs &FromDoc, &ToDoc, &PackageDoc, &AccountDoc;
Local number &ret;

&QE_COST = GetInterlink(Interlink.QE_COST_EX);

/* Get some values for input, such as &ORIGIN (code not shown) */

&CalcCostIn = &QE_COST.GetInputDocs("");
&ret = &CalcCostIn.AddValue("input_param1","value");

&FromDoc = &CalcCostIn.AddDoc("From");
&ret = &FromDoc.AddValue("OriginCountry", "United States");
&ret = &FromDoc.AddValue("OriginPostal_Code", &ORIGIN);
&ret = &FromDoc.AddValue("Ship_Date", &SHIPDATE);

/* Call AddDoc, AddValue for Package, Account_Info_List, and also call AddNextDoc f⇒
or Account_Info_List (code not shown) */
```

The following shows the input structure for this example. It contains five input parameters: input\_param1, From, To, Package\_Info, and Account\_Info\_List.

## BulkExecute

### Syntax

```
BulkExecute(RECORD.inputrecname [, RECORD.outputrecname] [, {user_process_inst | user_operid}])
```

### Description

The BulkExecute method uses the data in the specified record to populate the input buffer, copying like-named fields. Then the method executes, and, optionally, fills the record specified by *outputrecname* with data from the Business Interlink output buffer. BulkExecute results in significantly faster performance for transactions that process large amounts of data. Instead of adding one input row at a time, then fetching the values one at a time, you might write the data to a staging table, use the BulkExecute method and then read the data from the output table. This would be especially effective in Application Engine programs that process sets of data rather than individual rows.

This method assumes that the names of the fields in the record match the names of the inputs (or outputs) defined in the Business Interlink Definition. If there is no field in the *inputrecname* for a Business Interlink input parameter, the parameter's default value is used. If no default is specified, an empty string is passed. You must ensure that this default value is legitimate.

Fields in the output buffer are matched against the fields specified in the output record. You do not have to specify an output record. If you don't specify an output record, the output buffers are not populated.

If you specify an output record, and if you have fields in the output record that are not specified as output parameters, they aren't populated with the BulkExecute method. In addition, they shouldn't be set as NOT NULL, otherwise inserts fail.

---

**Note:** Before you use this method, you should flush the record used for output and remove any residual data that might exist in it.

---

If you specify an output record, and you want to use the output record for error checking, you must add the following fields to your output record:

- RETURN\_STATUS
- RETURN\_STATUS\_MSG

---

**Note:** The field names in the output record must match these names exactly.

---

Then you must mark one or more input parameters as "key fields" in the Business Interlink definition (using the BulkExecute ID check box.) The value of these key fields are copied to the output record, and you can use these fields to match error messages with input (or output) rows.

To order your input (and output) rows, you must add the BI\_SEQ\_NUM column to both the input and output table:

---

**Note:** The field name in your input and output records must match this name exactly.

---

The input rows are read in the order of numbers in BI\_SEQ\_NUM, and the output rows are generated using the same order number.

This method automatically executes, so you don't need to use the Execute method with this method.

Whether this method halts on execution depends on the setting of the StopAtError configuration parameter. The default value is True, that is, stop if the error number returned is something other than a 1 or 2. This configuration parameter must be set before using the BulkExecute method.

## Parameters

| <b>Parameter</b>                | <b>Description</b>                                                                                                                                                                                                                                                                                                      |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RECORD</b> .inputrecname     | Specify a record (SQL table) that contains the data to populate the input buffer of the Business Interlink.                                                                                                                                                                                                             |
| <b>RECORD</b> .outputrecname    | Specify a record (SQL table) that will hold the data that populates the output buffer of the Business Interlink. This is optional; it is often used to error check the input.                                                                                                                                           |
| user_process_inst   user_operid | This is an optional parameter that allows either different Application Engine programs or different clients to populate the same <b>RECORD</b> . outputrecname at the same time.                                                                                                                                        |
|                                 | For user_process_inst, the parameter takes an integer. <b>RECORD</b> . outputrecname must have a PROCESS_INSTANCE field. The PROCESS_INSTANCE field is used to identify the Application Engine program that is using this Business Interlink. You can use the %PROCESS_INSTANCE variable to populate user_process_inst. |
|                                 | For user_operid, the parameter takes a string. <b>RECORD</b> . outputrecname must have an OPERID field. The OPERID field is used to identify the client who is using this Business Interlink. You can use the %OPERID variable to populate user_operid.                                                                 |

## Returns

The following are the valid returns:

| <b>Value</b> | <b>Description</b>                                  |
|--------------|-----------------------------------------------------|
| 1            | The Business Interlink object executes successfully |
| 2            | The Business Interlink object failed to execute     |
| 3            | Transaction failed                                  |
| 4            | Query failed                                        |

| <b>Value</b> | <b>Description</b>      |
|--------------|-------------------------|
| 5            | Missing criteria        |
| 6            | Input mismatch          |
| 7            | Output mismatch         |
| 8            | No response from server |
| 9            | Missing parameter       |
| 10           | Invalid user name       |
| 11           | Invalid password        |
| 12           | Invalid server name     |
| 13           | Connection error        |
| 14           | Connection refused      |
| 15           | Timeout reached         |
| 16           | Unequal lists           |
| 17           | No data for output      |
| 18           | Output parameters empty |
| 19           | Driver not found        |
| 20           | Internet connect error  |
| 21           | XML parser error        |
| 22           | XML deserialize         |

Example

This image is an example of input record for BulkExecute. Here are two PeopleSoft records that could be used as input and output records for BulkExecute. The key fields in the input record, which need to have the BulkExecute ID check box checked in Application Designer, are QE\_RP\_PO\_NUMBER and QE\_RP\_SITENAME. These key fields are used both for input and output.

| QE_RP_PO (Record) |                  |             |     |        |   |                 |                  |
|-------------------|------------------|-------------|-----|--------|---|-----------------|------------------|
| Record Fields     |                  | Record Type |     |        |   |                 |                  |
| Num               | Field Name       | Type        | Len | Format | H | Short Name      | Long Name        |
| 1                 | QE_RP_PO_NUMBER  | Char        | 40  | Mixed  |   | QE_RP_PONUMBER  | QE_RP_PONUMBER   |
| 2                 | QE_RP_PODATE     | DtTm        | 26  |        |   | QE_RP_PODATE    | QE_RP_PODATE     |
| 3                 | QE_RP_SITENAME   | Char        | 15  | Mixed  |   | SITE_NAME       | SITE_NAME        |
| 4                 | QE_RP_VENDORNAME | Char        | 30  | Mixed  |   | QE_RP_VENDORNAM | QE_RP_VENDORNAME |

This image is an example of output record for BulkExecute.

| QE_RP_PO_OUT1 (Record) |                   |             |     |        |   |                 |                   |
|------------------------|-------------------|-------------|-----|--------|---|-----------------|-------------------|
| Record Fields          |                   | Record Type |     |        |   |                 |                   |
| Num                    | Field Name        | Type        | Len | Format | H | Short Name      | Long Name         |
| 1                      | QE_RP_PO_NUMBER   | Char        | 40  | Mixed  |   | QE_RP_PONUMBER  | QE_RP_PONUMBER    |
| 2                      | QE_RP_SITENAME    | Char        | 15  | Mixed  |   | SITE_NAME       | SITE_NAME         |
| 3                      | RETURN_STATUS     | Sign        | 3   |        |   | RETURN_STATUS   | RETURN_STATUS     |
| 4                      | RETURN_STATUS_MSG | Char        | 254 | Mixed  |   | RETURN_STAT_MSG | RETURN_STATUS_MSG |

The following is an example of Business Interlink inputs for BulkExecute. Here are the corresponding inputs and outputs for a Business Interlink that has had its inputs and outputs renamed to match the field names in the records. The inputs and outputs have been renamed where necessary to match the record field names.

| QE_RP_CREATEP01 (Business Interlink) |  |                    |             |             |          |           |                                     |         |
|--------------------------------------|--|--------------------|-------------|-------------|----------|-----------|-------------------------------------|---------|
| Input                                |  | Output             |             |             |          |           |                                     |         |
| Test                                 |  | Settings           |             |             |          |           |                                     |         |
| transaction_create_purchase_order    |  |                    |             |             |          |           |                                     |         |
| transaction_create_purcha            |  | Input Name         | Input Path  | Default     | Data Typ | Attribute | BulkExec Id                         | Path Ir |
| class_name                           |  | 1 class_name       | class_name  | Purchase_Or | string   | required  | <input type="checkbox"/>            | string  |
| order_date                           |  | 2 QE_RP_PODATE     | order_date  |             | string   | required  | <input type="checkbox"/>            | string  |
| vendor_name                          |  | 3 QE_RP_VENDORNAME | vendor_name |             | string   | required  | <input type="checkbox"/>            | string  |
| po_number                            |  | 4 QE_RP_PO_NUMBER  | po_number   |             | string   | required  | <input checked="" type="checkbox"/> | string  |
| site_name                            |  | 5 QE_RP_SITENAME   | site_name   |             | string   | required  | <input checked="" type="checkbox"/> | string  |

The following image is an example of Business Interlink inputs for BulkExecute.

The PeopleCode program using these records could contain the following code to run BulkExecute.

```
Local Interlink &CREATE_PO;
Local number &EXECSRSLT;

&CREATE_PO = GetInterlink(INTERLINK.QE_RP_CREATEPO1);

/* The next three lines set configuration parameters, which are not shown in the previous examples. */
&CREATE_PO.SERVER_NAME = "bc1";
&CREATE_PO.RSERVER_HOST = "192.0.2.1";
&CREATE_PO.RSERVER_PORT = "2200";

&EXECSRSLT = &CREATE_PO.BulkExecute(RECORD.QE_RP_PO, RECORD.QE_RP_PO_OUT1);
```

[StopAtError](#)

**Clear**

**Syntax**

```
clear()
```

## Description

The Clear method clears the input and output buffers. If you're using Business Interlinks in a batch program, every time after you use the Execute method, use the Clear method to flush out the input and output buffers.

## Parameters

None.

## Returns

None.

## Example

```
For &n = 1 to x
    &myinterlink.AddInputRow("input1", value1, "input2", value2);
    &myinterlink.Execute();
    &myinterlink.FetchNextRow("output1", value1, "output2", value2);
    /* do processing on data */
    &myinterlink.Clear();
    &n = &n + 1;
End-for;
```

[Execute](#)

[BulkExecute](#)

## Execute

### Syntax

**Execute** ()

### Description

When an Interlink object executes the Execute method, the transaction associated with the Interlink object is executed.

If there is only one row, after appropriate substitution is made, the transaction is executed only once. Otherwise, the data is "batched up" and sent once. You have to call Execute only once to execute all the rows of the input buffer.

Generally, you would only use the Execute method after using the AddInputRow method. If you create a PeopleCode "template" by dragging the Business Interlink definition from the Project window in Application Designer to an open PeopleCode editor window, the usual order of the execution of methods is shown in the template.

If you're using Business Interlinks in a batch program, every time after you use the Execute method, use the Clear method to flush out the input and output buffers.

Whether this method halts on execution depends on the setting of the `StopAtError` configuration parameter. The default value is `True`, that is, stop if the error number returned is something other than a 1 or 2. This configuration parameter must be set *before* using the `Execute` method.

## Parameters

None.

## Returns

The following are the valid returns:

| <b>Value</b> | <b>Description</b>                                  |
|--------------|-----------------------------------------------------|
| 1            | The Business Interlink object executes successfully |
| 2            | The Business Interlink object failed to execute     |
| 3            | Transaction failed                                  |
| 4            | Query failed                                        |
| 5            | Missing criteria                                    |
| 6            | Input mismatch                                      |
| 7            | Output mismatch                                     |
| 8            | No response from server                             |
| 9            | Missing parameter                                   |
| 10           | Invalid user name                                   |
| 11           | Invalid password                                    |
| 12           | Invalid server name                                 |
| 13           | Connection error                                    |
| 14           | Connection refused                                  |
| 15           | Timeout reached                                     |

| <b>Value</b> | <b>Description</b>      |
|--------------|-------------------------|
| 16           | Unequal lists           |
| 17           | No data for output      |
| 18           | Output parameters empty |
| 19           | Driver not found        |
| 20           | Internet connect error  |
| 21           | XML parser error        |
| 22           | XML deserialize         |

## Example

```

Local number &EXECRESLT;
.
.
&EXECRESLT = &SRA_ALL_1.Execute();
If (&EXECRESLT <> 1) Then
/* The instance failed to execute */
/* Do Error Processing */
End-If;

```

“GetInterlink” (PeopleCode Language Reference)

## FetchIntoRecord

### Syntax

```
FetchIntoRecord (RECORD.recname, [, {user_process_inst | user_operid}])
```

### Description

The `FetchIntoRecord` method copies the data from the output buffer into the specified record (SQL table) copying *like-named* fields. This method assumes that the names of the fields in the record match the names of the outputs defined in the Business Interlink definition.

You can use the `FetchIntoRecord` method to perform a transaction on a large amount of data that you want to receive from your system. Instead of executing your Business Interlink and then fetching one output row at a time, you might execute your Business Interlink, then use the `FetchIntoRecord` method to write the data returned from the Business Interlink to a staging table.

**Note:** Before you use this method, you should flush the record used for output and remove any residual data that might exist in it.

If your data is hierarchical, that is, in a rowset, and you want to preserve the hierarchy, use `FetchIntoRowset` instead of this method.

To order your output rows, you must add the `BI_SEQ_NUM` column to the record.

This column is populated with a sequence number that corresponds to the order in which each row of the record was written to by the method.

Parameters

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RECORD</b> . <i>recname</i>                | Specify a record (SQL table) that you want to populate with data from the output buffers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>user_process_inst</i>   <i>user_operid</i> | <p>This is an optional parameter that enables either different Application Engine programs or different clients to populate the same <b>RECORD</b>.<i>outputrecname</i> at the same time.</p> <p>For <i>user_process_inst</i>, the parameter takes an integer. <b>RECORD</b>.<i>outputrecname</i> must have a <code>PROCESS_INSTANCE</code> field. The <code>PROCESS_INSTANCE</code> field is used to identify the Application Engine program that is using this Business Interlink. You can use the <code>%PROCESS_INSTANCE</code> variable to populate <i>user_process_inst</i>.</p> <p>For <i>user_operid</i>, the parameter takes a string. <b>RECORD</b>.<i>outputrecname</i> must have an <code>OPERID</code> field. The <code>OPERID</code> field is used to identify the client who is using this Business Interlink. You can use the <code>%OPERID</code> variable to populate <i>user_operid</i>.</p> |

Returns

Number of rows fetched if one or more non-empty rows are returned.

If an empty row is returned, that is, every if field is empty except the `return_status` and `return_status_msg` fields, this method returns one of the following error messages:

| Number | Meaning           |
|--------|-------------------|
| 0      | No error          |
| 1      | NoInterfaceObject |
| 2      | ParamCountError   |

| <b>Number</b> | <b>Meaning</b>              |
|---------------|-----------------------------|
| 3             | IncorrectParameterType      |
| 4             | NoColumnForOutputParm       |
| 5             | NoColumnForInputParm        |
| 6             | BulkInsertStartFailed       |
| 7             | BulkInsertStopFailed        |
| 8             | CouldNotCreateSelectCursor  |
| 9             | CouldNotCreateInsertCursor  |
| 10            | CouldNotDestroySelectCursor |
| 11            | CouldNotDestroyInsertCursor |
| 12            | InputRecordDoesNotExist     |
| 13            | OutputRecordDoesNotExist    |
| 14            | ContainEmptyRow             |
| 15            | SQLExecError                |
| 201           | FieldTooLarge               |
| 202           | IgnoreSignNumber            |
| 203           | ConvertFloatToInt           |

## Example

```

&RSLT = &QE_SM_CONCAT.FetchIntoRecord(RECORD.PERSONAL__VENDR_DATA);

If &RSLT = 0 Then
/* no rows fetched */
Else
    /* do processing */
End-If;

```

[BulkExecute](#)

## FetchIntoRowset

### Syntax

```
FetchIntoRowset (&Rowset)
```

### Description

The FetchIntoRowset method copies the data from the output buffer into the specified rowset, copying *like-named* fields. This method assumes that the names of the fields in the rowset match the names of the outputs defined in the Business Interlink definition, and that the structure is the same.

---

**Note:** Before you use this method, you should flush the rowset used for output and remove any residual data that might exist in it.

---

Use this method only if you have a hierarchical data structure and you want to preserve the hierarchy. Otherwise, use BulkExecute or FetchIntoRecord.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Rowset</i>      | Specify rowset object that you want to populate with data from the output buffers. This must be an existing, instantiated rowset. |

### Returns

Number of rows fetched if one or more non-empty rows are returned.

If an empty row is returned, that is, every if field is empty except the return\_status and return\_status\_msg fields, this method returns one of the following error messages:

| <i><b>Value</b></i> | <i><b>Description</b></i> |
|---------------------|---------------------------|
| 0                   | No error                  |
| 1                   | NoInterfaceObject         |
| 2                   | ParamCountError           |
| 3                   | IncorrectParameterType    |

| <b>Value</b> | <b>Description</b>          |
|--------------|-----------------------------|
| 4            | NoColumnForOutputParm       |
| 5            | NoColumnForInputParm        |
| 6            | BulkInsertStartFailed       |
| 7            | BulkInsertStopFailed        |
| 8            | CouldNotCreateSelectCursor  |
| 9            | CouldNotCreateInsertCursor  |
| 10           | CouldNotDestroySelectCursor |
| 11           | CouldNotDestroyInsertCursor |
| 12           | InputRecordDoesNotExist     |
| 13           | OutputRecordDoesNotExist    |
| 14           | ContainEmptyRow             |
| 15           | SQLExecError                |
| 201          | FieldTooLarge               |
| 202          | IgnoreSignNumber            |
| 203          | ConvertFloatToInt           |

## Example

The following is an image of EMPLOYEE\_CHECKLIST Page order. The example uses the rowset on level one from the EMPLOYEE\_CHECKLIST page. A PeopleCode program running in a field on level zero in that page can access the level one (child rowset).

|    | Lvl | Label              | Type           | Field           | Record           | Display Control                     | Related Display                     | Related Control |

EMPL\_CHECKLIST is the primary database record for the level one scrollbar on the EMPLOYEE\_CHECKLIST page. The following PeopleCode accesses the level one rowset using EMPL\_CHECKLIST. The Business Interlink object name is QE\_BI\_EMPL\_CHECKLIST. This Business Interlink object uses the level one rowset as its input and its output.

The InputRowset method uses this rowset as input for QE\_BI\_EMPL\_CHECKLIST. Then a blank duplicate of the rowset is created with CreateRowset, and then the output of QE\_BI\_EMPL\_CHECKLIST is fetched into the blank rowset with FetchIntoRowset.

```
&MYROWSET = GetRowset(SCROLL.EMPL_CHECKLIST);
&ROWCOUNT = &QE_BI_EMPL_CHECKLIST.InputRowset(&MYROWSET);
&RSLT = &QE_BI_EMPL_CHECKLIST.Execute();
/* do some error processing */
&WorkRowset = CreateRowset(&MYROWSET);
&ROWCOUNT = &QE_BI_EMPL_CHECKLIST.FetchIntoRowset(&WorkRowset);

If &ROWCOUNT = 0 Then
/* do some error processing */
Else
/* Process the rowset from QE_BI_EMPL_CHECKLIST. Check it for errors. */
For &I = 1 to &WorkRowset.RowCount
For &K = 1 to &WorkRowset(&I).RecordCount
&REC = &WorkRowset(&I).GetRecord(&K);
&REC.ExecuteEdits();
For &M = 1 to &REC.FieldCount
If &REC.GetField(&M).EditError Then
/* there are errors */
/* do other processing */
End-If;
End-For;
End-For;
End-for;
```

End-if;

“Understanding Data Buffer Access” (PeopleCode Developer’s Guide)

FetchNextRow

Syntax

**FetchNextRow**(*outputname*, *value*)

where *outputname* and *value* are in matched pairs, in the form:

*outputname1*, *value1* [, *outputname2*, *value2*] . . .

Description

After the Business Interlink object executes the method `Execute`, the `FetchNextRow` method can be used to retrieve a row of output and store the values of the output name (*outputname*) to PeopleCode variables or record fields (*value*). These must be entered in matched pairs, that is, every output name must be followed by its matching value.

**Note:** The output *name*, not the output path of the interface definition is used for this method.

There must be an *outputname* for every output name defined in the interface definition used to instantiate the Business Interlink object.

If you specify a record field that is not part of the record the PeopleCode program is associated with, you must use *recname.fieldname* for that *value*.

You can specify default values for every output name in the interface definition (created in Application Designer.) These values are used if you create a PeopleCode "template" by dragging the interface definition from the Project window in Application Designer to an open PeopleCode Editor window.

Parameters

| Parameter         | Description                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>outputname</i> | Specify the output name. There must be one <i>outputname</i> for every output name defined in the interface definition used to instantiate the Business Interlink object. |
| <i>value</i>      | Specify the value for the output name. This can be a constant, a variable, or a record field. Each <i>value</i> must be paired with an <i>outputname</i> .                |

Returns

A Boolean value: True if the row of output parameters was fetched. Otherwise, it returns False.

Example

In the following example, the Business Interlink object name is SRA\_ALL\_1, and the output names, such as costs, are being bound to record fields, such as STR\_COST.

```
&RSLT = &SRA_ALL_1.FetchNextRow("costs", &STR_COST,
    "unit_costs", &STR_UNIT_COST,
    "customer_ship_dates", &STR_SHIP_DATE,
    "quantities", &STR_QUANTITY,
    "so_numbers", &STR_SO_NUM,
    "so_names", &STR_SO_NAME,
    "line_numbers", &STR_LINE_NUM,
    "ship_sets", &STR_SHIP_SET,
    "customer_receipt_dates", &STR_RECPT_DATE);
```

“GetInterlink” (PeopleCode Language Reference)

GetCount

Syntax

```
GetCount (docname)
```

Description

The GetCount method returns the number of documents within a document list contained within an output structure for a Business Interlink object.

Parameters

| Parameter | Description                    |
|-----------|--------------------------------|
| docname   | The name of the document list. |

Returns

The number of documents in the list.

Example

In the following example, the output structure for Calculate Cost, or the root level document, is accessed with the GetOutputDocs method. The Calculate Cost output parameter output\_param2\_List is a document, so the GetDoc method gets it from the output structure. Because output\_param2\_List is a document list, GetCount gets the number of documents in the list.

```
Local Interlink &QE_COST;
Local number &count;
Local BIDocs &CalcCostOut;
Local BIDocs &OutlistDoc;
Local number &ret;
```

```

&QE_COST = GetInterlink(Interlink.QE_COST_EX);
/* Get inputs, execute. (code not shown) */

&CalcCostOut = &QE_COST.GetOutputDocs("");

/* Call GetValue for output_param1, call GetDoc, GetValue for
Service_Rate (code not shown) */

&OutlistDoc = &CalcCostOut.GetDoc("output_param2_List");
&count = &CalcCostOut.GetCount("output_param2_List");

&I = 0;
While (&I < &count)
    &ret = &OutlistDoc.GetValue("output_member1", &VALUE1);
    &ret = &OutlistDoc.GetValue("output_member2", &VALUE2);
    If &ret = 0 Then
        /* Process output values */
        &I = &I + 1;
        &retoutput = &OutlistDoc.GetNextDoc();
    End-If;
End-While;

```

The following example shows the output structure for this example. It contains three output parameters: output\_param1, Service\_Rate, and output\_param2\_List.

## GetDoc

### Syntax

**GetDoc** (*docname*)

### Description

The GetDoc method gets a document from an output structure. The document is an output parameter for a Business Interlink object that is not of simple type (such as integer or string). You must get the document from the output structure before you can get values from its members with GetValue.

You can call GetDoc using dot notation, to access documents that are "nested" within other documents. For example, the following accesses a document nested three levels deep:

```
&Docs3 = &CalcCostOut.GetDoc("Doc1.Doc2.Doc3");
```

## Parameters

| <i>Parameter</i> | <i>Description</i>                                                         |
|------------------|----------------------------------------------------------------------------|
| <i>docname</i>   | The name of the document that GetDoc should get from the output structure. |

## Returns

A reference to the document received from the output structure.

## Example

In the following example, the Output structure for Calculate Cost(Domestic), or the root level document, is created with the GetOutputDocs method. (To create, or get, more Output structures, call GetNextDoc.) The Calculate Cost output parameter Service\_Rate is a document, so the GetDoc method gets it from the Output structure.

```

Local Interlink &QE_COST;
Local number &count;
Local BIDocs &CalcCostOut;
Local BIDocs &ServiceRateDoc;
Local number &ret;

&QE_COST = GetInterlink(Interlink.QE_COST_EX);
// Get inputs, execute. (code not shown)

&CalcCostOut = &QE_COST.GetOutputDocs("");
&ret = &CalcCostOut.GetValue("output_param1", &VALUE);
&ServiceRateDoc = &CalcCostOut.GetDoc("Service_Rate");
&ret = &ServiceRateDoc.GetValue("Service_Type", &SERVICE_TYPE);
&ret = &ServiceRateDoc.GetValue("Rate", &RATE);
/* Call GetDoc, GetValue, GetNextDoc for output_param2_List (code not shown) */
If &ret = 0 Then
    /* Process output values */
End-If;

```

The following illustration shows the Output structure for this example. It contains three output parameters: output\_param1, Service\_Rate, and output\_param2\_List. This is a version of the Federal Express plug-in that was modified for this example (output\_param1 and output\_param2\_List were added).

In the following example, GetDoc is used to access a document that is nested more deeply. To access a document that is more deeply nested, you can either call GetDoc for each nesting, or you can call GetDoc once using the nesting feature.

Calling GetDoc with the nesting feature:

```
Local Interlink &QE_4GETDOC;
Local BIDocs &CalcCostOut, &Docs3;
Local number &ret;

&QE_4GETDOC = GetInterlink(Interlink.QE_4GETDOC_EX);
// Get inputs, execute. (code not shown)

&CalcCostOut = &QE_4GETDOC.GetOutputDocs("");
&Docs3 = &CalcCostOut.GetDoc("Doc1.Doc2.Doc3");
&ret = &Docs3.GetValue("output_member3", &VALUE);
```

Calling GetDoc without the nesting feature:

```
Local Interlink &QE_4GETDOC;
Local BIDocs &CalcCostOut, &Docs1, &Docs2, &Docs3;
Local number &ret;

&QE_4GETDOC = GetInterlink(Interlink.QE_4GETDOC_EX);
// Get inputs, execute. (code not shown)

&CalcCostOut = &QE_4GETDOC.GetOutputDocs("");
&Docs1 = &CalcCostOut.GetDoc("Doc1");
&Docs2 = &Docs1.GetDoc("Doc2");
&Docs3 = &Docs2.GetDoc("Doc3");
&ret = &Docs3.GetValue("output_member3", &VALUE);
```

The following image is an example of output structure with nested documents.

## GetFieldCount

### Syntax

```
GetFieldCount()
```

### Description

Use the GetFieldCount method to support dynamic output. It returns the number of columns in the output buffer, which is the same as the number of outputs in each row of the output buffer.

---

**Note:** This method can also be used with hierarchical doc data.

---

### Parameters

None.

## Returns

The number of columns in the output buffer, which is the same as the number of outputs in each row of the output buffer.

## Example

The following example moves to the first column, first field of the output buffer. The Repeat loop goes through every row in the output buffer. The For loop processes every field in every row.

```
If (&MYBI.MoveFirst()) Then
  Repeat
    For &I = 1 to &MYBI.GetFieldCount
      &TYPE = &MYBI.GetFieldType(&I);
      Evaluate &TYPE
      Where = 1
      /* do processing */
      .
      .
      .
    End-Evaluate;
  End-For;
  Until Not (&MYBI.MoveNext());
Else
  /* do error processing - output buffer not returned */
End-If;
```

## GetFieldType

### Syntax

**GetFieldType**(*index*)

### Description

Use the GetFieldType method to support dynamic output. It returns the type of field specified by *index*. You can use this method only after you have used the MoveFirst method: otherwise the system doesn't know where to start.

---

**Note:** This method can also be used with hierarchical doc data.

---

### Parameters

| <i>Parameter</i> | <i>Description</i>                                            |
|------------------|---------------------------------------------------------------|
| <i>index</i>     | Specify the number of the field you want to find the type of. |

## Returns

A number indicating the type of the field. The values are:

| <b>Value</b> | <b>Description</b> |
|--------------|--------------------|
| 1            | String             |
| 2            | Integer            |
| 3            | Float              |
| 4            | Boolean            |
| 5            | Date               |
| 6            | Time               |
| 7            | DateTime           |
| 8            | Binary             |
| 9            | Object             |

## Example

In the following example, the Business Interlink object name is &MYBI. The example uses MoveFirst to move to the first row of the output buffer, and to the first column, or first field, in that row. The Repeat loop uses MoveNext to go through every row in the output buffer. The For loop processes every field in every row, using the GetFieldCount method to get the number of fields, or outputs, in the row. Within the For loop, GetFieldType gets the type of the field data (string, integer, and so on.)

```
/* Add inputs to the BusinessInterlink object, then call Execute
to execute the Business Interlink object.
You are then ready to get the outputs using the following code. */
```

```
If (&MYBI.MoveFirst()) Then
  Repeat
    For &I = 1 to &MYBI.GetFieldCount
      &TYPE = &MYBI.GetFieldType(&I);
      Evaluate &TYPE
      Where = 1
      &STRING_VARIABLE = &MYBI.GetFieldValue(&I);
      /* test for_ and process other field types */
      End-Evaluate;
    End-For;
  Until Not (&MYBI.MoveNext());
Else
  /* Process error - no output buffer */
End-If;
```

## GetFieldValue

### Syntax

**GetFieldValue** (*index*)

### Description

Use the GetFieldValue method to support dynamic output. It returns the value of the field specified by index. You can use this method only after you have used the MoveFirst method: otherwise the system doesn't know where to start.

---

**Note:** This method can also be used with hierarchical doc data.

---

### Parameters

| <i>Parameter</i> | <i>Description</i>                                             |
|------------------|----------------------------------------------------------------|
| <i>index</i>     | Specify the number of the field you want to find the value of. |

### Returns

A string containing the value of the field.

### Example

In the following example, the Business Interlink object name is &MYBI. The example uses MoveFirst to move to the first row of the output buffer, and to the first column, or first field, in that row. The Repeat loop uses MoveNext to go through every row in the output buffer. The For loop processes every field in every row, using the GetFieldCount method to get the number of fields, or outputs, in the row. Within the For loop, GetFieldValue gets the value of the field data.

```
/* Add inputs to the Business Interlink object, then call Execute to execute
the Business Interlink object. You are then ready to get the
outputs using the following code. */
```

```
If (&MYBI.MoveFirst()) Then
  Repeat
    For &I = 1 to &MYBI.GetFieldCount
      &TYPE = &MYBI.GetFieldType(&I);
      Evaluate &TYPE
      Where = 1
        &STRING_VARIABLE = &MYBI.GetFieldValue(&I);
      /* test for and process other field types */
    End-Evaluate;
```

```

        End-For;
    Until Not(&MYBI.MoveNext());
Else
    /* Process error - no output buffer */
End-If;

```

## GetInputDocs

### Syntax

```
GetInputDocs ("")
```

### Description

The GetInputDocs method gets the top input document at the root level for a Business Interlink object. This is a hierarchical structure that contains the values for the inputs for this Business Interlink object. The methods that you use to put the input values into this document are the hierarchical data methods.

### Parameters

A null string.

### Returns

An input document. This is the document at the top of the root level of the input document for a Business Interlink object.

### Example

```

Local Interlink &QE_COST;
Local BIDocs &CalcCostOut, &CalcCostIn;

&QE_COST = GetInterlink(Interlink.QE_COST_EX);
&CalcCostIn = &QE_COST.GetInputDocs("");

/* You can now insert the input values and execute the BI object */

```

## Related Links

[Using Hierarchical Data \(BIDocs\)](#)

## GetNextDoc

### Syntax

```
GetNextDoc ()
```

## Description

The GetNextDoc method gets a document from one of the following levels:

- The root level of the Output structure for a Business Interlink object. This level was accessed with the GetOutputDocs method.
- When a document within the Output structure is a list, GetNextDoc gets another document from the list. If you use GetNextDoc on a document that is not a list, GetNextDoc fails and returns an error.

## Parameters

None.

## Returns

The following are the valid returns:

| <i><b>Number</b></i> | <i><b>Enum Value</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                        |
|----------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                    | eNoError                 | The method succeeded.                                                                                                                                                                                                                                            |
| 1                    | eNO_DOCUMENT             | The document referenced by this method does not exist.                                                                                                                                                                                                           |
| 2                    | eDOCLIST_OUT_RANGE       | You tried to access a document in a list, but the document list is out of range. For example, if a document list contains five documents, and then you call GetDoc/GetOutputDocs once, you can call GetNextDoc four times; the fifth time results in this error. |
| 3                    | eDOCUMENT_UNINITIALIZED  | Internal error                                                                                                                                                                                                                                                   |
| 4                    | eNOT_DOCUMENTTYPE        | You tried to perform an operation upon a parameter that is not a document type.                                                                                                                                                                                  |
| 5                    | eNOT_LISTTYPE            | You tried to perform a GetNextDoc or AddNextDoc upon a document that is not a list.                                                                                                                                                                              |
| 7                    | eNOT_BASICTYPE           | You tried to perform a GetValue or AddValue upon a parameter that is not of basic type: Integer, Float, String, Time, Date, DateTime.                                                                                                                            |
| 8                    | eNO_DATA                 | You tried to retrieve data from a document that contained no data.                                                                                                                                                                                               |

## Example

In this example, the Output structure for Calculate Cost, or the root level document, is accessed with the `GetOutputDocs` method. The `GetNextDoc` method gets another Output structure, assuming that there is more than one of them. The Calculate Cost output parameter `output_param2_List` is a document, so the `GetDoc` method gets it to the Output structure. `output_param2_List` is also a document list, so `GetNextDoc` method gets the next `output_param2_List` document.

```
Local Interlink &QE_COST;
Local number &count1, &count2;
Local BIDocs &CalcCostOut;
Local BIDocs &OutlistDoc;
Local number &ret1, &ret2;

&QE_COST = GetInterlink(Interlink.QE_COST_EX);
// Get inputs, execute. (code not shown)

&CalcCostOut = &QE_COST.GetOutputDocs("");

&ret1 = 0;
While (&ret1)
    &ret1 = &CalcCostOut.GetValue("output_param1", &VALUE);
    &ServiceRateDoc = &CalcCostOut.GetDoc("Service_Rate");
    &ret1 = &ServiceRateDoc.GetValue("Service_Type", &SERVICE_TYPE);
    &ret1 = &ServiceRateDoc.GetValue("Rate", &RATE);
    /* Process output values */

    &OutlistDoc = &CalcCostOut.GetDoc("output_param2_List");
    &count2 = &CalcCostOut.GetCount("output_param2_List");
    While (&I < &count2)
        &ret2 = &OutlistDoc.GetValue("output_member1", &VALUE1);
        &ret2 = &OutlistDoc.GetValue("output_member2", &VALUE2);
        If &ret2 = 0 Then
            /* Process output values */
            &I = &I + 1;
            &ret2 = &OutlistDoc.GetNextDoc();
        End-If; &ret1 = &CalcCostOut.GetNextDoc();
    End-While;
```

The following shows the Output structure for this example. It contains three output parameters: `output_param1`, `Service_Rate`, and `output_param2_List`.

## GetOutputDocs

### Syntax

```
GetOutputDocs ("" )
```

## Description

The `GetOutputDocs` method gets the top output document at the root level for a Business Interlink object. This is a hierarchical structure that contains the values for the outputs for this Business Interlink object. The methods that you use to get output values from this document are the hierarchical data methods.

## Parameters

A null string.

## Returns

An output document. This is the document at the top of the root level of the output document for a Business Interlink object.

## Example

```
Local Interlink &QE_COST;  
Local BIDocs &CalcCostIn, &CalcCostOut;  
  
&QE_COST = GetInterlink(Interlink.QE_COST_EX);  
  
&CalcCostOut = &QE_COST.GetOutputDocs("");  
  
/* You can now execute the Business Interlink object and get the output values. */
```

## Related Links

[Using Hierarchical Data \(BIDocs\)](#)

# GetPreviousDoc

## Syntax

```
GetPreviousDoc()
```

## Description

The `GetPreviousDoc` method gets the previous document from either the root level of the Output structure for a Business Interlink object, or from a document within the Output structure. When these documents are in a list, `GetPreviousDoc` gets the previous document in the list. You must get the document before you can get its values with `GetValue`.

## Parameters

None.

## Returns

The following are the possible returns:

| <b>Number</b> | <b>Enum Value</b>       | <b>Description</b>                                                                                                                                                                                                                                               |
|---------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0             | eNoError                | The method succeeded.                                                                                                                                                                                                                                            |
| 1             | eNO_DOCUMENT            | The document referenced by this method does not exist.                                                                                                                                                                                                           |
| 2             | eDOCLIST_OUT_RANGE      | You tried to access a document in a list, but the document list is out of range. For example, if a document list contains five documents, and then you call GetDoc/GetOutputDocs once, you can call GetNextDoc four times; the fifth time results in this error. |
| 3             | eDOCUMENT_UNINITIALIZED | Internal error                                                                                                                                                                                                                                                   |
| 4             | eNOT_DOCUMENTTYPE       | You tried to perform an operation upon a parameter that is not a document type.                                                                                                                                                                                  |
| 5             | eNOT_LISTTYPE           | You tried to perform a GetNextDoc or AddNextDoc upon a document that is not a list.                                                                                                                                                                              |
| 7             | eNOT_BASICTYPE          | You tried to perform a GetValue or AddValue upon a parameter that is not of basic type: Integer, Float, String, Time, Date, DateTime.                                                                                                                            |
| 8             | eNO_DATA                | You tried to retrieve data from a document that contained no data.                                                                                                                                                                                               |

## Example

In this example, the Output structure for Calculate Cost, or the root level document, is accessed with the GetOutputDocs method. It contains one output parameter, output\_param2\_List, which is also a list. The GetCount and MoveToDoc methods point to the last output\_param2\_List document in the list. The GetPreviousDoc method is used in a loop to cycle through the output\_param2\_List list, starting with the last and ending with the first in the list, and get each output\_param2\_List document and its values.

```

Local Interlink &QE_COST;
Local number &count;
Local BIDocs &CalcCostOut;
Local BIDocs &OutlistDoc;
Local number &ret;

&QE_COST = GetInterlink(Interlink.QE_COST_EX);
// Get inputs, execute. (code not shown)

&CalcCostOut = &QE_COST.GetOutputDocs("");

/* Call GetValue for output_param1, call GetDoc, GetValue for Service_Rate (code no→

```

```
t shown) */

&OutlistDoc = &CalcCostOut.GetDoc("output_param2_List");
&count = &CalcCostOut.GetCount("output_param2_List");
&ret = &OutlistDoc.MoveToDoc(&count-1);
&I = &count;
While (&I > 0)
    &ret = &OutlistDoc.GetValue("output_member1", &VALUE1);
    &ret = &OutlistDoc.GetValue("output_member2", &VALUE2);
    If &ret = 0 Then
        /* Process output values */
        &I = &I - 1;
        &retoutput = &OutlistDoc.GetPreviousDoc("");
    End-If;
End-While;
```

The following shows the Output structure for this example. It contains three output parameters: output\_param1, Service\_Rate, and output\_param2\_List.

GetStatus

Syntax

```
GetStatus ()
```

Description

The GetStatus method tests the BIDocs document. To find the status for any BIDocs method that does not return a status value, call GetStatus just after you call that BIDocs method.

Parameters

None.

Returns

The following are the possible returns:

| Number | Enum Value | Description           |
|--------|------------|-----------------------|
| 0      | NoError    | The method succeeded. |

| <b>Number</b> | <b>Enum Value</b>      | <b>Description</b>                                                                                                                                                                                                                                               |
|---------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1             | NO_DOCUMENT            | The document referenced by this method does not exist.                                                                                                                                                                                                           |
| 2             | LIST_OUT_RANGE         | You tried to access a document in a list, but the document list is out of range. For example, if a document list contains five documents, and then you call GetDoc/GetOutputDocs once, you can call GetNextDoc four times; the fifth time results in this error. |
| 3             | DOCUMENT_UNINITIALIZED | Internal error.                                                                                                                                                                                                                                                  |
| 4             | NOT_DOCUMENTTYPE       | You tried to perform an operation upon a parameter that is not a document type.                                                                                                                                                                                  |
| 5             | NOT_DOCUMENTLISTTYPE   | You tried to perform a GetNextDoc or AddNextDoc upon a document that is not a list.                                                                                                                                                                              |
| 6             | NOT_LISTTYPE           | You tried to perform a list operation using GetValue, AddValue, on a non-list.                                                                                                                                                                                   |
| 7             | NOT_SINGLEBASICTYPE    | You tried to perform a GetValue or AddValue upon a list that does not use a single basic type: Integer, Float, String, Time, Date, DateTime.                                                                                                                     |
| 9             | NO_DATA                | You tried to retrieve data from a document that contained no data.                                                                                                                                                                                               |
| 10            | GENERIC_ERROR          | There was an error with the transaction.                                                                                                                                                                                                                         |

## GetValue

### Syntax

**GetValue**(*paramname*, *value*)

### Description

The GetValue method gets a value from an output parameter within a document of the Output structure for a Business Interlink object.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Paramname</i>        | The name of the member of the document that is having a value retrieved from it.                                                                     |
| <i>Value</i>            | The value that is retrieved. This can be a variable or a record field. The data type can be String, Integer, Double, Float, Time, Date, or DateTime. |

## Returns

The following are the possible return values:

### Return Status for Integer

| <i><b>Number</b></i> | <i><b>Enum value and Meaning</b></i>                                        |
|----------------------|-----------------------------------------------------------------------------|
| 0                    | NoError. The method succeeded.                                              |
| 1                    | NO_DOCUMENT. The document referenced by this method does not exist.         |
| 9                    | NO_DATA. You tried to retrieve data from a document that contained no data. |
| 10                   | GENERIC_ERROR. There was an error with the transaction.                     |

## Example

In the following example, the Business Interlink object name is QE\_COST.

In the following example, the Output structure for Calculate Cost, or the root level document, is created with the GetOutputDocs method. (If you wanted to create, or get, more Output structures, you would call GetNextDoc.) The Calculate Cost output parameter Service\_Rate is a document, so the GetDoc method gets it from the Output structure. Then the GetValue method gets values from each of the Service\_Rate document members.

```

Local Interlink &QE_COST;
Local BIDocs &CalcCostOut;
Local BIDocs &ServiceRateDoc;
Local number &ret;

&QE_COST = GetInterlink(Interlink.QE_COST_EX);

// Get inputs, execute. (code not shown)

&CalcCostOut = &QE_COST.GetOutputDocs("");
&ret = &CalcCostOut.GetValue("output_param1", &PARAM1);

```

```
&ServiceRateDoc = &CalcCostOut.GetDoc("Service_Rate");
&ret = &ServiceRateDoc.GetValue("Service_Type", &SERVICE_TYPE);
&ret = &ServiceRateDoc.GetValue("Rate", &RATE);

/* Call GetDoc, GetValue, GetNextDoc for output_param2_List (code not shown) */
```

The following illustration shows the Output structure for this example. It contains three output parameters: output\_param1, Service\_Rate, and output\_param2\_List. This is a version of the Federal Express plug-in that was modified for this example (output\_param1 and output\_param2\_List were added).

InputRowset

Syntax

```
InputRowset (&Rowset)
```

Description

The InputRowset method uses the data in the specified rowset to populate the input buffer, copying *like-named* fields in the appropriate structure. This method assumes that the names of the fields in the rowset match the names of the inputs defined in the Business Interlink definition, and that the structure of both rowsets are the same.

Use this method only if you have a hierarchical data structure and you want to preserve the hierarchy. Otherwise, use BulkExecute or AddInputRow.

Parameters

| Parameter | Description                                      |
|-----------|--------------------------------------------------|
| &Rowset   | Specify an existing, instantiated rowset object. |

Returns

An optional value: the number of rows inserted into the output buffer.

## Example

The example uses the rowset on level one from the EMPLOYEE\_CHECKLIST page. A PeopleCode program running in a field on level zero in that panel can access the child rowset (level one), shown below from Scroll Bar 1 to Scroll Bar 2.

| EMPLOYEE_CHECKLIST.ENG (Panel) |     |                    |                |                 |                  |                                     |                                     |                 |
|--------------------------------|-----|--------------------|----------------|-----------------|------------------|-------------------------------------|-------------------------------------|-----------------|
| Panel Designer                 |     | Order              |                |                 |                  |                                     |                                     |                 |
|                                | Lvl | Label              | Type           | Field           | Record           | Display Control                     | Related Display                     | Related Control |

| 21                             | 2   | Status Date        | Edit Box       | STATUS_DT       | EMPL_CHKLIST_ITM | <input type="checkbox"/>            | <input type="checkbox"/>            |                 |

EMPL\_CHECKLIST is the primary database record for the level one scrollbar on the EMPLOYEE\_CHECKLIST page. The following PeopleCode access the level one rowset using EMPL\_CHECKLIST. The Business Interlink object name is QE\_BI\_EMPL\_CHECKLIST. This Business Interlink object uses the level one rowset as its input and its output.

The InputRowset method uses this rowset as input for QE\_BI\_EMPL\_CHECKLIST. Then a blank duplicate of the rowset is created with CreateRowset, and then the output of QE\_BI\_EMPL\_CHECKLIST is fetched into the blank rowset with FetchIntoRowset.

```

&MYROWSET = GetRowset(SCROLL.EMPL_CHECKLIST);
&ROWCOUNT = &QE_BI_EMPL_CHECKLIST.InputRowset(&MYROWSET);
&RSLT = &QE_BI_EMPL_CHECKLIST.Execute();
/* do some error processing */
&WorkRowset = CreateRowset(&MYROWSET);
&ROWCOUNT = &QE_BI_EMPL_CHECKLIST.FetchIntoRowset(&WorkRowset);

If &ROWCOUNT = 0 Then
/* do some error processing */
Else
  /* Process the rowset from QE_BI_EMPL_CHECKLIST. Check it for errors. */
  For &I = 1 to &WorkRowset.RowCount
    For &K = 1 to &WorkRowset(&I).RecordCount
      &REC = &WorkRowset(&I).GetRecord(&K);
      &REC.ExecuteEdits();
      For &M = 1 to &REC.FieldCount
        If &REC.GetField(&M).EditError Then
          /* there are errors */
          /* do other processing */
        End-If;
      End-For;
    End-For;
  End-For;
End-for;

```

```
End-if;
```

## MoveFirst

### Syntax

```
MoveFirst()
```

### Description

Use the MoveFirst method to support dynamic output. This method moves your cursor to the first column, first row of the output buffer. You must use this method before you try to access any data.

### Parameters

None.

### Returns

Boolean: True if successfully positioned cursor at the first column, first row of the output buffer, False otherwise.

### Example

In the following example, the Business Interlink object name is &MYBI. The example uses MoveFirst to move to the first row of the output buffer, and to the first column, or first field, in that row. The Repeat loop uses MoveNext to go through every row in the output buffer. The For loop processes every field in every row, using the GetFieldCount method to get the number of fields, or outputs, in the row.

```
/* Add inputs to the Business Interlink object, then call Execute to execute the Bu→
siness Interlink object. You are then ready to get the outputs using the following →
code. */
```

```
If (&MYBI.MoveFirst()) Then
  Repeat
    For &I = 1 to &MYBI.GetFieldCount
      &TYPE = &MYBI.GetFieldType(&I);
      Evaluate &TYPE
      Where = 1
        &STRING_VARIABLE = &MYBI.GetFieldValue(&I);
      /* test for and process other field types */
      End-Evaluate;
    End-For;
  Until Not (&MYBI.MoveNext());
Else
  /* Process error - no output buffer */
End-If;
```

## MoveNext

### Syntax

**MoveNext** ( )

### Description

Use the MoveNext method to support dynamic output. This method moves your cursor to the first column of the next row of the output buffer. You can use this method only after you have used the MoveFirst method: otherwise, the system doesn't know where to start.

### Parameters

None.

### Returns

Boolean: True if successfully positioned cursor at the next row of the output buffer, False otherwise.

### Example

In the following example, the Business Interlink object name is &MYBI. The example uses MoveFirst to move to the first row of the output buffer, and to the first column, or first field, in that row. The Repeat loop uses MoveNext to go through every row in the output buffer. The For loop processes every field in every row, using the GetFieldCount method to get the number of fields, or outputs, in the row.

```
/* Add inputs to the Business Interlink object, then call Execute to execute the Bu⇒
siness Interlink object. You are then ready to get the outputs using the following ⇒
code. */
```

```
If (&MYBI.MoveFirst()) Then
  Repeat
    For &I = 1 to &MYBI.GetFieldCount
      &TYPE = &MYBI.GetFieldType(&I);
      Evaluate &TYPE
      Where = 1
      &STRING_VARIABLE = &MYBI.GetFieldValue(&I);
      /* test for and process other field types */
      End-Evaluate;
    End-For;
  Until Not(&MYBI.MoveNext());
Else
  /* Process error - no output buffer */
End-If;
```

## MoveToDoc

### Syntax

```
MoveToDoc(list_number)
```

### Description

Within a list of documents in the Output structure, the MoveToDoc method moves to the documents given by the parameter *list\_number*. After using MoveToDoc, the GetValue method gets the values of the document that is in the *list\_number*+1 location in the list.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| list_number             | The number indicating the document that MoveToDoc moves to. After using MoveToDoc, the GetValue method gets the values of the document that is in the <i>list_number</i> +1 location in the list. For example, if <i>list_number</i> is zero, then MoveToDoc moves to the first document in the list. |

### Returns

This method returns an integer. The values are:

| <i><b>Value</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                   | eNoError. The method succeeded.                                                                                                                                                                                                                                                      |
| 1                   | eNO_DOCUMENT. The document referenced by this method does not exist.                                                                                                                                                                                                                 |
| 2                   | eDOCLIST_OUT_RANGE. You tried to access a document in a list, but the document list is out of range. For example, if a document list contains five documents, and then you call GetDoc/GetOutputDocs once, you can call GetNextDoc four times; the fifth time results in this error. |
| 3                   | eDOCUMENT_UNINITIALIZED. Internal error.                                                                                                                                                                                                                                             |

| <b>Value</b> | <b>Description</b>                                                                                                                                    |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4            | eNOT_DOCUMENTTYPE. You tried to perform an operation upon a parameter that is not a document type.                                                    |
| 5            | eNOT_LISTTYPE. You tried to perform a GetNextDoc or AddNextDoc upon a document that is not a list.                                                    |
| 7            | eNOT_BASICTYPE. You tried to perform a GetValue or AddValue upon a parameter that is not of basic type: Integer, Float, String, Time, Date, DateTime. |
| 8            | eNO_DATA. You tried to retrieve data from a document that contained no data.                                                                          |

## Example

The following example gets the values of the last document in the output\_param2\_List list. It uses GetCount to get the number of documents in the list, and then uses MoveToDoc to move to the last document in the list.

```

Local Interlink &QE_COST;
Local number &count;
Local BIDocs &CalcCostOut;
Local BIDocs &OutlistDoc;
Local number &ret;

&QE_COST = GetInterlink(Interlink.QE_COST_EX);
// Get inputs, execute. (code not shown)

&CalcCostOut = &QE_COST.GetOutputDocs("");
&OutlistDoc = &CalcCostOut.GetDoc("output_param2_List");
&count = &CalcCostOut.GetCount("output_param2_List");
&ret = &OutlistDoc.MoveToDoc(&count-1);
&ret = &OutlistDoc.GetValue("output_member1", &VALUE1);
&ret = &OutlistDoc.GetValue("output_member2", &VALUE2);

```

The following illustration shows the Output structure for this example. It contains three output parameters: output\_param1, Service\_Rate, and output\_param2\_List. This is a version of the Federal Express plug-in that was modified for this example (output\_param1 and output\_param2\_List were added).

## ResetCursor

### Syntax

```
ResetCursor()
```

### Description

The ResetCursor method resets the cursor in the Output structure for a Business Interlink object to the top. After you call this method, the next time you call GetValue, you get an output value from the first document of the Output structures for a Business Interlink object.

### Parameters

None.

### Returns

None.

### Example

The following code uses ResetCursor to reset the cursor in the Output structure to the top.

```
Local Interlink &QE_COST;  
Local BIDocs &CalcCostOut;  
  
&QE_COST = GetInterlink(Interlink.QE_COST_EX);  
  
// Get inputs, execute. (code not shown)  
  
&CalcCostOut = &QE_COST.GetOutputDocs("");  
  
// Perform actions on the output documents (code not shown)  
  
&CalcCostOut.ResetCursor();
```

---

## Incoming Business Interlink Methods

This section describes the PeopleCode methods you use with Incoming Business Interlinks.

## AddAttribute

### Syntax

```
AddAttribute(attributeName, attributeValue)
```

### Description

The AddAttribute method adds an attribute name and its value to an XML element referenced by a BiDocs object.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>           |
|-------------------------|-------------------------------------|
| <i>attributename</i>    | String. The name of the attribute.  |
| <i>attributevalue</i>   | String. The value of the attribute. |

## Returns

Number. The return status. NoError, or 0, means the method succeeded.

## Example

Here is a set of XML response code.

```
<?xml version="1.0"?>
  <postreqresponse>
    <candidate>
      <user>
        <location scenery="great" density="low" blank="eh?">
        </location>
      </user>
    </candidate>
  </postreqresponse>
```

Here is the PeopleCode that builds it.

```
Local BIDocs &rootDoc, &postreqresponse;
Local BIDocs &candidates, &location, &user;
Local number &ret;

&rootDoc = GetBiDoc("");
&ret = &rootDoc.AddProcessInstruction("<?xml version=""1.0""?>");
&postreqresponse = &rootDoc.CreateElement("postreqresponse");
&candidates = &postreqresponse.CreateElement("candidates");
&user = &candidates.CreateElement("user");
&location = &user.CreateElement("location");
&ret = &location.AddAttribute("scenery", "great");
&ret = &location.AddAttribute("density", "low");
&ret = &location.AddAttribute("blank", "eh?");
```

## AddComment

### Syntax

**AddComment** (*comment*)

## Description

The AddComment method adds an XML comment after the beginning tag of an XML element referenced by a BiDoc object.

## Parameters

| <i>Parameter</i> | <i>Description</i>   |
|------------------|----------------------|
| <i>comment</i>   | String. The comment. |

## Returns

Number. The return status. NoError, or 0, means the method succeeded.

## Example

Here is a set of XML response code.

```
<?xml version="1.0"?>
  <postreqresponse>
    <error>
      <!--this is a comment line-->
      <errorcode>1</errorcode>
      <errortext></errortext>
    </error>
  </postreqresponse>
```

Here is the PeopleCode that builds it.

```
Local BIDocs &rootDoc, &postreqresponse, &error, &errorcode, &errortext;
Local string &blob;
Local number &ret;
&rootDoc = GetBiDoc("");

/* add a processing instruction*/
&ret = &rootDoc.AddProcessInstruction("<?xml version=""1.0""?>");
/* create an element and add text*/
&postreqresponse = &rootDoc.CreateElement("postreqresponse");
&error = &postreqresponse.CreateElement("error");
&ret = &error.AddComment("this is a comment line");
&errorcode = &error.CreateElement("errorcode");
&ret = &errorcode.AddText("1");
&errortext = &error.CreateElement("errortext");
```

## Related Links

[GetStatus](#)

## AddProcessInstruction

### Syntax

```
AddProcessInstruction(instruction)
```

## Description

The AddProcessInstruction method adds an XML processing instruction to a BiDocs object. Use this method at the root level of the BiDocs object for Incoming Business Interlinks before you add anything else to the BiDocs object.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>           |
|-------------------------|-------------------------------------|
| <i>instruction</i>      | String. The processing instruction. |

## Returns

Number. The return status. NoError, or 0, means the method succeeded.

## Example

Here is a set of XML response code.

```
<?xml version="1.0"?>
  <postreqresponse>
    <error>
      <!--this is a comment line-->
      <errorcode>1</errorcode>
      <errortext></errortext>
    </error>
  </postreqresponse>
```

Here is the PeopleCode that builds it.

```
Local BiDocs &rootDoc, &postreqresponse;
Local BiDocs &error, &errorcode, &errortext;
Local number &ret;
&rootDoc = GetBiDoc("");

/* add a processing instruction*/
&ret = &rootDoc.AddProcessInstruction("<?xml version=\"1.0\"?>");
/* create an element and add text*/
&postreqresponse = &rootDoc.CreateElement("postreqresponse");
&error = &postreqresponse.CreateElement("error");
&ret = &error.AddComment("this is a comment line");
&errorcode = &error.CreateElement("errorcode");
&ret = &errorcode.AddText("1");
&errortext = &error.CreateElement("errortext");
```

[GetStatus](#)

## AddText

### Syntax

**AddText** (*text*)

## Description

The AddText method adds text to an XML element referenced by a BiDocs object.

## Parameters

| <i>Parameter</i> | <i>Description</i> |
|------------------|--------------------|
| <i>text</i>      | String. The text.  |

## Returns

Number. The return status. NoError, or 0, means the method succeeded.

## Example

Here is a set of XML response code.

```
<?xml version="1.0"?>
  <postreqresponse>
    <error>
      <!--this is a comment line-->
      <errorcode>1</errorcode>
      <errortext></errortext>
    </error>
  </postreqresponse>
```

Here is the PeopleCode that builds it.

```
Local BiDocs &rootDoc, &postreqresponse;
Local BiDocs &error, &errorcode, &errortext;
Local number &ret;
&rootDoc = GetBiDoc("");

/* add a processing instruction*/
&ret = &rootDoc.AddProcessInstruction("<?xml version=""1.0""?>");
/* create an element and add text*/
&postreqresponse = &rootDoc.CreateElement("postreqresponse");
&error = &postreqresponse.CreateElement("error");
&ret = &error.AddComment("this is a comment line");
&errorcode = &error.CreateElement("errorcode");
&ret = &errorcode.AddText("1");
&errortext = &error.CreateElement("errortext");
```

## Related Links

[GetStatus](#)

## CreateElement

### Syntax

**CreateElement** (*elementname*)

## Description

The CreateElement method creates an XML element with the given name within a BiDoc object.

## Parameters

| <i>Parameter</i>   | <i>Description</i>            |
|--------------------|-------------------------------|
| <i>elementname</i> | String. The XML element name. |

## Returns

BiDocs. The reference to the created element.

## Example

Here is a set of XML response code.

```
<?xml version="1.0"?>
  <postreqresponse>
    <error>
      <errorcode>1</errorcode>
      <errortext></errortext>
    </error>
  </postreqresponse>
```

Here is the PeopleCode that builds it.

```
Local BiDocs &rootDoc, &postreqresponse;
Local BiDocs &error, &errorcode, &errortext;
Local number &ret;

&rootDoc = GetBiDoc("");

/* add a processing instruction*/
&ret = &rootDoc.AddProcessInstruction("<?xml version=""1.0""?>");
/* create an element and add text*/
&postreqresponse = &rootDoc.CreateElement("postreqresponse");
&error = &postreqresponse.CreateElement("error");
&errorcode = &error.CreateElement("errorcode");
&ret = &errorcode.AddText("1");
&errortext = &error.CreateElement("errortext");
```

## GenXMLString

### Syntax

**GenXMLString()**

### Description

The GenXMLString method creates an XML string from a BiDocs object. The BiDocs object must contain the shape and data needed for an XML string. This is part of the Incoming Business Interlink functionality, which enables PeopleCode to receive an XML request and return an XML response.

Parameters

None.

Returns

String. The XML string containing the shape and data of the BiDocs object. For example, you can use this method to create an XML string containing an XML response.

Example

The following example takes a BiDocs structure that contains an XML response and puts that into a text string. After this is done, the %Response.Write function can send this as an XML response.

```
Local BiDocs &rootDoc;  
Local string &xmlString;  
  
/* Create a BiDoc structure containing the data and shape of your XML response (code not shown) */  
  
/* Generate the XML string containing the data and shape of your XML response from the BiDoc structure */  
&xmlString = &rootDoc.GenXMLString();  
%Response.Write(&xmlString);
```

GetAttributeName

Syntax

```
GetAttributeName(attributenum)
```

Description

The GetAttributeName method gets the name of an attribute within an XML element referenced by a BiDocs object.

Parameters

| Parameter    | Description                                |
|--------------|--------------------------------------------|
| attributenum | Number. The index number of the attribute. |

Returns

String. The name of the attribute.

Example

Here is a set of XML request code.

```
<?xml version="1.0"?>
  <postreq>
    <email>joe_blow@example.com</email>
    <location scenery="great" density="low" blank="eh?">
      <city>San Rafael</city>
      <state>CA</state>
      <zip>94522</zip>
      <country>US</country>
    </location>
  </postreq>
```

Here is the PeopleCode that gets the name of the second attribute in the location node. &attrName is density.

```
Local BIDocs &rootInDoc, postreqDoc, &locationDoc;
Local string &blob, &attrName;
&blob = %Request.GetContentBody();

&rootInDoc = GetBiDoc(&blob);
&postreqDoc = &rootInDoc.GetNode("postreq");
&locationDoc = &postreqDoc.GetNode("location");
&attrName = &locationDoc.GetAttributeName(2);
```

GetAttributeValue

Syntax

```
GetAttributeValue({attributename | attributenum})
```

Description

The GetAttributeValue method gets the value of an attribute within an XML element referenced by a BiDocs object.

Parameters

| Parameter                                  | Description                                                                                                                                                                                        |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>attributenum</i>   <i>attributename</i> | Specify the attribute that you want to get the value for. You can specify either the attribute number (1 for the first attribute, 2 for the second, and so on) or the attribute name (an XML tag.) |

Returns

String. The value of the attribute.

Example

Here is a set of XML request code.

```
<?xml version="1.0"?>
  <postreq>
    <email>joe_blow@example.com</email>
    <location scenery="great" density="low" blank="eh?">
      <city>San Rafael</city>
      <state>CA</state>
      <zip>94522</zip>
      <country>US</country>
    </location>
  </postreq>
```

Here is the PeopleCode that gets the value of the second attribute in the location node. &attrValue is low.

```
Local BiDocs &rootInDoc, &postreqDoc, &locationDoc;
Local string &blob, &attrValue;
&blob = %Request.GetContentBody();

&rootInDoc = GetBiDoc(&blob);
&postreqDoc = &rootInDoc.GetNode("postreq");
&locationDoc = &postreqDoc.GetNode("location");
&attrValue = &locationDoc.GetAttributeValue(2);
```

GetNode

Syntax

```
GetNode({nodename | nodenumber})
```

Description

The GetNode method returns a BiDocs reference to a child XML node (element or comment). Use the GetNode method upon a BiDocs reference to an XML element to access the child nodes for that element.

Parameters

| Parameter                           | Description                                                                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>nodenumber</i>   <i>nodename</i> | Specify the node that you want to reference. You can specify either a node number (the first node is 1, the second 2, and so on) or a node name (that is, the XML tag.) |

Returns

BiDocs. The returned XML element within a BiDocs object.

Example

Here is a set of XML request code.

```
<?xml version="1.0"?>
  <postreq>
```

```
<email>joe_blow@example.com</email> <projtitle>
  <projsubtitle>first_subtitle</projsubtitle>
  <projsubtitle>second_subtitle</projsubtitle> <projsubtitle>third_subtitle<=>
</projsubtitle>
</projtitle>
</postreq>
```

Here is the PeopleCode that gets the postreqDoc element and the projtitle element.

```
Local BIDsocs &rootInDoc, &postreqDoc, &projtitleDoc;
Local string &name, &blob;
&blob = %Request.GetContentBody();

&rootInDoc = GetBiDoc(&blob);
&postreqDoc = &rootInDoc.GetNode("postreq");
&projtitleDoc = &postreqDoc.GetNode("projtitle");
```

Here is the PeopleCode that gets the postreqDoc element, the projtitle element, and the third projsubtitle element.

```
Local BIDsocs &rootInDoc, &postreqDoc, &projtitleDoc, &projsubtitleDoc;
Local string &name, &blob;
&blob = %Request.GetContentBody();

&rootInDoc = GetBiDoc(&blob);
&postreqDoc = &rootInDoc.GetNode(1);
&projtitleDoc = &postreqDoc.GetNode(2);
&projsubtitleDoc = &projtitleDoc.GetNode(3);
```

To parse a list of elements like <projsubtitle>, where elements have the same name, you must call GetNode using an index number rather than the element name.

ParseXMLString

Syntax

```
ParseXMLString(XMLstring [, DTDValidation])
```

Description

The ParseXMLString methods fills an existing BiDocs object with the data and shape from an XML string. This is part of the Incoming Business Interlink functionality, which enables PeopleCode to receive an XML request and return an XML response.

Parameters

| Parameter | Description                          |
|-----------|--------------------------------------|
| XMLstring | A string containing an XML document. |

| <b>Parameter</b>     | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DTDValidation</i> | <p>Specify whether to validate a document type definition (DTD. ) This parameter takes a Boolean value. If you specify true, the DTD validation occurs if a DTD is provided. If you specify false, and if a DTD is provided, it is ignored and the XML isn't validated against the DTD. The default value for this parameter is false.</p> <p>In the case of application messaging, if a DTD is provided, it's always ignored and the XML isn't validated against the DTD.</p> <p>If the XML cannot be validated against a DTD, an error is thrown saying that there was an XML parse error.</p> |

## Returns

Number. The return status. NoError, or 0, means the method succeeded.

## Example

The following example gets an XML request, creates an empty BiDoc, and then fills the BiDoc with the data and shape contained in the XML string. After this is done, the GetDoc method and the GetValue method can get the value of the skills XML element, which is contained within the postreq element in the XML request.

```
Local BiDocs &rootInDoc, &postreqDoc;
Local string &blob;
Local number &ret;

&blob = %Request.GetContentBody();
/* process the incoming xml(request)- Create a BiDoc and fill with the request*/
&rootInDoc = GetBiDoc("");
&ret = &rootInDoc.ParseXMLString(&blob);
&postreqDoc = &rootInDoc.GetDoc("postreq");
&ret = &postreqDoc.GetValue("skills", &skills);
```

# Incoming Business Interlink Properties

This section describes the PeopleCode properties you use with Incoming Business Interlinks.

## AttributeCount

### Description

The AttributeCount property gets the number of attributes within an XML element referenced by a BiDocs object.

This property is read-only.

## Example

Here is a set of XML request code.

```
<?xml version="1.0"?>
  <postreq>
    <email>joe_blow@example.com</email>
    <location scenery="great" density="low" blank="eh?">
      <city>San Rafael</city>
      <state>CA</state>
      <zip>94522</zip>
      <country>US</country>
    </location>
  </postreq>
```

Here is the PeopleCode that gets the number of attributes in the location XML element. &count should be 3, for scenery, density, and blank.

```
Local BIDocs &rootInDoc, &postreqDoc, &locationDoc;
Local string &blob;
Local number &count;
&blob = %Request.GetContentBody();

&rootInDoc = GetBiDoc(&blob);
&postreqDoc = &rootInDoc.GetNode("postreq");
&locationDoc = &postreqDoc.GetNode("location");
&count = &locationDoc.AttributeCount;
```

## ChildNodeCount

### Description

The ChildNodeCount property returns the number of XML child nodes within the element referenced by the BiDocs object. Child nodes include XML elements, comments, and processing instructions.

This property is read-only.

## Example

Here is a set of XML request code.

```
<?xml version="1.0"?>
  <postreq>
    <email>joe_blow@example.com</email>
    <projtitle>
      <!--this is a comment line-->
      <projsubtitle>first_subtitle</projsubtitle>
      <projsubtitle>second_subtitle</projsubtitle>
      <projsubtitle>third_subtitle</projsubtitle>
    </projtitle>
  </postreq>
```

Here is the XML code that gets the number of nodes within <postreq> and <projtitle>. &count1 is 2, for <email> and <projtitle>, and &count2 is 4, for the three <projsubtitle> nodes and the comment node.

```
Local BIDocs &rootInDoc, &projtitleDoc;
Local string &blob;
Local number &count1, &count2;
&blob = %Request.GetContentBody();
```

```
&rootInDoc = GetBiDoc(&blob);
&postreqDoc = &rootInDoc.GetNode("postreq");
&count1 = &postreqDoc.ChildNodeCount;
&projtitleDoc = &postreqDoc.GetNode("projtitle");
&count2 = &projtitleDoc.ChildNodeCount;
```

nodeName

Description

The nodeName property gets the name of an XML element referenced by a BiDocs object. Use this to get the name of an XML element when you used GetNode with an index number to retrieve it (meaning that you did not have the name of the XML element when you used GetNode).

This property is read-only.

Example

Here is a set of XML request code.

```
<?xml version="1.0"?>
  <postreq>
    <email>joe_blow@example.com</email>
    <projtitle>
      <projsubtitle>first_subtitle</projsubtitle>
      <projsubtitle>second_subtitle</projsubtitle>
      <projsubtitle>third_subtitle</projsubtitle>
    </projtitle>
  </postreq>
```

Here is the PeopleCode that gets the name of the <email> element, email.

```
Local BiDocs &rootInDoc, &postreqDoc, &emailDoc;
Local string &emailName, &blob;
&blob = %Request.GetContentBody();

&rootInDoc = GetBiDoc(&blob);
&postreqDoc = &rootInDoc.GetNode(1);
&emailDoc = &postreqDoc.GetNode(1);
&emailName = &emailDoc.NodeName;
```

NodeType

Description

The NodeType property returns the type of an XML tag within a BiDocs object as an integer. The values are:

| Value | Description                |
|-------|----------------------------|
| 1     | Element (a normal XML tag) |
| 7     | Processing instruction     |

| <b>Value</b> | <b>Description</b> |
|--------------|--------------------|
| 8            | Comment            |

This property is read-only.

## Example

Here is a set of XML request code.

```
<?xml version="1.0"?>
  <postreq>
    <email>joe_blow@example.com</email> <!--this is a comment-->
    <projtitle>
      <projsubtitle>first_subtitle</projsubtitle>
      <projsubtitle>second_subtitle</projsubtitle>
      <projsubtitle>third_subtitle</projsubtitle>
    </projtitle>
  </postreq>
```

Here is the PeopleCode that gets types: &xmlprocType is 7 for processing instruction, postreqDoc is 1 for element, and commentType is 8 for comment.

```
Local BIDocs &rootInDoc, &postreqDoc, &commentDoc;
Local number &xmlprocType, &postreqType, &commentDoc;
Local string &blob;
&blob = %Request.GetContentBody();

/* <?xml version="1.0"?> */
&rootInDoc = GetBiDoc(&blob);
&xmlprocType = &rootInDoc.NodeType;

/* <postreq> */
&postreqDoc = &rootInDoc.GetNode(1);
&postreqType = &postreqDoc.NodeType;

/* <!--this is a comment--> */
&commentDoc = &postreqDoc.GetNode(2);
&commentType = &commentDoc.NodeType;
```

## NodeValue

### Description

The NodeValue property returns the value of a node within an XML document as a string.

This property is read-only.

## Example

Here is a set of XML request code.

```
<?xml version="1.0"?>
  <postreq>
    <email>joe_blow@example.com</email>
    <projtitle>
      <projsubtitle>first_subtitle</projsubtitle>
      <projsubtitle>second_subtitle</projsubtitle>
```

```

        <projsubtitle>third_subtitle</projsubtitle>
    </projtitle>
</postreq>

```

Here is the PeopleCode that gets the value of the third <projsubtitle> element, third\_subtitle.

```

Local BIDocs &rootInDoc, &postreqDoc, &projtitleDoc, &projsubtitleDoc;
Local string &name, &blob;
&blob = %Request.GetContentBody();

&rootInDoc = GetBiDoc(&blob);
&postreqDoc = &rootInDoc.GetNode(1);
&projtitleDoc = &postreqDoc.GetNode(2);
&projsubtitleDoc = &projtitleDoc.GetNode(3);
&projsubtitleName = &projsubtitleDoc.NodeValue;

```

## Business Interlink Class Property

This section explains the StopAtError property.

### StopAtError

#### Description

The StopAtError property specifies whether the execution of the PeopleCode program stops when there's an error, or if the PeopleCode program tries to capture the errors.

This property takes a Boolean value: True to halt execution of your PeopleCode program at an error, False to continue executing. The default value is True.

This property is read/write.

#### Example

```
&QE_RP_SRAALL_1.StopAtError = False;
```

## Configuration Parameters

There are two types of configuration parameters: the ones defined by the Interlink plug-in the Business Interlink definition is based on, and the ones that are standard, that is, defined for every Business Interlink object.

All configuration parameters must be set before you add any data to the input buffers.

### Interlink Plug-in Configuration Parameters

The configuration parameters defined by the Interlink plug-in are accessed as if they were properties on the Business Interlink object. That is, in PeopleCode, you assign the value of a configuration parameter by using the Business Interlink object followed by a dot and the configuration parameter, in this format:

```
&MYINTERLINK.parameter = value;
```

You can also return the value of a configuration parameter:

```
&MYVALUE = &MYINTERLINK.parameter;
```

Each Business Interlink plug-in has its own set of configuration parameters. For example, the email project uses configuration parameters of SMTP\_MAIL\_SERVER, POP3MAIL\_SERVER, LOGIN\_NAME, PASSWORD, SENDERS\_EMAIL\_ADDRESS and REPLY\_EMAIL\_ADDRESS, while the Red Pepper transaction driver uses SERVER\_NAME, RSERVER\_HOST, RSERVER\_PORT, and TIMEOUT.

You can specify default values for every configuration parameter in the Business Interlink definition (created in Application Designer.) These values are used if you create a PeopleCode "template" by dragging the Business Interlink definition from the Project window in Application Designer to an open PeopleCode editor window.

In the following example, the Interlink object name is QE\_RP\_SRAALL\_1, and the driver is the Red Pepper driver:

```
&QE_RP_SRAALL_1.SERVER_NAME = "server";
&QE_RP_SRAALL_1.RSERVER_HOST = "pt-sun02.example.com";
&QE_RP_SRAALL_1.RSERVER_PORT = "9884";
&QE_RP_SRAALL_1.TIMEOUT = 999;
&QE_RP_SRAALL_1.URL = "HTTP://www.example.com";
&QE_RP_SRAALL_1.StopAtError = False;
```

## URL Configuration Parameter

Specifies the location and name of the Business Interlink plug-in to be used to connect to the external system. This configuration parameter takes a string value.

If the plug-in is located on a web server, you have to specify the name of the web server.

If you specify a file, you can specify either a relative or an absolute path:

- If you specify an absolute path, you must specify the drive letter:

```
&MYBI.URL = "File://D:\TEMP.MYDLL";
```

- If you specify a relative path, just use the file name:

```
&MYBI.URL = "File://TEMP.MYDLL";
```

If you specify a relative path, the system firsts looks for the file in the Location directory (specified by the user when the Business Interlink was first created), then it looks in the directory where PeopleTools is installed, in the PSTOOLS/Interface Drivers directory.

## BIDocValidate Configuration Parameter

Specifies whether the system should verify whether the hierarchical data object (BIDoc) exists before adding or getting values from it. This configuration parameter takes a Boolean value: True if the system should verify before accessing the object, False otherwise.

The default value is True.

If this configuration parameter is specified as True, and the object specified doesn't exist, the PeopleCode program halts execution and an error is displayed.

# Charting Classes

---

## Understanding the Charting Classes

PeopleTools delivers multiple charting classes to address specific charting needs. An overview of each charting class is provided in following sections.

### Chart Classes

- Chart class

Use the Chart class to visually display data series in common formats, including bar charts, line charts, pie charts, bubble charts, and funnel charts.

- ChartClientState class

The ChartClientState class is used in conjunction with the Chart class to manage and maintain user-selected data items on charts.

- Series class

The Series class is used in conjunction with the Chart class to override the default chart type (as defined for the Chart object) for each specified data series. Using the Series class allows you to create combination (or overlay) type charts.

- ToolTipLabel class

The ToolTipLabel class is used in conjunction with the Chart class to display custom tooltips (also referred to as “data hints” or “hover text) on charts thereby overriding the default tooltips that are automatically created from the chart data.

- ReferenceArea class

The ReferenceArea class is used in conjunction with the Chart class to display bands of color to be drawn with the chart based on numeric values along a chart axis. For each band of color, you would create a separate instance of the ReferenceArea class.

- ReferenceLine class

The ReferenceLine class is used in conjunction with the Chart class to display colored lines to be drawn with the chart based on numeric values along a chart axis. For each reference line, you would create a separate instance of the ReferenceLine class.

This chart was created from the Chart class with a chart type of bar:

**Related Links**

- [Creating PeopleSoft Charts](#)
- [Using the Chart Class](#)

**Gantt Class**

Use the Gantt class to create interactive Gantt charts that enable you to display and edit project and task information.

This chart created from the Gantt class shows both the task area and chart area of a Gantt chart:

**Related Links**

- [Using the Gantt Class](#)

**Gauge Classes**

The gauge classes are:

- LEDGauge class.
- RatingGauge, RatingGaugeState, and GaugeThreshold classes.
- StatusMeterGauge class.

- Threshold class.

Use the gauge classes to create gauges that display metrics in several common formats, including status meters, ratings, and LEDs.

The Threshold class is used in conjunction with the gauge classes: LEDGauge and StatusMeterGauge. The Threshold class provides a way to add reference areas and color coding to your gauges.

## Related Links

[Using the Gauge Classes](#)

## OrgChart Class

Use the OrgChart class to create interactive organization charts that enable you to visually represent a hierarchy of information as a series of connected nodes.

This chart created from the OrgChart class shows an organization chart:

## Related Links

[Using the OrgChart Class](#)

## RatingBoxChart Class

Use the `RatingBoxChart` class to create rating box charts that enable you to display and manipulate points of information in two-dimensional bins.

This chart created from the `RatingBoxChart` class shows a rating box chart:

### Related Links

[Using the RatingBoxChart Class](#)

## Spark Chart Class

Use the `SparkChart` class with the `SparkChartItem` class to create visualizations of the trend of a data set in a compact form factor.

The following example illustrates five spark chart types: an area chart, a bar chart, a floating bar chart, a line chart, and a line with area chart.

## Related Links

[Using the Spark Chart Classes](#)

# Creating PeopleSoft Charts

This section discusses the process of creating charts using any of the PeopleSoft charting classes. Further details can be found in the specific section for each chart class.

The topics discussed in this section relate to all of the charting classes.

## Creating a Chart on a Page

This section summarizes the basic steps to create a chart. The basic steps are essentially the same for all charting classes.

At the end of this chapter are examples of charts with step-by-step instructions and complete PeopleCode programs.

The Chart class section has fundamental, detailed instructions for creating a chart using the Chart class. Each specialized class – Gantt class, OrgChart class, and RatingBoxChart class – has detailed instructions that build on the Chart class instructions.

**Note:** The following steps are for creating a chart on a PeopleSoft application page. You can also create a chart for a web page using an iScript. Only Chart class charts can be created using an iScript.

See [Creating a Chart Using an iScript](#).

To create a chart on a page:

1. In Application Designer, place a chart control on a page and associate the chart with a record field.
2. Create a record to hold your chart data.

For charts made using the `OrgChart` class and the `RatingBoxChart` class, you also create a record that controls the appearance of the chart. Place each record on a level-1 grid on the page so the chart records are present in the component buffer at runtime. You can optionally hide the grid. You can also optionally place the grid on another page on the same component.

Place the page on a component and register the component.

3. Add `PeopleCode`, probably on the page `Activate` event, to instantiate the chart object and associate it with the page control.

For example, this is the minimum `PeopleCode` to create a bar chart using the `Chart` class.

```
/* Declare and instantiate a chart object; */
Component Chart &cChart11;
&cChart11 = GetChart(DOC_CHRT_WRK.DOC_CHRT_FLD_11);

/* Set the chart data record and specify x-axis, y-axis, and series data; */

&cChart11.SetData(Record.DOC_CHRT_SLS_2);
&cChart11.SetDataXAxis(DOC_CHRT_SLS_2.DOC_CHRT_RGN);
&cChart11.SetDataYAxis(DOC_CHRT_SLS_2.DOC_CHRT_SALES);
```

4. View the chart in the browser.

Suppose you have this data in `DOC_CHRT_SLSREC`:

| <b>Region</b> | <b>Sales</b> |
|---------------|--------------|
| Arizona       | 62           |
| California    | 50           |
| Oregon        | 42           |
| Washington    | 50           |

This is the bar chart generated by the example code and data. The default chart type for the `Chart` class is a bar chart. Since no colors are specified, the chart uses the default colors.

This example illustrates a simple bar chart:

5. Add PeopleCode to control the behavior of the chart or to modify its appearance at runtime. For example, for a bar chart you might add FieldChange PeopleCode to the y-axis field on your data record to display information when a user clicks a data point.

See “Adding Drilldown” in [Creating a Chart Using the Chart Class](#).

You can also add FieldChange PeopleCode to a Gantt chart, organization chart, or rating box chart to enable the user to interact with the chart.

[Using the Chart Class](#)

[Using the Gauge Classes](#)

[Using the Spark Chart Classes](#)

[Using the Gantt Class](#)

[Using the OrgChart Class](#)

[Using the RatingBoxChart Class](#)

## Creating a Chart Using an iScript

If possible, you should put a chart on a page definition. If not possible, then you can build a chart at runtime using an iScript and call the chart using a URL. Use the CreateObject function in the iScript instead of the GetChart function. You can then use the GetChartURL Response class method to use the URL in your application.

---

**Note:** You can create only Chart class charts using an iScript. Any charts created using an iScript have limited functionality as compared to charts defined using the Application Designer chart control. Notably, neither interactivity (the charts will be static) nor animations are available. Gauge chart classes, Gantt class, OrgChart class, and RatingBoxChart class charts cannot be created with an iScript.

---

For example, this PeopleCode would build a chart using a standalone rowset:

```
Function IScript_GetChartURL()
local object &MYCHART;
local string &MYURL;

&MYCHART = CreateObject("Chart");
&MYCHART.SetData(xx);

/* xx will be a data row set */

&MYURL = %Response.GetChartURL(&MYCHART);

/* use &MYURL in your application */
...
End-Function;
```

### Related Links

[Creating a Chart Using an iScript](#)

---

## Special Considerations for Charts

This section discusses special considerations for using the PeopleSoft charting classes.

### Component Processor Considerations

Sometimes, records at level zero on a page are considered *work* records, even when they are not specified as such in Application Designer. Work records are not updated by the database and are skipped when the component is run.

A level-zero record is marked as a work record when any of these conditions is true:

- The record is designated as a work record in Application Designer.
- All fields for the record are used as read-only fields.
- All values for these fields can be read from the input keys.

When a chart area is attached to a level-zero record field of a record considered to be a work record, it is also skipped when the system determines that record's 'work' status.

### Related Links

“Understanding Component Buffer Structure and Contents” (PeopleCode Developer’s Guide)

### Translation Considerations

If you hard code a value for a label, a title, a data hint, and so on, then that value is *not* translated. Be sure to specify field values as message catalog entries that will be translated.

### Text Considerations for the Chart Class

Text can be found at the following locations in a Chart class chart:

- Chart title.
- Chart subtitle.
- Chart footnote.
- Chart data item labels.
- X-axis and y-axis titles.
- X-axis and y-axis labels.
- Legend descriptions.
- Pie chart segment labels.
- Data hints (hover or mouse over text).

Font types and sizes for chart titles, subtitles, footnotes, axis titles, and axis labels in charts are defined as style classes in PeopleSoft style sheets. The delivered style classes are designed to work with the overall theme of the PeopleSoft user interface. The delivered style classes apply to all charts in the system. Although they are changeable in the Application Designer, Oracle recommends that you keep them as delivered unless you have a good reason to change them.

Axis labels are positioned by the charting engine as part of the overall rendering of the chart graphic. The general pattern for axis and pie chart segment label display is this:

- The font size of the label text remains constant.
- The charting engine will try to maximize the size of the chart graphic while fitting all label text around the graphic.
- The chart graphic area will shrink to a minimum threshold size as the text for labels grows longer.
- After the minimum chart graphic area threshold size is reached, the chart graphic no longer shrinks and labels are displayed in an unpredictable fashion.

There are special considerations depending on whether the type of label is for an x-axis, a y-axis, or a pie chart segment.

## **Best Practices for Managing Chart Text**

The best ways to minimize the chance of unpredictable text are:

- Use the smallest font that is readable for text labels. PeopleTools is delivered with a small point size for axis labels in order to allow more characters to be rendered.
- The larger the chart area is defined, the more room will be available for labels.
- Try to build your charts using short (but descriptive) fields for axis labels.
- Make sure that data hints are always used in your charts to compensate when labels cannot be displayed.

## Tooltips (Data Hints or Hover Text)

Each data item in a chart (a bar in a bar chart, for instance) has a tooltip. A default tooltip is created automatically based on the composition of the chart.

The following example displays a bar chart with the default tooltip for the selected data item:

The following example displays a bubble chart with the default tooltip for the selected data item:

The default tooltip text that appears is constructed from information about the composition of the chart that you have defined and the row of data being charted.

You can modify the labels for the tooltip items by using the `TooltipLabel` class in conjunction with the `Chart` class. Your custom labels will be displayed in the default format.

The following example displays a bar chart with custom tooltips for the selected data item generated using the `TooltipLabel` class:

Alternatively, to fully customize tooltips for chart data items you can use the `SetDataHints` method of the `Chart` class.

## Related Links

[Using the `TooltipLabel` Class](#)

[SetDataHints](#)

## Text Considerations for the Gantt Class

For Gantt charts, use double quotes to correctly display the use of single quotes in your label, if applicable.

## Considerations for Using Mobile Devices

Because mobile devices such as mobile phones, the Apple iPad, or Windows tablets do not use a mouse and rely on touch interactions instead, you interact with charts differently on these devices. To click a button, link, or chart object, tap the touch screen with one finger. To display tooltips for a chart, tap the touch screen twice (double-tap). Tooltips disappear after a few seconds or when you tap another object with a tooltip.

To move a node in a rating box chart, tap once to select the node. Then, tap once in a different grid box to move the node to that box.

---

**Note:** Drag-and-drop on Gantt charts is not supported on mobile devices.

---

## Fluid Mode Considerations for Charts and Gauges

Defining charts and gauges for fluid pages is very similar to defining charts and gauges for classic mode. There are some key differences that you need to take into account.

The following information is specific to the following classes:

- Chart class
- DialGauge class
- LEDGauge class
- RatingGaugeChart class
- StatusMeterGauge class
- SparkChart class

### Each Chart Must be Enclosed by a Dedicated Group Box

In Application Designer, always place the chart control within a group box and ensure that no other controls are within the group box.

In this example, there are three charts on this fluid page. Each is in its own group box, and all three charts and their group boxes are within a containing group box:

The group boxes that immediately contain the chart controls must be defined as Container group boxes:

You can specify other styles as well to help position the chart or gauge within the page.

## Specifying Chart Dimensions

When a chart or gauge is placed on a fluid page, the width, height, and aspect ratio are all considered when determining its size. Each chart should be contained by a group box that only has that chart within it.

The width of the chart is determined by the width of the parent group box that contains the chart. The width of the group box (and therefore the chart) can be further controlled by applying a style in the Fluid tab of the group box control in Application Designer.

The height of the chart is determined by the width of the chart and the `AspectRatio` property. The height will be calculated as the width multiplied by the aspect ratio. If no `AspectRatio` property is provided, the `Height` property will be used to determine the fixed height of the chart or gauge.

---

**Note:** The `AspectRatio` property does not apply to the `DialGauge` class; use the `Height` property instead.

---

**Important!** If both the `Width` and `Height` properties are supplied with no `AspectRatio` property, they will be used to produce a fixed size chart or gauge. This chart will not be realizable once its rendered.

---

On the Fluid tab of the enclosing group box, add a style that specifies the width of the container. The chart will use this information to dynamically determine its width. In this example, the containing group box is styled to use 85% of the container (that is, the group box) that contains it:

```
psc_width-85pct
```

If necessary, you can specify overrides for different form factors to achieve an appropriately sized chart or gauge.

Typically, you specify the height of the chart or gauge as a proportion of the width by assigning a value to the AspectRatio property in PeopleCode. Here's an example:

```
&cChart.AspectRatio = 0.8;
```

The `AspectRatio` property value should be greater than 0. If this property is not specified, the default value of 1 is used. `AspectRatio` is a property of the following classes:

- Chart class: [AspectRatio](#)
- LEDGauge class: [AspectRatio](#)
- RatingGaugeChart class: [AspectRatio](#)
- StatusMeterGauge class: [AspectRatio](#)
- SparkChart class: [AspectRatio](#)

## Sizing a Chart or Gauge in Classic Mode

When a chart or gauge is placed on a classic page, the size of the chart or gauge is determined in one of two ways:

- By the `Height` and `Width` properties, which specify the dimensions in pixels.
- By the dimensions of the chart page control in Application Designer.

If the class `Height` and `Width` properties are not specified, the dimensions from the chart control are used.

## Styling PeopleSoft Charts

PeopleSoft charts are flexible in terms of styling. Styling covers colors and fonts that you see when you look at a chart. Style specifications are generally defined in Application Designer style sheets so that they are accessible to application developers. Specifically, they are defined in sub style sheets that are then attached to high-level system style sheets such as `PSSTYLEDEF_TANGERINE` which are used throughout a system ensuring consistent look and feel.

## Charting Sub Style Sheet Organization

The organization of the charting sub style sheets is straightforward. Each chart class has its own set of styles. These styles are in one or more sub style sheets that have a naming convention as shown in the table below.

| <b>Charting Class</b>                                                                                                              | <b>Sub Style Sheet Begins With</b> |
|------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| Chart<br>DialGauge<br>LEDGauge<br>ReferenceArea<br>ReferenceLine<br>Series<br>StatusMeterGauge<br>Threshold<br><b>ToolTipLabel</b> | PSCHARTSTYLE, PSJET                |
| Gantt                                                                                                                              | PSCHARTGANTT                       |
| OrgChart                                                                                                                           | PSORGCHART                         |
| RatingBoxChart                                                                                                                     | PSRATEBOX                          |

Different specifications of the styles will be in sub style sheets that are appended with an underscore (“\_”) followed by a suffix, which is usually the name of the theme.

For instance, PSCHARTSTYLE and PSCHARTSTYLE\_TANGERINE have the same styles but the specifications for these styles differ because PSCHARTSTYLE is used for the Swan user interface theme while PSCHARTSTYLE\_TANGERINE is used for the Tangerine user interface theme. Similarly, the \_FMODE suffix specifies fluid mode style sheets.

See “Configuring Branding System Options” (Portal Technology) for more information on how to specify the theme and default style sheet for your system..

## Altering Style Specifications

The styles delivered for charting are designed to work harmoniously with the branding theme that they are associated with. There may be times, however, when you want a different look and feel from the delivered one. Scenarios may include:

- You want to implement a system-wide change in theme (including not only charts but other visual elements such as headers, grids, and so on).
- You want to implement a system-wide change in chart style specification within the context of one of the PeopleSoft delivered themes. An example might be to change the sequence in which colors appear on charts or to change the font size of one of the chart text elements such as the axis titles.

- You want to implement a style modification on a particular chart or particular family of charts. For instance, there may be certain charts that appear on pagelets in which you want the main title to have a large font and be bold.

Different approaches lend themselves to these different scenarios.

*Scenario 1: Implement system-wide change in theme*

In this scenario you would most likely be creating a new system style sheet for your implementation probably by cloning one of the high level style sheets that PeopleSoft delivers. Once you have done this, follow the steps in Scenario 2 for the charting sub style sheets.

*Scenario 2: System-wide change in chart style specifications*

1. Identify the charting style classes that you want to change.
2. Identify the charting sub style sheet in which those style classes reside.
3. Clone those sub style sheets.
4. In the cloned sub style sheets, update the values of the style classes that you want to change.
5. Attach the cloned sub style sheets to the default style sheet for your PeopleSoft system.
6. Detach the delivered sub style sheets from the same default style sheet.
7. Test the results.

---

**Important!** Do not change the delivered style sheets and sub style sheets. The best practice is to clone them and make changes to the clones.

---

---

**Important!** Do not delete style classes from original or cloned style sheets or sub style sheets. Doing so may compromise chart creation.

---

There is no guarantee that the style sheet value changes that you make will work as expected in the application, as style class specification changes may impact chart creation. You must test the results of your changes to verify that they are working. If changes are not working as expected, you need to try a different style class value.

*Scenario 3: Minor style modification*

PeopleSoft charting provides a means to override delivered styles on a granular basis on the Chart class and gauge classes. If you need to override one or more delivered style class definitions found in a PSCHARTSTYLE\* sub style sheet, do the following:

1. Create a new free form sub style sheet in Application Designer.
2. Open up the PSCHARTSTYLE\* sub style sheet that contains the style class definitions.
3. Copy the specific style class definitions and paste them into the new free form sub style sheet.

---

**Note:** Putting the style class definitions into a new free form sub style sheet will simplify your future PeopleTools upgrades.

---

4. Append an underscore (“\_”) to the end of the copied style class names followed by an identifier of your own choosing. These new style class definitions are the overriding styles. For example, an overriding style class name for the PSCHARTLEGEND style class could be PSCHARTLEGEND\_NEW.
5. Edit the new style class definitions that you have created to suit your needs and save the sub style sheet.
6. Insert the new free form sub style sheet into the default system style sheet that your environment is using.
7. For any chart that you want to use your custom styles, set the AdditionalStyleSuffix property to the identifier you used in step 4.

When the chart is generated at runtime, it will first use any styles that have your override identifier. If such a style class definition is not found, the chart will use the base style that you copied instead.

See Chart class: AdditionalStyleSuffix, DialGauge class: AdditionalStyleSuffix, LEDGauge class: AdditionalStyleSuffix, and StatusMeterGauge class: AdditionalStyleSuffix.

## Accessibility Settings for Charts

Use the Chart Options page to specify system-wide accessibility settings. When accessibility is enabled for a chart type and the user signs in with screen reader mode on, the system generates the chart data in an HTML table that is in an accessible format for assistive technologies. For some chart types, this “accessible table” is in addition to the graphical rendering of the chart; in other cases, the accessible table is the only output generated.

- For the Chart class and the gauge classes, the accessible table is in addition to the graphical rendering of the chart.
- For the Gantt class, the accessible table is the only output generated.

Navigation:

**PeopleTools > Utilities > Administration > Chart Options**

This example illustrates the fields and controls on the Chart Options page.

[illegible]

| <b>Field or Control</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Color Contrast Mode for Charts

By default, the adjacent colors in a chart are separated by a gap between the colors and a black border to fulfil accessibility requirements, and this setting is defined by the *PTCOLORCONTRAST* property, which is specified on the Chart Options page.

*PTCOLORCONTRAST* is a system-wide setting that defines the color contrast mode for all charts.

The following examples show the differences between a pie chart that is enabled for color contrast mode and a pie chart that is not enabled for color contrast mode.

Example of a pie chart with the color contrast mode set to enabled, which is the default rendering.

Example of a pie chart with the color contrast mode set to disabled.

You can override the default color contrast mode using either of the following options:

- Access the Chart Options page (**PeopleTools > Utilities > Administration > Chart Options**) and set the value of the *PTCOLORCONTRAST* property to 0. The default value is 1, that is, the color contrast mode is enabled.

You should remember that *PTCOLORCONTRAST* is a system-wide setting.

- For an individual chart, you can set the chart property *IsColorContrastMode*, in PeopleCode, to false.

---

**Note:** When you set the color contrast mode using the *IsColorContrastMode* property for an individual chart, it takes highest precedence. That is, it overrides the color contrast mode, which is set on the Chart Options page, for the individual chart.

---

For more details, see [IsColorContrastMode](#).

## Using the Chart Class

Use the Chart class to create charts that display data series in several common formats, including bar charts, line charts, pie charts, and others.

This section provides an overview of Chart class terms and discusses how to use various Chart classes.

## Understanding Chart Class Terms

The following is a list of Chart class terms and their descriptions:

| <i><b>Field or Control</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                                                                                 |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Label                          | Text that identifies the data on one of the axes.                                                                                                                                                                                                                                                                         |
| Legend                         | Text that identifies the different series in the chart.                                                                                                                                                                                                                                                                   |
| Series                         | A grouping of related information. For example, if you were tracking sales for several divisions over many years, each division could be a series. Generally, every series in a chart has a distinct color. You can have more than one series in a chart for comparison. Each line in a line chart represents one series. |
| Title                          | The three titles are main, x-axis, and y-axis. Each title identifies a portion of the chart.                                                                                                                                                                                                                              |
| Subtitle                       | The subtitle appears to the left of the main title.                                                                                                                                                                                                                                                                       |
| Footnote                       | The footnote appears at the bottom left of the chart.                                                                                                                                                                                                                                                                     |
| X-axis                         | The axis that data is measured against.                                                                                                                                                                                                                                                                                   |

| <b>Field or Control</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Y-axis                  | The axis that contains the data. In most charts, this is the vertical axis. In a horizontal bar chart, this is the horizontal axis.                                                                                                                                                                                                                                                                                                                   |
| Secondary y-axis        | A secondary y-axis (or Y2 axis) is one that contains data that differs from the primary y-axis but is measured against the same x-axis data and plotted on the same chart as the primary y-axis data.                                                                                                                                                                                                                                                 |
| Reference area          | A reference area is displayed in conjunction with a chart as a band of color drawn based on numeric values along a chart axis. For each band of color, you would create a separate instance of the ReferenceArea class.                                                                                                                                                                                                                               |
| Reference line          | A reference line is displayed in conjunction with a chart as a colored line drawn based on a numeric value along a chart axis. For each line, you would create a separate instance of the ReferenceLine class                                                                                                                                                                                                                                         |
| Series                  | A series is a set of data grouped together based on a common attribute and most often is plotted on the y-axis. In PeopleSoft applications, chart data series are a grouping of related information. For example, if you were tracking sales for several divisions over many years, each division could represent a series. Generally, every series in a chart has a distinct color and you can have more than one series in a chart for comparison.. |
| Tooltip                 | A tooltip is a message that appears when the cursor is positioned over a data point, legend or other element in a chart. The tooltip provides more information about the item of interest. While default tooltips are generated automatically, the ToolTipLabel class and the SetDataHints method provide two alternative methodologies for generating custom tooltips.                                                                               |

## Creating Charts Using the Chart Class

You can specify a rowset and have it graphed using a chart object with minimal PeopleCode. Within this rowset, one column must contain data for the x-axis and another column must contain data for the y-axis. If more than one series of data is used, an additional column is required for each series. You can also set color and data hint text for each point in this rowset using additional columns.

The following distinguishable types of data can be included in a chart:

- Primary data.
- Secondary data.

For a conceptual overview, a chart is easier to view in parts; however, these parts do not represent sub-objects. A chart contains the following major parts:

- X-axis.
- Y-axis.
- Legend.
- Data .
- Title.
- Subtitle.
- Footnote

The x- and y-axes have access to titles and labels associated with their data.

## Chart Class Chart Types

The following chart types are available for the Chart class:

- Bar.
- Bubble.
- Funnel.
- Histogram.
- Horizontal bar.
- Horizontal percent bar.
- Horizontal stacked bar.
- Line.
- Percent bar.
- Pie.
- Ring.
- Scatter.
- Stacked bar.

## Chart Class Design Guidelines

These topics provide an overview of how charts represent data and discuss:

- Charting numeric data sets.

- Determining the appropriate chart type.
- Setting chart colors.
- Setting chart legends.

## Understanding How Charts Represent Data

PeopleSoft charts are an alternative means of visualizing tabular data.

For example, here is an example data table (with column headings):

| <b><i>Product</i></b> | <b><i>Color</i></b> | <b><i>Created In</i></b> | <b><i>Applied in<br/>Month</i></b> | <b><i>Salesperson</i></b> | <b><i>Chart<br/>Height*</i></b> | <b><i>Units*</i></b> | <b><i>Revenue*</i></b> |
|-----------------------|---------------------|--------------------------|------------------------------------|---------------------------|---------------------------------|----------------------|------------------------|
| Bicycle               | Red                 | 2012                     | 01                                 | Terry                     | 72                              | 5                    | 360                    |
| Tricycle              | Blue                | 2012                     | 01                                 | Jim                       | 84                              | 3                    | 600                    |
| Unicycle              | Silver              | 2012                     | 02                                 | Terry                     | 72                              | 1                    | 150                    |

\* Numeric data

Some of the columns carry numeric measures (in our example, Units, Revenue, and Chart Height in Inches) and other columns have values that describe the data (for example, Product, Color, Month, Year, and Salesperson). Some of the data columns are numeric; others are not.

To create a chart you need to determine which fields you want to see in the chart. Then, you pass those into certain Chart class methods:

- `SetDataXAxis`.
- `SetDataYAxis`.
- `SetDataSeries`.
- `SetDataZAxis`.
- `SetFunnelDataActual` (for funnel charts only).
- `SetFunnelDataTarget` (for funnel charts only).

Each of these methods takes `RECORD.FIELD` as a parameter. In addition, `SetDataYAxis` can take multiple `RECORD.FIELD` parameters.

## Charting Numeric Data Sets

These sections discuss:

- Charting one set of numeric data.
- Charting two sets of numeric data.

- Charting three sets of numeric data.

## Charting One Set of Numeric Data

In general, you pass a field with numeric data to `SetDataYAxis` and a field with non-numeric data to `SetDataXAxis`. These two methods are required.

Here's a simple example. Suppose you want to show revenue by product as a chart. Essentially, this is the rowset that you'll be working with, a subset of the rowset introduced previously:

| <b><i>Product</i></b> | <b><i>Revenue*</i></b> |
|-----------------------|------------------------|
| Product               | Revenue*               |
| Bicycle               | 360                    |
| Tricycle              | 600                    |
| Unicycle              | 150                    |

\* Numeric data

In this case, choose the Revenue field to be passed to `SetDataYAxis` and the Product field to be passed to `SetDataXAxis`.

If you choose to display this as a pie chart, you end up with this:

Or, you could display the data as a bar chart:

Alternatively, you could display the data with any chart type that can display one dimension of data, such as a horizontal bar, a line, a histogram, or other chart type.

What if you also wanted to show the same information but with additional month information? The table of data that you would be interested in is:

| <b>Product</b> | <b>Month</b> | <b>Revenue*</b> |
|----------------|--------------|-----------------|
| Bicycle        | 01           | 360             |
| Tricycle       | 01           | 600             |
| Unicycle       | 02           | 150             |

\* Numeric data

In that case, choose the Revenue field to be passed to `SetDataYAxis` , the Product field to be passed to `SetDataXAxis` , and the month field to be passed to `SetDataSeries`.

You would need to use a chart type that can display two dimensions along with the data. This rules out the pie chart, but you can still use a bar chart:

To get a different view of the same data, you can change the method assignments, so that Month is passed in SetDataXAxis and Product is passed in SetDataSeries. The chart that results is this:

## Charting Two Sets of Numeric Data

The following chart types allow you to plot two sets of numeric data:

- Scatter chart
- Line chart
- Histogram
- Funnel chart

- Overlay chart

The scatter and line charts let you plot one set of numeric data vertically along the y-axis and one set of data horizontally along the x-axis.

The funnel chart lets you plot both sets of numeric data vertically on the y-axis.

Here’s an example of a scatter chart representing the following table of data:

| <i><b>Tenure*</b></i> | <i><b>Salary*</b></i> |
|-----------------------|-----------------------|
| 11                    | 88000                 |
| 12.2                  | 96200                 |
| 4.6                   | 101300                |
| 6.6                   | 83000                 |
| 14                    | 111200                |
| 8.5                   | 118000                |

\* Numeric data

This example illustrates the scatter chart for the preceding data:

You can also use a line chart to represent the same data. Whereas the scatter chart requires both x- and y-axes to be numeric, the line chart x-axis can be either numeric or non-numeric.

In a funnel chart one set of data is specified using the `SetFunnelDataActual` method and the other set of data is specified using the `SetFunnelDataTarget` method.

Here’s an example of a funnel chart that graphs two sets of data, a target amount and an actual amount:

For funnel charts, these additional considerations apply:

- `SetData` and `SetDataXAxis` are required.
- `SetFunnelChartDataActual` can be used instead of `SetDataYAxis`; either are valid.
- `SetFunnelChartDataTarget` is optional. When used, `SetFunnelChartDataTarget` must specify the same record as `SetFunnelChartDataActual`.

**Note:** Legends are not available for funnel charts. The use of Chart class methods and properties for legends has no effect on a funnel chart.

### Charting Three Sets of Numeric Data

You can use the bubble chart to display three sets of numeric data. The first two sets are along the x- and y-axes just as if you were plotting two sets of numeric data. The third set of numeric data is displayed as the size of the bubble positioned at the (x,y) coordinate in the chart and is set by passing the field in the `SetDataZAxis` method.

Using the same data as the previous scatter chart example, a third column of numeric data (Age) is included:

| <i><b>Tenure*</b></i> | <i><b>Salary*</b></i> | <i><b>Age*</b></i> | <i><b>Name</b></i> |
|-----------------------|-----------------------|--------------------|--------------------|
| 11                    | 88000                 | 39                 | Joyce              |

| <i><b>Tenure*</b></i> | <i><b>Salary*</b></i> | <i><b>Age*</b></i> | <i><b>Name</b></i> |
|-----------------------|-----------------------|--------------------|--------------------|
| 12.2                  | 96200                 | 55                 | Tolstoy            |
| 4.6                   | 101300                | 32                 | Shelley            |
| 6.6                   | 83000                 | 48                 | Tolkien            |
| 14                    | 111200                | 59                 | Dickens            |
| 8.5                   | 118000                | 49                 | Hemingway          |

\* Numeric data

This example illustrates the bubble chart for the preceding data:

## Determining the Appropriate Chart Type

Use the following procedures to determine the chart types that are appropriate for your data set:

- One set of numeric data.
- Two sets of numeric data.
- Three sets of numeric data.

Care should be taken when using the line chart with non-numeric data on the x-axis. You should only use it when the data along the x-axis suggests some sort of progression. For example, using a line chart when the x-axis represents a sequence of months is appropriate; using a line chart when the x-axis represents a list of people in alphabetical order probably is not.

Use the following flowchart to determine which chart types are appropriate to your data. In addition, the flowchart visually presents the methods and properties to use with your chart:

## Determining the Chart Type for One Set of Numeric Data

Use the following procedure to determine the chart type and methods and properties to use for one set of numeric data:

1. Use the following flowchart to determine which chart types are appropriate to your data. In addition, the flowchart visually presents the methods and properties to use with your chart:

Pass numeric data to SetDataYAxis.

2. Pass non-numeric data to `SetDataXAxis`.
3. Does the numeric data include 0 or negative values? If yes, finish by selecting one of these appropriate chart types:
  - Bar
  - Stacked bar
  - Horizontal bar
  - Horizontal stacked bar
  - Line
  - Histogram

---

**Note:** Negative values cannot be displayed in any type of percent bar chart.

---

4. Otherwise, do you need to display more than one series of data? If no, finish by selecting one of these appropriate chart types:
  - Pie
  - Ring
  - Bar
  - Stacked bar
  - Percent bar
  - Horizontal bar
  - Horizontal stacked bar
  - Horizontal percent bar
  - Line
  - Histogram
5. Otherwise, select one of these appropriate chart types:
  - Bar
  - Stacked bar
  - Percent bar
  - Horizontal bar
  - Horizontal stacked bar
  - Horizontal percent bar
  - Line

- Histogram

## Determining the Chart Type for Two Sets of Numeric Data

Use the following procedure to determine the chart type and methods and properties to use for two sets of numeric data:

1. Do you have other non-numeric data to display? If no, complete steps 2 and 3:
2. Select one of these appropriate chart types:
  - Line.
  - Histogram.
  - Scatter.
  - Funnel (with both actual and target data).
  - Overlay.
3. Use these methods and properties for scatter, line, and histogram charts:
  - a. Pass numeric data to `SetDataYAxis`.
  - b. Pass numeric data to `SetDataXAxis`.
4. Otherwise, if you need to display more than one series of data in a funnel chart, complete the following:
  - a. Pass the non-numeric data to `SetDataXAxis`.
  - b. Pass numeric data to `SetFunnelDataActual`. (Alternatively, pass the numeric data to `SetDataYAxis`).
  - c. (Optional) Pass numeric data to `SetFunnelDataTarget`.

## Determining the Chart Type for Three Sets of Numeric Data

Use the following procedure to determine the chart type and methods and properties to use for three sets of numeric data:

1. Select the appropriate chart type: Bubble.
2. Pass numeric data to `SetDataYAxis`.
3. Pass numeric data to `SetDataXAxis`.
4. Pass numeric data to `SetDataZAxis`.

## Setting Chart Colors

Chart colors are determined in the following ways:

- Automatically.
- By using the `SetColorArray` method to specify an array of color choices.
- By using the `SetDataColor` method to specify a field on a record that holds a color value.

Automatic color determination occurs when neither of the other two methods is used. For all charts except pie charts, each data series is assigned a color; all data points within a series share that color. For pie charts each data point is assigned its own color. In that way it's easier to distinguish pie segments from one another. Here is an example of the base data that will be charted:

| <i><b>Year</b></i> | <i><b>Review Rating</b></i> | <i><b>Percent</b></i> | <i><b>Color</b></i> |
|--------------------|-----------------------------|-----------------------|---------------------|
| 2011               | 1-POOR                      | 2.00                  | 0                   |
| 2011               | 2-FAIR                      | 5.00                  | 1                   |
| 2011               | 3-GOOD                      | 50.00                 | 2                   |
| 2011               | 4-VERY GOOD                 | 20.00                 | 3                   |
| 2011               | 5-OUTSTANDING               | 10.00                 | 4                   |
| 2011               | 6-NONE                      | 13.00                 | 5                   |
| 2012               | 1-POOR                      | 5.00                  | 6                   |
| 2012               | 2-FAIR                      | 10.00                 | 7                   |
| 2012               | 3-GOOD                      | 15.00                 | 8                   |
| 2012               | 4-VERY GOOD                 | 20.00                 | 9                   |
| 2012               | 5-OUTSTANDING               | 10.00                 | 10                  |
| 2012               | 6-NONE                      | 40.00                 | 11                  |

The Review Rating field is assigned to the x-axis, Percent is assigned to the y-axis, and Year is assigned to the data series:

```
&cChart.SetData(Record.CJY_RVW_DSTRBTN);
&cChart.SetDataXAxis(CJY_RVW_DSTRBTN.CJY_RVW_RTG);
```

```
&cChart.SetDataYAxis(CJY_RVW_DSTRBTN.CJY_DSTRBTN_PCT);
&cChart.SetDataSeries(CJY_RVW_DSTRBTN.CJY_YR);
```

**Note:** In the following examples, because pie charts can display one series of numeric data only, the pie charts reflect data from the first six rows only (the first data series). The bar charts reflect both series of data.

Automatic color generation results in the following bar and pie charts:

SetColorArray allows you to create an array of color values in PeopleCode and pass that to the charting engine for use in rendering the chart. It works the same way as using automatic color assignment, except that it allows you to pass in a color sequence that differs from the style sheet's default sequence. For bar charts, each data series is assigned a color; all data points within a series share that color. In the preceding example, all data for the year 2011 is displayed in blue bars; for the year 2012, in red bars. For pie charts each data point is assigned its own color.

Using the same data as before, the SetColorArray method can be used to specify a color array:

```
&clr_array = CreateArray(%ChartColor_Black,%ChartColor_Blue,%ChartColor_Cyan,%ChartColor_DarkGray,%ChartColor_Gray, %ChartColor_Green);
rem The preceding is equivalent to CreateArray(0,1,2,3,4,5);
&cChart.SetColorArray(&clr_array);
```

Specifying the color array results in these charts:

SetDataColor works a bit differently from SetColorArray. By using the value of a record field, SetDataColor provides more granular control of bar chart colors, in that you can vary bar color data point by data point and not by the higher level data series:

```
&cChart.SetDataColor(CJY_RVW_DSTRBTN.CJY_COLOR);
```

Note that in the preceding data grid, each row of data also includes a color value. The charts that result are:

If both SetColorArray and SetDataColor are set for a chart, SetDataColor takes precedence and SetColorArray is ignored.

## Setting Chart Legends

The chart property HasLegend must be set to true for a legend to appear.

```
&cChart.HasLegend = True;
```

Legend entries are determined in two ways:

- Automatically

- By using the SetLegend method to specify an array of legend entries

Here are charts that have automatically generated legend entries:

The default position for the legend is to the left of the chart. Set the chart property LegendPosition to move the legend to other locations next to the chart.

A legend entry provides a text description that explains what a color in the chart represents. The colors in the legend are sequenced in the same order as the data and colors are sequenced in the chart.

In all chart types except pie charts, the default legend entries describe the data series. In a pie chart, the default legend entries describe the data points (that is, the pie segments). In a pie chart if you have a legend, each pie chart segment is automatically labeled with the percentage it contributes to the whole.

If you use SetLegend to create legend entries, as an application developer you must ensure that the number of entries in the legend array matches exactly the number of data points that appear in your chart.

```
&LegendArray = CreateArray("Entry 1", "Entry 2");
&cChart.SetLegend(&LegendArray);
```

These charts use the specified legend array:

Note that in the case of the pie chart, there were not enough legend entries in the array to account for all the segments in the pie chart. Therefore, for the pie chart, the default legend was used.

If the number of entries in the array is increased to match the number of pie slices, there are more entries than are needed for the bar chart, which produces several undesirable results.

```
&LegendArray = CreateArray("Entry 1", "Entry 2", "Entry 3", "Entry 4", "Entry 5", "⇒
Entry 6");
&cChart.SetLegend(&LegendArray);
```

The bar chart displays the default legend entries (2) ignoring any additional entries that were supplied in the legend array:

If the number of entries is increased to be larger than needed for either the bar chart or the pie chart, similar undesirable results are displayed for the bar chart.

```
&LegendArray = CreateArray("Entry 1", "Entry 2", "Entry 3", "Entry 4", "Entry 5",
"Entry 6", "Entry 7");
&cChart.SetLegend(&LegendArray);
```

In this case, the pie chart reverts to the automatically generated legend:

If color is set by `SetDataColor` and the default legend is chosen, the bar chart only shows legend entries for the data series.

```
&cChart.SetDataColor(CJY_RVW_DSTRBTN.CJY_COLOR);
&cChart.HasLegend = True;
```

The bar chart and pie charts show default legends.

If color is set by `SetDataColor` and the legend array is larger than needed for either chart type, the results are also undesirable.

```
&cChart.SetDataColor(CJY_RVW_DSTRBTN.CJY_COLOR);
&cChart.HasLegend = True;
&LegendArray = CreateArray("Entry 1", "Entry 2", "Entry 3", "Entry 4", "Entry 5", "Entry 6", "Entry 7", "Entry 8", "Entry 9", "Entry 10", "Entry 11", "Entry 12");
```

The bar chart displays the default legend entries (2) ignoring any additional entries that were supplied in the legend array.

If color is set by `SetDataColor` and the legend array is the size required by the pie chart, the results are also undesirable.

```
&cChart.SetDataColor(CJY_RVW_DSTRBTN.CJY_COLOR);
&cChart.HasLegend = True;
&LegendArray = CreateArray("Entry 1", "Entry 2", "Entry 3", "Entry 4", "Entry 5", "Entry 6");
```

The pie chart uses the specified legend array.

If color is set by `SetDataColor` and the legend array is the size required by the bar chart, the desired results are produced for both charts.

```
&cChart.SetDataColor(CJY_RVW_DSTRBTN.CJY_COLOR);
&cChart.HasLegend = True;
&LegendArray = CreateArray("Entry 1", "Entry 2");
```

The legends for both charts are correct. The bar chart uses the specified legend array; the pie chart uses the default legend.

## Creating and Using Data Series with Charts

In PeopleSoft applications, chart data series are a grouping of related information. For example, if you were tracking sales for several divisions over many years, each division could be a series. Generally, every series in a chart has a distinct color. You can have more than one series in a chart for comparison. Each line in a line chart represents one series.

In the following example, the region has been set as the data series:

You can identify the data that you want in each series in two alternative ways:

- Using the `SetDataSeries` method.
- Specifying more than one field with the `SetDataYAxis` method.

If you use `SetDataSeries`, you pass into that method a `RECORD.FIELD` reference. That field will have values for each data item in the chart that associates the data item with a series. For instance, consider this layout of the `PRODUCT_SALES` table:

| <i><b>Year</b></i> | <i><b>Sales</b></i> | <i><b>Region</b></i> |
|--------------------|---------------------|----------------------|
| 2011               | 120K                | Northeast            |
| 2011               | 220K                | South                |
| 2011               | 220K                | Midwest              |
| 2012               | 140K                | Northeast            |
| 2012               | 225K                | South                |
| 2012               | 240K                | Midwest              |
| 2013               | 130K                | Northeast            |
| 2013               | 230K                | South                |
| 2013               | 250K                | Midwest              |

The relevant PeopleCode would look as follows:

```
SetDataXAxis (PRODUCT_SALES.YEAR) ;
SetDataYAxis (PRODUCT_SALES.SALES) ;
SetDataSeries (PRODUCT_SALES.REGION) ;
```

This would produce the red, blue, and yellow lines in the preceding line chart.

If you specify more than one field in SetDataYAxis, each field passed into SetDataYAxis will result in one data series in the chart. For instance, here's an alternative table layout for the PRODUCT\_SALES table:

| <b>Year</b> | <b>SALES_NE</b> | <b>SALES_S</b> | <b>SALES_MW</b> |
|-------------|-----------------|----------------|-----------------|
| 2011        | 120K            | 220K           | 220K            |
| 2012        | 140K            | 225K           | 240K            |
| 2013        | 130K            | 230K           | 250K            |

The relevant PeopleCode would look as follows:

```
SetDataXAxis (PRODUCT_SALES.YEAR) ;

SetDataYAxis (PRODUCT_SALES.NE, PRODUCT_SALES.SALES_S,
PRODUCT_SALES.MW) ;
```

This would also produce exactly the same red, blue, and yellow lines in the preceding line chart.

## Creating a Chart with Two Y-Axes

When the values in a chart vary widely from data series to data series, or when you have mixed types of data (for example, both revenue and quantity data), you can plot the additional data series on a second vertical axis referred to as a “secondary y-axis” (or Y2 axis). The scale of the secondary y-axis reflects the values for the associated data series.

Two y-axes can only be displayed for bar charts, horizontal bar charts, stacked bar charts, horizontal stacked bar charts, and the line charts. In addition, you must specify multiple fields when you invoke the SetDataYAxis method; you cannot display multiple y-axes when only one field is specified.

Consider the following table of revenue data:

| <b>Account Name</b> | <b>Year</b> | <b>Actual</b> | <b>Budget</b> | <b>Forecast</b> | <b>Quantity</b> |
|---------------------|-------------|---------------|---------------|-----------------|-----------------|
| Revenue             | 2011        | 12000         | 14000         | 15000           | 500             |

| <b>Account Name</b> | <b>Year</b> | <b>Actual</b> | <b>Budget</b> | <b>Forecast</b> | <b>Quantity</b> |
|---------------------|-------------|---------------|---------------|-----------------|-----------------|
| Revenue             | 2012        | 21000         | 20000         | 22000           | 800             |
| Revenue             | 2013        | 15000         | 16000         | 12000           | 110             |

One set of data (quantity) varies widely from the other three sets— actual revenue, budgeted revenue, and forecast revenue. All of the revenue can be plotted on the primary y-axis and quantity on the secondary y-axis. The x-axis (year) is common between the two y-axes.

Use certain PeopleCode methods and properties to specify the format of charts with two y-axes. Use the `SetDataYAxis` method to specify all of the fields that will be plotted on the y-axes. In this example, the four fields are specified as follows:

```
&oChart.SetDataYAxis(QE_COL_MULTI_2Y.LY_AMOUNT_ACTUAL, QE_COL_MULTI_2Y.LY_AMOUNT_BU⇒
DGET, QE_COL_MULTI_2Y.LY_AMOUNT_FORECAST, QE_COL_MULTI_2Y.QE_QUANTITY);
```

Then, use the `SetYAxisColumnType` method to specify which values appear on the primary y-axis and which appear on the secondary y-axis. Use the following constants to indicate which axis:

| <b>Constant</b>       | <b>Description</b>                        |
|-----------------------|-------------------------------------------|
| <code>%Axis_Y</code>  | Associate column to the primary y-axis.   |
| <code>%Axis_Y2</code> | Associate column to the secondary y-axis. |

For example, only the fourth field will appear on the secondary y-axis:

```
&oChart.SetYAxisColumnType(CreateArray(%Axis_Y, %Axis_Y, %Axis_Y, %Axis_Y2));
```

You can use the `Y2AxisTitle` property to specify the title for the secondary y-axis. For example:

```
&oChart.Y2AxisTitle = "Quantity";
```

The following example displays the revenue data plotted on the primary y-axis and the quantity data plotted on the secondary y-axis:

The following PeopleCode was used to generate the preceding chart:

```
Component Chart &oChart;

&oChart = GetChart(QE_JET_2YWRK.QE_CHART_FIELD);
&oChart.Reset();
&oChart.Type = %ChartType_2DBar;

rem Set the record for chart data;
&oChart.SetData(Record.QE_COL_MULTI_2Y);

rem Specify the field for the x-axis;
&oChart.SetDataXAxis(QE_COL_MULTI_2Y.LY_YEARS);

rem Specify multiple fields for the y-axes;
&oChart.SetDataYAxis(QE_COL_MULTI_2Y.LY_AMOUNT_ACTUAL, QE_COL_MULTI_2Y.LY_AMOUNT_BU⇒
DGET, QE_COL_MULTI_2Y.LY_AMOUNT_FORCAST, QE_COL_MULTI_2Y.QE_QUANTTY);

&oChart.SetSeriesLabels(CreateArray("Actual", "Budgeted", "Forecast", "Quantity"));

rem Specify which fields appear on which y-axis;
&oChart.SetYAxisColumnType(CreateArray(%Axis_Y, %Axis_Y, %Axis_Y, %Axis_Y2));

&oChart.XAxisTitle = "Years";
&oChart.YAxisTitle = "Revenue";
&oChart.Y2AxisTitle = "Quantity";

rem Specify whether the Y2 axis is split from the primary y-axis;
&oChart.IsSplitDualY = False;

&oChart.HasLegend = True;
&oChart.LegendPosition = %ChartLegend_Bottom;
```

With the addition of the following PeopleCode excerpt that instantiates a Series object, the preceding PeopleCode program will plot the secondary y-axis data as a line chart instead of as a bar chart:

```
rem defining new Series object with its type;
Local Series &S1;

&S1 = GetSeries();
```

```

&S1.Name = "Quantity";
&S1.Type = %SeriesType_Line;
&jSeries = CreateArray(&S1);
&oChart.SetSeries(CreateArray(&S1));

```

In the following chart example, the a Series object is used to plot data on the secondary y-axis as a line chart to visually differentiate it from the revenue data:

In addition, the IsSplitDualY property allows you to split the chart into two charts: one displaying the primary y-axis and the displaying the secondary y-axis.

Set IsSplitDualY to True to create a chart similar to the following:

Additional properties provide ways for you to modify the secondary y-axis including: IsY2AxisInteger, Y2AxisMin, Y2AxisMax, and Y2AxisPrecision.

## Selecting and Highlighting Data Points

Users can select one or more data points (bars, slices, and so on) on a chart. Selection creates a highlight around the data item. Users can also de-select one or more of these items.

Selection can trigger:

- `FieldChange PeopleCode` for those data items.
- Redirection to a URL for the data items as defined by the `SetDataURLs` method.

De-selection can trigger:

- `FieldChange PeopleCode` for the `RECORD.FIELD` associated with the chart control.
- Redirection to a URL for the chart as defined by the `ChartURL` property.

In addition, users can interactively change the chart type—for example, changing a pie chart to display as a bar chart.

`PeopleCode` features allow PeopleSoft application to manage and maintain user-selected data items:

- Use the `DataSelectionMode` property of the `Chart` class to specify whether data selection is available for a chart.
- Use the `aSelections` property of the `ChartClientState` class to identify which data items are selected on a chart.
- Use the `nType` property of the `ChartClientState` class to identify which chart type was selected by the user.
- Use the `SetSelectedData` method of the `Chart` class to redraw a chart while maintaining which data items were previously selected by the user.

## Using the ReferenceArea Class

The `ReferenceArea` class is used in conjunction with the `Chart` class to display bands of color to be drawn with the chart based on numeric values along a chart axis. For each band of color, you would create a separate instance of the `ReferenceArea` class.

## Creating Reference Areas Using the ReferenceArea Class

The essential steps to use the ReferenceArea class are:

1. Create an instance of the ReferenceArea class in PeopleCode by using the GetReferenceArea built-in function:

```
&ref1 = GetReferenceArea();
```

2. Set the properties on the instance of ReferenceArea class that you created.
3. Add the instance to an array of ReferenceArea instances:

```
&ref_areas = CreateArray(&ref1);
```

---

**Note:** For each band of color, you would add a separate instance of the ReferenceArea class to this array.

---

4. Pass the array into the SetReferenceArea method of the Chart class:

```
&cChart.SetReferenceArea(&ref_areas);
```

## Using Reference Areas with Charts

To produce a bar chart similar to the following example that displays a reference area, you would create two instances of the ReferenceArea class:

While it is not required, you could create a user-defined PeopleCode function that returns the array of reference areas.

```
Function bld_ref_areas Returns array;
    &ref1 = GetReferenceArea();
    &ref1.Association = %Ref_Association_Y1;
    &ref1.Description = "1 STD from Mean";
    &ref1.ShortText = "Ref Area1";
    &ref1.IsDisplayedTextInLegend = True;
    &ref1.ReferenceAreaColor = %ChartColor_Yellow;
```

```

    &ref1.ReferenceAreaValues = CreateArray(50000, 30000);
    &ref_areas = CreateArray(&ref1);
    Return &ref_areas;
End-Function;

```

Then, you associate the array returned by this function to the instance of Chart class using the `SetReferenceArea` method:

```

&cChart.SetReferenceArea(bld_ref_areas());

```

[ReferenceArea Class Properties](#)

[SetReferenceArea](#)

## Using the ReferenceLine Class

The `ReferenceLine` class is used in conjunction with the `Chart` class to display colored lines to be drawn with the chart based on numeric values along a chart axis. For each reference line, you would create a separate instance of the `ReferenceLine` class.

### Creating Reference Lines Using the ReferenceLine Class

The essential steps to use the `ReferenceLine` class are:

1. Create an instance of the `ReferenceLine` class in PeopleCode by using the `GetReferenceLine` built-in function:

```

&refln1 = GetReferenceLine();

```

2. Set the properties on the instance of `ReferenceLine` class that you created.
3. Add the instance to an array of `ReferenceLine` instances:

```

&ref_lines = CreateArray(&refln1);

```

---

**Note:** For each reference line, you would add a separate instance of the `ReferenceLine` class to this array.

---

4. Pass the array into the `SetReferenceLine` method of the `Chart` class:

```

&cChart.SetReferenceLine(&ref_lines);

```

## Using Reference Lines with Charts

To produce a chart similar to the following example that displays a reference line, you would create two instances of the ReferenceLine class:

While it is not required, you could create a user-defined PeopleCode function that returns the array of reference lines.

```
Function bld_ref_lines() Returns array;
    &refln1 = GetReferenceLine();
    &refln1.Association = %Ref_Association_Y1;
    &refln1.Description = "Average";
    &refln1.ShortText = "Avg";
    &refln1.IsDisplayedTextInLegend = False;
    &refln1.ReferenceLineLocation = %Ref_Back;
    &refln1.ReferenceLineColor = %ChartColor_Red;
    &refln1.ReferenceLineValue = CJY_CHRT_REF_WK.CJY_AMT;
    &reflines = CreateArray(&refln1);
    Return &reflines;
End-Function;
```

Then, you associate the array returned by this function to the instance of Chart class using the SetReferenceLine method:

```
Function bld_chrt();
    &cChart = GetChart(CJY_CHRT_REF_WK.CJY_CHRT1);
    &cChart.Reset();
    &cChart.SetData(Record.CJY_SLRY);
    &cChart.SetDataXAxis(CJY_SLRY.CJY_NM);
    &cChart.setDataYAxis(CJY_SLRY.CJY_SLRY);
    &cChart.SetReferenceLine(bld_ref_lines());
End-Function;
```

## Using the Series Class

The Series class is used in conjunction with the Chart class to override the default chart type (as defined by the Type property for the Chart object) for selected members of the data series. (The field representing the data series is specified using the SetDataSeries method.) Using the Series class allows you to render more than one chart type simultaneously.

The Series class can only be used in conjunction with bar charts, horizontal bar charts, stacked bar charts, horizontal stacked bar charts, and the line charts.

### Using the Series Class with the Chart Class

The essential steps to use the Series class are:

1. Specify the field representing the data series for the chart.

```
&cChart.SetDataSeries(RECORD.FIELD);
```

2. Create an instance of the Series class in PeopleCode by using the GetSeries built-in function:

```
&series1 = GetSeries();
```

3. Set the Name and Type properties on each instance of the Series class that you created.

---

**Note:** The value of the Name property must match exactly the value of a member in the data series as specified by either the SetDataSeries method or set by the SetSeriesLabel method.

---

4. Add the instance to an array of Series instances:

```
&all_series = CreateArray(&series1);
```

---

**Note:** Add a separate instance of the Series class to this array for each member of the data series that you want to override the default chart type. Members not explicitly added to this array will inherit the default chart type. Alternatively, you can use the %SeriesType\_Inherit constant to specify that a data series member inherit the default chart type.

---

5. Pass the array into the SetSeries method of the Chart class:

```
&cChart.SetSeries(&all_series);
```

## Overriding the Chart Type Using the Series Class

In the following example of a bar chart, two of the five series are displayed as different chart types:

To produce a bar chart similar to the preceding example that uses a different chart type for the first and the fourth of five series, you would create two instances of the Series class. In this example, the Name property matches the value of the field as specified by the SetDataSeries method:

```
Component Chart &oChart;

&oChart = GetChart(QE_JET_CHARTWRK.QE_JET);
&oChart.Reset();
&oChart.Type = %ChartType_2DBar;

&oChart.SetData(Record.QE_CHART_NPARKS);

&oChart.SetDataYAxis(QE_CHART_NPARKS.QE_VISITORS);
&oChart.SetDataXAxis(QE_CHART_NPARKS.QE_YEARS);

&oChart.SetDataSeries(QE_CHART_NPARKS.QE_PARKNAME);

&oChart.XAxisTitle = "Years";
&oChart.YAxisTitle = "No. of visitors";
&oChart.MainTitle = "Visiting National Parks";

&oChart.HasLegend = True;
&oChart.LegendPosition = %ChartLegend_Left;

Local Series &S1, &S2;

&S1 = GetSeries();
&S1.Name = "YELLOWSTONE";
&S1.Type = %SeriesType_Line;

&S2 = GetSeries();
```

```
&S2.Name = "ARCHES";  
&S2.Type = %SeriesType_Area;  
  
&oChart.SetSeries(CreateArray(&S1, &S2));
```

[SetSeries](#)

## Using the ToolTipLabel Class

The ToolTipLabel class is used in conjunction with the Chart class to display custom tooltips (also referred to as “data hints” or “hover text”) on chart data points thereby overriding the default tooltips that are automatically created from the chart data.

### Using the ToolTipLabel Class with the Chart Class

The essential steps to use the ToolTipLabel class are:

1. Create an instance of the ToolTipLabel class in PeopleCode by using the GetToolTip built-in function:

```
&label1 = GetToolTip();
```

2. Set the ToolTipLabelType and ToolTipLabelValue properties on each ToolTipLabel object that you created.

3. Add the object to an array of ToolTipLabel objects:

```
&tooltip_labels = CreateArray(&label1, &label2);
```

4. Pass the array into the SetToolTipLabels method of the Chart object:

```
&cChart.SetToolTipLabels(&tooltip_labels);
```

## Creating Custom Tooltips

To create custom tooltips similar to the following example, you would create three instances of the `ToolTipLabel` class.

In the preceding example, the custom tooltip displays the x-axis data (`%ToolTipLbl_X`), y-axis data (`%ToolTipLbl_Y`), and the data series (`%ToolTipLbl_Series`). The following PeopleCode program would generate these custom tooltips:

```
/* Declare and instantiate a chart object */
Component Chart &QEChart;
Component ToolTipLabel &label1, &label2, &label3;
Component array of ToolTipLabel &tooltip_labels;

&QEChart = GetChart(QE_CHART_T2_CHR.QE_CHART_T2_CHRTFL);
&QEChart.Reset();

/* Set the chart parameters for chart descriptions */
&QEChart.Type = %ChartType_2DBar;
&QEChart.MainTitle = "Shoes sales data for North America";
&QEChart.XAxisTitle = "Product Category";
&QEChart.YAxisTitle = "Sales in Millions";
&QEChart.HasLegend = True;

/* Set the chart data record and specify x-axis, y-axis, and series data */
&QEChart.SetData(Record.QE_CHART_T1_PRO);
&QEChart.SetDataXAxis(QE_CHART_T1_PRO.QE_CHART_T1_PROD);
&QEChart.SetDataYAxis(QE_CHART_T1_PRO.QE_CHART_T1_SALES);
&QEChart.SetDataSeries(QE_CHART_T1_PRO.QE_CHART_T1_REGION);
&label1 = GetToolTip();
&label1.ToolTipLabelType = %ToolTipLbl_X;
&label1.ToolTipLabelValue = "Product";
&label2 = GetToolTip();
&label2.ToolTipLabelType = %ToolTipLbl_Series;
&label2.ToolTipLabelValue = "Region";
&label3 = GetToolTip();
&label3.ToolTipLabelType = %ToolTipLbl_Y;
&label3.ToolTipLabelValue = "Sale (M)";
&tooltip_labels = CreateArray(&label1, &label2, &label3);
&QEChart.SetToolTipLabel(&tooltip_labels);
```

**Related Links**

[“GetToolTip” \(PeopleCode Language Reference\)](#)

[ToolTipLabel Class Properties](#)

[SetToolTipLabels](#)

**Scope and Data Type of a Chart Object**

A Chart object can be instantiated only from PeopleCode. You can use this object only in PeopleCode programs that are associated with an online process, not in an Application Engine program, a message notification, a Component Interface, and so on.

Chart objects are declared using the Chart data type. For example:

```
Local Chart &MyChart;  
  
Component Chart &Abs_Hist_Chart;
```

**Error Handling**

The PeopleCode program is terminated if a field or record is missing at runtime.

If a valid record is specified but no data is found, or for any other error, the chart is replaced by the message "Image creation failed."

If the Java Runtime Environment (JRE) is missing, an error appears and is logged.

---

**Using the Gauge Classes**

This section provides an overview of gauge terms and gauge types, and discusses how to use the gauge classes

**Understanding Gauge Terms**

The following is a list of terms pertaining to the gauge classes and their descriptions:

| <i><b>Field or Control</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                                                     |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Metric                         | Refers to the actual numeric data point that you want to display in the gauge.                                                                                                                                                                                                                |
| Tick marks                     | Refers to the major and minor markings along the value axis of the gauge.                                                                                                                                                                                                                     |
| Threshold values               | (Optional) Provide additional context about the metric that you display in your gauge. On dial and status meter gauges you can add bands of color to the background by associating an instance of the Threshold class, typically to help indicate whether the metric is low, medium, or high. |

## Gauge Types

Use the gauge classes to create gauges that display metrics in several common formats, including status meters, LEDs, and ratings.

Three gauge classes are available: LEDGauge, RatingGaugeChart, and StatusMeterGauge. Each of these gauges must be implemented and instantiated as a different class.

Of these gauge types, the LEDGauge and StatusMeterGauge classes share many common characteristics, including the methods you can invoke and the properties you can set. While rating gauges share some characteristics with the other gauge types, the RatingGaugeChart class and supporting classes are described separately within this topic.

The following examples use the same value, 54.5, as the gauge metric. In addition, an instance of the Threshold class is used to specify the color shading on the dial gauge and the status meter gauge, as well as the color of the LED.

### Example of an LED Gauge

The following example displays an LED gauge:

### Example of a Status Meter Gauge

The following example displays a status gauge:

## Creating Gauges Using the Gauge Classes

You can specify a field in a rowset and have it depicted graphically as a gauge with minimal PeopleCode. The data in the field must be numeric. You can also choose to make the gauge interactive.

The high-level steps involved in creating any gauge are:

1. Identify a field on a record that has a numeric value that you want to show in a gauge.
2. Add a chart area to a page in Application Designer. Associate the record and field in Step 1 with that chart area.
3. In PeopleCode instantiate a gauge object using one of the built-in functions available for gauges:
  - `GetLEDGauge`
  - `GetRatingGauge`
  - `GetStatusMeterGauge`
4. Set property values for the gauge object as needed, keeping in mind the design guidelines below. Most properties have default values, so you can start by reviewing your gauge with no properties set and then set those that you need to in order to tailor the appearance and functionality of the gauge.
5. Depending on the gauge type:
  - For the `LEDGauge` and `StatusMeterGauge` classes, optionally, create an instance of the `Threshold` class and associate it with your instance of the gauge.
  - For the `RatingGaugeChart` class, create instances of the `RatingGaugeState` class and of the `GaugeThreshold` class and associate them with your instance of the gauge.

## Design Guidelines

The following design guidelines apply to dial gauges, LED gauges, and status meter gauges only.

### Sizing

The height and width for a gauge is determined differently depending on whether the chart control for the gauge appears on a fluid page or a classic page:

- See [Fluid Mode Considerations for Charts and Gauges](#)
- See [Sizing a Chart or Gauge in Classic Mode](#)

The overall dimensions of the gauge area will be used and will need to hold all the elements that you choose to have along with the gauge graphic itself. This includes:

- Top labels
- Bottom labels
- Metric labels
- Legends

The more elements that you want to include in the gauge area, the smaller the gauge graphic will become. The gauge rendering software will try to make a best fit.

As you design your gauge, it's important to carefully consider what you want your gauge to contain and to review the results of your gauge as you use edge cases of small and large values and labels as well as

most likely cases. Also, consider the design of your gauge in the context of the rest of the page in which the gauge will appear. For example, do other elements on the page provide enough context so that you can reduce or eliminate the use of labels and legends in the gauge area?

## Scaling

You can use the `GaugeMinimum` and `GaugeMaximum` properties to provide the low and high points of your dial or status meter gauge. Knowledge of the nature of your data will help you determine an appropriate scale.

You'll also want to consider for a gauge whether you want the gauge minimums and maximums to be static (for example, minimum of 0 and maximum of 100 because test results can only fall within that range), or whether you want them to be dynamic (for example, make the minimum half of the metric value and make the maximum 50% greater than the metric value).

## Labels

Three types of labels can be placed in the gauge – a top label, a bottom label, and a label for the metric. The top and bottom labels are customizable – they can be any text you desire. The metric label will always be the numeric value of the gauge metric.

The labels can be positioned in different locations along with the gauge. Any label can be placed inside the gauge. Additionally, top labels can appear above the gauge, bottom labels can appear below the gauge, and metric labels can be positioned with the bottom label or below it.

Generally, it's better to constrain the use of labels to the minimum needed. Labels will take up space from the gauge itself, making the gauge smaller, and too much text in a label can result in ellipses that don't look good and can be difficult to read.

## Reference Areas and Legends

You can provide additional context about the metric that you display in your dial gauge, LED gauge, or status meter gauge by associating an instance of the `Threshold` class to the gauge using the `SetThreshold` method (available with all gauge classes). On dial and status meter gauges, you can add bands of color to the gauge background, typically to help indicate whether the metric is low, medium, or high. On LED gauges the values in the threshold instance determine the color and direction of the LED.

For more information on using the `Threshold` class, see [Using the Threshold Class](#).

A legend is available if you use thresholds. The legend will show the colors and descriptions of all reference areas on your gauge.

## Tick Marks

Tick marks on status meter gauges can often provide useful context information but possibly at the cost of making the gauge appear busy and cluttered. You should try them to see if they work for your situation.

## Gauge Interactivity

You can make your gauges interactive. You can either run `FieldChange` `PeopleCode` or redirect users to a URL. Interactivity will be initiated when a user clicks on (or touches) the gauge.

As illustrated in the following flowchart, in order to have your gauge be interactive, you must set the `IsDrillable` property to `True`. Then, if you have set the `GaugeURL` property to a valid URL, a click will redirect the user to that URL. If `GaugeURL` is not set, but there is `FieldChange PeopleCode` on the field that defines the gauge's metric (that is, the field you passed into the `GetStatusMeterGauge` or `GetLEDGauge` function), then that `PeopleCode` will run. Otherwise, if neither `GaugeURL` is set nor `FieldChange PeopleCode` is present, then there is no interactivity even if `IsDrillable` is `True`.

## Using the Threshold Class

The Threshold class is used in conjunction with the two gauge classes: LEDGauge and StatusMeterGauge. The Threshold class provides a way to add reference areas and color coding to your gauges.

On the LED gauge, the Threshold class can be used to color the LED gauge according to the defined threshold values.

## Creating Thresholds Using the Threshold Class

To use the Threshold class, follow these basic steps:

1. Create an instance of the Threshold class in PeopleCode by using the GetThreshold built-in function:

```
&thrshld = GetThreshold();
```

2. Set the properties on the instance of Threshold class that you created.
3. Associate the instance of the Threshold class to an instance of one of the gauge classes.

```
&gauge.SetThreshold(&thrshld);
```

## Using Thresholds with Gauges

The following example presents a LED gauge with color from the Threshold class:

To render the gauge in this way, you would create an instance of the Threshold class. Each property of the Threshold class is an array that you would populate as follows:

| <b>Values array</b>           | <b>Colors array</b> |
|-------------------------------|---------------------|
| Value of first threshold      | Yellow              |
| Value of the second threshold | Green               |
| NA                            | Red                 |

A user-defined PeopleCode function that instantiates this instance of the Threshold class looks like this:

```
Function bld_thrshld Returns Threshold;
    Local Threshold &thrshld;
    &thrshld = GetThreshold();
    &thrshld.Values = CreateArray(CJY_SLRY.CJY_SLRY_MIN, CJY_SLRY.CJY_SLRY_MAX);
    &thrshld.Colors = CreateArray(%ChartColor_Yellow, %ChartColor_Green, %ChartColor⇒
_Red);
    Return &thrshld;
End-Function;
```

However, you can add a Descriptions array to control what is displayed in data hints and in the legend:

| <b>Values array</b>           | <b>Descriptions array</b> | <b>Colors array</b> |
|-------------------------------|---------------------------|---------------------|
| Value of first threshold      | Below Range               | Yellow              |
| Value of the second threshold | Within Range              | Green               |
| NA                            | Above Range               | Red                 |

The Descriptions array is added to the same user-defined PeopleCode function:

```
Function bld_thrshld Returns Threshold;
    Local Threshold &thrshld;
    &thrshld = GetThreshold();
    &thrshld.Values = CreateArray(CJY_SLRY.CJY_SLRY_MIN, CJY_SLRY.CJY_SLRY_MAX);
    &thrshld.Descriptions = CreateArray("Below Range", "Within Range", "Above Range"⇒
);
    &thrshld.Colors = CreateArray(%ChartColor_Yellow, %ChartColor_Green, %ChartColor⇒
_Red);
    Return &thrshld;
End-Function;
```

## Using the Rating Gauge Classes

Rating gauges are typically used to display or accept user feedback on a product or service. A rating gauge can be interactive or display only.

Display-only rating gauges (the `ReadOnly` property is `True`) set the gauge to the value of the field that was used when the rating gauge was created with the `GetRatingGauge` built-in function. The value of the rating gauge cannot be changed by the user.

Interactive rating gauges (the `ReadOnly` property is `False`) can update the underlying value in the `RECORD.FIELD` that was used when the rating gauge was created with the `GetRatingGauge` built-in function. If there is `FieldChange PeopleCode` on the field, the `PeopleCode` executes only for an interactive rating gauge.

The display of a rating gauge can be changed in two ways:

- Based on the state of the rating gauge.
- Based on threshold values against which the value of the rating gauge is compared.

A rating gauge can support four different states depending on the chart type:

- Unselected
- Selected
- Hover (interactive only)
- Changed (interactive only)

Here’s an example of a gauge transitioning through three states. Each state displays the gauge data differently:

| <i>Field or Control</i>                                                             | <i>Description</i>                      |
|-------------------------------------------------------------------------------------|-----------------------------------------|
|  | A rating gauge in the unselected state. |
|  | A rating gauge in the hover state.      |
|  | A rating gauge in the selected state.   |

You can set the display characteristics for each state using the `RatingGaugeState` class. You create an instance of this class, set its properties, and assign the instance to the corresponding state property on the `RatingGaugeChart` instance that you created.’

In addition, a rating gauge supports up to three thresholds. Different thresholds can cause the rating gauge to change color and present different tooltip text based on the gauge value:

| <b>Field or Control</b>                                                           | <b>Description</b>                                   |
|-----------------------------------------------------------------------------------|------------------------------------------------------|
|  | A rating gauge with thresholds (Outstanding rating)  |
|  | A rating gauge with thresholds (Satisfactory rating) |

You can set the characteristics for each threshold value using the `GaugeThreshold` class. You create an instance of this class and set its properties, including the threshold maximum. Create an array of `GaugeThreshold` instances and assign the array to the `RatingGaugeChart` object using its `SetRatingGaugeThresholds` method. If a gauge color or border color is set in a gauge threshold, those colors override the colors set by the rating gauge states.

## Scope and Data Type of Gauge Objects

Any gauge and threshold objects can be instantiated from PeopleCode only. You can use these objects only in PeopleCode programs that are associated with an online process, not in an Application Engine program, a message notification, a component interface, and so on.

Gauge objects are declared using the one of the three gauge classes data types. For example:

```
Component LedGauge &oLED;
Component RatingGaugeChart &oRating;
Component StatusMeterGauge &oSM;
```

In addition, optional threshold objects for use with dial gauges, LED gauges, and status meter gauges are declared using the `Threshold` class:

```
Component Threshold &oThrshld;
```

Gauge state objects and gauge threshold objects for use with rating gauges are declared using the `RatingGaugeState` class and the `GaugeThreshold` class respectively:

```
Local RatingGaugeState &oRatGaugeSelState, &oRatGaugeUnSelState, &oRatGaugeHovState=>
, &oRatGaugeChangState;

Local GaugeThreshold &oGTresh1, &oGTresh2, &oGTresh3, &oGTresh4;
```

## Error Handling

The PeopleCode program is terminated if a field or record is missing at runtime.

If a valid record is specified but no data is found, or for any other error, the chart is replaced by the message "Image creation failed."

If the Java Runtime Environment (JRE) is missing, an error appears and is logged.

## Properties of the Gauge Classes

The properties can be grouped as follows:

- Gauge type – You can select different visual representations for each gauge class
- Minimums and maximums – You can specify the range of values that you want the gauge to cover
- Labels – You can determine which, if any, labels, you want to accompany the gauge
- Gauge increments – Specify gauge increments if more numeric context is needed.
- Legends – A legend can be displayed to help users interpret the reference areas.
- Animation – You can choose the type and duration of animation for the gauge display.
- Interactivity – You can choose to have an event occur if the user clicks (or touches) the gauge.

| <b>Category</b>       | <b><i>LEDGauge</i></b>   | <b><i>StatusMeterGauge</i></b> | <b><i>RatingGaugeChart</i></b> |
|-----------------------|--------------------------|--------------------------------|--------------------------------|

## Using the Spark Chart Classes

Spark charts are used to visualize the trend of a data set in a compact form factor. They are best used to view trends over time, especially when paired with additional context such as in a table. Absolute values and individual data points are not emphasized, so spark charts should not be used to visualize data where such things are important.

While the typical chart is designed to show as much data as possible, spark charts are intended to be succinct, memorable, and located where they are discussed.

The following example illustrates five spark chart types: an area chart, a bar chart, a floating bar chart, a line chart, and a line with area chart.

Spark charts should be used to convey trend and relative change, not detail values. The spark chart does not have axis labels or any other text. Thus, the axes must be intuitive to the viewer. In a spark chart, the y-axis is almost always numerical and the x-axis is either numerical or a time series.

A typical example of a spark chart is a stock pricing chart. In PeopleSoft applications, spark charts might be good for showing data such as general ledger account balances over time or a grid displaying employee vacation balances over time.

Typically, spark charts are defined as interactive, so that clicking or touching one would take the user to more detail. You can define the interaction result to be a URL or a PeopleCode program.

To create a spark chart on a page you need to:

1. Place a chart control on a page in Application Designer.
2. Create an instance of the SparkChart class in PeopleCode.
3. Create one or more instances of the SparkChartItem class in PeopleCode.
4. Add those SparkChartItem instances to an array.
5. Associate the array to the SparkChart class instance.

```
&aS = GetSparkChart(RECORD_NAME.FIELD_NAME);
```

```
&aS1 = GetSparkChartItem();
```

```
&aS.SetSparkChartItems(CreateArray(&aS1, &aS2, ...));
```

## Creating Spark Charts

The following example displays the five spark chart types: bar chart, line chart, area chart, line with area chart, and floating bar chart.

The following PeopleCode example was used to generate the preceding spark charts. The properties for each spark chart item determine its value, color, marker type, and so on.

```
Local SparkChart &aS;
Local SparkChartItem &aS1, &aS2, &aS3, &aS4, &aS5, &aS6, &aS7, &aS8, &aS9;

&aS = GetSparkChart(QE_DVTSCR_WRK.QE_CHRT1);

&aS1 = GetSparkChartItem();
&aS1.Value = 60;
&aS1.FloatValue = 60;
&aS1.Color = 10;
&aS1.BorderColor = 18;
&aS1.MarkerDisplayed = True;
&aS1.MarkerShape = %SparkMarker_Square;

&aS2 = GetSparkChartItem();
&aS2.Value = 70;
&aS2.FloatValue = 40;
&aS2.Color = 8;
&aS2.BorderColor = 11;
&aS2.MarkerDisplayed = True;
&aS2.MarkerShape = %SparkMarker_TriangleDown;

&aS3 = GetSparkChartItem();
&aS3.Value = 90;
```

```

&aS3.FloatValue = 10;
&aS3.Color = 11;
&aS3.BorderColor = 18;
&aS3.MarkerDisplayed = True;
&aS3.MarkerShape = %SparkMarker_Auto;

&aS4 = GetSparkChartItem();
&aS4.Value = 75;
&aS4.FloatValue = 25;
&aS4.Color = 2;
&aS4.BorderColor = 9;
&aS4.MarkerDisplayed = False;
&aS4.MarkerShape = %SparkMarker_Diamond;

&aS5 = GetSparkChartItem();
&aS5.Value = 70;
&aS5.FloatValue = 0.1;
&aS5.Color = 3;
&aS5.BorderColor = 18;
&aS5.MarkerDisplayed = True;
&aS5.MarkerShape = %SparkMarker_Circle;

&aS6 = GetSparkChartItem();
&aS6.Value = 90;
&aS6.FloatValue = - 20;
&aS6.Color = 68;
&aS6.BorderColor = 9;
&aS6.MarkerDisplayed = True;
&aS6.MarkerShape = %SparkMarker_Human;

&aS7 = GetSparkChartItem();
&aS7.Value = 70;
&aS7.FloatValue = - 10;
&aS7.Color = 4;
&aS7.BorderColor = 9;
&aS7.MarkerDisplayed = False;
&aS7.MarkerShape = %SparkMarker_Diamond;

&aS8 = GetSparkChartItem();
&aS8.Value = 60;
&aS8.FloatValue = 0.1;
&aS8.Color = 5;
&aS8.BorderColor = 18;
&aS8.MarkerDisplayed = True;
&aS8.MarkerShape = %SparkMarker_Circle;

&aS9 = GetSparkChartItem();
&aS9.Value = 40;
&aS9.FloatValue = 0.1;
&aS9.Color = 6;
&aS9.BorderColor = 9;
&aS9.MarkerDisplayed = True;
&aS9.MarkerShape = %SparkMarker_Human;

&aS.Width = 200;
&aS.AspectRatio = 0.3;

&aS.AnimationDuration = 1;
&aS.AnimationType = 1;

Local integer &row;
&row = CurrentRowNumber();
Evaluate &row
When 1
    &aS.Type = %SparkChart_Bar;
When 2

```

```

    &aS.Type = %SparkChart_Line;
When 3
    &aS.Type = %SparkChart_Area;
When 4
    &aS.Type = %SparkChart_LineWithArea;
When 5
    &aS.Type = %SparkChart_FloatingBar;
End-Evaluate;

&aS.IsDrillable = True;
&aS.LineType = %SparkLine_Straight;
&aS.LineStyle = %SparkLineStyle_Solid;
&aS.barGapRatio = 0.5;
&aS.LineWidth = 2;
&aS.SparkChartURL = "www.yahoo.com";
&aS.Title = "spark title2";
&aS.Color = %ChartColor_Green;

&aS.SetSparkChartItems(CreateArray(&aS1, &aS2, &aS3, &aS4, &aS5, &aS6, &aS7, &aS8, =>
&aS9));

```

# Using the Gantt Class

Use the Gantt class to create Gantt charts. A Gantt chart displays tasks and milestones along a time line. Gantt charts are frequently used in project management because they provide a graphical illustration of a schedule, which helps in planning, coordinating, and tracking project tasks.

This section provides an overview of Gantt chart terminology and discusses how to use the Gantt Class.

## Understanding Gantt Chart Terms

Many of the elements, such as titles and labels, available on conventional chart like the bar chart are also available on the Gantt chart. The following terms apply specifically to Gantt charts:

| <i><b>Field or Control</b></i> | <i><b>Description</b></i>                                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Activity or Task               | See <b>Task</b> .                                                                                                                        |
| Baseline                       | A point-in-time snapshot of the project plan that allows the user to identify how the project plan has changed since that point in time. |

| Field or Control | Description                                                                                                                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data area        | The part of the chart that graphically shows the span of dates that each task (or activity) covers. (This area is the right side of the displayed chart.)                                                                                           |
| Dependencies     | A relationship between one task and other tasks that drives when tasks can begin and end. A dependent task cannot start before the task it is dependent on is either started or completed (depending on business rules defined in the application). |
| Milestone        | A specialized mark on the chart that names a meaningful point in time.                                                                                                                                                                              |
| Resource         | A source of supply or support that is assigned to work on an activity or task.                                                                                                                                                                      |
| Task or Activity | In a Gantt chart, each row (task or activity), is represented in the y-axis of the chart, and the span of dates for each row is displayed on the x-axis.                                                                                            |
| X-axis           | The x-axis displays dates that are spanned by items in the y-axis.                                                                                                                                                                                  |
| X-axis labels    | The part of the chart that lists the time scale. The x-axis labels support multiple levels of granularity: second, minute, hour, day, week, month, year.                                                                                            |
| Y-axis           | The y-axis is the display of tasks or activities, and is displayed as rows.                                                                                                                                                                         |
| Y-axis labels    | The part of the chart that lists activities and their attributes. Activities are shown hierarchically, and subtasks can be hidden or displayed by expanding or collapsing higher level tasks.                                                       |

Using Gantt Charts in the PeopleSoft Pure Internet Architecture

The Gantt chart consists of two sections: a table section and a chart section.

The left side of the chart, where you see the table, is the table section. The other side, where you see the bars, is the chart section. Horizontal scroll bars below the table section support scrolling through the task-related columns; below the task section, they support scrolling through the charted tasks. Vertical scroll bars (when present) support scrolling through the task list.

## Table Section

The table section contains all of the tasks and associated subtasks, and displays them in a hierarchy. Tasks that contain subtasks are called *parent tasks*, and subtasks are called *child tasks*. You can click on the expand (collapse) image to the left of the task name (Baby, above) to expand or collapse the subtask hierarchy. Note that subtasks may also act as parent tasks to other subtasks.

Each task has a name (Born, Baby, Childhood, and so on). It also has a level. Parent tasks have a higher level than child tasks.

## Chart Section

The chart section displays the tasks, task dependencies, and milestones graphically.

In the previous example, each horizontal bar represents a single task. The progress bar (that is, the percentage complete for a particular task) is indicated with a bar of a different color above the task bar. The milestone date (Graduate in the previous example) is represented with a circle.

You can also have dependencies between tasks. These are represented as lines connecting the task bars.

You can execute custom FieldChange PeopleCode when a user clicks a task bar or a task dependency line.

## User Interaction

A user can interact directly with a chart to change the underlying chart data.

These user actions are supported:

- Resize the task bar.
- Reposition the task bar.
- Reposition a milestone glyph.
- Move the separator between the table section and the chart section.
- Update task details, task start time and end time, and the progress bar.

When a user changes values in the chart section by dragging and dropping bars, the Planned Start, Planned End, and Progress values in the grid column will also be updated if the grid and the chart section use the same record and fields.

---

**Note:** Drag-and-drop is not supported on an Apple iPad.

---

You can control the level the user is able to interact with the chart using the Gantt class properties `InteractiveStart`, `InteractiveEnd`, `InteractiveProgress`, and `InteractiveMove`.

See [InteractiveStart](#), [InteractiveEnd](#), [InteractiveProgress](#), [InteractiveMove](#).

## Creating Gantt Charts Using the Gantt Class

Every Gantt chart has at least one data set used to define the tasks and the information related to each task, such as start date, end date, milestones, percent finished, and so on.

A second data set can be used to describe dependencies between tasks.

The following methods are required for using the Gantt chart:

- **SetTaskData**

Use this method to specify where most of the information for the Gantt chart is stored. You can specify either a rowset or a record.

- **SetTaskID**

Use this method to specify the task ID, or name, of the task. Every task must have a unique task identifier. The task ID is used to support task linking and dependencies.

- **SetPlannedStartDate**

Use this method to specify the planned starting date of the task. Each task must have its own planned starting date.

- **SetPlannedEndDate**

Use this method to specify the planned ending date of the task. Each task must have its own planned ending date.

Though not required, Oracle recommends using the **SetTaskName** method to display meaningful information in the table section of the Gantt chart.

If you only use the required methods and do not use the **SetTaskAppData** method, Oracle recommends that you also use the **SetChartArea** method and dedicate most, if not all, of the entire area to the chart, and not the table.

If you specify one actual date, either for start or end, then you must specify the other (**SetActualStartDate**, **SetActualEndDate**).

In addition, if you want to use dependency data, the following methods are required:

- **SetTaskDependencyData**

Use this method to specify where most of the information for the dependency data is stored. You can specify either a rowset or a record.

- **SetTaskDependencyParentID**

In a dependency, one task depends on another. Use this method to specify the parent task, that is, the one that the other (child) task depends upon.

- **SetTaskDependencyChildID**

In a dependency, one task depends on another. Use this method to specify the child task, that is, the one that depends on another.

## Specifying Time Line Axis Formats

The date-time axis (the x-axis) of a Gantt chart is referred to as the “time line” axis. You can control the display label format for the time line through a combination of user personalization settings and various Gantt class methods for setting date entity formats. These settings and methods are described in this documentation. The time line’s start and end can also be adjusted by using the Timeline Range picker or by using the `AxisStartDateTime` and `AxisEndDateTime` methods. If none of the properties or methods is set for controlling the time line, then the charting engine plots the time line based on the time difference between the earliest start date and latest end date of all tasks in the Gantt chart.

The time line axis can display the following units of measure: years, months, days, hours, minutes, and seconds. The time line does not support the following units: centuries, quarter years (such as Q1, Q2, and so on), weeks, and milliseconds.

Depending on the time difference between the earliest start date/time and latest end date/time of the data displayed in the Gantt chart, the chart is displayed with a minor axis only, or with major and minor axes.

The following Gantt chart displays a minor axis only due to the wide range between the start and end dates of the displayed data:

Valid pairs of major and minor axes include:

- Year and month
- Month and day
- Day and hour
- Hour and second

The following Gantt chart displays both a major and a minor axis:

The Timeline Range picker is activated by clicking a date on the time line. Use the Timeline Range picker to specify the start and end date and time for the data to be displayed in the Gantt chart:

The date slider is activated by clicking a time in the Timeline Range picker. Click AM or PM to toggle between these two settings.

## Working with Start and End Dates

You must set the end date to be after the start date, for both the planned as well as actual dates, or else you will receive an error.

Both the start and end dates you specify for a task must fall within the axis dates, that is, the dates specified by the `AxisEndTime` and `AxisStartTime` properties. If you specify task dates that fall outside of the axis dates, the task appears in the table section of the Gantt chart, but no bar appears in the chart section of the Gantt chart, even if one of the dates falls *inside* the axis dates.

## Using Gantt Glyphs

You can use all of the following glyphs with a Gantt chart. You can use either the numeric or constant value.

**Note:** For values that have been deprecated, the new value is substituted automatically.

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Glyph</b></i> | <i><b>Notes</b></i>                                                                |
|-----------------------------|------------------------------|---------------------|------------------------------------------------------------------------------------|
| 1                           | %ChartGlyph_Axe              | NA                  | This constant has been deprecated; use %ChartGlyph_X (17) instead.                 |
| 2                           | %ChartGlyph_Bar              | NA                  | This constant has been deprecated; use %ChartGlyph_Exclamation (13) instead.       |
| 3                           | %ChartGlyph_Box              | NA                  | This constant has been deprecated; use %ChartGlyph_Fisheye (25) instead.           |
| 4                           | %ChartGlyph_Circle           | ●                   | NA                                                                                 |
| 5                           | %ChartGlyph_Cross            | NA                  | This constant has been deprecated; use %ChartGlyph_Dagger (20) instead.            |
| 6                           | %ChartGlyph_Diamond          | ◆                   | NA                                                                                 |
| 7                           | %ChartGlyph_Dodecahedron     | NA                  | This constant has been deprecated; use %ChartGlyph_Triangle_Inverted (18) instead. |
| 8                           | %ChartGlyph_Icosahedron      | NA                  | This constant has been deprecated; use %ChartGlyph_Star (11) instead.              |
| 9                           | %ChartGlyph_Sphere           | NA                  | This constant has been deprecated; use %ChartGlyph_CrossHairs (21) instead.        |
| 10                          | %ChartGlyph_Square           | ■                   | NA                                                                                 |

| <b>Numeric Value</b> | <b>Constant Value</b>         | <b>Glyph</b> | <b>Notes</b> |
|----------------------|-------------------------------|--------------|--------------|
| 11                   | %ChartGlyph_Star              | ★            | NA           |
| 13                   | %ChartGlyph_Exclamation       | !            | NA           |
| 14                   | %ChartGlyph_QuestionMark      | ?            | NA           |
| 15                   | %ChartGlyph_Asterisk          | *            | NA           |
| 16                   | %ChartGlyph_Check             | ✓            | NA           |
| 17                   | %ChartGlyph_X                 | ×            | NA           |
| 18                   | %ChartGlyph_Triangle_Inverted | ▼            | NA           |
| 19                   | %ChartGlyph_Dollar            | \$           | NA           |
| 20                   | %ChartGlyph_Dagger            | †            | NA           |
| 21                   | %ChartGlyph_CrossHairs        | ⊕            | NA           |
| 22                   | %ChartGlyph_Euro              | €            | NA           |
| 23                   | %ChartGlyph_Yen               | ¥            | NA           |
| 24                   | %ChartGlyph_PoundSterling     | £            | NA           |
| 25                   | %ChartGlyph_Fisheye           | ⊙            | NA           |

## Scope and Data Type of a Gantt Object

A Gantt object can be instantiated only from PeopleCode. You can use this object only in PeopleCode programs that are associated with an online process, not in an Application Engine program, a message notification, a Component Interface, and so on.

Gantt objects are declared using the Gantt data type. For example:

```
Local Gantt &MyGantt;
```

## Error Handling

The PeopleCode program is terminated if a field or record is missing at runtime.

If a valid record is specified but no data is found, or for any other error, the chart is replaced by the message "Image creation failed."

## Using the OrgChart Class

Use the OrgChart class to create organization charts. An organization chart represents hierarchical data as boxes arrayed in levels, which can be oriented top to bottom, with horizontal rows, or left to right, with vertical rows. Connectors show parent and child relationships between boxes on adjacent levels.

You can use this chart type to display many different types of hierarchical relationships, including, but not limited to:

- People in organizations
- Positions in organizations
- Departments in organizations
- Components in bills of materials

This section provides an overview of organization chart terminology and discusses how to use the OrgChart Class.

## Understanding Organization Chart Terms

Organization charts can be composed of many different elements, such as the main chart, nodes, connectors, pop-up nodes, and so on. These terms apply specifically to organization charts:

| <i>Field or Control</i> | <i>Description</i>                                                                                                                                                                                          |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Breadcrumbs             | You can configure an organization chart to optionally display links at the top of an organization chart. Typically, these are the names of people in an organization hierarchy.                             |
| Child node              | <p>A node that is one level below its parent node (except for the top-level node).</p> <p>Every node except the top-level node has one parent node.</p>                                                     |
| Connector               | Lines that link the boxes in an organization chart. Connectors denote parent and child relationships. A connector also shows the relationship between a pop-up node and the predecessor node of the pop-up. |

| <b>Field or Control</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Descriptor              | <p>A text string that conveys information about a node. A main chart node has up to seven descriptors by default, and can be configured with up to 99 descriptors. A pop-up node has up to eight descriptors. Each descriptor can have an image associated with it and can be configured as a link. On the main chart, a descriptor can also be configured as an IM presence icon, a related actions menu, or a button that is associated with a drop-down list box.</p> <p>FieldChange PeopleCode associated with a descriptor can invoke a pop-up, change the display characteristics of the chart, and perform other processing logic.</p> |
| Drop-down               | <p>You can configure a descriptor as a link associated with a drop-down menu or a drop down list box. A drop-down can be linkable or read-only. If the drop-down is linkable, PeopleCode related to the descriptor executes when a user clicks a list item.</p>                                                                                                                                                                                                                                                                                                                                                                               |
| Header                  | Information that appears at the top of a pop-up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Level                   | <p>An organization chart is made up of boxes, representing nodes, at different levels. The position of a node in a chart is determined by its parent node (PTPARENT_CHART_ND) and display order (PTND_DISPLAY_ORDER).</p>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Main chart              | <p>The primary chart in an organization chart showing individual entities, such as employees, in boxes related to one another hierarchically. A user can invoke PeopleCode that displays a pop-up node by clicking a link in a box, or node, of the main chart or by clicking a link in a pop-up node.</p>                                                                                                                                                                                                                                                                                                                                    |
| Node                    | <p>A representation of a single entity, an individual instance of data, in an organization chart. A node is represented as a box with vertical lines connecting it to its parent node and to its child nodes, if any.</p>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Node record             | <p>A derived/work record that contains the properties and data values for each node on the main chart.</p> <p>The node record is created using a clone of the PTORGNODE_SBR subrecord.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Parent node             | <p>A node that has one or more subordinate nodes, or child nodes, one level below it. Each node can be a parent for other nodes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b><i>Field or Control</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                                                                                  |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pop-up                         | <p>A new window that displays information specifically related to a node on the main chart or another pop-up.</p> <p>A pop-up can be invoked from a link on a main chart node or from a link on a pop-up node. FieldChange PeopleCode controls the appearance and content of a pop-up.</p> |
| Pop-up node                    | A single instance of data on a pop-up. A pop-up can have one or more nodes, all related to one node of the main chart or one node of another pop-up.                                                                                                                                       |
| Pop-up node record             | <p>A derived/work record that contains the properties and data values for each pop-up node on the main chart.</p> <p>The node record is created using a clone of the PTORGPOPUPNODE_SBR subrecord.</p>                                                                                     |
| Related-actions menu           | You can configure a descriptor as a related actions menu. A user can select a link from a cascading drop down menu that invokes a related action from the related content framework.                                                                                                       |

## Using Organization Charts in the PeopleSoft Pure Internet Architecture

A PeopleSoft organization chart consists of two parts: the main hierarchical chart and pop-ups that enable the user to access additional related data for each node.

An organization chart can be oriented vertically or horizontally. Use the Direction to set the orientation of an organization chart.

The following example shows a vertically oriented organization chart:

The following example shows a horizontally oriented organization chart:

## Main Chart

The main chart can have multiple levels. Each level consists of one or more nodes. Each node represents an individual entity, such as an employee, in the organization. A node has one parent node (except the top-level node, which does not have a parent node) and zero, one, or more child nodes. Each node in the main chart has up to 99 descriptors and each descriptor can be configured as a link or as a button associated with a drop-down list box. Application developers can associate FieldChange PeopleCode with each descriptor link or button associated with a linkable drop-down list box.

## Pop-up Chart

A pop-up displays a pop-up chart with information specifically related to the node from which it was invoked. A connector line visually links the pop-up chart to the predecessor node, the node in the chart from which the pop-up was invoked.

If the pop-up contains more nodes than can be displayed (that is, if MaxPopupDisplayNode is set to a number that is less than the total number of nodes) then a scroll bar appears in the pop-up. In some circumstances when a pop-up has a scroll bar and has more than one level, when a user clicks a link on a level other than the top level the new pop-up may not appear in the display area. If this occurs, the user can scroll down using the scroll bar in the initial pop-up to view the new pop-up node.

**Note:** The amount of time it takes for a pop-up to appear is proportional to the number of nodes in the pop-up. A pop-up with hundreds of nodes may take a long time to appear. An hourglass appears to let the user know the system is working to retrieve the nodes.

A pop-up is invoked through PeopleCode associated with the FieldChange event for a descriptor link on a main chart node or another pop-up node.

A pop-up consists of a header and one or more nodes with each node having up to eight descriptors. Each descriptor can be configured as a link.

The user can drag-and-drop a pop-up node to reposition it but the new position will not be retained after any action that requires a server trip that reloads the chart.

## Creating Organization Charts Using the OrgChart Class

When you add an organization chart to a page in Application Designer, you use the chart properties to associate the chart control with a chart record field. You will use this field name to identify the chart in PeopleCode.

You will need to create a record that will be the organization chart node record. The organization chart node record holds the values for the properties and data for each of the nodes of the main chart. If your chart uses pop-ups, you will also need a pop-up node record that holds the values for the properties and data for each of the pop-up nodes.

The organization chart node records must be in the component buffer at runtime. This means that you will have to place them on a page at level one in the component. You can hide them.

The maximum number of nodes you can create is limited according to browser, as shown in the following table:

| <b><i>Browser</i></b> | <b><i>Maximum Nodes</i></b> |
|-----------------------|-----------------------------|
| Google Chrome         | 600                         |
| Mozilla Firefox       | 1000                        |
| Apple Safari          | 600                         |

The records can have any name, but they must include clones of the PeopleTools-delivered subrecords PTORGNODE\_SBR and PTORGPOPUPNODE\_SBR. Since the subrecords will carry the FieldChange PeopleCode for the chart, in most cases you should create unique subrecords for each chart.

Your PeopleCode will create and populate two rowsets . These must be component rowsets, linked to the node records of the chart, not standalone rowsets. The organization chart node rowset has one row for each node in the organization chart, and the pop-up node rowset has one row for each pop-up node.

You place FieldChange PeopleCode on the fields of the node records to invoke pop-up charts, update displayed data, process application logic, and refresh the chart.

## Overview of Creating an Organization Chart

To create an organization chart you will develop an application that comprises these elements:

- A chart page control that displays the chart on a page.

You can place more than one chart control on a page. Each chart control must be associated with a different field.

If more than one pagelet with organization charts appear simultaneously, each chart must be associated with a unique chart record field.

- A chart data record, or organization chart node record, based on the PTORGNODE\_SBR subrecord, that contains the data for the chart.
- A PeopleCode program, usually in the page Activate event, that instantiates the chart, links the chart to the chart control, defines the chart attributes, and populates the chart data rowset.
- FieldChange PeopleCode programs associated with the chart data record fields.

See [Organization Chart Actions and Events](#).

Depending on which organization chart features your chart implements, you may need to include these elements in your application:

- A pop-up chart data record, based on the PTORGPOPUPNODE\_SBR subrecord.
- A breadcrumb record, based on the PTORGCRMB\_SBR subrecord.
- Drop-down list records, based on the PTORGBOXLIST\_SBR and PTORGBOXFLD\_SBR subrecords.
- A node display record, based on the PTNODE\_DISP\_SBR subrecord.
- An IM data record, based on the PTORGIM\_SBR subrecord.
- Additional PeopleCode to manage the corresponding record data and set attributes for the chart features.
- FieldChange PeopleCode programs associated with the corresponding record fields.

See [Organization Chart Actions and Events](#).

The chart data record and all of the records you use to implement organization chart features, such as the pop-up data record, drop down list records, node display record, must be in the component buffer at runtime.

If your application implements zooming, or schema levels, you will need to incorporate PeopleCode to manage the schema levels.

See [Implementing Zoom Schemas \(Optional\)](#).

## Creating an Organization Chart

This section presents the steps to create a full-featured organization chart. Some aspects of an organization chart are optional, and not required. The following sections explain how to:

- Display breadcrumbs (optional).
- Define descriptors.

- Configure menus and drop-down lists (optional).
- Define drop down lists.
- Configure IM presence (optional).
- Design organization chart nodes.
- Implement zooming (optional).
- Configure connector lines and borders.

## Displaying Breadcrumbs (Optional)

You can configure an organization chart to display breadcrumbs. Typically, breadcrumbs display the names of people in an organization hierarchy.

The following example shows an organization chart with breadcrumbs:

An organization chart can have only one set of breadcrumbs. The breadcrumbs appear horizontally at the top of an organization chart, above the chart legend if the legend is set. The breadcrumbs string wraps automatically if it is wider than the organization chart. If a breadcrumb contains a space, the breadcrumb string may wrap at the space, causing the breadcrumb to appear on two lines.

Style classes control the formatting of breadcrumbs. The default style classes are PT\_ORGCHART\_BRDCRM and PT\_ORGCHART\_UNLINK\_BRDCRM. You can specify your own style classes using the CrumbDescrStyle and UnlinkCrumbDescrStyle properties.

You can specify an image to separate breadcrumb entries. If an image is not specified, the breadcrumbs are separated by three spaces. Each breadcrumb entry can be configured to be linkable. This configuration is similar to linkable text on organization chart nodes.

To implement breadcrumbs in an organization chart, you:

- Clone the breadcrumb subrecord PTORGCRMB\_SBR.
- Add the clone of PTORGCRMB\_SBR to a work record.
- Add the work record to a page such that it is available in the component buffer so that PeopleCode can be invoked from the record fields.

One way to accomplish this is to include the record in a level 1 grid on the same page as the organization chart, and hide the grid.

- To make a breadcrumb linkable, set the corresponding PTORGCRMBLINKABLE field to “Y”, in much the same way as you make a descriptor linkable in an organization chart node.
- Add PeopleCode to provide application-specific processing when a linkable breadcrumb is selected.

When a user clicks a linkable breadcrumb, any FieldEdit and FieldChange PeopleCode in the PTORGCRMBID field executes.

At runtime, your PeopleCode will add rows to the work record that holds the information for each breadcrumb (person).

Each breadcrumb in a chart is defined by a row in the record.

See [Organization Chart Subrecord Definitions](#), [CrumbDescrStyle](#).

## Breadcrumb Methods and Properties

The following OrgChart class methods and properties control the appearance of breadcrumbs:

- SetCrumbData
- SetCrumbRecord
- UnlinkCrumbDescrStyle
- CrumbDescrStyle
- CrumbMaxDisplayLength
- CrumbSeparatorImage

## Defining Descriptors

An organization chart node contains a set of descriptors. Each descriptor represents one element of data related to the node.

The descriptors for a node are defined in the organization chart node data record, which includes a clone of the PTORGNODE\_SBR subrecord. The organization chart node record can define up to 99 descriptors. One row in the organization chart node record defines one node in the organization chart.

See “PTORGNODE\_SBR” in [Organization Chart Subrecord Definitions](#).

These fields on the PTORGNODE\_SBR define the descriptors for a node (where  $n$  is a number from 1 to 99; for example, PTNODE\_DESCR1):

- PTNODE\_DESCR $n$
- PTNDDESC $n$ LINKABLE
- PTDESCR $n$ \_ICON\_IMG
- PTDESCR $n$ \_ICON\_POS

PTORGNODE\_SBR is delivered with fields for seven descriptors. If you are using a node display template and need additional descriptors, you will need to add sets of descriptor fields, to a maximum of 99 descriptors.

Use the PTNODE\_DISPLAY\_ID field to optionally designate a node display template, which defines other display characteristics for nodes.

See “Using Node Display Templates” in [Designing Organization Chart Nodes](#).

## Descriptor Fields

The PTNODE\_DESCR $n$  field specifies the text for a descriptor, where  $n$  is a number from 1 to 99 (for example, PTNODE\_DESCR1).

The PTNDDESC $n$ LINKABLE field specifies the descriptor type. A descriptor can be one of the following types:

- Y - Linkable text
- N - Static text
- A - Related action menu
- D - Linkable drop-down menu
- R - Read-only (non-linkable) drop-down menu
- L - Linkable drop-down list box
- I - Linkable Icon
- O - Icon only
- M - IM icon

When a user clicks a linkable descriptor, a linkable drop-down menu item, or a drop-down list box item, FieldChange PeopleCode associated with the PTNDDESC $n$ LINKABLE field executes.

See [Organization Chart Actions and Events](#).

When a user selects a related action menu item, the corresponding action executes. PeopleSoft Related Content Framework must be configured for related action menus.

If the descriptor includes an icon, specify the image name and position using the PTDESCRn\_ICON\_IMG and PTDESCRn\_ICON\_POS fields.

Suppose your application includes a node row with this data (some fields in the PTORGNODE\_SBR subrecord are omitted for simplicity):

| <b>Field</b>      | <b>Value</b>      |
|-------------------|-------------------|
| PTCHART_NODE      | ADIAZ             |
| PTPARENT_CHART_ND | TMONT             |
| PTORGCHRTIMG      | (BLOB)            |
| PTNODE_DESCR1     | Arron Diaz        |
| PTNDDESC1LINKABLE | Y                 |
| PTDESCR1_ICON_IMG |                   |
| PTDESCR1_ICON_POS |                   |
| PTNODE_DESCR2     | Director, Upgrade |
| PTNDDESC2LINKABLE |                   |
| PTDESCR2_ICON_IMG | STATUS_COMP_ICN   |
| PTDESCR2_ICON_POS | L                 |
| PTNODE_DESCR3     | Experience: Low   |
| PTNDDESC3LINKABLE | Y                 |
| PTDESCR3_ICON_IMG | EXP_ICN           |
| PTDESCR3_ICON_POS | R                 |

The following example shows the node that is created using the previous attributes:

Drop-down lists require additional configuration.

See [Designing Organization Chart Nodes](#).

See [Configuring Drop-Downs](#).

## Using Images with Organization Charts

If your organization chart uses images, such as photographs, then the scroll area or grid with the fields that contain the images must have unlimited occurs count enabled. That is, the Unlimited Occurs Count check box must be selected on any scroll area or grid that includes a record with the fields from PTORGNODE\_SBR or PTORGPOPUPNODE\_SBR, but only when images are used.

See [Implementing Menus and Drop-Down Lists \(Optional\)](#).

## Implementing Menus and Drop-Down Lists (Optional)

You can configure an organization chart to include menus and drop-down lists for any of the node descriptors.

### Understanding Menus and Drop-Down Lists

This section discusses the following types of drop-downs:

- Related action menu.
- Drop-down menu.
- Drop-down list box.

### Related Action Menu

A related action menu is dynamically generated based on a related service configuration that has been defined in the PeopleSoft Related Content Framework. Related action links in the menu take the user directly to the target, using related values supplied by the node. Because the menu structure and links are defined by the related service configuration, the developer does not need to populate the drop-down rowset or to write PeopleCode for related action drop-down menus. You do need to verify that the related action services mapping page fields are included in the node record.

The following example shows a node configured with a related action menu.

## Drop-Down Menu

A drop-down menu presents list items in a folder menu structure.

Drop-down menus can contain folders and menu items. Folders can be nested.

A drop-down menu can be linkable or read-only. If the drop-down menu is linkable, FieldChange PeopleCode associated with the descriptor field PTNDDESCnLINKABLE executes when a user clicks on a menu item. If the drop-down menu is read-only, FieldChange PeopleCode does not execute.

The following example shows a node configured with a drop-down menu.

## Drop-Down List Box

A drop-down list box presents a list of linkable items.

The following example shows a node with a drop-down list box.

The width of a drop-down list box is the width of the widest list item that the box contains.

## Configuring Related Action Menus

A related action menu is dynamically rendered based on related content configuration that is mapped to the level 1 chart node record field PTCHART\_NODE on the chart page. The services that make up the related content configuration are rendered as links on the related actions menu. The related content layout defines the hierarchical structure of the related actions menu. A related content menu consists of folders and menu items. Folders can be nested.

---

**Important!** SmartNavigation has been deprecated. This information remains for backward compatibility only.

An Actions folder can also be configured to display in drop-down SmartNavigation menus (that is, the portal breadcrumb menu). The Actions folder displays depending on the configuration of related actions for SmartNavigation. If the related actions are attached at the chart component level, the Actions folder will not appear in the dropdown menu. If the related actions are attached to the data source's detail component, the Actions folder will appear in the drop down menu.

---

Related content services are defined using the Define Related Content Service component. Then, related actions are assigned using the Manage Related Content Service component. Both components are part of the PeopleSoft Related Content Framework.

See “Creating and Managing Related Content Service Definitions” (Portal Technology) and “Configuring Related Content, Related Actions, and Menu and Frame Layouts” (Portal Technology).

To configure a descriptor as a related action menu, set the corresponding PTNDDESC $n$ LINKABLE value to "A". Using the Manage Related Content Service component, associate the related actions as *page level* related content to the chart node record field PTCHART\_NODE on the chart page at level 1.

## Configuring the Node Record for Drop-Downs

For each drop-down, add the fields PTDESCR $n$ \_DD\_ID and PTDESCR $n$ \_SI\_ID to your node data record, where  $n$  represents the number of the descriptor. For example, to configure PTNODE\_DESCR7 as a drop-down, add the fields PTDESCR7\_DD\_ID and PTDESCR7\_SI\_ID. Add one set of PTDESCR $n$ \_DD\_ID and PTDESCR $n$ \_SI\_ID for each descriptor you configure as a drop-down (PTNDDESC $n$ LINKABLE="D", "R", or "L").

You will populate PTDESCR $n$ \_DD\_ID with a unique identifier for the drop-down.

When the user clicks on a list item in the drop-down, the system sets the PTDESCR $n$ \_SI\_ID field to the value of the list item ID, making it available for use by FieldChange PeopleCode.

### Configuring the Node Record Without a Display Template

Oracle recommends using a display template to configure your organization chart. Organization charts created with PeopleTools version 8.51 do not use display templates. If your organization chart does not use a display template, you need to configure the node record differently.

Add the fields in the PTORGBOXFLD\_SBR subrecord to your node record. The subrecord contains the fields PTDESCR $n$ \_DROPDOWN\_ID and PTDES $n$ \_SLCT\_ITM\_ID, where  $n$  is an integer from 1 to 7, for example PTDESCR1\_DROPDOWN\_ID and PTDES1\_SLCT\_ITM\_ID, and so on.

You will populate PTDESCR $n$ \_DROPDOWN\_ID with a unique identifier for the drop-down.

See "PTORGBOXFLD\_SBR" in [Organization Chart Subrecord Definitions](#).

## Configuring Drop-Downs

To configure a descriptor as a drop-down menu or drop-down list box:

1. Set the PTNDDESC $n$ LINKABLE field to "D" for a linkable drop-down menu.  
Set the field to "R" for a read-only (non-linkable) drop-down menu.  
Set the field to "L" for a linkable drop-down list box.
2. Populate the PTDESCR $n$ \_DD\_ID field (or the PTDESCR $n$ \_DROPDOWN\_ID if your chart does not use a display template) with the drop-down ID.
3. Create a derived/work record that contains the fields in the subrecord PTORGBOXLST\_SBR.
4. Add PeopleCode to set the drop-down data record and the drop-down rowset.

For example:

```
&ocPBOrg.SetDropDownRecord(Record.DropDown);
&ocPBOrg.SetDropDownData(&rsDropDown);
```

5. Populate the drop-down data rowset with the list information for each of the drop-down list IDs.

See [Populating the Drop-Down Rowset](#).

- Place FieldChange PeopleCode on the PTNODE\_DESCRn field to perform corresponding logic when a list item is selected in a linkable drop-down.

## Populating the Drop-Down Rowset

The drop-down rowset defines the content for drop-down list boxes and defines the menu structure as well as the content for drop-down menus.

Populate the drop-down ID field (PTDESCRn\_DD\_ID using a display template, or PTDESCRn\_DROPDOWN\_ID if not using a display template) on the node record with a unique identifier, such as EMPL.

Populate the drop-down data rowset according to these rules:

- Each list item in the menu is either a folder or a menu item.

Assign a unique value in PTORGDRPLSTITM\_ID for each item.

- Populate PTNODE LISTDESCR with a label for each item.
- Folders have children.
- Menu items have no children.
- Determine the parent for each item. This is the group ID.

Set PTORGDRPLS\_GRP\_ID to the parent ID, PTORG DRPLSTITM\_ID.

- Top-level list items have no parent. Set the group ID to blank.
- Drop-down list box items have no parent. Set the group ID to blank.
- Determine the display order of each list item within its group.

For example, suppose you want to create a drop-down menu with the following structure:

| <b>Level 1</b> | <b>Level 2</b> | <b>Level 3</b> |
|----------------|----------------|----------------|
| Talent         | Teamwork       |                |
|                | Planning       |                |
| Compensation   | Objectives     | Objective A    |

| <b>Level 1</b> | <b>Level 2</b> | <b>Level 3</b> |
|----------------|----------------|----------------|
|                |                | Objective B    |
|                | Performance    | Self Appraisal |
|                |                | Peer Appraisal |
| Time           |                |                |
| Absence        |                |                |

For this example, the drop-down data rowset contains these rows:

| <b><i>PTDESCR_DRP<br/>DWN_ID</i></b> | <b><i>PTORG DRPLST<br/>ITM_ID</i></b> | <b><i>PTORG DRPLS_<br/>GRP_ID</i></b> | <b><i>PTND_DISPLAY_<br/>ORDER</i></b> | <b><i>PTNODE<br/>LISTDESCR</i></b> |
|--------------------------------------|---------------------------------------|---------------------------------------|---------------------------------------|------------------------------------|
| EMPL                                 | TALENT                                |                                       | 1                                     | Talent                             |
| EMPL                                 | COMP                                  |                                       | 2                                     | Competency                         |
| EMPL                                 | TIME                                  |                                       | 3                                     | Time                               |
| EMPL                                 | ABS                                   |                                       | 4                                     | Absence                            |
| EMPL                                 | TEAM                                  | TALENT                                | 1                                     | Teamwork                           |
| EMPL                                 | PLAN                                  | TALENT                                | 2                                     | Planning                           |
| EMPL                                 | OBJ                                   | COMP                                  | 1                                     | Objectives                         |
| EMPL                                 | PERF                                  | COMP                                  | 2                                     | Performance                        |
| EMPL                                 | OBJA                                  | OBJ                                   | 1                                     | Objective A                        |
| EMPL                                 | OBJB                                  | OBJ                                   | 2                                     | Objective B                        |
| EMPL                                 | SELF                                  | PERF                                  | 1                                     | Self Appraisal                     |
| EMPL                                 | PEER                                  | PERF                                  | 2                                     | Peer Appraisal                     |

## Setting Drop-Down Styles

Set the style sheet for the drop down descriptor using the PT\_CNT\_STYLE field on the node display record.

The default style sheet for the drop down depends on the display type of the descriptor.

The following list shows the default style sheet for each drop down type:

- A – PT\_ORGNODE\_DESC7
- D - PT\_ORGNODE\_DESC7
- R - PT\_ORGNODE\_DESC7
- L – PT\_ORG\_DDLIST

The style class for the drop down list item is set using the PTORGLISTDESCSTYLE field in the drop down record. If no style is specified, the default style class is used.

The default style sheet for the drop down list item is:

- A - PT\_ACTION\_LIST\_ITEM
- D - PT\_ACTION\_LIST\_ITEM
- R - PT\_READONLY\_LIST\_ITEM

## Designing Organization Chart Nodes

This section describes the basic design of an organization chart node and explains how to use node display templates to configure more complex organization chart nodes.

### Using Node Display Templates

You can optionally define node display templates for more precise control over the display characteristics of descriptors on a node.

A node display template is keyed to a single organization chart node row, using the PTNODE\_DISPLAY\_ID field. A node display template comprises the set of rows that share a value in PTNODE\_DISPLAY\_ID. Conversely, an organization chart node is associated with a single node display template.

Each row in the node display template defines one descriptor.

Using a node display template, you control:

- Which descriptors appear on the node. Only descriptors included in the node display template and that have PT\_DISPLAY\_FLAG set to “Y” will appear in the node.
- Display type of descriptors (this overrides display types set in PTNDDESCnLINKABLE).
- Line position and display order of a descriptor.
- Number of display items on a node line.

- Spacing between descriptors.

You can associate a node display template with one or more schemas, or zoom levels. Each schema level assigns different display characteristics to the descriptors.

See [Implementing Zoom Schemas \(Optional\)](#).

You can define your chart to use different node display templates for different nodes by assigning different values to PTNODE\_DISPLAY\_ID. For example, you might choose to configure the nodes for executive management to display names and photos, but no telephone numbers, locations, emails, or IM presence, while nodes for everyone else display telephone numbers, locations, and emails, but not photos.

## Implementing Node Display Templates

To implement node display templates:

1. Create a node display record that includes a clone of the PTNODE\_DISP\_SBR.
2. Add PeopleCode to set the node display record and the node display rowset.
3. For example:

```
&ocPBOrg.SetNodeDisplayDataRecord(Record.&recDisplay);
&ocPBOrg.SetNodeDisplayData(&rsDisplay);
```

See “PTNODE\_DISP\_SBR” in [Organization Chart Subrecord Definitions](#).

See [SetNodeDisplayDataRecord](#).

See [SetNodeDisplayData](#).

## Example: Designing a Node

This section demonstrates how to lay out a node that looks like the following example:

## Node Descriptors

The organization chart node (PTORGNODE\_SBR) sample data in the following table generates the descriptors in the previous node example (for simplicity, not all fields are shown):

| <b>Field</b>       | <b>Data</b>   |
|--------------------|---------------|
| PTCHART_NODE       | CROBE         |
| PTPARENT_CHART_ND  | BSTOM         |
| PTND_DISPLAY_ORDER | 3             |
| PTNODE_DESCR1      | Chase Roberts |
| PTNDDESC1LINKABLE  | Y             |
| PTNODE_DESCR2      | Sr. Manager   |
| PTNODE_DESCR3      | My Teams      |
| PTNDDESC3LINKABLE  | D             |
| PTNODE_DESCR4      | KU0035        |
| PTNODE_DESCR5      | 2/8/1998      |
| PTDESCR5_ICON_POS  | L             |
| PTNODE_DESCR6      | \$125,000     |
| PTNDDESC6LINKABLE  | N             |
| PTNODE_DESCR7      | Actions       |
| PTNDDESC7LINKABLE  | A             |
| PTDESCR7_ICON_POS  | L             |
| PTADJUSTFORNULLS   | Y             |
| PTNODE_DISPLAY_ID  | DEMO17        |
| PTPHOTO_START      | 2             |

| <b>Field</b>       | <b>Data</b>       |
|--------------------|-------------------|
| PTNODE_DESCR8      | Org Chart         |
| PTDESCR8_ICON_IMG  | QE_ORG_CHART_ICON |
| PTDESCR8_ICON_POS  | L                 |
| PTNDDESC8LINKABLE  | Y                 |
| PTNODE_DESCR9      | Person ID:        |
| PTNODE_DESCR10     | Hire Date:        |
| PTNODE_DESCR11     | Comp Rate:        |
| PTNODE_DESCR12     |                   |
| PTNDDESC12LINKABLE |                   |
| PTNODE_DESCR13     | Org chart         |
| PTDESCR13_ICON_IMG | QE_SUCCSORGCHART  |
| PTDESCR3_DD_ID     | DEMO17B           |
| PTDESCR7_DD_ID     | DEMO17            |

## Node Display Template

The organization chart node display (PTNODE\_DISP\_SBR) data looks like this:

| <b>PTNODE_DISPLAY_ID</b> | <b>PT_SCHEMA_LEVEL_ID</b> | <b>PT_CNT_ID</b> | <b>PT_NODE_VIEW</b> | <b>PT_LINE_NUM</b> | <b>PTND_DISPLAY_ORDER</b> | <b>PT_DISPLAY_TYPE</b> | <b>PT_PADDING_LEFT</b> | <b>PT_PADDING_RIGHT</b> |
|--------------------------|---------------------------|------------------|---------------------|--------------------|---------------------------|------------------------|------------------------|-------------------------|
| DEMO17                   | 3                         | PTNODE_DESCR12   | VIEW1               | 1                  | 1                         | M                      | Y                      | 0                       |
| DEMO17                   | 3                         | PTNODE_DESCR13   | VIEW1               | 1                  | 2                         | I                      | Y                      | 0                       |

| <i><b>PTNODE_DISPLAY_ID</b></i> | <i><b>PT_SCHEMA_LEVEL_ID</b></i> | <i><b>PT_CNT_ID</b></i> | <i><b>PT_NODE_VIEW</b></i> | <i><b>PT_LINE_NUM</b></i> | <i><b>PTND_DISPLAY_ORDER</b></i> | <i><b>PT_DISPLAY_TYPE</b></i> | <i><b>PT_PADDING_LEFT</b></i> | <i><b>PT_PADDING_RIGHT</b></i> |
|---------------------------------|----------------------------------|-------------------------|----------------------------|---------------------------|----------------------------------|-------------------------------|-------------------------------|--------------------------------|
| DEMO17                          | 3                                | PTNODE_DESCR1           | VIEW1                      | 2                         | 1                                | Y                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR2           | VIEW1                      | 3                         | 1                                | N                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR8           | VIEW1                      | 4                         | 1                                | Y                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR9           | VIEW1                      | 5                         | 1                                | N                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR4           | VIEW1                      | 5                         | 2                                | N                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR10          | VIEW1                      | 6                         | 1                                | N                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR5           | VIEW1                      | 6                         | 2                                | N                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR11          | VIEW1                      | 7                         | 1                                | N                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR6           | VIEW1                      | 7                         | 2                                | N                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR3           | VIEW1                      | 8                         | 2                                | D                             | Y                             | 0                              |
| DEMO17                          | 3                                | PTNODE_DESCR7           | VIEW1                      | 8                         | 1                                | A                             | Y                             | 0                              |

## Default Node Design

Node display templates are a feature of PeopleTools Release 8.52. Organization charts created prior to PeopleTools Release 8.52 continue to be supported using the default node design.

Oracle recommends using node display templates for PeopleTools Release 8.52 and later organization charts. If you choose not to implement the optional node display templates, your organization chart will

follow the default node design. An organization chart that is defined using the default node design has the following characteristics:

- If an icon image is specified in the PTNDMAINICON\_IMAGE field, it appears on the first line, at the right.
- If a node image, such as a photo, is specified (PTORGCHRTIMG), it appears by default on the left, beginning on line two. You can use the ImageLocation property to specify left or right position.
- Each descriptor appears on a separate line. The node displays the first seven descriptors, ordered by the descriptor number.
- PTDESCR\_UNDER\_IMG specifies the first line that appears under the image. Previous lines appear beside the image.

## Adjusting Node Sizing

By default, organization chart nodes are sized dynamically based on the contents of the node and can vary from node to node.

For a vertical organization chart, the width of each node is based on the width of the data in the node. Width can vary from node to node. All the nodes in a given row are the same height, based on height of the tallest node, but node height can vary from row to row.

For a horizontal organization chart, the height of each node is based on the height of the data in the node. Height can vary from node to node. All the nodes in a given column are the same width, based on width of the widest node, but node width can vary from column to column.

You can use the NodeProportion property to control how nodes are sized on a chart. NodeProportion takes the following values:

0 = Variable node sizing. (Default.)

1 = Uniform node height.

2 = Uniform node width.

3 = Uniform node height and width.

4 = Square nodes.

The following example shows a vertical organization chart with uniform node height and width (NodeProportion = 3):

Applying constant node widths can create nodes with extra blank space in the node. You can reduce the node width by reducing value of the NodeMaxDisplayDescLength property.

See [NodeProportion](#).

See [NodeMaxDisplayDescLength](#).

## Implementing Node Views (Optional)

Node views allow you to display alternate information on a node. Using node views, you can determine which attributes to show in the node based on the organization chart's node display template. For instance, one node view might show a person's name, photo, and job information, while another view might show that person's name and contact information.

Users are able to select different node views of the organization chart to see less or more data in the nodes. When node views are implemented for an organization chart, the chart displays a view controller that enables a user to select a node view.

You can define multiple node views for an organization chart. A node view definition would include a full definition of the node contents defined by the following attributes:

- Which icons are displayed.
- Which descriptors are displayed.
- The style of the node descriptor.
- The position of the descriptors on the node.

## Node View Controller

The node view controller appears in the top part of the chart above the nodes but below any chart breadcrumbs or legend. The node view controller is made up of push buttons without text where each button represents a view. A data hint is used to provide the text description of the view.

The node view controller in this example displays the “Personal” node view data hint:

## Creating Node Views

To set up the node view controller to enable node views, use the following two organization chart methods:

```
&oOrgChart.SetNodeViewEntries(&NodeViewArray);
&oOrgChart.SetNodeViewText(&NodeViewText);
```

NodeViewArray represents an array of node view IDs. NodeViewText is an array of data hints for each corresponding node view ID.

Additionally, the organization chart property, InitialView, must be set to indicate which view is initially displayed in the chart. For example, the property might be set as follows to show the view that is labeled “Personal.”

```
&OrgChart.InitialView="VIEW1";
```

The following example shows an organization chart with three node views defined:

Transitioning between node views will be done without a server trip. Therefore, it's not possible to have a field change event when changing between views. Also, once the user navigates away from the chart or

the chart is refreshed, the current view state is not saved. Therefore, the chart will always show the initial view set in the chart property whenever the chart is viewed again.

## Implementing Zoom Schemas (Optional)

Zoom schemas enable you to define different visual schemas for organization charts.

Although schemas are designed to give the appearance of zooming in or out on the organization chart, in fact they are predefined views of the organization chart at different levels. Using schemas, you define what attributes to show on the node, and which nodes are displayed in each schema level. Users are able to select different views of the organization chart to see more or fewer nodes, and to see less or more data in the nodes.

You can define up to ten schema levels for an organization chart.

When zoom schemas are implemented for an organization chart, the chart displays a zoom control that enables a user to select a schema level.

The following example shows an organization chart with a zoom control and four schemas defined. The chart in this example displays schema level 3.

The chart in the following example displays schema level 1, which displays less data on each node, allowing the chart to display more nodes in the same area.

Each schema level defines the following attributes, based on the organization chart's node display template:

- Which icons are displayed.
- Which descriptors are displayed.
- The style of the node descriptor.
- The position of the descriptors on the node.

See “Using Node Display Templates” in [Designing Organization Chart Nodes](#).

In addition, you can place FieldChange PeopleCode on the PTCHART\_SCHEMA\_ID field of the node record to control which nodes are displayed.

When the user changes schema levels, FieldChange PeopleCode on the PTCHART\_SCHEMA\_ID field of the node record executes. You can set the DISPLAYED\_FLAG field on the node data rowset to control whether a node is displayed at the new schema level, or you can use PeopleCode to populate the organization chart node data rowset with only the nodes you want available at the new schema level.

Use the SchemaLevel object ImageHeight property to define whether the image (photo) is displayed in the node and the height of the image.

The size of the chart nodes is determined dynamically based on the subset of data within the node and the corresponding style properties for the schema level.

## SchemaLevel Class

The SchemaLevel PeopleCode class provides methods and properties to set organization chart display information for each schema level.

SchemaLevel objects are declared using the SchemaLevel data type.

For example:

```
Local SchemaLevel &SchemaLevel1;  
Component Chart &Abs_Hist_Chart;
```

Instantiate SchemaLevel objects using the CreateObject("SchemaLevel") PeopleCode function.

## Implementing Schema Zooming

To implement schema zooming:

1. Add PeopleCode to specify the initial schema level.

Example:

```
&oOrgChart.ChartCurrentSchemaLevel=4;
```

2. Instantiate a SchemaLevel object for each schema level your chart will use.

Example:

```
SchemaLevel &oSchemaLevel1 = Createobject("SchemaLevel");
```

3. Add PeopleCode to define each schema level.

Example:

```
/** Create an instance of of schema zoom level 1 class and instantiate it **=>
/
SchemaLevel &oSchemaLevel1 =Createobject("SchemaLevel");
&oSchemaLevel1.ID=1;
& oSchemaLevel1.ImageHeight=0;
/** Create an instance of of schema zoom level 2 class and instantiate it **=>
*/
SchemaLevel &oSchemaLevel2 =Createobject("SchemaLevel");
&oSchemaLevel2.ID=2;
& oSchemaLevel2.ImageHeight=40;
/** Create an instance of of schema zoom level 3 class and instantiate it ***
SchemaLevel &oSchemaLevel3 =Createobject("SchemaLevel");
& oSchemaLevel3.ID=3;
& oSchemaLevel3.ImageHeight=45;

/** Create an instance of of schema zoom level 4 class and instantiate it **=>
*/
SchemaLevel &oSchemaLevel4 =Createobject("SchemaLevel");
&oSchemaLevel4.ID=4;
& oSchemaLevel4.ImageHeight=50;
```

4. Assign the SchemaLevel instances to the OrgChart object.

Example:

```
/** Assign the 4 schema level instance to the org chart object ***/
&SchemaLevls=CreateArray(&oSchemaLevel1, &oSchemaLevel2, &oSchemaLevel3,
&oSchemaLevel4)
&oOrgChart.SetZoomSchemaLevels(&SchemaLevls)
```

5. Write FieldChange PeopleCode on the PTCHART\_SCHEMA\_ID field to execute when the user clicks on the schema zoom control to change the schema level.

Example:

```
Component Rowset &rs, &rsGrid;
Component object &oOrgChart;
rem WinMessage("value =" | &oOrgChart.ChartCurrentSchemaLevel);
&currentZoom = &oOrgChart.ChartCurrentSchemaLevel;
```

```

If &currentZoom = 1 Then
    /* display all records and no image */
    For &i = 1 To &rsGrid.ActiveRowCount
        &RecGrid = &rsGrid.GetRow(&i).GetRecord(Record.QE_ORG_Z2_DRV);
        &RecGrid.GetField(Field.PTDESCR_UNDER_IMG).value = 0;
        /* show all records */
        &RecGrid.GetField(Field.DISPLAYED_FLAG).value = "Y"
    End-For;
Else
    If &currentZoom = 2 Then
        &limit = 6;
    Else
        If &currentZoom = 3 Then
            &limit = 4;
        Else
            &limit = 3;
        End-If;
    End-If;
    For &i = 1 To &rsGrid.ActiveRowCount
        &RecGrid = &rsGrid.GetRow(&i).GetRecord(Record.QE_ORG_Z2_DRV);
        &RecGrid.GetField(Field.PTDESCR_UNDER_IMG).value = 3;
        If &RecGrid.GetField(Field.QE_ORG_SCHEMA_ROW).value < &limit Then
            &RecGrid.GetField(Field.DISPLAYED_FLAG).value = "Y";
        Else
            &RecGrid.GetField(Field.DISPLAYED_FLAG).value = "N";
        End-If;
    End-For;
End-If;

```

## Schema Events

When a user selects a different schema level using the zoom control, the following events take place:

- The system sets the value in the CurrentSchemaLevel property to the new schema value.
- The systems sets the value in the PTCHART\_SCHEMA\_ID to the new schema value.
- FieldChange PeopleCode on the PTCHART\_SCHEMA\_ID field executes.
- The system displays the organization chart at the new schema level.

You can also set the CurrentSchemaLevel property using PeopleCode.

## Specifying Scroll Types

If an organization chart is larger than the viewable area, the user needs to scroll to view other areas of the chart. You can specify whether the organization chart will use scroll bars or alternative scrolling.

If you specify alternative scrolling, a scroll navigator and a hand cursor appear instead of vertical and horizontal scroll bars.

**Note:** On an Apple iPad a user navigates using two fingers on a touch screen, so scroll bars, the scroll navigator, and mouse hand features are not displayed on an Apple iPad.

The arrows on the scroll navigator enable the user to quickly position the right, left, top, or bottom of the chart in the viewable area.

If the user scrolls the chart, the center button of the scroll navigator returns the chart to its initial display position. If the user changes focus by selecting a different node, the chart centers on that node. The center button then returns the chart to display centered on the focus node.

If alternative scrolling is implemented, the user can dismiss a drop-down menu only by clicking within the node areas in the chart unless no scrolling is needed, in which case the user can click on the background or on a node to dismiss the menu.

**Note:** If the breadcrumbs and chart legend are so large that there is not sufficient room to display the scroll navigator in the upper left portion of the chart, it will appear in the lower left corner.

The hand cursor enables the user to grab the background of the chart and move it within the viewable area.

**Note:** When using the hand cursor to scroll, you must position the hand cursor in the chart area outside the chart nodes and popup nodes. Scrolling does not work if the hand cursor is positioned within a chart node or pop-up node.

Use the `ChartScrollType` property to specify which type of scrolling to use. The default is scroll bars.

## Configuring Connector Lines and Node Borders

Use the `PTCONNECTLINESTYLE` field on the organization chart node record to specify the style sheet that defines the following characteristics of the connector lines:

- Line style (unbroken, broken, pattern)
- Line weight
- Line color

The `PSORGCHART` style sheet includes these style classes for connector lines:

| <b>Style Class</b>   | <b>Connector Style</b> |
|----------------------|------------------------|
| PT_ORGCHART_CONNECT1 | Solid gray             |
| PT_ORGCHART_CONNECT2 | Solid black            |
| PT_ORGCHART_CONNECT3 | Dotted red             |
| PT_ORGCHART_CONNECT4 | Dashed gray            |

The default connector line style class is `PT_ORGCHART_CONNECT1` (solid gray).

Use the `PTNODESTYLENAME` field on the organization chart node record to specify the style sheet that defines the following characteristics of the node border:

- Line style (unbroken, broken, pattern)
- Line weight
- Line color
- Shading
- Shading color

The `PSORGCHART` style sheet includes these style classes for connector lines:

| <b>Style Class</b> | <b>Connector Style</b> |
|--------------------|------------------------|
| PT_ORGNODE         | Solid gray             |
| PT_PT_ORGNODE_DASH | Dashed gray            |

The default node border style class is `PT_ORGNODE`.

---

**Note:** We recommend using the default line weight, 1 pixel, for connector lines and node borders. Thicker line weights may cause inconsistencies between connector lines and node borders.

---

## Organization Chart Actions and Events

An organization chart can execute `FieldEdit` or `FieldChange` PeopleCode in response to these user actions:

- Select an expand/collapse icon.
- Click a descriptor link.
- Select a linkable drop-down menu item or drop-down list box item.
- Close a pop-up node.
- Select a breadcrumb.
- Click on a node image.
- Click on a node.

### Selecting Expand/Collapse Icons

When the user clicks an expand/collapse icon, the system toggles the `EXPANDED_FLAG` field value from “Y” to “N” or from “N” to “Y” and changes the icon on the node to collapsed or expanded, correspondingly. This action triggers field change processing (`FieldEdit` and `FieldChange` events) on `EXPANDED_FLAG`. Typically, `FieldChange` PeopleCode checks the `EXPANDED_FLAG` and `PARENT_FLAG` of the node and performs these actions:

- If `EXPANDED_FLAG="Y"` and `PARENT_FLAG="X"`, loads the child rows into the rowset and sets `PARENT_FLAG="Y"`. The updates appear when the chart is refreshed.
- If `EXPAND_FLAG="N"` (collapse action), it does nothing.
- If `EXPAND_FLAG="Y"` (expand action) and `PARENT_FLAG="Y"` (child data is already in rowset), it does nothing.

---

**Note:** If your PeopleCode doesn’t populate the `CollapsedImage` and `ExpandedImage` properties of the organization chart, then no expand/collapse icon appears on any nodes in the chart, and the expand/collapse action is disabled for the chart.

---

### Clicking a Descriptor Link

When the user clicks a descriptor link or linkable drop-down list item, field change processing is triggered on the `PTNODE_DESCRn` field in the node record.

For instance, suppose descriptor 2 is linked to a pop-up chart. When the user clicks the descriptor 2 link, `FieldChange` PeopleCode on the `PTNODE_DESCR2` field in the node record performs the following actions:

- Sets the node’s `sPTPOPUPEXPAND_FLAG = "Y"`.
- Sets the node’s `PTPOPUPHDRMAINDESC`.

- Sets the node's `PTPOPUPHDRMAINICON`.
- If the node's `PTHASPOPUP_FLAG = "X"`, then populates the pop-up node rowset and sets `PTHASPOPUP_FLAG = "Y"` to indicate that the node's descriptor was clicked for the first time.
- Refresh the chart with the pop-up displayed.

### Closing a Pop-up Node

When the user closes a pop-up node it triggers field change processing on the `PTPOPUPEXPAND_FLAG` field.

FieldChange PeopleCode on the `PTPOPUPEXPAND_FLAG` field would need to restore any changes that were made to the originating node's display characteristics and reset the node's `PTPOPUPEXPAND_FLAG = "N"`.

### Selecting a Linkable Menu Item or Drop-Down List Box Item

When a user selects a linkable menu item or drop-down list box item, the system sets the `PTDESCRn_SI_ID` (`PTDESCn_SLCT_ITM_ID` if not using a node display record) field value to the value of the list item ID and FieldChange PeopleCode associated with the `PTNDDESCnLINKABLE` field executes.

### Selecting a Breadcrumb

When a user clicks on a linkable breadcrumb, any FieldEdit and FieldChange PeopleCode in the `PTORGCRMBID` field executes. Typically PeopleCode is used to redraw the organization giving focus to the node that was clicked.

### Clicking on a Photograph

When a user clicks on a node image, field change PeopleCode on the `PTNDMAINICON_IMAGE` field executes.

### Clicking on a Node

When a user clicks on the body of a node – not on a link, linkable drop-down list, or image – field change PeopleCode on the `PTCHART_NODE` field executes.

## Organization Chart Subrecord Definitions

This section describes the following organization chart subrecord definitions:

- `PTORGNODE_SBR`
- `PTORGGPOPUP_SBR`
- `PTORGCRMB_SBR`
- `PTORGBOXLST_SBR`
- `PTORGBOXFLD_SBR`
- `PTORGIM_SBR`

- PTNODE\_DISP\_SBR

## PTORGNODE\_SBR

This table describes the fields in PTORGNODE\_SBR:

| <b>Field</b>       | <b>Description</b>                                                                                                                                                                                                                                                                |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTCHART_NODE       | Specifies the node name.<br><br>This is a key field.                                                                                                                                                                                                                              |
| PTPARENT_CHART_ND  | Specifies the parent of the current chart node.<br><br>This is a key field.<br><br>If a node does not have a parent node defined, then the node is placed on the first level.                                                                                                     |
| PTND_DISPLAY_ORDER | Specifies the display order of the sibling nodes for the same parent node.<br><br>Nodes display left to right according to display order.<br><br>By default, the nodes are ordered as they appear in the rowset.                                                                  |
| PTCONNECTLINESTYLE | Specifies the style class name for connection line style. The default style class is PT_ORGCHART_CONNECT1.                                                                                                                                                                        |
| PTNDMAINICON_IMAGE | Specifies the main icon image name for the node.                                                                                                                                                                                                                                  |
| PTNODESTYLENAME    | Specifies the style class name for the node to control node background color, border, style, and so on.<br><br>The default style class is PT_ORGNODE.                                                                                                                             |
| PTFOCUS_FLAG       | Specifies a focused node (that is, the node that has focus).<br><br>Y – Focused node.<br><br>N – Not a focused node.<br><br>If more than one node is set to focused, only the first focused node in the rowset will be recognized as the focused node.<br><br>The default is “N”. |

| <b>Field</b>    | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PARENT_FLAG     | <p>Indicates whether a node is a parent.</p> <p>Y – The node is a parent and its direct children are already loaded into the rowset.</p> <p>X – The node is a parent and its direct children are not loaded in the rowset (that is, they will be loaded on demand).</p> <p>N – The node is not a parent.</p> <p>The default value is “N”.</p> <p>An expanded/collapsed icon is only displayed on the parent node. If your PeopleCode does not set the CollapsedImage and ExpandedImage properties of the organization chart, no expanded/collapsed icon is displayed on any of the nodes and all expand/collapse actions are disabled.</p> |
| EXPANDED_FLAG   | <p>Indicates whether the node is expanded or collapsed.</p> <p>Y – The chart shows the node expanded with the expanded image icon and its immediate children displayed.</p> <p>N – The chart shows the node collapsed with the collapsed image icon.</p>                                                                                                                                                                                                                                                                                                                                                                                   |
| DISPLAYED_FLAG  | <p>Specifies whether the node displays in the chart.</p> <p>Y – The node displays if the parent node's EXPANDED_FLAG = "Y" (the parent node is not collapsed).</p> <p>N – This node and its child nodes do not display in the chart's display area.</p> <p>The default is “Y”.</p>                                                                                                                                                                                                                                                                                                                                                         |
| PTHASPOPUP_FLAG | <p>Indicates whether the node has a pop-up.</p> <p>Y – This node has a link that invokes a pop-up and the data for the pop-up is already loaded into the pop-up node rowset.</p> <p>X – This node has a link that invokes a pop-up and the data for the pop-up is not loaded in the rowset. The data will be loaded on demand.</p> <p>N – This node does not have a link to invoke a pop-up chart. The default value is “N”.</p>                                                                                                                                                                                                           |

| <b>Field</b>      | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTPOPUEXPAND_FLAG | <p>Indicates whether a node's pop-up nodes display.</p> <p>Y – Pop-up nodes display.</p> <p>N – No pop-up nodes display.</p> <p>If the user clicks the close icon in the pop-up node, the FieldChange event for PTPOPUEXPAND_FLAG executes. The application sets the value of PTPOPUEXPAND_FLAG to “N” when the pop-up node is closed.</p>                                                                                                                                                                                                                                                                                                                                                                                  |
| PTNODE_DESCR $n$  | <p>Specifies the text for descriptor<math>n</math> of the node, where <math>n</math> is an integer that starts at 1 and increments by one for each descriptor used by the chart; for example, PTNODE_DESCR2.</p> <p>The PTORGNODE_SBR subrecord is delivered with fields for descriptors 1 – 7. If you need more than seven descriptors, add a set of descriptor fields (PTNODE_DESCR<math>n</math>, PTNDDESCnLINKABLE, PTDESCRn_ICON_IMG, and PTDESCRn_ICON_POS) for each additional descriptor, to a maximum of 99 descriptors.</p> <p>If this is an icon-only descriptor (PTNDDESCnLINKABLE = “I” or “O”), the text in this field is used as the data hint for the icon.</p> <p>The maximum length is 50 characters.</p> |

| <b>Field</b>          | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTNDDESC $n$ LINKABLE | <p>Specifies the descriptor type for descriptor <math>n</math>, where <math>n</math> is an integer from 1 to 99; for example, PTNDDESC2LINKABLE.</p> <p>Y - Linkable text</p> <p>N - Static text</p> <p>I - Linkable Icon</p> <p>O - Icon only</p> <p>A -Related action menu</p> <p>D - Linkable drop-down menu</p> <p>R - Read-only (non-linkable) drop-down menu</p> <p>L - Linkable drop-down list box</p> <p>M - IM icon</p> <p>The default value is “N”.</p> <p>The value in this field is overridden by the node display template, if one is implemented.</p> |
| PTDESCR $n$ _ICON_IMG | <p>Specifies the name of the image associated with descriptor <math>n</math>, where <math>n</math> is an integer from 1 to 99; for example, PTDESCR2_ICON_IMG.</p> <p>For icon-only descriptors (“I” or “O”), the text in PTNODE_DESCR<math>n</math> is the data hint text.</p> <hr/> <p><b>Note:</b> If PTDESCR<math>n</math>_ICON_IMG is set to a valid image, the image is only displayed if PTNDDESC<math>n</math>LINKABLE is set to “Y”, “N”, “I”, or “O”..</p> <hr/>                                                                                          |
| PTDESCR $n$ _ICON_POS | <p>Indicates the position of the icon relative to descriptor <math>n</math>, where <math>n</math> is an integer from 1 to 7; for example, PTDESCR2_ICON_POS.</p> <p>L – To the left of the description.</p> <p>R – To the right of the description.</p> <p>The default value is based on user language. For instance, “L” for English and “R” for Hebrew.</p>                                                                                                                                                                                                       |

| <b>Field</b>       | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTADJUSTFORNULLS   | <p>Indicate whether to collapse empty attributes to conserve vertical space within the nodes.</p> <p>Y – Collapse.</p> <p>N – Do not collapse.</p> <p>The default value is “N”.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PTPOPUPHDRMAINDESC | Specifies the main descriptor of the pop-up chart header for this node                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PTPOPUPHDRMAINICON | Specifies the name of the image to place on the top left of the pop-up chart header.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| PTORGCHRTIMG       | <p>Specifies the node image.</p> <p>The maximum image size depends on your database platform.</p> <hr/> <p><b>Note:</b> If this field is placed on a grid on the page and the column is hidden (Visible = False), the node images do not appear on the chart.</p> <hr/>                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PSIMAGEVER         | A unique number that is assigned to each image. This is a system-maintained value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PTDESCR_UNDER_IMG  | <p>If you are using a node display template, this specifies the first node line number that appears under the node image. The specified line number and all following lines appear below the image. All lines prior to the specified line appear to the side of the image. If you are not using a node display template, specify an integer from 1 to 7. The corresponding descriptor and all following descriptors appear below the image. All descriptors prior to the one specified appear to the side of the image. If no value is specified, the node lines all appear to the side.</p> <p>If no image is displayed, this field is ignored.</p> <p>This field takes an integer value.</p> |
| PTPHOTO_START      | Specifies the node line number on which the photo starts. This field only applies if you are using a node display template.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PTNODE_DISPLAY_ID  | Specifies which display template ID to use with this node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Field</b>      | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTCHART_SCHEMA_ID | <p>Specifies the current schema value.</p> <p>The system sets this value using the ChartCurrentSchemaLevel OrgChart property value.</p> <p>When the user selects a different schema value, the system sets field to the new value, sets the ChartCurrentSchemaLevel OrgChart property value to the new value, and redraws the chart using the new schema level.</p> <p>If the application changes the ChartCurrentSchemaLevel OrgChart property value, the system sets this field to the new value and redraws the chart using the new schema level.</p> |

## PTORGPOPUP\_SBR

This table describes the fields in PTORGPOPUP\_SBR.

| <b>Field</b>       | <b>Description</b>                                                                                                                                                                                                                             |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTCHART_NODE       | <p>Specifies the name of the node that invoked this pop-up chart.</p> <p>This is a key field.</p>                                                                                                                                              |
| PT_POP_UP_ID       | <p>The unique ID for the pop-up.</p> <p>This is a key field.</p>                                                                                                                                                                               |
| PTPREDECESSOR_NODE | <p>Specifies the name of the predecessor node to the current chart node. The predecessor node is the node that invoked this node.</p> <p>Your application PeopleCode must set this value when the link is clicked on the predecessor node.</p> |
| PTND_DISPLAY_ORDER | <p>Sets the display order of the nodes within the same pop-up.</p> <p>By default the nodes are ordered as they appear in the rowset.</p>                                                                                                       |
| PTNDMAINICON_IMAGE | <p>Specifies the main icon image name for the node.</p>                                                                                                                                                                                        |
| PTNODESTYLENAME    | <p>Specifies the style class name for the node to control node background color, border, style, and so on.</p> <p>If no style class name is specified the PeopleTools default style class is used.</p>                                         |

| <b>Field</b>          | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PT_POPUP_PARENT_ID    | Set to the ID of the parent pop-up chart to which the PT_POPUP_ID is attached. If the chart ID PT_POPUP_ID is connected from the organization node, then its corresponding PT_POPUP_PARENT_ID value is NULL.                                                                                                                                                                                                                     |
| PTHASPOPUP_FLAG       | <p>Indicates whether the node has a pop-up.</p> <p>Y – This node has a link that invokes a pop-up and the data for the pop-up is already loaded into the pop-up node rowset.</p> <p>X – This node has a link that invokes a pop-up and the data for the pop-up is not loaded in the rowset. The data will be loaded on demand.</p> <p>N – This node does not have a link to invoke a pop-up chart. The default value is “N”.</p> |
| PTPOPUEXPAND_FLAG     | <p>Indicates whether a node’s pop-up nodes display.</p> <p>Y – Pop-up nodes display.</p> <p>N – No pop-up nodes display.</p> <p>If the user clicks the close icon in the pop-up node, the FieldChange event for PTPOPUEXPAND_FLAG executes. The application sets the value of PTPOPUEXPAND_FLAG to “N” when the pop-up node is closed.</p>                                                                                       |
| DISPLAYED_FLAG        | <p>Indicates whether the node will appear in the pop-up chart.</p> <p>Y = The node appears in the pop-up chart.</p> <p>N = The node never appears in the pop-up chart, including its pop-up nodes.</p> <p>Default is “Y”.</p>                                                                                                                                                                                                    |
| PTNODE_DESCR $n$      | Specifies the descriptor $n$ of the node, where $n$ is an integer from 1 to 8; for example, PTNODE_DESCR2. Maximum length is 50 characters.                                                                                                                                                                                                                                                                                      |
| PTNDDESC $n$ LINKABLE | <p>Specifies whether the descriptor <math>n</math> is linkable, where <math>n</math> is an integer from 1 to 8; for example, PTNDDESC2LINKABLE.</p> <p>Y – Linkable</p> <p>N – Not linkable</p>                                                                                                                                                                                                                                  |

| <b>Field</b>          | <b>Description</b>                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTDESCR $n$ _ICON_IMG | Specifies the name of the image associated with descriptor $n$ , where $n$ is an integer from 1 to 8; for example, PTDESCR2_ICON_IMG.                                                                                                                                                                                                                         |
| PTDESCR $n$ _ICON_POS | <p>Indicates the position of the icon relative to descriptor <math>n</math>, where <math>n</math> is an integer from 1 to 8; for example, PTDESCR2_ICON_POS.</p> <p>L – To the left of the description.</p> <p>R – To the right of the description.</p> <p>The default value is based on user language. For instance, “L” for English and “R” for Hebrew.</p> |
| PTADJUSTFORNULLS      | <p>Indicates whether to collapse empty attributes to conserve vertical space within the nodes.</p> <p>Y – Collapse</p> <p>N – Do not collapse</p>                                                                                                                                                                                                             |
| PTPOPUPHDRMAINDESC    | Specifies the main descriptor of the pop-up chart header for this node.                                                                                                                                                                                                                                                                                       |
| PTPOPUPHDRMAINICON    | Specifies the name of the image to place on the top left of the pop-up chart header.                                                                                                                                                                                                                                                                          |

## PTORGCRMB\_SBR

This table describes the fields in PTORGCRMB\_SBR:

| <b>Field</b>       | <b>Description</b>                                                                                                                                                      |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTORGCRMBID        | <p>Assigns the breadcrumb ID.</p> <p>PTORGCRMBID is a key field.</p>                                                                                                    |
| PTPARENT_ORGCRMBID | <p>Specifies the breadcrumb ID of Parent node.</p> <p>Only one row, which will be the first breadcrumb, can have this field blank or there will be a runtime error.</p> |

| <b>Field</b>      | <b>Description</b>                                                                             |
|-------------------|------------------------------------------------------------------------------------------------|
| PTORGCRMBDESCR    | Sets the breadcrumb description. In an organization chart this is generally a name.            |
| DISPLAYED_FLAG    | The displayed flag.<br><br>Y = Displayed.<br><br>N = Not displayed.<br><br>The default is “N”. |
| PTORGCRMBLINKABLE | The linkable flag.<br><br>Y = Linkable<br><br>N = Not linkable<br><br>The default is “Y”.      |

## PTORGBOXLST\_SBR

This table describes the fields in PTORGBOXLST\_SBR:

| <b>Field</b>      | <b>Description</b>                                                                                                                                                                                                                                                                                           |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTDESCR_DRPDWN_ID | Specifies the node description drop-down list box ID.<br><br>PTDESCR_DRPDWN_ID is a key field.                                                                                                                                                                                                               |
| PTORGDRPLSTITM_ID | The drop down list item ID for the specified drop down list.<br><br>PTORGDRPLSTITM_ID is a key field.                                                                                                                                                                                                        |
| PTORGDRPLS_GRP_ID | Specify the group ID for the drop down list item in the drop-down box.<br><br>For a folder menu, set this value to the list item ID (PTORGDRPLSTITM_ID) of the parent folder.<br><br>For a top-level folder, set this value to blank. For a flat (single-level) drop-down list box, set this value to blank. |

| <b>Field</b>       | <b>Description</b>                                                                                                                                                                               |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTND_DISPLAY_ORDER | <p>Set the display order of the list item within the same drop-down box.</p> <p>By default, the list will display in the order the list items appear in the rowset.</p>                          |
| PTNODELISTDESCR    | <p>The text that will appear for the drop down list item. The maximum length is 60 characters.</p>                                                                                               |
| PTORGLISTDESCSTYLE | <p>Specify the style class for the list item.</p> <p>The default style class for drop down list items depends on the type of drop down.</p> <p>See <a href="#">Setting Drop-Down Styles</a>.</p> |

## PTORGBOXFLD\_SBR

This table describes the fields in PTORGBOXFLD\_SBR:

---

**Note:** This subrecord is retained for backward compatibility. With PeopleTools version 8.52 and later, Oracle recommends using node display templates. The PTORGBOXFLD\_SBR is not used with a chart that implements node display templates.

---

See [Configuring the Node Record for Drop-Downs](#).

| <b>Field</b>           | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTDESCR $n$ _DROPDOWN  | <p>The drop down list ID for descriptor <math>n</math>, where <math>n</math> is an integer from 1 to 7; for example, PTDESCR2_DROPDOWN.</p>                                                                                                                                                                                                                                                                                                                      |
| PTDES $n$ _SLCT_ITM_ID | <p>The selected list Item ID in the drop-down box for descriptor <math>n</math>, where <math>n</math> is an integer from 1 to 7; for example, PTDES2_SLCT_ITM_ID.</p> <p>The system sets this field to the value of the list item ID when the user clicks on a list item in the drop-down list box for descriptor <math>n</math>. You can add PeopleCode to the PTNODE_DESCR<math>n</math> field that performs business logic using the value in this field.</p> |

## PTORGIM\_SBR

---

**Note:** PTORGIM\_SBR has been deprecated and currently exists for backward compatibility only.

---

## PTNODE\_DISP\_SBR

This table describes the fields in PTNODE\_DISP\_SBR:

| <b>Field</b>       | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTNODE_DISPLAY_ID  | Specifies the ID of a display template.<br><br>The PTNODE_DISPLAY_ID field on the organization chart node record specifies the node display template to be used for the node.                                                                                                                                                                                                                                                                                                                                                                      |
| PT_SCHEMA_LEVEL_ID | Specifies the schema level. Specify a numeric value 1-10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PT_CNT_ID          | Specifies the descriptor. For example, PTNODE_DESCR1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PT_NODE_VIEW       | Specifies the name of the node view.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PT_LINE_NUM        | Specifies the node line number on which the descriptor will appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PT_DISPLAY_TYPE    | Specifies the display item type.<br><br>Y - Linkable text<br><br>N - Static text<br><br>I - Linkable Icon<br><br>O - Icon only<br><br>A -Related action menu<br><br>D - Linkable drop-down menu<br><br>R - Read-only (non-linkable) drop-down menu<br><br>L - Linkable drop-down list box<br><br>M - IM icon<br><br>If this field is set to "M" but no rows are defined in the PT_ORGIM_SBR for the node, no IM icon will be shown.<br><br>The value in this field overrides the value in PTNDDESCnLINKABLE in the organization chart node record. |

| <b>Field</b>       | <b>Description</b>                                                                                                                                                                                                                                                                                                                                           |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PT_DISPLAY_FLAG    | Specifies whether the descriptor will be displayed in the node.<br><br>The default value is “Y”.                                                                                                                                                                                                                                                             |
| PTND_DISPLAY_ORDER | Sets the display order of the descriptor/icon within the line number.                                                                                                                                                                                                                                                                                        |
| PT_PADDING_RIGHT   | Specifies the padding, in pixels, to the right of the descriptor.<br><br>If PT_COL_ALIGN is set to centered or left aligned, this field is ignored.                                                                                                                                                                                                          |
| PT_PADDING_LEFT    | Specifies the padding, in pixels, to maintain to the left of the descriptor.<br><br>If PT_COL_ALIGN is set to centered or right aligned, this field is ignored.                                                                                                                                                                                              |
| PT_CNT_STYLE       | Specifies the style class name that will be used to control the style of the descriptor.<br><br>The default style class for drop downs depends on the type of drop down.<br><br>See <a href="#">Setting Drop-Down Styles</a> .                                                                                                                               |
| PT_DESCR_MAX       | Specifies the maximum length for the descriptor.<br><br>If the full descriptor text is longer than PT_DESCR_MAX, then an ellipsis (“...”) is appended to the displayed text. The entire text appears in a data hint.<br><br>The default value is 50 characters.<br><br>This value overrides any value set in the NodeMaxDisplayDescLength OrgChart property. |

## Minimum Methods and Properties

At a minimum, these methods are needed to create an organization chart:

- SetNodeData
- SetNodeRecord

These methods are required if your organization chart uses pop-ups:

- SetPopUpNodeData
- SetPopUpNodeRecord

These methods and properties are required if your organization chart uses IM presence:

- SetIMRecord
- SetIMData
- IMPresence

These methods are required if your organization chart uses node display templates:

- SetNodeDisplayDataRecord
- SetNodeDisplayData

These methods and properties are required if your organization chart uses zooming schemas:

- SetSchemaLevels
- ChartCurrentSchemaLevel
- ID SchemaLevel class property
- ImageHeight SchemaLevel class property

These methods are required if your organization chart uses breadcrumbs:

- SetCrumbData
- SetCrumbRecord

These methods are required if your organization chart uses drop-down list boxes:

- SetDropdownData
- SetDropdownRecord

## Scope and Data Type of an OrgChart Object

Chart objects are declared using the Chart data type. For example,

```
Local OrgChart &MyOrgChart;
```

A chart object can be instantiated only from PeopleCode.

You can use this object only in PeopleCode programs that are associated with an online process, not in an Application Engine program, a message notification, a Component Interface, and so on.

## Using the RatingBoxChart Class

A rating box chart is an interactive chart that displays nodes on a two-dimensional grid. If drag-and-drop is enabled for the chart, a user can move the nodes from one quadrant to another on the grid. When the user moves a node, the underlying data is updated automatically.

The rating box chart in this example displays ratings on the dimensions of potential and performance. The nine combinations of ratings produces a grid with nine quadrants:

This section provides an overview of rating box chart terminology and discusses how to use the RatingBoxChart Class.

## Understanding Rating Box Chart Terms

The following is a list of terms that apply specifically to rating box charts.

| Field or Control | Description                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Box              | A rating box chart is an array of boxes (referred to as quadrants) arranged in a grid along the x and y axes. See <i>Quadrant</i> for more information. |

| <b>Field or Control</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description             | A text string that is associated with a node. The node description optionally displays with the node icon.                                                                                                                                                                                                                                        |
| Icon                    | An image associated with a node that displays in a quadrant on the rating box chart.                                                                                                                                                                                                                                                              |
| Node                    | A single data point on a rating box chart. A node represents an individual entity, such as an employee, customer, or product. You can drag-and-drop a node to other quadrants in the rating box chart grid.                                                                                                                                       |
| Node record             | A record that contains the properties and data values for each node on the rating box chart. The node record must include a copy of the subrecord PTRATINGBIX_SBR.                                                                                                                                                                                |
| Quadrant                | <p>A rating box chart is an array of quadrants arranged in a grid along the x and y axes. Each quadrant represents a pair of ratings, one for the x value and one for the y value.</p> <p>Each quadrant can display a custom label as defined by an instance of the QuadrantSchema class. See <a href="#">Using the QuadrantSchema Class</a>.</p> |
| Rating                  | A text string that is assigned to each quadrant in the rating chart. Each quadrant has an x rating, based on its position on the horizontal axis, and a y rating, based on its position on the vertical axis.                                                                                                                                     |
| Title                   | There are three titles: Main title, x-axis title, and y-axis title. A title is text that identifies that portion of the chart.                                                                                                                                                                                                                    |

## Using Rating Box Charts in PeopleSoft Applications

A rating box chart displays nodes on a chart that is divided into two or more quadrants arrayed in a grid.

An application can correlate nodes, represented by icons, with various entities, such as employees, customers, or products, and various attribute pairs, such as potential/performance, cost/benefit, or opportunity/risk.

A user interacts with the rating box by dragging nodes to different quadrants. When a node is moved, its underlying x (horizontal) and y (vertical) values are updated. A user can also interact with the rating box by changing a node's x or y values in the grid that contains the rating box values if the application makes the grid visible and editable.

To drag and drop a node using an Apple iPad, tap the node's description. A copy of the node with a red dashed border appears. Then tap the quadrant to which you want to move the node. The node appears in the new location.

The **View all** pop-up automatically closes if the user moves a node to another quadrant.

Using PeopleCode, you can associate each node with an image, or icon, and a description. You can configure a rating box to display nodes with icons and descriptions or with only icons.

If a quadrant contains more nodes than the number set in the RatingBoxChart property BoxMaxDisplayItems, the user can click a link at the bottom of the quadrant to launch a pop-up that contains all the nodes. The quadrant border changes color to indicate that the quadrant has a pop-up open. A vertical scrollbar enables the user to scroll through all the nodes in the list as shown in this example:

## Creating Rating Box Charts Using the RatingBoxChart Class

When you add a rating box chart to a page in Application Designer, you use the chart properties to associate the chart control with a record field. You will use this field name to identify the chart in PeopleCode.

You will need to create a record that will be the rating box chart node record. The record can be a standard database record or a derived/work record. The node record holds the values for the properties and data for each of the rating box chart nodes.

The record can have any name, but it must include a clone of the PeopleTools-delivered subrecord PTRATINGBOX\_SBR. Since the subrecord will carry the FieldChange PeopleCode for the chart, in most cases you should create a unique subrecord for each chart. The node record must be placed on a page at

level one on the component so that its PeopleCode will be loaded into the component buffer. It can be hidden.

In your chart PeopleCode, typically in the Activate event, you will create and populate a rowset linked to the chart's node record. This must be a component rowset, linked to the chart's node record, not a standalone rowset. The rowset has one row for each node in the chart.

## Actions and Events

When the IsDragable property is set to True, drag-and-drop is allowed for the rating box chart. Otherwise, drag-and-drop is not allowed.

When a user drags the node from one quadrant to another, PeopleTools updates the values for the node's PTXAXISRATINGS and PTYAXISRATINGS values, changing the node's x and y values to the new values. This change invokes field change processing on the PTXAXISRATINGS and PTYAXISRATINGS fields on the rating box node record. Typically, FieldChange PeopleCode performs business logic and refreshes the chart display.

## Text Orientation

The orientation of the main title in a rating box chart is always horizontal.

The orientation of the x-axis title and x-axis labels is always horizontal.

The orientation of the y-axis title and y-axis labels is always vertical.

## Rating Box Chart Subrecord Definition

These are the fields in PTRATINGBOX\_SBR:

| <b>Field</b>       | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTCHART_NODE       | Specifies the node name. This is the key to the record.                                                                                                                                                                                                                                                                                                                                                       |
| PTND_DISPLAY_ORDER | Specifies the display order of the nodes within the chart. By default nodes will display in the same order as in the rowset.<br><br>You must provide a unique value for display order for each node in the rating box rowset so that the nodes will display in the correct order in the chart. A runtime error message is thrown when the display order is not unique for each node in the rating box rowset. |
| PTNODE_DESCR1      | Specifies the main description for the node.                                                                                                                                                                                                                                                                                                                                                                  |
| PTNODEDESCRSTYLE   | Specifies the style class that defines the description's text font, type, color, size, and so on.                                                                                                                                                                                                                                                                                                             |
| PTNDDESC1LINKABLE  | Reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Field</b>      | <b>Description</b>                                                                                                                                                                                      |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PTDESCR1_ICON_IMG | Specifies the image name for the main description.                                                                                                                                                      |
| PTDESCR1_ICON_POS | Indicates where to place the icon relative to the description.<br><br>L – Left of the description<br><br>R – Right of the description                                                                   |
| PTXAXISRATINGS    | Specifies the x-axis rating for the current node.                                                                                                                                                       |
| PTYAXISRATINGS    | Specifies the y-axis rating for the current node.                                                                                                                                                       |
| DISPLAYED_FLAG    | Indicates whether the node will display in the chart area.<br><br>Y – The node will display in the chart area.<br><br>N – The node will not display in the chart area.<br><br>The default value is “Y”. |

## Minimum Methods

At a minimum these methods are needed to create a rating box chart.

- SetRBNodeData
- SetRBNodeRecord
- SetXAxisLabels
- SetYAxisLabels

## Minimum Properties

At a minimum, these properties are needed to create a rating box chart.

- XAxisBoxNum
- YAxisBoxNum

These properties are required if the chart includes a view all pop-up:

- PopUpWidth
- PopUpHeight

## Using the QuadrantSchema Class

You can attach instances of the QuadrantSchema class to your rating box chart to provide additional information to users. Specifically, you can label quadrants in the rating box chart.

In the following example, six of the nine available quadrants in the rating box chart are associated with a QuadrantSchema object and have custom labels; the other three quadrants are unlabeled.

Each label is defined by an instance of QuadrantSchema. These instances are created independently in PeopleCode and then attached as an array to your instance of RatingBoxChart.

For each instance of QuadrantSchema you must specify the x-value/y-value pair that defines the quadrant for the text. You can also specify the location of the text within the quadrant.

The following PeopleCode example demonstrates how to create unique instances of QuadrantSchema, set their properties, and assign them to a rating box chart in order to display a custom label in six rating box quadrants.

```

/***** Create Quadrant Schema 1 *****/
&oQuadrantSchema1 = CreateObject("QuadrantSchema");
&oQuadrantSchema1.XRating = "Low";

```

```

&oQuadrantSchema1.YRating = "Low";
&oQuadrantSchema1.LabelText = "Lowest";
&oQuadrantSchema1.LabelPosition = %Bottom_Left;

/***** Create Quadrant Schema 2*****/
&oQuadrantSchema2 = CreateObject("QuadrantSchema");
&oQuadrantSchema2.XRating = "High";
&oQuadrantSchema2.YRating = "High";
&oQuadrantSchema2.LabelText = "Highest";
&oQuadrantSchema2.LabelPosition = %Top_Right;

/***** Create Quadrant Schema 3*****/
&oQuadrantSchema3 = CreateObject("QuadrantSchema");
&oQuadrantSchema3.XRating = "Medium";
&oQuadrantSchema3.YRating = "Medium";
&oQuadrantSchema3.LabelText = "This label should not overflow the quadrant!";
&oQuadrantSchema3.LabelPosition = %Bottom_Right;

/***** Create Quadrant Schema 4*****/
&oQuadrantSchema4 = CreateObject("QuadrantSchema");
&oQuadrantSchema4.XRating = "High";
&oQuadrantSchema4.YRating = "Low";
&oQuadrantSchema4.LabelText = "High-Low";
&oQuadrantSchema4.LabelPosition = %Bottom_Right;

/***** Create Quadrant Schema 5*****/
&oQuadrantSchema5 = CreateObject("QuadrantSchema");
&oQuadrantSchema5.XRating = "Low";
&oQuadrantSchema5.YRating = "High";
&oQuadrantSchema5.LabelText = "Low-High";
&oQuadrantSchema5.LabelPosition = %Top_Left;
rem &oQuadrantSchema5.LabelPosition = 4;

/***** Create Quadrant Schema 6*****/
&oQuadrantSchema6 = CreateObject("QuadrantSchema");
&oQuadrantSchema6.XRating = "Medium";
&oQuadrantSchema6.YRating = "Low";
&oQuadrantSchema6.LabelText = "Overlapped?";
&oQuadrantSchema6.LabelPosition = %Bottom_Right;

```

Then, the following portion of the program builds an array of these instances and that then associates that array to the instance of RatingBoxChart:

```

&QuadrantSchemas = CreateArray(&oQuadrantSchema1, &oQuadrantSchema2, &oQuadrantSchema3,
&oQuadrantSchema4, &oQuadrantSchema5, &oQuadrantSchema6);

&oRatingBoxChart.SetQuadrantSchemas(&QuadrantSchemas);

/* Reduce clutter in the chart by hiding the axis labels */
&oRatingBoxChart.ShowAxisLabels = False;

```

## Data Type of a RatingBoxChart Object

Chart objects are declared using the Chart data type. For example,

```
Local RatingBoxChart &RatingBoxChart;
```

## Scope of a RatingBoxChart Object

A chart object can be instantiated only from PeopleCode.

You can use this object only in PeopleCode programs that are associated with an online process, not in an Application Engine program, a message notification, a Component Interface, and so on.

## Chart Class Methods

These methods are used by the Chart class. The methods are listed in alphabetical order.

### Reset

#### Syntax

```
Reset ()
```

#### Description

Use the Reset method to clear all existing chart settings and data.

#### Parameters

None.

#### Returns

None.

#### Related Links

[Refresh](#)

### SetColorArray

#### Syntax

```
SetColorArray (&Array_of_Color)
```

#### Description

PeopleSoft charts are delivered with a default color sequence. If you want to specify a different sequence, use the SetColorArray method to set the colors for a series. You can specify only a one-dimensional array for the parameter.

This method applies to the base chart and to the overlay chart. Color values are applied first to the base chart, then to the overlay chart. For example, if the base chart contains four series, then the fifth color value is applied to the first series in the overlay chart, and so on.

The type of array can be any of the following:

- String
- Number
- Integer
- Decimal

Use the `SetColorArray` method for line charts instead of `SetDataColor` because `SetDataColor` does not work with line charts. Individual line segments cannot be colored because there are fewer line segments than points. Use `SetColorArray` instead to color each complete line (series).

## Parameters

| <b>Parameter</b>           | <b>Description</b>                                                                                                                                |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_Color</i> | Specify an already instantiated array that contains the color values that you want for the series. You can specify either a constant or a number. |

The following lists all the values you can specify. You can use either the numeric or constant value.

| <b>Numeric Value</b> | <b>Constant Value</b>                   | <b>Description</b>                                                                                                                                                                                                                                                   |
|----------------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -1                   | <code>%ChartColor_Series_Default</code> | Default series color. When a data point is set to this, the default series color or the color that has been set by the programmer for that series is used instead. This value works only with the <code>SetColorArray</code> method of the <code>Chart</code> class. |
| 0                    | <code>%ChartColor_Black</code>          | Black                                                                                                                                                                                                                                                                |
| 1                    | <code>%ChartColor_Blue</code>           | Blue                                                                                                                                                                                                                                                                 |
| 2                    | <code>%ChartColor_Cyan</code>           | Cyan                                                                                                                                                                                                                                                                 |
| 3                    | <code>%ChartColor_DarkGray</code>       | Dark gray                                                                                                                                                                                                                                                            |
| 4                    | <code>%ChartColor_Gray</code>           | Gray                                                                                                                                                                                                                                                                 |
| 5                    | <code>%ChartColor_Green</code>          | Green                                                                                                                                                                                                                                                                |

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b> |
|-----------------------------|------------------------------|---------------------------|
| 6                           | %ChartColor_LightGray        | Light gray                |
| 7                           | %ChartColor_Magenta          | Magenta                   |
| 8                           | %ChartColor_Orange           | Orange                    |
| 9                           | %ChartColor_Pink             | Pink                      |
| 10                          | %ChartColor_Red              | Red                       |
| 11                          | %ChartColor_White            | White                     |
| 12                          | %ChartColor_Yellow           | Yellow                    |
| 13                          | %ChartColor_Red_Orange       | Red-orange                |
| 14                          | %ChartColor_Yellow_Green     | Yellow-green              |
| 15                          | %ChartColor_Blue_Violet      | Blue-violet               |
| 16                          | %ChartColor_Purple           | Purple                    |
| 17                          | %ChartColor_Yellow_Orange    | Yellow-orange             |

## Returns

None.

## Example

The following example sets the four series in the chart:

```
&NumArray = CreateArray(1, 3, 6, 9);
&oChart.SetColorArray(&NumArray);
```

## SetData

### Syntax

```
SetData ({Record_Name | &Rowset})
```

## Description

Use the `SetData` method to specify where the data from the chart is coming from.

You can use either a record name or an already instantiated, populated rowset. In general, specify a record when building a chart from page data and a rowset when building a chart from a standalone rowset.

If you make a change to the underlying data of a chart, call the `SetData` method again to update the chart.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name</i>      | Specify the name of a record to be used to populate the chart with data.                                                   |
| <i>&amp;Rowset</i>      | Specify the name of an already instantiated rowset to populate the chart with data. This is generally a standalone rowset. |

## Returns

None.

## Example

The following is the minimum code you need to create a PeopleSoft chart.

```
Local Chart &MyChart;

&MyChart = GetChart (ABS_HIST.CHART);
&MyChart.SetData (ABS_HIST);
&MyChart.SetDataYAxis (ABS_HIST.Reason);
&MyChart.SetDataXAxis (ABS_HIST.Duration);
```

The following example creates a chart using a standalone rowset.

```
Function IScript_GetChartURL()
local object &MYCHART;
local string &MYURL;
local rowset &MYROWSET;

&MYCHART = CreateObject ("Chart");

&MYROWSET = CreateRowset (Record.ABS_HIST);

&EmplID = %Emplid;

&MYROWSET.Fill ("Where EMPLID :=1", &EmplID);

&MYCHART.SetData (&MYROWSET);
&MYCHART.SetDataXAxis (ABS_HIST.ABSENCE_TYPE);
&MYCHART.SetDataYAxis (ABS_HIST.DURATION_DAYS);

&MYURL = %Response.GetChartURL (&MYCHART);

/* use &MYURL in your application */
...
End-Function;
```

## SetDataColor

### Syntax

```
SetDataColor(Record_Name.Field_Name1, ...)
```

### Description

Use the SetDataColor method to specify a field that contains the color for each data point. Each field for each data point must contain either a number or a constant that specifies the color you want to use.

Use the SetColorArray method for line charts instead of SetDataColor because SetDataColor does not work with line charts. Individual line segments cannot be colored because fewer line segments exist than points. Use SetColorArray instead to color each complete line (series). See [SetColorArray](#).

---

**Note:** This method has no effect when used with an overlay.

---

### Parameters

| <i><b>Parameter</b></i>              | <i><b>Description</b></i>                                                                                                                                                                                                                                                         |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1</i> , ... | <p>Specify the name of the record and one or more fields on that record that contain the colors for the data items for the chart.</p> <hr/> <p><b>Note:</b> The number and order of fields specified must correspond to the order specified by the SetDataYAxis method.</p> <hr/> |

See [SetColorArray](#).

### Returns

None.

## Related Links

[SetDataYAxis](#)

## SetDataHints

### Syntax

```
SetDataHints(Record_Name.Field_Name1, ...)
```

## Description

Use the `SetDataHints` method to override the default text that appears as a caption when you mouse over data in a chart (that is, a bar, a pie slice, or a data point).

---

**Important!** The `ToolTipLabel` class provides an alternative method for creating custom tooltips for data items on charts. See [Using the ToolTipLabel Class](#) for more information.

---

The default data hint text that appears is constructed from information about the composition of the chart that you have defined and the row of data being charted. Specifically, its structure depends on whether the chart has a data series or not.

If you do not specify `SetDataHints` and do not specify `SetDataSeries`, then the value of the x-axis (Group) and the value of the y-axis appear in the data hint:

If you do not specify `SetDataHints` but do specify `SetDataSeries`, then the value of the x-axis (Group), the y-axis, and the series appear in the data hint:

If you use `SetDataHints`, the text that appears as a caption when you mouse over data will be precisely that which is in the `RECORD.FIELD` for that row of data. This is true whether a data series is present or not.

For example, `SetDataHints` is set as follows:

```
&cChart12.SetDataHints(DOC_CHRT_SLS_2.DOC_CHRT_MASCOT);
```

Mousing over the bar representing California reveals *Golden Bears* as the value of the `DOC_CHRT_MASCOT` field for that row in the `DOC_CHRT_SLS_2` rowset:

In the following example, `SetDataSeries` is already set, and `SetDataHints` is set as follows:

```
&cChart13.SetDataHints(DOC_CHRT_SLSREC.DOC_CHRT_RGN);
```

Mousing over any bar in the bar chart will display the region represented by the bar.

Parameters

| Parameter                           | Description                                                                                                                                                                                                                                                                          |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1, ...</i> | <p>Specify the name of the record and one or more fields on that record that contain the tooltips for the data items for the chart.</p> <p><b>Note:</b> The number and order of fields specified must correspond to the order specified by the <code>SetDataYAxis</code> method.</p> |

Returns

None.

Example

```
&cChart13.SetDataHints(DOC_CHRT_SLSREC.DOC_CHRT_RGN);
```

SetDataLabel

Syntax

```
SetDataLabel (Record_Name.Field_Name1, ...)
```

Description

Use the SetDataLabel method to set labels for each data series when multiple fields are passed to SetDataYAxis. Otherwise, each series is identified by its field name.

Parameters

| Parameter                           | Description                                                                                                                                                                                                                                                                       |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1, ...</i> | <p>Specify the name of the record and one or more fields on that record that contain the labels for the data items for the chart.</p> <hr/> <p><b>Note:</b> The number and order of fields specified must correspond to the order specified by the SetDataYAxis method.</p> <hr/> |

Returns

None.

Example

Consider the following data for a chart.

---

**Note:** For ease of viewing, the data has been split into two tables.

---

Chart data part 1:

| <b><i>QE_PARKNAME</i></b> | <b><i>QE_YEARS</i></b> | <b><i>QE_VISITORS</i></b> | <b><i>QE_CHART_COLOR</i></b> | <b><i>QE_CHART_LABEL</i></b> | <b><i>QE_CHART_LABELSTYL</i></b> |
|---------------------------|------------------------|---------------------------|------------------------------|------------------------------|----------------------------------|
| ARCHES                    | 1970                   | 1640758                   | 2                            | ar                           | font-size:8px;                   |

| SEQUOIA            | beforeMarker        | 8                 | triangleDown           | 9                         |
| SEQUOIA            | auto                | 7                 | triangleDown           | 9                         |
| YELLOWSTONE        | insideBarEdge       | 8                 | human                  | 12                        |
| YELLOWSTONE        | outsideBarEdge      | 7                 | plus                   | 12                        |
| YELLOWSTONE        | center              | 8                 | diamond                | 12                        |
| YOSEMITE           | aboveMarker         | 7                 | triangleUp             | 15                        |
| YOSEMITE           | belowMarker         | 8                 | triangleUp             | 15                        |
| YOSEMITE           | auto                | 7                 | triangleUp             | 15                        |

The following PeopleCode program will render the chart data as a bar chart:

```

rem Set up the chart;
&oChart = GetChart(QE_JET_CHARTWRK.QE_JET2);
&oChart.Reset();
&oChart.Type = %ChartType_2DBar;

rem Set chart data;
&oChart.SetData(Record.QE_CHART_NPARKS);

&oChart.SetDataYAxis(QE_CHART_NPARKS.QE_VISITORS);
&oChart.SetDataXAxis(QE_CHART_NPARKS.QE_YEARS);
&oChart.SetDataSeries(QE_CHART_NPARKS.QE_PARKNAME);
&oChart.XAxisTitle = "Years";
&oChart.YAxisTitle = "No. of visitors";
&oChart.FootNote = "Visitors";
&oChart.MainTitle = "Visiting National Parks";

rem Set data labels and markers;
&oChart.SetDataLabel(QE_CHART_NPARKS.QE_CHART_LABEL);
&oChart.SetDataLabelPosition(QE_CHART_NPARKS.QE_CHART_POS);
&oChart.SetDataLabelStyle(QE_CHART_NPARKS.QE_CHART_LABELSTYL);
&oChart.SetDataMarker(QE_CHART_NPARKS.QE_CHART_MARKER);

```

```

&oChart.SetDataMarkerSize(QE_CHART_NPARKS.QE_CHART_MARKERSIZ);

rem Set z-axis value;
&oChart.SetDataZAxis(QE_CHART_NPARKS.QE_CHART_Z);

rem for bubble charts;
rem &oChart.SetDataGlyphScale(QE_CHART_NPARKS.QE_CHART_Z);

```

Because bar charts do not support data markers, the chart that is rendered does not display markers.

The preceding PeopleCode program can be modified to display the same data as a line chart by changing the chart type:

```

&oChart.Type = %ChartType_2DLine;

```

The line chart that is rendered from the same data includes the data labels and data markers.

## SetDataLabelPosition

### Syntax

```
SetDataLabelPosition (Record_Name.Field_Name1, ...)
```

### Description

Use the `SetDataLabelPosition` method to set the position of the data labels, which are set by the `SetDataLabel` method.

## Parameters

| <i><b>Parameter</b></i>             | <i><b>Description</b></i>                                                                                                                                                                                                                                              |

| belowMarker         | Below the marker for the data item.*                                                                                                                                                                                                                                                                                                                                                                                           |
| beforeMarker        | Before the marker for the data item.*                                                                                                                                                                                                                                                                                                                                                                                          |
| afterMarker         | After the marker for the data item.*                                                                                                                                                                                                                                                                                                                                                                                           |
| insideBarEdge       | Inside the edge of a bar chart data item.                                                                                                                                                                                                                                                                                                                                                                                      |
| outsideBarEdge      | Outside the edge of a bar chart data item.                                                                                                                                                                                                                                                                                                                                                                                     |
| outsideSlice        | Outside the slice of a pie chart data item.                                                                                                                                                                                                                                                                                                                                                                                    |
| auto                | The chart engine determines the best position for the label based on the chart type, chart size, label size and other factors. Specifically, for the bar chart family of charts: <ul style="list-style-type: none"> <li>On bar charts that aren't stacked, setting the label's position to auto will act as insideBarEdge.</li> <li>On stacked bar charts, setting the label's position to auto will act as center.</li> </ul> |

\* This value is not supported for any of the bar chart family of charts; on bar charts, the auto value is substituted instead.

## Returns

None.

## Example

```
&oChart.SetDataLabelPosition(QE_CHART_NPARKS.QE_CHART_POS);
```

# SetDataLabelStyle

## Syntax

```
SetDataLabelStyle(Record_Name.Field_Name1, ...)
```

## Description

Use the SetDataLabelStyle method to set a string defining the CSS style for the data label.

## Parameters

| <i><b>Parameter</b></i>             | <i><b>Description</b></i>                                                                                                                                                                                                                                                              |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1, ...</i> | <p>Specify the name of the record and one or more fields on that record that contain the CSS styles for the data labels for the chart.</p> <hr/> <p><b>Note:</b> The order of fields specified must correspond to the number and order specified by the SetDataYAxis method.</p> <hr/> |

## Returns

None.

## Example

```
&oChart.SetDataLabelStyle(QE_CHART_NPARKS.QE_CHART_LABELSTYL);
```

# SetDataMarker

## Syntax

```
SetDataMarker(Record_Name.Field_Name1, ...)
```

## Description

Use the `SetDataMarker` method to set the shape of data markers, which can be used to highlight certain data points on a chart. Data markers can be used only with line charts, bubble charts, and scatter charts.

The String value of this field must be one of these values:

| <b>Value</b> | <b>Description</b>                         |
|--------------|--------------------------------------------|
| square       | Square                                     |
| circle       | Circle                                     |
| diamond      | Diamond                                    |
| plus         | Plus sign                                  |
| triangleDown | Triangle with tip down                     |
| triangleUp   | Triangle with tip up                       |
| human        | Human                                      |
| auto         | Automatically selected by the chart engine |

## Parameters

| <b>Parameter</b>                    | <b>Description</b>                                                                                                                                                                                                                                                                                  |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1, ...</i> | <p>Specify the name of the record and one or more fields on that record that contain the data for the data marker types for the chart.</p> <hr/> <p><b>Note:</b> The order of fields specified must correspond to the number and order specified by the <code>SetDataYAxis</code> method.</p> <hr/> |

## Returns

None.

## Example

```
&oChart.SetDataMarkerSize(QE_CHART_NPARKS.QE_CHART_MARKER);
```

## SetDataMarkerSize

### Syntax

```
SetDataMarkerSize(Record_Name.Field_Name1, ...)
```

### Description

Use the SetDataMarkerSize method to set the size of the data markers.

### Parameters

| <i><b>Parameter</b></i>              | <i><b>Description</b></i>                                                                                                                                                                                                                                                              |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1</i> , ... | <p>Specify the name of the record and one or more fields on that record that contain the data for the data marker sizes for the chart.</p> <hr/> <p><b>Note:</b> The order of fields specified must correspond to the number and order specified by the SetDataYAxis method.</p> <hr/> |

### Returns

None.

### Example

```
&oChart.SetDataMarkerSize(QE_CHART_NPARKS.QE_CHART_MARKERSIZ);
```

## Related Links

[SetDataYAxis](#)

## SetDataSeries

### Syntax

```
SetDataSeries(Record_Name.Field_Name)
```

### Description

Use the SetDataSeries method to specify the name of the field containing the series values. Every distinct value in this field is considered a unique series.

The series is plotted in the order given by the record.

By default, the legend is populated by the value of this field.

If this value is Null, the system assumes there is only one series to plot.

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record, and the field on that record, that contains the series values for the chart. |

## Returns

None.

## Example

```
&MYCHART.SetDataSeries(MYRECORD.MYSERIES);
```

## Related Links

[SetDataXAxis](#)

[SetDataYAxis](#)

## SetDataURLs

### Syntax

```
SetDataURLs(Record_Name.Field_Name1, ...)
```

### Description

Use the SetDataURLs method to specify a URL to be launched when a data point is clicked in the chart. The URL for each point must be a fully formed URL specified as a string. For example:

```
http://example.org/index.htm
```

The IsDrillable property must be set to True to enable clicking on data points within the chart.

## Parameters

| <i><b>Parameter</b></i>             | <i><b>Description</b></i>                                                                                                                                                                                                                                                       |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1, ...</i> | <p>Specify the name of the record and one or more fields on that record that contain the URLs for the data items for the chart.</p> <hr/> <p><b>Note:</b> The number and order of fields specified must correspond to the order specified by the SetDataYAxis method.</p> <hr/> |

## Returns

None.

## Example

```
&oChart.IsDrillable = True;  
&oChart.SetDataURLs(PB_CHART_RECORD.PB_CHART_DESC);
```

## Related Links

[IsDrillable](#)

## SetDataXAxis

### Syntax

```
SetDataXAxis (Record_Name.Field_Name)
```

### Description

Use the SetDataXAxis method to specify the groups along the x-axis.

If this value is not set or Null, the y values are plotted along the x-axis in groups labeled by their order number.

The order of the data is plotted in the order of the data in the record.

By default, the labels along the x-axis are populated by the value of this field.

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | <p>Specify the name of the record, and the field on that record, that contains the data for the x-axis for the chart.</p> |

## Returns

None.

## Example

```
&cChart = GetChart(PB_CHART_DUMREC.PB_CHART_FIELD);

&cChart.SetData(Record.PB_CHART_RECORD);
&cChart.SetDataSeries(PB_CHART_RECORD.PB_CHART_PRODUCT);
&cChart.SetDataXAxis(PB_CHART_RECORD.PB_CHART_REGION);
&cChart.SetDataYAxis(PB_CHART_RECORD.PB_CHART_SALES);
```

In the following example, the y-axis is set to a numeric amount, while the x-axis is set to the region:

## Related Links

[SetDataYAxis](#)

[SetData](#)

## SetDataYAxis

### Syntax

```
SetDataYAxis(Record_Name.Field_Name1, ...)
```

### Description

Use the `SetDataYAxis` to specify the data to plot in the chart. The y-axis is always considered the data axis.

---

**Note:** For a funnel chart, you can alternatively use the `SetFunnelDataActual` method to specify this data. You can pass more than one field to the `SetDataYAxis` method to specify more than one data series for a chart. Each field passed into `SetDataYAxis` will result in one data series in the chart. This methodology is an alternative to using the `SetDataSeries` method to specify more than one data series. See [Creating and Using Data Series with Charts](#) for more information.

---

## Parameters

| <b>Parameter</b>                    | <b>Description</b>                                                                                                                                                                                                                                                               |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1, ...</i> | Specify the name of the record and one or more fields on that record that contain the data values for the data items for the chart.<br><br><b>Note:</b> The number and order of fields specified must correspond to the order specified by the <code>SetDataYAxis</code> method. |

## Returns

None.

## Example1

Consider the following table containing chart data. This data is organized so that a single column (Amount) is passed to `SetDataYAxis` and Account Type is passed to `SetDataSeries`:

| <b>Account Name</b> | <b>Year</b> | <b>Account Type</b> | <b>Amount</b> | <b>URL</b>                                                                    | <b>Chart Color</b> | <b>Glyphscale</b> |
|---------------------|-------------|---------------------|---------------|-------------------------------------------------------------------------------|--------------------|-------------------|
| Revenues            | 2010        | Actual              | 8200000       | <a href="http://www.nps.gov/ak/index.htm">http://www.nps.gov/ak/index.htm</a> | 1                  | 1                 |
| Revenues            | 2010        | Budgeted            | 7600000       | <a href="http://www.nps.gov/as/index.htm">http://www.nps.gov/as/index.htm</a> | 5                  | 3                 |
| Revenues            | 2010        | Forecast            | 8100000       | <a href="http://www.nps.gov/az/index.htm">http://www.nps.gov/az/index.htm</a> | 8                  | 5                 |
| Revenues            | 2011        | Actual              | 8300000       | <a href="http://www.nps.gov/ca/index.htm">http://www.nps.gov/ca/index.htm</a> | 1                  | 1                 |
| Revenues            | 2011        | Budgeted            | 7650000       | <a href="http://www.nps.gov/co/index.htm">http://www.nps.gov/co/index.htm</a> | 5                  | 3                 |
| Revenues            | 2011        | Forecast            | 7400000       | <a href="http://www.nps.gov/ct/index.htm">http://www.nps.gov/ct/index.htm</a> | 8                  | 5                 |
| Revenues            | 2012        | Actual              | 8450000       | <a href="http://www.nps.gov/fl/index.htm">http://www.nps.gov/fl/index.htm</a> | 1                  | 1                 |
| Revenues            | 2012        | Budgeted            | 8000000       | <a href="http://www.nps.gov/ga/index.htm">http://www.nps.gov/ga/index.htm</a> | 5                  | 3                 |

| <b>Account Name</b> | <b>Year</b> | <b>Account Type</b> | <b>Amount</b> | <b>URL</b>                      | <b>Chart Color</b> | <b>Glyphscale</b> |
|---------------------|-------------|---------------------|---------------|---------------------------------|--------------------|-------------------|
| Revenues            | 2012        | Forecast            | 6500000       | http://www.nps.gov/gu/index.htm | 8                  | 5                 |

However, in the preceding table, there is a considerable amount of redundant data that needs to be passed to the Chart object to create a chart. For the same account there are nine rows of data; and for each year, much of the data is repeated.

Now, consider the same data reorganized as three rows. (For ease of viewing, the data has been split into two tables.)

Chart data part 1:

| <b>Account Name</b> | <b>Year</b> | <b>Actual Amount</b> | <b>Budget Amount</b> | <b>Forecast Amount</b> | <b>URL Actual</b> | <b>URL Budget</b> | <b>URL Forecast</b> |
|---------------------|-------------|----------------------|----------------------|------------------------|-------------------|-------------------|---------------------|
| Revenues            | 2010        | 8200000              | 7600000              | 8100000                | <URL_A>           | <URL_B>           | <URL_F>             |
| Revenues            | 2011        | 8300000              | 7650000              | 7400000                | <URL_A>           | <URL_B>           | <URL_F>             |
| Revenues            | 2012        | 8450000              | 8000000              | 6500000                | <URL_A>           | <URL_B>           | <URL_F>             |

Chart data part 2:

| <b>Account Name</b> | <b>Year</b> | <b>Actual Color</b> | <b>Budget Color</b> | <b>Forecast Color</b> | <b>Glyphscale</b> | <b>Glyphscale</b> | <b>Glyphscale</b> |
|---------------------|-------------|---------------------|---------------------|-----------------------|-------------------|-------------------|-------------------|
| Revenues            | 2010        | 1                   | 5                   | 8                     | 1                 | 3                 | 5                 |
| Revenues            | 2011        | 1                   | 5                   | 8                     | 1                 | 3                 | 5                 |
| Revenues            | 2012        | 1                   | 5                   | 8                     | 1                 | 3                 | 5                 |

Since the SetDataYAxis method now allows you to specify multiple RECORD.FIELD parameters, you can specify data from multiple columns from the same data record. Doing so reduces the need to have duplicate data in row format. The following PeopleCode program could be used to display the preceding data:

```
rem Initialize the chart;
&Chart = GetChart(QE_COL_MULTIWRK.QE_CHART_FIELD);
&Chart.Reset();

rem Call function to check the chart type;
&Chart.Type = %ChartType_2DBar;

rem Set chart data record;
&Chart.SetData(Record.QE_COL_MULTI);
```

```

rem Set the x-axis;
&Chart.SetDataXAxis(QE_COL_MULTI.LY_YEARS);

rem Set multiple y-axis data columns;
&Chart.SetDataYAxis(QE_COL_MULTI.LY_AMOUNT_ACTUAL, QE_COL_MULTI.LY_AMOUNT_BUDGET, Q⇒
E_COL_MULTI.LY_AMOUNT_FORECAST);

rem Set multi y-axis colors;
&Chart.SetDataColor(QE_COL_MULTI.LY_CHART_COLOR_1, QE_COL_MULTI.LY_CHART_COLOR_2, Q⇒
E_COL_MULTI.LY_CHART_COLOR_3);

rem Set multi-column item size;
&Chart.SetDataZAxis(QE_COL_MULTI.LY_CHART_GLYPHSCL1, QE_COL_MULTI.LY_CHART_GLYPHSCL⇒
2, QE_COL_MULTI.LY_CHART_GLYPHSCL3);

rem Need labels for all y columns, which now act like series here;
&Chart.SetSeriesLabels(CreateArray("Actual", "Budgeted", "Forecast"));

&Chart.MainTitle = "Multi Columns Y Axis Chart";
&Chart.XAxisTitle = "Year";
&Chart.YAxisTitle = "Revenue";

rem Set the chart legend;
&Chart.HasLegend = True;
&Chart.LegendPosition = %ChartLegend_Bottom;

&Chart.IsDrillable = True;
&Chart.SetDataURLs(QE_COL_MULTI.LY_CHRT_URL_1, QE_COL_MULTI.LY_CHRT_URL_2, QE_COL_M⇒
ULTI.LY_CHRT_URL_3);

```

The preceding PeopleCode would produce the following chart:

If the `SetDataZAxis` method is commented out of the preceding `PeopleCode`, the following chart with equal width bars is produced instead:

```
rem &Chart.SetDataZAxis(QE_COL_MULTI.LY_CHART_GLYPHSCL1,  
QE_COL_MULTI.LY_CHART_GLYPHSCL2, QE_COL_MULTI.LY_CHART_GLYPHSCL3);
```

## Example2

If you want to plot a specific data series differently from the other series, you can use the `Series` class. The `Series` class is used in conjunction with the `Chart` class to override the default chart type (as defined by the `Type` property for the `Chart` object) for selected members of the data series. See [Using the Series Class](#) for more information on how to use the `Series` class to override the default chart type.

The addition of the following code excerpt at the end of the preceding PeopleCode program allows the forecast data to be plotted as a line chart instead of as a bar:

```
Local Series &S1;

&S1 = GetSeries();

&S1.Name = "Forecast";

&S1.Type = %SeriesType_Line;

&Chart.SetSeries(CreateArray(&S1));
```

## SetDataZAxis

### Syntax

```
SetDataZAxis(Record_Name.Field_Name)
```

### Description

Use the SetDataZAxis method to specify a field that contains numerical data defining the size of each data point in a bubble chart or the width of the bar in a bar chart (or the height of the bar in a horizontal bar chart).

Parameters

| Parameter                     | Description                                                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record and the field on that record that contains numerical data defining the size of each data point. |

Returns

None.

Example

```
&oChart.SetDataZAxis(QE_CHART_NPARKS.QE_CHART_Z);
```

Because no z-axis data is specified for the following stacked horizontal bar chart, the height of each bar is the same.

Because z-axis data is specified for the following stacked horizontal bar chart, the height of each bar varies according to the data value.

[SetDataYAxis](#)

## SetExplodedSectorsArray

### Syntax

**SetExplodedSectorsArray**(&Array)

### Description

Use the `SetExplodedSectorsArray` method to specify the sectors in a pie chart that you want exploded. Specify a one-dimensional array of type integer to specify which sectors to explode. This is an optional method. The default is no sectors are exploded.

Sector numbers correspond to the rows of data used to generate the chart.

The `PIECHARTSEGMENTEXPLOSIONDISTANCE` style class in the `PSCHARTSTYLE_FREEFORM` and in the `PSCHARTSTYLE_TANGERINE_FREEFM` style sheets controls the explode offset for all pie chart sectors. The explode offset is expressed as a proportion of the pie radius. This style class is delivered with a default value. If you want exploded segments displayed farther from the pie chart center, adjust the

value up; if you want segments displayed closer to the center of the pie chart, adjust the value down. We recommend using a value for `PIECHARTSEGMENTEXPLOSIONDISTANCE` between 0 and 100. The default in `PSCHARTSTYLE_FREEFORM` is 40 and in `PSCHARTSTYLE_TANGERINE_FREEFM` it is 100.

Parameters

| Parameter         | Description                                                                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Array</i> | <p>Specify an already instantiated one-dimensional array of number.</p> <p>This array lists the sector numbers that will be exploded. Sector numbers must be integer values. The default is no sectors are exploded.</p> |

Returns

None.

Example

```
Local array of number &ExplodedArray;  
&ExplodedArray = CreateArray(1,2,3,4,5)  
&cChart.SetExplodedSectorsArray(&ExplodedArray);
```

The following example shows an exploded 2D pie chart:

SetFunnelDataActual

Syntax

```
SetFunnelDataActual (Record_Name.Field_Name)
```

## Description

Use the `SetFunnelDataActual` method to specify a field that contains the actual numeric data for the funnel chart. Alternatively, this data can be specified using the `SetDataYAxis` method. This data is required for a funnel chart, and must be specified by one of these two methods.

The target data for a funnel chart can be specified in either of these ways:

- Using the `SetFunnelDataTarget` method to specify a field. In this way, the target data can vary for each data point.
- Using the `FunnelPercentMeasure` property. When this property is `True`, a default target value of 100.00 is used (which overrides any target data is specified by the `SetFunnelDataTarget` method).

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record, and the field on that record, that contains the data for the y-axis for the funnel chart. |

## Returns

None.

## Related Links

[SetDataYAxis](#)

[SetFunnelDataTarget](#)

[FunnelPercentMeasure](#)

## SetFunnelDataTarget

### Syntax

```
SetFunnelDataTarget (Record_Name.Field_Name)
```

### Description

Use the `SetFunnelDataTarget` method to specify a field that contains the target numeric data for the funnel chart. Target data is optional. However, when it is specified, the field must reside on the same record definition as specified with the `SetFunnelDataActual` method.

---

**Note:** If the `FunnelPercentMeasure` property is `True`, then any specified target data is ignored.

---

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                                  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record, and the field on that record, that contains the optional target data for the funnel chart. |

## Returns

None.

## Example

In the following example, the actual and target data for the funnel chart come from the same record definition, which is a required condition for using the `SetFunnelDataTarget` method:

```
&oChart.SetFunnelDataActual (CHART_RECORD.CHART_SALES) ;  
&oChart.SetFunnelDataTarget (CHART_RECORD.CHART_X_NUMERIC) ;  
rem &oChart.FunnelPercentMeasure = True;
```

## Related Links

[FunnelPercentMeasure](#)

## SetGlyphArray

### Description

This method has been deprecated and is ignored.

## SetLegend

### Syntax

```
SetLegend (&Array_of_String)
```

### Description

Use the `SetLegend` method to specify alternative legends. By default, the legends are populated from the record field specified with `SetDataSeries`.

This method is used to write both the overlay legend and the series legend. The labels are overwritten in the order of elements in the array, that is, the first element overwrites the first series, the second overwrites the second, and so on, with the last element in the array overwriting the overlay legend. There can be more than one series in an overlay.

If you do not specify an element for an array (that is, a blank or a null) then no legend is listed for that series.

---

**Note:** Default label text is not automatically translated. If you set your own labels, be sure to use translated text, such as message catalog entries.

---

---

**Note:** Legends are not available for funnel charts. Therefore, this method is not applicable for a funnel chart.

---

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | Specify an already instantiated array of string, containing the text that you want to use for the legend. |

## Returns

None.

## Example

The following example displays a legend containing only the overlay.

```
&LegendArray = CreateArray("", "", "Revenue");  
&MyChart.SetLegend(&LegendArray);
```

## Related Links

[SetDataSeries](#)

## SetOldData

### Syntax

```
SetOldData ({Record_Name|&Rowset})
```

### Description

Use the SetOldData method to specify where the data for the overlay is coming from.

If you make a change to the underlying data of a chart, call the SetOldData method again to update the chart.

There are no default values for the overlay data. You must specify the data.

You can specify two different y-axis fields, but you must make certain that different data plotted against the same axis makes sense. For example, while plotting two currency amounts would work technically—plotting currency amounts against number of units sold and sharing the same axis—would not look correct.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------|
| <i>Record_Name</i>      | Specify the name of a record to be used to populate the overlay of the chart with data.            |
| <i>&amp;Rowset</i>      | Specify the name of an already instantiated rowset to populate the overlay of the chart with data. |

## Returns

None.

## Related Links

[SetDataXAxis](#)

[SetDataYAxis](#)

[SetData](#)

## SetOLDataSeries

### Syntax

```
SetOLDataSeries (Record_Name.Field_Name)
```

### Description

Use the SetOLDataSeries method to specify the name of the field containing the overlay series values. Every distinct value in this field is considered a unique series.

The series is plotted in the order given by the rows in the record.

If this value is Null, the system assumes there is only one series to plot.

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record, and the field on that record, that contains the series values of the overlay for the chart. |

## Returns

None.

## Related Links

[SetDataSeries](#)

## SetOldDataXAxis

### Syntax

```
SetOldDataXAxis (Record_Name.Field_Name)
```

### Description

Use the SetOldDataXAxis method to specify the groups along the x-axis if the axis is non-numeric for the overlay.

If the x-axis is numeric, this method is used to give the position of the points along the axis. Only discrete values are supported for the x-axis.

If this value is Null, the y values are plotted along the x-axis in groups labeled by their order number.

The order of the data is plotted in the order of rows in the record.

### Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record, and the field on that record, that contains the data for the x-axis for the overlay of the chart. |

### Returns

None.

## SetOldDataYAxis

### Syntax

```
SetOldDataYAxis (Record_Name.Field_Name)
```

### Description

Use the SetOldDataYAxis to specify the data to plot for the overlay of the chart.

This value must always be numeric.

This method has no default value.

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record, and the field on that record, that contains the data for the overlay of the chart. |

## Returns

None.

## Related Links

[SetDataXAxis](#)

[SetDataYAxis](#)

## SetReferenceArea

### Syntax

```
SetReferenceArea (&Array_of_RefAreas)
```

### Description

Use the SetReferenceArea method to specify one or more reference areas for the chart.

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_RefAreas</i> | Specify an already instantiated array of ReferenceArea objects as the reference areas for this chart. |

## Returns

None.

## Related Links

[Creating and Using Data Series with Charts](#)

## SetReferenceLine

### Syntax

```
SetReferenceLine (&Array_of_RefLines)
```

## Description

Use the `SetReferenceLine` method to specify one or more reference lines for the chart.

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_RefLines</i> | Specify an already instantiated array of <code>ReferenceLine</code> objects as the reference lines for this chart. |

## Returns

None.

## Related Links

[Using the ReferenceLine Class](#)

[ReferenceLine Class Properties](#)

## SetSelectedData

### Syntax

**SetSelectedData** (*Record\_Name.Field\_Name*)

### Description

Use the `SetSelectedData` method to redraw a chart while maintaining which data items were previously selected by the user. The specified field must be a single-character `String` storing the value Y or N.

The information on which data items have been selected by the user are returned in the [aSelections](#) property of the `ChartClientState` class as an array of `String`.

## Parameters

| <i><b>Parameter</b></i>             | <i><b>Description</b></i>                                                                                                                                                                                  |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Record_Name.Field_Name</code> | Specify the name of the record and field that indicates whether this data item is selected as one of these two <code>String</code> values: <ul style="list-style-type: none"><li>• Y</li><li>• N</li></ul> |

## Returns

None.

## Example

```
&oChart.SetSelectedData(QE_CHARTPROPS.QE_SELECTED);
```

## SetSeries

### Syntax

```
SetSeries(&Array_of_Series)
```

### Description

Use the SetSeries method to specify one or more Series objects for the chart to override the default chart type (as defined by the Type property for the Chart object) for selected members of the data series.

### Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                             |
|-----------------------------|-------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_Series</i> | Specify an already instantiated array of Series objects as the overriding chart types for this chart. |

### Return

None.

## Example

```
&all_series = CreateArray(&series1, &series2, &series3, &series4);  
&cChart.SetSeries(&all_series);
```

## Related Links

[Using the Series Class](#)

## SetSeriesLabels

### Syntax

```
SetSeriesLabels(&Array_of_SeriesLabels)
```

## Description

Use the `SetSeriesLabels` method to method to set the label for each series, which are specified by the `SetDataYAxis` method. These labels are displayed in the legend and tooltips.

## Parameters

| <i><b>Parameter</b></i>           | <i><b>Description</b></i>                                                                                                                                                                                                            |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_SeriesLabels</i> | Specify an already instantiated array of String values specifying the label for each series.<br><br><b>Note:</b> The order of labels specified must correspond to the field order specified by the <code>SetDataYAxis</code> method. |

## Returns

None.

## Example

```
oChart.SetSeriesLabels(CreateArray("Actual", "Budgeted", "Forecast", "Quantity"));⇒
```

## Related Links

[SetDataYAxis](#)

## SetSvgGradientColor1

### Syntax

```
SetSvgGradientColor1(Record_Name.Field_Name1,  
...)
```

### Description

Use the `SetSvgGradientColor1` method to assign the first color for the <stop> SVG element. The field must be a string storing a number or a constant that specifies the color you want to use. Value will be ignored if corresponding `SetSvgGradientOffset1()` is not called to set the offset or a value is not provided in the data row for a specific data item.

---

**Note:** The `SetSvgGradientColor1` method can be used for bar charts only.

---

The String value of this field must be one of these values:

| <b><i>Value</i></b> | <b><i>Description</i></b> |
|---------------------|---------------------------|
| Blank               | Default series color.     |
| 0                   | Black                     |
| 1                   | Blue                      |
| 2                   | Cyan                      |
| 3                   | Dark gray                 |
| 4                   | Gray                      |
| 5                   | Green                     |
| 6                   | Light gray                |
| 7                   | Magenta                   |
| 8                   | Orange                    |
| 9                   | Pink                      |
| 10                  | Red                       |

## SetSvgGradientColor2

### Syntax

```
SetSvgGradientColor2(Record_Name.Field_Name1,  
...)
```

### Description

Use the `SetSvgGradientColor2` method to assign the second color for the <stop> SVG element. The field must be a String storing a number or a constant that specifies the color you want to use. Value will be ignored if corresponding `SetSvgGradientOffset2()` is not called to set the offset or a value is not provided in the data row for a specific data item.

---

**Note:** The `SetSvgGradientColor2` method can be used for bar charts only.

---

## Parameters

| <i>Parameter</i>               | <i>Description</i>                                                                                                                                                                                                                                                                            |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1</i> | <p>Specify the name of the record and one or more fields on that record that contain the color value for the data items for the chart.</p> <hr/> <p><b>Note:</b> The number and order of fields specified must correspond to the order specified by the <i>SetDataYAxis</i> method.</p> <hr/> |

## SetSvgGradientColor3

### Syntax

```
SetSvgGradientColor3(Record_Name.Field_Name1,  
...)
```

### Description

Use the `SetSvgGradientColor3` method to assign the third color for the <stop> SVG element. The field must be a String storing a number or a constant that specifies the color you want to use. Value will be ignored if corresponding `SetSvgGradientOffset3()` is not called to set the offset or a value is not provided in the data row for a specific data item.

---

**Note:** The `SetSvgGradientColor3` method can be used for bar charts only.

---

## Parameters

| <i><b>Parameter</b></i>        | <i><b>Description</b></i>                                                                                                                                                                                                                                                                     |

## SetToolTipLabels

### Syntax

```
SetToolTipLabels(&Array_of_ToolTipLabels)
```

### Description

Use the SetToolTipLabel method to display custom tooltips (also referred to as “data hints” or “hover text”) on charts thereby overriding the default tooltips that are automatically created from the chart data.

## Parameters

| <i>Parameter</i>                   | <i>Description</i>                                                                             |
|------------------------------------|------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_ToolTipLabels</i> | Specify an already instantiated array of ToolTipLabel objects as the tool tips for this chart. |

## Returns

None.

## Example

```
&tooltip_labels = CreateArray(&label1, &label2, );
&cChart.SetToolTipLabels(&tooltip_labels);
```

## Related Links

[ToolTipLabel Class Properties](#)

“GetToolTip” (PeopleCode Language Reference)

## SetXAxisLabels

### Syntax

```
SetXAxisLabels (&Array_of_String)
```

### Description

Use the SetXAxisLabels method to specify an array of labels for the x-axis. By default, the labels are populated from the record field specified by SetDataXAxis. Labels specified with SetXAxisLabels overwrite the default labels.

---

**Note:** Default label text is not automatically translated. If you set your own labels, be sure to use translated text, such as message catalog entries.

---

### Parameters

| <i>Parameter</i>            | <i>Description</i>                                                                                           |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | Specify an already instantiated array of string that contain the labels that you want to use for the x-axis. |

### Returns

None.

## Related Links

## SetYAxisColumnType

### Syntax

```
SetYAxisColumnType (&Array_of_Y_Axes)
```

## Description

Use the `SetYAxisColumnType` method to assign fields to either the primary y-axis or the secondary y-axis.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                                                                             |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_Y_Axes</i> | Specify an already instantiated array of numeric values.<br><br><b>Note:</b> The order of fields specified must correspond to the number and order specified by the <code>SetDataYAxis</code> method. |

You can specify either an Integer or constant value for the elements of this array. The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>                   |
|-----------------------------|------------------------------|---------------------------------------------|
| 1                           | <code>%Axis_Y</code>         | Display this field on the primary y-axis.   |
| 2                           | <code>%Axis_Y2</code>        | Display this field on the secondary y-axis. |

## Returns

None.

## Example

```
&oChart.SetYAxisColumnType(CreateArray(%Axis_Y, %Axis_Y, %Axis_Y, %Axis_Y2));
```

## Related Links

[SetDataYAxis](#)

## SetYAxisLabels

### Syntax

```
SetYAxisLabels ((&Array_of_String))
```

### Description

Use the `SetYAxisLabels` method to specify an array of labels for the y-axis. Labels specified with `SetYAxisLabels` overwrite the default labels.

If the greatest y-axis value is less than ten, the default y-axis labels are given a decimal place. If the greatest y-axis value is greater than or equal to ten, the default y-axis labels are displayed as integers.

---

**Note:** Default label text is not automatically translated. If you set your own labels, be sure to use translated text, such as message catalog entries.

---

If you set the labels yourself, you should set `YAxisTicks` and `YAxisMax` because you no longer have numbers that correlate to the data points. `YAxisTick` is used to calculate the increment of each major tick mark. If `YAxisTick` is not set, tick mark increment will be set to 1.

---

**Note:** The `SetYAxisLabels` method does not work with negative y-axis value.

---

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                    |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | Specify an already instantiated array of string that contain the labels that you want to use for the y-axis. |

## Returns

None.

## Chart Class Properties

These properties are used by the `Chart` class. The properties are described in alphabetic order.

### AdditionalStyleSuffix

#### Description

---

**Note:** The `AdditionalStyleSuffix` property is no longer used in PeopleTools 8.57 and will be ignored.

---

### AnimationDuration

#### Description

---

**Note:** The `AnimationDuration` property is no longer used in PeopleTools 8.57 and will be ignored.

---

## AnimationType

### Description

---

**Note:** The AnimationType property is no longer used in PeopleTools 8.57 and will be ignored.

---

## AspectRatio

### Description

Use this property to specify a Float value indicating the height of the chart as a proportion of its width.

If the aspect ratio is not defined, a default value of 1 is used on fluid pages.

---

**Note:** AspectRatio is ignored on classic pages; instead, the height is determined by the height of the chart page control defined in Application Designer or by the Height and Width properties.

---

This property is read/write.

### Example

```
&cChart.AspectRatio = 0.8;
```

### Related Links

[Height](#)

[Width](#)

[Fluid Mode Considerations for Charts and Gauges](#)

[Sizing a Chart or Gauge in Classic Mode](#)

## AspectRatioPortrait

### Description

Use this property to specify a Float value indicating the height of the chart as a proportion of its width in Portrait mode.

If the aspect ratio portrait is not defined, a default value of 1 is used on fluid pages.

---

**Note:** AspectRatioPortrait is ignored on classic pages; instead, the height is determined by the height of the chart page control defined in Application Designer or by the Height and Width properties.

---

This property is read/write.

### Example

```
&cChart.AspectRatioPortrait = 0.56
```

**Related Links**

**ChartURL**

**Description**

Use this property to specify a URL to be launched when the chart background is clicked. The URL must be a fully formed URL specified as a string. For example:

```
http://example.org/index.htm
```

The IsChartDrillable property must be set to True to enable clicking on the chart background.

**Example**

```
&oChart.IsChartDrillable = True;  
&oChart.ChartURL = "http://example.org/index.htm";
```

**DataSelectionMode**

**Description**

Use this property to specify an Integer value that indicates the data selection mode for this Chart instance.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i>                                                                                 | <i><b>Description</b></i>                                             |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| 0                           | <div>%Chart_DataSelection_None</div> <div><b>Note:</b> %Chart_DataSelection_None is the default value.</div> | Data selection is not enabled for this Chart instance.                |
| 1                           | %Chart_DataSelection_Single                                                                                  | Only one data point at a time may be selected on this Chart instance. |
| 2                           | %Chart_DataSelection_Multiple                                                                                | Multiple data points may be selected on this Chart instance.          |

This property is read/write.

## Example

```
&oChart.DataSelectionMode = %Chart_DataSelection_Single;
```

## Related Links

[SetSelectedData](#)

[Selecting and Highlighting Data Points](#)

## DataStartRow

### Description

This property sets or returns the row number (after any preprocessing) at which to start plotting. This is useful when you have many rows of data in a rowset, and you want to start at a particular row. This can also be useful for creating your own 'scrolling' effect, by specifying both the start row and how many rows to be displayed (by using the `DataWidth` property).

If this property is not set, then the value is 1.

This property is read/write.

## Related Links

[DataWidth](#)

## DataWidth

### Description

This property returns or sets the number of rows to plot for a series. The starting point for the number of rows is set with the `DataStartRow` property. If the `DataWidth` property value is not set, then the width is from the `DataStartRow` to the last element in the rowset. If the property value is less than zero, then it will automatically be set to one.

This property is read/write.

## Example

Suppose your rowset returned 400 rows. You wouldn't want all 400 to display in your chart. Instead, you'd pick a subset of those rows. The row to start with is set with `DataStartRow`, while how many rows to display is set with `DataWidth`.

The following code could be used with a push button connected with a chart. The push button enables the next set of data to appear with the chart.

You do not need to refresh after setting this property. When a method or property is used, the chart is automatically refreshed.

```
Local Chart &MyChart;  
  
&MyChart = GetChart (ChartRec.DisplayField);  
&Start = &MyChart.DataStartRow;
```

```
/* display the next 20 rows of data */
&MyChart.DataStartRow = &Start + 20;
&MyChart.DataWidth = 20;
```

## FooterAlignment

### Description

Use this property to specify an Integer value indicating the alignment for the footer text.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i>                             | <i><b>Description</b></i>       |
|-----------------------------|----------------------------------------------------------|---------------------------------|
| 1                           | %ChartTextAlign_Center                                   | Center the displayed text.      |
| 2                           | %ChartTextAlign_End                                      | Right-align the displayed text. |
| 3                           | %ChartTextAlign_Start                                    | Left-align the displayed text.  |
|                             | <b>Note:</b> %ChartTextAlign_Start is the default value. |                                 |

This property is read/write.

## Related Links

## FunnelOrientation

### Description

Use this property to specify whether the funnel chart is displayed horizontally or vertically.

You can specify a constant value for this property. Values are:

| <i>Constant Value</i> | <i>Description</i>                          |
|-----------------------|---------------------------------------------|
| %Chart_Horizontal     | The funnel chart is displayed horizontally. |
| %Chart_Vertical       | The funnel chart is displayed vertically.   |

The default orientation of the funnel chart is vertical.

This property is read/write.

### Example

```
&oChart.FunnelOrientation = %Chart_Horizontal;
```

## FunnelPercentMeasure

### Description

Use this property to set a Boolean value indicating whether to display the funnel chart data as a percentage of the default target value: 100.00.

---

**Note:** If this property is True, then any target data specified by the SetFunnelDataTarget method is ignored.

---

This property is read/write.

## Example

```
&oChart.SetFunnelDataActual(CHART_RECORD.CHART_SALES);  
&oChart.FunnelPercentMeasure = True;
```

## Related Links

[SetFunnelDataActual](#)

[SetFunnelDataTarget](#)

## HasLegend

### Description

Use this property to specify if a legend is displayed with the chart. This property takes a Boolean value: True, if the legend is displayed with the chart, False otherwise.

The default value is False.

This property is read/write.

---

**Note:** Legends are not available for funnel charts. Therefore, this property is not applicable for a funnel chart.

---

## HasXAxis

### Description

Use this property to specify whether the X-axis title is displayed with the chart.

This property takes a Boolean value: True, if the X-axis title appears with the chart; False otherwise.

The default value is True.

---

**Note:** When you set the HasXAxis property to false, in addition to the X-axis title, the following auto-generated text is also suppressed: axis line, tick marks, and tick labels.

---

This property is read/write.

## Example

```
&oChart.HasXAxis = False;
```

## Related Links

[XAxisTitle](#)

## HasYAxis

### Description

Use this property to specify whether the Y-axis title is displayed with the chart.

This property takes a Boolean value: True, if the Y-axis title appears with the chart; False otherwise.

The default value is True.

---

**Note:** When you set the HasYAxis property to false, in addition to the Y-axis title, the following auto-generated text is also suppressed: axis line, tick marks, and tick labels.

---

This property is read/write.

### Example

```
&oChart.HasYAxis = False;
```

### Related Links

[YAxisTitle](#)

## Height

### Description

On a classic page, use this property to specify a Number value indicating the height of the chart in pixels.

---

**Note:** On a fluid page, the combination of the AspectRatio, Height, and Width properties are used to determine the size of the chart.

---

Generally this property is used with charts created for iScripts, to specify the height of the image, before generating the image map. You can also use it to overwrite the height set in Application Designer.

If you try to read this property before setting it, the value returned is zero.

---

**Note:** The Height and Width properties must be set to the same value to change the size of a 2D Scatter chart, that is, a chart with the Type property set to %ChartType\_2DScatter.

---

This property is read/write.

# HideShowBehavior

## Description

Use this property to specify an Integer value that indicates whether the user can toggle the series legend entries to hide or show the corresponding data points for that series.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <i>Numeric Value</i> | <i>Constant Value</i>    | <i>Description</i>                                                                                                                                                                        |
|----------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                    | %ChartHideShow_None      | <div>Toggling of the series legend entries is disabled.</div> <div><b>Note:</b> %ChartHideShow_None is the default value.</div>                                                           |
| 1                    | %ChartHideShow_NoRescale | If the chart displays a legend, the user can toggle the series legend entries to hide or show the corresponding data points for that series and the y-axis will not be rescaled.          |
| 2                    | %ChartHideShow_Rescale   | If the chart displays a legend, the user can toggle the series legend entries to hide or show the corresponding data points for that series and the y-axis will be rescaled as necessary. |

This property is read/write.

# ImageMap

## Description

This property returns the HTML client-side image map. The image map is what makes the chart interactive.

This property is read-only.

## Related Links

[Creating PeopleSoft Charts](#)

# IsChartDrillable

## Description

Use this property to specify a Boolean value indicating whether the chart background (that is, the entire chart control) is interactive.

If both `IsChartDrillable` and `IsDrillable` are set to `True`, the interactivity depends on where the user clicks on the chart. If the user clicks on a data point within the chart (for example, a bar, a pie segment, a dot, and so on), the interactivity specified by `IsDrillable` is triggered. If the user clicks anywhere else on the chart, the interactivity is specified by either of these two conditions:

- Any `FieldChange` `PeopleCode` that is defined on the record field of the chart control.
- The URL specified by the `ChartURL` property.

This property is read/write.

## Related Links

[ChartURL](#)

[IsDrillable](#)

## IsColorContrastMode

### Description

Use this property to specify a Boolean value indicating whether the color contrast mode for charts is enabled or disabled.

By default, the color contrast mode is enabled for charts.

You can use this property to override the system-wide default. When you use this property to set the color contrast mode for charts, it takes highest precedence.

This property is read/write.

### Example

```
&Chart = GetChart(QE_CDEMO_WRK.QE_CHART_NP);  
&Chart.Reset();
```

```
rem set color contrast mode on/off;  
&Chart.IsColorContrastMode = False;
```

```
&Chart.Type = GetChartType();
```

## Related Links

[Color Contrast Mode for Charts](#)

## IsDrillable

### Description

Use this property to specify a Boolean value indicating whether the chart is interactive—that is, whether the user can click on (or touch) the chart to trigger an action. The default value is `False`.

If both `IsChartDrillable` and `IsDrillable` are set to `True`, the interactivity depends on where the user clicks on the chart. If the user clicks on a data point within the chart (for example, a bar, a pie segment, a dot, and so on), the interactivity specified by `IsDrillable` is triggered. If the user clicks anywhere else on the

chart, the interactivity specified by `IsChartDrillable` is triggered. When `IsDrillable` is triggered, the source of interactivity on a chart can come from one of two places:

- A URL passed through the chart's `SetDataURLs` method
- `FieldChange PeopleCode` on the y-axis data field.

If both a URL is passed through `SetDataURLs` and `FieldChange PeopleCode` exists on the y-axis data field, the URL will take precedence over the `PeopleCode`.

---

**Note:** The record that contains the `PeopleCode` must be in the component buffer at runtime.

---

See [Creating a Chart Using the Chart Class](#).

This property is read/write.

### Related Links

[SetDataURLs](#)

[IsChartDrillable](#)

## IsLineChartLineSmoothing

### Description

Use this property to specify a Boolean value indicating whether to display the line chart with smoothed lines. If this property is set to `True`, the lines that connect the data points on the line chart are smoothed, resulting in curved lines. If this property is set to `False`, the lines between the data points are drawn straight.

This property is read/write.

## IsPlainImage

### Description

Use this property to specify whether the chart is built without interactivity features, such as data hints or drill capability.

If this property is specified as `True`, you will not be able to click on the chart to trigger an event. In addition, the pop-up data hints will not appear when you pass a mouse over the chart. However, you may see a performance improvement if your chart has an extremely complicated image map and you specify this property as `True`.

This property takes a Boolean value: `True` if the chart is built without interactivity, `False` otherwise.

The default value of this property is `False`.

This property is read/write.

## IsSplitDualY

### Description

Use this property to specify a Boolean value indicating whether a chart with two y-axes will be split and displayed as two charts.

The default value is False.

This property is read/write.

### Related Links

[Creating a Chart with Two Y-Axes](#)

## IsTrueXY

### Description

This property has been deprecated and is ignored.

## IsXAxisInteger

### Description

Specify whether the x-axis will display integers. Set IsXAxisInteger to True if the x-axis represents integer data, such as the number of people or the number of tasks.

Setting IsXAxisInteger to True is only applicable to line charts, scatter charts, and bubble charts.

This property takes a Boolean value.

The default value of this property is False.

This property is read/write.

## IsYAxisInteger

### Description

Specify whether the y-axis will display integers. Set IsYAxisInteger to True if the y-axis represents integer data, such as the number of people or the number of tasks.

IsYAxisInteger is not used with pie charts and percentage bar charts.

This property takes a Boolean value.

The default value of this property is False.

This property is read/write.

## IsY2AxisInteger

### Description

Use this property to specify a Boolean value indicating whether the secondary y-axis will display integers. Set IsY2AxisInteger to True if the secondary y-axis represents integer data, such as the number of people or the number of tasks.

IsY2AxisInteger is not used with pie charts and percentage bar charts.

The default value is False.

This property is read/write.

## LegendPosition

### Description

Use this property to specify where the legend should appear, in relationship to the chart. You can specify either a numeric or constant value for this property.

---

**Note:** ChartLegend\_Separate generates a legend without a chart. The legend takes over the entire charting area.

---

The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>                 |
|-----------------------------|------------------------------|-------------------------------------------|
| 0                           | %ChartLegend_Left            | Display legend to the left of the chart.  |
| 1                           | %ChartLegend_Right           | Display legend to the right of the chart. |
| 2                           | %ChartLegend_Top             | Display legend on top of the chart.       |
| 3                           | %ChartLegend_Bottom          | Display legend below the chart.           |
| 4                           | %ChartLegend_Separate        | Generate a legend without a chart.        |

This property is read/write.

## OLType

### Description

Use this property to specify that you want an overlay line chart to be displayed on the chart.

---

**Note:** Only charts with the property Type set to 0 (or %ChartType\_2DBar) can have an overlay chart. If you specify any other chart type while specifying a value for the OLType property, no overlay chart will be displayed.

---

You can specify either a numeric or a constant value for this property. The value is:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>      |
|-----------------------------|------------------------------|--------------------------------|
| 4                           | %ChartType_2DLine            | Overlay is drawn as a 2D line. |

This property is read/write.

## PieCenterLabelStyle

### Description

## Width

### Description

On a classic page, use this property to specify a Number value indicating the width of the chart in pixels.

---

**Note:** On a fluid page, the combination of the AspectRatio, Height, and Width properties are used to determine the size of the chart.

---

Generally this property is used with charts created for iScripts, to specify the width of the image, before generating the image map. You can also use it to overwrite the width set in Application Designer.

If you try to read this property before setting it, the value returned is zero.

---

**Note:** The Height and Width properties must be set to the same value to change the size of a 2D Scatter chart, that is, a chart with the Type property set to %ChartType\_2DScatter.

---

This property is read/write.

### Related Links

[YAxisCrossPoint](#)

## XAxisLabelOrient

### Description

This property has been deprecated and is ignored.

## XAxisMax

### Description

The maximum value of the x-axis.

This property is read/write.

## XAxisMin

### Description

The minimum value of the x-axis.

This property is read/write.

## XAxisPrecision

### Description

Use the XAxisPrecision property to control the number of decimal places displayed in the labels of a numeric x-axis.

This property is read/write.

### Related Links

[YAxisPrecision](#)

## XAxisTitle

### Description

Use this property to specify the text for the x-axis title.

This property is read/write.

## XAxisTitleOrient

### Description

This property has been deprecated and is ignored.

## Y2AxisMax

### Description

Use this property to specify the maximum value of the secondary y-axis as a Number value.

The maximum value sets the largest value that is displayed on the axis.

---

**Note:** If the Y2AxisMax and Y2AxisMin properties are not set, or are set to too narrow a range, ticks may not appear on the secondary y-axis.

---

This property is read/write.

## Y2AxisMin

### Description

Use this property to specify the minimum value of the y-axis as a Number value.

The minimum value sets the point at which the chart plots in positive and negative directions.

The default minimum value is the default value of the secondary y-axis.

---

**Note:** If the Y2AxisMax and Y2AxisMin properties are not set, or are set to too narrow a range, ticks may not appear on the secondary y-axis.

---

This property is read/write.

## Y2AxisPrecision

### Description

Use this property to specify an Integer value that controls the number of decimal places displayed in the labels of a numeric, secondary y-axis.

This property is read/write.

Y2AxisTitle

Description

Use this property to specify the title for the secondary y-axis as a String value.

This property is read/write.

Y2AxisTitleOrient

Description

Use this property to specify the orientation of the title for the secondary y-axis.

You can specify either an Integer or constant value for this property. The values are:

| <i>Numeric Value</i> | <i>Constant value</i> | <i>Description</i>                                    |
|----------------------|-----------------------|-------------------------------------------------------|
| 0                    | %ChartText_Horizontal | The secondary y-axis title is displayed horizontally. |
| 90                   | %ChartText_Vertical   | The secondary y-axis title is displayed vertically    |

This property is read/write.

YAxisCrossPoint

YAxisLabelOrient

Description

This property has been deprecated and is ignored.

## YAxisMax

### Description

Use this property to specify the maximum value of the y (data) axis. This property takes a numeric value.

The maximum value sets the largest value that is displayed on the axis.

---

**Note:** If the YAxisMax and YAxisMin properties are not set, or are set to too narrow a range, ticks may not appear on the y-axis.

---

This property is read/write.

## YAxisMin

### Description

Use this property to specify the minimum value of the y-axis. This property takes a numeric value.

The minimum value sets the point at which the chart plots in positive and negative directions.

The default minimum value is the default value of the y-axis.

---

**Note:** If the YAxisMax and YAxisMin properties are not set, or are set to too narrow a range, ticks may not appear on the y-axis.

---

This property is read/write.

## YAxisPrecision

### Description

Use the YAxisPrecision property to control the number of decimal places displayed in the labels of a numeric y-axis.

This property is read/write.

## ChartClientState Class Methods

In this section, the ChartClientState class methods are presented in alphabetical order.

## ChartClientState

### Syntax

```
ChartClientState(Record_name, Field_Name)
```

### Description

Use the ChartClientState constructor to instantiate a ChartClientState object.

### Parameters

| <b><i>Parameter</i></b> | <b><i>Description</i></b>                                       |
|-------------------------|-----------------------------------------------------------------|
| <i>Record_Name</i>      | Specify the name of the record that contains the chart control. |
| <i>Field_Name</i>       | Specify the name of the field that contains the chart control.  |

### Returns

A reference to a ChartClientState object.

## Example

```
import PTCHART:ChartClientState;
Local PTCHART:ChartClientState &myObj = create
PTCHART:ChartClientState("QE_CHARTPROPWRK", "QE_CHART_FIELD");
```

# ChartClientState Class Properties

In this section, the ChartClientState class properties are presented in alphabetical order.

## aSelections

### Description

Use this property to return an array of String representing the data items selected by the user. Each element of the array is in the following format with the first row represented as row 0:

```
RECORD_NAME.FIELD_NAME.ROW_NUM
```

This property is read only.

### Example

Each element of the aSelections array is in the following format with the first row represented as row 0:

```
RECORD_NAME.FIELD_NAME.ROW_NUM
```

You must parse each element of the array to extract the row number returned and then update the appropriate row in the RECORD.FIELD that stores the Y/N values used by the SetSelectedData method of the Chart class whenever the chart is redrawn. Similarly, deselecting a data item must reset the value of that RECORD.FIELD to N.

In the following PeopleCode example, the field name, QE\_SELECTED, is hard-coded in the program. For debugging purposes, this program also writes the complete set of selected data items to the QE\_CHARTPROP.QE\_CHARTSELECTION field:

```
import PTCHART:ChartClientState;

Local PTCHART:ChartClientState &myObj = create PTCHART:ChartClientState("QE_CHARTPR⇒
OPWRK", "QE_CHART_FIELD");

rem display selected chart type ;
Local integer &nRet = &myObj.nType;
QE_CHARTPROP.QE_CHARTTYPE = &nRet;

Local array of string &aSelected = &myObj.aSelections;

rem clean the session storage everytime;
```

```

QE_CHARTPROP.QE_CHARTSELECTION = "";
Local string &sForm = "win0";
Local string &sR = "QE_CHARTPROPWRK";
Local string &sF = "QE_CHART_FIELD";
Local string &sOc = "0";

AddOnLoadScript("oGlblChrt.RemoveTypeFromStorage('" | &sForm | "',''" | &sR | "',''" =>
| &sF | "',''" | &sOc | "')");
AddOnLoadScript("oGlblChrt.RemoveSelectionFromStorage('" | &sForm | "',''" | &sR | ">
','" | &sF | "',''" | &sOc | "')");
rem end clean;

rem display selected datapoints if any;
rem when datapoint is not selected;
Local string &stest = ".";
If Find(&stest, &aSelected [1]) = 0 Then
    QE_CHARTPROP.QE_CHARTSELECTION = "No Data Selected!";

    rem Also save N in database ;
    Local Rowset &RS;
    &RS = GetLevel0().GetRow(1).GetRowset(Scroll.QE_CHARTPROPS);
    &Allrows = &RS.ActiveRowCount;
    For &i = 1 To &Allrows
        &Rec = &RS.GetRow(&i).GetRecord(Record.QE_CHARTPROPS);
        &Rec.GetField(Field.QE_SELECTED).value = "N";
    End-For;
    rem end save;

Else
    rem when datapoint is selected;
    Local string &sSelected = &aSelected.Join(", ", "", "");

    rem clean the database first;
    &RS = GetLevel0().GetRow(1).GetRowset(Scroll.QE_CHARTPROPS);
    &Allrows = &RS.ActiveRowCount;
    For &i = 1 To &Allrows
        &Rec = &RS.GetRow(&i).GetRecord(Record.QE_CHARTPROPS);
        &Rec.GetField(Field.QE_SELECTED).value = "N";
    End-For;
    rem end clean;

    QE_CHARTPROP.QE_CHARTSELECTION = &sSelected;
    rem split it and save to the database as Y;
    For &i = 1 To (&aSelected.Len)
        &aRecFieldRow = Split(&aSelected [&i], ".");
        &recName = LTrim(&aRecFieldRow [1], "");
        &rowNum = RTrim(&aRecFieldRow [3], "");
        &RecField = &recName | "." | "QE_SELECTED";
        UpdateValue(@&RecField, Value(&rowNum + 1), "Y");
    End-For;

End-If;

```

## nChartRow

### Description

Use this property to specify an Integer representing the row number for the chart.

This property is read/write.

### Example

```
import PTCHART:ChartClientState;

Local PTCHART:ChartClientState &chartState = create PTCHART:ChartClientState("QE_CH⇒
ARTPROPWRK", "QE_CHART_FIELD");
&chartState.nChartRow = 1;
```

## nType

### Description

Use this property to return an Integer representing the new chart type as selected by the user.

The returned Integer values are:

| <i><b>Numeric Value</b></i> | <i><b>Description</b></i> |
|-----------------------------|---------------------------|
| 0                           | Bar chart.                |
| 4                           | Line chart.               |
| 6                           | Pie chart.                |
| 13                          | Horizontal bar chart      |

This property is read-only.

### Example

```
import PTCHART:ChartClientState;

Local PTCHART:ChartClientState &myObj = create PTCHART:ChartClientState("QE_CHARTPR⇒
OPWRK", "QE_CHART_FIELD");
Local integer &nRet = &myObj.nType;
QE_CHARTPROP.QE_CHARTTYPE = &nRet;
```

## Association

### Description

Use this property to specify which chart axis the reference area will be associated with. There is no default value; you must explicitly set the value of this property or the reference area will not appear in the chart. You can specify either an Integer or constant value for this property.

The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>                                                                                                             |
|-----------------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| 1                           | %Ref_Association_Y1          | Associate the reference area with the y-axis.                                                                                         |
| 2                           | %Ref_Association_X1          | Associate the reference area with the x-axis.<br><hr/> <b>Note:</b> This association can be made only if the x-axis is numeric. <hr/> |
| 3                           | %Ref_Association_Y2          | Associate the reference area with the second y-axis.                                                                                  |

This property is read/write.

## Description

### Description

Use this property to specify a description of the reference area as a String value. This text will appear in the chart legend and should describe what the reference area represents in the chart. The text will be displayed only when the IsDisplayedTextInLegend property is True.

See “Setting Chart Legends” in the Chart class design guidelines for more information on creating chart legends.

This property is read/write.

## IsDisplayedTextInLegend

### Description

Use this property to specify a Boolean value indicating whether the Description property is displayed in the chart legend. The default value is True.

This property is read/write.

## LineType

### Description

Use this property to specify the style for a reference area with varied values. This property is ignored when the reference area contains a single set of minimum and maximum values. You can specify either an Integer or constant value for this property.

The following table lists the values you can specify:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i>                                                              | <i><b>Description</b></i> |
|-----------------------------|-------------------------------------------------------------------------------------------|---------------------------|
| 1                           | %ChartLine_Straight<br><hr/> <b>Note:</b> %ChartLine_Straight is the default value. <hr/> | Straight line             |
| 2                           | %ChartLine_Curved                                                                         | Curved line               |
| 3                           | %ChartLine_Stepped                                                                        | Stepped line              |
| 4                           | %ChartLine_Segmented                                                                      | Segmented line            |
| 5                           | %ChartLine_CenteredSegmented                                                              | Segmented line (centered) |
| 6                           | %ChartLine_CenteredStepped                                                                | Stepped line (centered)   |

This property is read/write.

## ReferenceAreaColor

### Description

Use this property to specify the color of the reference area as an Integer or constant value.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                                  |
|-----------------------------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -1                          | %ChartColor_Series_Default   | Default series color. When a data point is set to this, the default series color or the color that has been set by the programmer for that series is used instead. This value works only with the SetColorArray method of the Chart class. |
| 0                           | %ChartColor_Black            | Black                                                                                                                                                                                                                                      |
| 1                           | %ChartColor_Blue             | Blue                                                                                                                                                                                                                                       |
| 2                           | %ChartColor_Cyan             | Cyan                                                                                                                                                                                                                                       |
| 3                           | %ChartColor_DarkGray         | Dark gray                                                                                                                                                                                                                                  |
| 4                           | %ChartColor_Gray             | Gray                                                                                                                                                                                                                                       |
| 5                           | %ChartColor_Green            | Green                                                                                                                                                                                                                                      |
| 6                           | %ChartColor_LightGray        | Light gray                                                                                                                                                                                                                                 |
| 7                           | %ChartColor_Magenta          | Magenta                                                                                                                                                                                                                                    |
| 8                           | %ChartColor_Orange           | Orange                                                                                                                                                                                                                                     |
| 9                           | %ChartColor_Pink             | Pink                                                                                                                                                                                                                                       |
| 10                          | %ChartColor_Red              | Red                                                                                                                                                                                                                                        |
| 11                          | %ChartColor_White            | White                                                                                                                                                                                                                                      |
| 12                          | %ChartColor_Yellow           | Yellow                                                                                                                                                                                                                                     |
| 13                          | %ChartColor_Red_Orange       | Red-orange                                                                                                                                                                                                                                 |
| 14                          | %ChartColor_Yellow_Green     | Yellow-green                                                                                                                                                                                                                               |
| 15                          | %ChartColor_Blue_Violet      | Blue-violet                                                                                                                                                                                                                                |
| 16                          | %ChartColor_Purple           | Purple                                                                                                                                                                                                                                     |
| 17                          | %ChartColor_Yellow_Orange    | Yellow-orange                                                                                                                                                                                                                              |

This property is read/write.

## ReferenceAreaLocation

### Description

Use this property to specify whether the reference area is displayed in front of or behind the chart. You can specify either an Integer or constant value for this property.

The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>                       |
|-----------------------------|------------------------------|-------------------------------------------------|
| 2                           | %Ref_Back                    | Display the reference area behind the chart.    |
|                             |                              | <b>Note:</b> %Ref_Back is the default value.    |
|                             |                              |                                                 |
| 1                           | %Ref_Front                   | Display the reference area on top of the chart. |

This property is read/write.

## ReferenceAreaValues

### Description

Use this property to specify an array of two numeric values. The values indicate the minimum and maximum for the reference area. The order of the values does not matter.

This property is read/write.

## ReferenceAreaValueSet

### Description

Use this property to specify an array of minimum and maximum value arrays. These pairs of minimum and maximum values, at different x-coordinates, are used to form a reference area. Each set of values maps to a group on the chart. ReferenceAreaValues will be ignored if ReferenceAreaValueSet is specified.

This property is read/write.

### Example

```
&jRefAr1.ReferenceAreaValueSet = CreateArray(CreateArray(80000, 95570), CreateArray(
(30000, 50970), CreateArray(40000, 90070), CreateArray(24000, 57000));
```

# ShortText

## Description

Use this property to specify a short description for the reference area as a String value. This text will be displayed as the data hint for the reference area.

This property is read/write.

---

# ReferenceLine Class Properties

These properties are used by the ReferenceLine class. The properties are described in alphabetic order.

## Related Links

[Using the ReferenceLine Class](#)

# Association

## Description

Use this property to specify which chart axis the reference line will be associated with. There is no default value; you must explicitly set the value of this property or the reference line will not appear in the chart. You can specify either an Integer or constant value for this property.

The values are:

| <i>Numeric Value</i> | <i>Constant Value</i> | <i>Description</i>                                                                                                        |
|----------------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| 1                    | %Ref_Association_Y1   | Associate the reference line with the y-axis.                                                                             |
| 2                    | %Ref_Association_X1   | Associate the reference line with the x-axis.<br><b>Note:</b> This association can be made only if the x-axis is numeric. |
| 3                    | %Ref_Association_Y2   | Associate the reference line with the second y-axis.                                                                      |

This property is read/write.

# Description

## Description

Use this property to specify a description of the reference line as a String value. This text will appear in the chart legend and should describe what the reference line represents in the chart. The text will be displayed only when the IsDisplayedTextInLegend property is True.

See “Setting Chart Legends” in the Chart class design guidelines for more information on creating chart legends.

This property is read/write.

**IsDisplayedTextInLegend**

**Description**

Use this property to specify a Boolean value indicating whether the Description property is displayed in the chart legend. The default value is True.

This property is read/write.

**LineType**

**Description**

Use this property to specify the style for a reference line with varied values. This property is ignored when the reference line contains a single value. You can specify either an Integer or constant value for this property.

The following table lists the values you can specify:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i>                           | <i><b>Description</b></i> |
|-----------------------------|--------------------------------------------------------|---------------------------|
| 1                           | %ChartLine_Straight                                    | Straight line             |
|                             | <b>Note:</b> %ChartLine_Straight is the default value. |                           |
|                             |                                                        |                           |
| 2                           | %ChartLine_Curved                                      | Curved line               |
| 3                           | %ChartLine_Stepped                                     | Stepped line              |
| 4                           | %ChartLine_Segmented                                   | Segmented line            |
| 5                           | %ChartLine_CenteredSegmented                           | Segmented line (centered) |
| 6                           | %ChartLine_CenteredStepped                             | Stepped line (centered)   |

This property is read/write.

## ReferenceLineColor

### Description

Use this property to specify the color of the reference line as an Integer or constant value.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b>                                                                                                                                                                                                                  |
|-----------------------------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -1                          | %ChartColor_Series_Default   | Default series color. When a data point is set to this, the default series color or the color that has been set by the programmer for that series is used instead. This value works only with the SetColorArray method of the Chart class. |
| 0                           | %ChartColor_Black            | Black                                                                                                                                                                                                                                      |
| 1                           | %ChartColor_Blue             | Blue                                                                                                                                                                                                                                       |
| 2                           | %ChartColor_Cyan             | Cyan                                                                                                                                                                                                                                       |
| 3                           | %ChartColor_DarkGray         | Dark gray                                                                                                                                                                                                                                  |
| 4                           | %ChartColor_Gray             | Gray                                                                                                                                                                                                                                       |
| 5                           | %ChartColor_Green            | Green                                                                                                                                                                                                                                      |
| 6                           | %ChartColor_LightGray        | Light gray                                                                                                                                                                                                                                 |
| 7                           | %ChartColor_Magenta          | Magenta                                                                                                                                                                                                                                    |
| 8                           | %ChartColor_Orange           | Orange                                                                                                                                                                                                                                     |
| 9                           | %ChartColor_Pink             | Pink                                                                                                                                                                                                                                       |
| 10                          | %ChartColor_Red              | Red                                                                                                                                                                                                                                        |
| 11                          | %ChartColor_White            | White                                                                                                                                                                                                                                      |
| 12                          | %ChartColor_Yellow           | Yellow                                                                                                                                                                                                                                     |
| 13                          | %ChartColor_Red_Orange       | Red-orange                                                                                                                                                                                                                                 |

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i> |
|-----------------------------|------------------------------|---------------------------|
| 14                          | %ChartColor_Yellow_Green     | Yellow-green              |
| 15                          | %ChartColor_Blue_Violet      | Blue-violet               |
| 16                          | %ChartColor_Purple           | Purple                    |
| 17                          | %ChartColor_Yellow_Orange    | Yellow-orange             |

This property is read/write.

## ReferenceLineLocation

### Description

Use this property to specify whether the reference line is displayed in front of or behind the chart. You can specify either an Integer or constant value for this property.

The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>                                                                                |
|-----------------------------|------------------------------|----------------------------------------------------------------------------------------------------------|
| 2                           | %Ref_Back                    | Display the reference line behind the chart.<br><hr/> <b>Note:</b> %Ref_Back is the default value. <hr/> |
| 1                           | %Ref_Front                   | Display the reference line on top of the chart.                                                          |

This property is read/write.

## ReferenceLineValue

### Description

Use this property to specify the axis value for the reference line as a Number. If this property is not specified, no reference line is displayed.

This property is read/write.

## ReferenceLineValueSet

### Description

Use this property to specify an array of numeric values. This set of values, at different x-coordinates, are used to form the reference line. Each value maps to a group on the chart. ReferenceLineValue will be ignored if ReferenceLineValueSet is specified.

This property is read/write.

### Example

```
&jRefLn2.ReferenceLineValueSet = CreateArray(3000, 5700, 4500);
```

## ShortText

### Description

Use this property to specify a short description for the reference line as a String value. This text will be displayed as the data hint for the reference line.

This property is read/write.

---

## Series Class Properties

In this section, the Series class properties are presented in alphabetical order.

### Related Links

[Using the Series Class](#)

## Name

### Description

Use this property to identify the series as a String value.

---

**Important!** The value of the Name property must match exactly the value of a member in the data series as specified by either the SetDataSeries method or set by the SetSeriesLabel method.

---

This property is read/write.

## Type

### Description

Use this property to specify the override chart type for this data series.

You can specify either an Integer or constant value for this property. The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>                      |
|-----------------------------|------------------------------|------------------------------------------------|
| 0                           | %SeriesType_Bar              | Display this series as a bar chart.            |
| 1                           | %SeriesType_Line             | Display this series as a line chart.           |
| 2                           | %SeriesType_Area             | Display this series as an area chart.          |
| 3                           | %SeriesType_LineWithArea     | Display this series as a line with area chart. |
| 4                           | %SeriesType_Inherit          | Inherit the series type from the Chart object. |

This property is read/write.

---

## ToolTipLabel Class Properties

In this section, the ToolTipLabel class properties are presented in alphabetical order.

## ToolTipLabelType

### Description

Use this property to specify which data elements are displayed as part of the custom tooltip.

You can specify either an Integer or constant value for this property. The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>                                              |
|-----------------------------|------------------------------|------------------------------------------------------------------------|
| 0                           | %ToolTipLbl_Group            | Defaults to the value of SetDataSetSeries when that method is invoked. |

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b>                                                                          |
|-----------------------------|------------------------------|----------------------------------------------------------------------------------------------------|
| 1                           | %TooltipLbl_Series           | Display the data series as specified by the SetDataSeries method.                                  |
| 2                           | %TooltipLbl_Value            | Display a funnel chart's actual data as specified by the SetFunnelDataActual method.               |
| 3                           | %TooltipLbl_TargetValue      | Display a funnel chart's actual data as specified by the SetFunnelDataTarget method.               |
| 4                           | %TooltipLbl_X                | Display the x-axis data as specified by the SetDataXAxis method.                                   |
| 5                           | %TooltipLbl_Y                | Display the primary y-axis data as specified by the SetDataYAxis method.                           |
| 6                           | %TooltipLbl_Y2               | Display the secondary y-axis data as specified by the SetDataYAxis and SetYAxisColumnType methods. |
| 7                           | %TooltipLbl_Z                | Display the z-axis data as specified by the SetDataZAxis method.                                   |

This property is read/write.

## ToolTipLabelValue

Use this property to specify the text string for the label as a String value.

This property is read/write.

## LEDGauge Class Methods

These methods are used by the LEDGauge class. The methods are described in alphabetic order.

## Refresh

### Description

---

**Note:** The Refresh method is no longer used in PeopleTools 8.57 and will be ignored.

---

## SetThreshold

### Description

---

**Note:** The SetThreshold method is no longer used in PeopleTools 8.57 and will be ignored.

---

---

## LEDGauge Class Properties

These properties are used by the LEDGauge class. The properties are described in alphabetic order.

## AdditionalStyleSuffix

### Description

This property has been deprecated and is ignored.

## AnimationDuration

### Description

---

**Note:** The AnimationDuration property is no longer used in PeopleTools 8.57 and will be ignored.

---

## AnimationType

### Description

---

**Note:** The AnimationType property is no longer used in PeopleTools 8.57 and will be ignored.

---

## AspectRatio

### Description

Use this property to specify a Float value indicating the height of the chart as a proportion of its width.

If the aspect ratio is not defined, a default value of 1 is used on fluid pages.

---

**Note:** AspectRatio is ignored on classic pages; instead, the height is determined by the height of the chart page control defined in Application Designer or by the Height and Width properties.

---

This property is read/write.

### Example

```
&lGauge.AspectRatio = 0.8;
```

Type

Description

Use this property to specify the visual representation of the gauge. You can specify either an Integer or constant value for this property.

The values are:

| <i>Numeric Value</i> | <i>Constant Value</i>    | <i>Description</i>                                                                                                                                                                        |
|----------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26                   | %GaugeType_LED_Dot       | <div>Display an LED gauge as a dot:<br/><br/><b>Note:</b> %GaugeType_LED_Dot is the default value.</div> |
| 27                   | %GaugeType_LED_Arrow     | <div>Display an LED gauge as an arrow:<br/></div>                                                       |
| 28                   | %GaugeType_LED_Triangle  | <div>Display an LED gauge as a triangle:<br/></div>                                                    |
| 29                   | %GaugeType_LED_Rectangle | <div>Display an LED gauge as a rectangle:<br/></div>                                                   |
| 30                   | %GaugeType_LED_Square    | <div>Display an LED gauge as a square:<br/></div>                                                      |

This property is read/write.

Example

In the following example, the status meter gauge is displayed horizontally.

```
&cLEDGauge.Type = %GaugeType_StatusMeter_Horiz;
```

Width

Description

On a classic page, use this property to specify a Number value indicating the width of the gauge in pixels.

**Note:** On a fluid page, the combination of the AspectRatio, Height, and Width properties are used to determine the size of the gauge.

This property is read/write.

RatingGaugeChart Class Methods

In this section, the RatingGaugeChart class methods are presented in alphabetical order.

SetRatingGaugeThresholds

Syntax

```
SetRatingGaugeThresholds (&Array_of_GaugeThresholds)
```

Description

Use the SetRatingGaugeThresholds method to set one or more threshold values for the rating gauge chart.

Parameters

| Parameter                 | Description                                                                                                                                                                                           |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| &Array_of_GaugeThresholds | <div>Specify an already instantiated array of GaugeThreshold objects as the thresholds for this rating gauge chart.</div> <div><b>Note:</b> This array can contain a maximum of three elements.</div> |

## Returns

None.

## Example

```
&oGTreshArray = CreateArray(&oGTresh1, &oGTresh2, &oGTresh3, &oGTresh4);  
&oRating.SetRatingGaugeThresholds(&oGTreshArray);
```

# RatingGaugeChart Class Properties

In this section, the RatingGaugeChart class properties are presented in alphabetical order.

## AspectRatio

### Description

Use this property to specify a Float value indicating the height of the chart as a proportion of its width.

If the aspect ratio is not defined, a default value of 1 is used on fluid pages.

---

**Note:** AspectRatio is ignored on classic pages; instead, the height is determined by the height of the chart page control defined in Application Designer or by the Height and Width properties.

---

This property is read/write.

### Example

```
&rGauge.AspectRatio = 0.8;
```

## Related Links

[Width](#)

## ChangedState

### Description

Use this property to specify the definition for the gauge's changed state as a RatingGaugeState object.

This property is read/write.

## Example

```
&oRating.ChangedState = &oRatGaugeChangedState;
```

## Related Links

[RatingGaugeState Class Properties](#)

## HoverState

### Description

Use this property to specify the definition for the gauge's hover state as a RatingGaugeState object.

This property is read/write.

### Example

```
&oRating.HoverState = &oRatGaugHoverState;
```

## Related Links

[RatingGaugeState Class Properties](#)

## Max

### Description

Use this property to specify the maximum number for the rating scale as an Integer value. The default value is 5.

---

**Note:** If the maximum is too large and the size of the gauge too small, the gauge shape will not be displayed.

---

## Min

### Description

Use this property to specify the minimum number for the rating scale as a Float value. The default value is 0.

This property is read/write.

## ReadOnly

### Description

Use this property to specify a Boolean value indicating whether the gauge is interactive—that is, whether the user can click on (or touch) the gauge to trigger an action. The default value is False; the gauge is interactive.

---

**Note:** If there is FieldChange PeopleCode on the field, the PeopleCode will not execute when the ReadOnly property is True.

---

## SelectedState

### Description

Use this property to specify the definition for the gauge's selected state as a RatingGaugeState object.

This property is read/write

### Example

```
&oRating.SelectedState = &oRatGaugSelState;
```

### Related Links

[RatingGaugeState Class Properties](#)

## Step

### Description

Use this property to specify the rating increments as any Float value. As examples, a value of 0.5 displays ratings in half-increments; a value of 1 displays ratings in whole number-increments.

---

**Note:** The default value is 1.

---

## Title

### Description

Use this property to specify the title for the rating gauge chart as a String value. The title is displayed as a tooltip for the rating gauge chart and is generated as part of the chart information for accessibility purposes.

If no value is specified, then the rating gauge chart title is automatically generated.

This property is read/write.

## UnselectedState

### Description

Use this property to specify the definition for the gauge's unselected state as a `RatingGaugeState` object.

This property is read/write.

### Example

```
&oRating.UnselectedState = &oRatGaugUnSelState;
```

### Related Links

[RatingGaugeState Class Properties](#)

## Width

### Description

On a classic page, use this property to specify a `Number` value indicating the width of the gauge in pixels.

---

**Note:** On a fluid page, the combination of the `AspectRatio`, `Height`, and `Width` properties are used to determine the size of the gauge.

---

This property is read/write.

## RatingGaugeState Class Properties

In this section, the `RatingGaugeState` class properties are presented in alphabetical order.

## BorderColor

### Description

Use this property to specify the border color for the shape representing this rating gauge status as an `Integer` value.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b>                                                                      | <b><i>Description</i></b>                         |
|-----------------------------|---------------------------------------------------------------------------------------------------|---------------------------------------------------|
| -1                          | %ChartColor_Series_Default<br><hr/> <b>Note:</b> %ChartColor_Series_Default is the default value. | Default color as selected by the charting engine. |
| 0                           | %ChartColor_Black                                                                                 | Black                                             |
| 1                           | %ChartColor_Blue                                                                                  | Blue                                              |
| 2                           | %ChartColor_Cyan                                                                                  | Cyan                                              |
| 3                           | %ChartColor_DarkGray                                                                              | Dark gray                                         |
| 4                           | %ChartColor_Gray                                                                                  | Gray                                              |
| 5                           | %ChartColor_Green                                                                                 | Green                                             |
| 6                           | %ChartColor_LightGray                                                                             | Light gray                                        |
| 7                           | %ChartColor_Magenta                                                                               | Magenta                                           |
| 8                           | %ChartColor_Orange                                                                                | Orange                                            |
| 9                           | %ChartColor_Pink                                                                                  | Pink                                              |
| 10                          | %ChartColor_Red                                                                                   | Red                                               |
| 11                          | %ChartColor_White                                                                                 | White                                             |

| 14                          | %ChartColor_Yellow_Green                                                                          | Yellow-green                                      |
| 15                          | %ChartColor_Blue_Violet                                                                           | Blue-violet                                       |
| 16                          | %ChartColor_Purple                                                                                | Purple                                            |
| 17                          | %ChartColor_Yellow_Orange                                                                         | Yellow-orange                                     |

This property is read/write.

## Color

### Description

Use this property to specify the color for the shape representing this rating gauge status as an Integer value.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b>                                                                            | <b><i>Description</i></b>                         |
|-----------------------------|---------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| -1                          | %ChartColor_Series_Default<br><hr/> <b>Note:</b> %ChartColor_Series_Default is the default value. <hr/> | Default color as selected by the charting engine. |
| 0                           | %ChartColor_Black                                                                                       | Black                                             |
| 1                           | %ChartColor_Blue                                                                                        | Blue                                              |
| 2                           | %ChartColor_Cyan                                                                                        | Cyan                                              |
| 3                           | %ChartColor_DarkGray                                                                                    | Dark gray                                         |
| 4                           | %ChartColor_Gray                                                                                        | Gray                                              |

## Shape

### Description

Use this property to specify the shape representing this rating gauge status as an Integer value.

| <i><b>Value</b></i> | <i><b>Constant</b></i>                                                          | <i><b>Description</b></i> |
|---------------------|---------------------------------------------------------------------------------|---------------------------|
| 0                   | %RatingGauge_Star<br><hr/> <b>Note:</b> %RatingGauge_Star is the default value. | Star                      |
| 1                   | %RatingGauge_Circle                                                             | Circle                    |
| 2                   | %RatingGauge_Rectangle                                                          | Rectangle                 |
| 3                   | %RatingGauge_Diamond                                                            | Diamond                   |
| 4                   | %RatingGauge_Triangle                                                           | Triangle                  |

---

## GaugeThreshold Class Properties

In this section, the GaugeThreshold class properties are presented in alphabetical order.

## BorderColor

### Description

Use this property to specify the border color for the shape representing this rating gauge threshold as an Integer value.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i>                                                                            | <i><b>Description</b></i>                         |
|-----------------------------|---------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| -1                          | %ChartColor_Series_Default<br><hr/> <b>Note:</b> %ChartColor_Series_Default is the default value. <hr/> | Default color as selected by the charting engine. |
| 0                           | %ChartColor_Black                                                                                       | Black                                             |
| 1                           | %ChartColor_Blue                                                                                        | Blue                                              |
| 2                           | %ChartColor_Cyan                                                                                        | Cyan                                              |
| 3                           | %ChartColor_DarkGray                                                                                    | Dark gray                                         |
| 4                           | %ChartColor_Gray                                                                                        | Gray                                              |
| 5                           | %ChartColor_Green                                                                                       | Green                                             |
| 6                           | %ChartColor_LightGray                                                                                   | Light gray                                        |
| 7                           | %ChartColor_Magenta                                                                                     | Magenta                                           |

| 12                          | %ChartColor_Yellow           | Yellow                    |
| 13                          | %ChartColor_Red_Orange       | Red-orange                |
| 14                          | %ChartColor_Yellow_Green     | Yellow-green              |
| 15                          | %ChartColor_Blue_Violet      | Blue-violet               |
| 16                          | %ChartColor_Purple           | Purple                    |
| 17                          | %ChartColor_Yellow_Orange    | Yellow-orange             |

This property is read/write.

## Description

### Description

Use this property to specify as String value to be displayed as a tooltip for this rating gauge threshold.

## MaxValue

### Description

Use this property to specify the threshold value as a Number value.

This property is read/write.

## StatusMeterGauge Class Properties

These properties are used by the StatusMeterGauge class. The properties are described in alphabetic order.

## AdditionalStyleSuffix

### Description

This property has been deprecated and is ignored.

## AnimationDuration

### Description

---

**Note:** The AnimationDuration property is no longer used in PeopleTools 8.57 and will be ignored.

---

## AnimationType

### Description

---

**Note:** The AnimationType property is no longer used in PeopleTools 8.57 and will be ignored.

---

## AspectRatio

### Description

Use this property to specify a Float value indicating the height of the chart as a proportion of its width.

If the aspect ratio is not defined, a default value of 1 is used on fluid pages.

---

**Note:** AspectRatio is ignored on classic pages; instead, the height is determined by the height of the chart page control defined in Application Designer or by the Height and Width properties.

---

This property is read/write.

### Example

```
&smGauge.AspectRatio = 0.8;
```

## Height

### Description

On a classic page, use this property to specify a Number value indicating the height of the gauge in pixels.

---

**Note:** On a fluid page, the combination of the AspectRatio, Height, and Width properties are used to determine the size of the gauge.

---

This property is read/write.

Description

**Note:** The TopLabelPosition property is no longer used in PeopleTools 8.57 and will be ignored.

Type

Description

Use this property to specify the visual representation of the gauge. You can specify either an Integer or constant value for this property.

The values are:

| <i>Numeric Value</i> | <i>Constant Value</i>        | <i>Description</i>                                                                                                                                                                              |
|----------------------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24                   | %GaugeType_StatusMeter_Horiz | Display a horizontal status meter gauge:<br>                                                                 |
| 25                   | %GaugeType_StatusMeter_Vert  | Display a vertical status meter gauge:<br><br><b>Note:</b> %GaugeType_StatusMeter_Vert is the default value. |

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>                                                                                                    |
|-----------------------------|------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| 34                          | %GaugeType_StatusMeter_Circ  | Display a circular status meter gauge:<br> |

This property is read/write.

### Example 1

The following example demonstrates creating a circular status meter gauge without a threshold:

In the following example, the status meter gauge is displayed horizontally.

```
Local StatusMeterGauge &oSM;

/* Instantiate a StatusMeterGauge object */
&oSM = GetStatusMeterGauge(QE_GAUGEMETRIC.QE_SM1);
&oSM.Type = %GaugeType_StatusMeter_Circ;

&oSM.GaugeMinimum = 1;
&oSM.GaugeMaximum = 100;
&oSM.IsDrillable = True;
&oSM.GaugeURL = "http://irs.gov";
&oSM.Width = 400;
&oSM.Height = 400;
```

```
&oSM.MetricLabelType = %Percent;

rem this property works for DVT gauge but not for JET gauge;
rem &oSM.MetricLabelPosition = %Label_None;
```

## Example 2

The following example demonstrates creating a circular status meter gauge with thresholds:

```
Declare Function get_gauge_thresholds PeopleCode FUNCLIB.THRESHOLDS FieldFormula;

Local StatusMeterGauge &oSM;

/* Instantiate a StatusMeterGauge object */
&oSM = GetStatusMeterGauge(QE_GAUGEMETRIC.QE_SM1);
&oSM.Type = %GaugeType_StatusMeter_Circ;

/* Set the gauge thresholds */
&oSM.SetThreshold(get_gauge_thresholds());

/* Set properties for the status meter gauge */
&oSM.GaugeMinimum = 1;
&oSM.GaugeMaximum = 100;
&oSM.IsDrillable = True;
&oSM.GaugeURL = "http://irs.gov";
&oSM.Width = 400;
&oSM.Height = 400;
&oSM.MetricLabelType = %Percent;
&oSM.MetricLabelPosition = %Label_On;

/* Function definition from FUNCLIB.THRESHOLDS */
Function get_gauge_thresholds() Returns Threshold;
    Local Threshold &oThr1;
    Local array of number &Values, &Colors;
    Local array of string &Descr;

    &oThr1 = GetThreshold();
    &oThr1.Id = 1;
    &Values = CreateArray(30, 75, 100);
    &Colors = CreateArray(17, 1, 14, 5, 6);
```

```
&Descr = CreateArray("Low", "Med", "High");
&oThr1.Values = &Values;
&oThr1.Colors = &Colors;
&oThr1.Descriptions = &Descr;
Return &oThr1;
End-Function;
```

Width

Description

On a classic page, use this property to specify a Number value indicating the width of the gauge in pixels.

**Note:** On a fluid page, the combination of the AspectRatio, Height, and Width properties are used to determine the size of the gauge.

This property is read/write.

Colors

Description

Use this property to specify the color values as an Array of Number. Choose a color for each reference area on the gauge.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <i>Numeric Value</i> | <i>Constant Value</i>                                                                                          | <i>Description</i>                                |
|----------------------|----------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| -1                   | <div>%ChartColor_Series_Default</div> <div><b>Note:</b> %ChartColor_Series_Default is the default value.</div> | Default color as selected by the charting engine. |

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b> |
|-----------------------------|------------------------------|---------------------------|
| 0                           | %ChartColor_Black            | Black                     |
| 1                           | %ChartColor_Blue             | Blue                      |
| 2                           | %ChartColor_Cyan             | Cyan                      |
| 3                           | %ChartColor_DarkGray         | Dark gray                 |
| 4                           | %ChartColor_Gray             | Gray                      |
| 5                           | %ChartColor_Green            | Green                     |
| 6                           | %ChartColor_LightGray        | Light gray                |
| 7                           | %ChartColor_Magenta          | Magenta                   |
| 8                           | %ChartColor_Orange           | Orange                    |
| 9                           | %ChartColor_Pink             | Pink                      |
| 10                          | %ChartColor_Red              | Red                       |
| 11                          | %ChartColor_White            | White                     |
| 12                          | %ChartColor_Yellow           | Yellow                    |
| 13                          | %ChartColor_Red_Orange       | Red-orange                |
| 14                          | %ChartColor_Yellow_Green     | Yellow-green              |
| 15                          | %ChartColor_Blue_Violet      | Blue-violet               |
| 16                          | %ChartColor_Purple           | Purple                    |
| 17                          | %ChartColor_Yellow_Orange    | Yellow-orange             |

This property is read/write.

## Example

In the following example, the colors red, yellow, and green are specified by numeric value rather than by constant:

```
&Colors = CreateArray(10, 12, 5);  
&oThr1.Colors = &Colors;
```

## Related Links

[Descriptions](#)

# Descriptions

## Description

Use this property to specify the descriptions as an Array of String. The number of descriptions in the Descriptions array should match the number of colors that you have defined in the Colors array.

This property is read/write.

## Example

The Descriptions array provides descriptions for the color values:

```
&Descr = CreateArray("Low", "Med", "High");  
&oThr1.Descriptions = &Descr;
```

## Related Links

[Colors](#)

# Id

## Description

Use this property to optionally specify an identifier for the Threshold object as a Number.

This property is read/write.

# Values

## Description

Use this property to specify the values as an Array of Number. Since the values mark the boundaries between the colors in the threshold, the number of entries in the Values array should be one less than the number of colors in the Colors array.

This property is read/write.

Example

In this example, the number items in the Values array is one less than the number items in the Colors array:

```
&Values = CreateArray(30, 75);
&Colors = CreateArray(%ChartColor_Red, %ChartColor_Yellow, %ChartColor_Green);
&Descr = CreateArray("Low", "Med", "High");
&oThr1.Values = &Values;
&oThr1.Colors = &Colors;
&oThr1.Descriptions = &Descr;
```

[SparkChartItem Class Properties](#)

SetSparkChartItems

Syntax

```
SetSparkChartItems (&Array_of_ChartItems)
```

Description

Use the SetSparkChartItems method to set one or more items for the spark chart.

Parameters

| Parameter                       | Description                                                                                        |
|---------------------------------|----------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_ChartItems</i> | Specify an already instantiated array of SparkChartItem objects as the items for this spark chart. |

Returns

None.

Example

```
&aS.SetSparkChartItems(CreateArray(&aS1, &aS2, &aS3, &aS4, &aS5, &aS6, &aS7, &aS8, =>
&aS9));
```

# SparkChart Class Properties

In this section, the SparkChart class properties are presented in alphabetical order.

## AnimationDuration

### Description

Use this property to specify an Integer value (0 or greater) indicating how long (in milliseconds) the spark chart animation should last.

If this property is not specified, it defaults to 0.5 seconds.

This property is read/write.

## AnimationType

### Description

Use this property to specify the animation type for the spark chart.

You can specify either an Integer or constant value for this property. The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i>                                                                        |
|-----------------------------|-----------------------------------------------------------------------------------------------------|
| 0                           | %Animation_None                                                                                     |
| 1                           | %Animation_Auto                                                                                     |
|                             | <b>Note:</b> The automatic animation is determined by the charting engine and varies by chart type. |
|                             | <b>Note:</b> %Animation_Auto is the default value.                                                  |

This property is read/write.

## AspectRatio

### Description

Use this property to specify a Float value indicating the height of the chart as a proportion of its width.

If the aspect ratio is not defined, a default value of 1 is used on fluid pages.

**Note:** AspectRatio is ignored on classic pages; instead, the height is determined by the height of the chart page control defined in Application Designer or by the Height and Width properties.

This property is read/write.

## Example

```
&oSpChart.AspectRatio = 0.8;
```

## Related Links

[Width](#)

[Sizing a Chart or Gauge in Classic Mode](#)

[Fluid Mode Considerations for Charts and Gauges](#)

## barGapRatio

### Description

Use this property to specify the gap between spark chart bars as a Number value from 0 to 1 inclusive. This property is valid for bar charts and floating bar charts only. When the value is 0, there is no gap between spark chart bars; when the value is 0.5, the gap width is 50% of the total bar width. For example:

```
&oSpChart.barGapRatio = 0;
```

```
&oSpChart.barGapRatio = 0.5;
```

```
&oSpChart.barGapRatio = 0.9;
```

The default value is 0.

This property is read/write

## Related Links

[Type](#)

## Color

### Description

Use this property to specify the primary color for spark line charts, area charts, or line with area charts.

The following lists all the values you can specify. You can use either the numeric or constant value.

| <b>Numeric Value</b> | <b>Constant Value</b>                                                                                   | <b>Description</b>                                |
|----------------------|---------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| -1                   | %ChartColor_Series_Default<br><hr/> <b>Note:</b> %ChartColor_Series_Default is the default value. <hr/> | Default color as selected by the charting engine. |
| 0                    | %ChartColor_Black                                                                                       | Black                                             |
| 1                    | %ChartColor_Blue                                                                                        | Blue                                              |
| 2                    | %ChartColor_Cyan                                                                                        | Cyan                                              |
| 3                    | %ChartColor_DarkGray                                                                                    | Dark gray                                         |
| 4                    | %ChartColor_Gray                                                                                        | Gray                                              |
| 5                    | %ChartColor_Green                                                                                       | Green                                             |
| 6                    | %ChartColor_LightGray                                                                                   | Light gray                                        |
| 7                    | %ChartColor_Magenta                                                                                     | Magenta                                           |
| 8                    | %ChartColor_Orange                                                                                      | Orange                                            |
| 9                    | %ChartColor_Pink                                                                                        | Pink                                              |
| 10                   | %ChartColor_Red                                                                                         | Red                                               |
| 11                   | %ChartColor_White                                                                                       | White                                             |
| 12                   | %ChartColor_Yellow                                                                                      | Yellow                                            |
| 13                   | %ChartColor_Red_Orange                                                                                  | Red-orange                                        |
| 14                   | %ChartColor_Yellow_Green                                                                                | Yellow-green                                      |

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i> |
|-----------------------------|------------------------------|---------------------------|
| 15                          | %ChartColor_Blue_Violet      | Blue-violet               |
| 16                          | %ChartColor_Purple           | Purple                    |
| 17                          | %ChartColor_Yellow_Orange    | Yellow-orange             |

This property is read/write.

IsDrillable

Description

Use this property to specify a Boolean value indicating whether the spark chart is interactive—that is, whether the user can click on (or touch) the spark chart to trigger an action. The default value is False.

The source of interactivity on a spark chart can come from one of two places:

- A URL set in the chart’s SparkChartURL property.
- FieldChange PeopleCode on the record field that holds the chart area (that is, the Application Designer chart control).

If both a URL is set in the SparkChartURL property and FieldChange PeopleCode exists on the record field of the chart control, the URL will take precedence over the PeopleCode.

This property is read/write.

LineStyle

Description

Use this property to specify the style for spark line charts and line with area charts.

You can specify either an Integer or constant value for this property. The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i>                                                                 | <i><b>Description</b></i> | <i><b>Example</b></i>                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------|---------------------------|--------------------------------------------------------------------------------------|
| 0                           | %SparkLineStyle_Solid<br><div><b>Note:</b> %SparkLineStyle_Solid is the default value.</div> | Solid line                |  |

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i> | <i><b>Example</b></i>                                                              |
|-----------------------------|------------------------------|---------------------------|------------------------------------------------------------------------------------|
| 1                           | %SparkLineStyle_Dashed       | Dashed line               |  |
| 2                           | %SparkLineStyle_Dotted       | Dotted line               |  |

This property is read/write.

## LineWidth

### Description

Use this property to specify the line width for spark line charts and line with area charts as a Number value. For example:

```
&oSpChart.lineWidth= 1;
```

```
&oSpChart.lineWidth=5;
```

The default value is 1.

This property is read/write.

## SparkChartURL

### Description

Use this property to specify a valid URL as a String value. If IsDrillable is true, then the user is redirected to this URL after clicking on (or touching) the spark chart.

This property is read/write.

## Related Links

[IsDrillable](#)

## Title

### Description

Use this property to specify the title for the spark chart as a String value. The title is displayed as a tooltip for the spark chart and is generated as part of the chart information for accessibility purposes.

If no value is specified, then the spark chart title is automatically generated.

This property is read/write.

This property is read/write.

Width

Description

On a classic page, use this property to specify a Number value indicating the width of the gauge in pixels.

**Note:** On a fluid page, the combination of the AspectRatio, Height, and Width properties are used to determine the size of the gauge.

# SparkChartItem Class Properties

In this section, the SparkChartItem class properties are presented in alphabetical order.

## BorderColor

### Description

Use this property to specify the border color for the shape representing this spark chart item as an Integer value

The following lists all the values you can specify. You can use either the numeric or constant value.

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i>                                                                                   | <i><b>Description</b></i>                         |
|-----------------------------|----------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| -1                          | <div>%ChartColor_Series_Default</div> <div><b>Note:</b> %ChartColor_Series_Default is the default value.</div> | Default color as selected by the charting engine. |
| 0                           | %ChartColor_Black                                                                                              | Black                                             |
| 1                           | %ChartColor_Blue                                                                                               | Blue                                              |
| 2                           | %ChartColor_Cyan                                                                                               | Cyan                                              |
| 3                           | %ChartColor_DarkGray                                                                                           | Dark gray                                         |
| 4                           | %ChartColor_Gray                                                                                               | Gray                                              |
| 5                           | %ChartColor_Green                                                                                              | Green                                             |
| 6                           | %ChartColor_LightGray                                                                                          | Light gray                                        |

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b> |
|-----------------------------|------------------------------|---------------------------|
| 8                           | %ChartColor_Orange           | Orange                    |
| 9                           | %ChartColor_Pink             | Pink                      |
| 10                          | %ChartColor_Red              | Red                       |
| 11                          | %ChartColor_White            | White                     |
| 12                          | %ChartColor_Yellow           | Yellow                    |
| 13                          | %ChartColor_Red_Orange       | Red-orange                |
| 14                          | %ChartColor_Yellow_Green     | Yellow-green              |
| 15                          | %ChartColor_Blue_Violet      | Blue-violet               |
| 16                          | %ChartColor_Purple           | Purple                    |
| 17                          | %ChartColor_Yellow_Orange    | Yellow-orange             |

This property is read/write.

## Color

### Description

Use this property to specify the color for the shape representing this spark chart item as an Integer value.

The following lists all the values you can specify. You can use either the numeric or constant value

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b>                                                                      | <b><i>Description</i></b>                         |
|-----------------------------|---------------------------------------------------------------------------------------------------|---------------------------------------------------|
| -1                          | %ChartColor_Series_Default<br><hr/> <b>Note:</b> %ChartColor_Series_Default is the default value. | Default color as selected by the charting engine. |
| 0                           | %ChartColor_Black                                                                                 | Black                                             |
| 1                           | %ChartColor_Blue                                                                                  | Blue                                              |

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b> |
|-----------------------------|------------------------------|---------------------------|
| 2                           | %ChartColor_Cyan             | Cyan                      |
| 3                           | %ChartColor_DarkGray         | Dark gray                 |
| 4                           | %ChartColor_Gray             | Gray                      |
| 5                           | %ChartColor_Green            | Green                     |
| 6                           | %ChartColor_LightGray        | Light gray                |
| 7                           | %ChartColor_Magenta          | Magenta                   |
| 8                           | %ChartColor_Orange           | Orange                    |
| 9                           | %ChartColor_Pink             | Pink                      |
| 10                          | %ChartColor_Red              | Red                       |
| 11                          | %ChartColor_White            | White                     |
| 12                          | %ChartColor_Yellow           | Yellow                    |
| 13                          | %ChartColor_Red_Orange       | Red-orange                |
| 14                          | %ChartColor_Yellow_Green     | Yellow-green              |
| 15                          | %ChartColor_Blue_Violet      | Blue-violet               |
| 16                          | %ChartColor_Purple           | Purple                    |
| 17                          | %ChartColor_Yellow_Orange    | Yellow-orange             |

This property is read/write.

## FloatValue

### Description

Use this property to specify float value for this spark chart item as a Number value. The float value becomes the floor, or starting point, for the spark chart item in pixels. The value of the Value property is added to the float.

If this property is not specified, the default value is to start the bar from the x-axis, effectively 0.

**Note:** This property applies only when the Type property of the SparkChart instance is set to %SparkChartType\_FloatingBar.  
This property is read/write.

**Related Links**

[Type](#)

[Value](#)

**MarkerDisplayed**

**Description**

Use this property to specify a Boolean value indicating whether a marker is displayed for this spark chart item.

The default value is False.

This property is read/write.

**Related Links**

[MarkerShape](#)

**MarkerShape**

**Description**

Use this property to specify the marker shape for this spark chart item.

**Note:** The marker is displayed only if the MarkerDisplayed property for this spark chart item is True.

You can specify either an Integer or constant value for this property. The values are:

| <i>Numeric Value</i> | <i>Constant Value</i>                                | <i>Description</i> |
|----------------------|------------------------------------------------------|--------------------|
| 0                    | %SparkMarker_Auto                                    | Auto               |
|                      | <b>Note:</b> %SparkMarker_Auto is the default value. |                    |
| 1                    | %SparkMarker_Square                                  | Square             |
| 2                    | %SparkMarker_Circle                                  | Circle             |
| 3                    | %SparkMarker_Diamond                                 | Diamond            |

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>  |
|-----------------------------|------------------------------|----------------------------|
| 4                           | %SparkMarker_Plus            | Plus sign                  |
| 5                           | %SparkMarker_TriangleDown    | Triangle with the tip down |
| 6                           | %SparkMarker_TriangleUp      | Triangle with the tip up   |
| 7                           | %SparkMarker_Human           | Human                      |

This property is read/write.

[MarkerDisplayed](#)

## Value

### Description

Use this property to specify the value (or height in pixels) for this spark chart item as a Numeric value.

---

**Note:** If the Type property of the SparkChart instance is set to %SparkChartType\_FloatingBar and a float value is defined for this spark chart item, then FloatValue and Value are added to determine the top of the bar.

---

This property is read/write.

## Gantt Class Methods

These methods are used by the Gantt class. The methods are described in alphabetic order.

## Refresh

### Syntax

```
Refresh ()
```

### Description

Use the Refresh method if the underlying data of the chart has changed, and you want to update the chart.

---

**Note:** This method has been deprecated and remains for backward compatibility only. Use the `SetTaskAppData` method or `SetTaskData` method instead.

---

You don't need to refresh after setting a property or method of the chart itself, such as setting the starting point or changing colors. When a method or property is used, the chart is automatically refreshed.

## Parameters

None.

## Returns

None.

## Example

```
&MyChart.Refresh();
```

## Related Links

[SetTaskAppData](#)

[SetTaskData](#)

# Reset

## Syntax

```
Reset()
```

## Description

Use the `Reset` method to clear all existing chart settings and data.

## Parameters

None.

## Returns

None.

## SetActualEndDate

### Syntax

**SetActualEndDate** (*RecordName.FieldName*)

### Description

Use the SetActualEndDate method to specify the field in the record that defines the actual end date. This is an optional method, and is used in conjunction with the SetPlannedEndDate method. If an actual end date is specified, then an actual start date must also be specified. When defined, the actual or baseline tasks are visually shown as a separate task bar and are layered beneath the planned task if the two overlap.

---

**Note:** For any task that has a bad date format (from either SetActualEndDate or SetActualStartDate), any overlaid baseline information is not displayed in the chart section.

---

### Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field and its associated record that contains the value used to define the actual end date. This field must be of DateTime or Date type. |

### Returns

None.

### Related Links

[SetActualStartDate](#)

[SetPlannedEndDate](#)

[SetPlannedStartDate](#)

## SetActualStartDate

### Syntax

**SetActualStartDate** (*RecordName.FieldName*)

### Description

Use the SetActualStartDate method to specify the field in the record that defines the actual start date. This is an optional method, and is used in conjunction with the SetPlannedStartDate method. If an actual start date is specified, then an actual end date must also be specified. When defined, the actual or baseline tasks are visually shown as a separate task bar and are layered beneath the planned task if the two overlap.

---

**Note:** For any task that has a bad date format (from either `SetActualEndDate` or `SetActualStartDate`), any overlaid baseline information is not displayed in the chart section.

---

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field and its associated record that contains the value used to define the actual start date. This field must be of <code>DateTime</code> or <code>Date</code> type. |

## Returns

None.

# SetActualTaskBarColor

## Syntax

**SetActualTaskBarColor** (*RecordName.FieldName*)

## Description

Use the `SetActualTaskBarColor` method to specify the field in the record that defines the colors for either the actual task bar or the actual milestone glyph.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                                                       |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field, and its associated record, that defines the task bar color. This field must be of type number, which means you can only use the numeric value for the color. |

## Returns

None.

[SetPlannedTaskBarColor](#)

## TaskMilestoneGlyph

### SetChartArea

#### Syntax

**SetChartArea** (*Percentage*)

#### Description

Use the SetChartArea method to specify what percentage of the Gantt chart is allocated to displaying the chart section. By default, both the task and chart sections are allocated 50% of the available space provided by the Gantt chart.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Percentage</i>       | <p>Specify the percentage of the page space for a Gantt chart that is allocated for displaying the chart area. Oracle recommends setting this value above .20 or 20%. Any point below .20 may cause the task bars and task dependency lines to become compressed and hard to read. If the percentage is set less than 0, this method uses a value of 0, enabling the table area to occupy the entire Gantt chart area.</p> <p>This parameter takes a float value.</p> |

#### Returns

None.

### SetDayFormat

#### Syntax

**SetDayFormat** (*Format*)

#### Description

Use the SetDayFormat method to specify the format of the day on a time line axis.

#### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                            |
|-------------------------|----------------------------------------------------------------------|
| <i>Format</i>           | <p>Specify the format the day should display in. The values are:</p> |

| <b>Value</b>                | <b>Description</b>                                                                                         |
|-----------------------------|------------------------------------------------------------------------------------------------------------|
| %Chart_DayFormat            | Display the day in a one- or two-digit format.<br><hr/> <b>Note:</b> This is the default format. <hr/>     |
| %Chart_DayFormat_2Digit     | <hr/> <b>Note:</b> This constant has been deprecated; if specified, it defaults to %Chart_DayFormat. <hr/> |
| %Chart_DayFormat_Name       | Display the day using the full name, such as Monday, Tuesday, and so on.                                   |
| %Chart_DayFormat_DOY        | Display the day of the year in a numeric format, that is 1–366.                                            |
| %Chart_DayFormat_DOY_2Digit | <hr/> <b>Note:</b> This constant has been deprecated; if specified, it defaults to %Chart_DayFormat. <hr/> |
| %Chart_DayFormat_ShortName  | Display the day using the short name, such as Mon, Tue, and so on.                                         |

## Returns

None.

# SetPlannedEndDate

## Syntax

**SetPlannedEndDate** (*RecordName.FieldName*)

## Description

Use the SetPlannedEndDate method to specify the field in the record that defines the planned end date. If planned versus actual dates are not used, this method specifies the end date of the task.

This method is required when creating a Gantt chart.

---

**Note:** For any task that has a bad date format (from either SetPlannedEndDate or SetPlannedStartDate), any overlaid baseline information is not displayed in the chart section.

---

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                             |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field and its associated record that contains the value used to define the planned end date. This field must be of DateTime or Date type. |

## Returns

## SetPlannedStartDate

### Syntax

**SetPlannedStartDate** (*RecordName.FieldName*)

### Description

Use the SetPlannedStartDate method to specify the field in the record that defines the planned start date. If planned versus actual dates are not used, this method specifies the start date of the task.

This method is required when creating a Gantt chart.

---

**Note:** For any task that has a bad date format (from either SetPlannedEndDate or SetPlannedStartDate), any overlaid baseline information is not displayed in the chart section.

---

### Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|

## SetSecondFormat

### Syntax

```
SetSecondFormat (Format)
```

### Description

This method has been deprecated and is ignored. The second format is determined by a user's personalization settings.

### Related Links

“Defining User Preferences” (Applications User’s Guide)

## SetTableXScrollbar

### Syntax

```
SetTableXScrollbar (Scroll_ArrowAmount)
```

### Description

This method has been deprecated and is ignored.

## SetTaskAppData

### Syntax

```
SetTaskAppData (RecordName.FieldName1 [, RecordName.FieldName2 [, RecordName.FieldName3 . . .]])
```

## Description

Use the `SetTaskAppData` method to specify the fields in the record that define the application data to be viewed in the table section.

In the table section, column one (or the left-most column) always displays the work breakdown structure (WBS) numbering (if given) and name of the task (or task ID if the name is not given). This method allows applications to define additional task data columns to be displayed in the right-most columns of the table section.

## Parameters

| <i><b>Parameter</b></i>      | <i><b>Description</b></i>                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldNames</i> | Specify the fields and their associated record that defines one or more application specific fields to be displayed as a column in the table section. The order in which the fields are given as parameters defines their column order in the table section. Because the task name (or task ID if the name is not given) is always shown in column one, the first record field value is displayed in column two. |

## Returns

None.

## Related Links

[SetTaskAppDataTitles](#)

[SetTaskData](#)

[SetTaskDependencyData](#)

## SetTaskAppDataTitles

### Syntax

```
SetTaskAppDataTitles (&TitleArray)
```

### Description

Use the `SetTaskAppDataTitles` method to specify the column titles to be displayed in the table section, starting with column two. The title for column one (that is, the left-most column) in the table section is set using the `SetTaskTitle` method.

The length of the array should match the number of application data fields specified with the `SetTaskAppData` method. Additional strings beyond the number of application data fields are not displayed. If the number of strings in the array specified by this method is less than the number of application data fields, the blanks are displayed in these title columns.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------|
| <i>&amp;TitleArray</i>  | Specify an array of strings containing the column titles to be displayed in the table section. |

## Returns

None.

## Related Links

[SetTaskAppData](#)

[TaskTitle](#)

## SetTaskBarURL

### Syntax

**SetTaskBarURL** (*RecordName*, *FieldName*)

### Description

Use the SetTaskBarURL method to specify the field in the record which defines the URL the browser redirects to when the user clicks on a task bar.

By default, the FieldChange event on the planned end date field of the Gantt task data record is triggered if the image map based interactivity is turned on (using the IsDrillable property). This can be overridden by specifying a URL that is triggered when the task bar is clicked.

Use the SetTaskDependencyURL method to specify the URL to be used when the user clicks on a dependency line in the chart section.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record.FieldName</i> | Specify the field, and its associated record, that defines the URL the browser is redirected to when the task bar is clicked. This field must be of type character. The URL must be an absolute URL. |

## Returns

None.

[SetTaskDependencyURL](#)  
[IsDrillable](#)

SetTaskData

Syntax

```
SetTaskData ({Record.RecordName | &Rowset})
```

Description

Use the SetTaskData method to specify from where the task data is to be populated, either from a record or an already instantiated rowset.

**Note:** If you specify a rowset, the data in the rowset must be provided in the correct display order.

This method is required when you're creating a Gantt chart.

Parameters

| Parameter            | Description                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| RecordName   &Rowset | Specify the record or rowset that contains the task data. If you specify a record, you must prefix the record name with the keyword <b>Record</b> . |

Returns

None.

SetTaskDependencyChildID

Syntax

```
SetTaskDependencyChildID (RecordName.FieldName)
```

Description

The *dependent* task is the task where the dependency arrow ends. Use the SetTaskDependencyChildID method to specify the field in the record that defines the task ID for the dependent task.

The ID must match up to an ID in the Task data set.

This method is required if you specify dependency data.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field, and its associated record, that defines the task ID for the dependant task. This field must be of type number. |

## Returns

None.

# SetTaskDependencyData

## Syntax

```
SetTaskDependencyData ({RecordName | &Rowset})
```

## Description

Use the SetTaskDependencyData method to specify either a record, or an already instantiated rowset, that contains the dependency data.

---

**Note:** If you specify a rowset, the data in the rowset must be provided in the correct display order.

---

## Parameters

| <i><b>Parameter</b></i>         | <i><b>Description</b></i>                                                                                                                           |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName   &amp;Rowset</i> | Specify the record or rowset that contains the task data. If you specify a record, you must prefix the record name with the keyword <b>Record</b> . |

## Returns

None.

## SetTaskDependencyParentID

### Syntax

**SetTaskDependencyParentID** (*RecordName.FieldName*)

### Description

The *depender* task is the task where the dependency arrow originates. Use the SetTaskDependencyParentID method to specify the field in the record that defines the task ID for the depender task.

The ID must match up to an ID in the Task data set.

This method is required if you specify dependency data.

### Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                      |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field and its associated record that defines the task ID for the depender task. This field must be of type number. |

### Returns

None.

## SetTaskDependencyType

### Syntax

**SetTaskDependencyType** (*RecordName.FieldName*)

### Description

Use the SetTaskDependencyType method to specify the type of dependency relationship between predecessor and successor tasks.

The values for type are as follows:

| <b>Type</b>      | <b>Description</b>                                                                                                                 |
|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| Finish-to-Start  | The arrow starts at the end of the predecessor task bar and ends at the start of the successor task bar. This is the default value |
| Finish-to-Finish | The arrow starts at the end of the predecessor task bar and ends at the end of the successor task bar.                             |
| Start-to-Start   | The arrow starts at the start of the predecessor task bar and ends at the start of the successor task bar.                         |
| Start-to-Finish  | The arrow starts at the start of the predecessor task bar and ends at the end of the successor task bar.                           |

## Parameters

| <b>Parameter</b>            | <b>Description</b>                                                                                                                                                                                |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field, and its associated record, that defines the type of dependencies between predecessor and successor tasks. This field must be of type integer, and one of the following values: |

| <b>Value</b>                  | <b>Description</b> |
|-------------------------------|--------------------|
| 0 or any value greater than 3 | Finish-to-Start    |
| 1                             | Finish-to-Finish   |
| 2                             | Start-to-Start     |
| 3                             | Start-to-Finish    |

## Returns

None.

## SetTaskDependencyURL

### Syntax

**SetTaskDependencyURL** (*RecordName.FieldName*)

### Description

Use the SetTaskDependencyURL method to specify the field in the record that defines the URL the browser redirects to when the user clicks on a task bar.

By default, the FieldChange event on the child ID field of the task dependency record is triggered if the image map based interactivity is turned on (using the IsDrillable property). This can be overridden by specifying a URL that is triggered when the task bar is clicked.

Use the SetTaskBarURL method to specify the URL to be used when the user clicks on a task bar in the chart section.

### Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                                                                                    |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field, and its associated record, that defines the URL the browser is redirected to when the dependency arrow is clicked. This field must be of type character. The URL must be an absolute URL. |

### Returns

None.

## SetTaskDrill

### Syntax

**SetTaskDrill** (*Recordname.FieldName*)

### Description

Use the SetTaskDrill method to specify for which field PeopleCode FieldEdit and FieldChange events will execute when the user clicks the task bar.

The field can be any field that is loaded in the component buffer.

The system does not change the value in the field when the user clicks the field. Any changes or other processing for the field must be done within the PeopleCode program.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the record name and the field name of the field to be used for field change processing. The field must be available in the component buffer. |

## Returns

None.

## SetTaskExpanded

### Syntax

```
SetTaskExpanded ( (RecordName.FieldName) )
```

### Description

This method has been deprecated and is ignored.

## SetTaskID

### Syntax

```
SetTaskID ( RecordName.FieldName )
```

### Description

Use the SetTaskID method to specify the field that defines the unique task identifier. The task ID is used to support task linking and dependencies.

---

**Note: The field must be of type number.**

---

This method is required when you're creating a Gantt chart.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                                      |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the record name and the field name of the field that defines the unique task identifier.<br><hr/> <b>Note: The field must be of type number.</b> <hr/> |

## Returns

None.

[SetTaskName](#)

## SetTaskLabel

### Syntax

**SetTaskLabel** (*RecordName.FieldName*)

### Description

Use the SetTaskLabel method to specify the field in the record that defines the task label. The label is displayed alongside its corresponding task bar in the chart area. If a task label is not provided, the task name is used instead. If a task name is not provided, the task id is used.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field, and its associated record, that contains the task label. This field must be of type character. |

## Returns

None.

## Related Links

[SetTaskName](#)

# SetTaskLevel

## Syntax

```
SetTaskLevel (RecordName.FieldName)
```

## Description

Use the SetTaskLevel method to specify the field in the record that defines the level for the task. The outermost summary tasks are always defined as task level one. Tasks with task levels greater than one are subtasks. Subtasks may also contain other subtasks.

If a field is not provided to define the level, all tasks are defined at level 1. A maximum of 32 levels are supported.

The following table shows an example of the different levels that could be used, as well as what the parent task level is.

**Note:** The parent task is not actually part of the data.

| Task Name       | Task Level | Parent Level  |
|-----------------|------------|---------------|
| Phase I         | 1          | None          |
| Evaluation      | 2          | Phase I       |
| Research        | 3          | Evaluation    |
| Report Findings | 3          | Evaluation    |
| Create Budget   | 2          | Phase I       |
| Approve Budget  | 3          | Create Budget |
| Phase II        | 1          | None          |
| Code and Test   | 2          | Phase II      |
| Phase III       | 1          | None          |
| Training        | 2          | Phase III     |

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field, and its associated record, that contains the information about the task level. This field must be of type number. Up to 32 levels are supported. |

## Returns

None.

## SetTaskMilestone

### Syntax

**SetTaskMilestone** (*RecordName.FieldName*)

### Description

Use the SetTaskMilestone method to specify the field in the record that defines whether the task should be treated as a milestone.

The fields specified by the SetPlannedStartDate and SetActualStartDate methods are used for determining the dates for the planned and actual milestones. The other date fields in the rowset are ignored

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                                                                                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field and its associated record that defines whether the task should be treated as a milestone. The field must be of type Character, and be one character long. The possible values for this field are Y, used to specify that this task is a milestone, or N, if not. |

## Returns

None.

## Related Links

[SetActualStartDate](#)

[SetTaskMilestone](#)

[SetPlannedStartDate](#)

## SetTaskName

### Syntax

**SetTaskName** (*RecordName.FieldName*)

### Description

Use the SetTaskName method to specify the field in the record that defines the task name. If you do not specify a task name, the task ID is used in the table section of the Gantt chart.

Although this method is not required, Oracle recommends using it to display meaningful information in the table section of the Gantt chart.

### Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field name and its associated record that defines the task name. The field must be of type character. |

### Returns

None.

### Related Links

[SetTaskID](#)

## SetTaskProgress

### Syntax

**SetTaskProgress** (*RecordName.FieldName*)

### Description

Use the SetTaskProgress method to specify the field in the record that defines the length of the progress bar for this task as shown in the chart area of the Gantt chart.

The value in the field must be between 0 and 100, inclusive. Zero indicates no progress bar is shown, 100 indicates that the progress bar should cover the entire length of the task bar. Values greater than 100 are automatically converted to 100.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field, and its associated record, that defines the length of the progress bar for this task. This field must be of type number. The value in the field must be between 0 and 100, inclusive. You must not specify a value greater than 100. |

## Returns

None.

[SetTaskProgressBarColor](#)

# SetTaskProgressBarColor

## Syntax

**SetTaskProgressBarColor** (*RecordName.FieldName*)

## Description

Use the SetTaskProgressBarColor method to specify the field in the record that defines the color for the progress bar.

For the progress bar to be visible, its color must contrast with the task bar color. No borders are drawn around the progress bar.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field, and its associated record, that defines the task progress bar color. This field must be of type numeric, which means that you can only use the numeric value for the chart colors, not the constant. |

## Returns

None.

## Related Links

[SetActualTaskBarColor](#)

[SetTaskProgress](#)

# SetWBSNumbering

## Syntax

**SetWBSNumbering** (*RecordName.FieldName*)

## Description

Use the SetWBSNumbering method to specify the field in the record that defines the WBS numbering to be displayed for each task row in the table section of the Gantt chart.

A WBS is very similar in structure and layout to a document outline. Each item at a specific level of a WBS is numbered consecutively (that is, 10, 20, 30, 40, 50). Each item at the next level is numbered within the number of its parent item (that is, 10.1, 10.2, 10.3, 10.4). For example:

```
1.
  1.1
    1.1.1
    1.1.2
    1.1.3
  1.2
    1.2.1
    1.2.2
2.
. . .
```

If no field name is provided, WBS numbering is not displayed along with the tasks.

Regardless if WBS numbering is provided, child tasks are indented to the right of their parent task.

## Parameters

| Parameter                   | Description                                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>RecordName.FieldName</i> | Specify the field name and its associated record that defines the WBS numbering to be displayed. The field must be of type character. |

## Returns

None.

# SetYearFormat

## Syntax

**SetYearFormat** (*Format*)

## Description

Use the SetYearFormat method to specify the format of years on the time line axis.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                              |
|-------------------------|------------------------------------------------------------------------|
| <i>Format</i>           | Specify the format of how the year should be displayed.<br>Values are: |

| <i><b>Value</b></i>      | <i><b>Description</b></i>                                                                              |
|--------------------------|--------------------------------------------------------------------------------------------------------|
| %Chart_YearFormat        | Display the year in a numeric one- or two-digit format.                                                |
| %Chart_YearFormat_2Digit | <b>Note:</b> This constant has been deprecated; if specified, it defaults to %Chart_YearFormat_4Digit. |
| %Chart_YearFormat_4Digit | Display the year in a numeric four-digit format.<br><b>Note:</b> This is the default format.           |

## Returns

None.

## Gantt Class Properties

These properties are used by the Gantt class. The properties are described in alphabetic order.

### AdditionalStyleSuffix

#### Description

This property has been deprecated and is ignored.

### AxisEndTime

#### Description

Use this property to specify the date and time where the time line should end. The value must be of type Date or DateTime.

This property is read/write.

AxisStartDateTime

Description

Use this property to specify the date and time where the time line should begin. The value must be of type Date or DateTime.

This property is read/write.

DataStartRow

Description

This property has been deprecated and is ignored.

DataWidth

Description

This property has been deprecated and is ignored.

GridLines

Description

Use this property to specify whether to show grid lines with the chart.

Gantt charts only support the %ChartGrid\_Vertical and %ChartGrid\_None values.

Grid lines are shown within the chart section of the Gantt chart, if enabled, and are tied to the major tick mark. The major tick mark is associated with the smallest time increment displayed on the time line axis. For example, if both years and months are displayed on the time line axis, the major tick marks denote the months.

If you do not specify a value, no grid lines are shown (%ChartGrid\_None).

This property controls only the display of grid lines. If you want to specify the style of the grid lines, use the GridLineType property.

The values are:

| <i>Numeric Value</i> | <i>Constant Value</i> | <i>Description</i>              |
|----------------------|-----------------------|---------------------------------|
| 0                    | %ChartGrid_None       | Don't show grid lines (default) |
| 2                    | %ChartGrid_Vertical   | Show vertical grid lines        |

This property is read/write.

## Related Links

[GridLineType](#)

# GridLineType

## Description

Use this property to specify the style of the grid lines when vertical grid lines are turned on—that is, the `GridLines` property must be set to `%ChartGrid_Vertical`.

The default value is `%ChartLine_Dash`. The possible values are:

| <i><b>Numeric Value</b></i> | <i><b>Value</b></i>           | <i><b>Description</b></i>                                |
|-----------------------------|-------------------------------|----------------------------------------------------------|
| 0                           | <code>%ChartLine_Solid</code> | Draw grid lines with solid lines.                        |
| 1                           | <code>%ChartLine_Dash</code>  | Draw grid lines with lines composed of dashes (default). |
| 2                           | <code>%ChartLine_Dot</code>   | Draw grid lines with lines composed of dots.             |

This property is read/write.

## Related Links

[GridLines](#)

# Height

## Description

Use this property to specify the height of the chart. This property takes a numeric value. The unit of measurement is pixels.

You can use this property to overwrite the height set in Application Designer.

If you try to read this property before setting it, the value returned is zero.

This property is read/write.

# ImageMap

## Description

This property has been deprecated and is ignored.

## InteractiveEnd

### Description

Use this property to specify whether the user can change the end date of a task by dragging and dropping.

---

**Note:** Drag-and-drop is not supported on touch-friendly mobile devices such as an Apple iPad.

---

This property takes a Boolean value: True if the user can change the end date, False otherwise.

The default value of this property is False.

This property is read/write.

## InteractiveMove

### Description

Use this property to specify whether the user can move a task bar by dragging and dropping.

---

**Note:** Drag-and-drop is not supported on an Apple iPad.

---

This property takes a Boolean value: True if the user can move the bar, False otherwise.

The default value of this property is False.

This property is read/write.

## InteractiveProgress

### Description

Use this property to specify whether the user can change the progress value of a task by dragging and dropping.

---

**Note:** Drag-and-drop is not supported on an Apple iPad.

---

This property takes a Boolean value: True if the user can change the progress value, False otherwise.

The default value of this property is False.

This property is read/write.

## InteractiveStart

### Description

Use this property to specify whether the user can change the start date of a task by dragging and dropping.

---

**Note:** Drag-and-drop is not supported on an Apple iPad.

---

This property takes a Boolean value: True if the user can change the start date, False otherwise.

The default value of this property is False.

This property is read/write.

## IsDrillable

### Description

The IsDrillable property is used with the task bars as well as the task dependency lines in the chart section of a Gantt chart. Where the user is directed depends on whether a URL is provided or not, as detailed in this table:

| <i><b>User Action</b></i>      | <i><b>If URL is not provided:</b></i>                                                        | <i><b>If URL is provided:</b></i>                                                    |
|--------------------------------|----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| Clicks a task bar.             | FieldChange event is associated with the field that is set with SetTaskDrill.                | Redirects to URL provided by field identified using the SetTaskBarURL method.        |
| Clicks a task dependency line. | FieldChange event is associated with the <b>Child ID</b> field in the Task Dependency table. | Redirects to URL provided by field identified using the SetTaskDependencyURL method. |

This property takes a Boolean value: True if the end-user can click the chart to initiate an action, and False otherwise.

The default value for this property is False.

This property is read/write.

## IsPlainImage

### Description

This property has been deprecated and is ignored.

## PixelsPerRow

### Description

Use this property to set or return the row height for each row in the Gantt chart as Number value representing pixels. The default value is 25 pixels.

This property is read/write.

## RevertToPre850

### Description

This property has been deprecated and is ignored.

## ShowTaskLabels

### Description

Use this property to specify whether or not task labels are displayed alongside the corresponding task bar in the chart area. This property takes a boolean value; true to display the labels, false to not display the labels. The default is to display the labels.

This property is read/write.

## Style

### Description

Use this property to specify the style class that defines the overall appearance attributes of the chart . The value must be a valid style class within the style sheet specified for the chart.

This property is read/write.

### Related Links

[Styling PeopleSoft Charts](#)

## StyleSheet

### Description

This property has been deprecated and is ignored.

### Related Links

[Styling PeopleSoft Charts](#)

## TaskDependencyLineType

### Description

Use this property to specify an integer value that specifies the line type of the line connecting dependent tasks. This value affects all the dependency lines for the entire Gantt chart, not just for a specific set of tasks.

This property is read/write.

See [Styling PeopleSoft Charts](#).

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b>  |
|-----------------------------|------------------------------|----------------------------|
| 0                           | %ChartLine_Solid             | Solid line                 |
| 1                           | %ChartLine_Dashed            | Dashed line                |
| 2                           | %ChartLine_Dotted            | Dotted line                |
| 3                           | %ChartLine_Mixed             | Mixture of dashes and dots |

## TaskMilestoneGlyph

### Description

Use this property of type integer to specify which field in the record defines the glyph to represent a task milestone (for both planned and actual milestones). This glyph is used for the entire chart, not just for a specific task.

By default a diamond shaped glyph will be used.

Milestones associated with planned dates use colors defined by the SetPlannedTaskBarColor method. Milestones associated with actual dates use colors defined by the SetActualTaskBarColor method.

This property is read/write.

### Related Links

[Using Gantt Glyphs](#)

## TaskTitle

### Description

Use this property to specify the column title to be displayed in column one (that is, the left-most column) in the table section of the Gantt chart. Use the SetTaskAppDataTitles method to specify the column titles for the application specific data fields (that is, column two and beyond).

This property is read/write.

### Related Links

[SetTaskAppDataTitles](#)

# Width

## Description

Use this property to specify the width of the chart. This property takes a numeric value. The unit of measurement is pixels.

Generally this property is used with charts created for iScripts, to specify the width of the image, before generating the image map. You can also use it to overwrite the width set in Application Designer.

If you try to read this property before setting it, the value returned is zero.

This property is read/write.

---

# OrgChart Class Methods

These methods are used by the OrgChart class. The methods are described in alphabetic order.

## SetCrumbData

### Syntax

`SetCrumbData (&Rowset)`

### Description

Use the SetCrumbData method to specify the source for the data for the organization chart breadcrumbs. Use an already instantiated and populated level-1 component rowset that contains the breadcrumb data.

### Parameters

| Parameter          | Description                                           |
|--------------------|-------------------------------------------------------|
| <i>&amp;Rowset</i> | A level-1 rowset populated with the breadcrumbs data. |

### Returns

None.

## SetCrumbRecord

### Syntax

`SetCrumbRecord (Record.Record_Name)`

## Description

Use the SetCrumbRecord method to specify the derived/working record name that contains the information about the breadcrumbs.

The breadcrumb record is an application-specific derived/work record created using a clone of the PTORGCRMB\_SBR subrecord definition.

## Parameters

| <i><b>Parameter</b></i>    | <i><b>Description</b></i>                                                                                                                  |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Record. <i>Record_Name</i> | Specify the name of the derived/work record that contains the data for the breadcrumbs.<br><br>You must include the <b>Record</b> keyword. |

## Returns

None.

## SetDropdownData

### Syntax

SetDropdownData (&Rowset)

### Description

Use the SetDropdownData method to specify the source for the data for the organization chart drop-down menus/lists. Use an already instantiated and populated level-1 component rowset that contains the drop-down list data.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                |
|-------------------------|----------------------------------------------------------|
| &Rowset                 | A level-1 rowset populated with the drop-down list data. |

## Returns

None

## SetDropDownRecord

### Syntax

SetDropDownRecord(**Record**.*RecordName*)

### Description

Use the SetDropDownRecord method to specify the derived/working record name that contains the information about the drop-down menus/lists.

The drop-down record is an application-specific derived/work record created using a clone of the PTORGBOXLST\_SBR subrecord definition.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name</i>      | Specify the name of the derived/work record that contains the data for the drop-down lists.<br><br>You must include the <b>Record</b> keyword. |

### Returns

None

## SetIMData

---

**Note:** This method has been deprecated and currently exists for backward compatibility only.

---

## SetIMRecord

---

**Note:** This method has been deprecated and currently exists for backward compatibility only.

---

## SetLegend

### Syntax

SetLegend(&Array\_of\_String)

### Description

Use the SetLegend method to specify legend text. Legend text labels the images set using SetLegendImg.

If you do not specify an element for an array (that is, a blank or a null) then no legend is listed for that node.

---

**Note:** Legend text is not automatically translated. If you set your own labels, be sure to use translated text, such as message catalog entries.

---

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | Specify an already instantiated array of string, containing the text that you want to use for the legend. |

## Returns

None.

## Example

```
&LegendArray = CreateArray("A", "B", "C", "D ");  
&ocOrgChart.SetLegend (&LegendArray);
```

## Related Links

[SetDataSeries](#)

# SetLegendImg

## Syntax

```
SetLegendImg (&Array_of_String)
```

## Description

Use the SetLegendImg method to specify the legend image names.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | An already instantiated array containing the names of the images that you want to use with the legend. |

## Returns

None.

## SetNodeData

### Syntax

**SetNodeData** (*&Rowset*)

### Description

Use the SetNodeData method to specify the source for the node data for the organization chart. Use an already instantiated and populated level-1 component rowset that contains the node data.

This is a required method to build an organization chart.

If you make a change to the underlying data of a chart, call the SetNodeData method again to update the chart.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------|
| <i>&amp;Rowset</i>      | A level-1 component rowset populated with the node data. This rowset references the node record of the chart. |

### Returns

None.

## SetNodeDisplayDataRecord

### Syntax

**SetNodeDisplayDataRecord**(**Record**.*Record\_Name*)

### Description

Use the SetNodeDisplayDataRecord method to specify the node display record.

The node display record is an application-specific derived/work record created using a clone of the PTNODE\_DISP\_SBR subrecord definition.

This method is required for an organization chart that implements node display templates.

## Parameters

| <i><b>Parameter</b></i>         | <i><b>Description</b></i>                                                                                                                               |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Record.Record_Name</code> | Specify the name of the derived/work record that contains the node display data for the organization chart.<br><br>You must include the Record keyword. |

## Returns

None.

## SetNodeDisplayData

### Syntax

**SetNodeDisplayData**(*&rsRowset*)

### Description

Use the SetNodeDisplayData method to specify the source for the node display data for the organization chart. Use an already instantiated and populated level-1 standalone rowset that contains the node display data.

This method is required for an organization chart that implements node display templates.

If you make a change to the node display data of a chart, call the SetNodeDisplayData method again to update the chart.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;rsRowset</i>    | A level-1 component rowset populated with the node display data. This rowset references the node display record of the organization chart. |

## Returns

None.

## SetNodeRecord

### Syntax

**SetNodeRecord**(**Record**.*Record\_Name*)

## Description

Use the `SetNodeRecord` method to specify the organization node record.

The node record is an application-specific derived/work record created using a clone of the `PTORGNODE_SBR` subrecord definition.

This method is required to build an organization chart.

## Parameters

| <i><b>Parameter</b></i>         | <i><b>Description</b></i>                                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Record.Record_Name</code> | Specify the name of the derived/work record that contains the data for the organization node.<br><br>You must include the <b>Record</b> keyword. |

## Returns

None.

## SetNodeViewEntries

### Syntax

```
SetNodeViewEntries (&NodeViewArray)
```

## Description

Use this method to specify the array of string representing the node view IDs.

## Parameters

| <i><b>Parameter</b></i>         | <i><b>Description</b></i>                                    |
|---------------------------------|--------------------------------------------------------------|
| <code>&amp;NodeViewArray</code> | Specifies an array of string representing the node view IDs. |

## Returns

None.

## Example

```
&OrgChart.SetNodeViewEntries (&NodeViewArray);  
&OrgChart.SetNodeViewText (&DataHintArray);  
  
&OrgChart.InitialView="VIEW1";
```

## Related Links

[SetNodeViewText](#)

[InitialView](#)

[Implementing Node Views \(Optional\)](#)

## SetNodeViewText

### Syntax

```
SetNodeViewText (&DataHintArray)
```

### Description

Use this method to specify the array of string representing the data hint (mouse-over text) for each node view.

### Parameters

| <i>Parameter</i>          | <i>Description</i>                                                                            |
|---------------------------|-----------------------------------------------------------------------------------------------|
| <i>&amp;DataHintArray</i> | Specifies an array of string representing the data hint (mouse-over text) for each node view. |

### Returns

None.

### Example

```
&OrgChart.SetNodeViewEntries (&NodeViewArray);  
&OrgChart.SetNodeViewText (&DataHintArray);  
  
&OrgChart.InitialView="VIEW1";
```

## Related Links

[SetNodeViewEntries](#)

## SetPopUpNodeData

### Syntax

```
SetPopUpNodeData (&Rowset)
```

## Description

Use the `SetPopUpNodeData` method to specify the source for the pop-up node data for the organization chart. Use an already instantiated and populated level-1 component rowset that contains the pop-up node data.

This method is not required if no pop-up chart is available to be displayed in the organization chart.

If you make a change to the underlying data of a pop-up chart, call the `SetPopUpNodeData` method again to update the chart.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Rowset</i>      | A level-1 rowset populated with the pop-up node data. This rowset references the pop-up node record of the chart. |

## Returns

None.

## SetPopUpNodeRecord

### Syntax

```
SetPopUpNodeRecord (Record.Record_Name)
```

### Description

Use the `SetNodeRecord` method to specify the pop-up node record.

The node record is an application-specific derived/work record created using a clone of the PTORGPOPUP\_SBR subrecord definition.

This method is not required if no pop-up chart is available to be displayed in the organization chart.

## Parameters

| <i><b>Parameter</b></i>   | <i><b>Description</b></i>                                                                                                                  |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record.Record_Name</i> | Specify the name of the derived/work record that contains the data for the pop-up node.<br><br>You must include the <b>Record</b> keyword. |

Returns

None.

SetSchemaLevels

Syntax

SetSchemaLevels(*&Array*) ;

Description

Use this method to specify the schema levels for an organization chart. Use an array of instantiated SchemaLevel instances. The size of the array is the total number of the schemas defined for this organization chart.

Parameters

| Parameter         | Description                                     |
|-------------------|-------------------------------------------------|
| <i>&amp;Array</i> | An array of instantiated SchemaLevel instances. |

Returns

None.

Example

```
SchemaLevel &oSchemaLevel1 = Createobject("SchemaLevel");
SchemaLevel &oSchemaLevel2 = Createobject("SchemaLevel");
SchemaLevel &oSchemaLevel3 = Createobject("SchemaLevel");
SchemaLevel &oSchemaLevel4 = Createobject("SchemaLevel");

/**      Create an instance of of schema zoom level 1 class and instantiate it */
SchemaLevel &oSchemaLevel1 =Createobject("SchemaLevel");
&oSchemaLevel1.ID=1;
& oSchemaLevel1.ImageHeight=0;
.... (add code to instantiate &oSchemaLevel1, &oSchemaLevel2,
      &oSchemaLevel3, &oSchemaLevel4 instances).
&SchemaLevels=CreateArray(&oSchemaLevel1, &oSchemaLevel2, &oSchemaLevel3, &oSchemaL
evel4)
&ocOrgChart.SetZoomSchemaLevels (&SchemaLevls)
```

Related Links

[SchemaLevel Class Properties](#)

OrgChart Class Properties

These properties are used by the OrgChart class. The properties are described in alphabetic order.

## CenterFocusNode

### Description

Specify whether the node with focus displays centered in the chart area.

| <i><b>Value</b></i> | <i><b>Direction</b></i>      |
|---------------------|------------------------------|
| 0                   | Center the focus node        |
| 2                   | Do not center the focus node |

The focus node is not centered if the chart fits in the chart area without a horizontal scroll, even if CenterFocusNode = 0.

The focus node is not centered if any pop-ups are opened. The display of pop-ups in the visible chart area takes priority over focus node centering.

---

**Note:** If multiple pop-ups are opened, the last popup opened is not necessarily set to the visible area. This is determined by the position of the pop-up in the rowset.

---

The default is 0.

This property is read/write.

## ChartCurrentSchemaLevel

### Description

Set this property to specify the initial schema zoom level.

Valid values are 1 to the number of total schema instances set in the PeopleCode for the organization chart.

When a user selects a different schema level using the zoom control the systems sets the value in the PTCHART\_SCHEMA\_ID field to the new schema value and sets the value in the CurrentSchemaLevel property to the new schema value, then displays the chart using the new schema level.

If this property is changed to a new value by PeopleCode, the chart is displayed with the new schema level view.

The default value is 1.

### Related Links

[Implementing Zoom Schemas \(Optional\)](#)

## ChartScrollType

### Description

Specify whether to use scroll bars or alternative scrolling to move the chart within the visible chart area.

| <b>Value</b> | <b>Direction</b>                                                                                                                                                            |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Use scroll bars                                                                                                                                                             |
| 1            | Use alternative scrolling. This allows the user to use the scroll navigator or to grab the surface of the organization chart background to move the chart in any direction. |

---

**Note:** To use the mouse hand feature, the chart background color must be specified in the PSORGCHART style sheet. By default, the background color is white.

---

---

**Note:** On an Apple iPad a user navigates using a finger on a touch screen, so scroll bars, the scroll navigator, and mouse hand features are not displayed on an Apple iPad. For an Apple iPad the behavior is the same for both ChartScrollType= 1 and ChartScrollType = 0.

---

This property takes an integer value.

The default is 0.

This property is read/write.

## Collapsed\_Msg

### Description

Specify the data hint for the collapsed icon image.

An error message is issued if Collapsed\_Msg is set but CollapsedImage is not set.

The default is “Expand”.

This property is read/write.

## CollapsedImage

### Description

Specify a string value for the name of the image that represents a collapsed node. When a user clicks on the collapsed image, the node will be *expanded*.

If the CollapsedImage and ExpandedImage properties are not specified, then no expanded/collapsed icon appears on the node and the expand/collapse actions are disabled.

This property is read/write.

### Example

```
&ocOrgChart.CollapsedImage ="PT_COLLAPSED_NODE";
```

## CollapseMainIconSpace

### Description

Specify whether to reduce the space at the top of the node reserved for the main icon. This property is ignored for charts that use a display template.

See “Using Node Display Templates” in [Designing Organization Chart Nodes](#).

| <i><b>Value</b></i> | <i><b>Direction</b></i>                                             |
|---------------------|---------------------------------------------------------------------|
| 0                   | Reserve space at the top of the node for the main icon.             |
| 1                   | Reduce the space at the top of the node reserved for the main icon. |

This property takes an integer value.

The default is 0.

This property is read/write.

## CrumbDescrStyle

### Description

Use this property to specify the style class name that will be used to control the style of linkable breadcrumbs.

The default style class is PT\_ORGCHART\_BRDCRM.

Oracle recommends that you use the default breadcrumb style.

This property is read/write.

## CrumbMaxDisplayLength

### Description

Use this property to set the maximum description length that will appear for the breadcrumb.

A breadcrumb description has a maximum of 50 characters in length. If CrumbMaxDisplayLength is set to 30, then only the first 30 characters of the description appear and an ellipsis (“...”) is appended.

On mouse-over, the whole text of the breadcrumb appears.

The default is to show the full description.

This property takes a number value.

This property is read/write.

## CrumbSeparatorImage

### Description

Use this property to specify the image name for the image that appears between breadcrumb entries.

If this property is not set, then no image appears between breadcrumb entries. Instead, breadcrumb entries are separated by three spaces.

This property takes a string value.

This property is read/write.

## DefaultImage

### Description

Use this property to set the default image name for the image that will appear if ImageLocation is not 0 and no image is set in the work record.

This property is read/write.

## Direction

### Description

Use this property to specify organization chart orientation.

| <b><i>Value</i></b> | <b><i>Orientation</i></b> |
|---------------------|---------------------------|
| 0                   | Horizontal                |
| 2                   | Vertical                  |

The default is 2 (vertical).

This property is read/write.

## DropDownBoxStyle

### Description

This property is retained for backward compatibility. PeopleTools version 8.52 and later do not use this property.

Specify the style for the drop-down list box header for the organization chart.

| <b>Value</b>              | <b>Description</b>                                              |
|---------------------------|-----------------------------------------------------------------|
| PT_ACTION_POSITION        | The button appears to left, aligned with the other descriptors. |
| PT_ACTION_POSITION_RIGHT  | The button appears to right.                                    |
| PT_ACTION_POSITION_CENTER | The button appears in the center of the node.                   |

The default style class is PT\_ACTION\_POSITION.

This property is read/write.

## Expanded\_Msg

### Description

Specify the data hint for the expanded icon image.

An error message is issued if Expanded\_Msg is set but ExpandedImage is not set.

The default is “Collapse”.

This property is read/write.

## ExpandedImage

### Description

Specify a string value for the name of the image that represents an expanded node. When a user clicks on the expanded image, the node will be *collapsed*.

If the CollapsedImage and ExpandedImage properties are not specified, then no expanded/collapsed icon appears on the node and the expand/collapse actions are disabled.

This property is read/write.

### Example

```
&ocOrgChart.ExpandedImage = "PT_EXPANDED_NODE";
```

## FocusNodeStyle

### Description

Use this property to specify the style class name that will be used to control the focus node.

The default style class is PT\_ORGNODE\_SELECT.

This property is read/write.

## HasLegend

### Description

Use this property to specify if a legend appears with the chart. This property takes a Boolean value: True if the legend appears with the chart, and False otherwise.

The default value is False.

This property is read/write.

## Height

### Description

Use this property to specify the height of the chart. This property takes a numeric value. The unit of measurement is pixels.

If you try to read this property before setting it, the value returned is 0.

This property is read/write.

### Related Links

[Height](#)

## ImageHeight

### Description

Use this property to specify the height of the node image. This property takes a numeric value. The unit of measurement is pixels.

---

**Note:** If ImageHeight is very large relative to the chart, data hints may not have room to display properly. If this occurs, you need to reduce ImageHeight or increase chart size.

---

The default is 0.

This property is read/write.

## Related Links

[Height](#)

## ImageLocation

### Description

Use this property to specify chart node image location:

| <i>Value</i> | <i>Direction</i>   |
|--------------|--------------------|
| 0            | No image           |
| 1            | Image on the left  |
| 2            | Image on the right |

The default is 0 (No image).

This property is read/write.

## ImageMouseoverMagnificationFactor

### Description

Use this property to specify the mouse-over magnification factor on the node image. This property takes a numeric value. A value of 100 produces a mouse-over image the same size as the node image. If the value is set to 0 or 100, no image magnification will occur.

---

**Note:** ImageMouseoverMagnificationFactor is ignored on the Apple iPad. On an Apple iPad the user is able to zoom the entire page to enlarge the image.

---

Valid values are 0 to 1000.

The default is 0.

This property is read/write.

## Related Links

[Height](#)

## IMPresence

---

**Note:** This property has been deprecated and currently exists for backward compatibility only.

---

## IMRefreshInterval

---

**Note:** This property has been deprecated and currently exists for backward compatibility only.

---

## InitialView

### Description

Use this property to set or return the initial node view ID as a string.

This property is read/write.

### Example

```
&OrgChart.InitialView="VIEW1";
```

### Related Links

[SetNodeViewEntries](#)

[Implementing Zoom Schemas \(Optional\)](#)

## LegendPosition

### Description

The OrgChart class only supports %ChartLegend\_Top, which is to display the legend on top of the chart.

This property is read/write.

## LegendStyle

### Description

Use this property to specify the style of the legend. The values for this property are the style classes contained in the style sheet associated with the chart.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_ORGCHART\_LEGEND.

This property is read/write.

### Related Links

[Styling PeopleSoft Charts](#)

## LegendTopSpace

### Description

Use this property to set the space between the breadcrumb and legend.

The default is no space between the legend and the breadcrumbs.

This property is read/write.

### Related Links

[Styling PeopleSoft Charts](#)

## MainTitle

### Description

Use this property to specify the text for the main title of the chart.

This property takes a string value.

This property is read/write.

## MainTitleStyle

### Description

Use this property to specify the style of the main title. The values for this property are the style classes contained in the style sheet associated with the chart.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default value is “PT\_ORGCHART\_TITLE”.

This property is read/write.

## MaxDropdownDisplayItem

### Description

Specify the maximum number of list items that will appear in the drop down box before the up-and-down arrow vertical scrolling is implemented.

This property is retained for backward compatibility. PeopleTools version 8.52 and later charts do not use this property.

This property takes an integer value.

The default value is 7.

This property is read/write.

## MaxPopupDisplayNode

### Description

The maximum number of nodes to be displayed in the pop-up before a vertical scrollbar appears in the pop-up.

For instance, if MaxPopupDisplayNode is set to 3 and the pop-up has more than 3 nodes, then the pop-up will only display the first 3 nodes with a scrollbar in the pop-up so the user can scroll down to see the other nodes.

The default value is 3.

This property is read/write.

## NodeDescr1Style

### Description

The style class name that will be used to control the style of the main chart node descriptor number 1.

NodeDescr*n*Style properties are ignored with charts that use a node display template. Instead, use the PT\_CNT\_STYLE field in the display template.

Each node can have up to seven descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_ORGNODE\_DESC1.

This property is read/write.

## NodeDescr2Style

### Description

The style class name that will be used to control the style of the main chart node descriptor number 2.

NodeDescr*n*Style properties are ignored with charts that use a node display template. Instead, use the PT\_CNT\_STYLE field in the display template.

Each node can have up to seven descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_ORGNODE\_DESC2.

This property is read/write.

## NodeDescr3Style

### Description

The style class name that will be used to control the style of the main chart node descriptor number 3.

NodeDescr*n*Style properties are ignored with charts that use a node display template. Instead, use the PT\_CNT\_STYLE field in the display template.

Each node can have up to seven descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_ORGNODE\_DESC3.

This property is read/write.

## NodeDescr4Style

### Description

The style class name that will be used to control the style of the main chart node descriptor number 4.

NodeDescr*n*Style properties are ignored with charts that use a node display template. Instead, use the PT\_CNT\_STYLE field in the display template.

Each node can have up to seven descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_ORGNODE\_DESC4.

This property is read/write.

## NodeDescr5Style

### Description

The style class name that will be used to control the style of the main chart node descriptor number 5.

NodeDescr*n*Style properties are ignored with charts that use a node display template. Instead, use the PT\_CNT\_STYLE field in the display template.

Each node can have up to seven descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_ORGNODE\_DESC5.

This property is read/write.

## NodeDescr6Style

### Description

The style class name that will be used to control the style of the main chart node descriptor number 6.

NodeDescr*n*Style properties are ignored with charts that use a node display template. Instead, use the PT\_CNT\_STYLE field in the display template.

Each node can have up to seven descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_ORGNODE\_DESC6.

This property is read/write.

## NodeDescr7Style

### Description

The style class name that will be used to control the style of the main chart node descriptor number 7.

NodeDescr*n*Style properties are ignored with charts that use a node display template. Instead, use the PT\_CNT\_STYLE field in the display template.

Each node can have up to seven descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_ORGNODE\_DESC7.

This property is read/write.

## NodeMaxDisplayDescLength

### Description

Set the maximum descriptor length that will appear in the node.

This property is ignored on charts that use a display template. Instead use the PT\_DESCR\_MAX display template field to limit descriptor length.

If the full descriptor text is longer than NodeMaxDisplayDescLength, then an ellipsis (“...”) is appended to the displayed text. The entire text appears in a data hint.

The default value is 50 characters.

This property is read/write.

## NodeProportion

### Description

Use the NodeProportion property to control whether nodes can have varying sizes or are sized uniformly.

| <b>Value</b> | <b>Direction</b>                                             |
|--------------|--------------------------------------------------------------|
| 0            | Node size is variable, based on the content of each node.    |
| 1            | Node height is uniform, based on the tallest node.           |
| 2            | Node width is uniform, based on the widest node.             |
| 3            | Node height and width are uniform.                           |
| 4            | Nodes are square, based on the largest node height or width. |

This property takes an integer value.

The default is 0.

This property is read/write.

## OptimizeHorizontalSpace

### Description

Set this property to automatically maximize or minimize the chart area horizontally.

| <b>Value</b> | <b>Direction</b>                                                                                                                                                                                                                      |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Use the specified size.                                                                                                                                                                                                               |
| 1            | Expand horizontally to the right edge of the browser page.<br><br>This option should only be used when there is only blank space to the right of the chart. Otherwise, any objects in that area will be pushed off the viewable area. |
| 2            | Contract horizontally to just to the right of the node furthest to the right.                                                                                                                                                         |
| 3            | Fit the chart area to the chart horizontally.                                                                                                                                                                                         |

This property takes an integer value.

The default is 0.

This property is read/write.

## OptimizeVerticalSpace

### Description

Set this property to automatically maximize or minimize the chart area vertically.

| <i><b>Value</b></i> | <i><b>Direction</b></i>                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                   | Use the specified size.                                                                                                                                                                                                               |
| 1                   | Expand vertically to the bottom edge of the browser page.<br><br>This option should only be used when there is only blank space at the bottom of the chart. Otherwise, any objects in that area will be pushed off the viewable area. |
| 2                   | Contract vertically to just below the bottom of the last visible chart node.                                                                                                                                                          |
| 3                   | Fit the chart area to the chart vertically.                                                                                                                                                                                           |

This property takes an integer value.

The default is 0.

This property is read/write.

## PopupHeaderStyle

### Description

The style class that will be used to control the style of the pop-up header and the header descriptor.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_POPUPNODE\_HEADER.

This property is read/write.

## PopupNodeDescr1Style

### Description

The style class name that will be used to control the style of the pop-up node descriptor number 1.

Each node can have up to eight descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_POPUPNODE\_DESC1.

This property is read/write.

## PopupNodeDescr2Style

### Description

The style class name that will be used to control the style of the pop-up node descriptor number 2.

Each node can have up to eight descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_POPUPNODE\_DESC2.

This property is read/write.

## PopupNodeDescr3Style

### Description

The style class name that will be used to control the style of the pop-up node descriptor number 3.

Each node can have up to eight descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_POPUPNODE\_DESC3.

This property is read/write.

## PopupNodeDescr4Style

### Description

The style class name that will be used to control the style of the pop-up node descriptor number 4.

Each node can have up to eight descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_POPUPNODE\_DESC4.

This property is read/write.

## PopupNodeDescr5Style

### Description

The style class name that will be used to control the style of the pop-up node descriptor number 5.

Each node can have up to eight descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_POPUPNODE\_DESC5.

This property is read/write.

## PopupNodeDescr6Style

### Description

The style class name that will be used to control the style of the pop-up node descriptor number 6.

Each node can have up to eight descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_POPUPNODE\_DESC6.

This property is read/write.

## PopupNodeDescr7Style

### Description

The style class name that will be used to control the style of the pop-up node descriptor number 7.

Each node can have up to eight descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_POPUPNODE\_DESC7.

This property is read/write.

## PopupNodeDescr8Style

### Description

The style class name that will be used to control the style of the pop-up node descriptor number 8.

Each node can have up to eight descriptors, each with its own style.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_POPUPNODE\_DESC8.

This property is read/write.

## Style

### Description

Use this property to specify the style class that defines the overall appearance attributes of the chart . The value must be a valid style class within the style sheet specified for the chart.

This property is read/write.

### Related Links

[Styling PeopleSoft Charts](#)

## SuppressPeopleCodeOnNode

### Description

Specify whether to suppress processing, such as re-centering the chart, when a user clicks on a chart node if no PeopleCode is associated with the node.

This property takes a Boolean value: True to suppress a click on a chart node, and False otherwise.

The default value is False.

This property is read/write.

## SuppressPeopleCodeOnImage

### Description

Specify whether to suppress a processing, such as re-centering the chart, when a user clicks on a chart image if no PeopleCode is associated with the image.

This property takes a Boolean value: True to suppress a click on a chart image, and False otherwise.

The default value is False.

This property is read/write.

## UnlinkCrumbDescrStyle

### Description

Use this property to specify the style class name that will be used to control the style of the unlinkable breadcrumb.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_ORGCHART\_UNLINK\_BRDCRM.

Oracle recommends that you use the default breadcrumb unlinkable style.

This property is read/write.

## VerticalSpace

### Description

Use this property to specify the amount of space above the first level of nodes in an organization chart. If the chart has a legend, the vertical space is measured as the distance from the top of the first level of nodes to the bottom of the legend. If the chart has no legend, the vertical space is the distance from the top of the first level of nodes to the top of the chart area.

This property only applies to charts with a vertical orientation (Direction = 2).

This property takes a numeric value. The unit of measurement is pixels.

The default value is 10 pixels.

This property is read/write.

## Width

### Description

Use this property to specify the width of the chart. This property takes a numeric value. The unit of measurement is pixels.

If you try to read this property before setting it, the value returned is 0.

This property is read/write.

---

## SchemaLevel Class Properties

These properties are used by the SchemaLevel class. The properties are described in alphabetic order.

## ID

### Description

Use this property to specify the ID for the schema level.

Specify a number from 1 –  $n$ , where  $n$  is the number of schema levels defined for the chart.  $n$  must be in the range 1 – 10.

This property is read/write.

## ImageHeight

### Description

Use this property to specify the height of the node image (photo) displayed for the schema level.

Specify the height of the node image (photo) displayed, in pixels, for this schema level.

This property is read/write.

---

## RatingBoxChart Class Methods

These methods are used by the RatingBoxChart class. The methods are described in alphabetic order.

## SetLegend

### Syntax

```
SetLegend (&Array_of_String)
```

### Description

Use the SetLegend method to specify legend text. Legend text labels the images set in the RatingBoxChart class method SetLegendImg.

---

**Note:** Legend text is not automatically translated. Be sure to use translated text, such as message catalog entries.

---

### Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | Specify an already instantiated array of string, containing the text that you want to use for the legend. |

## Returns

None.

## Example

```
&LegendArray = CreateArray("A","B", "C","D");  
&oRatingBoxChart.SetLegend(&LegendArray);
```

## Related Links

[SetDataSeries](#)

[SetLegendImg](#)

# SetLegendImg

## Syntax

```
SetLegendImg(&Array_of_String)
```

## Description

Use the SetLegendImg method to specify the legend image names.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | An already instantiated array containing the names of the images that you want to use with the legend. |

## Returns

None.

# SetQuadrantSchemas

## Syntax

```
SetQuadrantSchemas(&Quadrant_Array)
```

## Description

Use the SetQuadrantSchemas method to specify an array of QuadrantSchema objects to be used with this rating box chart.

Not all quadrants within the rating box chart require a QuadrantSchema object. Moreover, the QuadrantSchema objects in the array can be specified in any order.

## Parameters

| <i>Parameter</i>           | <i>Description</i>                                       |
|----------------------------|----------------------------------------------------------|
| <i>&amp;Quadrant_Array</i> | An already instantiated array of QuadrantSchema objects. |

## Returns

None.

## Example

```
&QuadrantSchemas = CreateArray(&q_schema1, &q_schema2, &q_schema3, &q_schema4, &q_s→  
chema5, &q_schema6);  
&oRatingBoxChart.SetQuadrantSchemas(&QuadrantSchemas);
```

## Related Links

[Using the QuadrantSchema Class](#)

[QuadrantSchema Class Properties](#)

## SetRBNodeData

### Syntax

```
SetRBNodeData (&Rowset)
```

### Description

Use the SetRBNodeData method to specify the level 1 component rowset that is the source for the node data for the rating box chart.

If you make a change to the underlying data of a chart, call the SetRBNodeData method again to update the chart.

## Parameters

| <i>Parameter</i>   | <i>Description</i>                                                                                          |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <i>&amp;Rowset</i> | An already instantiated and populated component rowset object that references the rating chart node record. |

## Returns

None.

## SetRBNodeRecord

### Syntax

```
SetRBNodeRecord (Record.RecordName)
```

### Description

Use the SetRBNodeRecord method to specify the record that is to contain the node data for the rating box chart.

### Parameters

| <i>Parameter</i>  | <i>Description</i>                                            |
|-------------------|---------------------------------------------------------------|
| Record.RecordName | Specify the name of the record to be used as the node record. |

### Returns

None.

## SetXAxisLabels

### Syntax

```
SetXAxisLabels (&Array_of_String)
```

### Description

Use the SetXAxisLabels method to specify an array of labels for the x-axis.

---

**Note:** The labels will not be displayed if the ShowAxisLabels property is explicitly set to False.

---

### Parameters

| <i>Parameter</i> | <i>Description</i>                                                                                                                                                                                                                     |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| &Array_of_String | Specify an already instantiated array of string that contain the labels that you want to use for the x-axis. The array size must match the value in the XAxisBoxNum property. If they do not match, the system throws a runtime error. |

### Returns

None.

## Related Links

[ShowAxisLabels](#)

## SetYAxisLabels

### Syntax

```
SetYAxisLabels (&Array_of_String)
```

### Description

Use the SetYAxisLabels method to specify an array of labels for the y-axis.

---

**Note:** The labels will not be displayed if the ShowAxisLabels property is explicitly set to False.

---

### Parameters

| <i>Parameter</i>            | <i>Description</i>                                                                                                                                                                                                                     |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | Specify an already instantiated array of string that contain the labels that you want to use for the y-axis. The array size must match the value in the YAxisBoxNum property. If they do not match, the system throws a runtime error. |

### Returns

None.

---

## RatingBoxChart Class Properties

These properties are used by the RatingBoxChart class. The properties are described in alphabetic order.

## BoxMaxDisplayItems

### Description

Specify how many nodes are to be shown in the displayable area of the quadrant. When the number of nodes to be shown exceeds BoxMaxDisplayItems, a link labeled “View all (N)” appears at the bottom right of the quadrant, where *N* is the total number of nodes in the quadrant. The user can click the link to launch a pop-up that contains all the nodes. A scrollbar enables the user to scroll through all the nodes in the list.

Only one pop-up window will appear in the rating box chart, so when the user clicks another “View all (N)” link in another quadrant, the previous pop-up window closes and the new pop-up window opens at the center of the quadrant.

If an invalid (negative) value is specified, an error will be thrown at runtime.

The default value is 1.

This property is read/write.

## DraggedNodeStyle

### Description

Use this property to specify the style class that controls the appearance of a node as it is being dragged.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_RATBOX\_DRAGGED\_NODE.

This property is read/write.

### Related Links

[Styling PeopleSoft Charts](#)

## EnableRelatedActions

### Description

Specify a Boolean value indicating whether a user can click on a node in the rating box chart to invoke related actions on the node. The default value is False.

To enable related actions on a rating box chart, you must do the following:

- Set the IsDragable property to False.
- Set the EnableRelatedActions property to True.
- Use the Manage Related Content Service component to configure related actions on the PTCHART\_NODE page field of the page displaying the rating box chart.

### Related Links

[IsDragable](#)

“Assigning Related Content to Classic Components and Pages” (Portal Technology)

## GridLineType

### Description

Use this property to specify the style of the grid lines.

The default value is %ChartLine\_Solid. The possible values are:

| <b>Value</b>     | <b>Description</b>                             |
|------------------|------------------------------------------------|
| %ChartLine_Solid | Draw grid lines with solid lines.              |
| %ChartLine_Dash  | Draw grid lines with lines composed of dashes. |
| %ChartLine_Dot   | Draw grid lines with lines composed of dots.   |

This property is read/write.

## HasLegend

### Description

Use this property to specify if a legend appears with the chart. This property takes a Boolean value: True if the legend appears with the chart, and False otherwise.

The default value is False.

This property is read/write.

## Height

### Description

Use this property to specify the height of the chart. This property takes a numeric value. The unit of measurement is pixels.

The default value is the height of the chart control on the page definition.

If you set a chart height value that cannot fit the x-axis and label areas of the chart, a runtime error is thrown and the chart is not rendered.

If you set a negative value, a runtime error is thrown and the chart is not rendered.

If you try to read this property before setting it, the value returned is 0.

This property is read/write.

**Related Links**

[Height](#)

**IconOnlySelectedQuadrantStyle**

**Description**

Use this property to specify the style class that controls the appearance of border properties of the selected quadrant of an icon-only rating box chart when the system displays the view all pop-up.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default is PT\_RATBOX\_ICONONLY\_BOX.

This property is read/write.

**Related Links**

[Styling PeopleSoft Charts](#)

**IsDragable**

**Description**

Specify whether nodes in the rating box chart can be dragged and dropped. If the property is specified as *True*, then user will be able to drag a node in the rating box chart and drop it to another quadrant. If the property is *False*, then the drag and drop action is disabled.

The default value is *True*.

This property is read/write.

**Related Links**

[Height](#)

**LegendPosition**

**Description**

Use this property to specify where the legend should appear in relationship to the chart. You can specify either a numeric or constant value for this property.

The values are:

| <i><b>Numeric Value</b></i> | <i><b>Constant Value</b></i> | <i><b>Description</b></i>               |
|-----------------------------|------------------------------|-----------------------------------------|
| 2                           | %ChartLegend_Top             | Display legend at the top of the chart. |

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b>       |
|-----------------------------|------------------------------|---------------------------------|
| 3                           | %ChartLegend_Bottom          | Display legend below the chart. |

If you set a value other than 2 or 3, a runtime error is thrown and the chart is not rendered.

This property is read/write.

## MainTitle

### Description

Use this property to specify the text for the main title of the chart.

This property takes a string value.

This property is read/write.

## MainTitleStyle

### Description

Use this property to specify the style of the main title. The values for this property are the style classes contained in the style sheet associated with the chart.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_RATBOX\_TITLE.

This property is read/write.

## NDMaxDisplayDescLength

### Description

Specify the maximum number of characters that will display for the description.

When the ShowNodeDescription chart property is set to True, then both the icon and the description of the node will appear in the quadrant.

If the description is larger than NDMaxDisplayDescLength then the node displays the number of characters specified in NDMaxDisplayDescLength, followed by an ellipsis.

If the full node description or the number of characters specified in NDMaxDisplayDescLength cannot fit in a quadrant at runtime the description is automatically truncated. An ellipsis (...) follows the truncated text.

You only need to set this property if you want the truncated text to be less than the automatically truncated text.

When the user mouses over the truncated node description, the whole text displays in a data hint.

If an invalid (negative) value is specified, an error will be thrown at runtime.

The default value is 50.

This property is read/write.

## PopUpHeaderStyle

### Description

Use this property to specify the style class that controls the appearance of the pop-up header.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_RATBOX\_POPUP\_HEADER.

This property is read/write.

### Related Links

[Styling PeopleSoft Charts](#)

## PopUpHeight

### Description

Specify the height of the pop-up chart in pixels.

This parameter takes a number value.

The recommended value is half of the rating box chart height.

If you set a pop-up chart height value that cannot fit the x-axis area of the popup chart, a runtime error is thrown.

The default value is 0. If a negative value is specified, an error will be thrown at runtime.

This property is read/write.

## PopUpStyle

### Description

Use this property to specify the style class that controls the appearance of the pop-up.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_RATBOX\_POPUP.

This property is read/write.

### **Related Links**

[Styling PeopleSoft Charts](#)

## **PopUpWidth**

### **Description**

Specify the width of the pop-up chart in pixels.

This parameter takes a number value.

The recommended value is half of the rating box chart width.

If you set a pop-up chart width value that cannot fit the y-axis area of the popup chart, a runtime error is thrown.

The default value is 0. If a negative value is specified, an error will be thrown at runtime.

This property is read/write.

## **SelectedQuadrantStyle**

### **Description**

Use this property to specify the style class that controls the appearance of the quadrant when it is selected.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_RATBOX\_SELECTED\_BOX.

This property is read/write.

### **Related Links**

[Styling PeopleSoft Charts](#)

## **ShowAxisLabels**

### **Description**

Specify a Boolean value indicating whether the rating box chart should show the x- and y-axis labels. The default value is True.

This property is read/write.

## Related Links

[SetXAxisLabels](#)

[SetYAxisLabels](#)

## ShowNodeDescription

### Description

Specify whether the chart should show the node description. This property takes a Boolean value.

| <i><b>Value</b></i> | <i><b>Description</b></i>                          |
|---------------------|----------------------------------------------------|
| True                | Both the icon and description for the node appear. |
| False               | Only the icon for the node appears.                |

The default value is True.

This property is read/write.

## Style

### Description

Use this property to specify the style class that defines the overall appearance attributes of the chart . The value must be a valid style class within the style sheet specified for the chart.

This property is read/write.

## Related Links

[Styling PeopleSoft Charts](#)

## ViewAllStyle

### Description

Use this property to specify the style class that controls the appearance of the **View All** link.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_RATBOX\_VIEWALL\_DESCR.

This property is read/write.

## Related Links

[Styling PeopleSoft Charts](#)

## Width

### Description

Use this property to specify the width of the chart. This property takes a numeric value. The unit of measurement is pixels.

The default value is the width of the chart control on the page definition.

If you set a chart width value that cannot fit the y-axis and label areas of the chart, a runtime error is thrown.

If a negative value is specified, an error will be thrown at runtime and the chart will not be rendered.

If you try to read this property before setting it, the value returned is 0.

This property is read/write.

## XAxisBoxNum

### Description

Specify the number of quadrants in the x-axis.

This property is required. The value must be equal to or greater than 1.

If a value less than 1 is specified, an error will be thrown at runtime.

This property is read/write.

## XAxisLabelStyle

### Description

Use this property to specify the style of the x-axis label. The values for this property are the style classes contained in the style sheet associated with the chart.

The values for this property are controlled by the specified style class in the style sheet associated with the chart.

The default style class is PT\_RATBOX\_XAXIS.

This property is read/write.

## Related Links

**LabelPosition****Description**

Use this property to specify the position for the label for this quadrant as a Integer. You can specify either an Integer or constant value for this property.

The values are:

| <b><i>Numeric Value</i></b> | <b><i>Constant Value</i></b> | <b><i>Description</i></b>                                      |
|-----------------------------|------------------------------|----------------------------------------------------------------|
| 0                           | %Top_Left                    | Position the label in the top left corner of the quadrant.     |
|                             |                              | <b>Note:</b> %Top_Left is the default value.                   |
|                             |                              |                                                                |
| 1                           | %Top_Right                   | Position the label in the top right corner of the quadrant.    |
| 2                           | %Bottom_Left                 | Position the label in the bottom left corner of the quadrant.  |
| 3                           | %Bottom_Right                | Position the label in the bottom right corner of the quadrant. |

This property is read/write.

## LabelStyle

### Description

Use this property to specify a style class for the label for this quadrant as a String. The default value is PT\_RATBOX\_LABEL.

This property is read/write.

## LabelText

### Description

Use this property to specify a label for this quadrant as a String.

This property is read/write.

## XRating

### Description

Use this property to specify the x rating for this quadrant as a String. The value for this property needs to be in the array of values for the x-axis specified by the SetXAxisLabels method; otherwise, a runtime error occurs.

This property is read/write.

## Timeline Class Methods

In this section, the Timeline class methods are presented in alphabetical order.

## SetData

### Syntax

```
SetData ({Record_Name | &Rowset})
```

### Description

Use the SetData method to specify where the data for the chart is coming from.

You can use either a record name or an already instantiated, populated rowset. In general, specify a record when building a chart from page data and a rowset when building a chart from a standalone rowset.

If you make a change to the underlying data of a chart, call the SetData method again to update the chart.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name</i>      | Specify the name of a record to be used to populate the timeline with data.                                                   |
| <i>&amp;Rowset</i>      | Specify the name of an already instantiated rowset to populate the timeline with data. This is generally a standalone rowset. |

### Returns

None.

## Example

```
&oChart.SetData(Record.QE_COL_MULTI_2Y);
```

## SetDataSeries

### Syntax

```
SetDataSeries(Record_Name.Field_Name)
```

### Description

Use the SetDataSeries method to specify the identifier for the timeline series. Every distinct value in this field is considered a unique series. Only a maximum of two series is allowed.

### Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record and the field on that record that contains the series values for a timeline item. |

### Returns

None.

### Example

```
&oChart.SetDataSeries(RECORD.FIELD);
```

## SetDataItemStart

### Syntax

```
SetDataItemStart(Record_Name.Field_Name)
```

### Description

Use the SetDataItemStart method to specify the Datetime field in the record that defines the start time for a timeline item.

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                                                               |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record and the field on that record that contains the start time value for a timeline item. The field must be of type Datetime. |

## Returns

None.

## Example

```
&oChart.SetDataItemStart (RECORD.FIELD) ;
```

## SetDataItemDescription

### Syntax

```
SetDataItemDescription (Record_Name.Field_Name)
```

### Description

Use the SetDataItemDescription method to specify the description for a timeline item.

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record and the field on that record, which contains the description of a timeline item. |

## Returns

None.

## Example

```
&oChart.SetDataItemDescription (RECORD.FIELD) ;
```

## SetDataItemTitle

### Syntax

```
SetDataItemTitle (Record_Name.Field_Name)
```

## Description

Use the `SetDataItemTitle` method to specify the title text to display for a time line item.

## Parameters

| <i><b>Parameter</b></i>       | <i><b>Description</b></i>                                                                                   |
|-------------------------------|-------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name</i> | Specify the name of the record and the field on that record, which contains the title for a time line item. |

## Returns

None.

## Example

```
&oChart.SetDataItemTitle(RECORD.FIELD);
```

## SetSeriesEmptyText

### Syntax

```
SetSeriesEmptyText (&Array_of_String)
```

### Description

Use the `SetSeriesEmptyText` method to specify the text to display for an empty timeline series. For a timeline with only one series, use the *TimelineEmptyText* property.

## Parameters

| <i><b>Parameter</b></i>     | <i><b>Description</b></i>                                                                                                  |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | Specify an already instantiated array of string containing the text that you want to display for an empty timeline series. |

## Returns

None.

## Example

```
&oChart.SetSeriesEmptyText(CreateArray("Timeline Empty 1", "Timeline Empty 2"));
```

## Related Links

[TimelineEmptyText](#)

## SetSeriesLabels

### Syntax

```
SetSeriesLabels (&Array_of_String)
```

### Description

Use the SetSeriesLabels method to specify the labels to display for a timeline series. For a timeline with only one series, use the *TimelineLabel* property.

### Parameters

| <i>Parameter</i>            | <i>Description</i>                                                                                        |
|-----------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>&amp;Array_of_String</i> | Specify an already instantiated array of string containing the labels to display for the timeline series. |

### Returns

None.

### Example

```
&oChart.SetSeriesLabels(CreateArray("TimeLine Series 1", "TimeLine Series 2"));
```

## Timeline Class Properties

In this section, the TimeLine class properties are presented in alphabetical order.

### AspectRatio

#### Description

Use this property to specify a Float value indicating the height of the chart as a proportion of its width.

If the aspect ratio is not defined, a default value of 1 is used on fluid pages.

---

**Note:** AspectRatioPortrait is ignored on classic pages; instead, the height is determined by the height of the chart page control defined in Application Designer or by the Height and Width properties.

---

This property is read/write.

## Example

```
&oChart.AspectRatio = 0.8;
```

## End

### Description

Use this property to specify the end time for the timeline. The value must be of type Date or DateTime.

This property is read/write, and is required.

### Example

```
&oChart.End = "2019-01-13 11:00:00";
```

## Height

### Description

On a classic page, use this property to specify a number value indicating the height of the timeline in pixels.

This property is read/write.

### Example

```
&oChart.Height = 800;
```

### Related Links

[Width](#)

[AspectRatio](#)

## MajorAxisScale

### Description

Use this property to specify a string value indicating the time scale of the major axis.

The values are case sensitive, and it should be in lower case. The valid values are:

- days
- hours
- minutes
- months
- quarters

- seconds
- weeks
- years

If a value is not specified, the axis labels are not displayed above the minor axis or in the overview.

This property is read/write, and is required.

### Example

```
&oChart.MajorAxisScale = "quarters";
```

## MinorAxisScale

### Description

Use this property to specify a string value indicating the time scale of the minor axis.

The values are case sensitive, and it should be in lower case. The valid values are:

- days
- hours
- minutes
- months
- quarters
- seconds
- weeks
- years

If a value is not specified, the chart is not rendered.

This property is read/write, and is required.

### Example

```
&oChart.MinorAxisScale = "weeks";
```

## MinorAxisZoomOrder

### Description

An array of strings containing the names of scales used for zooming from longest to shortest.

This property is read/write.

## Example

```
oChart.MinorAxisZoomOrder = CreateArray("quarters", "months", "weeks", "days");
```

## Orientation

### Description

Use this property to specify whether the timeline is displayed horizontally or vertically. You can specify a constant value for this property.

Valid values are:

- %Chart\_Horizontal - The timeline is displayed horizontally.
- %Chart\_Vertical - The timeline is displayed vertically.

This property is read/write.

### Example

```
&oChart.Orientation = %Chart_Vertical;
```

## Start

### Description

Use this property to specify the start time for the timeline. The value must be of type Date or DateTime.

This property is read/write, and is required.

### Example

```
&oChart.Start= "2015-01-13 11:00:00";
```

### Related Links

[End](#)

## TimelineEmptyText

### Description

Use this property to specify the text for an empty timeline series. For a timeline with more than one series, use the *SetSeriesEmptyText* method.

This property is read/write.

### Related Links

## Charting Examples

This section includes example of charts, with the PeopleCode used to create them.

### Creating a Chart Using the Chart Class

This section demonstrates how to create a simple chart based on the Chart class. This chart is meant to be used to demonstrate basic principles of creating charts and give an opportunity to experiment with different chart types. It is not typical of how a chart is used in PeopleSoft applications.

The first six steps also apply to creating charts using the Gantt class, the OrgChart class, and the RatingBoxChart class.

The steps to create a chart are:

1. Place a chart control on a page.
2. Associate the chart control with a record field.
3. Create the chart data record.
4. Add PeopleCode to instantiate a chart object.
5. Set the data source.
6. View the page in the browser.
7. Add data for the chart.
8. Specify the series data.
9. Specify chart colors.
10. Add text elements.
11. Review the complete program.

### **Placing a Chart Control on a Page**

In Application Designer, create a new page.

Select Insert, Chart and draw a rectangle to represent the area the chart will occupy. The chart can be any size, and you can have more than one chart on a page.

Place the page on a component and register the component.

## Associating the Chart Control with a Record Field

Each chart on a component must be associated with a unique field. Double-click the chart control to access the Chart Properties dialog box and enter a record name and field name.

The chart field has no special requirements. Its only purpose is to provide a reference to the field in PeopleCode.

This sample chart uses a derived/work record named DOC\_CHRT\_WRK that is dedicated to this purpose.

## Creating the Chart Data Record

The chart needs either a record or a rowset to serve as the data source. This sample chart uses a record. See the Chart class `SetData` method for details about using a rowset.

See [SetData](#).

At a minimum, the record must have fields for the x-axis data and the y-axis data. Optionally, the record can have fields for series data, chart color, and glyph size.

| PB_CHART_RECORD (Record) |                    |      |     |      |     |      |             |      |     |      |      |        |         |
|--------------------------|--------------------|------|-----|------|-----|------|-------------|------|-----|------|------|--------|---------|
| Record Fields            |                    |      |     |      |     |      | Record Type |      |     |      |      |        |         |
| Num                      | Field Name         | Type | Key | Ordr | Dir | CurC | Srch        | List | Sys | Audt | InTy | EnTypA | Default |
| 1                        | PB_CHART_PRODUCT   | Char | Key | 1    | Asc |      | No          | No   | No  |      | No   | No     |         |
| 2                        | PB_CHART_REGION    | Char | Key | 2    | Asc |      | No          | No   | No  |      | No   | No     |         |
| 3                        | PB_CHART_SALES     | Sign |     |      |     |      | No          | No   | No  |      | No   | No     |         |
| 4                        | PB_CHART_DESC      | Char |     |      |     |      | No          | No   | No  |      | No   | No     |         |
| 5                        | PB_CHART_COLOR     | Nbr  |     |      |     |      | No          | No   | No  |      | No   | No     |         |
| 6                        | PB_CHART_X_NUMERIC | Sign |     |      |     |      | No          | No   | No  |      | No   | No     |         |
| 7                        | PB_CHART_GLYPHSCLE | Sign |     |      |     |      | No          | No   | No  |      | No   | No     |         |

The record must be available in the component buffer at runtime. You can use a database record that is already part of your application or you can use a derived/work record or a component rowset that you populate at runtime. For greatest control, you will normally populate your record or rowset at runtime.

For the sample chart, place the record on a grid on a second page on the sample component. This placement gives you the opportunity to experiment with the data.

Your chart data record must be placed at level 1 on the same component as the chart so that the data is available in the component buffer at runtime. In your application, you can hide the grids or scroll areas that hold the records. For the sample chart, you will keep the grid visible so you can enter sample data.

| PB_CHART_DATA (Page) |         |        |       |             |
|----------------------|---------|--------|-------|-------------|
| Layout               |         | Order  |       |             |
|                      | Product | Region | Sales | Chart Color |
| 1                    |         |        |       |             |
| 2                    |         |        |       |             |
| 3                    |         |        |       |             |
| 4                    |         |        |       |             |
| 5                    |         |        |       |             |
| 6                    |         |        |       |             |
| 7                    |         |        |       |             |

Adding PeopleCode to Instantiate a Chart Object

This example instantiates a chart object using the Chart class, so it can be used to create bar charts, line charts, pie charts, and so on. Other examples in this section demonstrate how to create charts based on the Gantt class, OrgChart class, and RatingBoxChart class.

See [Creating a Gantt Chart](#), [Creating a Rating Box Chart](#).

Add this PeopleCode to the Activate event on the page:

```
/* Declare and instantiate a chart object */
Component Chart &cChart;

&cChart = GetChart(DOC_CHRT_WRK.DOC_CHRT_FLD);
```

Chart PeopleCode is commonly placed on the Activate event, but it can be placed on any appropriate event. You could, for instance, execute the chart PeopleCode from a FieldChange event associated with a push button.

## Setting the Data Source

The SetData method takes either a record or a rowset as an argument. In general, specify a record or component rowset when building a chart from page data and a standalone rowset when building a chart using an iScript.

In this example, the PeopleCode sets Product as the series data and sets Region to the x-axis, so that in a bar chart products will be grouped along the x-axis by region. In a line chart, each series is represented by a line. Sales figures are charted on the y-axis.

---

**Note:** SetData, SetDataXAxis, and SetDataYAxis are Chart class methods. The other charting classes provide equivalent methods to specify data sources.

---

```
/* Set the chart data record and specify x-axis, y-axis, and series data */

&cChart.SetData(Record.DOC_CHRT_SLSREC);
&cChart.SetDataXAxis(DOC_CHRT_SLSREC.DOC_CHRT_RGN);
&cChart.SetDataYAxis(DOC_CHRT_SLSREC.DOC_CHRT_SALES);
```

See [SetData](#), [SetDataSeries](#), [SetDataXAxis](#), [SetDataYAxis](#), [Creating a Chart Using an iScript](#).

## Viewing the Page in the Browser

This is the most basic Chart class chart. It has no data and only the default y-axis.

## Adding Data for the Chart

Add the following data to the chart:

| <b>Region</b> | <b>Sales</b> |
|---------------|--------------|
| Arizona       | 60           |
| California    | 55           |
| Oregon        | 50           |
| Washington    | 45           |

This bar chart is generated by the example code and data:

This chart graphs sales on the y-axis (the vertical axis) and regions on the x-axis (the horizontal axis).

When the data for the chart is grouped according to values, a set of data representing a single value is called a *series*. For instance, if a chart shows sales for different products in each region, then the set of data for each product is a series.

At this point, the chart has only one series, so you do not need to set the series record field.

## Specify the Series Data

If you want to graph more than one product on your chart, you need to specify the source of the series data.

For example, add the products shown in this table to your data:

| <b>Product</b> | <b>Region</b> | <b>Sales</b> |
|----------------|---------------|--------------|
| Footballs      | Arizona       | 60           |
| Rackets        | Arizona       | 50           |

| <b>Product</b> | <b>Region</b> | <b>Sales</b> |
|----------------|---------------|--------------|
| Shoes          | Arizona       | 42           |
| Tents          | Arizona       | 35           |
| Footballs      | California    | 55           |
| Rackets        | California    | 46           |
| Shoes          | California    | 30           |
| Tents          | California    | 35           |
| Footballs      | Oregon        | 50           |
| Rackets        | Oregon        | 40           |
| Shoes          | Oregon        | 30           |
| Tents          | Oregon        | 25           |
| Footballs      | Washington    | 45           |
| Rackets        | Washington    | 30           |
| Shoes          | Washington    | 20           |
| Tents          | Washington    | 15           |

Add this PeopleCode to set the series record field:

```
&cChart.SetDataSeries(DOC_CHRT_SLSREC.DOC_CHRT_PRDCT);
```

The resulting chart is a default 2D bar chart with bars for each region grouped by series:

The chart has four series:

- Footballs
- Rackets
- Shoes
- Tents

Each series shows four regions along the x-axis:

- Arizona
- California
- Oregon
- Washington

Sales values appear against the y-axis as bar height.

The chart uses the default colors.

**Specifying Chart Colors**

If you do not want to use the default colors, you need a column containing the colors for each bar. Typically, the bars in a series are colored alike.

| <i>Product</i> | <i>Region</i> | <i>Sales</i> | <i>Chart Color</i> |
|----------------|---------------|--------------|--------------------|
| Footballs      | Arizona       | 60           | 1                  |

| <b>Product</b> | <b>Region</b> | <b>Sales</b> | <b>Chart Color</b> |
|----------------|---------------|--------------|--------------------|
| Footballs      | California    | 55           | 1                  |
| Footballs      | Oregon        | 50           | 1                  |
| Footballs      | Washington    | 45           | 1                  |
| Rackets        | Arizona       | 50           | 13                 |
| Rackets        | Oregon        | 46           | 13                 |
| Rackets        | Washington    | 40           | 13                 |
| Rackets        | California    | 30           | 13                 |
| Shoes          | Arizona       | 42           | 5                  |
| Shoes          | California    | 30           | 5                  |
| Shoes          | Oregon        | 30           | 5                  |
| Shoes          | Washington    | 20           | 5                  |
| Tents          | Arizona       | 35           | 15                 |
| Tents          | California    | 35           | 15                 |
| Tents          | Oregon        | 25           | 15                 |
| Tents          | Washington    | 15           | 15                 |

Add the following PeopleCode to your program to set the colors for your chart:

```
/* Associate color field with chart */
&cChart.SetDataColor(DOC_CHRT_SLSREC.DOC_CHRT_COLOR);
```

## Adding Text Elements

The following PeopleCode adds these elements to your chart:

- Title

- Legend
- Y-axis title
- X-axis title

```
/* Set title and legend properties */
&cChart.MainTitle = "Recreational Product Sales by Region";
&cChart.HasLegend = True;
&cChart.LegendPosition = %ChartLegend_Right;

/* Set axis text properties */
&cChart.XAxisTitle = "Region";
&cChart.YAxisTitle = "Sales";
```

This is the resulting chart:

## Reviewing the Complete Program

The PeopleCode for this bar chart has been presented in snippets. Here is the complete program that produced the chart:

```
/* Declare and instantiate a chart object */
Component Chart &cChart;

&cChart = GetChart(DOC_CHRT_WRK.DOC_CHRT_FLD);

/* Set the chart data record and specify x-axis, y-axis, and series
data */

&cChart.SetData(Record.DOC_CHRT_SLSREC);
&cChart.SetDataXAxis(DOC_CHRT_SLSREC.DOC_CHRT_RGN);
&cChart.SetDataYAxis(DOC_CHRT_SLSREC.DOC_CHRT_SALES);
&cChart.SetDataSeries(DOC_CHRT_SLSREC.DOC_CHRT_PRDCT);

/* Associate color field with chart */
&cChart.SetDataColor(DOC_CHRT_SLSREC.DOC_CHRT_COLOR);

/* Set title and legend properties */
&cChart.MainTitle = "Recreational Product Sales by Region";
&cChart.HasLegend = True;
&cChart.LegendPosition = %ChartLegend_Right;

/* Set axis text properties */
```

```
&cChart.XAxisTitle = "Region";  
&cChart.YAxisTitle = "Sales";
```

## Other Modifications

The remainder of this section shows the effects of modifying other aspects of your chart.

## Changing X-Axis and Series Values

```
&cChart2.SetDataXAxis(DOC_CHRT_SLSREC.DOC_CHRT_PRDCT);  
&cChart2.SetDataSeries(DOC_CHRT_SLSREC.DOC_CHRT_RGN);  
  
&cChart2.MainTitle = "Recreational Product Sales by Product";  
&cChart2.XAxisTitle = "Product";
```

To group sales by product instead of by region, switch the series and the x-axis. You will also need to reorder colors to correspond to regions instead of products:

## Axis Properties

If your chart has negative values, the bars automatically extend below the x-axis:

If you want to remove the tick marks from the x- or y-axis, you need to specify an empty array for the `SetXAxisLabels` or `SetYAxisLabels` methods.

The following example removes the tick marks from the y-axis:

```
Local array of string &Arr;

&Arr = CreateArray("");
&Chart.SetYAxisLabels(&Arr);
```

If you set the x-axis labels to an empty array to remove the ticks, you must be plotting a single series on the chart because labels are automatically generated for each series if you do not provide them.

See [SetXAxisLabels](#), [SetYAxisLabels](#).

You can also use the `XAxisMin`, `XAxisMax`, `YAxisMin`, `YAxisMax`, and other axis properties to control the appearance of the axes.

See [XAxisLabelOrient](#), [YAxisLabelOrient](#), [YAxisMax](#), [YAxisMin](#)

## Chart Class Chart Types

Use the `Type` property to set the chart type.

### 2D Bar Chart

```
&cChart.Type=%ChartType_2DBar;
```

The default Chart class chart type is a 2D bar chart:

The following examples show the various chart types using the same data. Each example gives the PeopleCode snippet that creates that chart type.

For a complete list of all Chart class chart types, see Chart class Type property.

See [Type](#).

The Charting Examples section provides other examples of PeopleCode for charts using Gantt class, OrgChart class, and RatingBoxChart class at the end of the chapter.

See [Creating a Gantt Chart](#), [Creating a Rating Box Chart](#).

## Horizontal Bar Chart

Use this line of code to specify a horizontal bar chart:

```
&cChart.Type = %ChartType_2DHorizBar;
```

This example illustrates a horizontal bar chart:

## Stacked Bar Chart

With a the stacked bar chart, you can place a different emphasis on the same data. The stacked column shows total sales per region as well as the product segments that contribute to the total.

Use this line of code to specify a stacked bar chart:

```
&cChart.Type = %ChartType_2DStackedBar;
```

This example illustrates a stacked bar chart:

## Horizontal Stacked Bar Chart

Use this line of code to specify a horizontal stacked bar chart:

```
&cChart.Type = %ChartType_2DHorizStackedBar;
```

This example illustrates a horizontal stacked bar chart:

## Percent Bar Chart

A percent bar is similar to a stacked bar, but the segments of each bar add up to 100. The segments show the proportional contribution of each product to total sales.

---

**Note:** Negative values cannot be displayed in any type of percent bar chart.

---

Use this line of code to specify a stacked percent bar chart:

```
&cChart.Type = %ChartType_2DPercentBar;
```

This example illustrates a percent bar chart:

## Horizontal Percent Bar Chart

**Note:** Negative values cannot be displayed in any type of percent bar chart.

Use this line of code to specify a horizontal percent bar chart:

```
&cChart.Type = %ChartType_2DHorizPercentBar;
```

This example illustrates the fields and controls on a horizontal percent bar chart:

## Line Chart

A line chart is useful for showing changes and trends over time or across categories.

Use this line of code to specify a line chart:

```
&cChart.Type = %ChartType_2DLine;
```

This example illustrates a line chart:

## Overlay Chart

You can overlay one chart on top of another to compare two different but related sets of data. The following chart uses a second set of data, showing average temperature for each region.

Use the `OLType` property to specify whether the overlay is a line chart or a histogram.

Add this PeopleCode to the PeopleCode for your bar chart to create 2D line chart overlay:

```
/* Create Overlay */
&cChart3.SetOLData(Record.DOC_CHRT_OLREC);
rem &cChart.SetOLDataSeries(DOC_CHRT_OLREC.SC_CHART_SERIES);
&cChart3.SetOLDataXAxis(DOC_CHRT_OLREC.DOC_CHRT_RGN);
&cChart3.SetOLDataYAxis(DOC_CHRT_OLREC.DOC_CHRT_SALES);
&cChart3.OLType = %ChartType_2DLine;
```

This example illustrates a 2D line chart overlay on a vertical bar chart:

## Scatter Chart

Use this line of code to specify a scatter chart:

```
&cChart.Type = %ChartType_2DScatter;
```

A scatter chart compares number pairs. Each pair is plotted against the horizontal x-axis and the vertical y-axis. The data values are scattered across the chart. XY scatter charts are good for showing comparisons of numbers, such as scientific or statistical data, where several measurements need to be plotted on a single chart.

A scatter chart is a true XY chart, meaning that the x-axis is numeric. The `IsTrueXY` property is automatically set to `True`.

For example, this sample data could be used to make an XY scatter chart:

| <i><b>Tenure</b></i> | <i><b>Salary</b></i> |
|----------------------|----------------------|
| 11                   | 88000                |

| <i><b>Tenure</b></i> | <i><b>Salary</b></i> |
|----------------------|----------------------|
| 12.2                 | 96200                |
| 4.6                  | 101300               |
| 6.6                  | 83000                |
| 14                   | 111200               |
| 8.5                  | 118000               |

You use this code snippet to make a scatter chart:

```
&cChart5.Type = %ChartType_2DScatter;
&cChart5.SetData(Record.DOC_CHRT_XYDATA);
&cChart5.SetDataXAxis(DOC_CHRT_XYDATA.DOC_CHRT_X);
&cChart5.SetDataYAxis(DOC_CHRT_XYDATA.DOC_CHRT_Y);
```

This example illustrates the scatter chart for the preceding data:

**Note:** If you have only one point of data, that is, only one x and y pair, use a scatter chart. You may have unexpected results if you use a line chart with only one point.

## Bubble Chart

A bubble chart is a special type of scatter chart.

If you add a third data set, the z-axis, to a scatter chart, you can create a bubble chart, which uses the size of the markers to represent a third dimension of numeric data.

You can also set annotations for scatter charts and bubble charts.

This chart example uses Age to determine the size of the bubble markers on the chart and Name to set the annotations:

| <b><i>Tenure</i></b> | <b><i>Salary</i></b> | <b><i>Age</i></b> | <b><i>Name</i></b> |
|----------------------|----------------------|-------------------|--------------------|
| 11                   | 88000                | 39                | Joyce              |
| 12.2                 | 96200                | 55                | Tolstoy            |
| 4.6                  | 101300               | 32                | Shelley            |
| 6.6                  | 83000                | 48                | Tolkien            |
| 14                   | 111200               | 59                | Dickens            |
| 8.5                  | 118000               | 49                | Hemingway          |

```
&cChart6.Type = %ChartType_2DBubble;
&cChart6.SetData(Record.DOC_CHRT_XYDATA);
&cChart6.SetDataXAxis(DOC_CHRT_XYDATA.DOC_CHRT_X);
&cChart6.SetDataYAxis(DOC_CHRT_XYDATA.DOC_CHRT_Y);
&cChart6.SetDataZAxis(DOC_CHRT_XYDATA.DOC_CHRT_AGE);
&cChart6.SetDataAnnotations(DOC_CHRT_XYDATA.DOC_CHRT_LASTNAME);
```

This example illustrates the bubble chart for the preceding data:

## Pie Chart

A pie chart shows comparisons within a single set of values, and it shows how parts contribute to a whole. It is an ideal chart type to display the contribution of each region to an annual sales total.

A pie chart ignores the series and only plots x-axis data against y-axis values. Our original bar chart has four regions times four products, resulting in 16 XY pairs. A pie chart with all of those slices would be confusing and not helpful. Instead, suppose you want to show just the data for tents, which are in rows 13–16. You can use a combination of the `DataWidth` and `DataStartRow` properties to select which rows to display.

You can make a pie chart showing only rows 13–16 by adding this snippet of code:

```
&cChart.DataWidth = 4;  
&cChart.DataStartRow = 13;  
&cChart.Type = %ChartType_2DPie;
```

This example illustrates a 2D pie chart generated from a portion of the rowset:

## Exploded Pie Chart

Use the `SetExplodedSectorsArray` Chart class method to specify the sectors to explode. Sectors correspond to rows of data used by the pie chart. Sector 1 is the first row of data, or the row specified with the `DataStartRow` chart class property, if it is used, and so on.

The following snippet of code explodes sectors 1 and 3:

```
Local array of number &ExplodedArray;  
&ExplodedArray = CreateArray(1,3);  
&cChart.SetExplodedSectorsArray(&ExplodedArray);
```

This example illustrates an exploded pie chart:

See the [SetExplodedSectorsArray](#) property.

### 3D Pie Chart

Use this line of code to specify a 3D pie chart:

```
&cChart.Type = %ChartType_3DPie;
```

This example illustrates a 3D pie chart.

### Adding Drilldown

If you set the property `IsDrillable` to `True` and add `FieldChange` PeopleCode to your chart, your user can get more information by clicking a chart data element—a bar, line segment, data point, or pie slice.

For a simple example, add this PeopleCode to the `FieldChange` event on the y-axis field:

```
MessageBox(0, "", 0, 0, "Sales for " | DOC_CHRT_SLSREC.DOC_CHRT_PRDCT | " in " | DO⇒  
C_CHRT_SLSREC.DOC_CHRT_RGN | " = " | DOC_CHRT_SLSREC.DOC_CHRT_SALES | "");
```

And add this code to the page `Activate` event for your pie chart:

```
&cChart.IsDrillable = True;
```

When the user clicks the Arizona slice of the pie chart, this message appears:

Current context provides the values for fields in the current row in the component buffer. You can use drilldown with your chart data fields along with any other data in the component buffer to accomplish anything `FieldChange` PeopleCode is capable of.

If the bars on a bar chart are too narrow, a user may not be able to click them. Sometimes, a few bars on a chart are affected, sometimes all of the bars cannot be clicked. The workaround is to put fewer bars on your chart or to make your chart bigger so that each bar is wider.

See [IsDrillable](#).

Using the Other Charting Classes

In addition to the all the charts you can create with the Chart class, you can create specialized charts using the Gantt class, the OrgChart class, and the RatingBoxChart class.

You follow the same initial steps to create these specialized charts as you do for the Chart class chart types. The PeopleCode programs to set the data and properties are similar as well, but Gantt charts, organization charts, and rating box charts use data differently and interact with the user in different ways than do the Chart class charts.

See [Creating a Gantt Chart](#)[Creating a Gantt Chart](#), [Creating a Rating Box Chart](#).

Creating a Gantt Chart

The PeopleCode and data used in this example create the following Gantt chart:

This example uses the following data in the record QE\_GANTT\_TASK:

This example illustrates Gantt task data:

| Tasks    |        |                   |                       |                       |
|----------|--------|-------------------|-----------------------|-----------------------|
| 'Task ID | 'Level | TASK NAME         | 'PLANNED START DATE   | 'PLANNED END DATE     |
| 1        | 1      | Birth             | 01/01/1963 12:00:00AM | 01/01/1963 12:00:00AM |
| 2        | 1      | Baby              | 01/01/1963 12:00:00AM | 06/30/1964 12:00:00AM |
| 3        | 2      | Toddler           | 07/01/1964 12:00:00AM | 07/01/1966 12:00:00AM |
| 4        | 1      | Childhood         | 07/01/1966 12:00:00AM | 09/01/1980 12:00:00AM |
| 5        | 2      | Elementary School | 09/01/1968 12:00:00AM | 06/01/1973 12:00:00AM |
| 6        | 2      | Middle School     | 09/01/1973 12:00:00AM | 06/01/1976 12:00:00AM |
| 7        | 2      | High School       | 09/01/1976 12:00:00AM | 06/01/1980 12:00:00AM |
| 8        | 2      | Graduate          | 06/20/1980 12:00:00AM | 06/20/1980 12:00:00AM |
| 9        | 1      | Adult             | 09/02/1980 12:00:00AM | 12/31/1983 12:00:00AM |
| 10       | 1      | End of Life       | 01/01/1987 12:00:00AM | 01/01/1987 12:00:00AM |

The chart also uses the following dependency data in the record QE\_GANTT\_TASKD:

This example illustrates Gantt dependency data:

| Dependencies |                |                 |                       |
|--------------|----------------|-----------------|-----------------------|
| Task ID      | Parent Task ID | Dependency Type | URL                   |
| 2            | 1              |                 |                       |
| 5            | 3              |                 | http://www.google.com |
| 6            | 5              |                 |                       |
| 7            | 6              |                 |                       |
| 8            | 7              |                 |                       |
| 9            | 8              |                 |                       |

To create a Gantt chart:

1. In Application Designer, add a chart control to a page and associate the chart control with a record name and a field name.

See [Creating a Chart Using the Chart Class](#).

2. Initialize a Gantt chart object.

Initialize the chart using the GetGanttChart function. The arguments of the function are the record and field name specified for the chart definition in Application Designer.

```
Local Gantt &gGantt;  
&gGantt = GetGanttChart(QE_CHART_DUMREC.QE_CHART_FIELD);
```

3. Specify values for the required methods.

At a minimum, specify the source of the task data and which fields contain task ID, start date, and end date.

```
&gGantt.SetTaskData(Record.QE_GANTT_TASK);
&gGantt.SetTaskID(QE_GANTT_TASK.QE_TASK_ID);
&gGantt.SetPlannedStartDate(QE_GANTT_TASK.QE_PLANNED_START);
&gGantt.SetPlannedEndDate(QE_GANTT_TASK.QE_PLANNED_END);
```

#### 4. Specify values for the additional methods controlling the appearance of the data.

After setting the required methods, you can set additional methods to control the appearance of the chart. The following code specifies the percentage of the entire chart that is taken up by the chart area, the width and height of the chart, if the user can click the chart area of the Gantt chart and either execute a function or a URL, and whether labels should appear with the tasks in the task section.

```
&gGantt.SetChartArea(50);
&gGantt.Width = 700;
&gGantt.Height = 380;
&gGantt.IsDrillable = True;
&gGantt.ShowTaskLabels = True;
```

#### 5. Specify the appearance of grid lines.

Depending on the type of data that you are using, you can specify the type of grid lines that should appear in the chart section of the Gantt chart.

```
&gGantt.GridLineType = %ChartLine_Solid;
&gGantt.GridLines = %ChartGrid_Vertical;
```

#### 6. Specify the appearance of data.

The following methods control the appearance of the different parts of the task data, such as the label, which hints appear when you pass the mouse over the task data, and so on.

```
&gGantt.SetTaskName(QE_GANTT_TASK.QE_TASK_NAME);
&gGantt.SetWBSNumbering(QE_GANTT_TASK.QE_HINTS);
&gGantt.SetTaskLevel(QE_GANTT_TASK.QE_LEVEL);
&gGantt.SetTaskLabel(QE_GANTT_TASK.QE_TASK_LABEL);
&gGantt.SetTaskProgress(QE_GANTT_TASK.QE_TASK_PROGRESS);
&gGantt.SetTaskBarURL(QE_GANTT_TASK.QE_URL);
&gGantt.SetTaskMilestone(QE_GANTT_TASK.QE_TASK_MILESTONE);
&gGantt.TaskMilestoneGlyph = QE_GANTT_PROJ.QE_MILESTONE_GLYPH;

&gGantt.SetPlannedTaskBarColor(QE_GANTT_TASK.QE_PLANNED_COLOR);
&gGantt.SetActualTaskBarColor(QE_GANTT_TASK.QE_ACTUAL_COLOR);
&gGantt.SetTaskProgressBarColor(QE_GANTT_TASK.QE_PROGRESS_COLOR);
```

#### 7. Specify the additional fields that will appear in the table section.

You can also specify application data that will appear with the task data.

```
&gGantt.SetTaskAppData(QE_GANTT_TASK.QE_PLANNED_START,
    QE_GANTT_TASK.QE_PLANNED_END, QE_GANTT_TASK.QE_TASK_PROGRESS,
    QE_GANTT_TASK.QE_TASK_NAME);
```

#### 8. Specify titles for the task bars.

```
&gGantt.TaskTitle = "Tasks";
&appDataArray = CreateArray("Start", "End", "Progress", "Name");
&gGantt.SetTaskAppDataTitles(&appDataArray);
```

#### 9. Specify the fields for task dependency data.

You do not need to specify dependency data. However, if you do, you must also specify the parent ID and the child ID (where the dependency data starts and ends). You can also specify the type of line used between dependencies and a URL that the browser will open to if the user clicks a dependency line.

```
&gGantt.SetTaskDependencyData(Record.QE_GANTT_TASKD);
&gGantt.SetTaskDependencyParentID(QE_GANTT_TASKD.QE_PARENT_TASK_ID);
&gGantt.SetTaskDependencyChildID(QE_GANTT_TASKD.QE_TASK_ID);
&gGantt.TaskDependencyLineType = %ChartLine_Solid;
&gGantt.SetTaskDependencyURL(QE_GANTT_TASKD.URL);
```

#### 10. Specify the actual dates for the project.

If you know the actual start and end dates, in addition to the planned date, you can add those to your chart.

```
&gGantt.SetActualStartDate(QE_GANTT_TASK.QE_ACTUAL_START);
&gGantt.SetActualEndDate(QE_GANTT_TASK.QE_ACTUAL_END);
```

#### 11. Specify the time line axis values.

You can specify values for where the time line axis starts and ends.

```
&gGantt.AxisStartDateTime = DateTimeValue("01/01/1963 8:00:00");
&gGantt.AxisEndDateTime = DateTimeValue("01/01/1987 8:00:00");
```

#### 12. Specify the format of the time line axis values.

You can specify the format of the time line elements, such as the appearance of the days of the week, whether as a number or using the full name, and so on.

```
&gGantt.SetMonthFormat(%Chart_MonthFormat_FullName);
&gGantt.SetDayFormat(%Chart_DayFormat_2Digit);
```

## Creating an Organization Chart

The PeopleCode used in this example creates the following organization chart:

To create an organization chart:

1. Add a chart control to a page in Application Designer.

Associate the chart control with a record name and field name.

See [Creating a Chart Using the Chart Class](#).

2. Add the organization node record and the pop-up node record to the component.

These records are derived/work records that contain clones of the subrecords PTORGNODE\_SBR and PTPOPUPNODE\_SBR. These records must be in the component buffer. You can add them to a hidden grid on the page, or you can place them on another page in the same component.

3. If the chart will have breadcrumbs, add the breadcrumb node record to the component.

This derived/work record contains a clone of the subrecord PTORGCRMB\_SBR. The record must be in the component buffer.

4. Prepare the organization chart data.

In an event such as PreBuild, instantiate two rowset objects and populate them with the organization node data and the pop-up node data.

This example shows one possible way. How you do it depends on how your data is stored and how you intend to present it.

```
Component Rowset &rs, &rsP, &rsBC, &rsOrgNode, &rsOrgPopupND, &rsBreadCrumbs;
Component OrgChart &ocOrgChart;

Local Rowset &RSGridDR;
Local Rowset &RSAGRID;

/* The record QE_ORG_NODEDATA has the data for the org chart **
** You will probably fill the rowset with some subset of the data**
** in the database. This example uses all the rows. */
&rs = CreateRowset(Record.QE_ORG_NODEDATA);
&rs.Fill();

/* Get the grid on the page for the node data and initialize to nulls */
&rsOrgNode = GetLevel0()(1).GetRowset(Scroll.QE_ORG_NODE);
&rsOrgNode.Flush();

/* Copy data from database table, QE_ORG_NODEDATA to the derived/work
** record QE_ORG_NODE_DR */
&rs.CopyTo(&rsOrgNode, Record.QE_ORG_NODEDATA, Record.QE_ORG_NODE_DR);

/* The record QE_ORG_POPDATA has the data for the popup chart */
&rsP = CreateRowset(Record.QE_ORG_POPDATA);
&rsP.Fill();

/* Get the grid on the page for the popup data and initialize to nulls */
&rsOrgPopupND = GetLevel0()(1).GetRowset(Scroll.QE_ORG_POPUP);
&rsOrgPopupND.Flush();

/* Copy data from database table, QE_ORG_POPDATA to the derived/work
** record QE_ORG_POP_DR */
&rsP.CopyTo(&rsOrgPopupND, Record.QE_ORG_POPDATA, Record.QE_ORG_POP_DR);

/* Fill in the breadcrumb information for this chart if the chart **
** uses breadcrumbs. */
&rsBC = CreateRowset(Record.QE_ORG_CRMB);
&rsBC.Fill();

/* Get the grid on the page for the pop data and initialize to nulls */
&rsBreadCrumbs = GetLevel0()(1).GetRowset(Scroll.QE_ORG_BCRMB);
&rsBreadCrumbs.Flush();

/* Copy data from database table, QE_ORG_CRMB to the derived/work
** record QE_ORG_CRMB_DR */
&rsBC.CopyTo(&rsBreadCrumbs, Record.QE_ORG_CRMB, Record.QE_ORG_CRMB_DR);
```

## 5. Instantiate an OrgChart object.

In an event such as Activate, add PeopleCode to instantiate and define your organization chart.

Get the chart using the GetOrgChart function. The argument for this function is the record name and field name specified on the Records tab of the Chart Properties dialog box in Application Designer.

```
Component Rowset &rsOrgNode, &rsOrgPopupND, &rsBreadCrumbs;
Component OrgChart &ocOrgChart;
&ocOrgChart = GetOrgChart(QE_CHART_DUMREC.QE_CHART_FIELD);
```

## 6. Specify the organization node record and the pop-up node record.

These records contain the clones of the subrecords PTORGNODE\_SBR and PTORGPOPUP\_SBR, respectively.

```
&ocOrgChart.SetNodeRecord(Record.QE_ORG_NODE_DR);
&ocOrgChart.SetPopUpNodeRecord(Record.QE_ORG_POP_DR);
```

## 7. Specify the node data and pop-up node data rowset objects.

```
/*&RSORGND and &RSORGPOPUPND are level 1 component rowsets that contain the
** organization node data and pop-up node data respectively.*/
```

```
&ocOrgChart.SetNodeData(&rsOrgNode);
&ocOrgChart.SetPopUpNodeData(&RSORGPOPUPND);
```

## 8. (Optional) Specify values for the chart display properties.

```
&ocOrgChart.MainTitle = "Application Development";
&ocOrgChart.MainTitleStyle = "PT_ORGCHART_TITLE";
&ocOrgChart.Direction = 2;
&ocOrgChart.Height = 380;
&ocOrgChart.Width = 700;
&ocOrgChart.VerticalSpace = 15;
&ocOrgChart.ImageLocation = 1;
&ocOrgChart.Style= "PTORGCHART";
&ocOrgChart.HasLegend = True;
&ocOrgChart.NodeMaxDisplayDescLength =30;
&ocOrgChart.CollapsedImage ="PT_COLLAPSED_NODE";
&ocOrgChart.ExpandedImage ="PT_EXPANDED_NODE";
&Expanded_Msg=MsgGetText(110, 100);
&Collapsed_Msg=MsgGetText(110, 101);
&ocOrgChart.Expanded_Msg =&Expanded_Msg
&ocOrgChart.Collapsed_Msg =&Collapsed_Msg
```

## 9. Specify values for the legend. This is required only if the chart has a legend.

```
&ocOrgChart.LegendStyle = PT_ORGCHART_LEGEND;
&LegendArray = CreateArray("Main", "1-2yrs", "3-5yrs", "Emergency",
"Retirement", "Key", "Successors");
&LegendImgArray = CreateArray("QE_NOWORGCHART", "QE_12ORGCHART",
"QE_34ORGCHART", "QE_EMORGCHART", "QE_RETIRORG", "QE_KPERSON",
"QE_SUCCSORGCHART");

&ocOrgChart.SetLegend(&LegendArray);
&ocOrgChart.SetLegendImg(&LegendImgArray);
&ocOrgChart.LegendPosition = %ChartLegend Top;
&ocOrgChart.LegendStyle = "PT_ORGCHART_LEGEND";
```

## 10. (Optional) Specify image values.

```
&ocOrgChart.ImageLocation =1;
&ocOrgChart.ImageHeight =150;
&ocOrgChart.ImageMouseoverMagnificationFactor =150;
&ocOrgChart.DefaultImage=PT_CHART_DEFAULTIMG;
```

## 11. Specify the breadcrumb data and the rowset and display properties. These are required only if your chart uses breadcrumbs.

```
&ocOrgChart.SetCrumbRecord(Record.QE_ORG_CRMB_DR);
&ocOrgChart.SetCrumbData(&rsBreadCrumbs);
&ocOrgChart.CrumbMaxDisplayLength = 24;
&ocOrgChart.CrumbSeparatorImage = "PT_ORG_BRCRM_SEP";
&ocOrgChart.CrumbDescrStyle = "PT_ORGCHART_BRDCRM";
```

## 12. (Optional) Specify the maximum number of nodes that will appear in the pop-up without a vertical scroll bar.

```
&ocOrgChart.MaxPopUpDisplayNode = 2;
```

## 13. (Optional) Assign style class names to control the styles of each node descriptor.

If you do not specify a style class name, then the PeopleTools default style class is used.

This example uses the default style class names, so this segment of code could be omitted. It is shown for demonstration purposes only.

```
&ocOrgChart.NodeDescr1Style = "PT_ORGNODE_DESC1";
&ocOrgChart.NodeDescr2Style = "PT_ORGNODE_DESC2";
&ocOrgChart.NodeDescr3Style = "PT_ORGNODE_DESC3";
&ocOrgChart.NodeDescr4Style = "PT_ORGNODE_DESC4";
&ocOrgChart.NodeDescr5Style = "PT_ORGNODE_DESC5";
&ocOrgChart.NodeDescr6Style = "PT_ORGNODE_DESC6";
&ocOrgChart.NodeDescr7Style = "PT_ORGNODE_DESC7";
```

#### 14. (Optional) Assign style class names to control the styles of each pop-up node descriptor.

If you do not specify a style class name, then the PeopleTools default style sheet is used.

This example uses the default style class names, so this segment of code could be omitted. It is shown for demonstration purposes only.

```
&ocOrgChart.PopupNodeDescr1Style = "PT_POPNODE_DESC1";
&ocOrgChart.PopupNodeDescr2Style = "PT_POPNODE_DESC2";
&ocOrgChart.PopupNodeDescr3Style = "PT_POPNODE_DESC3";
&ocOrgChart.PopupNodeDescr4Style = "PT_POPNODE_DESC4";
&ocOrgChart.PopupNodeDescr5Style = "PT_POPNODE_DESC5";
&ocOrgChart.PopupNodeDescr6Style = "PT_POPNODE_DESC6";
&ocOrgChart.PopupNodeDescr7Style = "PT_POPNODE_DESC7";
&ocOrgChart.PopupNodeDescr8Style = "PT_POPNODE_DESC8";
&ocOrgChart.PopupHeaderStyle = "PT_POPNODE_HEADER";
```

## Creating a Rating Box Chart

The PeopleCode used in the following example creates this rating box chart:

Follow these steps to create a rating box chart.

1. Create the rating box chart node record.
  - a. Clone the PTRATINGBOX\_SBR subrecord to create an application-specific subrecord.
  - b. Create a new application-specific record and insert the new subrecord.
2. Add a chart control to a page in Application Designer.

See [Creating a Chart Using the Chart Class](#).

3. Add the rating box chart node record to the component.

This record must be in the component buffer. If you do not want to give the user access to the data you can add the record to a hidden grid on the page. Alternatively, you can place it on another page in the same component.

4. Add PeopleCode.
  - In an event such as PreBuild, add PeopleCode to create a component buffer rowset that references the rating box chart node record.

- Add PeopleCode, probably in the page Activate event, to populate the rowset and define the chart.
- Add FieldChange PeopleCode that will execute when drag-and-drop events occur.

## PeopleCode for the Rating Box Chart Example

Complete these steps to create a rating box chart:

1. Prepare the data for the chart.

Typically, write PeopleCode in an event such as PreBuild to populate a rowset with the data you want to display in the rating box chart.

```
Component Rowset &rs, &rsRatingBox;
Component RatingBoxChart &rbRatingBoxChart;

/* the record QE_RATEBOX_DATA has the data for the RATING BOX chart */
&rs = CreateRowset(Record.QE_RATEBOX_DATA);
&rs.Fill("Where QE_RATEBOX_TC=:1", QE_RATEBOX_TC.QE_RATEBOX_TC.Value);

/* Get the grid on the page for the node data and initialize to nulls */
&rsGrid = GetLevel0() (1).GetRowset(Scroll.QE_RATEBOX_TC);
&rsGrid.Flush();

/* Copy data from database table, QE_RATEBOX_DATA, to the
level 1 component rowset associated with the component derived working
record QE_RATEBOX_DR */

&rs.CopyTo(&rsGrid, Record.QE_RATEBOX_DATA, Record.QE_RATEBOX_DR);
```

2. Define the RatingBoxChart.

Add PeopleCode in an event such as Activate.

Instantiate a RatingBoxChart object using the GetRatingBoxChart built-in function to reference the page control field of the chart.

```
Component Rowset &rs, &rsGrid;
Component RatingBoxChart &rbRatingBoxChart;

&rbRatingBoxChart = GetRatingBoxChart(QE_CHART_DUMREC.QE_CHART_FIELD);
```

3. Set the required display properties for the chart.

```
&rbRatingBoxChart.XaxisBoxNum = 3;
&rbRatingBoxChart.YaxisBoxNum = 3;
&rbRatingBoxChart.PopUpWidth = 200;
&rbRatingBoxChart.PopUpHeight = 200;
&XAxisArray = CreateArray("Low", "Medium", "High");
&YAxisArray = CreateArray("Low", "Medium", "High");

&rbRatingBoxChart.SetXAxisLabels(&XAxisArray);
&rbRatingBoxChart.SetYAxisLabels(&YAxisArray);
```

4. (Optional) Specify other values for the chart display properties.

If you do not specify these properties, the following default value will be used:

```
&rbRatingBoxChart.IsDragable = True;
&rbRatingBoxChart.BoxMaxDisplayItems = 3;
&rbRatingBoxChart.NDMaxDisplayDescLength = 25;
&rbRatingBoxChart.ShowNodeDescription = True;
&rbRatingBoxChart.GridLineType = %ChartLine_Solid;
```

```

&rbRatingBoxChart.XAxisTitle = "Performance";
&rbRatingBoxChart.YAxisTitle = "Potential";
&rbRatingBoxChart.NDMaxDisplayDescLength = 15;
&rbRatingBoxChart.BoxMaxDisplayItems = 5;

&rbRatingBoxChart.Height = 400;
&rbRatingBoxChart.Width = 400;
&rbRatingBoxChart.ShowNodeDescription = true;
&rbRatingBoxChart.GridLineType=%ChartLine_Solid;
&rbRatingBoxChart.IsDragable = True;
&rbRatingBoxChart.BoxMaxDisplayItems= 1;
&rbRatingBoxChart.NDMaxDisplayDescLength = 50;

```

##### 5. (Optional) Assign style class names for the chart and x- and y-axis title and labels.

If you do not specify a style class name, the PeopleTools default style sheet is used.

```

&rbRatingBoxChart.Style = "PSCHARTDEFAULT";
&rbRatingBoxChart.XAxisTitleStyle = "PT_RATBOX_XTTL";
&rbRatingBoxChart.YAxisTitleStyle = "PT_RATBOX_YTTL";
&rbRatingBoxChart.XAxisLabelStyle = "PT_RATBOX_XAXIS";
&rbRatingBoxChart.YAxisLabelStyle = "PT_RATBOX_YAXIS";

```

##### 6. (Optional) Specify title and legend properties.

```

&rbRatingBoxChart.MainTitle = "Development Division";
&rbRatingBoxChart.MainTitleStyle="PT_RATBOX_TITLE"
&rbRatingBoxChart.HasLegend = True;
&rbRatingBoxChart.LegendPosition = %ChartLegend_Bottom;
&LegendArray = CreateArray("Architect", "Engineer", "Director", "Manager",
    "Senior Director", "Vice-President");
&LegendImgArray = CreateArray("PT_ACECUBE", "PT_WF_PERSON", "PT_STATUS_ALERT_IC⇒
N",
    "PT_STATUS_ASSIGNED_ICN", "QE_SUCCSORGCHART", "QE_KPERSON");
&rbRatingBoxChart.SetLegend(&LegendArray);
&rbRatingBoxChart.SetLegendImg(&LegendImgArray);

```

##### 7. Set the node data rowset and record.

The chart refreshes when the SetRBNodeData method is called.

```

/* Set the node data rowset and the node record. */
&rbRatingBoxChart.SetRBNodeData(&rsGrid);
&rbRatingBoxChart.SetRBNodeRecord(Record.QE_RATEBOX_DR);

```

##### 8. Add FieldChange PeopleCode on the fields PTXAXISRATINGS and PTYAXISRATINGS if you want to perform other logic after the drag and drop operation.

This example shows a call to the SetRBNodeData function to redraw the chart the user changes the values in either of these two fields in the component:

```

/* FieldChange PeopleCode for fields PTXAXISRATINGS and PTYAXISRATINGS*/
&rbRatingBoxChart.SetRBNodeData(&rsGrid);

```

## Creating a Chart Using an iScript

You can also create a Chart class chart using an iScript. The following example creates a chart, populates it, and then sends the chart URL to a Response object. The complete code sample is shown.

---

**Note:** You cannot create a chart from gauge classes, the Gantt class, the OrgChart class, or the RatingBoxChart class using an iScript.

---

```
Function iScript_GetChartURL()

    Local Chart &cChart;
    Local Rowset &rsRowset;
    Local string &sMap;
    Local string &sURL;

    &cChart = CreateObject("Chart");

    &rsRowset = CreateRowset(Record.QE_CHART_RECORD);
    &rsRowset.Fill("where QE_CHART_REGION= :1", "MIDWEST");
    &cChart.SetData(&rsRowset);

    &cChart.Width = 400;
    &cChart.Height = 300;

    &cChart.SetDataYAxis(QE_CHART_RECORD.QE_CHART_SALES);
    &cChart.SetDataXAxis(QE_CHART_RECORD.QE_CHART_PRODUCT);
    &cChart.SetDataSeries(QE_CHART_RECORD.QE_CHART_REGION);

    &cChart.HasLegend = True;
    &cChart.LegendPosition = %ChartLegend_Right;

    &sURL = %Response.GetChartURL(&cChart);
    &sMap = &cChart.ImageMap;

    %Response.Write("<HTML><IMG SRC=");
    %Response.Write(&sURL);
    %Response.Write(" USEMAP=#THEMAP></IMG><MAP NAME=THEMAP>");
    %Response.Write(&sMap);
    %Response.Write("</MAP></HTML>");

End-Function;
```

See “CreateObject” (PeopleCode Language Reference).

Complete these steps to create a chart using an iScript:

1. Create the chart object.

For this example, no chart control is available on a page to be referenced. To create the chart object, use the CreateObject function. The string passed in to the function must be the name of the class you are instantiating. For instance, to instantiate a chart from the Chart class, pass the string “Chart”.

```
&cChart = CreateObject("Chart");
```

2. Create a rowset for the chart data and set the chart data.

The CreateRowset function creates a standalone rowset data structure. Use the Fill method to populate the empty rowset with data. The SetData method associates the rowset data with the chart.

```
&rsRowset = CreateRowset(Record.QE_CHART_RECORD);
&rsRowset.Fill("where QE_CHART_REGION= :1", "MIDWEST");
&cChart.SetData(&rsRowset);
```

3. Set the height and width of the chart.

Because the chart is not associated with a chart control on a page, you have to specify the size of the chart image to be generated using the Height and Width properties. The unit of measurement for both of these properties is pixels.

```
&cChart.Width = 400;
&cChart.Height = 300;
```

#### 4. Set the data axes, series, and legend for the chart.

As with all charts, you must set the data axes. If necessary for your data, also set the data series and the legend.

```
&cChart.SetDataYAxis(QE_CHART_RECORD.QE_CHART_SALES);
&cChart.SetDataXAxis(QE_CHART_RECORD.QE_CHART_PRODUCT);
&cChart.SetDataSeries(QE_CHART_RECORD.QE_CHART_REGION);

&cChart.HasLegend = True;
&cChart.LegendPosition = %ChartLegend_Right;
```

#### 5. Generate the URL for the chart.

Use the GetChartURL method of the Response class to generate the URL that will reference the chart data.

```
&sURL = %Response.GetChartURL(&cChart);
```

#### 6. Generate the image map.

Use the ImageMap property to generate the image map for the chart. The Response object uses this value to draw the map.

```
&sMap = &cChart.ImageMap;
```

#### 7. Create the response chart.

Use the Write Response class method to generate the chart. Note that first, the data is set using the URL generated with GetChartURL, and then the image map is used.

```
%Response.Write("<HTML><IMG SRC=");
%Response.Write(&sURL);
%Response.Write(" USEMAP=#THEMAP></IMG><MAP NAME=THEMAP>");
%Response.Write(&sMap);
%Response.Write("</MAP></HTML>");
```

---

**Note:** If one or more labels does not render in the chart, increase the width of the chart, use shorter label text, or reduce the data set being charted.

---

## Creating a Timeline Chart

Complete the following steps to create a timeline chart with two series:

1. Place a chart control on a page in Application Designer.
2. Create an instance of the Timeline class in PeopleCode.

```
&oTChart = GetTimeline(QE_CDEMO_WRK.QE_CHART_TIMELINE);
```

## 3. Specify labels for the series.

```
&oTChart.SetSeriesLabels(CreateArray("TimeLine Series 1", "TimeLine Series 2")⇒
);
```

## 4. Set the scale of the major axis.

```
&oTChart.MajorAxisScale = "quarters";
```

## 5. Set the scale of the minor axis.

```
&oTChart.MinorAxisScale = "months";
```

## 6. Set zoom order of the timeline.

```
&oTChart.MinorAxisZoomOrder = CreateArray("months", "weeks");
```

## 7. Specify start time of the timeline.

```
&oTChart.Start = DateTimeValue("2012-11-01 00:30:40.12-0600");
```

## 8. Specify end time of the timeline.

```
&oTChart.End = DateTimeValue("2013-12-30 00:30:40.12-0600");
```

## 9. Set the record for chart data.

```
&oTChart.SetData(Record.QE_TLINE_DATA);
```

## 10. Specify the field representing the identifier for the time line series.

```
&oTChart.SetDataSeries(QE_TLINE_DATA.QE_TIMELINE_SERIES);
```

## 11. Specify the field for the start time of the timeline item.

```
&oTChart.SetDataItemStart(QE_TLINE_DATA.QE_TIMELINE_START);
```

## 12. Specify the field for the description to display on the timeline item.

```
&oTChart.SetDataItemDescription(QE_TLINE_DATA.QE_DESCR50);
```

## 13. Specify the field for the title to display on the timeline item.

```
&oTChart.SetDataItemTitle(QE_TLINE_DATA.QE_CHARTTITLE);
```

## 14. Specify the timeline orientation.

```
&oTChart.Orientation = %Chart_Vertical;
```

The preceding lines of PeopleCode generate the following timeline chart assuming that sample data is provided for the chart.

A resulting timeline chart.

## Deprecated Chart Class Methods

This section lists the deprecated Chart class methods in alphabetical order.

### Refresh

#### Syntax

`Refresh ()`

#### Description

**Note:** This method has been deprecated and remains for backward compatibility only. Use instead the `SetData` method or `SetOldData` method.  
If you make a change to the underlying data of a chart, call the `SetData` method again to update the chart.

You don't need to refresh after setting a property or method of the chart itself, such as setting the starting point or changing colors. When a method or property is used, the chart is automatically refreshed.

#### Parameters

None.

#### Returns

None.

## Example

```
&MyChart.Refresh();
```

## Related Links

[SetData](#)

[SetOldData](#)

# SetDataAnnotations

## Syntax

```
SetDataAnnotations (Record_Name.Field_Name1, ...)
```

## Description

---

**Note:** This method has been deprecated and remains for backward compatibility only. Use instead the `SetDataLabel` and `SetDataLabelPosition` methods.

---

Use the `SetDataAnnotations` method to specify an optional text label that can be associated with each point in the chart.

This method is applicable for scatter and bubble charts only; it is ignored for all other chart types

## Parameters

| <i><b>Parameter</b></i>             | <i><b>Description</b></i>                                                                                                                                                                                                                                                                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1, ...</i> | <p>Specify the name of the record and one or more fields on that record that contain the annotations for the data items for the chart.</p> <hr/> <p><b>Note:</b> The number and order of fields specified must correspond to the order specified by the <code>SetDataYAxis</code> method.</p> <hr/> |

## Returns

None.

## Related Links

[SetDataLabel](#)

[SetDataYAxis](#)

## SetDataGlyphScale

### Syntax

```
SetDataGlyphScale (Record_Name.Field_Name1, ...)
```

### Description

**Note:** This method has been deprecated and remains for backward compatibility only. Use instead the SetDataZAxis method.

Use the SetDataGlyphScale method to specify a field that contains numerical data defining the size of each glyph for bubble charts (scatter charts). These values are mapped to a range of size values between a predefined minimum and maximum.

This method affects bubble charts only (%ChartType\_2DBubble).

### Parameters

| Parameter                           | Description                                                                                                                                                                                                                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Record_Name.Field_Name1, ...</i> | <p>Specify the name of the record and one or more fields on that record that contain the sizes for the data items for the chart.</p> <hr/> <p><b>Note:</b> The number and order of fields specified must correspond to the order specified by the SetDataYAxis method.</p> <hr/> |

### Returns

None.

## SetOldDataAnnotations

### Syntax

```
SetOldDataAnnotation (Record_Name.Field_Name)
```

### Description

This method has been deprecated and is ignored.

## SetOLDDataGlyphScale

### Syntax

```
SetOLDDataGlyphScale(Record_Name.Field_Name)
```

### Description

This method has been deprecated and is ignored.

---

## Deprecated Chart Class Properties

This section lists the deprecated Chart class properties in alphabetical order.

### GridLines

#### Description

This property has been deprecated and is ignored. Use instead the PSVERTICALGRIDLINES and PSHORIZONTALGRIDLINES style classes to control grid line visibility and style.

### GridLineType

#### Description

This property has been deprecated and is ignored. Use instead the PSVERTICALGRIDLINES and PSHORIZONTALGRIDLINES style classes to control grid line visibility and style.

## HighlightSelectedDataPoint

### Description

Use this property to specify a Boolean value indicating whether a data point selected by a user is highlighted on a chart or not. The default value is False.

---

**Important!** The HighlightSelectedDataPoint property has been deprecated and retained for backward compatibility only. Do not use this property to enable data point selection in newly created charts. Instead, use the DataSelectionMode property, the SetSelectedData method, and the ChartClientState class to manage data item selection in charts. The HighlightSelectedDataPoint property is incompatible with this new methodology.

This property is read/write.

---

### Example

```
&oChart.HighlightSelectedDataPoint = True;
```

# Component Interface Classes

---

## Understanding Component Interface Class

*Component Interfaces* are the focal points for externalizing access to existing PeopleSoft components. They provide real-time synchronous access to the PeopleSoft business rules and data associated with a component outside the PeopleSoft online system. Component Interfaces can be viewed as "black boxes" that encapsulate PeopleSoft data and business processes, and hide the details of the structure and implementation of the underlying page and data.

Component Interfaces are one of the many APIs that PeopleSoft provides for enabling integration with other systems.

A Component Interface maps to one, and only one, PeopleSoft component. The *Component Interface object*, instantiated from a session object, is created at runtime to access the data specified by the Component Interface.

When you instantiate a Component Interface object:

- All the PeopleCode programs associated with the record fields, pages, component, and so on, and
- The runtime component processor still perform all of the work that they do in the online environment.

The exceptions are any GUI manipulation found in a PeopleCode program, and search dialog specific processing.

Component Interfaces are programmable through a C interface, an OLE/COM or C/C++ interface, and through PeopleCode. Application Engine programs, message notification programs, or any other PeopleCode programs are able to use Component Interfaces.

Like a component, you create the structure of a Component Interface in Application Designer, then at runtime, you populate the structure with data. This document is concerned with the runtime portion of a Component Interface.

When you populate a Component Interface with data, the first thing you fill out are its keys, as you would in a component. These can be keys for getting an existing instance of the data or for creating a new instance of the data.

In addition to keys, a Component Interface is composed of *properties* and *methods*.

- Component Interface *properties* provide access to the data in a component buffer.
- Component Interface *methods* are functions that can be called to perform operations on a Component Interface.

There are two types of both methods and properties: standard and user-defined. Standard properties and methods are provided automatically when you create a Component Interface. They perform operations common to all Component Interfaces, such as indicating what mode to operate the Component Interface,

saving, or creating a Component Interface. User-defined properties are the specific record fields that an application developer has chosen to expose to an external system with the Component Interface. User-defined methods are PeopleCode programs that an application developer can write to perform operations on a Component Interface. Each is specific to that Component Interface.

At runtime if drop zone configurations are detected, the Component Interface properties of the components from the custom subpages can be accessed and updated using Component Interfaces objects similar to other properties.

You can instantiate a Component Interface object only from a session object. Through the session object you can control access to the Component Interface, check for errors, control the runtime environment, and so on.

[Reusing Existing Code](#)

[Understanding Session Class](#)

[Understanding Component Interface Class](#)

---

## Life Cycle of a Component Interface

At runtime, there are certain things you want to do with a Component Interface, such as getting an instance of it, populating it with data, and so on. The following is an overview of this process. These steps are expanded in other sections.

1. Execute the `GetCompIntfc` method on the PeopleSoft session object to get a Component Interface.
2. Set the key values for the Component Interface object. If the keys you specify don't uniquely describe a component (partial keys), proceed to step 3. If the keys uniquely describe a component, skip to step 4.
3. Do *one* of the following:
  - Execute the `Find` standard method on the Component Interface. This returns a collection of Component Interfaces with their key values filled out. The user can then select the unique Component Interface they want.
  - Execute either the `Get` or `Create` standard method to instantiate the Component Interface (populate it with data.)
4. Get property values, set property values, or execute user-defined methods. Setting a property value will fire the standard PeopleSoft business rules for the field associated with the property (any PeopleCode program associated with `FieldChange`, `RowInsert`, and so on.)
5. Execute the `Save` standard method to fire the standard PeopleSoft save business rules (any PeopleCode programs associated with `SavePreChange`, `WorkFlow`, and so on.) and commit any changes to the database.
6. At any point, the standard method `Cancel` can be executed to reset the Component Interface to its state in step 1.

The following is a flow chart diagram of Component interface life cycle such as getting an instance of it, populating it with data, and so on.

## Setting Component Interface Keys

The keys for a Component Interface are based on the key fields of the underlying component. There can be different types of keys for a Component Interface.

- **CREATEKEYS:** A list of the primary key fields of the search record specified to be used in Add mode for the component. This list is automatically generated.
- **GETKEYS:** A list of the primary (required) key fields on the search record. This list is automatically generated.

- **FINDKEYS:** A list of primary and alternate key fields on the primary search record for the component.

If the Component Interface has **CREATEKEYS**, these are the keys you must set before you execute the **Create()** method to create a new instance of the data. If the Component Interface doesn't have **CREATEKEYS**, use the **GETKEYS** to specify a new instance of the data.

Use either the **GETKEYS** or **FINDKEYS** to specify an existing instance of the data.

To set key values, use the field names listed under **GETKEYS**, **CREATEKEYS** or **FINDKEYS** like properties on the Component Interface object. The following example sets the **CREATEKEYS** values to create a new instance of the data.

```
&MYCI = GetCompIntfc(CompIntfc.EXPRESS_ISSUE);
&MYCI.BUSINESS_UNIT = "H01B";
&MYCI.INTERNAL_FLG = "Y";
&MYCI.ORDER_NO = "NEXT";
&MYCI.Create();
```

## Standard and User-Defined Component Interface Methods

Every Component Interface comes with a standard set of methods:

- **Cancel()**
- **Create()**
- **Find()**
- **Get()**
- **Save()**

Use these methods during runtime to affect the data of the Component Interface.

The application developer can, at design time, disable any of these methods for the Component Interface.

In addition, an application developer can write their own methods. These methods are written as Functions using Component Interface PeopleCode. For example, suppose you wanted to be able to copy an instance of Component Interface data. You might write your own **Clone** method.

---

**Note:** User-defined method names must *not* be named *GetPropertyName*. The C header for Component Interfaces creates functions with that name so you can access each property. If you create your own *GetPropertyName* functions, you receive errors at runtime. User-defined methods can take only simple types of arguments (such as number, character, and so on) because user-defined methods can be called from C/C++ as well as from PeopleCode. PeopleCode can use more complex types (like rowset, array, record, and so on), but these types of arguments are unknown to C/C++.

---

[Component Interface Class Properties](#)

“Creating User-Defined Methods” (Component Interfaces)

## Accessing Component Interface Standard Properties

Every Component Interface comes with a standard set of properties. These properties can be divided as follows:

### Properties that affect how the Component Interface is executed

The following properties affect how a component interface is executed:

- EditHistoryItems
- GetHistoryItems
- InteractiveMode

These properties must be set before the Component Interface is populated with data. That is, you must set these properties before you use the Get or Create methods.

EditHistoryItems and GetHistoryItems work together to determine how data is accessed:

- If EditHistoryItems is False (the default) and GetHistoryItems is True, you access the data in the Component Interface in a similar manner as if you were accessing a component in update/display All mode. This means all history rows are returned, however, you can edit rows only with a date set in the future.
- If EditHistoryItems is True and GetHistoryItems is True, you access the data in the Component Interface in a similar manner as if you were accessing a component in correction mode. This means all history rows are returned, and you can edit them.
- If GetHistoryItems is False, you access the data in the Component Interface in a similar manner as if you were accessing a component in update mode. The EditHistoryItems has no effect when GetHistoryItems is False.

InteractiveMode causes the Component Interface to emulate an online component. For example, if you set a value for a field in a Component Interface and you have set InteractiveMode to True, then any FieldChange PeopleCode programs associated with that field fire as soon as you set that value.

### Properties that return information about the structure of the Component Interface

The following properties return information about the structure of the Component Interface:

- CreateKeyInfoCollection
- FindKeyInfoCollection
- GetKeyInfoCollection
- PropertyInfoCollection

### Related Links

[Component Interface Class Properties](#)

## Accessing User-Defined Component Interface Properties

Every user-defined property in a Component Interface *definition* can be used like a property on the *object* instantiated from that Component Interface at runtime.

For example, the following Component Interface definition has RETURN\_DT defined as one of its properties.

This example illustrates the fields and controls on the RETURN\_DT Component Interface property highlighted. You can find definitions for the fields and controls later on this page.

At runtime, you can use PeopleCode to assign a value to that property (field), or to access the value of that field.

```
&MYCI.RETURN_DT = "05/05/2000";

/* OR */

&DATE = &MYCI.RETURN_DT;
```

## Data Type of a Component Interface Object

Component Interfaces are declared as type ApiObject. For example,

```
Local ApiObject &MYCI;
```

**Note:** Component Interface objects can be declared only as Local.

---

## Scope of a Component Interface Object

A Component Interface can be instantiated from PeopleCode, from a Visual Basic program, from Java, COM and C/C++.

This object can be used anywhere you have PeopleCode, that is, in an application class, Application Engine PeopleCode, record field PeopleCode, and so on.

If you're instantiating a Component Interface from an online page, after you finish working with the component, you may want to refresh your page. The Refresh method, on a rowset object, reloads the rowset (scroll) using the current page keys. This causes the page to be redrawn. GetLevel0().Refresh() refreshes the entire page. If you want a particular scroll only to be redrawn, you can refresh just that part.

### Considerations Using Component Interfaces and Related Languages

If you update a field using a Component Interface through an external program (such as Java, VB, and so on) the Related Language Table gets updated, even if they are using a base language of ENG.

### Considerations Using Component Variables With Component Interfaces

A component variable is scoped locally to its component or its Component Interface. This means that you cannot use a component variable to share data between a component and a Component Interface. In order to share information between components, use global variables.

If your page (component) calls a Component Interface (using the existing session), that in turn initializes a component variable, that component variable is shared with the calling component. When the Component Interface is closed, the component variable is no longer in scope.

When the calling component is closed, any component scoped variables created by it or by the Component Interface go out of scope.

---

## Implementing a Component Interface

After you create your Component Interface definition, you can use PeopleCode to access it. This PeopleCode can be long and complex. Rather than write it directly, you can drag and drop the Component Interface definition from Application Designer Project View into an open PeopleCode edit pane. Application Designer analyzes the definition and generates initial PeopleCode as a template, which you can modify.

You can also access your Component Interface using COM. You can automatically generate a Visual Basic or a C template, similar to the PeopleCode template, to get you started.

The following are the usual actions that you perform with a Component Interface:

- Create a new instance of data

- Get an existing instance of data
- Retrieve a list of instances of data

The following procedures cover each of these actions in more detail.

Another standard action is inserting or deleting a row of data (an item). This involves traversing a Component Interface (going from level zero to level one, from level one to level two, and so on) and accessing data collections.

You may want to work with effective-dated information. There are several properties you can set to allow you to do this.

In addition to these standard actions, you can also look at the structure of a Component Interface.

---

## Component Interface Methods and Timeouts

The file `pstools.properties` controls when a Component Interface method times out. If you're having problems with methods timing out, you may want to change the values in this file. This file is located in the default directory for the application you're running. If this file isn't in this directory, copy it into the directory before you make your changes to it.

---

## Traversing a Component Interface and Using Data Collections

The data in a Component Interface can be contained in a hierarchy: like the page it's built on, there may be data at level zero, level one, level two, and so on.

Each level of data in a Component Interface is known as a collection, such as:

```
level zero
    -- level one (Collection)
        -- Level 2 (Collection)
```

A *collection* is a set of similar things, like a group of already existing Component Interfaces. Most collections have the same standard properties and methods, with some additional ones specific to that collection. For example, all collections have the property *Count*, which indicates how many items are in that collection, but only a data collection has the method *ItemByKeys*.

A *data collection* is the collection of data, available at runtime or during test mode, associated with a particular scroll (or record.) The data collection object returns information about every *row of data* (item) that is returned for that record at runtime.

To access the level two collection, in general, you could use the following:

```
&Level_1 = &CI.Level_1;
&Level_1_Item = &Level_1.Item(ItemNumber);

&Level_2 = &Level_1_Item.Level_2;
```

This example illustrates the fields and controls on the Sample Component Interface with collection highlighted. You can find definitions for the fields and controls later on this page.

This example shows a Component Interface with a two-level hierarchy, that is, *two* data collections: EMPL\_CHECKLIST and EMPL\_CHKLIST\_ITM. To get a data collection for the first level, use the following code:

```
&Level1 = &MYCI.EMPL_CHECKLIST;
```

To access the secondary scroll (EMPL\_CHKLIST\_ITM) you have to get the appropriate row (item) of the upper level scroll first:

```
&Level1 = &MYCI.EMPL_CHECKLIST;
&Item = &Level1.Item(1);
&Level2 = &Item.EMPL_CHKLIST_ITM;
```

---

**Note:** Scrolls represent a hierarchical order. You must get the first level row that contains the secondary scroll *before* you can access the secondary scroll.

---

Every data collection has a set of methods and standard properties.

[Data Collection Methods](#)[Data Collection Properties](#)[“Understanding Data Buffer Access” \(PeopleCode Developer’s Guide\)](#)

---

## Working With Effective-Dated Data

When you work with effective-dated data, use some combination of the following methods:

- [CurrentItem](#)
- [GetEffectiveItem](#)

Both these methods return an item, however, there are some differences:

- The [CurrentItem](#) method takes no parameters, so it bases the item it returns on the *current system date*.
- The [GetEffectiveItem](#) method bases the item it returns on a *user-provided date*. They all perform the same logic, they just use a different date.

---

**Note:** To show all history for an effective-dated collection, you must set [GetHistoryItems](#) to True before you populate the Component Interface.

---

### Related Links

[CurrentItem](#)[GetEffectiveItem](#)[GetHistoryItems](#)[Inserting Effective-Dated Data Example](#)[Inserting Effective-Dated Data Example Using Visual Basic](#)

## How a Developer Uses GetEffectiveItem

If a user is making an update to an effective-dated record, they don’t always want to insert a row at the end.

Suppose the database contained the following data:

| <i><b>EMPLID</b></i> | <i><b>EFFDT</b></i> | <i><b>SEQNO</b></i> |
|----------------------|---------------------|---------------------|
| 8000                 | 3/1/99              | 0                   |
| 8000                 | 7/1/99              | 0                   |
| 8000                 | 9/1/99              | 0                   |
| 8000                 | 12/1/99             | 0                   |

Now suppose the user wants to enter info with EFFDT of 11/1/99. If they were looking at a PeopleSoft component, they would visually scan to see where that date falls and then press **ALT+7** and **ENTER** at the row that they want to insert after.

GetEffectiveItem enables you to pass in the correct effective date, instead of having to loop through every item in the collection doing a comparison, looking for the correct item.

### Why Can't it Just Go at the End?

The InsertItem method simulates pressing **ALT+7** and **ENTER** online to insert a row in a scroll. Part of the logic that occurs in the Component Processor is that if the scroll is effective-dated, the **ALT+7** and **ENTER** carries the values forward from the previous row. This functionality is still there if you use InsertItem at the end of the collection, but the values may be incorrect.

---

## Reusing Existing Code

One of the advantages of using a Component Interface is that it enables you to reuse existing PeopleCode and business logic. However, a Component Interface isn't exactly equivalent to a component, which means there are a few key areas in which you should expect differences in behavior between a Component Interface and the component it is based on. This section discusses these differences.

### Differences in Search Dialog Processing

When you run a Component Interface, the *SearchInit*, *SearchSave*, and *RowSelect* events don't fire. This means that any PeopleCode associated with these events won't run. The first event to run is *RowInit*.

### Differences in PeopleCode Event and Function Behavior

PeopleCode events and functions that relate exclusively to the page interface (the GUI) and online processing can't be used by Component Interfaces. These include:

- Menu PeopleCode and pop-up menus.

The ItemSelected and PrePopup PeopleCode events are not supported. In addition, the DisableMenuItem, EnableMenuItem, and HideMenuItem functions aren't supported.

- Transfers between components, including modal transfers.

The DoModal, EndModal, IsModal, Transfer, TransferPage, DoModalComponent, TransferNode, TransferPortal, and IsModalComponent functions cannot be used.

- Cursor position.

SetControlValue cannot be used.

- WinMessage cannot be used.
- Save in the middle of a transaction.

DoSave cannot be used.

- The page Activate event cannot be used.

When executed using a component interface, these functions do nothing and return a default value. In addition, using the Transfer function terminates the current PeopleCode program.

For the unsupported functions, you should put a condition around them, testing whether there's an existing Component Interface.

```
If %ComponentName Then
    /* process is being called from a Component Interface */
    /* do CI specific processing */
Else
    /* do regular processing */
    .
End-if;
```

## Using %Menu Conditions

If you associate a Component Interface definition with a menu in Application Designer, a PeopleCode program that conditionally checks for that menu runs when the Component Interface is executed. For example, suppose you associate a Component Interface with the MP\_HR\_MENU. The following PeopleCode program, if called from that Component Interface, executes:

```
If %Menu = MP_HR_MENU Then
```

## Session Class Methods

Component Interfaces don't have any built-in functions. They are instantiated from the Session class.

This section discusses the Session class methods used to instantiate Component Interfaces. The methods are discussed in alphabetical order.

## FindCompIntfcs

### Syntax

```
FindCompIntfcs ([ ComponentName ])
```

### Description

The FindCompIntfcs method, used with the Session object, returns a reference to a Component Interface collection, filled with zero or more Component Interfaces. The *ComponentName* parameter takes a string value. You can use a partial value to limit the set of Component Interfaces returned. You can also specify a null value, that is, two quotation marks with no space between them, (""), to return the entire list of Component Interfaces available.

Using the FindCompIntfcs method is equivalent to using File, Open, and selecting Component Interface in Application Designer.

## Example

In the following example, a partial key was used to open all components starting with "APP".

```
Local ApiObject &MYSESSION;
Local ApiObject &MYCI;

&MYSESSION = %Session;
&MYCICOLL = &MYSESSION.FindCompIntfcs("APP");
&MYCI = &MYCICOLL.First();
```

## GetCompIntfc

### Syntax

```
GetCompIntfc ([COMPINTFC.] ComponentName)
```

### Description

The GetCompIntfc method, used with the session object, returns a reference to a Component Interface. *ComponentName* when used by itself takes a string value. If you use COMPINTFC.*componentname* it isn't a string value: it's a constant that automatically is renamed in your code if the Component Interface definition is ever renamed. You must specify an existing Component Interface, otherwise you receive a runtime error.

### Example

```
Local ApiObject &MYSESSION;
Local ApiObject &MYCI;

&MYSESSION = %Session;
&MYCI = &MYSESSION.GetCompIntfc(COMPINTFC.PERSONAL_DATA_BC);
```

The following example uses the '@' operator to dynamically call a Component Interface from PeopleCode.

```
&MYCI = &MYSESSION.GetCompIntfc(@"CompIntfc." | &CIname));
```

## ValidateCompIntfc

### Syntax

```
ValidateCompIntfc (ComponentInterfaceName)
```

### Description

The ValidateCompIntfc method, used with the Session object, returns an integer value indicating whether the validation is successful. The validation fails if no component interface exists with the given name. The primary purpose of this method is to validate the successful compilation of all PeopleCode programs associated with both the component and the component interface. In addition, this method verifies other relationships of the component interface to the component, such as, but not limited to checking whether the component interface:

- Contains a reference to an invalid component.

- Is defined with CREATEKEYS, but the component does not allow the add action.
- Is defined with CREATEKEYS, but the specified field is not a search key.
- Has a reference to an invalid field.
- Has a reference to an invalid record.
- Is defined with FINDKEYS, but the specified field is not a search key or an alternate search key.
- Is defined with GETKEYS, but the specified field is not a search key.
- Has references to a search or add record that is invalid.

## Parameters

| <i>Parameter</i>              | <i>Description</i>                                |
|-------------------------------|---------------------------------------------------|
| <i>ComponentInterfaceName</i> | Specify the component interface name as a string. |

## Returns

An integer value indicating whether the validation is successful: 0 indicates success; any non-zero value indicates failure.

## Example

In the following example, a component interface with name "DEMOAPP\_CI" is validated.

```
Local ApiObject &MYSESSION;  
Local integer &nRet;  
  
&MYSESSION = %Session;  
&nRet = &MYSESSION.ValidateCompIntfc("DEMOAPP_CI");  
  
If &nRet <> 0 Then  
    /* Failure Case */  
Else  
    /* Success Case */  
End-If;
```

---

## Component Interface Collection Methods

A Component Interface collection is a list of the available Component Interfaces. An equivalent list is generated by starting Application Designer, selecting File, Open, Component Interface.

You get a Component Interface collection by using the FindCompIntfcs method with a session object.

## First

### Syntax

```
First()
```

### Description

The First method returns the first Component Interface in the Component Interface collection object executing the method. This returns the structure of the Component Interface with only the key fields filled in. The rest of the data is not present. To populate the Component Interface with data, you must set the key values and use the Get method.

### Example

```
&MYCI = &CICOLLECTION.First();
```

## Item

### Syntax

```
Item(number)
```

### Description

The Item returns the Component Interface that exists at the number position in the Component Interface collection executing the method. This returns the structure of the Component Interface with only the key fields filled in. The rest of the data is not present. To populate the Component Interface with data, you must set the key values and use the Get method. *number* takes a number value.

### Example

```
For &I = 1 to &COLLECTION.Count;  
&MYCI = &COLLECTION.Item(&I);  
/* do processing */  
End-For;
```

## Next

### Syntax

```
Next()
```

### Description

The Next method returns the next Component Interface in the Component Interface collection object executing the method. You can use this method only after you have used either the First or Item methods: otherwise the system doesn't know where to start. This returns the structure of the Component Interface with only the key fields filled in. To populate the Component Interface with data, you must set the key values and use the Get method.

## Example

```
&MYCI = &COLLECTION.Next ();
```

---

# Component Interface Collection Property

This section discusses the Count property.

## Count

### Description

This property returns the number of Component Interfaces in the Component Interface collection, as a number.

This property is read-only.

### Example

```
&COUNT = &MYCI_COLLECTION.Count;
```

---

# Component Interface Class Methods

This section discusses the Component Interface class methods. The methods are discussed in alphabetical order.

## Cancel

### Syntax

```
Cancel ()
```

### Description

The Cancel method cancels the instance of the Component Interface object executing the method, rolling back any changes that were made. This sets the Component Interface state to the same state it was in immediately after it was created by GetCompIntfc. This closes the Component Interface.

### Parameters

None.

### Returns

A Boolean value: True if component was successfully cancelled, False otherwise.

# CopyRowset

## Syntax

```
CopyRowset(&Rowset [, InitialRow] [, record_list]);
```

Where *record\_list* is a list of record names in the form:

```
[RECORD.source_recname1, RECORD.target_recname1  
[, RECORD.source_recname2, RECORD.target_recname2]]. . .
```

## Description

The CopyRowset method copies the specified rowset object to the Component Interface executing the method, copying like-named record fields and data collections (child rowsets) at corresponding levels. If pairs of source and destination record names are given, these are used to pair up the records and data collections *before* checking for like-named record fields.

CopyRowset uses the Page Field order when copying properties. This helps ensure that dependent fields are set in the required order.

---

**Note:** This method works in PeopleCode only. This method uses the names of the records in the collection, *not* the name you may give the collection when you create the Component Interface.

---

If there are blanks in *source* rowset or record, they are copied over to the Component Interface only if the field's IsChanged property is set to True. Otherwise blanks are *not* copied.

Use this method when you are using a Component Interface to verify the data in your application message.

---

**Note:** The structure of the rowset you're copying data from must exactly match the existing rowset structure, with the same records at level zero, 1, 2, and so on. CopyRowset is intended to be used with a notification process, that is, with message data. As all notifications work only in two-tier mode, CopyRowset works only in two-tier mode.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Rowset</i>      | Specify an existing, instantiated rowset object that contains data.                                                                                                                                                                                                     |
| <i>InitialRow</i>       | Specify the initial transaction row to begin with. This parameter provides a quick way to loop through a rowset that has multiple level zero rows. The default value for this parameter is 1.                                                                           |
| <i>record_list</i>      | Specify a list of source and target record names. All <i>source_recnames</i> are records being copied <i>from</i> , in the rowset object being copied from. All <i>target_recnames</i> are records being copied <i>to</i> , in the Component Interface being copied to. |

## Returns

None.

## Example

The following example would be in your notification PeopleCode. The Exit(1) causes all changes to be rolled back, and the message is marked with the status ERROR so you can correct it.

```
Local message &MSG;
Local ApiObject &SESSION;
Local ApiObject &PO;
Local rowset &ROWSET;

&MSG = %IntBroker.GetMessage();
&ROWSET = &MSG.GetRowset();

&SESSION = %Session;

If &SESSION <> NULL Then
/* Session connected correctly */
/* Set key values to create component */
&PO = &SESSION.GetCompIntfc (COMPINTFC.PO);
&PO.BU = &MSG(&I).PO_HDR.BU.Value;
&PO.PO_ID = &MSG(&I).PO_HDR.PO_ID.Value;
&PO.Create();

&PO.CopyRowset (&ROWSET);
If NOT (&PO.Save()) Then
    Exit(1);
End-if;
Else
/* do error processing */
End-If;
```

The following example loops through all the transactions of a message rowset.

```
Local message &MSG;
Local ApiObject &SESSION;
Local ApiObject &CI;
Local rowset &ROWSET;

&MSG = %IntBroker.GetMessage();
&ROWSET = &MSG.GetRowset();

&SESSION = %Session;
If &SESSION <> Null Then
    &CI = &SESSION.GetCompIntfc (CompIntfc.VOL_ORG);
    &I = 0;
    While (&I < &ROWSET.RowCount)
        &I = &I + 1;
        &CI.VOLUNTEER_ORG = &ROWSET.GetRow(&I).VOLNTER_ORG_2. VOLUNTEER_ORG.Value;
        If &CI.Create() Then
            If &CI.CopyRowset (&ROWSET, &I, Record.VOLNTER_ORG_TBL, Record.VOLNTER_ORG_⇒
TBL) Then

                /* App specific processing */

                If Not &CI.Save() Then
                    Winmessage("Save Failed");
                    /* Other app specific processing */
                End-If;
            End-If;
        End-If;
    End-If;
    &CI.Cancel();
```

```
End-While;
End-If;
```

## CopyRowsetDelta

### Syntax

```
CopyRowsetDelta (&Rowset [, InitialRow] [, record_list]);
```

Where *record\_list* is a list of record names in the form:

```
[RECORD.source_recname1, RECORD.target_recname1  
[, RECORD.source_recname2, RECORD.target_recname2]]. . .
```

### Description

The CopyRowsetDelta method copies the changed rows in the specified rowset object to the Component Interface executing the method, copying like-named record fields and data collections (child rowsets) at corresponding levels. If pairs of source and destination record names are given, these are used to pair up the records and data collections *before* checking for like-named record fields.

---

**Note:** This method works in PeopleCode only. This method uses the names of the records in the collection, *not* the name you give the collection when you create the Component Interface.

---

If there are blanks in *source* rowset or record, they are copied over to the Component Interface only if the field's IsChanged property is set to True. Otherwise blanks are *not* copied.

You will generally use this method with a Component Interface to verify data from a message.

---

**Note:** CopyRowsetDelta is intended for a notification process, that is, with message data. As all notifications work only in two-tier mode, CopyRowsetDelta works only in two-tier mode.

---

If the rowset you're copying from is a message rowset, the CopyRowsetDelta method uses the AUDIT\_ACTN field in the PSCAMA table in the message to know whether the row is to be inserted, updated, or deleted inside the Component Interface.

If the rowset you're copying from *is not* a message rowset, that rowset must have the same structure as a message, that is, it must have a PSCAMA record with an AUDIT\_ACTN field on every level of the rowset.

---

**Warning!** CopyRowsetDelta uses a record's keys to locate the target row to change for all audit actions other than Add. CopyRowsetDelta actions (other than Add) therefore work only on rowsets that have keys *that uniquely identify all rows in the rowset*. Rowsets that do *not* distinguish between rows using a key field will be updated in an unpredictable fashion.

---

### Considerations Using CopyRowsetDelta with Effective-Dated Rowsets

If a message data row inserted using a PSCAMA Audit action of "A" belongs to an effective dated scroll containing child scrolls, the insertion of the parent row causes child rows of the previous effective-dated row to be copied over, and their effective date is updated with that of the inserted parent.

If the message also contains a child row being inserted with a PSCAMA Audit action of "A", the component interface being populated will end up having two child rows: the one inserted as part of the Effective-dated processing and the one inserted using the PSCAMA Audit action "A" in the message.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Rowset</i>      | Specify an existing, instantiated rowset object that contains data.                                                                                                                                                                                                     |
| <i>InitialRow</i>       | Specify the initial transaction row to begin with. This parameter provides a quick way to loop through a rowset that has multiple level zero rows. The default value for this parameter is 1.                                                                           |
| <i>record_list</i>      | Specify a list of source and target record names. All <i>source_recnames</i> are records being copied <i>from</i> , in the rowset object being copied from. All <i>target_recnames</i> are records being copied <i>to</i> , in the Component Interface being copied to. |

## Returns

None.

## Example

The following PeopleCode would exist in your notification process. The Exit(1) causes all changes to be rolled back, and the message is marked with the status ERROR so you can correct it.

```

Local Message &MSG;
Local ApiObject &SESSION;
Local ApiObject &PO;
Local Rowset &ROWSET;

&MSG = %IntBroker.GetMessage();
&ROWSET = &MSG.GetRowset();

&SESSION = %Session;

If &SESSION <> Null Then
/* Session connected correctly */
/* Set key values to get component */
&PO = &SESSION.GetCompIntfc(COMPINTFC.PO);
&PO.BU = &MSG(&I).PO_HDR.BU.Value;
&PO.PO_ID = &MSG(&I).PO_HDR.PO_ID.Value;
&PO.Get();

&PO.CopyRowsetDelta(&ROWSET);
If NOT (&PO.Save()) Then
    Exit(1);
End-if;
Else
    /* do error processing */
End-If;

```

Related Links

“PSCAMA” (Integration Broker)

CopySetupRowset

Syntax

```
CopySetupRowset (&Rowset [, InitialRow] [, record_list]);
```

Where *record\_list* is a list of record names in the form:

```
RECORD.source_recname, RECORD.target_recname
```

Description

The CopySetupRowset method is used to copy a setup table application message to a Component Interface. A setup table has the same record at level zero and level one, while a Component Interface has only a single copy of a record. This method copies the contents of the message (at level zero) to the first level collection (level one) of the Component Interface.

The CopySetupRowset method copies *like-named* record fields. If a pair of source and destination record names are given, these are used to pair up the records and data collections *before* checking for like-named record fields.

**Note:** This method works in PeopleCode only. This method uses the names of the records in the collection, *not* the name you may give the collection when you create the Component Interface.

If there are blanks in *source* rowset or record, they are copied over to the Component Interface only if the field’s IsChanged property is set to True. Otherwise blanks are *not* copied.

**Note:** CopySetupRowset is for a notification process, that is, with message data. As all notifications work only in two-tier mode, CopySetupRowset works only in two-tier mode.

Parameters

| Parameter   | Description                                                                                                                                                                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| &Rowset     | Specify an existing, instantiated rowset object that contains data.                                                                                                                                                                                             |
| InitialRow  | Specify the initial transaction row to begin with. This parameter provides a quick way to loop through a rowset that has multiple level zero rows. The default value for this parameter is 1.                                                                   |
| record_list | Specify source and target record names. The <i>source_recname</i> is the record being copied <i>from</i> , in the rowset object being copied from. The <i>target_recname</i> is the record being copied <i>to</i> , in the Component Interface being copied to. |

## Returns

None.

## Example

The following example would be in your Notification PeopleCode.

```

Local ApiObject &SESSION;
Local ApiObject &PSMESSAGES;

Local ApiObject &CI;

Local Message &MSG;
Local Rowset &RS;

&SESSION = %Session;
&PSMESSAGES = &SESSION.psmessages;

&MSG = %IntBroker.GetMessage();
&RS = &MSG.GetRowset();

&CI = &SESSION.getcomponent(Component.VOL);

/** Set Business Component Properties */
&CI.gethistoryitems = True;
/*&CI.InteractiveMode = True;*/
/*&CI.stoponfirsterror = True;*/

For &TRANSACTION = 1 To &RS.RowCount

    &CI.VOLUNTEER_ORG = &RS(&TRANSACTION).VOLNTER_ORG_TBL.VOLUNTEER_ORG.Value;

    /* note: You can achieve better performance if you add code here to check if the
keys are the same L0 keys as the last time through the loop and, if so, skip the
Get/Create section. */

    If Not &CI.create() Then
        &PSMESSAGES.DeleteAll();
        If Not &CI.get() Then
            /** Check Error Messages */
            For &I = 1 To &PSMESSAGES.count
                &TYPE = &PSMESSAGES.item(&I).type;
                &TEXT = &PSMESSAGES.item(&I).text;
            End-For;
            Exit(1);
        End-If;
    End-If;

    If Not &CI.CopySetupRowset(&RS, &TRANSACTION) Then
        /** Check Error Messages */
        For &I = 1 To &PSMESSAGES.count
            &TYPE = &PSMESSAGES.item(&I).type;
            &TEXT = &PSMESSAGES.item(&I).text;
        End-For;
        Exit(1);
    End-If;

    If Not &CI.Save() Then
        /** Check Error Messages */
        For &I = 1 To &PSMESSAGES.count
            &TYPE = &PSMESSAGES.item(&I).type;
            &TEXT = &PSMESSAGES.item(&I).text;
        End-For;
        Exit(1);
    End-If;
End-For;

```

```

End-If;

    &CI.Cancel();
End-For;

```

## Related Links

[CopySetupRowsetDelta](#)

[CopyRowset](#)

# CopySetupRowsetDelta

## Syntax

```
CopySetupRowsetDelta(&Rowset [, InitialRow] [, record_list]);
```

Where *record\_list* is a list of record names in the form:

```
RECORD.source_recname, RECORD.target_recname
```

## Description

The CopySetupRowsetDelta method is used to copy a setup table with *changed* rows in an application message to a Component Interface. A setup table has the same record at level zero and level one, while a Component Interface has only a single copy of a record. This method copies the contents of the message (at level zero) to the first level collection (level one) of the Component Interface.

---

**Note:** This method works in PeopleCode only. CopySetupRowsetDelta copies all the like-named fields from the changed *row* into the message. It is *not* copying only the changed fields.

---

The CopySetupRowsetDelta method copies *like-named* record fields, in those rows where the IsChanged property is True. If a pair of source and destination record names are given, these are used to pair up the records and data collections *before* checking for like-named record fields.

---

**Note:** This method uses the names of the records in the collection, *not* the name you may give the collection when you create the Component Interface.

---

If there are blanks in *source* rowset or record, they are copied over to the Component Interface only if the field's IsChanged property is set to True. Otherwise blanks are *not* copied.

---

**Note:** CopySetupRowsetDelta is for a notification process, that is, with message data. As all notifications work only in two-tier mode, CopySetupRowsetDelta works only in two-tier mode.

---

---

**Warning!** CopySetupRowsetDelta uses a record's keys to locate the target row to change for all audit actions other than Add. CopySetupRowsetDelta actions (other than Add) therefore work only on rowsets that have keys that *uniquely identify all rows in the rowset*. Rowsets that do *not* distinguish between rows using a key field will be updated in an unpredictable fashion.

---

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&amp;Rowset</i>      | Specify an existing, instantiated rowset object that contains data.                                                                                                                                                                                             |
| <i>InitialRow</i>       | Specify the initial transaction row to begin with. This parameter provides a quick way to loop through a rowset that has multiple level zero rows. The default value for this parameter is 1.                                                                   |
| <i>record_list</i>      | Specify source and target record names. The <i>source_recname</i> is the record being copied <i>from</i> , in the rowset object being copied from. The <i>target_recname</i> is the record being copied <i>to</i> , in the Component Interface being copied to. |

## Returns

None.

## Example

```

Local ApiObject &SESSION;
Local ApiObject &PSMESSAGES;

Local ApiObject &CI;

Local Message &MSG;
Local Rowset &RS;

&SESSION = %Session;
&PSMESSAGES = &SESSION.psmessages;

&MSG = %IntBroker.GetMessage();
&RS = &MSG.GetRowset();

&CI = &SESSION.getcomponent(Component.VOL);

/** Set Business Component Properties */
&CI.gethistoryitems = True;
/*&CI.InteractiveMode = True;*/
/*&CI.stoponfirsterror = True;*/

For &TRANSACTION = 1 To &RS.RowCount

    &CI.VOLUNTEER_ORG = &RS(&TRANSACTION).VOLINTER_ORG_TBL.VOLUNTEER_ORG.Value;

    /* note: You can achieve much better performance if you add code here to check =>
if the keys are the same I0 keys as the last time through the loop and, if so, skip=>
the Get/Create section. */

    If Not &CI.create() Then
        &PSMESSAGES.DeleteAll();
    If Not &CI.get() Then
        /** Check Error Messages */
        For &I = 1 To &PSMESSAGES.count
            &TYPE = &PSMESSAGES.item(&I).type;

```

```

        &TEXT = &PSMESSAGES.item(&I).text;
    End-For;
    Exit(1);

End-If;
End-If;

If Not &CI.CopySetupRowsetDelta(&RS, &TRANSACTION) Then
    /** Check Error Messages **/
    For &I = 1 To &PSMESSAGES.count
        &TYPE = &PSMESSAGES.item(&I).type;
        &TEXT = &PSMESSAGES.item(&I).text;
    End-For;
    Exit(1);
End-If;

If Not &CI.Save() Then
    /** Check Error Messages **/
    For &I = 1 To &PSMESSAGES.count
        &TYPE = &PSMESSAGES.item(&I).type;
        &TEXT = &PSMESSAGES.item(&I).text;
    End-For;
    Exit(1);
End-If;

&CI.Cancel();

```

## Create

### Syntax

**Create** ()

### Description

The Create method associates the Component Interface object executing the method with a new, open Component Interface that matches the key values that were set prior to using the Create method. If there are CREATEKEYS values associated with the Component Interface, these are the values you must set. If there are no CREATEKEYS values, you must set the required GETKEYS values instead. All keys required for creating a new Component Interface must be set before using the Create method, otherwise you receive a runtime error. If you do not use unique key values, (that is, you try to set the keys to values that already exist in the database) you receive a runtime error.

Setting the key values prior to using the Create method is analogous to filling in the key values in the Add dialog for a component when you access it in add mode.

### Parameters

None.

### Returns

A Boolean value: True if component was successfully created, False otherwise.

## Example

```
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.ACTION_REASON);  
&MYCI.ACTION = "Additional Job";  
&MYCI.ACTION_REASON = "0001";  
&MYCI.Create();
```

## Find

### Syntax

**Find()**

### Description

---

**Note:** Find can be used only at level zero within the Component Interface.

---

You do not have to set values for all the key values. You can use the same wildcards in your Find that you can use in the search dialog, that is, % for one or more characters in a search pattern, and \_ (underscore) for exactly one character. In addition, you can use partial values. For example, the following code finds all the data items where the employee ID starts with an "8":

```
&MYCI.Emplid = "8";  
&MYDC = &MYCI.Find();
```

This is analogous to using a partial key from the search dialog, opening a component.

After you have a data collection, you can use one of the data collection methods to open the Component Interface.

### Parameters

None.

### Returns

A collection of Component Interfaces.

### Related Links

[Data Collection Methods](#)

## Get

### Syntax

**Get()**

## Description

The Get method associates the Component Interface object executing the method with an open Component Interface that matches the key values that were set prior to using the Get method. The key values you must set are the required GETKEYS values for the Component Interface.

---

**Note:** To retrieve all the history data for a Component Interface, you must specify the GetHistoryItems property as True *before* you use the Get method. If you want any PeopleCode programs associated with the fields to fire immediately after a value is changed, you must set the InteractiveMode property as True *before* you use the Get method.

---

After any execution of Get, you should check if there are any errors pending on the session object. In some special circumstances (involving failure of previously cached operations failing after the Get has executed) Get returns True even though the component wasn't retrieved.

## Parameters

None.

## Returns

A Boolean value: True if component was successfully retrieved, False otherwise.

## Example

```
&MYCI.EMPLID = "8001";
&MYCI.Get();
If %Session.ErrorPending Then
    /* Get Unsuccessful, do error processing */
Else
    /* do regular processing */
End-if;
```

## GetPropertyByName

### Syntax

**GetPropertyByName** (*string*)

### Description

The GetPropertyByName method returns the value of the property specified by *string*. For a collection, it returns a reference to the collection. Generally this function is used only in applications that cannot get the names of the component interface properties until runtime.

### Parameters

| <i>Parameter</i> | <i>Description</i>        |
|------------------|---------------------------|
| <i>string</i>    | The name of the property. |

## Returns

String. The value of the property.

ApiObject. For a collection. The value of the property.

## Example

```
Local ApiObject &oSession, &oCI;
Local array of string &Keys_Arr, &Temp_Arr, &Prop_Arr;
Local string &strCIName, &PropertyValue;
Local number &I, &J, &K;

Function getPropertyValue(&oDataColl As ApiObject, &PropertyName As string) Returns⇒
    string
    rem ***** Return property value
        Return &oDataColl.GetPropertyByName(&PropertyName);
    End-Function;

Function getCollection1(&collectionName As string)
    Local ApiObject &oL1_DataColl, &oL1_DataItem;
    rem ***** Return collection
        &oL1_DataColl = &oCI.GetPropertyByName(&collectionName);
        For &J = 1 To &oL1_DataColl.Count
            &oL1_DataItem = &oL1_DataColl.Item(&J);
            For &K = 1 To &Prop_Arr.Len
                &Temp_Arr = Split(&Prop_Arr [&K], "|");
                If &Temp_Arr [1] = "1" Then
                    If &Temp_Arr [3] = "Property" Then
                        &PropertyValue = getPropertyValue(&oL1_DataItem,
                            &Temp_Arr [2]);
                    Else
                        rem ***** Code to Get Collection 2 goes here *****;
                    End-If;
                End-If;
            End-For;
        End-For;
    End-Function;
```

## Related Links

[SetPropertyByName](#)

## Save

### Syntax

**Save** ()

### Description

Saves any changes that have been made to the data of the Component Interface executing the method. You must save any new Component Interfaces you create before they are added to the database.

The standard PeopleSoft save business rules (that is, any PeopleCode programs associated with SaveEdit, SavePreChange, WorkFlow, and so on.) is executed after you execute this method. If you didn't specify the Component Interface to run in interactive mode, FieldEdit, FieldChange, and so on, also run at this time.

If there are multiple errors, all errors are logged to the PSMessages collection, not just the first occurrence of an error. As you correct each error, you may want to delete it from the PSMessages collection.

---

**Note:** If you're running a Component Interface from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a COMMIT.

---

## Parameters

None.

## Returns

A Boolean value: True if component was successfully saved, False otherwise.

## Example

```
&MYCI.Emplid = "8001";  
&MYCI.Get();  
&MYCI.CHECKLIST_CD = "00001";  
&MYCI.Save;
```

## Related Links

# SetPropertyByName

## Syntax

```
SetPropertyByName (string, value)
```

## Description

The SetPropertyByName method sets the value of the property specified by *string*. Generally this function is used only in applications that cannot set the names of the component interface properties until runtime.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                     |
|-------------------------|-----------------------------------------------|
| <i>string</i>           | The name of the property.                     |
| <i>value</i>            | The value to which the property is to be set. |

## Returns

None.

## Example

```
Local ApiObject &oSession, &oCI;  
Local array of string &Keys_Arr, &Temp_Arr, &Prop_Arr;  
Local string &strCIName, &PropertyValue;  
Local number &I, &J, &K;  
  
&strCIName = "SDK_BUS_EXP";  
&Keys_Arr = CreateArrayRept("", 0);  
&Keys_Arr.Push("SDK_EMPLID|" | "8001");  
  
&oSession = %Session;  
&oCI = &oSession.GetCompIntfc(@"CompIntfc." | &strCIName));  
  
For &I = 1 To &Keys_Arr.Len  
    &Temp_Arr = Split(&Keys_Arr [1], "|");  
    &oCI.SetPropertyByName(&Temp_Arr [1], &Temp_Arr [2]);  
End-For;
```

# Component Interface Class Properties

In this section, we discuss the Component Interface class properties. The properties are discussed in alphabetical order.

## ComponentName

### Description

This property returns the name of the Component Interface, as defined in Application Designer, as a string.

This property is read-only.

## CreateKeyInfoCollection

### Description

This property returns a `CompIntfPropInfoCollection` collection that contains a `CompIntfPropInfoCollection` object for every key in `CREATEKEYS`.

This property is read-only.

### Example

```
&CREATEKEYS = &CI.CreateKeyInfoCollection;
```

## Related Links

[Accessing the Structure of a Component Interface](#)

## EditHistoryItems

### Description

This property works with the `GetHistoryItems` property to specify what data is accessed, and whether you can edit that data:

- If `EditHistoryItems` is `False` (the default) and `GetHistoryItems` is `True`, you access the data in the Component Interface in a similar manner as if you were accessing a component in `Update/Display All` mode. This means all history rows are returned, however, you can edit only rows with a date set in the future.
- If `EditHistoryItems` is `True` and `GetHistoryItems` is `True`, you access the data in the Component Interface in a similar manner as if you were accessing a component in `Correction` mode. This means all history rows are returned, and you can edit them.
- If `GetHistoryItems` is `False`, you access the data in the Component Interface in a similar manner as if you were accessing a component in `Update` mode. The `EditHistoryItems` has no effect when `GetHistoryItems` is `False`.

You must set this property to `True` *before* you execute the `Get` method.

This property is read/write.

### Related Links

[GetHistoryItems](#)

## FindKeyInfoCollection

### Description

This property returns a `CompIntfPropInfoCollection` collection that contains a `CompIntfPropInfoCollection` object for every key in `FINDKEYS`.

This property is read-only.

### Related Links

[Accessing the Structure of a Component Interface](#)

## GetDummyRows

### Description

When a new scroll is inserted on a page, that scroll is displayed even though it has no underlying data. Any scroll that is empty has one dummy row displayed with only the defaults set.

This property is `True` if the dummy row is to be displayed, `False` if you do not want to display the dummy row. The default value for this property is `True`.

This property is read/write.

## Example

```
&MyCI.GetDummyRows = False;
```

## GetHistoryItems

### Description

This property works with the EditHistoryItems property to specify what data is accessed, and whether you can edit that data:

- If EditHistoryItems is False (the default) and GetHistoryItems is True, you access the data in the Component Interface in a similar manner as if you were accessing a component in Update/Display All mode. This means all history rows are returned, however, you can edit only rows with a date set in the future.
- If EditHistoryItems is True and GetHistoryItems is True, you access the data in the Component Interface in a similar manner as if you were accessing a component in Correction mode. This means all history rows are returned, and you can edit them.
- If GetHistoryItems is False, you access the data in the Component Interface in a similar manner as if you were accessing a component in Update mode. The EditHistoryItems has no effect when GetHistoryItems is False.

You must set this property to True *before* you execute the Get method.

This property is read/write.

### Example

The following example checks the current status of the mode, then sets the GetHistoryItems and EditHistoryItems properties to True if the mode is Correction mode.

```
If %Mode = "C" Then  
    &CI.EditHistoryItems = True;  
    &CI.GetHistoryItems = True;  
End-if;
```

### Related Links

[EditHistoryItems](#)

## GetKeyInfoCollection

### Description

This property returns a CompIntfPropInfoCollection collection that contains a CompIntfPropInfoCollection object for every key in GETKEYS.

This property is read-only.

## Related Links

[Accessing the Structure of a Component Interface](#)

## InteractiveMode

### Description

When this property is set as True, the Component Interface runs the same as a component: that is, any PeopleCode programs associated with FieldChange, RowInsert, and so on, run immediately after you make a change. If this property is set to False, these programs won't run until you execute the Save method.

This property is read/write.

### Related Links

[ErrorPending](#)

## PropertyInfoCollection

### Description

This property returns a CompIntfPropInfoCollection object for every property that isn't a collection (that is, a scroll.) If the property is a collection (scroll), use the PropertyInfoCollection property to get another collection.

This property is read-only.

### Related Links

[Accessing the Structure of a Component Interface](#)

## StopOnFirstError

### Description

When this property is set as True, the CopyRowset (or CopyRowsetDelta) method currently executing halts its processing at the first error generated by the Component Interface.

When this property is set as True and InteractiveMode is set as False, processing of queued operations at save time is halted at the first error.

The default value is False.

This property is read/write.

---

## Data Collection Methods

A *data collection* is the collection of data, available at runtime or during test mode, associated with a particular scroll (or record.) The data collection object returns information about every *row of data* (item) that is returned for that record at runtime.

To access a data collection, use the name of the record (scroll) as a property on a Component Interface.

### Related Links

[Traversing a Component Interface and Using Data Collections](#)

## CurrentItem

### Syntax

```
CurrentItem()
```

### Description

If the component associated with the Component Interface is effective-dated, CurrentItem returns a reference to the current effective-dated item (row of data). To get a specific item based on a date, use GetEffectiveItem.

If there is no current item, a Null is returned.

### Example

```
&MYCD = &MYCI.EMPL_CHKLSITM;  
&ITEM = &MYDC.CurrentItem();
```

## DeleteItem

### Syntax

```
DeleteItem(number)
```

### Description

The DeleteItem method deletes the item (row of data) at the position specified by *number*. This parameter takes a number value.

When the DeleteItem method is executed, if there are any RowDelete PeopleCode programs associated with any of the fields, they fire as well, as if the user pressed ALT+8 and ENTER or clicked the DeleteRow icon. However, the programs are executed as if turbo mode was selected. (In turbo mode default processing is performed *only* for the row being deleted.)

If you set the InteractiveMode property to True, any RowDelete PeopleCode runs immediately after you execute DeleteItem. If this property is set to False, any RowDelete PeopleCode runs after you execute the Save method.

The deleted item is not actually deleted from the database until after you use the Save method.

## Example

Here is an example of EMPL\_CHK\_BC in Component Interface Tester where in , suppose your Component Interface had two scrolls: EMPL\_CHECKLIST and EMPL\_CHKLST\_ITM. The data collection EMPL\_CHECKLIST has four items (rows of data.) The data collection EMPL\_CHKLST\_ITM (under the third item) has five items (rows of data.) If you run this component in the Component Interface Tester, it would look as follows:

To delete the third row in the third item, use the following:

```
Local ApiObject &MYSESSION;
Local ApiObject &MYCI;

&MYSESSION = %Session;
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.EMPL_CHK_BC);
&MYLVL1 = &MYCI.EMPL_CHECKLIST;
&ITEM2 = &MYLVL1.Item(3);
&MYLVL2 = &ITEM2.EMPL_CHKLST_ITM;
&MYLVL2.DeleteItem(3);
&MYCI.Save();
```

## GetEffectiveItem

### Syntax

```
GetEffectiveItem(DateString, SeqNo)
```

### Description

If the component associated with the Component Interface is effective-dated, GetEffectiveItem returns a reference to the closest effective-dated item (row of data) that is less than or equal to the date specified by the *DateString*. To get an item based on the current effective date, use CurrentItem.

---

**Note:** *DateString* takes only a string value. You must convert a date variable into a string before you can use it for *DateString*. You can use the String function to do this.

---

### Parameters

| <i>Parameter</i>  | <i>Description</i>                                                                                                                                                                |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DateString</i> | Specify the year, month, and day of the effective date that you want to look for. This parameter takes a string value. You can specify the date either as YYYY-MM-DD or MM/DD/YY. |
| <i>SeqNo</i>      | Specify the sequence number of the effective date that you want to look for. This parameter takes a number value.                                                                 |

### Returns

A reference to an effective-dated item.

### Example

```
&MYCD = &MYCI.EMPL_CHKLIST_ITM;  
&DSTRING = String(&MYDATE);  
&ITEM = &MYDC.GetEffectiveItem(&DSTRING, 1);
```

### Related Links

“String” (PeopleCode Language Reference)

## GetEffectiveItemNum

### Syntax

```
GetEffectiveItemNum(DateString, SeqNo)
```

## Description

If the component associated with the Component Interface is effective-dated, `GetEffectiveItemNum` returns a reference to the number of the closest effective-dated item (row of data) that is less than or equal to the date specified by the *DateString*. To get an item number based on the current effective date, use `CurrentItemNum`.

---

**Note:** *DateString* takes only a string value. You must convert a date variable into a string before you can use it for *DateString*. You can use the `String` function to do this.

---

## Considerations for Returning Rows

`GetEffectiveItemNum` returns a valid row number only when `EFFDT` is less than or equal to *DateString*. If the value you use for *DateString* pre-dates all the rows in the data collection, this method returns a zero and logs a message in the `PSMessages` collection.

For example, if 12/01/1990 was the earliest date in the collection, the following would return zero:

```
&NUM = &MYDC.GetEffectiveItemNum("01/01/1900", 1);
```

## Parameters

| <i>Parameter</i>  | <i>Description</i>                                                                                                                                                                  |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DateString</i> | Specify the year, month, and day of the effective date that you want to look for. This parameter takes a string value. You can specify the date either as YYYY-MM-DD or MM/DD/YYYY. |
| <i>SeqNo</i>      | Specify the sequence number of the effective date that you want to look for. This parameter takes a number value.                                                                   |

## Returns

A number. This method returns 0 if no row matching the criteria is found.

## Example

```
&MYCD = &MYCI.EMPL_CHKLIST_ITM;
&DSTRING = String(&MYDATE);
&ITEMNUM = &MYDC.GetEffectiveItemNum(&DSTRING, 1);
```

## Related Links

“String” (PeopleCode Language Reference)

## InsertItem

### Syntax

```
InsertItem(number)
```

## Description

The `InsertItem` method inserts the item (row of data) at the position specified by *number*. This parameter takes a number value. You can insert items below only the zero level scroll. If you need to add a new data item, use the `Create` method instead.

`InsertItem` adds the new row *after* the current row. If the row has an effective date (EFFDT) or an effective sequence (EFFSEQ), these values are copied into the new row.

If a collection has *n* items and you specify *n* as the value for *number*, `InsertItem` inserts a new item (row) after the *last row*.

The `InsertItem` method returns a reference to the newly created item (row of data).

When the `InsertItem` method is executed, if there are any `RowInsert PeopleCode` programs associated with any of the fields, they fire also, as if the user pressed **ALT+7** and **ENTER** or clicked the `InsertRow` icon. However, the programs are executed as if turbo mode was selected. (In turbo mode default processing is performed *only* for the row being inserted.)

If you set the `InteractiveMode` property to `True`, any `RowInsert PeopleCode` runs immediately after you execute `InsertItem`. If this property is set to `False`, any `RowInsert PeopleCode` runs after you execute the `Save` method.

The inserted item is not added to the database until after you use the `Save` method.

## Example

In the following example a new item (row of data) is added at the *end* of the current collection.

```
&MYDC = &MYCI.EMPL_CHECKLIST;
&COUNT = &MYDC.Count;
&ITEM = &MYDC.InsertItem(&COUNT);
&ITEM.CHECKLIST_CD = "00001";
&ITEM.RESPONSIBLE_ID = "6609";
&RSLT = &MYCI.Save();
```

## Item

### Syntax

`Item` (*number*)

### Description

The `Item` returns the item (row of data) that exists at the *number* position in the data collection executing the method. The parameter takes a number value.

## ItemByKey

### Syntax

`ItemByKey` (&shy; *key\_values*)

## Description

The `ItemByKey`s method returns the item specified by the parameters. The number and type of keys are unique to each specific collection. Each key must be separated by a comma.

The collection reference must be the name of the Component Interface, followed by the record name. This method won't work on a collection reference (that is, `&CI.RECNAME.ItemByKey`s, not `&MYCOLLECTION.ItemByKey`s).

After you've returned an item, use the `ItemNum` property to determine the number of the item.

The keys must be in the *exact* order as in the Component Interface. A second level data collection also contains the keys of the parent data collection.

An easy way to determine the keys and their order in PeopleCode is to open the Component Interface in Application Designer, and use the Test Component. To determine the keys in Visual Basic, use the Object Browser.

See [ItemNum](#).

To see the signature for `ItemByKey`s:

1. Open the Component Interface in Application Designer.
2. Start the Component Interface Tester.

Select the open Component Interface, then right-click, and select Test Component Interface from the pop-up menu.

3. Instantiate an object.

Add data to the Get or Create keys and click Get Existing or Create New, respectively.

4. Expand the instantiated component until you find the collection in which you're interested.
5. Right-click on the collection and select `ItemByKey`s from the resulting pop-up menu.
6. The dialog that follows shows you the specific parameters, types, and order in which you should call `ItemByKey`s.

## Returns

An item (row) of data from a data collection.

## Example

```
Local ApiObject &MYSESSION;
Local ApiObject &CI;
Local ApiObject &CI_COLLECTION;
Local ApiObject &CI_ITEM;

&MYSESSION = %Session;
&CI = &MYSESSION.GetCompIntfc (COMPINTFC.CM_EVAL);
&CI.EMPLID = "8001";
If &CI.Get() <> 1 Then
    Exit;
End-If;
```

```

&CI_COLLECTION = &CI.CM_EVALUATIONS;
&COUNT = &CI_COLLECTION.Count;

&CI_ITEM = &CI.CM_EVALUATIONS.itembykeys("01");
&CI_ITEM.DESCR50 = "TEST";
If &CI.Save() <> 1 Then
    Exit;
End-If;

```

## Data Collection Properties

This section provides an overview of the Data Collection properties.

### Count

#### Description

This property returns the number of data items (rows of data) in the data collection.

This property is read-only.

#### Example

```

&CI = &MYSESSION.GetCompIntfc (COMPINTFC.CM_EVAL_BC);
&CI.EMPLID = "8001";
&CI.Get ()

&CI_COLLECTION = &CI.CM_EVALUATIONS;
&COUNT = &CI_COLLECTION.Count;

```

### CurrentItemNumber

#### Description

If the component associated with the Component Interface is effective-dated, this property returns the item number for the current effective-dated item (row of data).

This property is read-only.

---

## Data Item Class Property

This section discusses the ItemNum property.

## ItemNum

### Description

This property returns the number of the data item (row) in the collection. For example, many of the data collection methods takes a number as a parameter. Use this property to determine the item number (row number) of an item in a collection, then use that number in another method.

This property is read-only.

### Example

```
Evaluate USER_ACTION
. . .
When = "D"
  &CI_ITEM = &CI_LVL1_NAMES.ItemByKey(&NAME_TYPE, &NAME_PART);
  If &CI_ITEM <> Null then
    &I = &CI_LVL1_NAMES.ItemNum;
    &CI_LVL1_NAMES.DeleteItem(&I);
  End-if;
. . .
End-Evaluate;
```

---

## Accessing the Structure of a Component Interface

The structure of a Component Interface can be accessed using a `CompIntfPropInfoCollection` object. You access a `CompIntfPropInfoCollection` object from a `CompIntfPropInfoCollection` collection. There is more than one way to instantiate a `CompIntfPropInfoCollection` collection.

---

**Note:** You don't have to populate a Component Interface with data before you access the structure. You can access the structure of a Component Interface immediately after you use the `GetCompIntfc` method with a session object. Accessing the structure of a Component Interface before you populate it with data may increase your performance.

---

See [GetCompIntfc](#).

## CompIntfPropInfoCollection Collection

There are two types of `CompIntfPropInfoCollection` object properties: *field* properties and *collection* properties.

A *field* property maps to a specific record field. You can access structural information about the field using a `CompIntfPropInfoCollection` object. This information includes the name of the field, whether it's required, is it based on a prompt table, and so on.

A *collection* property is just that, a collection of properties. And before you can access a `CompIntfPropInfoCollection` object, you must first get a `CompIntfPropInfoCollection` *collection*. The following are the valid types of `CompIntfPropInfoCollection` collections:

- CREATEKEYS, GETKEYS and FINDKEYS

When you create a component, you must specify the search record to be used with that component. You can also specify an alternate search record to be used when the component is accessed in Add mode. The key fields from those records make up the GETKEYS, FINDKEYS, and CREATEKEYS collections.

---

**Note:** In order for a component interface to validate a key against a prompt table, both the Search Edit and List Box Item options must be selected in the record field properties for the key.

---

- **CREATEKEYS:** A collection containing the key fields of the search record specified to be used in Add mode. Use the `CreateKeyInfoCollection` property to instantiate the `CompIntfPropInfoCollection` collection.
- **GETKEYS:** A collection containing the primary required key fields from the primary search record. Use the `GetKeyInfoCollection` property to instantiate the `CompIntfPropInfo` collection.
- **FINDKEYS:** A collection containing the key fields and the alternate key fields from the primary search record. Use the `FindKeyInfoCollection` property to instantiate the `CompIntfPropInfo` collection.

- A page scroll

The fields associated with a page scroll are in this type of collection. This may or may not be all the fields associated with the record. Use the `PropertyInfoCollection` property to instantiate this kind of collection.

If the page the Component Interface is based on contains a secondary scroll, you can check the `Type` property to determine if the object is a `CompIntfPropInfoCollection` object (that is, a field), or a scroll. Then, to get the properties of the fields associated with that secondary scroll, you can use the `PropertyInfoCollection` property on the `CompIntfPropInfoCollection` object.

For example, the following Component Interface has a level zero and level one scroll.

This example illustrates the fields and controls on the Component Interface with secondary scroll. You can find definitions for the fields and controls later on this page.

The level zero scroll is made up of three fields: CHECKLIST\_CD, RESPONSIBLE\_ID, COMMENTS, and a level one scroll, EMPL\_CHKLIST\_ITM. The `CompIntfPropInfoCollection` collection for this Component Interface would have four items in it. Three would be `CompIntfPropInfoCollection` objects (the three fields.) The last item, EMPL\_CHKLIST\_ITM would *not* be a valid `CompIntfPropInfoCollection` object. You can use the `IsCollection` property to verify if an item in a collection is itself a collection or a valid `CompIntfPropInfoCollection` object.

To access the fields in a lower level scroll, you must use the `PropertyInfoCollection` property first, to return a collection of those fields.

The following example loops through a Component Interface. It pulls out the names of the properties in the first three levels of a Component Interface. If the property is a nested collection, it prefixes the ancestor collection name to the property name.

```
&MYSESSION = %Session;
&CI = &MYSESSION.GetCompIntfc (COMPINTFC.VOLNEW);
&PROPINFO_0 = &CI.PropertyInfoCollection;
For &I = 1 To &PROPINFO_0.Count;
    &PROPITEM_0 = &PROPINFO_0.Item(&I);
    Warning (&PROPITEM_0.Name);
    If (&PROPITEM_0.IsCollection) Then
        &PROPINFO_1 = &PROPITEM_0.PropertyInfoCollection;
        For &J = 1 To &PROPINFO_1.Count;
            &PROPITEM_1 = &PROPINFO_1.Item(&J);
            &S1 = &PROPITEM_0.Name | "." | &PROPITEM_1.Name;
            Warning (&S1);
            If (&PROPITEM_1.IsCollection) Then
                &PROPINFO_2 = &PROPITEM_1.PropertyInfoCollection;
                For &K = 1 To &PROPINFO_2.Count;
                    &PROPITEM_2 = &PROPINFO_2.Item(&K);
                    &S1 = &PROPITEM_0.Name | "." | &PROPITEM_1.Name | "." | &PROPITEM_2.N⇒
Name;
Warning (&S1);
```

```

        End-For;
    End-If
End-For;
End-If;
End-For;

```

---

## CompIntfPropInfoCollection Collection Methods

This section explains the CompIntfPropInfoCollection collection methods.

### First

#### Syntax

```
First()
```

#### Description

The First method returns the first CompIntfPropInfoCollection object in the CompIntfPropInfoCollection collection object executing the method.

#### Example

```
&CIINFO = &CIPOPCOLL.First();
```

### Item

#### Syntax

```
Item(number)
```

#### Description

The Item method returns a CompIntfPropInfoCollection object that exists at the *number* position in the CompIntfPropInfoCollection collection executing the method

If the specified item is *itself* a collection, the CompIntfPropInfoCollection object that gets returned is invalid (set to NULL). You can use the PropertyInfoCollection property to return a collection of CompIntfPropInfoCollection objects for the collection.

#### Example

```

&SCROLL1 = &MYCI.PropertyInfoCollection;
For &I = 1 to &SCROLL1.Count;
    &PROPERTY = &SCROLL1.Item(&I);
    If &PROPERTY.IsCollection Then
        &SCROLL2 = &PROPERTY.PropertyInfoCollection;
        /*do scroll 2 processing */
    Else
        /* do scroll 1 processing */
    End-If;
End-For;

```

## Next

### Syntax

**Next** ()

### Description

The Next method returns the next `CompIntfPropInfoCollection` object in the `CompIntfPropInfoCollection` collection object executing the method. You can use this method only after you have used either the First or Item methods: otherwise the system doesn't know where to start.

---

## CompIntfPropInfoCollection Collection Properties

This section explains the Count property.

### Count

#### Description

This property returns the number of `CompIntfPropInfoCollection` objects in the `CompIntfPropInfoCollection` collection object executing the method.

This property is read-only.

#### Example

```
&COUNT = &MYCIPROPINFOC.Count;
```

---

## CompIntfPropInfoCollection Object Properties

This section explains the `CompIntfPropInfoCollection` Object properties.

### Format

#### Description

This property returns the field format for the object executing the property (that is, name, phone, zip, SSN, and so on) as a number. The values are:

| <i>Value</i> | <i>Description</i> |
|--------------|--------------------|
| 0            | No Format          |

| <b>Value</b> | <b>Description</b>  |
|--------------|---------------------|
| 1            | Name                |
| 2            | Phone               |
| 3            | Zip                 |
| 4            | SSN                 |
| 5            | Routine             |
| 6            | Mixed Case          |
| 7            | Raw Binary          |
| 8            | Number only         |
| 9            | SIN                 |
| 10           | Phone International |
| 11           | Zip International   |
| 12           | Seconds             |
| 13           | Microseconds        |
| 14           | Custom              |

This property is read-only.

## IsCollection

### Description

This property returns True if the object executing the property is a data collection, False otherwise. If IsCollection is True, other field-oriented properties like Required, Type, Xlat, YesNo, Prompt and Format are undefined. If IsCollection is False, the object represents a field and all the previous properties are defined as described.

This property is read-only.

## IsReadOnly

### Description

This property returns True if the property marked Read Only in the Component Interface Definition; False otherwise.

This property is read-only.

## Key

### Description

This property returns True if the object executing the property is a key, False otherwise.

This property is read-only.

## LabelLong

### Description

This property returns the record field LongName value as a string. If there is a component override for this value, it is *not* included.

This property is read-only.

## LabelShort

### Description

This property returns the record field ShortName value as a string. If there is a component override for this value, it is *not* included.

This property is read-only.

## Length

### Description

This property returns the length of the field property as a number. If the property is a collection, this property returns a zero.

The length of the field is calculated by converting it to a string then getting the length of the string. This means that *everything* in the field is counted as a character, including spaces, date time separation characters, decimal points, sign indicators, and so on.

For example, the following string has 10 characters:

```
01/01/2001
```

The following string has five characters:

```
10.10
```

The following string has six characters:

```
-10.10
```

This property is read-only.

## Name

### Description

This property returns the name of the object executing the property as a string.

This property is read-only.

## Prompt

### Description

This property returns True if the object executing the property is associated with a prompt table, False otherwise.

This property is read-only.

## PropertyInfoCollection

### Description

This property returns another `CompIntfPropInfoCollection` collection if the object executing the property is a collection.

This property is read-only.

### Example

```
&SCROLL1 = &MYCI.PropertyInfoCollection;
For &I = 1 to &SCROLL1.Count;
    &PROPERTY = &SCROLL1.Item(&I);
    If &PROPERTY.IsCollection Then
        &SCROLL2 = &PROPERTY.PropertyInfoCollection;
        /*do scroll 2 processing */
    Else
        /* do scroll 1 processing */
    End-If;
End-For;
```

Required

Description

This property returns True if the object executing the property is a required property, False otherwise.

This property is read-only.

Type

Description

This property returns the field type, as a number, of the object. The values are:

| <i>Value</i> | <i>Description</i>                                       |
|--------------|----------------------------------------------------------|
| 0            | Character                                                |
| 1            | Long Character                                           |
| 2            | Number                                                   |
| 3            | Signed Number                                            |
| 4            | Date                                                     |
| 5            | Time                                                     |
| 6            | DateTime                                                 |
| 7            | SubRecord (Not supported with Component Interfaces)      |
| 8            | Image (Limited support with Component Interfaces)        |
| 9            | ImageReference (Not supported with Component Interfaces) |

This property is read-only.

Xlat

Description

This property returns True if the object executing the property is associated with an XLAT table, False otherwise.

This property is read-only.

## YesNo

### Description

This property returns True if the object executing the property is associated with the Yes/No table, False otherwise.

This property is read-only.

---

## Component Interface Examples

The following are examples of some of the most usual actions you're likely to perform using a Component Interface.

### Create a New Instance of Data Example

The following is an example of how to create a new instance of a Component Interface.

To create a new instance of data:

In this example, you are creating a new instance of data for the EXPRESS Component Interface, which is based on the EXPRESS\_ISSUE\_INV component. The following is the complete code sample: the steps explain each line.

```
Local ApiObject &MYSESSION;
Local ApiObject &MYCI;

&MYSESSION = %Session;
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.EXPRESS);
&MYCI.BUSINESS_UNIT = "H01B";
&MYCI.INTERNAL_FLG = "Y";
&MYCI.ORDER_NO = "NEXT";
&MYCI.Create();
&MYCI.CUSTOMER = "John's Chicken Shack";
&MYCI.LOCATION = "H10B6987";
.
.
.
If NOT(&MYCI.Save()) Then
  /* save didn't complete */
  &COLL = &MYSESSION.PSMessages;
  For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item(&I);
    &TEXT = &ERROR.Text;
    /* do error processing */
  End-For;
  &COLL.DeleteAll();
End-if;
```

1. Get a session object.

Before you can get a Component Interface, you have to get a session object. The session controls access to the Component Interface, provides error tracing, enables you to set the runtime environment, and so on.

```
&MYSESSION = %Session;
```

## 2. Get a Component Interface.

Use the `GetCompIntfc` method with a session object to get the Component Interface. You must specify a Component Interface definition that has already been created. You receive a runtime error if you specify a Component Interface that doesn't exist.

```
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.EXPRESS);
```

After you execute the `GetCompIntfc` method, you have only the *structure* of the Component Interface. You haven't populated the Component Interface with data yet.

## 3. Set the CREATEKEYS.

These key values are required to open a new instance of the data. If the values you specify aren't unique, that is, if an instance of the data already exists in the database with those key values, you receive a runtime error.

```
&MYCI.BUSINESS_UNIT = "H01B";
&MYCI.INTERNAL_FLG = "Y";
&MYCI.ORDER_NO = "NEXT";
```

## 4. Create the instance of data for the Component Interface.

After you set the key values, you must use the `Create` method to populate the Component Interface with the key values you set.

```
&MYCI.Create();
```

This creates an instance of this data. However, it hasn't been saved to the database. You must use the `Save` method before the instance of data is committed to the database.

## 5. Set the rest of the fields.

Assign values to the other fields.

```
&MYCI.CUSTOMER = "John's Chicken Shack";
&MYCI.LOCATION = "H10B6987";
.
.
.
```

If you have specified `InteractiveMode` as `True`, every time you assign a value or use the `InsertItem` or `DeleteItem` methods, any PeopleCode programs associated with that field (either with record field or the component record field) fires (`FieldEdit`, `FieldChange`, `RowInsert`, and so on.)

## 6. Save the data.

When you execute the `Save` method, the new instance of the data is saved to the database.

```
If NOT (&MYCI.Save()) Then
```

The `Save` method returns a Boolean value: `True` if the save was successful, `False` otherwise. You can use this value to do error checking.

The standard PeopleSoft save business rules (that is, any PeopleCode programs associated with SaveEdit, SavePreChange, WorkFlow, and so on.) are executed. If you didn't specify the Component Interface to run in interactive mode, FieldEdit, FieldChange, and so on, also run at this time for all fields that had values set.

---

**Note:** If you're running a Component Interface from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a COMMIT.

---

## 7. Check Errors.

You can check if there were any errors using the PSMessages property on the session object.

```
If NOT(&MYCI.Save()) Then
  /* save didn't complete */
  &COLL = &MYSESSION.PSMessages;
  For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item(&I);
    &TEXT = &ERROR.Text;
    /* do error processing */
  End-For;
  &COLL.DeleteAll();
End-if;
```

If there are multiple errors, all errors are logged to the PSMessages collection, not just the first occurrence of an error. As you correct each error, delete it from the PSMessages collection.

The Text property of the PSMMessage returns the text of the error message. At the end of this text is a contextual string that contains the name of the field that generated the error. The contextual string has the following syntax:

```
{BusinessComponentName.[CollectionName(Row).[CollectionName(Row).[CollectionName(Row)].PropertyNames(Row)]}.PropertyName}
```

For example, if you specified the incorrect format for a date field of the Component Interface named ABS\_HIST, the Text property would contain the following string:

```
Invalid Date {ABS_HIST.BEGIN_DT} (90), (1)
```

The contextual string (by itself) is available using the Source property of the PSMMessage.

---

**Note:** If you've called your Component Interface from an Application Engine program, all errors are also logged in the Application Engine error log tables.

---

See [Error Handling](#), [Source](#).

## Getting an Existing Instance of Data Example

The following is an example of how to get an existing instance of a Component Interface.

In this example, you are getting an existing instance of data for the EMPL\_CHKLIST\_BC Component Interface, which is based on the EMPLOYEE\_CHECKLIST component. The following is the complete code sample: the steps explain each line.

```
Local ApiObject &MYSESSION;
Local ApiObject &MYCI;
```

```

&MYSESSION = %Session;
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.EMPL_CHKLIST_BC);
&MYCI.EMPLID= "8001";
&MYCI.Get();

/* Get checklist Code */

&CHECKLIST_CD = &MYCI.CHECKLIST_CD;

/* Set Effective date */

&MYCI.EFFDT = "05-01-1990";
.
.
.
If NOT(&MYCI.Save()) Then
  /* save didn't complete */
  &COLL = &MYSESSION.PSMessages;
  For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item(&I);
    &TEXT = &ERROR.Text;
    /* do error processing */
  End-For;
  &COLL.DeleteAll();
End-if;

```

### 1. Get a session object.

Before you can get a Component Interface, you have to get a session object. The session controls access to the Component Interface, provides error tracing, enables you to set the runtime environment, and so on.

```
&MYSESSION = %Session;
```

### 2. Get a Component Interface.

Use the `GetCompIntfc` method with a session object to get the Component Interface. You must specify a Component Interface definition that has already been created. You receive a runtime error if you specify a Component Interface that doesn't exist.

```
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.EMPL_CHKLIST_BC);
```

After you execute the `GetCompIntfc` method, you have only the *structure* of the Component Interface. You haven't populated the Component Interface with data yet.

### 3. Set the GETKEYS.

These are the key values required to return a unique instance of existing data. If the keys you specify allow for more than one instance of the data to be returned, or if no instance of the data matching the key values is found, you receive a runtime error.

```
&MYCI.EMPLID = "8001";
```

### 4. Get the instance of data for the Component Interface.

After you set the key values, you have to use the `Get` method.

```
&MYCI.Get();
```

This populates the Component Interface with data, based on the key values you set.

### 5. Get field values or set field values.

At this point, you can either get values or set values.

```
&CHECKLIST_CD = &MYCI.CHECKLIST_CD;

/* OR */
&MYCI.EFFDT = "05-01-1990";
```

If you have specified `InteractiveMode` as `True`, every time you assign a value, any PeopleCode programs associated with that field (either with record field or the component record field) fires (`FieldEdit`, `FieldChange`, and so on.)

## 6. Save or Cancel the Component Interface, as appropriate.

If you've changed values and you want to save your changes to the database, you must use the `Save` method.

```
If NOT (&MYCI.Save ()) Then
```

The `Save` method returns a Boolean value: `True` if the save was successful, `False` otherwise. Use this value to do error checking.

The standard PeopleSoft save business rules (that is, any PeopleCode programs associated with `SaveEdit`, `SavePreChange`, `WorkFlow`, and so on.) are executed. If you didn't specify the Component Interface to run in interactive mode, `FieldEdit`, `FieldChange`, and so on, also run at this time.

---

**Note:** If you're running a Component Interface from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a `COMMIT`.

---

If you don't want to save any changes to the data, use the `Cancel` method. The Component Interface is reset to the state it was in just after you used the `GetCompIntfc` method.

```
&MYCI.Cancel ();
```

This is similar to a user pressing `ESC` while in a component, and choosing to not save any of their changes.

## 7. Check Errors.

You can check if there were any errors using the `PSMessages` property on the session object.

```
If NOT (&MYCI.Save ()) Then
  /* save didn't complete */
  &COLL = &MYSESSION.PSMessages;
  For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item (&I);
    &TEXT = &ERROR.Text;
    /* do error processing */
  End-For;
  &COLL.DeleteAll ();
End-if;
```

If there are multiple errors, all errors are logged to the `PSMessages` collection, not just the first occurrence of an error. As you correct each error, delete it from the `PSMessages` collection.

The `Text` property of the `PSMessage` returns the text of the error message. At the end of this text is a contextual string that contains the name of the field that generated the error. The contextual string has the following syntax:

```
{ComponentInterfaceName.[CollectionName (Row)].[CollectionName (Row)].[CollectionN⇒
```

```
ame(Row)]]].PropertyName}
```

For example, if you specified the incorrect format for a date field of the Component Interface named `ABS_HIST`, the Text property would contain the following string:

```
Invalid Date {ABS_HIST.BEGIN_DT} (90), (1)
```

The contextual string (by itself) is available using the Source property of the `PSMessage`.

---

**Note:** If you've called your Component Interface from an Application Engine program, all errors are also logged in the Application Engine error log tables.

---

See [Error Handling](#), [Source](#).

## Retrieving a List of Instance of Data Example

The following is an example of how to retrieve a list of instances of data.

To retrieve a list of instances of data:

In this example, you are getting a list of existing instances of data for the `EMPL_CHKLIST_CI` Component Interface, which is based on the `EMPLOYEE_CHECKLIST` component. The following is the complete code sample: the steps break it up and explain each line.

```
Local ApiObject &MYSESSION;
Local ApiObject &MYCI;
Local ApiObject &MYNEWCI;

&MYSESSION = %Session;
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.EMPL_CHKLIST_CI);
&MYCI.EMPLID= "8";
&MYCI.LAST_NAME_SRCH = "S";
&MYLIST = &MYCI.Find();
For &I = 1 to &MYLIST.Count;

    /* note: do not reuse the CI used to create the list, or the list will be destro⇒
    yed */

    &MYNEWCI = &MYLIST.Item(&I);

    /* CI from list still must be instantiated to use it */

    &MYNEWCI.Get();

    /* do some processing */

End-For;
```

### 1. Get a session object.

Before you can get a Component Interface, you have to get a session object. The session controls access to the Component Interface, provides error tracing, enables you to set the runtime environment, and so on.

```
&MYSESSION = %Session;
```

### 2. Get a Component Interface.

Use the `GetCompIntfc` method with a session object to get the Component Interface. You must specify a Component Interface definition that has already been created. You receive a runtime error if you specify a Component Interface that doesn't exist.

```
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.EMPL_CHKLIST_CI);
```

After you execute the `GetCompIntfc` method, you have only the *structure* of the Component Interface. You haven't populated the Component Interface with data yet.

### 3. Set the FINDKEYS values.

These can be alternate key values or partial key values. If no instance of the data matching the key values is found, you receive a runtime error.

```
&MYCI.EMPLID = "8";
&MYCI.LAST_NAME_SRCH = "S";
```

### 4. Get a list of data instances for the Component Interface.

After you set the alternate or partial key values, use the `Find` method to return a list of data instances for the Component Interface.

```
&MYLIST = &MYCI.Find();
```

---

**Note:** The `Find` method can be executed only at level zero in a Component Interface.

---

### 5. Select an instance of the data.

To select an instance of the data, you can use any of the following standard data collection methods:

- First
- Item
- Next

For example, you could loop through every instance of the data to do some processing:

```
For &I = 1 to &MYLIST.Count;
  /* note: do not reuse the Component Interface used to */
  /* create the list here, or the list will be destroyed */
  &MYNEWCI = &MYLIST.Item(&I);
  /* CI from list must still be instantiated to use it */
  &MYNEWCI.Get();
  /* do some processing */
End-For;
```

After you have a specific instance of the data, you can get values, set values, and so on.

See [Data Collection Methods](#).

## Inserting Effective-Dated Data Example

You can rename a collection in a Component Interface. For example, suppose you had the same record at level zero and at level one. You may want to rename the level one data collection to reflect this. The data in a data collection is associated with the primary database record of a scroll, *not* with the name you supply.

Here is an example of using a Component Interface that has the same record at level zero and level one. The Component Interface is based on the CURRENCY\_CD\_TBL component.

This example illustrates the fields and controls on the Example of CI with same record at level zero and level one. You can find definitions for the fields and controls later on this page.

The following code example is based on this Component Interface and does the following:

1. Gets an existing Component Interface.
2. Finds the current effective-dated item index.
3. Inserts a new row before the current effective-dated item using the InsertItem method.

```

Local ApiObject &Session;
Local ApiObject &CURRENCY_CD;
Local ApiObject &CURRENCY_CD_TBLCol;
Local ApiObject &CURRENCY_CD_TBLItm;
Local ApiObject &PSMessages;
Local string &ErrorText, &ErrorType;
Local number &ErrorCount;
Local Boolean &Error;

Function CheckErrorCodes()

    &PSMessages = &Session.PSMessages;
    &ErrorCount = &PSMessages.Count;
    For &i = 1 To &ErrorCount
        &ErrorText = &PSMessages.Item(&i).Text;
        &ErrorType = &PSMessages.Item(&i).Type;
    End-For;

End-Function;

/* Initialize Flags */
&Error = False;

&Session = %Session;

If &Session <> Null Then

    CheckErrorCodes();

```

```

/* Application Specific Error Processing */
Else
    &CURRENCY_CD = &Session.GetCompIntfc(CompIntfc.CURRENCY_CD);
    If &CURRENCY_CD = Null Then
        CheckErrorCodes();
        /* Application Specific Error Processing */
    Else
        /* Set Component Interface Get Keys */
        &CURRENCY_CD.CURRENCY_CD = "USD";
        If Not &CURRENCY_CD.Get() Then
            CheckErrorCodes();
            /* Application Specific Error Processing */
            &Error = True;
        End-If;
        If Not &Error Then
            &CURRENCY_CD_TBLCol = &CURRENCY_CD.CURRENCY_CD_TBL;
            &CURRENCY_CD_TBLItm = &CURRENCY_CD_TBLCol.InsertItem(&CURRENCY_CD_TBL⇒
Col.CurrentItemNum());
            &CURRENCY_CD_TBLItm.EFFDT = %Date;
            &CURRENCY_CD_TBLItm.EFF STATUS = "A";
            &CURRENCY_CD_TBLItm.DESCR = "NewCurrencyCode";
            &CURRENCY_CD_TBLItm.DESCRSHORT = "New";
            &CURRENCY_CD_TBLItm.COUNTRY = "USA";
            &CURRENCY_CD_TBLItm.CUR_SYMBOL = "?";
            &CURRENCY_CD_TBLItm.DECIMAL_POSITIONS = 4;
            &CURRENCY_CD_TBLItm.SCALE_POSITIONS = 0;
            /* Save Instance of Component Interface */
            If Not &CURRENCY_CD.Save() Then
                CheckErrorCodes();
                /* Application Specific Error Processing */
            End-If;
        End-If;
        /* End: Set Component Interface Properties */
        /* Cancel Instance of Component Interface */
        &CURRENCY_CD.Cancel();
    End-If;
End-If;

```

## Inserting Effective-Dated Data Example Using Visual Basic

Here's a code example in Visual Basic that does the same thing as the previous code example.

```

Private Sub CURRENCY_CD()
    On Error GoTo eMessage
    '***** Set Object References *****
    Dim oCISession As Object
    Dim oCURRENCY_CD As Object
    Dim oCURRENCY_CD_TBL As Object

```

```

Dim oCURRENCY_CD_TBLItem As Object

'***** Set Connect Parameters *****
strAppSeverPath = "//PSOFT101999:9000"
strOperatorID = "PTDMO"
strPassword = "PTDMO"

'***** Create PeopleSoft Session Object *****
Set oCISession = CreateObject("PeopleSoft.Session")

'***** Connect to the App Sever *****
oCISession.Connect 1, strAppSeverPath, strOperatorID, strPassword, 0

'***** Get the Component *****
Set oCURRENCY_CD = oCISession.GetCompIntfc("CURRENCY_CD")

'***** Set the Component Interface Mode *****
oCURRENCY_CD.InteractiveMode = False
oCURRENCY_CD.GetHistoryItems = True

'***** Set Component Get/Create Keys *****
oCURRENCY_CD.CURRENCY_CD = "USD"

'***** Execute Create *****
oCURRENCY_CD.Get

'Set CURRENCY_CD_TBL Collection Field Properties --
'Parent: PS_ROOT Collection
Set oCURRENCY_CD_TBL = oCURRENCY_CD.CURRENCY_CD_TBL
Set oCURRENCY_CD_TBLItem = oCURRENCY_CD_TBL.InsertItem(oCURRENCY_CD_TBL.Cur⇒
rentItemNum())

oCURRENCY_CD_TBLItem.EFFDT = Date
oCURRENCY_CD_TBLItem.EFF_STATUS = "A"
oCURRENCY_CD_TBLItem.DESCR = "NewCurrencyCode"
oCURRENCY_CD_TBLItem.DESCRSHORT = "New"
oCURRENCY_CD_TBLItem.COUNTRY = "USA"
oCURRENCY_CD_TBLItem.CUR_SYMBOL = "?"
oCURRENCY_CD_TBLItem.DECIMAL_POSITIONS = 4
oCURRENCY_CD_TBLItem.SCALE_POSITIONS = 0

'***** Save Component Interface *****
oCURRENCY_CD.Save
oCURRENCY_CD.Cancel

Exit Sub

eMessage:
'***** Display VB Runtime Errors *****
MsgBox Err.Description

'***** Display PeopleSoft Error Messages *****
If oCISession.PSMessages.Count > 0 Then
    For i = 1 To oCISession.PSMessages.Count
        MsgBox oCISession.PSMessages.Item(i).Text
    Next i
End If

End Sub

Sub MAIN()
    CURRENCY_CD
End Sub

```

## Inserting or Deleting a Row of Data Example

The CopyRowset and CopyRowsetDelta methods use the primary database name of a scroll, not the name you may give a collection.

A data collection represents a row of data. You often insert or delete a row of data.

To insert or delete a row of data:

In this example, you are getting an existing instance of data for the BUS\_EXP Component Interface, which is based on the BUSINESS\_EXPENSES component, then inserting (or deleting) a row of data in the second level scroll.

This example illustrates the fields and controls on the BUS\_EXP Component Interface definition. You can find definitions for the fields and controls later on this page.

The following is the complete code sample: the steps explain each line.

```
Local ApiObject &MYSESSION;
Local ApiObject &MYCI;

&MYSESSION = %Session;
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.BUS_EXP);
&MYCI.EMPLID= "8001";
&MYCI.Get();
&MYLEVEL1 = &MYCI.BUS_EXPENSE_PER;
/* get appropriate item in lvl1 collection */
For &I = 1 to &MYLEVEL1.Count
&ITEM = &MYLEVEL1.Item(&I);
&MYLEVEL2 = &ITEM.BUS_EXPENSE_DTL;
&COUNT = &MYLEVEL2.Count
/* get appropriate item in lvl2 collection */
For &J = 1 to &COUNT
&LVL2ITEM = &MYLEVEL2.Item(&J);
&CIDATE = &LVL2ITEM.CHARGE_DT;
If &CIDATE <> %Date Then
    /* insert row */
    &NEWITEM = &MYLEVEL2.InsertItem(&COUNT);
    /* set values for &NEWITEM */
Else
    /* delete last row */
    &MYLEVEL2.DeleteItem(&COUNT);
End-If;
End-For;
```

```

End-For;

If NOT(&MYCI.Save()) Then
  /* save didn't complete */
  &COLL = &MYSESSION.PSMessages;
  For &I = 1 to &COLL.Count
    &ERROR = &COLL.Item(&I);
    &TEXT = &ERROR.Text;
    /* do error processing */
  End-For;
  &COLL.DeleteAll();
End-if;

```

### 1. Get a session object.

Before you can get a Component Interface, you have to get a session object. The session controls access to the Component Interface, provides error tracing, enables you to set the runtime environment, and so on.

```
&MYSESSION = %Session;
```

### 2. Get a Component Interface.

Use the `GetCompIntfc` method with a session object to get the Component Interface. You must specify a Component Interface definition that has already been created. You receive a runtime error if you specify a Component Interface that doesn't exist.

```
&MYCI = &MYSESSION.GetCompIntfc (COMPINTFC.BUS_EXP);
```

After you execute the `GetCompIntfc` method, you have only the *structure* of the Component Interface. You haven't populated the Component Interface with data yet.

### 3. Set the GETKEYS.

These are the key values required to return a unique instance of existing data. If the keys you specify allow for more than one instance of the data to be returned, or if no instance of the data matching the key values is found, you receive a runtime error.

```
&MYCI.EMPLID = "8001";
```

### 4. Get the instance of data for the Component Interface.

After you set the key values, you must use the `Get` method.

```
&MYCI.Get();
```

This populates the Component Interface with data, based on the key values you set.

### 5. Get the level one scroll.

The name of the scroll can be treated like a property. It returns a data collection that contains all the level one data.

```
&MYLEVEL1 = &MYCI.BUS_EXPENSE_PER
```

### 6. Get the appropriate item in the level one data collection.

Remember, scroll data is hierarchical. You must get the appropriate level one row before you can access the level two data.

```
For &I = 1 to &MYLEVEL1.Count
```

```
&ITEM = &MYLEVEL1.Item(&I);
```

## 7. Get the level two scroll.

This is done the same way as you accessed the level one scroll, by using the scroll name as a property.

```
&MYLEVEL2 = &ITEM.BUS_EXPENSE_DTL;
```

## 8. Get the appropriate item in the level two data collection.

A data collection is made up of a series of items (rows of data.) You have to access the appropriate item (row) in this level also.

```
&COUNT = &MYLEVEL2.Count
/* get appropriate item in lvl2 collection */
For &J = 1 to &COUNT
&LVL2ITEM = &MYLEVEL2.Item(&J);
```

## 9. Insert or delete a row of data.

You can insert or delete a row of data from a data collection. The following example finds the last item (row of data) in the second level scroll. If it matches the value of %Date, the last item is deleted. If it doesn't match, a new row is inserted.

```
&CIDATE = &LVL2ITEM.CHARGE_DT;
If &CIDATE <> %Date Then
    /* insert row */
    &NEWITEM = &MYLEVEL2.InsertItem(&COUNT);
    /* set values for &NEWITEM */
Else
    /* delete last row */
    &MYLEVEL2.DeleteItem(&COUNT);
End-If;
```

## 10. Save the data.

When you execute the Save method, the new instance of the data is saved to the database.

```
If NOT(&MYCI.Save()) Then
```

The Save method returns a Boolean value: True if the save was successful, False otherwise. Use this value to do error checking.

The standard PeopleSoft save business rules (that is, any PeopleCode programs associated with SaveEdit, SavePreChange, WorkFlow, and so on) are executed. If you did not specify the Component Interface to run in interactive mode, FieldEdit, FieldChange, and so on, also run at this time.

---

**Note:** If you're running a Component Interface from an Application Engine program, the data won't actually be committed to the database until the Application Engine program performs a COMMIT.

---

## 11. Check Errors.

You can check if there were any errors using the PSMessages property on the session object.

```
If NOT(&MYCI.Save()) Then
    /* save didn't complete */
    &COLL = &SESSION.PSMessages;
    For &I = 1 to &COLL.Count
        &ERROR = &COLL.Item(&I);
        &TEXT = &ERROR.Text;
        /* do error processing */
    End-For;
```

```
&COLL.DeleteAll();
End-if;
```

If there are multiple errors, all errors are logged to the PSMessages collection, not just the first occurrence of an error. As you correct each error, delete it from the PSMessages collection.

The Text property of the PSMessage returns the text of the error message. At the end of this text is a contextual string that contains the name of the field that generated the error. The contextual string has the following syntax:

```
{BusinessComponentName.[CollectionName(Row).[CollectionName(Row).[CollectionName(Row)].PropertyNames(Row)].PropertyName}
```

For example, if you specified the incorrect format for a date field of the Component Interface named ABS\_HIST, the Text property contains the following string:

```
Invalid Date {ABS_HIST.BEGIN_DT} (90), (1)
```

The contextual string (by itself) is available using the Source property of the PSMessage.

---

**Note:** If you've called the Component Interface from an Application Engine program, all errors are also logged in the Application Engine error log tables.

---

See [Error Handling](#), [Source](#).

# Connected Query Classes

---

## Understanding the Connected Query Classes

Connected query is a PeopleTools managed object that supports typical managed object functionality such as:

- Creating a new object.
- Editing an existing object.
- Deleting an object.
- Copying an object.
- Renaming an object.<sup>1</sup>
- Caching an object.
- Adding an object to a project.
- Using project compare functionality.
- Copying to or restoring from a file.
- Upgrading to the database.

<sup>1</sup> Renaming a connected query object is supported on a managed object level, but is not exposed as a function in PeopleCode.

A connected query object is exposed to the report developer through the public methods and properties of the PT\_CONQRS application package. The remainder of this chapter provides reference on those classes, methods, and properties.

Connected queries are described in more detail in the PeopleSoft Query PeopleBook.

### Related Links

“Understanding Connected Query” (Query)

---

## Importing Connected Query Classes

The connected query classes are application classes, not built-in classes, like Rowset, Field, Record, and so on. Before you can use these classes in your PeopleCode program, you must import them into your program.

An import statement either names a particular application class or imports all the classes in a package.

Using the asterisks after the package name makes all the application classes directly contained in the named package available. Application classes contained in subpackages of the named package are not made available.

---

## CONQRSMGR Class

This section provides an overview of the CONQRSMGR class and discusses:

- CONQRSMGR class constructor.
- CONQRSMGR class methods.
- CONQRSMGR class properties.

---

## CONQRSMGR Class Constructor

This section presents the constructor for the CONQRSMGR class.

### CONQRSMGR

#### Example

```
import PT_CONQRS:CONQRSMGR;

Local PT_CONQRS:CONQRSMGR &objConQrsInst = create PT_CONQRS:CONQRSMGR(&sOprId, &sCO⇒
NQRSNAME);
```

---

**Note:** The first parameter is not required; an empty string can be specified instead.

---

#### Related Links

[Constructors](#)

[Import Declarations](#)

---

## CONQRSMGR Class Methods

In this section, the CONQRSMGR class methods are presented in alphabetical order.

### CleanOutputFile

#### Syntax

```
CleanOutputFile ()
```

## Description

Use this method to delete the connected query output file.

---

**Note:** This method is valid only for a connected query scheduled for running to a file—that is, when the run mode is equal to `RunMode_Sched_File`.

---

## Parameters

None.

## Returns

None.

## Close

### Syntax

```
Close()
```

## Description

Use this method to clean up connected query resources.

## Parameters

None.

## Returns

None.

## CopyDefn

### Syntax

```
CopyDefn(target_UserID, target_ID)
```

## Description

Use this method to copy the connected query definition to a new ID. The user's query access security is checked prior to the copy.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>target_UserID</i>    | Specifies the user ID of the owner of the new connected query as a string. An empty string indicates that the new connected query is public. |
| <i>target_ID</i>        | Specifies the ID for the new connected query as a string.                                                                                    |

## Returns

A Boolean value: True if the copy is successful, False otherwise.

## DeleteDefn

### Syntax

```
DeleteDefn()
```

### Description

Use this method to delete the current connected query definition.

### Parameters

None.

### Returns

A Boolean value: True if the delete was successful, False otherwise.

## ExistsByName

### Syntax

```
ExistsByName( ObjName)
```

### Description

Use this method to for the existence of a connected query definition based on the specified definition name.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                  |
|-------------------------|------------------------------------------------------------|
| <i>ObjName</i>          | Specifies the connected query definition name as a string. |

## Returns

A Boolean value: True if connected query definition exists, False otherwise.

## GetSampleXMLString

### Syntax

**GetSampleXMLString** (*RowNum*)

### Description

Use this method to generate and return a sample XML string. Use this string with BI Publisher data sources based on a connected query.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                             |
|-------------------------|-----------------------------------------------------------------------|
| <i>RowNum</i>           | Sets number of rows of sample data to generate for each member query. |

## Returns

A string representing the sample XML data.

## Open

### Syntax

**Open** (*IsNew*)

### Description

Use this method to open a new or existing connected query definition.

This method should be called after a connected query object constructor. It initializes a new or existed connected query object.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>IsNew</i>            | Specifies as a Boolean value whether the connected query object represents a new connected query definition (True), or an existing definition (False). |

## Returns

A Boolean value: True if the open was successful, False otherwise.

## ResetQueriesPrompt

### Syntax

```
ResetQueriesPrompt()
```

### Description

Use this method after a user clicks Cancel in a query prompt dialog.

### Parameters

None.

### Returns

None.

## Run

### Syntax

```
Run(Prompts, runProcessInfo)
```

### Description

Use this method to run the connected query. The Run method is valid for the following run modes only:

- RunMode\_Prev — Referred to as *preview mode*.
- RunMode\_Sched\_Web or RunMode\_Sched\_File — Referred to as *scheduled mode*.

If an error results, the Run method populates an error string with error details.

## Preview Mode

In preview mode, the connected query is run immediately on the application sever. The output data is displayed in a separate browser window. In preview mode, the *Prompts* parameter is required; the *runProcessInfo* parameter *must* be set to Null. The *Prompts* parameter should be retrieved using the *QueriesPromptsArray* property. If this array length is greater than 0, this array must be populated.

---

**Note:** If both parameters are not null, the scheduling information is used to run the connected query by Process Scheduler.

---

## Scheduled Mode

In scheduled mode, the connected query is run by Process Scheduler. In the case of *RunMode\_Sched\_File*, the output data is written to an XML file. In the case of *RunMode\_Sched\_Web*, the output data is accessible via a hyperlink in Process Monitor. In scheduled mode, the *runProcessInfo* parameter is required; the *Prompts* parameter should be set to Null.

---

**Note:** If both parameters are not null, the scheduling information is used to run the connected query by Process Scheduler.

---

## Parameters

| <i>Parameter</i>      | <i>Description</i>                                                                                                                                              |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Prompts</i>        | Specifies the prompts for execution of the queries as an array of QUERYITEMPROMPT objects. This parameter should be set to null when running in scheduled mode. |
| <i>runProcessInfo</i> | Specifies the scheduling information for running the queries as a SCHED_INFO object. This parameter <i>must</i> be null when running in preview mode.           |

## Returns

A Boolean value: True if the connected query was run successfully, False otherwise.

## Related Links

[QueriesPromptsArray](#)

[RunMode](#)

[QUERYITEMPROMPT Class](#)

[SCHED\\_INFO Class](#)

[Running a Connected Query in Scheduled Mode](#)

[Running a Connected Query in Preview Mode or Background Mode](#)

## RunToWindow

### Syntax

`RunToWindow()`

### Description

Use this method to run a connected query in *background mode*. Similar to preview mode, running a connected query in background mode results in the output data being displayed in a separate browser window. However, in background mode, the connected query is run through Process Scheduler with a REN server. Running a connected query in this manner prevents blocking on the application server. While the report file is generated, the user can continue working with the PeopleSoft application and the application server environment.

To specify the scheduling information, prior to invoking the RunToWindow method, you must invoke the SetRunControlData method as follows:

```
&res = &objConQrsInst.SetRunControlData(&objConQrsInst.Const.RunCntlId_Auto, False)⇒  
;
```

The RunToWindow method is valid for the RunMode\_Window run mode only.

### Parameters

None.

### Returns

The process ID as a number.

### Related Links

[Run](#)

[RunToXMLFormattedString](#)

[RunMode](#)

[Running a Connected Query in Preview Mode or Background Mode](#)

## RunToXMLFormattedString

### Syntax

`RunToXMLFormattedString(Prompts)`

### Description

Use this method to run the connected query immediately on the application server with output to an XML formatted string instead of an XML file.

The RunToXMLFormattedString method is valid for the RunMode\_XMLFormattedString run mode only.

## Parameters

| <i>Parameter</i> | <i>Description</i>                                                                                                                                                                                                                          |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Prompts</i>   | Specifies the prompts for execution of the queries as an array of QUERYITEMPROMPT objects. This parameter should be retrieved using the QueriesPromptsArray property. If this array length is greater than 0, this array must be populated. |

## Returns

The formatted XML as a string.

## Save

### Syntax

**Save** ()

### Description

Use this method to save the connected query object to the database as a connected query definition. If the connected query does not pass validation, it is saved with an inactive status.

### Parameters

None.

### Returns

A Boolean value: True if the save was successful, False otherwise.

## SaveRunControlParms

### Syntax

**SaveRunControlParms** (*runCntlID*)

## Description

Use this method to save the in-memory process request parameter array to the database. This method is also called internally from the `SetRunControlData` method when `IsChangeDB` is true.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                 |
|-------------------------|-------------------------------------------|
| <i>runCntlID</i>        | Specifies the run control ID as a string. |

## Returns

A Boolean value: True if the save was successful, False otherwise.

## Related Links

[SetRunControlData](#)

# SetRunControlData

## Syntax

```
SetRunControlData(runCntlID, IsNewCtrl, IsChangeDB)
```

## Description

Use this as an interactive method to prompt the user if member queries have prompts. This method saves prompt data to the database using the PSCONQRSRUNPRM or PSCONQRSRUNPRMX records if the `IsChangeDB` parameter is passed as true. Call this method prior to scheduling a connected query to run in scheduled mode.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------|
| <i>runCntlID</i>        | Specifies the run control ID as a string.                                                  |
| <i>IsNewCtrl</i>        | Specifies as a Boolean value whether the run control is new.                               |
| <i>IsChangeDB</i>       | Specifies as a Boolean value whether to write the run control information to the database. |

## Returns

A Boolean value: True if the run control parameters were set successfully, False otherwise.

## Validate

### Syntax

`Validate()`

### Description

Use this method to validate the following:

- The existence of each query used in the connected query.
- Whether mapped fields used in the connected query object are still part of the `QueryOutputFields` collection for each query.
- The user security access for each query.

If validation fails, `Validate` populates an error string with the error details.

### Parameters

None.

### Returns

A Boolean value: True if the connected query passes all the validation checks, False otherwise.

### Related Links

[QueryOutputFields](#)

## ValidateIfFieldsMapped

### Syntax

`ValidateIfFieldsMapped()`

### Description

Use this method to check whether all queries have mapped fields. Use this method to confirm that it is the report developer's intention to have unmapped fields in the queries.

If validation fails, `ValidateIfFieldsMapped` populates an error string with the names of the unlinked queries.

### Parameters

None.

## Returns

A Boolean value: True if all the queries have mapped fields, False otherwise.

## ValidateRunControlParms

### Syntax

```
ValidateRunControlParms (runCntlID)
```

### Description

Use this method to determine whether sufficient populated records exist in the or PSCONQSRUNPRMX tables for the specified run control ID. ValidateRunControlParms compares the number of entries in the parameter tables with the number of prompts required for the connected query.

If validation fails, ValidateRunControlParms populates an error string with the error details.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                 |
|-------------------------|-------------------------------------------|
| <i>runCntlID</i>        | Specifies the run control ID as a string. |

### Returns

A Boolean value: True if the validation is successful, False otherwise.

---

## CONQRSMGR Class Properties

In this section, the CONQRSMGR class properties are presented in alphabetical order.

## Const

### Description

This property returns a CONQRS\_CONST object.

This property is read-only.

### Related Links

[CONQRS\\_CONST Class](#)

## Description

### Description

Use this property to set or return a description for the connected query as a string.

This property is read/write.

## Details

### Description

Use this property to set or return a long description for the connected query as a string.

This property is read/write.

## ErrString

### Description

This property returns the error message as a string if an error occurs during processing.

This property is read-only.

## ExecutionLog

### Description

Use this property to return a Boolean value indicating whether to perform execution logging while executing the connected query.

This property is read-only.

---

**Note:** While this property is read-only, it can be set through the PropertyArray property.

---

The default value is False.

### Related Links

[IsDebugMode](#)

[PropertyArray](#)

## IgnoreRelFldOutput

### Description

Use this property to return a Boolean value indicating whether to create XML output without related field nodes.

This property is read-only.

---

**Note:** While this property is read-only, it can be set through the `PropertyArray` property.

---

The default value is `False`.

### Related Links

[PropertyArray](#)

## IsChanged

### Description

This property returns a Boolean value indicating whether the connected query has been changed.

---

**Note:** When an existing connected query is opened, `IsChanged` is initialized to `False`.

---

This property is read-only.

## IsDebugMode

### Description

Use this property to return a Boolean value indicating whether to perform logging while executing the connected query. In addition, in debug mode, temporary files generated during execution of the connected query are not deleted after execution is complete. The log also contains SQL statements generated by each member query as well as values for the related fields used to link the parent query to its children.

This property is read-only.

---

**Note:** While this property is read-only, it can be set through the `PropertyArray` property.

---

The default value is `False`.

### Related Links

[ExecutionLog](#)

[PropertyArray](#)

## IsInit

### Description

This property returns a Boolean value indicating whether the connected query object has been initialized (opened) after object instance was created.

This property is read-only.

## IsPublic

### Description

This property returns a Boolean value indicating whether the connected query is public.

This property is read-only.

## LastUpdatedBy

### Description

This property returns the user ID of the user to have last updated the connected query, as a string.

This property is read-only.

## LastUpdateDTTM

### Description

This property returns the last update date and time for the connected query, as a DateTime value.

This property is read-only.

## MaxRowsPerQuery

### Description

Use this property to set or return a number representing the maximum number of rows returned by each query in preview mode. If set to 0, no maximum is set.

This property is read/write.

## Name

### Description

This property returns the name of the connected query as a string.

This property is read-only.

## ObjectRowset

### Description

Use this property to set or return a Rowset object. The parent record for this rowset is PSCONQRSMAPVW; its child record is PSCONQRSFLDRLVW. Use of the ObjectRowset property and its associated rowset prevents the report developer from directly manipulating the managed object itself.

Getting the ObjectRowset property returns a Rowset object with the following structure, populated with Connected Query Manager data:

```
ObjectRowset = CreateRowset (Record.PSCONQSRMAPVW, CreateRowset (Record.PSCONQRSFLDRL⇒  
VW) ) ;
```

Setting the ObjectRowset property returns the rowset data back to the Connected Query Manager.

This property is read/write.

## Related Links

[Iterating Through a Connected Query Opened for Editing](#)

## OprID

### Description

This property returns a string representing the user ID to which the connected query belongs to for private queries. For public queries, an empty string is returned.

This property is read-only.

## OutProcessFileName

### Description

This property returns a string representing the output file name as an absolute path.

---

**Note:** This property is valid only for a connected query scheduled for running to a file—that is, when the run mode is equal to RunMode\_Sched\_File.

---

This property is read-only.

## PropertyArray

### Description

Use this property to set or return an array of CONQRSPROPERTY objects (properties) for the connected query. If no properties exist, this array returns the default set of properties.

This property is read/write.

The following read-only properties of the CONQRSMGR class are dynamically synchronized whenever the PropertyArray property is set or returned:

- ExecutionLog
- IgnoreRelFldOutput
- IsDebugMode

- ShowFormattedXML

## Example

The first example retrieves a set of properties from the database and populates the page grid using the Page Activate event:

```
import PT_CONQRS:CONQRSMGR;
import PT_CONQRS:CONQRSPROPERTY;

Component PT_CONQRS:CONQRSMGR &cConQrsInst;

Local array of PT_CONQRS:CONQRSPROPERTY &propArr;
Local Rowset &rsProp;
Local number &i, &j;

&propArr = &cConQrsInst.PropertyArray;
If &propArr.Len = 0 Then
    Return;
End-If;
Local Record &recProp, &recWrk;
&rsProp = GetLevel0()(1).GetRowset(Scroll.PSCONQRSPROP);
&rsProp.Flush();
For &i = 1 To &propArr.Len
    If &i > 1 Then
        &rsProp.InsertRow(&i - 1);
    End-If;
    &recProp = &rsProp(&i).PSCONQRSPROP;
    &recProp.PROPVVALUEOPTION.ClearDropDownList();
    For &j = 1 To &propArr [&i].PROPVVALUEARRAY.Len
        &recProp.PROPVVALUEOPTION.AddDropDownItem(&propArr [&i].PROPVVALUEARRAY [&j], &⇒
propArr [&i].PROPVVALUEARRAYDESC [&j]);
    End-For;
    &recProp.PROPNAME.Value = &propArr [&i].PROPNAME;
    &recProp.PROPVVALUEOPTION.Value = &propArr [&i].PROPVVALUE;
    &recProp.OPRID.Value = &cConQrsInst.OprID;
    &recProp.CONQRSNAME.Value = &cConQrsInst.Name;

    &recWrk = &rsProp(&i).PSCONQRS_WRK;
    &recWrk.PROPVVALUEOPTION.Value = &propArr [&i].PROPDEFAULT;
End-For;
```

The second example populates a property array from a page grid. This program is executed when a user hits the OK button on a secondary page, PSCONQRSPROPS:

```
import PT_CONQRS:CONQRSMGR;
import PT_CONQRS:CONQRSPROPERTY;

Component PT_CONQRS:CONQRSMGR &cConQrsInst;

If %Page = Page.PSCONQRSPROPS Then
    Local array of PT_CONQRS:CONQRSPROPERTY &propArr;
    Local Rowset &rsProp;
    Local number &i;
    Local Record &recProp, &recWrk;

    /* Get the property array from the database. */
    &propArr = &cConQrsInst.PropertyArray;
    If &propArr.Len = 0 Then
        Return;
    End-If;

    &rsProp = GetLevel0()(1).GetRowset(Scroll.PSCONQRSPROP);
    If &propArr.Len <> &rsProp.ActiveRowCount Then
        Return;
    End-If;
```

```

For &i = 1 To &rsProp.ActiveRowCount
    &recProp = &rsProp(&i).PSCONQRSPROP;
    &recWrk = &rsProp(&i).PSCONQRS_WRK;
    If None(&recProp.PROPNAMe.Value) Then
        &recProp.PROPNAMe.Value = &recWrk.PROPVALUEOPTION.Value;
    End-If;
    &propArr [&i].PROPNAMe = &recProp.PROPNAMe.Value;
    &propArr [&i].PROPVALUE = &recProp.PROPVALUEOPTION.Value;
    &propArr [&i].PROPDEFAULT = &recWrk.PROPVALUEOPTION.Value;
End-For;

/* Return the modified property array to the database. */
&cConQrsInst.PropertyArray = &propArr;
End-If;

```

## QueriesPromptsArray

### Description

This property returns an array of QUERYITEMPROMPT objects. This array is used by the connected query object as a parameter to the Run method in preview mode.

This property is read-only.

### Related Links

[QUERYITEMPROMPT Class](#)

## QueryArray

### Description

This property returns an array of string representing the query names that constitute the connected query object.

This property is read-only.

## RegisteredBy

### Description

This property returns a string representing the user ID of the user who created the connected query object.

This property is read-only.

## RegisteredDTTM

### Description

This property returns the creation date and time for the connected query, as a DateTime value.

This property is read-only.

## RunCntlId

### Description

This property returns a string representing the run control ID for scheduling the connected query.

This property is read-only.

## RunControlParArray

### Description

This property returns an array of PSCONQSRUNPRM records to be used for displaying and updating the set of scheduling parameters for the queries.

This property is read-only.

## RunMode

### Description

This property returns a number representing the run mode for a connected query instance. The values are:

| <i>Numeric Value</i> | <i>Constant Value</i> | <i>Description</i>                                                                                                                                                                                                                                                                                        |
|----------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**SchedInfo**

**Description**

Use this property to set or return a SCHED\_INFO object to be populated with scheduling details. Use the property as a parameter to the Run method for scheduling connected query execution when the run mode is RunMode\_Window, RunMode\_Sched\_Web, or RunMode\_Sched\_File.

This property is read/write.

## Related Links

[SCHED\\_INFO Class](#)

## SchedRequestType

### Description

Use this property to set or return a string indicating which application scheduled the connected query process. The values are:

| <i><b>Value</b></i> | <i><b>Description</b></i> |
|---------------------|---------------------------|
| CQR                 | Connected Query Manager   |
| XMLP                | BI Publisher              |

Separate run control parameter records (PSCONQRSRUNPRM or PSCONQRSRUNPRMX) are used for different values of this property.

This property is read/write.

## SecProfile

### Description

This property returns a SEC\_PROFILE object, which shows the user's query access level as defined for the query.

This property is read-only.

## Related Links

[SEC\\_PROFILE Class](#)

## ShowFormattedXML

### Description

Use this property to return a Boolean value indicating whether to retain indentation when generating XML output.

This property is read-only.

---

**Note:** While this property is read-only, it can be set through the PropertyArray property.

---

The default value is False.

## Related Links

[PropertyArray](#)

## Status

### Description

Use this property to set or return a string representing the status of the connected query. The values are:

| <i>Value</i> | <i>Description</i> |
|--------------|--------------------|
| A            | Active             |
| I            | Inactive           |

| <i>Value</i> | <i>Description</i> |
|--------------|--------------------|
| P            | In progress.       |

This property is read/write.

## XMLDataFileName

### Description

This property returns the short name for the XML data file as a string.

This property is read-only.

## XMLDataFullName

### Description

This property returns the long name for the XML data file as a string.

This property is read-only.

---

## CONQRSPROPERTY Class

The CONQRSPROPERTY class is a data structure that exposes connected query properties. Individual members of the CONQRSPROPERTY class should be retrieved and set through the CONQRSMGR class, PropertyArray property, which is an array of CONQRSPROPERTY objects.

**Related Links**

[PropertyArray](#)

---

## CONQRSPROPERTY Class Properties

In this section, the CONQRSPROPERTY class properties are presented in alphabetical order.

### PROPDEFAULT

**Description**

Use this property to set or return the default property value as a string.

This property is read/write.

### PROPNAME

**Description**

Use this property to set or return the property name as a string.

This property returns a Boolean value indicating that the specified connected query already exists. The value is False.

This property is read/write.

### PROPVALUE

**Description**

Use this property to set or return the current property value as a string.

This property is read/write.

### PROPVALUEARRAY

**Description**

Use this property to set or return an array of string representing the valid property values.

This property is read/write.

## PROPVALUEARRAYDESC

### Description

Use this property to set or return an array of string representing the descriptions for the valid property values.

This property is read/write.

---

## CONQRS\_CONST Class

This section provides an overview of the CONQRS\_CONST class and discusses CONQRS\_CONST class properties.

The CONQRS\_CONST class is a data structure that exposes read-only properties representing constant values. An instance of the CONQRS\_CONST class is created through the Const property of the CONQRSMR class.

### Related Links

[Const](#)

---

## CONQRS\_CONST Class Properties

In this section, the CONQRS\_CONST class properties are presented in alphabetical order.

### InitExisting

#### Description

This property returns a Boolean value indicating that the specified connected query already exists. The value is False.

Use InitExisting as an argument to the Open method.

This property is read-only.

#### Related Links

[Open](#)

### InitNew

#### Description

This property returns a Boolean value indicating that the specified connected query is new. The value is True.

Use InitNew as an argument to the Open method.

This property is read-only.

### Related Links

[Open](#)

## MsgSet

### Description

This property returns the number 241 as the message set number for connected query.

This property is read-only.

## RunCntlId\_Auto

### Description

This property returns the string PSCONQRS\_AUTORUN.

Use this property with the SetRunControlData method for the RunMode\_Window mode. It indicates that the run control ID for the connected query process should be generated automatically.

This property is read-only.

### Related Links

[SetRunControlData](#)

[RunMode\\_Window](#)

## RunMode\_Prev

### Description

This property returns the number 4, which represents the preview run mode with output to a separate browser window.

The connected query is executed immediately on the application server with output to a separate browser window. The output XML is not formatted internally; the only formatting that occurs is performed by the browser. Because results only exist for the browser session and are not preserved, this mode should be used during connected query creation, debugging, and tuning only.

---

**Note:** When using the preview mode, set a limit on the number of rows returned from each query.

---

This property is read-only.

[MaxRowsPerQuery](#)

[RunMode\\_Prev\\_DefRowNumber](#)

## RunMode\_Prev\_DefRowNumber

### Description

This property returns the number 6, which represents the default number of rows returned for connected queries running in the RunMode\_Prev or RunMode\_XMLFormattedString modes.

This property is read-only.

### Related Links

[MaxRowsPerQuery](#)

[RunMode\\_Prev](#)

[RunMode\\_XMLFormattedString](#)

## RunMode\_Sample

### Description

This property returns the number 5, which represents a run mode that produces a sample XML string that can be used by a BI Publisher data source as a sample XML string.

This property is read-only.

### Related Links

[RunMode](#)

## RunMode\_Sched\_File

### Description

This property returns the number 3, which represents the scheduled run mode with output to a file name and location specified by the user.

This property is read-only.

### Related Links

[Run](#)

[RunMode](#)

## RunMode\_Sched\_Web

### Description

This property returns the number 2, which represents the scheduled run mode with output to the web (that is, Report Manager).

The output can be accessed by the user via a Report Manager link.

This property is read-only.

### Related Links

[Run](#)

[RunMode](#)

## RunMode\_Window

### Description

This property returns the number 1, which represents the background run mode with output to a separate browser window.

The connected query runs via Process Scheduler and uses a REN server for delivering the output XML to the user. The XML result file is delivered to both the REN server window and the Report Manager.

This property is read-only.

### Related Links

[RunToWindow](#)

[RunMode](#)

## RunMode\_XMLFormattedString

### Description

This property returns the number 6, which represents the run mode that produces an formatted XML string. This formatted XML string is larger than the unformatted XML of the RunMode\_Prev mode.

The connected query is executed immediately on the application server with output to a formatted XML string. This string is formatted according to the XML DOM object and is suitable for displaying in a long edit box. This mode is used by the Connected Query Quick Start wizard in which XML results are shown on the application page in a long edit box.

---

**Note:** When using the preview mode, set a limit on the number of rows returned from each query.

---

This property is read-only.

**Related Links**[RunToXMLFormattedString](#)[RunMode](#)[MaxRowsPerQuery](#)[RunMode\\_\\_Prev\\_\\_DefRowNumber](#)**SchedRequest\_CQR****Description**

This property returns the string CQR representing that connected query execution was invoked by the Connected Query Manager. The value of this property is used as a part of the SCHED\_INFO data structure.

This property is read-only.

**SchedRequest\_XMLP****Description**

This property returns the string XMLP, representing that connected query execution was invoked by BI Publisher. The value of this property is used as a part of the SCHED\_INFO data structure.

This property is read-only.

**Stat\_Active****Description**

This property returns the string A indicating that the connected query definition is active.

This property is read-only.

**Stat\_InActive****Description**

This property returns the string I indicating that the connected query definition is inactive. A connected query can be set to inactive if it did not pass a validation.

This property is read-only.

## Stat\_InProgress

### Description

This property returns the string P indicating that the connected query definition is in progress. A connected query that is “in process” be run in preview mode only. It cannot be scheduled, and it is not be visible to BI Publisher.

This property is read-only.

---

## QUERYITEMPROMPT Class

This section provides an overview of the QUERYITEMPROMPT class and discusses QUERYITEMPROMPT class properties.

The QUERYITEMPROMPT class is a data structure that exposes read-only properties representing query prompts. An array of instances of this class is exposed via the QueriesPromptsArray property of the CONQRSMR class. Therefore, only an import statement is required, and no constructor:

```
import PT_CONQRS:QUERYITEMPROMPT;
```

### Related Links

[QueriesPromptsArray](#)

[Import Declarations](#)

---

## QUERYITEMPROMPT Class Properties

In this section, the QUERYITEMPROMPT class properties are presented in alphabetical order.

### QueryName

#### Description

This property returns as string representing the name of a query that participates in the connected query.

This property is read-only.

### QueryPromptRecord

#### Description

This property returns a Record object with the runtime prompts for the query.

This property is read-only.

---

## SCHED\_INFO Class

This section provides an overview of the SCHED\_INFO class and discusses SCHED\_INFO class properties.

The SCHED\_INFO class is a data structure that exposes the class constructor and read/write properties representing run controls and scheduling information. An instance of this class is exposed via the SchedInfo property of the CONQRSMR class. Therefore, only an import statement is required, and no constructor:

```
import PT_CONQRS:SCHED_INFO;
```

### Related Links

## SCHED\_INFO Class Properties

In this section, the SCHED\_INFO class properties are presented in alphabetical order.

### AE\_ID

#### Description

Use this property to set or return a string indicating which application scheduled execution of the connected query. The values are:

| <i><b>Value</b></i> | <i><b>Description</b></i> |
|---------------------|---------------------------|
| CQR (the default)   | Connected Query Manager   |
| XMLP                | BI Publisher              |

This property is read/write.

### DIRLOCATION

#### Description

Use this property to set or return a string representing the directory location for temporary files generated during processing of a scheduled connected query. This directory should be the same as the log/output directory specified in the psprcs.cfg file, allowing the connected query to use the distribution features of Process Scheduler.

This property is read/write.

## OPRID

### Description

Use this property to set or return a string representing the ID of the user who initiated the process.

This property is read/write.

## OUTDESTTYPE

### Description

Use this property to set or return the Process Scheduler output destination type as a number. The values are:

| <i><b>Value</b></i> | <i><b>Description</b></i> |
|---------------------|---------------------------|
| 2                   | File                      |
| 4                   | Window                    |
| 6                   | Web                       |

This property is read/write.

## PRCSFILENAME

### Description

Use this property to set or return the output file name as a string. This property is required when OUTDESTTYPE equals 2 (file). Specify an absolute path and file name that is accessible by the Process Scheduler server.

This property is read/write.

## PROCESS\_INSTANCE

### Description

Use this property to set or return the process instance as a string.

This property is read/write.

## RUN\_CNTL\_ID

### Description

Use this property to set or return the run control ID as a string.

This property is read/write.

---

## SEC\_PROFILE Class

This section provides an overview of the SEC\_PROFILE class and discusses:

- SEC\_PROFILE class constructor.
- SEC\_PROFILE class properties.

The SEC\_PROFILE class is a data structure that exposes the class constructor and read-only properties representing the security access to the connected query for this user's session.

### Related Links

[SecProfile](#)

---

## SEC\_PROFILE Class Constructor

This section presents the constructor for the SEC\_PROFILE class.

## SEC\_PROFILE

### Example

```
import PT_CONQRS:SEC_PROFILE;  
  
Local PT_CONQRS:SEC_PROFILE &SecProfile = create PT_CONQRS:SEC_PROFILE();
```

### Related Links

[Import Declarations](#)

---

## SEC\_PROFILE Class Properties

In this section, the SEC\_PROFILE class properties are presented in alphabetical order.

## CanCreatePublic

### Description

This property returns a Boolean value indicating whether the user can create a public connected query.

This property is read-only.

## CanModify

### Description

This property returns a Boolean value indicating whether the user can modify the connected query.

This property is read-only.

## CanRunQuery

### Description

This property returns a Boolean value indicating whether the user can run the connected query.

This property is read-only.

---

## UTILITY Class

This section provides an overview of the UTILITY class and discusses:

- UTILITY class constructor.
- UTILITY class methods.

The UTILITY class is a data structure that exposes the class constructor and utility methods used for validation. The UTILITY class does not require that a connected query be opened first.

---

## UTILITY Class Constructor

This section presents the constructor for the UTILITY class.

## UTILITY

### Example

```
import PT_CONQRS:UTILITY;  
  
Local PT_CONQRS:UTILITY &Utility = create PT_CONQRS:UTILITY();
```

## Related Links

### CheckQryForTreePrompt

#### Syntax

```
CheckQryForTreePrompt(QryName, scope)
```

#### Description

Use this method to checks if a specific query uses tree prompts.

---

**Important!** Connected query does not support queries with tree prompts.

---

#### Parameters

| <i>Parameter</i> | <i>Description</i>                                                                                                                                                                                                                  |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>QryName</i>   | Specifies the query name as a string.                                                                                                                                                                                               |
| <i>scope</i>     | Specifies the query scope as a string. If a valid value is not specified, CheckQryForTreePrompt searches to determine the scope. The values are: <ul style="list-style-type: none"><li>• R — Private</li><li>• U — Public</li></ul> |

#### Returns

The empty string if the query does not use tree prompts; otherwise, an error string.

### CheckQrySecurity

#### Syntax

```
CheckQrySecurity(QryName, IsPublicObject)
```

## Description

Use this method to check user access security for a single query. CheckQrySecurity performs the following checks:

- Whether the query is public for public connected queries (*IsPublicObject* is True).
- Whether the query is disabled.
- Whether the query has tree prompts by invoking CheckQryForTreePrompt.
- Whether there are query prompt security violations.

## Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>                                                   |
|-------------------------|-----------------------------------------------------------------------------|
| <i>QryName</i>          | Specifies the query name as a string.                                       |
| <i>IsPublicObject</i>   | Specifies a Boolean value indicating whether the connected query is public. |

## Returns

A Boolean value: True if the security validation was successful, False otherwise.

## GetQueryScopeByName

### Syntax

**GetQueryScopeByName** (*QryName*)

### Description

Use this method to check whether the specified query has a public or private scope.

### Parameters

| <i><b>Parameter</b></i> | <i><b>Description</b></i>             |
|-------------------------|---------------------------------------|
| <i>QryName</i>          | Specifies the query name as a string. |

### Returns

A number:

- 0 — Private query.

- 1 — Public query.
- 2 — Query not found.

ValidateObjectID

Syntax

```
ValidateObjectID (ID)
```

Description

Use this method to check whether the specified ID (connected query ID or run control ID) contains special characters. Valid characters for IDs include A-Z, 0–9, and \_.

Parameters

| Parameter | Description                                   |
|-----------|-----------------------------------------------|
| ID        | Specifies the ID to be validated as a string. |

Returns

An empty string if the validation was successful; otherwise, an error string.

Connected Query Classes Examples

This section includes examples of connected query classes in various modes.

Running a Connected Query in Scheduled Mode

In scheduled mode, the connected query is run by Process Scheduler. In the case of RunMode\_Sched\_File, the output data is written to an XML file. In the case of RunMode\_Sched\_Web, the output data is accessible via a hyperlink in Process Monitor. In scheduled mode, the runProcessInfo parameter is required; the Prompts parameter should be set to Null.

The following example represents a PeopleCode step to be run via Application Engine:

```
import PT_CONQRS:CONQRSMGR;
import PT_CONQRS:SCHED_INFO;

Local PT_CONQRS:CONQRSMGR &cConQrsInst;
Local boolean &result;
Local string &PRCSFILENAME;
Local string &sPrCsName = "PSCONQRS";
Local string &sPrCsType = "Application Engine";
Local number &nOrigPSMessagesMode = %Session.PSMessagesMode;
%Session.PSMessagesMode = 1;

/* While working with connected queries, it is recommended to use a try- */
/* catch block */
```

```

try

/* Create and open an object. System tries to find a connected query */
/* with private ownership first for current user. If not found, it */
/* uses a public ownership */

&ConQrsInst = create PT_CONQRS:CONQRSMGR("", PSCONQRS_AET.CONQRSNAME);

&result = &ConQrsInst.Open(&ConQrsInst.Const.InitExisting);

&str = &ConQrsInst.ErrString;
If &str <> "" Then
    WriteToLog(%ApplicationLogFence_Error, &ConQrsInst.ErrString);
    %Session.PSMessagesMode = &nOrigPSMessagesMode;
    Exit (1);
End-If;

If &result Then

    /* Get an empty SCHEDINFO structure and populate it. */
    &schedInfo = &ConQrsInst.SchedInfo;
    &schedInfo.DIRLOCATION = %FilePath;
    &schedInfo.OUTDESTTYPE = String(%OutDestType);
