This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software, software documentation, data (as defined in the Federal Acquisition Regulation), or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software," "commercial computer software documentation," or "limited rights data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed, or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle®, Java, MySQL, and NetSuite are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Part	Understanding Oracle Net Services	
1	Introducing Oracle Net Services	
	1.1 About Oracle Net Services	1-1
	1.1.1 Understanding Connectivity	1-1
	1.1.1.1 About Client/Server Application Connections	1-2
	1.1.1.2 About Web Client Application Connections	1-3
	1.1.2 Understanding Manageability	1-5
	1.1.2.1 About Service Name and Location Transparency	1-5
	1.1.2.2 About Centralized Configuration and Management	1-6
	1.1.2.3 About Quick Installation and Configuration	1-7
	1.1.3 Understanding Shared Server Architecture	1-7
	1.1.4 Understanding Performance	1-10
	1.1.4.1 Listener Queue Size	1-12
	1.1.4.2 Session Data Unit Size for Data Transfer Optimization	1-12
	1.1.4.3 Persistent Buffer Flushing for TCP/IP	1-12
	1.1.4.4 Sockets Direct Protocol	1-12
	1.1.4.5 Database Availability	1-12
	1.1.5 Understanding Network Security	1-13
	1.1.5.1 Firewall Access Control	1-13
	1.2 Understanding Database Instances	1-15
	1.3 Components of Oracle Net Services	1-17
	1.3.1 About Oracle Net	1-17
	1.3.1.1 Oracle Net Foundation Layer	1-17
	1.3.1.2 Oracle Protocol Support	1-18

1.3.2 About Oracle Net Listener

1-18

1.3.3	About Oracle Connection Manager	1-19
1.3.4	About Networking Tools	1-20
1.3.5	About Oracle Advanced Security	1-20
Identify	ing and Accessing the Database	
2.1 Und	erstanding Database Instances	2-1
2.2 Und	erstanding Database Services	2-3
2.3 Con	necting to a Database Service	2-5
2.3.1	About Connect Descriptors	2-5
2.3	3.1.1 About IPv6 Addresses in Connect Descriptors	2-6
2.3.2	About the Protocol Address	2-7
2.3.3	About Service Registration	2-7
2.3	3.3.1 Specifying an Instance Name	2-8
2.3	3.3.2 Specifying a Service Handler	2-8
2.4 Und	erstanding Service Handlers	2-9
2.4.1	About Dispatchers	2-9
2.4.2	About Dedicated Server Processes	2-10
2.4.3	About Database Resident Connection Pooling	2-12
2.5 Und	erstanding Naming Methods	2-13
2.5.1	About Naming Methods	2-14
2.5.2	Choosing a Naming Method	2-15
2.5.3	Establishing a Client Session Using a Naming Method	2-17
2.5.4	Entering a Connection String	2-17
2.6 Enh	ancing Service Accessibility Using Multiple Listeners	2-18
2.6.1	About Connect-Time Failover	2-19
2.6.2	About Transparent Application Failover	2-19
2.6.3	About Client Load Balancing	2-19
2.6.4	About Connection Load Balancing	2-19
Managi	ng Network Address Information	
3.1 Usir	ng Localized Management	3-1
3.2 Usir	ng a Directory Server for Centralized Management	3-3
3.2.1	Understanding the Directory Information Tree	3-4
3.3	2.1.1 Fully-Qualified Names for Domain Component Namespaces	3-6
3.3	2.1.2 Fully-Qualified Names for X.500 Namespaces	3-7
3.3	2.1.3 Using the Relative Name of an Entry	3-7
3.3	2.1.4 Using the Fully-Qualified Name of an Entry	3-8
3.2.2	Understanding Oracle Context	3-9
3.2.3	Understanding Net Service Alias Entries	3-10
3.2.4	Who Can Add or Modify Entries in the Directory Server	3-11

3.2.5	Client Connections Using Directory Naming	3-12
3.2.6	Considerations When Using Directory Servers	3-12
3.2	2.6.1 Performance Considerations	3-12
3.2	2.6.2 Security Considerations	3-13
3.2	2.6.3 Object Classes	3-16
3.2.7	Limitations of Directory Naming Support with Microsoft Active Directory	3-17
Underst	tanding the Communication Layers	
4.1 Unde	erstanding Oracle Net Stack Communication for Client/Server Applications	4-1
4.1.1	About the Client Communication Stack	4-3
4.1	1.1.1 Client Application Layer	4-3
4.1	1.1.2 Presentation Layer	4-3
4.1	1.1.3 Oracle Net Foundation Layer	4-3
4.1	1.1.4 Oracle Protocol Support Layer	4-4
4.1.2	About the Server Communication Stack	4-4
4.2 Usin	g Oracle Net Stack Communication for Java Applications	4-4
4.3 Usin	g Oracle Net Stack Communication for Web Clients	4-5
4.4 Unde	erstanding Oracle Protocol Support Layer	4-6
4.4.1	About TCP/IP Protocol	4-6
4.4	4.1.1 IPv6 Address Notation	4-7
4.4	4.1.2 IPv6 Interface and Address Configurations	4-9
4.4	4.1.3 IPv6 Network Connectivity	4-9
4.4	4.1.4 IPv6 Support in Oracle Database	4-10
4.4.2	About TCP/IP with TLS Protocol	4-11
4.4.3	About Named Pipes Protocol	4-12
4.4.4	About Sockets Direct Protocol (SDP)	4-12
4.4.5	About Exadirect Protocol	4-12
4.4.6	About Websocket Protocol	4-12
Underst	tanding Oracle Net Architecture	
5.1 Abou	ut Service Registration	5-1
5.2 Abou	ut the Listener and Connection Requests	5-2
5.3 Abou	ut Oracle Restart	5-3
5.4 Abou	ut Blocked Connection Requests	5-4
5.5 Unde	erstanding Database Server Process Architecture	5-4
5.5.1	About Shared Server Processes	5-4
5.5.2	About Dedicated Server Processes	5-5
5.6 Unde	erstanding Oracle Connection Manager Architecture	5-6
5.7 Com	plete Architecture	5-7

Part II Configuration and Administration of Oracle Net Services

Quick S	Start to Oracle Net Services	
6.1 Pre	requisites for Establishing Connectivity	6-1
6.2 Con	firming Network Availability	6-2
6.3 Star	ting Oracle Net Listener and the Oracle Database Server	6-2
6.4 Star	ting Oracle Connection Manager	6-4
6.5 Usir	ng Easy Connect to Connect to a Database	6-5
6.6 View	ving Connection Strings Using the connstr Utility	6-5
6.7 Con	necting to the Database	6-8
Managi	ng Oracle Net Services	
7.1 Usir	ng the User Interface Tools	7-1
7.1.1	Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services	7-1
7.	1.1.1 Accessing the Net Services Administration Page	7-2
7.1.2	Using Oracle Net Manager to Configure Oracle Net Services	7-2
7.	1.2.1 Starting Oracle Net Manager	7-3
7.	1.2.2 Navigating Oracle Net Manager	7-3
7.	1.2.3 Using Oracle Net Manager Wizards	7-3
7.1.3	Deciding When to Use Oracle Enterprise Manager Cloud Control and Oracle Net Manager	7-4
7.1.4	Using Oracle Net Configuration Assistant to Configure Network Components	7-5
7.2 Abo	ut the OracleNetAdmins Group	7-6
7.2.1	Adding Users To the OracleNetAdmins Group	7-6
7.2.2	Removing Users From the OracleNetAdmins Group	7-7
7.2.3	Changing Ownership of the OracleNetAdmins Group	7-7
7.3 Usir	ng Listener Control Utility to Administer the Listener	7-8
7.4 Perf	forming Common Network Tasks	7-8
Configu	uring Naming Methods	
8.1 Con	figuring the Local Naming Method	8-1
8.1.1	Configuring the tnsnames.ora File During Installation	8-2
8.1.2	Configuring the tnsnames.ora File After Installation	8-2
8.2 Con	figuring the Directory Naming Method	8-9
8.2.1	Configure Net Service Name, Database Service, and Alias Entries	8-9
8.2.2	Create Multiple Default Contexts in a Directory Naming Server	8-14

	8.2.3 E	xport Local Naming Entries to a Directory Naming Server	8-15
	8.2.4 C	configure the LDAP Naming Adapter to Use Wallets	8-17
	8.2.5 S	pecify LDAP Parameters Directly in a Connect Identifier	8-19
	8.2.6 E	xport Directory Naming Entries to the tnsnames.ora file	8-23
	8.3 Configu	ring the Centralized Configuration Provider Naming Method	8-23
	8.3.1 A	zure App Configuration Store	8-24
	8.3.1	1 Prerequisites for Using the Azure App Configuration Store	8-25
	8.3.1	2 Step 1: Create a Key-Value with the Connect Descriptor	8-26
	8.3.1	.3 Step 2: Add the User Name and Password Vault Reference (Optional)	8-28
	8.3.1	.4 Step 3: Add the Wallet Vault Reference (Optional)	8-30
	8.3.1	5 Step 4: Add Oracle Call Interface Parameters (Optional)	8-31
	8.3.1	Step 5: Use a Connect Identifier Containing Azure App Configuration Store Values	8-32
	8.3.2 C	OCI Object Storage JSON File	8-35
	8.3.2	1 Prerequisites for Using the OCI Object Storage JSON File	8-35
	8.3.2	2 Step 1: Create a JSON file with the Connect Descriptor	8-38
	8.3.2	.3 Step 2: Add the User Name and Password Vault Reference (Optional)	8-39
	8.3.2	.4 Step 3: Add the Wallet Vault Reference (Optional)	8-41
	8.3.2	5 Step 4: Add Oracle Call Interface Parameters (Optional)	8-43
	8.3.2	6 Step 5: Use a Connect Identifier Containing OCI Object Storage Values	8-45
	8.4 Configu	uring the Easy Connect Naming Method	8-47
	8.4.1 U	Inderstanding the Easy Connect Naming Method	8-48
	8.4.2 S	upport for Easy Connect Plus	8-50
	8.4.3 E	xamples of Easy Connect Naming Method	8-52
	8.4.4 C	configuring Easy Connect Naming on the Client	8-55
	8.4.5 C	configuring Easy Connect Naming to Use a DNS Alias	8-57
9	Configurir	ng and Administering Oracle Net Listener	
	9.1 Overvie	ew of Oracle Net Listener	9-1
	9.2 Configu	rring Dynamic Service Registration	9-2
	9.2.1 S	etting Initialization Parameters for Service Registration	9-3
	9.2.2 R	registering Information with a Local Listener	9-3
	9.2.3 R	registering Information with a Remote Listener	9-5
	9.2.4 R	registering Information with All Listeners in a Network	9-7
	9.2.5 C	Configuring a Naming Method	9-9
	9.3 Configu	ıring Oracle Net Listener During Installation	9-10
	9.4 Custom	nizing Oracle Net Listener Configuration	9-10
	9.4.1 C	configuring Listening Protocol Addresses	9-10
	9.4.1	 Configuring Listening Protocol Addresses Using Oracle Enterprise Manager Cloud Control 	9-10
	9.4.1	.2 Configuring Listening Protocol Addresses Using Oracle Net Manager	9-11
	9.4.2 H	landling Large Volumes of Concurrent Connection Requests	9-12

	9.4.3	Mana	ging Oracle Net Listener Security	9-12
	9.4.	3.1	Specifying Valid Nodes and Subnets	9-13
	9.5 Admir	nisterii	ng the Listener	9-14
	9.5.1	Startii	ng and Stopping a Listener	9-14
	9.5.	1.1	Starting or Stopping a Listener Using the Listener Control Utility	9-15
	9.5.		Starting or Stopping a Listener Using Oracle Enterprise Manager Cloud	
			Control	9-15
			ging a Listener in an Oracle Restart Configuration	9-16
	9.5.		Viewing Configured Listeners Using the SRVCTL Utility	9-16
	9.5.		Adding or Removing a Listener Using the SRVCTL Utility	9-17
			Starting or Stopping a Listener Using the SRVCTL Utility	9-17
			mining the Current Status of a Listener	9-17
	9.5.	3.1	Showing Status Using Listener Control	9-17
	9.5.	3.2	Showing Status Using Oracle Enterprise Manager Cloud Control	9-19
	9.5.4	Monit	oring Services of a Listener	9-19
	9.5.5	Monit	oring Service Registration Operations	9-21
	9.5.6	Monit	oring Listener Log Files	9-23
	9.6 Under	stand	ling Listener Redirects	9-23
10	Configur	ing a	and Administering Oracle Connection Manager	
	10.1 Setti	ng Up	Oracle Connection Manager	10-2
	10.1.1	Abo	ut the cman.ora File	10-2
	10.1.2	Con	figuring the cman.ora file for the Oracle Connection Manager Host	10-4
	10.1.3	Con	figuring Transport Layer Security on Oracle Connection Manager	10-5
	10.1.4	Enal	bling Access Control	10-7
	10.1.5	Con	figuring Clients for Oracle Connection Manager	10-7
	10.1.6		figuring the Oracle Database Server for Oracle Connection Manager	10-8
	10.1		Configuring Service Registration for Use with Oracle Connection	
			Manager	10-9
	10.1	L.6.2	Enabling Session Multiplexing for Oracle Connection Manager	10-10
	10.2 Conf	igurin	g Oracle Connection Manager in Traffic Director Mode	10-10
	10.2.1	Abou	ut Oracle Connection Manager in Traffic Director Mode	10-11
	10.2	2.1.1	Connection Modes	10-12
	10.2	2.1.2	Performance and Security	10-12
	10.2	2.1.3	Database Links	10-14
	10.2	2.1.4	Per-Service and Per-PDB Connection Pools	10-14
	10.2	2.1.5	Implicit Connection Pooling	10-16
	10.2.2		figuring cman.ora File for Oracle Connection Manager in Traffic Director	
		Mod		10-17
	10.2.3		figuring a Wallet for Oracle Connection Manager in Traffic Director Mode	10 10
		Prox	xy Authentication	10-18

Τ,	0.2.4	Password Store	10-19
10	0.2.5	Configuring Databases for Oracle Connection Manager in Traffic Director Mode Proxy Authentication	10-20
10	0.2.6	Configuring Service Registration with Oracle Connection Manager in Traffic Director Mode	10-21
10	0.2.7	Configuring Proxy Resident Connection Pooling in Oracle Connection Manager in Traffic Director Mode	10-21
10	0.2.8	Configuring Oracle Connection Manager in Traffic Director Mode for Unplanned Events	10-25
10	0.2.9	Configuring Oracle Connection Manager in Traffic Director Mode for Planned Down Events	10-26
10	0.2.10	Configuring Oracle Connection Manager in Traffic Director Mode for Service Affinity	10-26
10	0.2.11	Configuring Transport Layer Security on Oracle Connection Manager in Traffic Director Mode	10-27
10	0.2.12	Oracle Connection Manager in Traffic Director Mode Restrictions	10-28
10.3	Confi	guring Oracle Connection Manager in Tunneling Mode for Reverse Connection	10-29
10	0.3.1	Configure cman.ora for Oracle Connection Manager in Server Tunneling Mode	10-30
10	0.3.2	Configure cman.ora for Oracle Connection Manager in Client Tunnelling Mode	10-30
10	0.3.3	Configure Clients to Make Reverse Connection	10-31
10	0.3.4	Configure Rules in Server CMAN for Tunnel Registration and Client Access	10-31
	10.3	4.1 Configure Rules in Server CMAN using rule_list Syntax	10-31
	10.3	4.2 Configure Rules in Server CMAN Using rule_group Syntax	10-32
10	0.3.5	Configure Oracle Database Server for Client Oracle Connection Manager	10-33
10.4	Using	Oracle Connection Manager as a Bridge for IPv4 and IPv6	10-33
10.5	Using	Oracle Connection Manager to Prevent Denial-of-Service Attacks	10-35
10.6	Starti	ng and Stopping Oracle Connection Manager	10-36
10.7	Abou	t CMCTL REST Interface	10-37
10	0.7.1	Configuring CMCTL REST Interface	10-37
10	0.7.2	REST APIs for CMCTL Commands	10-39
10.8	Migra	ting CMAN Sessions During Patching	10-40
10.9	Orac	e Connection Manager Enhancements	10-40
Con	ıfiguri	ng a Shared Server Architecture	
11.1		Oracle Net Manages Client Loads	11-1
11.2	Abou	Dispatchers	11-1
13	1.2.1	Grouping Services by Dispatcher	11-2
13	1.2.2	Monitoring Dispatchers	11-2
11.3	Enab	ing Session Multiplexing	11-3
11.4	Confi	guring Clients for Environments with Both Shared and Dedicated Servers	11-3

11

12 Configuring Profiles

1	L2.1 (Overview o	of Profile Configuration	12-2
1	L2.2 (Configuring	g the Profile During Installation	12-2
1	L2.3 I	Jnderstand	ding Client Attributes for Names Resolution	12-2
	12.3	3.1 Abou	t the Default Domain for Clients	12-2
		12.3.1.1	Specifying a Default Domain	12-2
	12.3	3.2 Priori	itizing Naming Methods	12-3
	12.3	3.3 Routi	ing Connection Requests to a Process	12-4
1	L2.4 (Configuring	Database Access Control	12-4
1	L2.5	Setting the	Advanced Features in the sqlnet.ora File Using Oracle Net Services	12-
1	L2.6 (Configuring	g External Naming Methods	12-
1	L2.7 (Configuring	g Oracle Network Security	12-6
L3 E	Enab∣	ing Adv	anced Features of Oracle Net Services	
1	L3.1 (Configuring	g Advanced Network Address and Connect Data Information	13-1
	13.2	1 Creat	ting a List of Listener Protocol Addresses	13-2
	13.2	2 Abou	it the Address List Parameters	13-4
		13.1.2.1	Configuring Address List Parameters	13-6
	13.1	3 Abou	t the Advanced Connect Data Parameters	13-6
1	L3.2	Jnderstand	ding Connection Load Balancing	13-8
	13.2	2.1 Exam	nple of Connection Load Balancing for Shared Server Configuration	13-9
	13.2	2.2 Exam	nple of Connection Load Balancing for Dedicated Server Configuration	13-13
	13.2	2.3 COL	OCATION_TAG of Client Connections	13-13
1	L3.3 (Configuring	g Transparent Application Failover	13-14
	13.3	3.1 Abou	t Transparent Application Failover	13-15
	13.3	3.2 What	t Transparent Application Failover Restores	13-15
	13.3	3.3 Abou	t the FAILOVER_MODE Parameters	13-16
	13.3	3.4 Imple	ementing Transparent Application Failover	13-17
		13.3.4.1	TAF with Connect-Time Failover and Client Load Balancing	13-17
		13.3.4.2	TAF Retrying a Connection	13-18
		13.3.4.3	TAF Pre-establishing a Connection	13-18
	13.3	3.5 Verify	ying Transparent Application Failover	13-19
1	L3.4	Specifying	the Instance Role for Primary and Secondary Instance Configurations	13-20
1	L3.5 (Configuring	g Static Service Registration	13-22
	13.5	5.1 Parar	meters for Static Service Registration	13-22
	13.5	5.2 Confi	iguring Static Service Information for the Listener	13-24
1	L3.6 (Configuring	Connections to Third-Party Database Services	13-24
	13.6	6.1 Defa	ult Configuration for External Procedures	13-25
		13.6.1.1	Configuring Oracle Net Services for External Procedures	13-27
	13.6	6.2 Abou	t Oracle Net Services for Oracle Heterogeneous Services	13-32

	13.6.2.1 Configuring Oracle Database to Connect to Agents 13.6.3 Configuring Oracle Net Services for an Oracle Rdb Database	13-32 13-33
14	Optimizing Performance	
	14.1 Understanding the Benefits of Network Data Compression	14-1
	14.2 Configuring Session Data Unit	14-2
	14.2.1 Setting the SDU Size for the Database	14-2
	14.2.2 Setting the SDU Size for the Client	14-3
	14.3 Determining the Bandwidth-Delay Product	14-3
	14.4 Configuring I/O Buffer Space	14-4
	14.4.1 Configuring I/O Buffer Size on the Server	14-5
	14.4.1.1 Setting the Buffer Size Parameter for Shared Server Processes	14-5
	14.4.2 Configuring I/O Buffer Space on the Client	14-5
	14.5 Configuring SDP Support for InfiniBand Connections	14-6
	14.5.1 Prerequisites for Using SDP	14-7
	14.5.2 Configuring SDP on the Server	14-7
	14.5.3 Configuring SDP on the Client	14-7
	14.6 Configuring Exadirect Support for InfiniBand Connections	14-8
	14.6.1 Prerequisites for Using Exadirect	14-9
	14.6.2 Configuring Exadirect on the Server	14-9
	14.6.3 Configuring Exadirect on the Client	14-9
	14.7 Limiting Resource Consumption by Unauthorized Users	14-10
	14.8 Configuring Key-Based Routing for Client-Server Connections	14-11
	14.8.1 About Key-Based Routing	14-11
	14.8.2 Specifying a Sharding Key in the Connect String	14-12
	14.9 Configuring SNI for TLS connections	14-13
Part	Testing and Troubleshooting Oracle Net Services	
15	Testing Connections	
	15.1 Testing the Network	15-1
	15.2 Using the TNSPING Utility to Test Connectivity from the Client	15-2
	15.3 Using the TRCROUTE Utility to Test Connectivity from the Client	15-4
16	Troubleshooting Oracle Net Services	
	16.1 Understanding Automatic Diagnostic Repository	16-2
	16.1.1 ADRCI: ADR Command Interpreter	16-6
	16.2 Diagnosing Oracle Net Services	16-7
	16.2.1 Diagnosing Server Problems	16-7

	16.2.2	Diag	nosing Client Problems	16-9
16.3	Resc	lving	the Most Common Error Messages for Oracle Net Services	16-12
	16.3.1	ORA	A-03113	16-13
	16.3.2	ORA	n-12154	16-13
	16.3.3	ORA	A-12170	16-16
	16.3.4	ORA	n-12241	16-17
	16.3.5	ORA	n-12261	16-18
	16.3.6	ORA	n-12262	16-18
	16.3.7	ORA	A-12500	16-19
	16.3.8	ORA	A-12505	16-19

Preface

Oracle Database Net Services Administrator's Guide describes how to use Oracle Net Services. This guide describes the Oracle Net Services product and its components, as well as Oracle Net Services administrative and deployment topics.

- Audience
- Documentation Accessibility
- Diversity and Inclusion
- Conventions

Audience

Oracle Database Net Services Administrator's Guide is intended for the following readers:

- Network administrators
- Directory server administrators
- Database administrators
- Decision makers

This guide is especially targeted for network administrators who are responsible for ensuring connectivity. For network administrators, Oracle recommends:

- For a conceptual understanding of Oracle Net Services, read all of Understanding Oracle Net Services
- For essential configuration instructions, read all of Configuration and Administration of Oracle Net Services
- For troubleshooting, read Testing and Troubleshooting Oracle Net Services

For directory administrators, Oracle recommends:

- For understanding how Oracle Net Services uses a directory server, read Managing Network Address Information in Understanding Oracle Net Services
- For instructions about configuring naming information in a directory server, and exporting existing naming data to a directory server, read Configuring Naming Methods in Configuration and Administration of Oracle Net Services

For database administrators, Oracle recommends:

- For a general understanding of networking, read Introducing Oracle Net Services and Quick Start to Oracle Net Services
- For an overview of communication layers, read Understanding the Communication Layers
- For understanding how to configure Oracle database server features that require listener and shared server configuration, read Configuring and Administering Oracle Net Listener, Configuring a Shared Server Architecture, and Optimizing Performance

For decision makers, Oracle recommends

 For an understanding of how Oracle Net Services fits into the overall network architecture and for explaining the basics of Oracle Net Services, read Introducing Oracle Net Services, Managing Network Address Information, and Quick Start to Oracle Net Services

Oracle recommends that all readers look over Understanding Oracle Net Services, to ensure that they have the background required to benefit from the rest of the guide.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customer access to and use of Oracle support services will be pursuant to the terms and conditions specified in their Oracle order for the applicable services.

Diversity and Inclusion

Oracle is fully committed to diversity and inclusion. Oracle respects and values having a diverse workforce that increases thought leadership and innovation. As part of our initiative to build a more inclusive culture that positively impacts our employees, customers, and partners, we are working to remove insensitive terms from our products and documentation. We are also mindful of the necessity to maintain compatibility with our customers' existing technologies and the need to ensure continuity of service as Oracle's offerings and industry standards evolve. Because of these technical constraints, our effort to remove insensitive terms is ongoing and will take time and external cooperation.

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
monospace	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Part I

Understanding Oracle Net Services

Part I provides an overview of Oracle Net Services concepts, products, and tools.

This part contains the following chapters:

- Introducing Oracle Net Services
 Understand the basic elements of Oracle Net Services architecture and the Oracle Net foundation layer.
- Identifying and Accessing the Database
 Understand how databases are identified, and how clients access them.
- Managing Network Address Information
 Identify how the network address information for Oracle Net Services can be stored in local files or in a centralized directory server.
- Understanding the Communication Layers
 The primary function of Oracle Net is to establish and maintain connections between a client application and an Oracle database server.
- Understanding Oracle Net Architecture
 The Oracle Net listener is an application positioned on top of the Oracle Net foundation layer. The database receives an initial connection from a client application through the listener.

1

Introducing Oracle Net Services

Understand the basic elements of Oracle Net Services architecture and the Oracle Net foundation layer.

About Oracle Net Services

Oracle Net Services provides enterprise-wide connectivity solutions in distributed, heterogeneous computing environments. It eases the complexities of network configuration and management, maximizes performance, and improves network diagnostic capabilities.

Understanding Database Instances

A database has at least one instance. An instance is comprised of a memory area called the System Global Area (SGA) and Oracle background processes.

Components of Oracle Net Services
 Learn about the connectivity, manageability, scalability, and security features.

1.1 About Oracle Net Services

Oracle Net Services provides enterprise-wide connectivity solutions in distributed, heterogeneous computing environments. It eases the complexities of network configuration and management, maximizes performance, and improves network diagnostic capabilities.

The terms "SQL*Net" and "Net Services" are used interchangeably throughout Oracle documentation and both these terms refer to the same functionality.

This section introduces the basic networking concepts involved in a typical network configuration.

Understanding Connectivity

Oracle Net, a component of Oracle Net Services, enables a network session from a client application to an Oracle Database server.

- Understanding Manageability
- Understanding Shared Server Architecture
- Understanding Performance
- Understanding Network Security

1.1.1 Understanding Connectivity

Oracle Net, a component of Oracle Net Services, enables a network session from a client application to an Oracle Database server.

When a network session is established, Oracle Net acts as the data carrier for both the client application and the database. It is responsible for establishing and maintaining the connection

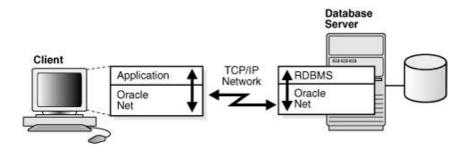

between the client application and database, as well as exchanging messages between them. Oracle Net is able to perform these jobs because it is located on each computer in the network.

- About Client/Server Application Connections
- About Web Client Application Connections

1.1.1.1 About Client/Server Application Connections

Oracle Net enables connections from traditional client/server applications to Oracle Database servers. Figure 1-1 shows how Oracle Net enables a network connection between a client and a database server. Oracle Net is a software component that resides on both the client and the database server. Oracle Net is layered on top of network Oracle protocol support, rules that determine how applications access the network and how data is subdivided into packets for transmission across the network. In the following figure, Oracle Net communicates with TCP/IP to enable computer-level connectivity and data transfer between the client and the database.

Figure 1-1 Client/Server Application Connection

Specifically, Oracle Net is comprised of the Oracle Net foundation layer, which establishes and maintains connections, and Oracle protocol support, which maps the foundation layer technology to industry-standard protocols.

Java Client Application Connections

1.1.1.1 Java Client Application Connections

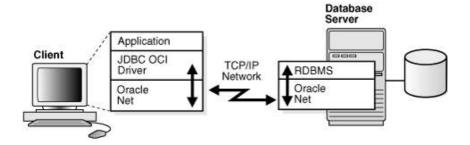

Java client applications access an Oracle database through a Java Database Connectivity (JDBC) Driver, a standard Java interface for connecting from Java to a relational database. Oracle offers the following drivers:

- JDBC OCI Driver for client-side use with an Oracle client installation.
- JDBC Thin Driver, a pure Java driver for client-side use without an Oracle installation, particularly with applets.

These drivers use Oracle Net to enable connectivity between a client application and an Oracle database.

The following figure shows a Java client application using a JDBC OCI driver and an Oracle Database server. The Java client application makes calls to the JDBC OCI driver, which translates the JDBC calls directly into the Oracle Net layer. The client then uses Oracle Net to communicate with Oracle Database that is also configured with Oracle Net.

Figure 1-2 Java Application Connection

See Also:

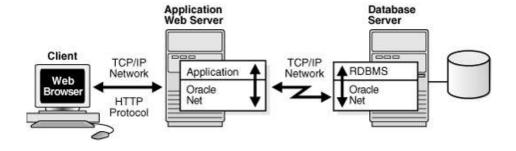

- Oracle Database JDBC Developer's Guide
- Oracle Database JDBC Java API Reference

1.1.1.2 About Web Client Application Connections

Internet connections from client web browsers to an Oracle Database server are similar to client/server applications, except that the connection request goes to an application web server.

Figure 1-3 shows the basic architecture for web client connections, including a client web browser, an application web server, and an Oracle Database server. The browser on the client communicates with HTTP to the web server to make a connection request. The web server sends the request to an application where it is processed. The application then uses Oracle Net to communicate with the Oracle Database server that also is configured with Oracle Net.

Figure 1-3 Web Client Connections through Application Web Server

The basic components have the following characteristics:

- HyperText Transport Protocol (HTTP)
 HTTP provides the language that enables web browsers and application web servers to communicate.
- Application Web Server

An application web server manages data for a website, controls access to that data, and responds to requests from web browsers. The application on the web server communicates with the database and performs the job requested by the web server.

- Web Client Connections Through Java Application Web Server
- Web Client Connections Without an Application Web Server

1.1.1.2.1 Web Client Connections Through Java Application Web Server

An application web server can host Java applications and servlets, as shown in Figure 1-4. Web browsers make a connection request by communicating through HTTP to an application web server. The application web server sends the request to an application or a servlet, which uses a JDBC OCI or a JDBC Thin driver to process the request. The driver then uses Oracle Net to communicate with the Oracle Database server that also is configured with Oracle Net.

Application Web Server Client Java Servlet Web JDBC OC Database Browse HTTP Driver TCP/IP Server Protocol Network Oracle Net RDBMS Oracle Net Java Servlet TCP/IP Client JDBC Thin Network Driver Web JavaNet Browse HTTP Protocol

Figure 1-4 Web Client Connections Through Java Application Web Server

1.1.1.2.2 Web Client Connections Without an Application Web Server

Web clients that do not require an application web server to access applications can access Oracle Database directly, for example, by using a Java applet. In addition to regular connections, the database can be configured to accept HTTP protocol, FTP, or WebDAV protocol connections. These protocols are used for connections to Oracle XML DB in the Oracle Database instance.

The following figure shows two different web clients. The first web client makes an HTTP connection to the database. The second web client uses a web browser with a JDBC Thin driver, which in turn uses a Java version of Oracle Net called JavaNet to communicate with the Oracle Database server that is configured with Oracle Net.

Oracle XML DB Developer's Guide

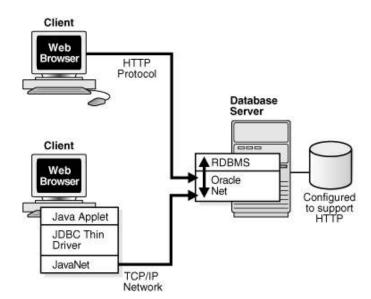

Figure 1-5 Web Client Connection Scenarios

1.1.2 Understanding Manageability

Oracle Net Services offers several manageability features to configure and manage networking components.

- About Service Name and Location Transparency
 Each database is represented by one or more services. A service is a program that responds to requests from various clients or performs some operation.
- About Centralized Configuration and Management
 To manage large networking environments, administrators can access a centralized repository to specify and modify the network configuration.
- About Quick Installation and Configuration
 Networking elements for the Oracle Database server and clients are preconfigured for most environments.

1.1.2.1 About Service Name and Location Transparency

Each database is represented by one or more services. A service is a program that responds to requests from various clients or performs some operation.

A service is identified by a service name, for example, sales.us.example.com. A client uses a service name to identify the database it must access. The information about the database service and its location in the network is transparent to the client because the information needed for a connection is stored in a repository.

The repository is represented by one or more naming methods. A naming method is a resolution method used by a client application to resolve a connect identifier to a connect descriptor when attempting to connect to a database service. Oracle Net Services offers several naming methods that support localized configuration on each client, or centralized configuration that can be accessed by all clients in the network.

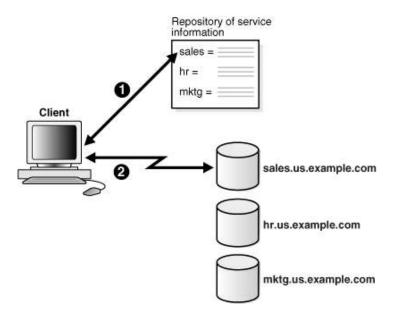

For example, in the following figure, a company has three databases that clients can access. Each database has a distinct service name, such as sales.us.example.com,

hr.us.example.com, and mktg.us.example.com.

- 1. The client uses the repository to find the information it needs for sales.us.example.com.
- 2. After the client has the information it needs, it connects to the database.

Figure 1-6 Service Information Repository

1.1.2.2 About Centralized Configuration and Management

To manage large networking environments, administrators can access a centralized repository to specify and modify the network configuration.

You can store the Oracle Net Services configuration in one of the following centralized repositories:

LDAP-Compliant Directory Server

Support of LDAP-compliant directory servers provides a centralized vehicle for managing and configuring a distributed Oracle network. The directory can act as a central repository for all information about database network components, user and corporate policies, and user authentication and security, thus replacing client-side and server-side localized configuration files. All computers on the network can refer to the directory for information.

When using the LDAP directory server, you can choose to specify LDAP parameters either in external configuration files (ldap.ora and sqlnet.ora) or directly in the connect identifier.

The following diagram shows clients, Oracle Database servers, and other servers (such as application web servers) connecting to a centralized directory server:

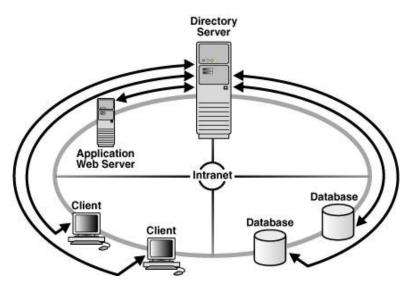

Figure 1-7 Centralized Storage of Network Configuration with a Directory Server

Centralized Configuration Provider

You can centralize connect descriptors and optionally database credential references in a Centralized Configuration Provider, such as Azure App Configuration store or Oracle Cloud Infrastructure (OCI) Object Storage as a JSON file.

This naming method stores network service names and addresses in a single location, facilitating administration (addition, deletion, or modification) of connect descriptors. This also enables you to centrally manage password change policies for all stored database user names and passwords.

Related Topics

- Using a Directory Server for Centralized Management
- Configuring the Directory Naming Method
 With this naming method, connect identifiers are mapped to connect descriptors contained
 in an LDAP-compliant directory server, such as Oracle Internet Directory, Oracle Unified
 Directory, or Microsoft Active Directory.
- Configuring the Centralized Configuration Provider Naming Method
 With this naming method, connect identifiers are mapped to connect descriptors contained
 in a Centralized Configuration Provider, such as Azure App Configuration store or Oracle
 Cloud Infrastructure (OCI) Object Storage as a JSON file.

1.1.2.3 About Quick Installation and Configuration

Networking elements for the Oracle Database server and clients are preconfigured for most environments.

The Easy Connect naming method is enabled by default, and does not require a repository. Clients connect using the hostname of the database. As a result, clients and servers are ready to connect out-of-the-box using Easy Connect, giving users the benefits of distributed computing.

1.1.3 Understanding Shared Server Architecture

The Oracle Database shared server architecture increases the scalability of applications and the number of clients that can simultaneously be connected to the database. The shared

server architecture also enables existing applications to scale up without making any changes to the application itself.

When using a shared server, clients do not communicate directly with a database server process, a database process that handles a client's requests on behalf of a database. Instead, client requests are routed to one or more dispatchers. The dispatchers place the client requests in a common queue. An idle shared server from the shared pool of server processes picks up and processes a request from the queue. This means a small pool of server processes can serve a large number of clients.

The Shared Server Architecture and Dedicated Server Architecture figures show the basic difference between the shared server connection model and the traditional dedicated server connection model. In the shared server model, a dispatcher can support multiple client connections concurrently. In the dedicated server model, there is one server process for each client. Each time a connection request is received, a server process is started and dedicated to that connection until completed. This causes a processing delay.

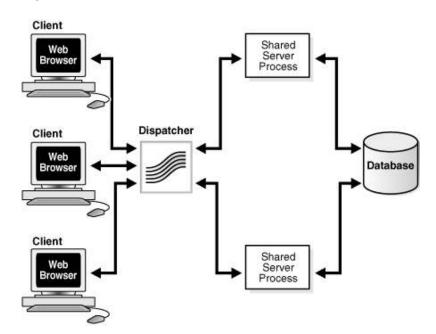

Figure 1-8 Shared Server Architecture

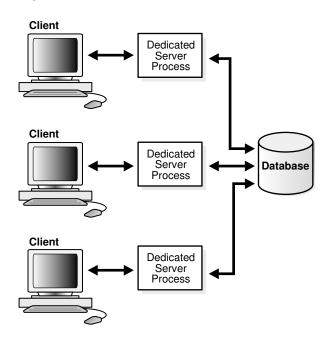

Figure 1-9 Dedicated Server Architecture

A shared server is ideal for configurations with a large number of connections because it reduces the server memory requirements. A shared server is well suited for both Internet and intranet environments.

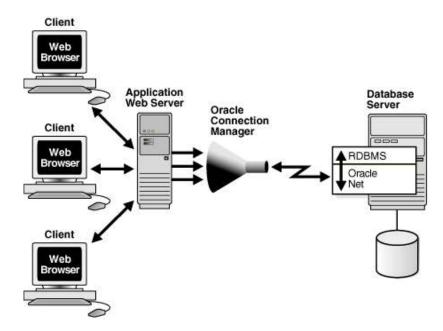

Utilization of server resources can be further enhanced with Oracle Connection Manager. Oracle Connection Manager, an Oracle Net Services component, enables multiple client network sessions to be multiplexed, or funneled, through a single network connection to a database.

The session multiplexing feature reduces the demand on resources needed to maintain multiple network sessions between two processes by enabling the server to use fewer network connection endpoints for incoming requests. In this way, the total number of network sessions that a server can handle is increased. One Oracle Connection Manager with multiple gateways enables thousands of concurrent users to connect to a server.

The following figure shows how session multiplexing can be used in a web architecture. When Oracle Connection Manager is run on the same computer as an application web server, the application web server can route multiple client sessions through Oracle Connection Manager to ensure that those sessions have continuous access to an Oracle Database server. This functionality is especially useful for web applications where session availability and response time are major concerns.

Figure 1-10 Session Multiplexing

The following are the advantages and disadvantages of session multiplexing. Session multiplexing is recommended for networks where continuous connectivity is required.

Advantages of Session Multiplexing

- Limits the number of network resources used for each process
- Supports large client populations
- Maximizes the number of client/server sessions over a limited number of process connections
- Optimizes resource utilization
- Enables identification and monitoring of real users
- Enables mid-tier applications to support additional services
- Requires only a single transport for clients with multiple applications
- Requires only a single network connection for database links

Disadvantage of Session Multiplexing

Clients must connect to Oracle Connection Manager.

1.1.4 Understanding Performance

System performance is important to users. Users usually start to notice performance when a system takes longer than one second to respond. Oracle Net configuration can be modified to enhance system performance.

This section discusses performance considerations.

- Listener Queue Size
- Session Data Unit Size for Data Transfer Optimization
- Persistent Buffer Flushing for TCP/IP

- Sockets Direct Protocol
- Database Availability

1.1.4.1 Listener Queue Size

If you anticipate receiving a large number of connection requests for a listening process (such as a listener or Oracle Connection Manager) over TCP/IP, then Oracle Net enables you to configure the listening queue to be higher than the system default.

1.1.4.2 Session Data Unit Size for Data Transfer Optimization

Before sending data across the network, Oracle Net buffers and encapsulates data into the session data unit (SDU). Oracle Net sends the data stored in this buffer when the buffer is full, flushed, or when database server tries to read data. When large amounts of data are being transmitted or when the message size is consistent, adjusting the size of the SDU buffers can improve performance, network utilization, or memory consumption. You can deploy SDU at the client, application web server, and database.

Tuning your application to reduce the number of round trips across the network is the best way to improve your network performance. If this is done, then it is also possible to optimize data transfer by adjusting the size of the SDU.

Considerations for Modifying the Size of the SDU

Modify the SDU size under the following situations:

- The data coming back from the server is fragmented into separate packets.
- You are on a wide area network (WAN) that has long delays.
- The packet size is consistently the same.
- Large amounts of data are returned.

Do not modify the SDU size under the following situations:

- The application can be tuned to avoid the delays listed in the adjacent column.
- You have a high speed network where the effect of the data transmission is negligible.
- Your requests return small amounts of data from the server.

Starting with Oracle Database 11*g*, Oracle Net Services optimizes bulk data transfer for certain components, such as Oracle SecureFiles LOBs and Oracle Data Guard redo transport services. The SDU size limit, as specified in the network parameter files, does not apply to these bulk data transfers. Bulk data transfer optimization does not apply when ASO options are enabled or TLS transport is used.

See Also:

"Configuring Session Data Unit"

1.1.4.3 Persistent Buffer Flushing for TCP/IP

Under certain conditions for some applications using TCP/IP, Oracle Net packets may not get flushed immediately to the network. Most often, this behavior occurs when large amounts of data are streamed. The implementation of TCP/IP itself is the reason for the lack of flushing, causing unacceptable delays. To remedy this problem, specify no delays in the buffer flushing process.

See Also:

Oracle Database Net Services Reference for additional information about the TCP.NODELAY parameter

1.1.4.4 Sockets Direct Protocol

Oracle Net Services provides support for InfiniBand high-speed networks. InfiniBand is a high-bandwidth I/O architecture designed to increase communication speed between CPUs, server-side devices, and network subsystems. Oracle Net Services provides support for Sockets Direct Protocol (SDP). SDP is an industry-standard wire protocol intended for use between InfiniBand network peers.

SDP reduces the overhead of TCP/IP by eliminating intermediate replication of data and transferring most of the messaging burden away from the CPU and onto the network hardware. The result is a low-latency, increased bandwidth, high-throughput connection that reduces the amount of CPU cycles dedicated to network processing.

The communication between clients, including Oracle WebLogic Server or any other third-party middle-tier client, and Oracle Database 12c release onwards can take advantage of high-speed interconnect benefits. Oracle WebLogic Server includes Oracle TCP/IP support as part of its installation.

A driver installed on the Oracle WebLogic Server servers transparently converts TCP/IP support to SDP support. The SDP requests are then sent to an InfiniBand switch that processes and forwards the requests from the Oracle WebLogic Server servers to the database server.

See Also:

"Configuring SDP Support for InfiniBand Connections"

1.1.4.5 Database Availability

Availability to the database is crucial for any network. You can configure multiple listeners to handle client connection requests for the same database service. This is beneficial in Oracle Real Application Clusters configurations, where each instance has a listener associated with it. Multiple listener configurations enable you to use the following features.

 Connect-time failover enables clients to request a different listener, usually on a different node, if the first listener fails. Client load balancing enables clients to randomize requests to the multiple listeners, usually on different nodes. These features can be used together or separately. Together, they ensure access to the database and distribute the load to not overburden a single listener.

1.1.5 Understanding Network Security

Data access and the secure transfer of data are important considerations when deploying Oracle Database. Granting and denying access to a database is crucial for a secure network environment. Oracle Net Services enables database access control using firewall access control and valid node registration.

Firewall Access Control

"Managing Oracle Net Listener Security" for information about valid node registration

1.1.5.1 Firewall Access Control

Oracle Connection Manager can be configured to grant or deny client access to a particular database service or a computer. By specifying filtering rules, you can allow or restrict specific client access to a server, based on the following criteria:

- Source host names or IP addresses for clients
- Destination host names or IP addresses for servers
- Destination database service names
- Client use of Oracle Net Services security features

Figure 1-11 shows an Oracle Connection Manager positioned between three clients and an Oracle Database server. Oracle Connection Manager is configured to allow access to the first two clients and to deny access to the third.

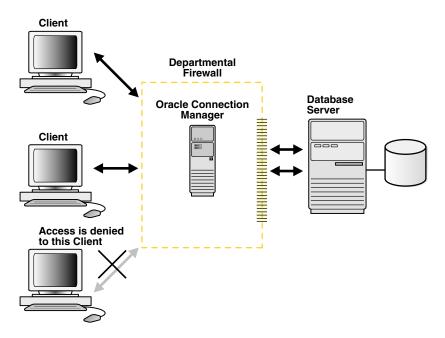

Figure 1-11 Intranet Network Access Control with Oracle Connection Manager

Although Oracle Connection Manager cannot be integrated with third-party firewall products, vendors can package it with their own products in a way that enables this product to serve as an application gateway.

In general, firewalls should be set to receive incoming requests, and allow outbound calls from Oracle Database. By defining filtering rules, you can limit access to the network.

Caution:

Incorrectly setting your firewall options can cause security problems. Before changing your firewall settings, discuss the options and your network site policies with your system administrator.

Figure 1-12 shows an application gateway controlling traffic between internal and external networks and providing a single checkpoint for access control and auditing. As a result, unauthorized Internet hosts cannot directly access the database inside a corporation, but authorized users can still use Internet services outside the corporate network. This capability is critical in Internet environments to restrict remote access to sensitive data.

Demilitarized Zone (DMZ)

Application Gateway

Clients

Corporate Network

Databases

Application Web Server

Figure 1-12 Internet Network Access Control with an Application Gateway

It is important to deploy at least two Oracle Connection Manager firewalls or Oracle Net Firewall proxies in an Internet network environment in the event that one firewall goes down.

1.2 Understanding Database Instances

A database has at least one instance. An instance is comprised of a memory area called the System Global Area (SGA) and Oracle background processes.

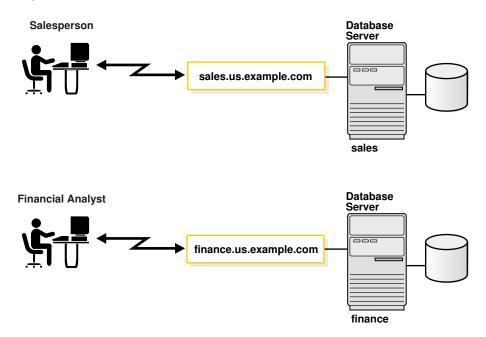

The memory and processes of an instance efficiently manage the associated database's data and serve the database users.

An instance also manages other services, such as Oracle XML DB.

The following figure shows two database instances, sales and finance, associated with their respective databases and service names.

Figure 1-13 One Instance for Each Database

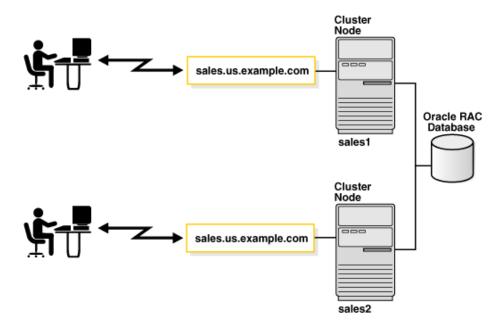

Instances are identified by an instance name, such as sales and finance in this example. The instance name is specified by the <code>INSTANCE_NAME</code> initialization parameter. The instance name defaults to the Oracle system identifier (SID) of the database instance.

Some hardware architectures allow multiple computers to share access to data, software, or peripheral devices. Oracle Real Application Clusters (Oracle RAC) can take advantage of such architecture by running multiple instances on different computers that share a single physical database.

The following figure shows an Oracle RAC configuration. In this example, two instances, sales1 and sales2, are associated with one database service, sales.us.example.com.

Figure 1-14 Multiple Instances Associated with an Oracle RAC Database

1.3 Components of Oracle Net Services

Learn about the connectivity, manageability, scalability, and security features.

- About Oracle Net
- About Oracle Net Listener
- About Oracle Connection Manager
- About Networking Tools
- About Oracle Advanced Security

Oracle Advanced Security is a separately licensable product that provides Oracle Database Transparent Data Encryption (TDE) and Oracle Data Redaction. TDE encrypts data so that only an authorized recipient can read it.

1.3.1 About Oracle Net

Oracle Net is a software layer that resides on the client and on the Oracle Database server. It is responsible for establishing and maintaining the connection between the client application and server, as well as exchanging messages between them, using industry-standard protocols. Oracle Net has two software components:

- Oracle Net Foundation Layer
- Oracle Protocol Support

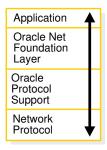

The Oracle Net foundation layer uses Oracle protocol support to communicate with these industry-standard network protocols.

1.3.1.1 Oracle Net Foundation Layer

On the client side, applications communicate with Oracle Net foundation layer to establish and maintain connections. The Oracle Net foundation layer uses Oracle protocol support that communicates with an industry-standard network protocol, such as TCP/IP, to communicate with the Oracle Database server.

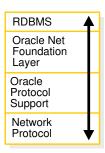

Figure 1-15 illustrates the communication stack on the client.

Figure 1-15 Oracle Net on the Client

The Oracle Database server side is similar to the client side as illustrated in Figure 1-16. A network protocol sends client request information to an Oracle protocol support layer, which then sends information to the Oracle Net foundation layer. The Oracle Net foundation layer then communicates with the Oracle Database server to process the client request.

Figure 1-16 Oracle Net on the Server

1.3.1.2 Oracle Protocol Support

The Oracle Net foundation layer uses Oracle protocol support to communicate with these industry-standard network protocols.

- TCP/IP (version 4 and version 6)
- TCP/IP with Transport Layer Security (TLS)
- Named Pipes
- SDP

Oracle protocol support maps Oracle Net foundation layer functionality to industry-standard protocols used in client/server connections.

Related Topics

Understanding Oracle Protocol Support Layer
 A network protocol is responsible for transporting data from the client computer to the database server computer. This section describes the protocols used by the Oracle Protocol Support layer of the Oracle Net communication stack.

1.3.2 About Oracle Net Listener

Oracle Database server receives the initial connection through Oracle Net Listener. Oracle Net Listener, referred to in this document as the listener, brokers a client request, handing off the request to the server. The listener is configured with a protocol address, and clients configured with the same protocol address can send connection requests to the listener. When a connection is established, the client and Oracle server communicate directly with one another.

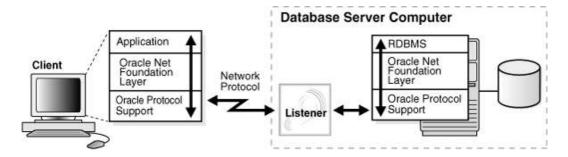

Oracle Net listener supports ACLs (Access Control Lists) for service and this is supported for all IP protocols.

DBSFWUSER.DBMS_SFW_ACL_ADMIN in *Oracle Database PL/SQL Packages* and *Types Reference* for more information about listener ACLs

The following figure shows the listener accepting a connection request from a client and forwarding that request to an Oracle server.

Figure 1-17 Listener in a Connection Request

Configuring and Administering Oracle Net Listener for additional information about the listener

1.3.3 About Oracle Connection Manager

Oracle Connection Manager is the software component that resides on its own computer, separate from a client or an Oracle Database server. It proxies and screens requests for the database server. In addition, it multiplexes database sessions.

In its session multiplexing role, Oracle Connection Manager funnels multiple sessions through a single transport protocol connection to a particular destination. In this way, Oracle Connection Manager reduces the demand on resources needed to maintain multiple sessions between two processes by enabling the Oracle Database server to use fewer connection endpoints for incoming requests.

As an access control filter, Oracle Connection Manager controls access to Oracle databases.

Note:

Oracle Connection Manager can act as a Connection Manager in Traffic Director Mode by setting tdm=yes in cman.ora.

Oracle Connection Manager in Traffic Director mode provides improved high availability (HA) (planned and unplanned), connection multiplexing support, and load balancing. This feature also provides an inband client notification mechanism to deliver planned shutdown for Oracle Connection Manager down and service down events to the OCI client.

See Also:

- "Understanding Shared Server Architecture"
- "Firewall Access Control" for a description of filtering

1.3.4 About Networking Tools

Oracle Net Services provides user interface tools and command-line utilities to configure, manage, and monitor the network.

- Oracle Net Configuration Assistant is a standalone tool that enables you to configure listeners and naming methods.
- Oracle Enterprise Manager Cloud Control combines configuration functionality across
 multiple file systems, along with listener administrative control to provide an integrated
 environment for configuring and managing Oracle Net Services.
- Oracle Net Manager provides configuration functionality for an Oracle home on a local client or server host.
- Command-line control utilities to configure, administer, and monitor network components, including listeners and Oracle Connection Managers.

With Oracle Enterprise Manager Cloud Control or Oracle Net Manager, you can fine-tune the listener and naming method configuration created with Oracle Net Configuration Assistant. In addition, Oracle Enterprise Manager Cloud Control and Oracle Net Manager offer built-in wizards and utilities to test connectivity, migrate data from one naming method to another, and create additional network components.

Managing Oracle Net Services

1.3.5 About Oracle Advanced Security

Oracle Advanced Security is a separately licensable product that provides Oracle Database Transparent Data Encryption (TDE) and Oracle Data Redaction. TDE encrypts data so that only an authorized recipient can read it.

Oracle Data Redaction enables an administrator to redact (mask) column data, using the following types of redaction:

- Full redaction redacts all the contents of the column data. The redacted value returned to
 the querying user depends on the data type of the column. For example, columns of the
 NUMBER data type are redacted with a zero (0) and character data types are redacted
 with a blank space.
- Partial redaction redacts a portion of the column data. For example, masking most of a credit card number with asterisks (*), except for the last four digits.

- Regular expressions enable using patterns of data to redact. For example, use regular
 expressions to redact email addresses, which can have varying character lengths. It is
 designed for use with character data only.
- Random redaction present the redacted data to the querying user as randomly-generated values each time it is displayed.
- No redaction enables an administrator to test the internal operation of the redaction policies, with no effect on the results of queries against tables with policies defined on them.

Identifying and Accessing the Database

Understand how databases are identified, and how clients access them.

Understanding Database Instances

A database has at least one instance. An instance is comprised of a memory area called the System Global Area (SGA) and Oracle background processes.

Understanding Database Services

An Oracle database is represented to clients as a service. A database can have one or more services associated with it.

Connecting to a Database Service

To connect to a database service, clients use a connect descriptor that provides the location of the database and the name of the database service.

Understanding Service Handlers

Service handlers act as connection points to an Oracle database. A service handler can be a dispatcher or a dedicated server process, or pooled.

Understanding Naming Methods

Oracle Net Services offers several types of naming methods that support localized configuration on each client, or centralized configuration that can be accessed by all clients in the network.

• Enhancing Service Accessibility Using Multiple Listeners

For some configurations, such as Oracle RAC, multiple listeners on multiple nodes can be configured to handle client connection requests for the same database service.

2.1 Understanding Database Instances

A database has at least one instance. An instance is comprised of a memory area called the System Global Area (SGA) and Oracle background processes.

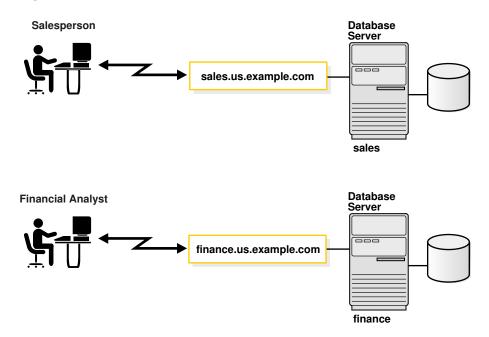

The memory and processes of an instance efficiently manage the associated database's data and serve the database users.

An instance also manages other services, such as Oracle XML DB.

The following figure shows two database instances, sales and finance, associated with their respective databases and service names.

Figure 2-1 One Instance for Each Database

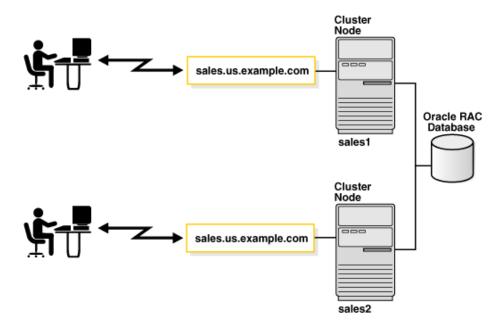

Instances are identified by an instance name, such as sales and finance in this example. The instance name is specified by the INSTANCE_NAME initialization parameter. The instance name defaults to the Oracle system identifier (SID) of the database instance.

Some hardware architectures allow multiple computers to share access to data, software, or peripheral devices. Oracle Real Application Clusters (Oracle RAC) can take advantage of such architecture by running multiple instances on different computers that share a single physical database.

The following figure shows an Oracle RAC configuration. In this example, two instances, sales1 and sales2, are associated with one database service, sales.us.example.com.

Figure 2-2 Multiple Instances Associated with an Oracle RAC Database

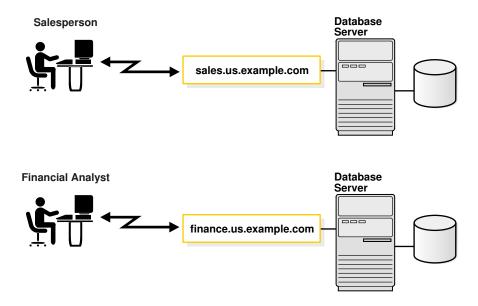

2.2 Understanding Database Services

An Oracle database is represented to clients as a service. A database can have one or more services associated with it.

The following figure shows two databases, each with its own database service for clients. One service, sales.us.example.com, enables salespersons to access the sales database. Another service, finance.us.example.com, enables financial analysts to access the finance database.

Figure 2-3 One Service for Each Database

The sales and finance databases are each identified by a service name,

sales.us.example.com and finance.us.example.com, respectively. A service name is a logical representation of a database. When an instance starts, it registers itself with a listener using one or more service names. When a client program or database connects to a listener, it requests a connection to a service.

A service name can identify multiple database instances, and an instance can belong to multiple services. For this reason, the listener acts as a mediator between the client and instances and routes the connection request to the appropriate instance. Clients connecting to a service need not specify which instance they require.

The service name is specified by the SERVICE_NAMES initialization parameter in the server parameter file. The server parameter file enables you to change initialization parameters with ALTER SYSTEM commands, and to carry the changes across a shutdown and startup. The DBMS_SERVICE package can also be used to create services. The service name defaults to the global database name, a name comprising the database name (DB_NAME initialization parameter) and domain name (DB_DOMAIN initialization parameter). In the case of sales.us.example.com, the database name is sales and the domain name is us.example.com.

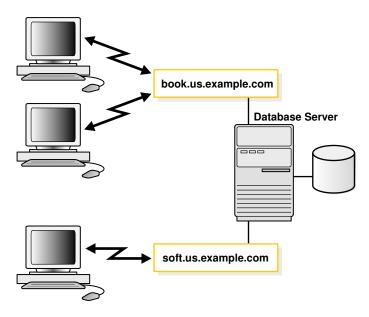

Note:

Starting with Oracle Database 19c, customer use of the <code>SERVICE_NAMES</code> parameter is deprecated. To manage your services, Oracle recommends that you use the <code>SRVCTL</code> or <code>GDSCTL</code> command line utilities, or the <code>DBMS_SERVICE</code> package.

The following figure shows clients connecting to multiple services associated with one database.

Figure 2-4 Multiple Services Associated with One Database

Associating multiple services with one database enables the following functionality:

- A single database can be identified different ways by different clients.
- A database administrator can limit or reserve system resources. This level of control enables better allocation of resources to clients requesting one of the services.

See Also:

- Oracle Database Administrator's Guide for additional information about initialization parameters
- Oracle Database SQL Reference for additional information about the ALTER SYSTEM statement
- Oracle Database Reference for additional information about the SERVICE_NAMES parameter
- Oracle Database PL/SQL Packages and Types Reference for additional information about the DBMS SERVICE package.

2.3 Connecting to a Database Service

To connect to a database service, clients use a connect descriptor that provides the location of the database and the name of the database service.

The following example is an Easy Connect descriptor that connects to a database service named sales.us.example.com, and the host sales-server (the port is 1521 by default):

```
sales-server/sales.us.example.com
```

The following example shows the entry in the tnsnames.ora file for the preceding Easy Connect connect descriptor and database service:

```
(DESCRIPTION=
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
  (CONNECT_DATA=
        (SERVICE NAME=sales.us.example.com)))
```

- About Connect Descriptors
- About the Protocol Address
- About Service Registration

Related Topics

Understanding Naming Methods

Oracle Net Services offers several types of naming methods that support localized configuration on each client, or centralized configuration that can be accessed by all clients in the network.

2.3.1 About Connect Descriptors

A connect descriptor is comprised of one or more protocol addresses of the listener and the connect information for the destination service in the tnsnames.ora file. Example 2-1 shows a connect descriptor mapped to the sales database.

Example 2-1 Connect Descriptor

```
sales=
(DESCRIPTION=
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
(CONNECT_DATA=
       (SID=sales)
       (SERVICE_NAME=sales.us.example.com)
       (INSTANCE_NAME=sales)))
```

As shown in Example 2-1, the connect descriptor contains the following parameters:

- The ADDRESS section contains the following:
 - PROTOCOL parameter, which identifies the listener protocol address. The protocol is tcp for TCP/IP.
 - HOST parameter, which identifies the host name. The host is sales-server.
 - PORT parameter, which identifies the port. The port is 1521, the default port number.
 - Optional HTTPS_PROXY and HTTPS_PROXY_PORT parameters, that allow the database client connection to traverse through the organization's forward web proxy.

These parameters are applicable only to the connect descriptors where PROTOCOL=TCPS.

- The CONNECT DATA section contains the following:
 - SID parameter, which identifies the system identifier (SID) of the Oracle database. The SID is sales.
 - SERVICE_NAME parameter, which identifies the service. The destination service name is a database service named sales.us.example.com.

The value for this connect descriptor parameter comes from the SERVICE_NAMES initialization parameter (SERVICE_NAMES uses a final S) in the initialization parameter file. The SERVICE_NAMES initialization parameter is typically the global database name, which includes the database name and domain name. In the example, sales.us.example.com has a database name of sales and a domain of us.example.com.

Note:

Starting with Oracle Database 19c, customer use of the <code>SERVICE_NAMES</code> parameter is deprecated. To manage your services, Oracle recommends that you use the <code>SRVCTL</code> or <code>GDSCTL</code> command line utilities, or the <code>DBMS_SERVICE</code> package.

 INSTANCE_NAME parameter, which identifies the database instance. The instance name is optional.

The INSTANCE_NAME parameter in the initialization parameter file defaults to the SID entered during installation or database creation.

About IPv6 Addresses in Connect Descriptors

A host can use IP version 4 (IPv4) and IP version 6 (IPv6) interfaces. IPv6 addresses and host names that resolve to IPv6 addresses are usable in the HOST parameter of a TNS connect address, which can be obtained through any of the supported net naming methods.

See Also:

"Understanding Database Instances", and "Understanding Database Services"

2.3.1.1 About IPv6 Addresses in Connect Descriptors

A host can use IP version 4 (IPv4) and IP version 6 (IPv6) interfaces. IPv6 addresses and host names that resolve to IPv6 addresses are usable in the HOST parameter of a TNS connect address, which can be obtained through any of the supported net naming methods.

End-to-end connectivity using IPv6 requires the following configuration:

- The client TNS connect address must connect to the Oracle Net Listener on the IPv6 endpoint.
- The database instance configured for Oracle Net Listener must listen for connection requests on IPv6 endpoints.

For a given host name, Oracle Net attempts to connect to all IP addresses returned by Domain Name System (DNS) name resolution until a successful connection is established or all addresses have been attempted. Suppose that in a connect descriptor, the sales-server host is an IPv4-only host that is accepting client connections. DNS maps sales-server to the following IP addresses:

- 1. IPv6 address 2001:0db8:0:0::200C:417A
- 2. IPv4 address 192.0.2.213

In this case, Oracle Net first tries to connect on the IPv6 address because it is first in the DNS list. In this example, sales-server does not support IPv6 connectivity, so this attempt fails. Oracle Net proceeds to connect to the IPv4 address, which succeeds.

Related Topics

- Choosing a Naming Method
 - Selecting the appropriate naming method for mapping names to connect descriptors depends upon the size of the organization.
- About TCP/IP Protocol
 - TCP/IP (Transmission Control Protocol/Internet Protocol) is the standard communication protocol suite used for client/server communication over a network.
- Configuring Listening Protocol Addresses
- Using Oracle Connection Manager as a Bridge for IPv4 and IPv6
 In some database connection environments, a client and database may use different versions of the IP protocol so that complete connectivity does not exist. In this case, at least two hops in the connection use different versions of the IP protocol.
- IPv6 Network Connectivity

2.3.2 About the Protocol Address

The address portion of the connect descriptor is the protocol address of the listener. To connect to a database service, clients first contact a listener process that typically resides on the database server. The listener receives incoming client connection requests and sends these requests to the database server. After the connection is established, the client and database server communicate directly.

The listener is configured to accept requests from clients at a protocol address. This address defines the protocol the listener is listening on and any other protocol-specific information. For example, the listener could be configured to listen at the following protocol address:

The preceding example shows a TCP/IP protocol address that specifies the host of the listener and a port number. Client connect descriptors configured with this same protocol address can send connection requests to this listener.

2.3.3 About Service Registration

The connect descriptor specifies the database service name with which clients seek to establish a connection. The listener knows which services can handle connection requests because Oracle Database dynamically registers this information with the listener. This process of registration is called service registration. Registration also provides the listener with information about the database instances and the service handlers available for each instance. A service handler can be a dispatcher or dedicated server.

- Specifying an Instance Name
- Specifying a Service Handler

2.3.3.1 Specifying an Instance Name

If connecting to a specific instance of the database is required, then clients can specify the INSTANCE_NAME of a particular instance in the connect descriptor. This feature can be useful for an Oracle RAC configuration. For example, the following connect descriptor specifies the instance name <code>sales1</code> that is associated with <code>sales.us.example.com</code>.

```
(DESCRIPTION=
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
  (CONNECT_DATA=
    (SERVICE_NAME=sales.us.example.com)
    (INSTANCE NAME=sales1)))
```

2.3.3.2 Specifying a Service Handler

Clients that always want to use a particular service handler type can use a connect descriptor to specify the service handler type. In the following example, the connect descriptor uses (SERVER=shared) to request a dispatcher when connecting to a database. The database may be configured to use dedicated servers by default.

```
(DESCRIPTION=
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
  (CONNECT_DATA=
    (SERVICE_NAME=sales.us.example.com)
        (SERVER=shared)))
```

When the listener receives the client request, it selects one of the registered service handlers. Depending on the type of handler selected, the communication protocol used, and the operating system of the database server, the listener performs one of the following actions:

- Hands the connect request directly off to a dispatcher.
- Sends a redirect message back to the client with the location of the dispatcher or dedicated server process. The client then connects directly to the dispatcher or dedicated server process.
- Spawns a dedicated server process and passes the client connection to the dedicated server process.

After the listener has completed the connection operation for the client, the client communicates directly with the Oracle database without the listener's involvement. The listener resumes listening for incoming network sessions.

The following should be considered when specifying service handlers:

- If you want the client to use a dedicated server, then specify (SERVER=dedicated). If the SERVER parameter is not set, then a shared server configuration is assumed. However, the client will use a dedicated server if no dispatchers are available.
- If database resident connection pooling is enabled on the server, then specify
 (SERVER=pooled) to get a connection from the pool. If database resident connection
 pooling is not enabled on the server, then the client request is rejected, and the user
 receives an error message.

See Also:

- "About the Listener and Connection Requests" for a discussion about how the listener works with service handlers

- Oracle Database Global Data Services Concepts and Administration Guide for additional information about management of global services

2.4 Understanding Service Handlers

Service handlers act as connection points to an Oracle database. A service handler can be a dispatcher or a dedicated server process, or pooled.

- About Dispatchers
- About Dedicated Server Processes
- About Database Resident Connection Pooling

2.4.1 About Dispatchers

The shared server architecture uses a dispatcher process to direct client connections to a common request queue. An idle shared server process from a shared pool of server processes picks up a request from the common queue. This approach enables a small pool of server processes to serve a large number of clients. A significant advantage of the shared server model over the dedicated server model is reduced system resources, enabling support of an increased number of users.

The listener uses the dispatcher as a type of service handler to which it can direct client requests. When a client request arrives, the listener performs one of the following actions:

- Hands the connection request directly to a dispatcher.
- Issues a redirect message to the client, containing the protocol address of a dispatcher.
 The client then terminates the network session to the listener and establishes a network session to the dispatcher, using the network address provided in the redirect message.

The listener uses direct hand off whenever possible. Redirect messages are used, for example, when dispatchers are remote to the listener.

The following figure shows the listener handing a connection request directly to a dispatcher.

- 1. The listener receives a client connection request.
- 2. The listener hands the connect request directly to the dispatcher.
- 3. The client is now connected to the dispatcher.

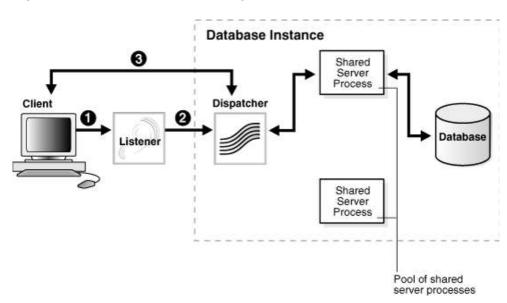

Figure 2-5 Direct Hand Off to a Dispatcher

The following figure shows the role of a dispatcher in a redirected connection.

- The listener receives a client connection request.
- 2. The listener provides the location of the dispatcher to the client in a redirect message.
- 3. The client connects directly to the dispatcher.

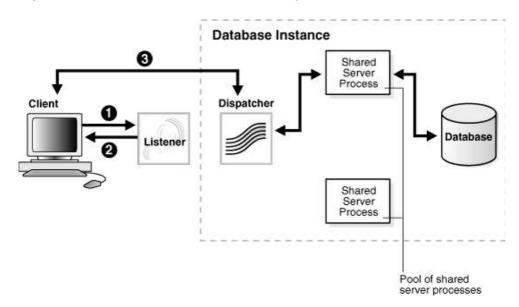

Figure 2-6 Redirected Connection to a Dispatcher

2.4.2 About Dedicated Server Processes

In a dedicated server configuration, the listener starts a separate dedicated server process for each incoming client connection request dedicated to servicing the client. After the session is complete, the dedicated server process terminates. Because a dedicated server process has

to be started for each connection, this configuration may require more system resources than shared server configurations.

A dedicated server process is a type of service handler that the listener starts when it receives a client request. To complete a client/server connection, one of the following actions occurs:

- The dedicated server inherits the connection request from the listener.
- The dedicated server informs the listener of its listening protocol address. The listener
 passes the protocol address to the client in a redirect message and terminates the
 connection. The client connects to the dedicated server directly using the protocol address.

One of the preceding actions is selected based on the operating system and the transport protocol.

If the client and database exist on the same computer, then a client connection can be passed directly to a dedicated server process without going through the listener. This is known as a bequeath protocol. The application initiating the session spawns a dedicated server process for the connection request. This happens automatically if the application used to start the database is on the same computer as the database.

In order for remote clients to connect to dedicated servers, the listener and the database instance must be running on the same computer.

Figure 2-7 shows the listener passing a client connection request to a dedicated server process.

- The listener receives a client connection request.
- The listener starts a dedicated server process, and the dedicated server inherits the connection request from the listener.
- 3. The client is now connected directly to the dedicated server.

Figure 2-7 Connection to a Dedicated Server Process

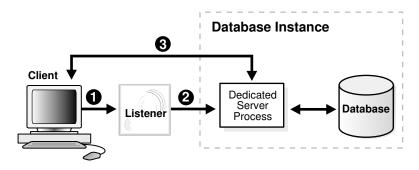

Figure 2-8 shows the role of a dedicated server in a redirected connection.

- The listener receives a client connection request.
- 2. The listener starts a dedicated server process.
- The listener provides the location of the dedicated server process to the client in a redirect message.

The client connects directly to the dedicated server.

2.4.3 About Database Resident Connection Pooling

Database resident connection pooling provides a connection pool in the database server for typical web application usage scenarios in which an application acquires a database connection, works on it for a relatively short duration, and then releases it. Database resident connection pooling pools "dedicated" servers. A pooled server is the equivalent of a server foreground process and a database session combined. Database resident connection pooling uses dynamic registration between the server and the listener. It cannot use static registration.

Database resident connection pooling complements middle-tier connection pools that share connections between threads in a middle-tier process. In addition, it enables sharing of database connections across middle-tier processes on the same middle-tier host and even across middle-tier hosts. This results in significant reduction in key database resources needed to support a large number of client connections, thereby reducing the database tier memory footprint and boosting the scalability of both middle-tier and database tiers. Having a pool of readily available servers has the additional benefit of reducing the cost of creating and closing client connections.

Database resident connection pooling provides pooling for dedicated connections across client applications and processes. This feature is useful for applications that must maintain persistent connections to the database and optimize server resources, such as memory.

Clients obtaining connections out of the database resident connection pool are persistently connected to a background process, the connection broker, instead of the dedicated servers. The connection broker implements the pool functionality and performs the multiplexing of inbound connections from the clients to a pool of dedicated servers with sessions.

When a client must perform database work, the connection broker picks up a dedicated server from the pool and assigns it to the client. Subsequently, the client is directly connected to the dedicated server until the request is served. After the server finishes processing the client request, the server goes back into the pool and the connection from the client is restored to the connection broker.

The following figure shows the process.

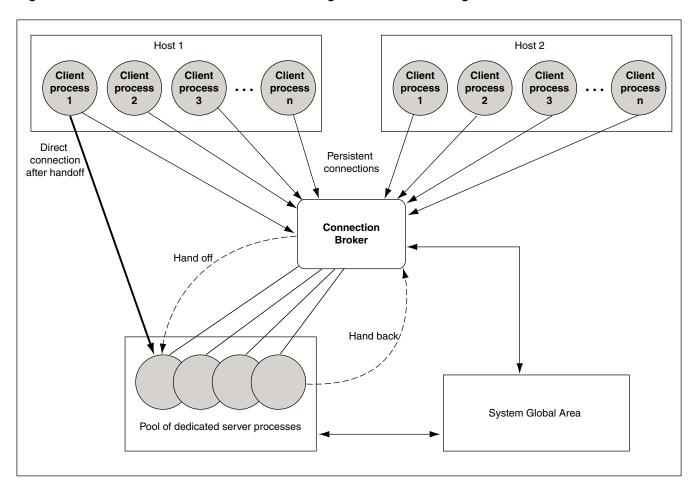

Figure 2-9 Dedicated Server Processes Handling Connections Through the Connection Broker Process

2.5 Understanding Naming Methods

Oracle Net Services offers several types of naming methods that support localized configuration on each client, or centralized configuration that can be accessed by all clients in the network.

- About Naming Methods
 - A naming method is a resolution method used by a client application to resolve a connect identifier to a connect descriptor when attempting to connect to a database service.
- Choosing a Naming Method
 Selecting the appropriate naming method for mapping names to connect descriptors depends upon the size of the organization.
- Establishing a Client Session Using a Naming Method
 Learn about a typical process for establishing a client session using a naming method.
- Entering a Connection String

You can make a connection across the network after the network components are started. How you make a connection depends upon the naming method and the tool used for the connection.

2.5.1 About Naming Methods

A naming method is a resolution method used by a client application to resolve a connect identifier to a connect descriptor when attempting to connect to a database service.

Overview

The information needed to use a service name to create a database connection can be stored in a repository, which is represented by one or more naming methods. Users initiate a connection request by providing a connect string.

A connect string includes a user name and password, along with a connect identifier. A connect identifier can be the connect descriptor or a name that resolves to a connect descriptor. The connect descriptor contains:

- Network route to the service, including the location of the listener through a protocol address
- A database service name or Oracle system identifier (SID)

The following CONNECT command uses a connect string that has a complete connect descriptor as the connect identifier instead of a network service name. The string should be entered on a single line. It is shown on two lines because of page width.

```
SQL> CONNECT hr@(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp) (HOST=sales-server1)
(PORT=1521)) (CONNECT_DATA=(SERVICE_NAME=sales.us.example.com)))
```

One of the most common connect identifiers is a network service name, a simple name for a service. The following CONNECT command uses a connect string that uses network service name sales as the connect identifier:

```
SQL> CONNECT hr@sales
```

When network service name sales is used, connection processing takes place by first mapping sales to the connect descriptor.

Types of Naming Methods

The mapped information is accessed by naming methods. The following naming methods are available:

- Local Naming
- Directory Naming
- Centralized Configuration Provider Naming
- Easy Connect Naming

How to Configure Naming Methods

A naming method configuration consists of the following steps:

- Select a naming method.
- Map connect descriptors to the names or to a connect identifier.
- Configure clients to use the naming method.

Related Topics

Configuring Naming Methods
 Find out how to configure connectivity information for client connections to the database server.

2.5.2 Choosing a Naming Method

Selecting the appropriate naming method for mapping names to connect descriptors depends upon the size of the organization.

- For a small organization with only a few databases, use Easy Connect Naming to make TCP/IP connections with the host name of the database server or local naming to store names in this names or a file on the clients.
- For large organizations with several databases, use Directory Naming to store names in a centralized directory server or Centralized Configuration Provider Naming to store names in a Centralized Configuration Provider.
- For an Internet network, configure the application web servers needed to connect to the databases with the Local Naming method.

This is a summary of the advantages and disadvantages of each naming method, and some recommendations for using them in the network:

Naming Method	Description	Advantages/Disadvantages	Recommended for:
Local Naming	Stores network service names and their connect descriptors in a localized configuration file named tnsnames.ora, which by default is located in the ORACLE_BASE_HOME/network/admin directory.	Advantages: Provides a straightforward method for resolving network service name addresses. Resolves network service names across networks running different protocols. Disadvantage: Requires local configuration of all network service name and address changes.	Simple distributed networks with a small number of services that change infrequently.
Directory Naming	Stores connect identifiers in a centralized LDAP-compliant directory server to access a database service.	 Advantages: Centralizes network names and addresses in a single place, facilitating administration of name changes and updates. This eliminates the need for an administrator to make changes to what potentially could be hundreds or even thousands of clients. Directory stores names for other services. Tools provide simple configuration. Provides an alternative method to specify LDAP name lookup by passing LDAP parameters directly in the connect identifier, instead of specifying external configuration files (such as ldap.ora and sqlnet.ora). Disadvantage: Requires access to a directory server.	Large, complex networks (with over 20 client computers) that change on a frequent basis.

Naming Method	Description	Advantages/Disadvantages	Recommended for:
Centralized Configuration Provider Naming	Stores connect descriptors and optionally database credential references in a Centralized Configuration Provider, such as Azure App Configuration store or Oracle Cloud Infrastructure (OCI) Object Storage as a JSON file.	Advantages: Centralizes network names and addresses in a single location, facilitating administration (addition, deletion, or modification) of connect descriptors. This eliminates the need for an administrator to change multiple client connect descriptors, which potentially could be hundreds or even thousands in number. For example, if a large number of connect descriptors are stored on a client using the Local Naming method (tnsnames.ora) or Easy Connect Naming method, then any modification would require an update to all those client connect descriptors. If you are using the instance based or managed identity based authentication, then the password to access the Centralized Configuration Provider is managed by Microsoft Azure or OCI. Enables you to centrally manage database password change policies for all stored database user names and	Large, complex networks (with over 20 client computers) that change on a frequent basis.
		 database passwords. Enables client applications running on multitenant cloud service environments (which may not have access to wallet stored in local system file) to centrally manage wallets in remote stores. Disadvantages: 	
		 Requires access to the OCI Object Storage or Azure App Configuration service. When used outside the instance-based or resource principal or managed identity-based authentication, might need you to modify cloud access user name and password in the connect identifier whenever there is a change in 	
Easy Connect Naming	Enables clients to connect to an Oracle database server by using a TCP/IP connect string consisting of a host name and optional port and service name.	 them. Advantages: Requires minimal user configuration. The user can provide only the name of the database host to establish a connection. The Easy Connect Naming method requires no client-side configuration. Eliminates the need to create and maintain a local names configuration file (tnsnames.ora). Disadvantage: Available only in a limited environment, as indicated in the Recommended for column. 	Simple TCP/IP networks that meet the following criteria: The client and server are connecting using TCP/IP. No features requiring a more advanced connect descriptor are required.

Related Topics

Configuring Naming Methods
 Find out how to configure connectivity information for client connections to the database server.

2.5.3 Establishing a Client Session Using a Naming Method

Learn about a typical process for establishing a client session using a naming method.

- 1. The client initiates a connect request by providing a connect identifier.
- 2. The connect identifier is resolved to a connect descriptor by a naming method.
- 3. The client makes the connection request to the address provided in the connect descriptor.
- **4.** A listener receives the request and directs it to the appropriate database server.
- 5. The connection is accepted by the database server.

Besides connect descriptors, you can use naming methods to map a connect name to a protocol address or protocol address list.

2.5.4 Entering a Connection String

You can make a connection across the network after the network components are started. How you make a connection depends upon the naming method and the tool used for the connection.

The connection string (or connect string) takes the following format:

CONNECT username@connect_identifier

Default Connect Identifier

On most operating systems, you can define a default connect identifier. When using the default, a connect identifier does not need to be specified in the connect string. To define a default connect identifier, use the <code>TWO_TASK</code> environment variable on Linux and UNIX platforms or the <code>LOCAL</code> environment variable or registry entry on Microsoft Windows.

For example, if the $\texttt{TWO}_\texttt{TASK}$ environment variable is set to sales, then you can connect to a database from SQL*Plus with CONNECT username rather than CONNECT username@sales. Oracle Net checks the TWO TASK variable, and uses the value sales as the connect identifier.

For instructions on setting the TWO_TASK and LOCAL environment variables, see the Oracle operating system-specific documentation.

Connect Identifier and Connect Descriptor Syntax Characteristics

Connect identifiers used in a connect string cannot contain spaces, unless enclosed within single quotation marks (') or double quotation marks ("). In the following examples, a connect identifier and a connect descriptor that contain spaces are enclosed within single quotation marks:

CONNECT scott@'(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=sales-server)(PORT=1521))(CONNECT DATA=(SERVICE NAME=sales.us.example.com)))'

```
Enter password: password

CONNECT scott@'cn=sales, cn=OracleContext, dc=us, dc=example, dc=com'
Enter password: password
```

Single quotation marks are required if double quotation marks are used in a connect identifier. For example:

```
CONNECT scott@'sales@"good"example.com'
Enter password: password
```

Similarly, double quotation marks are required if single quotation marks are used in a connect identifier. For example:

```
CONNECT scott@"cn=sales, cn=OracleContext, ou=Mary's Dept, o=example" Enter password: password
```

Oracle Database Connection String Utility

Starting with Oracle Database 23ai, you can use the Oracle Database Connection String command-line utility (connstr) to display connect strings for all the available network service names.

You can display these strings in various formats (such as Easy Connect, JDBC Thin, or connect descriptor) and use in client applications or tools (such as SQL*Plus, Python, or JDBC Thin clients) to quickly connect to the database. In addition, the connstr utility enables you to write service names and their connect descriptors in the tnsnames.ora file for use with the local naming method.

For example, the utility generates a tnsnames.ora file that contains the following connect descriptor for the sales.us.example.com service name:

The client application can use sales.us.example.com in the connect string to connect to the database, as follows:

```
sqlplus scott@sales.us.example.com
Enter password: password
```

Related Topics

Viewing Connection Strings Using the connstr Utility
 You can run the Oracle Database Connection String command-line utility (connstr) to display Oracle Database connect strings for all the available network service names.

2.6 Enhancing Service Accessibility Using Multiple Listeners

For some configurations, such as Oracle RAC, multiple listeners on multiple nodes can be configured to handle client connection requests for the same database service.

In the following example, sales.us.example.com can connect using listeners on either sales1-server or sales2-server.

A multiple-listener configuration also enables you to leverage the failover and load balancing features, either individually or in combination with each other.

- About Connect-Time Failover
- About Transparent Application Failover
- About Client Load Balancing
- About Connection Load Balancing

2.6.1 About Connect-Time Failover

The connect-time failover feature enables clients to connect to another listener if the initial connection to the first listener fails. The number of listener protocol addresses determines how many listeners are tried. Without connect-time failover, Oracle Net attempts a connection with only one listener.

2.6.2 About Transparent Application Failover

The Transparent Application Failover (TAF) feature is a runtime failover for high availability environments, such as Oracle Real Application Clusters. TAF fails over and reestablishes application-to-service connections. It enables client applications to automatically reconnect to the database if the connection fails and, optionally, resume a SELECT statement that was in progress. The reconnection happens automatically from within the Oracle Call Interface (OCI) library.

2.6.3 About Client Load Balancing

The client load balancing feature enables clients to randomize connection requests among the listeners. Oracle Net progresses through the list of protocol addresses in a random sequence, balancing the load on the various listeners. Without client load balancing, Oracle Net progresses through the list of protocol addresses sequentially until one succeeds.

2.6.4 About Connection Load Balancing

The connection load balancing feature improves connection performance by balancing the number of active connections among multiple dispatchers. In a single-instance environment, the listener selects the least-loaded dispatcher to handle the incoming client requests. In an Oracle Real Application Clusters environment, connection load balancing can balance the number of active connections among multiple instances.

Due to dynamic service registration, a listener is always aware of all instances and dispatchers regardless of their location. Depending on the load information, a listener decides which instance and, if shared server is configured, to which dispatcher to send the incoming client request.

In a shared server configuration, a listener selects a dispatcher in the following order:

Least-loaded node

- 2. Least-loaded instance
- 3. Least-loaded dispatcher for that instance

In a dedicated server configuration, a listener selects an instance in the following order:

- Least-loaded node
- 2. Least-loaded instance

If a database service has multiple instances on multiple nodes, then the listener chooses the least-loaded instance on the least-loaded node.

Managing Network Address Information

Identify how the network address information for Oracle Net Services can be stored in local files or in a centralized directory server.

Using localized management, network address information is stored in tnsnames.ora files on each computer in the network. Using centralized management, network address information is stored in centralized directory server.

- Using Localized Management
 When localized management is used.
 - When localized management is used, network computers are configured with configuration files. The files are stored locally on the computers.
- Using a Directory Server for Centralized Management

3.1 Using Localized Management

When localized management is used, network computers are configured with configuration files. The files are stored locally on the computers.

Table 3-1 Oracle Net Configuration Files Used with Localized Management

Configuration File	Description	
tnsnames.ora	Located primarily on the clients, this file contains network service names mapped to connect descriptors. This file is used for the local naming method.	
sqlnet.ora	Located on client and database server computers, this file may include the following:	
	 Client domain to append to unqualified service names or network service names 	
	 Order of naming methods the client should use when resolving a name 	
	 Logging and tracing features to use 	
	 Route of connections 	
	 External naming parameters 	
	 Oracle security parameters 	
	 Database access control parameters 	
listener.ora	Located on the database server, this configuration file for the listener may include the following:	
	 Protocol addresses it is accepting connection requests on 	
	 Database and nondatabase services it is listening for 	
	 Control parameters used by the listener 	

Table 3-1 (Cont.) Oracle Net Configuration Files Used with Localized Management

Configuration File	Description
cman.ora	Located on the computer where Oracle Connection Manager runs, this configuration file includes the following components:
	A listening endpoint
	Access control rule list
	Parameter list
	Each Oracle Connection Manager configuration is encapsulated within a single name-value (NV) string, which consists of the preceding components.

Typically, tools such as Oracle Database Configuration Assistant (DBCA) and Oracle Net Configuration Assistant (NETCA) create configuration files in the <code>ORACLE_HOME/network/admin</code> directory for Oracle Database installations, the <code>GRID_HOME/network/admin</code> directory for Oracle Grid Infrastructure installations, or the corresponding <code>ORACLE_BASE_HOME/network/admin</code> directory for a read-only Oracle home. If you have installed multiple databases, then these are created in the Oracle home or Grid home where DBCA or NETCA is run (or the Oracle base home for read-only instances). However, configuration files can be created in other directories.

For example, the order for checking the tnsnames.ora file is:

- 1. The directory specified by the TNS ADMIN environment variable
- 2. If the TNS_ADMIN environment variable is not set or the file is not found in the TNS_ADMIN directory:
 - On Linux and UNIX: The ORACLE_HOME/network/admin directory (or its
 ORACLE BASE HOME/network/admin directory for a read-only Oracle home)
 - On Windows: ORACLE_HOME\network\admin directory (or its
 ORACLE BASE HOME\network\admin directory for a read-only Oracle home)
- 3. For a read-only Oracle home, if the file is not found in the Oracle base home:
 - On Linux and UNIX: The ORACLE HOME/network/admin directory
 - On Windows: The ORACLE HOME\network\admin directory

Note:

- On Windows, the <code>ORACLE_HOME</code> location is determined by the <code>ORACLE_HOME\bin\oracle.key</code> file (which contains the name of the Windows Registry key where <code>ORACLE_HOME</code> is defined). Also, the <code>TNS_ADMIN</code> environment variable is used if it is set in the environment of the process. If you do not define the <code>TNS_ADMIN</code> environment variable in the environment or if the process is a service that does not have an environment, then Windows scans the registry for a <code>TNS_ADMIN</code> parameter.
- With Oracle Instant Client, tnsnames.ora is located in the subdirectory of the Oracle Instant Client software. For example, in the /opt/oracle/ instantclient release number/network/admin directory.

3.2 Using a Directory Server for Centralized Management

When an Oracle network uses a directory server, the directory server manages global database links as network service names for the Oracle databases in the network. Users and programs can use a global link to access objects in the corresponding database.

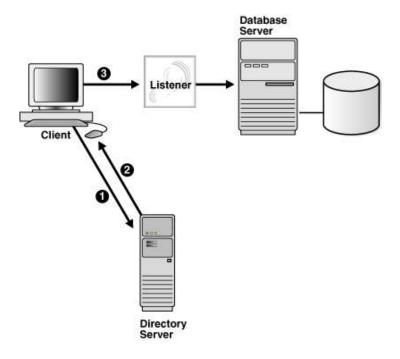

Oracle Net Services uses a centralized directory server as one of the primary methods for storing connect identifiers. Clients use the connect identifiers in their connect string, and the directory server resolves the connect identifier to a connect descriptor that is passed back to the client. This feature is called directory naming. This type of infrastructure reduces the cost of managing and configuring resources in a network.

Oracle Internet Directory provides a centralized mechanism for managing and configuring a distributed Oracle network. The directory server can replace client-side and server-side localized tnsnames.ora files.

The following figure shows a client resolving a connect identifier through a directory server.

- The client contacts the directory server to resolve a connect identifier to a connect descriptor.
- The directory server resolves the connect identifier and retrieves the connect descriptor for the client.
- 3. The client sends the connection request to the listener, using the connect descriptor.

Figure 3-1 Client Using a Directory Server to Resolve a Connect Identifier

Note:

Java Database Connectivity (JDBC) Drivers support directory naming. See *Oracle Database JDBC Developer's Guide* for additional information.

This section contains the following topics:

- Understanding the Directory Information Tree
- Understanding Oracle Context
 The entries under Oracle Context support various directory-enabled features, including directory naming.
- Understanding Net Service Alias Entries
- Who Can Add or Modify Entries in the Directory Server
- Client Connections Using Directory Naming
 Most clients needing to perform name lookups in the directory server access the directory
 server using anonymous authentication.
- Considerations When Using Directory Servers
- Limitations of Directory Naming Support with Microsoft Active Directory

3.2.1 Understanding the Directory Information Tree

Directory servers store information in a hierarchical namespace structure called a directory information tree (DIT). Each node in the tree is called an entry. Oracle Net Services uses both the tree structure and specific entries in the tree. DITs are commonly aligned with an existing domain structure such as a Domain Name System (DNS) structure or a geographic and organization structure.

The following figure shows a DIT structured according to DNS domain components.

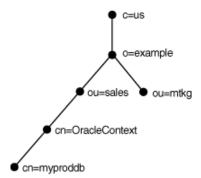

dc=com
dc=example
dc=us
dc=jp
cn=OracleContext

Figure 3-2 DNS Domain Component DIT

The following figure shows a DIT structured according to country, organization, and organizational units. This structure is commonly referred to as an X.500 DIT.

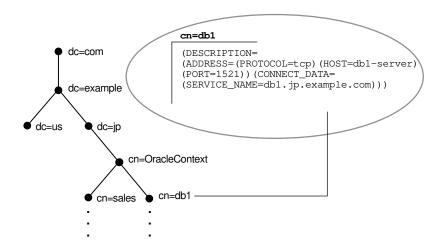

Figure 3-3 X.500 DIT

For example, consider Figure 3-4. The <code>cn=sales</code> and <code>cn=db1</code> entries represent a network service name and a database service, respectively. Additional entries under <code>cn=sales</code> and <code>cn=db1</code> contain the connect descriptor information. These entries are not represented in the graphic. The <code>cn=sales</code> and <code>cn=db1</code> entries enable clients to connect to the database using connect strings <code>CONNECT username@sales</code> and <code>CONNECT username@db1</code>.

Figure 3-4 Database Service and Net Service Entries in a DIT

Each entry is uniquely identified by a distinguished name (DN). The DN indicates exactly where the entry resides in the directory server hierarchy. The DN for db1 is dn:cn=db1,cn=OracleContext,dc=jp,dc=example,dc=com. The DN for sales is dn:cn=sales,cn=OracleContext,dc=jp,dc=example,dc=com. The format of a DN places the lowest component of the DIT to the left, then moves progressively up the DIT.

Each DN is made up of a sequence of relative distinguished names (RDNs). The RDN consists of an attribute, such as cn, and a value, such as db1 or sales. The RDN for db1 is cn=db1, and the RDN for sales is cn=sales. The attribute and its value uniquely identify the entry.

- Fully-Qualified Names for Domain Component Namespaces
- Fully-Qualified Names for X.500 Namespaces
- Using the Relative Name of an Entry
 If a client is configured with a default realm Oracle Context, then an entry can be identified
 by its relative name, and the service can be referred to by its common name. A relative

name can be used if the entry is in the same Oracle Context that is configured to be the default Oracle Context for the client's Oracle home.

Using the Fully-Qualified Name of an Entry

3.2.1.1 Fully-Qualified Names for Domain Component Namespaces

For domain component namespaces, the default directory entry defined for the client must be in one of the following formats:

```
dc[,dc][...]
ou,dc[,dc][...]
```

In the preceding syntax, [dc] represents an optional domain component, [...] represents additional domain component entries and ou represents the organizational unit entry.

The fully-qualified name used in the connect identifier by the client must be in one of the following formats:

```
cn.dc[.dc][...]
cn[.ou]@dc[.dc][...]
```

In the preceding syntax, [cn] represents the Oracle Net entry.

Example 3-1 Using a Fully-Qualified Name with an Organizational Unit

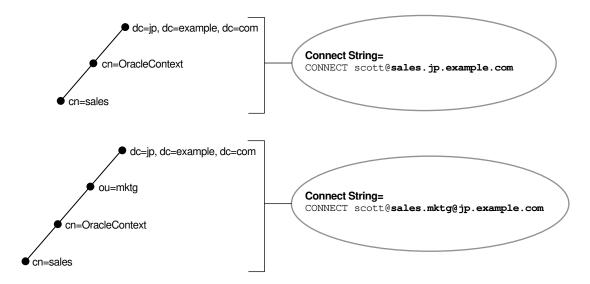

Consider a directory server that contains an entry for database object sales with a DN of cn=sales, cn=OracleContext, dc=jp, dc=example, dc=com. In this example, the client requires a connect identifier of sales.jp.example.com.

Consider a similar entry that contains database object sales with a DN of cn=sales, cn=OracleContext, ou=mktg, dc=jp, dc=example, dc=com.

Because domain components must be separated from organization units, the client must use the format cn.ou@dc.dc.dc. The client requires the connect identifier to be sales.mktq@jp.example.com.

Figure 3-5 illustrates the preceding example.

Figure 3-5 Fully-Qualified Name for Domain Component Namespaces

3.2.1.2 Fully-Qualified Names for X.500 Namespaces

For X.500 namespaces, the default directory entry defined for the client must be in one of the following formats:

```
[ou],o
[ou],o,c
```

In the preceding formats, [ou] represents an optional organizational unit name, o represents the organization, and c represents the country.

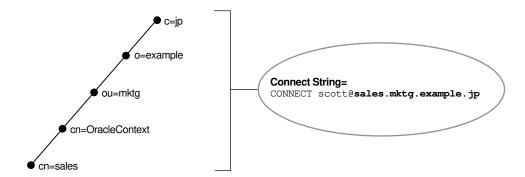

The fully-qualified name the client uses as the connect identifier must be in one of the following formats:

```
cn[.ou].o
cn[.ou].o.c
```

In the preceding formats, on represents the Oracle Net entry.

For example, if the directory contains database object sales with a DN of cn=sales, cn=OracleContext, ou=mktg, o=example, c=jp, then the client requires a connect identifier of sales.mktg.example.jp. Figure 3-6 illustrates this example.

Figure 3-6 Fully-Qualified Name for X.500 Namespaces

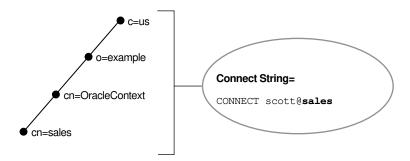

3.2.1.3 Using the Relative Name of an Entry

If a client is configured with a default realm Oracle Context, then an entry can be identified by its relative name, and the service can be referred to by its common name. A relative name can be used if the entry is in the same Oracle Context that is configured to be the default Oracle Context for the client's Oracle home.

Consider a directory server that contains an entry for a database called sales with a DN of dn:cn=sales,cn=OracleContext,o=example,c=us, as shown in Figure 3-7. If the client is configured with a default realm Oracle Context of cn=OracleContext,o=example,c=us, then the connect identifier can be sales.

Figure 3-7 Relative Naming

The JDBC OCI Driver supports both full-qualified and relative naming. The JDBC Thin Driver supports fully-qualified naming only when the complete DN is used.

Related Topics

Oracle Database JDBC Developer's Guide

3.2.1.4 Using the Fully-Qualified Name of an Entry

Consider the same directory structure as shown in Figure 3-7, but with the client's Oracle home configured with a default realm Oracle Context of cn=OracleContext, o=example, c=jp.

Because the client is configured with a default Oracle Context that does not match the location of sales in the directory server, a connect string that uses sales does not work. Instead, the client must specifically identify the location of sales, which can be done using one of the following ways:

The entry's complete DN can be used in the connect string, for example:

```
CONNECT username@"cn=sales,cn=OracleContext,o=example,c=us" Enter password: password
```

JDBC Thin drivers support fully-qualified naming only when the complete DN is used. However, many applications do not support the use of a DN.

 The entry can be referred to by a fully-qualified DNS-style name which is mapped by the Directory Naming adapter to the full x.500 DN of the database object in the LDAP directory, for example:

CONNECT username@sales.example.us Enter password: password

Note:

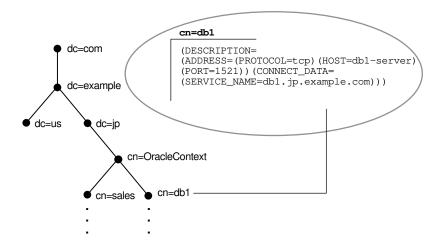

JDBC OCI Drivers support fully-qualified naming. JDBC Thin Drivers support fully-qualified naming only when the complete DN is used. See the *Oracle Database JDBC Developer's Guide* for additional information.

3.2.2 Understanding Oracle Context

The entries under Oracle Context support various directory-enabled features, including directory naming.

In Figure 3-8, the entries db1 and sales reside under cn=OracleContext. This entry is a special RDN called an Oracle Context.

Figure 3-8 Oracle Context in the DIT

During directory configuration, you set the default Oracle Context. Clients use this Oracle Context as the default location to look up connect identifiers in the directory server. With Oracle Internet Directory, an Oracle Context located at the root of the DIT, with DN of dn:cn=OracleContext, points to a default Oracle Context in an identity management realm. An identity management realm is a collection of identities governed by the same administrative policies. This Oracle Context is referred to as a realm Oracle Context. Unless configured to use another Oracle Context, clients use this realm-specific Oracle Context.

The default Oracle Context affects the connect string. For example, if a client must access the db1 and sales entry frequently, then a reasonable default Oracle Context would be dc=jp, dc=example, dc=com. If a client directory entry does not match the directory entry where a service is located, then the client must specify the fully-qualified name of an entry in the connect string, as described in "Client Connections Using Directory Naming".

The RDN cn=OracleContext does not have to be explicitly specified in the connect string.

Oracle Fusion Middleware Administering Oracle Internet Directory

3.2.3 Understanding Net Service Alias Entries

Directory naming enables you to create network service alias entries in addition to database service and network service name entries. A network service alias is an alternative name for a network service name or database service. A network service alias entry does not have connect descriptor information. Instead, it references the location of the entry for which it is an alias. When a client requests a directory lookup of a network service alias, the directory determines that the entry is a network service alias and completes the lookup as if it is the referenced entry. For example, in the following figure, a network service alias of db1alias is created for a database service of db1. When db1alias is used to connect to a database service, as in CONNECT username@db1alias, it will actually resolve to and use the connect descriptor information for db1.

dc=com

dc=example

dc=jp

cn=OracleContext

(Net Service Alias Entry)

Figure 3-9 Net Service Alias db1alias in a Directory Server

There are several uses for network service aliases. As shown in Figure 3-9, a network service alias can be useful as a way for clients to refer to a network service name by another name. Another use is to have a network service alias in one Oracle Context for a database service or network service name in a different Oracle Context. This enables a database service or network service name to be defined once in the directory server, but referred to by clients that use other Oracle Contexts.

In Figure 3-10, database service db1 resides in dc=jp, dc=example, dc=com. A network service alias named db1 is created in dc=us, dc=example, dc=com. This enables clients in both Japan and the United States to use the connect string CONNECT username@db1 as opposed to clients in the Unites States needing to specify CONNECT username@db1.jp.example.com.

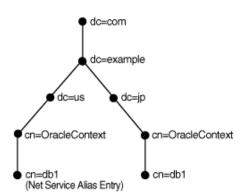

Figure 3-10 Net Service Alias db1 in a Directory Server

3.2.4 Who Can Add or Modify Entries in the Directory Server

The database service entries are configured during or after installation. You can then use Oracle Enterprise Manager Cloud Control or Oracle Net Manager to modify the Oracle Net attributes of the database service entries. You can also use these tools to create network service name and network service alias entries.

To use these configuration tools, a DIT structure containing a root Oracle Context, and identity management realm must exist. The directory administrator creates this structure with Oracle Internet Directory Configuration Assistant. For some deployments, the directory administrator may need to create additional Oracle Contexts. Additional Oracle Contexts are usually used to subdivide large sites, or separate a production environment from a test environment.

Certain tools are used by certain groups, and you must be a member of the group to use the tools, as described in the following:

- To create a database service entry with Database Configuration Assistant:
 - OracleDBCreators group (cn=OracleDBCreators, cn=OracleContext...)
 - OracleContextAdmins group
 (cn=OracleContextAdmins, cn=Groups, cn=OracleContext...)
- To create network service names or network service aliases with Oracle Net Manager:
 - OracleNetAdmins group (cn=OracleNetAdmins, cn=OracleContext...)
 - OracleContextAdmins group

The <code>OracleNetAdmins</code> group is owned by itself. Members of the <code>OracleNetAdmins</code> group have create, modify, and read access to Oracle Net objects and attributes. They can also add or delete members in the group, and add or delete groups to be owners of the <code>OracleNetAdmins</code> group.

Any member of the <code>OracleNetAdmins</code> group can add or delete other members from the <code>OracleNetAdmins</code> group. If you prefer another group to add or delete <code>OracleNetAdmins</code> members, then you can change the owner attribute of the <code>OracleNetAdmins</code> group to another group. The owner cannot be an individual user entry but must be a group entry, and the group entry is one comprised of the <code>LDAP</code> schema object classes <code>GroupOfUniqueNames</code> and <code>orclPriviledgeGroup</code>.

The OracleContextAdmins group is a super-user group for Oracle Context. Members of the OracleContextAdmins group can add all supported types of entries to Oracle Context.

The directory user that created Oracle Context is automatically added to these groups. Other users can be added to these groups by the directory administrator.

See Also:

- "Configuring the Directory Naming Method" for additional information about using Oracle Net Manager
- Oracle Database Administrator's Guide for additional information about registering a database service with Database Configuration Assistant

3.2.5 Client Connections Using Directory Naming

Most clients needing to perform name lookups in the directory server access the directory server using anonymous authentication.

To perform a lookup, the directory server must allow anonymous authentication. Directory servers usually allow anonymous authentication by default, however, some directory servers, such as earlier releases of Oracle Internet Directory, require directory configuration to allow anonymous access.

To look up entries, a client must be able to find the directory server in which that entry resides. Clients locate a directory server in one of two ways:

- Dynamically using DNS. In this case, the directory server location information is stored and managed in a central domain name server. The client, at request processing time, retrieves this information from DNS.
- Statically in the directory server usage file, ldap.ora, created by Oracle Internet Directory Configuration Assistant and stored on the client host.

After a directory is found, clients are directed to the realm Oracle Context from the root Oracle Context.

Clients make connections to a database using connect identifiers in the same way they might use other naming methods. A connect identifier can be a database service, network service name, or network service alias. These can be referred to by their common names (relative name) if the default Oracle Context is where the entity resides. If not, then the connect identifier needs a fully-qualified name or distinguished name.

3.2.6 Considerations When Using Directory Servers

The following considerations should be reviewed when using directory servers:

- Performance Considerations
- Security Considerations
- Object Classes

3.2.6.1 Performance Considerations

Connect identifiers are stored in a directory server for all clients to access. Depending on the number of clients, there can be a significant load on a directory server.

During a connect identifier lookup, a name is searched under a specific Oracle Context. Users expect relatively quick performance so the database connect time is not affected. Because of the scope of the lookup, users may begin to notice slow connect times if lookups take more than one second.

You can resolve performance problems by changing the network topology or implementing replication.

Directory server vendor documentation for details on resolving performance issues

3.2.6.2 Security Considerations

Administrative clients can create and modify entries in the directory server, so security is essential. This section contains the following security-related topics:

Authentication Methods

Clients use different methods of authentication depending upon the task to be performed, such as resolving connect string names and managing directory entries.

Access Control Lists

Authentication is used with access control lists (ACLs) to determine whether clients can read, modify, or add information in the directory server.

3.2.6.2.1 Authentication Methods

Clients use different methods of authentication depending upon the task to be performed, such as resolving connect string names and managing directory entries.

 Clients that perform lookups for information in the directory server typically use anonymous authentication.

You can configure the client LDAP naming adapter to authenticate the LDAP bind during name lookup. Sites that need to protect their network service data or disable anonymous binds to the directory must configure their clients to use wallets for authentication during name lookup.

This configuration involves mapping the DN in the client certificate to the user's DN in the directory server. You must set the following parameters in the sqlnet.ora file for these clients:

- NAMES.LDAP_AUTHENTICATE_BIND=TRUE
- WALLET LOCATION=location value

The Oracle wallet trust store must contain root certificates issued by the certificate authority of the LDAP server.

Starting with Oracle Database 21c, you can configure the client LDAP naming adapter to authenticate the LDAPS bind using simple authentication. This method uses LDAP over TLS connection (LDAPS) by accessing the user name and password stored in the wallet.

The parameter WALLET_LOCATION is deprecated for use with Oracle Database 23ai for the Oracle Database server. It is not deprecated for use with the Oracle Database client or listener.

For Oracle Database server, Oracle recommends that you use the WALLET_ROOT system parameter instead of using WALLET LOCATION.

- Clients that administer the directory server entries authenticate with the directory server.
 Database Configuration Assistant or Oracle Net Manager can be used to add or modify the entries. Only authenticated users with proper privileges can modify entries. Use one of the following authentication methods:
 - Simple Authentication

The client identifies itself to the directory server using a DN and password. The server verifies that the DN and password sent by the client matches the DN and password stored in the directory server.

Strong Authentication

The client identifies itself to the directory server using a public-key encryption available with Transport Layer Security (TLS). In public-key encryption, the sender of a message

encrypts the message with the public key of the recipient. Upon delivery, the recipient decrypts the message using the recipient's private key.

If you have configured the directory server with mutual TLS authentication and have mapped the DN in the client certificate to the directory user entry, then the directory server uses the client certificate for authentication.

Related Topics

About TCP/IP with TLS Protocol

The TCP/IP with Transport Layer Security (TLS) protocol enables an Oracle application on a client to communicate with remote databases through TCP/IP and TLS.

- Configure the LDAP Naming Adapter to Use Wallets
 The client LDAP naming adapter authenticates the LDAP bind while connecting to the LDAP directory to resolve connect string names. You can configure the adapter to use an Oracle wallet during the authentication.
- Oracle Database Security Guide

3.2.6.2.2 Access Control Lists

Authentication is used with access control lists (ACLs) to determine whether clients can read, modify, or add information in the directory server.

ACLs specify the following:

- The entries that the user can access.
- The authentication method used to access the entry.
- The access rights, or what the user can do with the object, such as read or write.

ACLs are established for a group of users. During Oracle Context creation, the OracleDBCreators, OracleNetAdmins, and OracleContextAdmins groups are created.

The user who creates Oracle Context using Oracle Net Configuration Assistant is automatically added as the first member of these groups.

Enterprise User Security (EUS) is deprecated with Oracle Database 23ai. Oracle recommends that you migrate to using Centrally Managed Users (CMU). This feature enables you to directly connect with Microsoft Active Directory without an intervening directory service for enterprise user authentication and authorization to the database. If your Oracle Database is in the cloud, you can also choose to move to one of the newer integrations with a cloud identity provider.

Table 3-2 describes ACL requirements for these groups, anonymous users, and their relation to Oracle Net entries in the directory server.

Table 3-2 ACL Requirements for User Groups

Group	ACL Requirements
Anonymous users	All Oracle Net attributes and objects in the directory server have read access for the anonymous user. Read access of these objects for anonymous is also applied to Oracle Context. This enables anonymous users to browse directory naming entries contained within the cn=OracleContext RDN.
	Oracle Net Configuration Assistant sets up this access during client installation.
OracleContextAdmins group users	Members of OracleContextAdmins (cn=OracleContextAdmins, cn=Groups, cn=OracleContext,) have create, modify, and read access to all directory naming objects. Oracle Net Configuration Assistant establishes these access rights for this group during Oracle Context creation.
	In addition to the Oracle Context creator, other users can be added to this group by the directory administrator using Oracle Enterprise Manager Cloud Control.
OracleDBCreators group users	Members of OracleDBCreators (cn=OracleDBCreators, cn=OracleContext,) have create and read access to database service objects and attributes. Oracle Net Configuration Assistant establishes the access rights for this group during Oracle Context creation.
	In addition to the Oracle Context creator, other users can be added to this group by the directory administrator with Oracle Enterprise Manager Cloud Control.
OracleNetAdmins group users	Members of OracleNetAdmins (cn=OracleNetAdmins, cn=OracleContext,) have create, modify, and read access to directory naming objects and attributes. Oracle Net Configuration Assistant establishes these access rights for this group during Oracle Context creation.
	In addition to the Oracle Context creator, other users can be added to this group by the directory administrator.

Situations in which a high degree of security is desired for lookup or read-access to Oracle Net Services name and related data, administrators can define additional read-access control for some or all of the data. Such ACL definitions can prevent anonymous users from reading the Oracle Net Services data. If read-access to Oracle Net Services data is restricted, then clients must use authenticated binds to do name lookups.

There are no predefined groups or procedures for the Oracle configuration tools for defining read-access restrictions on this data, so administrators must use standard object management tools from their directory system to manually create any necessary groups and ACLs.

ACLs can be added to Oracle Net Services objects using ldapmodify and an LDIF-format file. Example 3-2 shows how to restrict all access for user, cn=user1:

Example 3-2 Restricting User Access with an Access Control List

```
dn: cn=sales,cn=oraclecontext,dc=example,dc=com
replace: orclentrylevelaci
orclentrylevelaci: access to attr=(*)
by dn="cn=user1" (noread,nosearch,nowrite,nocompare)
```

The preceding example illustrates the basic form of an ACL for a single object. This approach is not necessarily the best way to define access because access definitions for objects are

complex and may involve security properties which are inherited from parent nodes in the DIT. Oracle recommends that administrators refer to the documentation for their directory systems, and integrate access management for Oracle Net Services objects into a directory-wide policy and security implementation.

For Oracle Internet Directory directories, oidadmin has functionality to create users, groups, and also define ACLs for objects and general directory security.

For more information on how to set ACLs on directory entry, see documentation from your directory server vendor.

Related Topics

Authentication Methods

Clients use different methods of authentication depending upon the task to be performed, such as resolving connect string names and managing directory entries.

About the OracleNetAdmins Group

To use Oracle Net Manager, you must be a member of the OracleNetAdmins group or the OracleContextAdmins group.

3.2.6.3 Object Classes

Directories must be populated with the correct version of the Oracle schema before Oracle Context, a database service or network service name entry can be created. The Oracle schema defines the type of objects, called object classes, that can be stored in the directory server and their attributes. The following table lists the object classes for database service, network service name, and network service alias entries.

Table 3-3 Oracle Net Services LDAP Main Object Classes

Object Class	Description
orclDbServer	Defines the attributes for database service entries.
orclNetService	Defines the attributes for network service name entries.
orclNetServiceAlias	Defines the attributes for network service alias entries.

The following table lists the object classes used by orclDbServer, orclNetService, and orclNetServiceAlias.

Table 3-4 Oracle Net Services LDAP Derived Object Classes

Object Class	Description
orclNetAddress	Defines a listener protocol address.
orclNetAddressList	Defines a list of addresses.
orclNetDescription	Specifies a connect descriptor containing the protocol address of the database and the connect information to the service.
orclNetDescriptionList	Defines a list of connect descriptors.

These object classes use attributes that specify the contents of connect descriptors.

See Also:

Oracle Database Net Services Reference for additional information about these object classes and their attributes

3.2.7 Limitations of Directory Naming Support with Microsoft Active Directory

In addition to Oracle Internet Directory, directory naming support is also provided with Microsoft Active Directory with the following limitations:

- Oracle provides support for Microsoft Active Directory only on Microsoft Windows operating systems. Therefore, client computers and the database server must run on Microsoft Windows operating systems to access or create entries in Microsoft Active Directory.
- The following features are not supported by Microsoft Active Directory:
 - Multiple Oracle Contexts
 - Microsoft Active Directory can support only one Oracle Context.
 - Net service aliases

You cannot create network service aliases in Microsoft Active Directory. However, you can create network service names.

Understanding the Communication Layers

The primary function of Oracle Net is to establish and maintain connections between a client application and an Oracle database server.

Oracle Net is comprised of several communication layers that enable clients and database servers to share, modify, and manipulate data.

- Understanding Oracle Net Stack Communication for Client/Server Applications
 A database server is the Oracle software managing a database, and a client is an
 application that requests information from the server. The way the client and server
 communicate is known as the client/server stack.
- Using Oracle Net Stack Communication for Java Applications
 The Oracle Java Database Connectivity (JDBC) Drivers provide Java applications access
 to an Oracle database. Oracle offers two JDBC drivers.
- Using Oracle Net Stack Communication for Web Clients
- Understanding Oracle Protocol Support Layer
 A network protocol is responsible for transporting data from the client computer to the database server computer. This section describes the protocols used by the Oracle Protocol Support layer of the Oracle Net communication stack.

Introducing Oracle Net Services
 Understand the basic elements of Oracle Net Services architecture and the Oracle Net foundation layer.

4.1 Understanding Oracle Net Stack Communication for Client/ Server Applications

A database server is the Oracle software managing a database, and a client is an application that requests information from the server. The way the client and server communicate is known as the client/server stack.

Information passed from a client application sent by the client communication stack across a network protocol is received by a similar communication stack on the database server side. The process flow on the database server side is the reverse of the process flow on the client side, with information ascending through the communication layers.

The following diagram illustrates the various layers on the client and on the database server after a connection has been established.

Client Database Server Client RDBMS Application (uses OPI) (uses OCI) Presentation -Presentation -TTC TTC Naming Methods Oracle Net Oracle Net Foundation Foundation Layer Oracle Layer Oracle Security Services Net Oracle Protocol Net Oracle Protocol Support Support Transport Protocol TCP/IP, TCP/IP with TLS, SDP Transport Protocol TCP/IP, TCP/IP with TLS, SDP and Named and Named Pipes Pipes

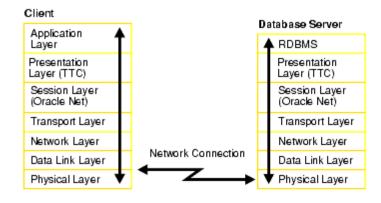

Figure 4-1 Layers Used in a Client/Server Application Connection

This communication architecture is based on the Open Systems Interconnection (OSI) model. In the OSI model, communication between separate computers occurs in a stack-like fashion with information passing from one node to the other through several layers of code, including:

- Physical layer
- 2. Data link layer
- 3. Network layer
- 4. Transport layer
- Session layer
- Presentation layer
- Application layer

The following diagram shows how Oracle Net software consisting of the Oracle Net foundation layer and Oracle Protocol Support fits into the session layer of the OSI model.

Figure 4-2 OSI Communication Layers

This section contains the following topics:

- About the Client Communication Stack
- About the Server Communication Stack

4.1.1 About the Client Communication Stack

The client communication stack includes the following:

- Client Application Layer
- Presentation Layer
- Oracle Net Foundation Layer
- Oracle Protocol Support Layer

4.1.1.1 Client Application Layer

During a session with the database, the client uses Oracle Call Interface (OCI) to interact with the database server. OCI is a software component that provides an interface between the application and SQL.

See Also:

Oracle Call Interface Programmer's Guide

4.1.1.2 Presentation Layer

Character set differences can occur if the client and database server run on different operating systems. The presentation layer resolves any differences. It is optimized for each connection to perform conversion when required.

The presentation layer used by client/server applications is Two-Task Common (TTC). TTC provides character set and data type conversion between different character sets or formats on the client and database server. At the time of initial connection, TTC is responsible for evaluating differences in internal data and character set representations and determining whether conversions are required for the two computers to communicate.

4.1.1.3 Oracle Net Foundation Layer

The Oracle Net foundation layer is responsible for establishing and maintaining the connection between the client application and database server, as well as exchanging messages between them. The Oracle Net foundation layer can perform these tasks because of Transparent Network Substrate (TNS) technology. TNS provides a single, common interface for all industry-standard OSI transport and network layer protocols. TNS enables peer-to-peer application connectivity, where two or more computers can communicate with each other directly, without the need for any intermediary devices.

On the client side, the Oracle Net foundation layer receives client application requests and resolves all generic computer-level connectivity issues, such as:

- The location of the database server or destination
- How many protocols are involved in the connection

 How to handle interrupts between client and database server based on the capabilities of each

On the server side, the Oracle Net foundation layer performs the same tasks as it does on the client side. It also works with the listener to receive incoming connection requests.

In addition to establishing and maintaining connections, the Oracle Net foundation layer communicates with naming methods to resolve names and uses security services to ensure secure connections.

4.1.1.4 Oracle Protocol Support Layer

Oracle protocol support layer is positioned at the lowest layer of the Oracle Net foundation layer. It is responsible for mapping TNS functionality to industry-standard protocols used in the client/server connection. This layer supports the following network protocols:

- TCP/IP (IPv4 and IPv6)
- TCP/IP with Transport Layer Security (TLS)
- Named Pipes
- Sockets Direct Protocol (SDP)
- Exadirect

All Oracle software in the client/server connection process requires an existing network protocol stack to establish the computer-level connection between the two computers for the transport layer. The network protocol is responsible for transporting data from the client computer to the database server computer, at which point the data is passed to the server-side Oracle protocol support layer.

Related Topics

Understanding Oracle Protocol Support Layer
 A network protocol is responsible for transporting data from the client computer to the database server computer. This section describes the protocols used by the Oracle Protocol Support layer of the Oracle Net communication stack.

4.1.2 About the Server Communication Stack

The server communication stack uses the same layers as the client stack with the exception that the database uses Oracle Program Interface (OPI). For each statement sent from OCI, OPI provides a response. For example, an OCI request to fetch 25 rows would elicit an OPI response to return the 25 rows after they have been fetched.

4.2 Using Oracle Net Stack Communication for Java Applications

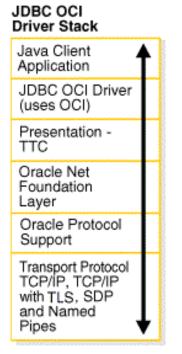

The Oracle Java Database Connectivity (JDBC) Drivers provide Java applications access to an Oracle database. Oracle offers two JDBC drivers.

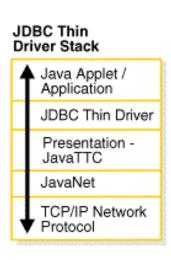

- JDBC OCI Driver is a type 2 JDBC driver which is used by client/server Java applications.
 The JDBC OCI driver uses a communication stack similar to a standard client/server
 communication stack. The JDBC OCI driver converts JDBC invocations to calls to OCI
 which are then sent over Oracle Net to the Oracle database server.
- JDBC Thin Driver is a type 4 driver which is used by Java applets. The JDBC Thin Driver
 establishes a direct connection to the Oracle database server over Java sockets. The
 JDBC Thin driver uses a Java implementation of the Oracle Net foundation layer called
 JavaNet and a Java implementation of TTC called JavaTTC to access the database.

The following figure shows the stack communication layers used by JDBC drivers.

Figure 4-3 Layers Used for Java-Client Applications

4.3 Using Oracle Net Stack Communication for Web Clients

The Oracle database server supports many other implementations for the presentation layer that can be used for web clients accessing features inside the database in addition to TTC. The listener facilitates this by supporting any presentation implementation requested by the database.

Figure 4-4 shows the stack communication layers used in an HTTP or FTP connection to Oracle XML DB in the Oracle database instance. WebDAV connections use the same stack communication layers as HTTP and FTP.

Figure 4-4 Layers Used in Web Client Connections

Oracle XML DB Developer's Guide

4.4 Understanding Oracle Protocol Support Layer

A network protocol is responsible for transporting data from the client computer to the database server computer. This section describes the protocols used by the Oracle Protocol Support layer of the Oracle Net communication stack.

About TCP/IP Protocol

TCP/IP (Transmission Control Protocol/Internet Protocol) is the standard communication protocol suite used for client/server communication over a network.

About TCP/IP with TLS Protocol

The TCP/IP with Transport Layer Security (TLS) protocol enables an Oracle application on a client to communicate with remote databases through TCP/IP and TLS.

About Named Pipes Protocol

The Named Pipes protocol is a high-level interface providing interprocess communications between clients and database servers using distributed applications.

About Sockets Direct Protocol (SDP)

The Sockets Direct Protocol (SDP) is an industry-standard wire protocol between InfiniBand network peers. When used over an InfiniBand network, SDP reduces TCP/IP overhead by eliminating intermediate replication of data and transferring most of the messaging burden away from the CPU and onto the network hardware.

About Exadirect Protocol

The Exadirect protocol is an innovative protocol for low overhead database access. Use the new transport to improve latency and throughput by leveraging Remote Direct Memory Access (RDMA) in an InfiniBand environment.

About Websocket Protocol

The Database client connection supports secure websocket protocol. The secure web socket connection establishment is designed to work over HTTPS, to support HTTPS proxies and intermediary proxies.

4.4.1 About TCP/IP Protocol

TCP/IP (Transmission Control Protocol/Internet Protocol) is the standard communication protocol suite used for client/server communication over a network.

TCP is the transport protocol that manages the exchange of data between hosts. IP is a network layer protocol for packet-switched networks.

Oracle Net supports IP in two versions: IP version 4 (IPv4) and IP version 6 (IPv6). IPv6 addresses the shortcomings of the currently used IPv4. The primary benefit of IPv6 is a large address space derived from the use of 128-bit addresses.

- IPv6 Address Notation
- IPv6 Interface and Address Configurations
- IPv6 Network Connectivity

IPv6 Support in Oracle Database

http://tools.ietf.org/html/rfc2460 for the IPv6 specification

4.4.1.1 IPv6 Address Notation

Oracle Database supports the standard IPv6 address notations specified by RFC 2732. A 128-bit IP address is generally represented as 8 groups of 4 hexadecimal digits, with the colon (:) symbol as the group separator. For example, the following address is in a valid IPv6 format:

```
2001:0db8:0000:0000:0000:0000:200C:417A
```

Each hexadecimal digit in the address represents 4 bits, so each group in the address represents 16 bits. The following addresses represent the first and last hosts in the 2001:0db8:0000:0000 subnet:

```
2001:0db8:0000:0000:0000:0000:0000
2001:0db8:0000:0000:FFFF:FFFF:FFFFF:FFFF
```

In shorthand notation, consecutive zero fields can be compressed with a double colon (::) separator, as shown in the following equivalent notations:

```
2001:0db8:0:0::200C:417A
2001:0db8::200C:417A
2001:DB8::200C:417A
```

- CIDR Notation
- IPv6 Addresses in URLs
- IPv4-Mapped Addresses

See Also:

- http://www.ietf.org/rfc/rfc2732.txt for RFC 2732, and information about notational representation
- http://www.ietf.org/rfc/rfc3513.txt for RFC 3513, and information about proper IPv6 addressing

4.4.1.1.1 CIDR Notation

Classless Inter-Domain Routing (CIDR) is a method of grouping IP addresses into subnets that are independent of the value of the addresses. Classless routing was designed to overcome the exhaustion of address space in the IP class system and the unmanageable growth in the size of routing tables.

CIDR denotes a network by the first address in the network and the size in bits of the network prefix in decimal, separated with a slash (/). For example, 2001:0db8::/32 indicates that the

first 32 bits of the address identify the network, whereas the remaining bits identify the hosts in the network.

CIDR uses an analogous notation for IPv4 address. For example, in the notation 192.0.2.0/24 the first 24 bits of the address represent the network prefix. The <code>DBMS_NETWORK_ACL_ADMIN</code> package, which provides an API to manage access control lists, supports CIDR notation for both IPv6 and IPv4 addresses and subnets.

See Also:

- Oracle Database PL/SQL Packages and Types Reference to learn about DBMS NETWORK ACL ADMIN
- http://tools.ietf.org/html/rfc4632 for RFC 4632

4.4.1.1.2 IPv6 Addresses in URLs

In URLs, IPv6 addresses are enclosed by the left bracket ([) and right bracket (]) characters. For example, the IPv6 address [2001:0db8:0:0:8:800:200C:417A] forms part of the following URLs:

```
http://[2001:0db8:0:0:8:800:200C:417A]
http://[2001:0db8:0:0:8:800:200C:417A]:80/index.html
```

4.4.1.1.3 IPv4-Mapped Addresses

IPv4-mapped addresses are a subclass of IPv6 addresses in which the following conditions are true:

- The first 80 bits are set to 0 in the standard IPv6 notation
- The second 16 bits are set to 1 in the standard IPv6 notation
- The last 32 bits are in IPv4 notation

An IPv4-mapped address can represent the addresses of IPv4-only nodes as IPv6 addresses.

Example 4-1 shows the same IP address in different notations. The first address uses standard IPv6 notation. The second address is an IPv4-mapped address in which the last 32 bits use dotted-decimal IPv4 notation. The last address uses a shorthand notation to compress the consecutive zero fields.

Example 4-1 IPv4-Mapped Address

```
0000:0000:0000:0000:0000:FFFF:COA8:0226
0000:0000:0000:0000:0000:FFFF:192.0.2.38
::FFFF:192.0.2.38
```

See Also:

http://tools.ietf.org/html/rfc4942 for security consideration relating to the use of IPv4-mapped addresses

4.4.1.2 IPv6 Interface and Address Configurations

A host may have different IPv4 and IPv6 interface configurations. The following configurations are possible for a host:

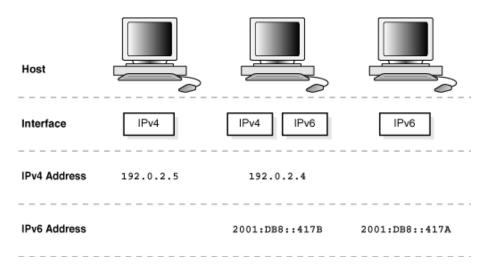

- Only an IPv4 interface, in which case the host is an IPv4-only host.
- Only an IPv6 interface, in which case the host is an IPv6-only host.
- Both an IPv4 and IPv6 interface, in which case the host is a dual-stack host.

A single host may also use different types of IP address. For example, a domain name server may associate a dual-stack host both by an IPv4 and an IPv6 address or only an IPv6 address. The IP address configurations that are not supported are the following:

- An IPv4-only host cannot use an IPv6 address.
- An IPv6-only host cannot use an IPv4 address.

Figure 4-5 shows possible host and interface configurations. The dual-stack host in the center of the diagram can communicate with IPv4 hosts over IPv4 and with IPv6 hosts over IPv6.

Figure 4-5 Supported Host and Interface Configurations

4.4.1.3 IPv6 Network Connectivity

The network connectivity of a host refers to its ability to communicate with another host over a network. For example, if a dual-stack client must communicate with an IPv6-only server, then the network and router must make end-to-end communication between these hosts possible.

A client or server host is IPv6-capable if it meets the following criteria:

- It has a configured IPv6 interface.
- It can connect to other hosts using the IPv6 protocol.

The IPv6 capability of a host is partially dependent on the network and partially dependent on its interface and address configuration. Figure 4-6 shows the possibilities for connectivity in a client/server network. For example, an IPv4-only host can connect to either an IPv4-only or dual-stack server, but not an IPv6-only server. Both dedicated and shared server modes are supported.

Figure 4-6 Client/Server Connectivity

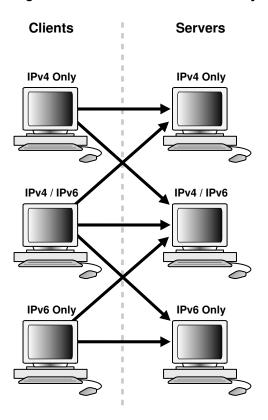

Table 4-1 summarizes the IP protocols used for client/server connectivity with different host and network configurations.

Table 4-1 Supported Host and Network Configurations

Client	IPv4-Only Server	Dual-Stack Server	IPv6-Only Server
IPv4-Only Client	Supported (v4)	Supported (v4)	Not Supported
Dual-Stack Client	Supported (v4)	Supported (v4, v6)	Supported (v6)
IPv6-Only Client	Not Supported	Supported (v6)	Supported

4.4.1.4 IPv6 Support in Oracle Database

Components in this release of Oracle Database support IPv6 in the configurations described in "IPv6 Network Connectivity", with the following exception:

Oracle Clusterware for private and ASM networks

Oracle Clusterware Administration and Deployment Guide

4.4.2 About TCP/IP with TLS Protocol

The TCP/IP with Transport Layer Security (TLS) protocol enables an Oracle application on a client to communicate with remote databases through TCP/IP and TLS.

Oracle Database supports mutual TLS (mTLS) and TLS authentication.

Mutual TLS or Two-Way Authentication

Mutual TLS (mTLS) authentication uses encryption data, such as certificates and private keys in Oracle wallets on both nodes to configure an encrypted secure link between the database server and database client. When the database client initiates a connection to the database server, mTLS performs a handshake between both the server and client using certificates stored in the wallet.

During the handshake, the following processes occur:

- The client and server negotiate a cipher suite (made up of a set of authentication, encryption, and data integrity types) to apply to the messages they exchange.
- With mTLS, the client and server exchange certificates to authenticate both the parties to each other. The certificate authenticity is checked against a root of trust by both the parties.
- The client and server agree upon a symmetric encryption key used to encrypt the communication channel.

The database checks the user certificate to verify that it bears the certificate authority's (CA) signature.

TLS or One-Way Authentication

If you do not require client authentication, similar to HTTPS connections that require only the web server to have a certificate, then you can configure TLS authentication. In this case, only the server authenticates to the client by presenting its server certificate and the client verifies whether the database server certificate is valid. This allows the client and server to establish the encrypted connection before exchanging any messages.

The database client recognizes and authenticates the identity of the database server in one of the following ways:

TLS Authentication with a Client Wallet:

TLS stores authentication data, such as trusted CA certificates and private keys, in an Oracle wallet. When the database server sends its certificate to the client, the database client verifies it using the trusted root certificate stored in the wallet.

TLS Authentication without a Client Wallet:

An Oracle client wallet with the server certificate is not required if the database server certificate is signed by a trusted root certificate that is already installed in the client system's default certificate store. The default certificate store is located in /etc/pki/tls/

cert.pem on Linux or in the Microsoft Certificate Store on Windows. When the server sends its certificate to the client, the database client verifies the server certificate using common root certificates from the default certificate store.

Walletless TLS authentication simplifies the client configuration and database client-server communication process because clients can use the system default certificate store to validate the server certificates, instead of configuring their own local wallets with trusted root certificates.

Oracle Database Security Guide

4.4.3 About Named Pipes Protocol

The Named Pipes protocol is a high-level interface providing interprocess communications between clients and database servers using distributed applications.

Named Pipes is specifically designed for Microsoft Windows LAN environments. One serverside process creates a named pipe, and the client-side process opens it by name. What one side writes, the other can read.

If a remote Oracle database is running on a host system that supports network communication using Named Pipes, then Oracle Net enables applications on a client to communicate with the Oracle database using Named Pipes.

4.4.4 About Sockets Direct Protocol (SDP)

The Sockets Direct Protocol (SDP) is an industry-standard wire protocol between InfiniBand network peers. When used over an InfiniBand network, SDP reduces TCP/IP overhead by eliminating intermediate replication of data and transferring most of the messaging burden away from the CPU and onto the network hardware.

4.4.5 About Exadirect Protocol

The Exadirect protocol is an innovative protocol for low overhead database access. Use the new transport to improve latency and throughput by leveraging Remote Direct Memory Access (RDMA) in an InfiniBand environment.

Exadirect protocol uses TCP for control communication and IB RC transport for data.

The Exadirect protocol adapter is supported only on Oracle Linux in this release.

4.4.6 About Websocket Protocol

The Database client connection supports secure websocket protocol. The secure web socket connection establishment is designed to work over HTTPS, to support HTTPS proxies and intermediary proxies.

This protocol offers a native connection to the database with minimum protocol overhead. Secure websocket protocol is used to negotiate SQL*Net protocol during connection establishment between the database server and the client. The secure websocket protocol uses TLS and requires wallet for operation.

The Web server should support web socket tunneling. Web server proxy module (in case of Apache or Oracle HTTP Server (OHS), mod_proxy_wstunnel)) proxies the secure web socket database connection data between the client and the backend database server. The Database

client connects using secure websocket protocol to Web server and the Web server connects to the database using websocket protocol.

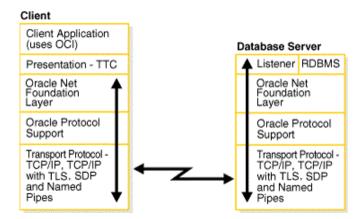

Understanding Oracle Net Architecture

The Oracle Net listener is an application positioned on top of the Oracle Net foundation layer. The database receives an initial connection from a client application through the listener.

The listener brokers client requests, handing off the requests to the Oracle database server. Every time a client requests a network session with a database, the listener receives the initial request.

The following diagram illustrates the various layers on the client and database during an initial connection. As shown in the diagram, the listener is at the top layer of the server-side network stack.

Figure 5-1 Layers Used in an Initial Connection

- About Service Registration
- About the Listener and Connection Requests
- About Oracle Restart
- About Blocked Connection Requests
- Understanding Database Server Process Architecture
- Understanding Oracle Connection Manager Architecture
- Complete Architecture
- Reverse Connection Using CMAN Tunnels
 Starting with Oracle Database 21c, you can use secure tunnels to connect to an Oracle Database instance, which is inside a network that supports only outbound connections.

5.1 About Service Registration

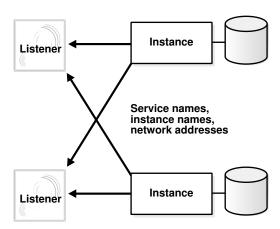

The listener determines whether a database service and its service handlers are available through service registration. During registration, the Listener Registration (LREG) process provides the listener with information about the following:

- Names of the database services provided by the database
- Name of the database instance associated with the services and its current and maximum load
- Service handlers (dispatchers and dedicated servers) available for the instance, including their type, protocol addresses, and current and maximum load

The preceding information enables the listener to direct a client request appropriately.

The following figure shows two database instances registering information with two listeners. The figure does not represent all the information that can be registered. For example, listening endpoints, such as the port numbers, can be dynamically registered with the listener.

Figure 5-2 Service Registration

If the listener is not running when an instance starts, then the LREG process cannot register the service information. LREG attempts to connect to the listener periodically, but it may take up to 60 seconds before LREG registers with the listener after it has been started. To initiate service registration immediately after the listener is started, use the SQL statement ALTER SYSTEM REGISTER. This statement is especially useful in high availability configurations.

5.2 About the Listener and Connection Requests

Each listener is configured with one or more protocol addresses that specify its listening endpoints. The protocol address defines the protocol the listener listens on and any other protocol-specific information. For example, the listener could be configured to listen at the following protocol address:

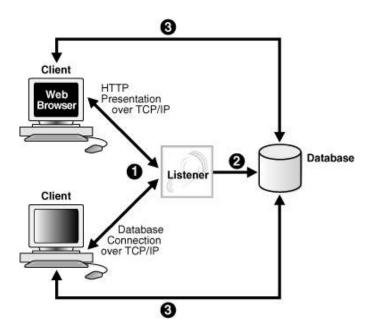

The preceding example shows a TCP/IP address that specifies the host of the listener (sales-server) and a port number (1521).

Clients configured with a protocol address can send connection requests to the listener. When a client request reaches the listener, it selects an appropriate service handler to service the request and forwards the request to the handler. A service handler is a dispatcher or a dedicated server process that acts as a connection point to a database.

The following figure illustrates the role of the listener during the establishment of a connection. The figure shows a browser making an HTTP connection and a client making a database connection.

- The browser or client send a connection request to the listener.
- The listener parses the request and forwards it to the service handler for the database service requested.
- 3. The browser or client connect to the database.

Figure 5-3 Listener Architecture

5.3 About Oracle Restart

Oracle Restart enhances the availability of Oracle databases in a single-instance environment. Using the Server Control (SRVCTL) utility, you can add components such as the listener to an Oracle Restart configuration. The configuration enables the listener to start automatically when the listener fails or is not running.

When using Oracle Restart, note the following:

- Use the SRVCTL utility to start and stop the listener. Do not use the listener control utility LSNRCTL.
- Each listener must have a unique name.

See Also:

- "Managing a Listener in an Oracle Restart Configuration"
- Oracle Database Administrator's Guide to learn how to configure Oracle Restart

5.4 About Blocked Connection Requests

Blocked connection requests can occur when an incoming request occurs before the respective instance has been registered, or when a database is in restricted mode, such as when a shutdown of the database is in progress. If a database instance is in restricted mode, then LREG instructs the listener to block all connections to the instance. Clients attempting to connect receive one of the following errors:

- ORA-12526: TNS:listener: all appropriate instances are in restricted mode
- ORA-12527: TNS:listener: all appropriate instances are in restricted mode or blocking new connections
- ORA-12528: TNS:listener: all appropriate instances are blocking new connections

The ORA-12528 error occurs when a database instance is not yet registered with the listener.

See Also:

- Oracle Database Error Messages for information about these error messages
- Oracle Database SQL Reference for information about the ALTER SYSTEM REGISTER statement
- Oracle XML DB Developer's Guide for information about dynamically registering HTTP, FTP, and WebDAV listening endpoints

5.5 Understanding Database Server Process Architecture

Based on the service handler type registered with the listener, the listener forwards requests to either a shared server or dedicated server process. The shared server architecture enables a database server to allow many client processes to share server processes. In a dedicated server configuration, the listener starts a separate dedicated server process for each incoming client connection request dedicated to servicing the client.

- About Shared Server Processes
- About Dedicated Server Processes

5.5.1 About Shared Server Processes

Shared server processes are used in the shared server architecture, as shown in Figure 5-4. With shared server architectures, client processes ultimately connect to a dispatcher. The LREG process registers the location and load of the dispatchers with the listener, enabling the listener to forward requests to the least loaded dispatcher. This registration process is not shown in the figure.

A dispatcher can support multiple client connections concurrently. Each client connection is bound to a virtual circuit. A virtual circuit is a piece of shared memory used by the dispatcher for client database connection requests and replies. The dispatcher places a virtual circuit on a common request queue when a request arrives. An idle shared server picks up the virtual circuit from the request queue, services the request, and relinquishes the virtual circuit before attempting to retrieve another virtual circuit from the request queue. Shared servers place all

completed requests into a dispatcher's response queue. Each dispatcher has its own response queue in the SGA (System Global Area). This approach enables a small pool of server processes to serve a large number of clients.

Client Database Server Web Browser HTTP Connection over TCP/IP Shared Server Client Process Dispatcher Virtual Web FTP Connection Circuits over TCP/IP Shared Server Database Process Dispatcher Client **Database Connection** over TCP/IP Shared Server Process Client **Database Connection**

Figure 5-4 Shared Server Architecture

5.5.2 About Dedicated Server Processes

In a dedicated server architecture, each client process connects to a dedicated server process. The server process is not shared by any other client. Figure 5-5 illustrates a dedicated server architecture.

LREG registers information about dedicated server processes with the listener. This enables the listener to start a dedicated server process when a client request arrives and forward the request to it.

Dedicated server architectures do not support HTTP, FTP, or WebDAV clients. Only database clients are supported.

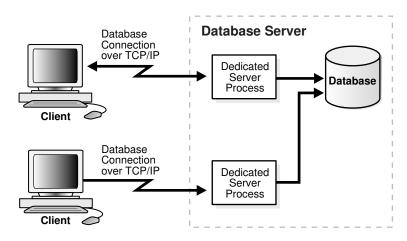

Figure 5-5 Dedicated Server Architecture

5.6 Understanding Oracle Connection Manager Architecture

Oracle Connection Manager is a gateway through which client connection requests are sent either to the next hop or directly to the database server. Clients who relay connection requests through an Oracle Connection Manager can take advantage of the session multiplexing and access control features configured on Oracle Connection Manager. It carries no service information until a LREG process registers its services.

Oracle Connection Manager consists of three components:

- listener
- CMGW (Oracle Connection Manager Gateway)
- CMADMIN (Oracle Connection Manager Administration)

The listener receives client connections and evaluates against a set of rules whether to deny or allow access. If it allows access, then the listener forwards a request to a gateway process, selecting the one with the fewest connections. The CMGW process, in turn, forwards the request to another Oracle Connection Manager or directly to the database server, relaying data until the connection terminates. If a connection to the server already exists, then the gateway multiplexes, or funnels, its connections through the existing connection. CMADMIN monitors the state of the gateway processes and the listener, shutting down or starting up processes as needed. In addition, it registers the location and load of the gateway processes with the listener, and it answers requests from the Oracle Connection Manager Control utility.

In the following figure, the listener screens connection requests. A gateway process registers with the CMADMIN process., and the CMADMIN process registers with the listener. Finally, the listener forwards the connection requests to the gateway process. After receiving the three valid client connections, the gateway process multiplexes them through a single network protocol connection to the database. The fourth connection is denied when it is evaluated against the set of rules.

Figure 5-6 Oracle Connection Manager Architecture

5.7 Complete Architecture

Oracle Net provides an architectural solution that allows for greater scalability in Internet and intranet environments.

Figure 5-7 shows how multiple connections to an Oracle database server are made more scalable with Oracle Connection Manager and a shared server architecture. Oracle Connection Manager is used to offload some of the network I/O of the application web servers, and a shared server is used to serve more concurrent users.

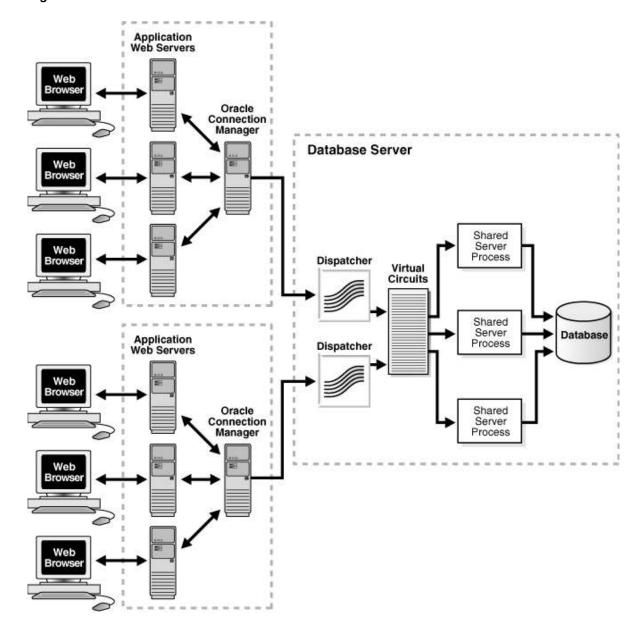

Figure 5-7 Scalable Architectural Solutions

5.8 Reverse Connection Using CMAN Tunnels

Starting with Oracle Database 21c, you can use secure tunnels to connect to an Oracle Database instance, which is inside a network that supports only outbound connections.

A network may allow only outbound connections and restrict inbound connections for security reasons. However, using the Oracle Connection Manager tunnel feature, you can connect to a database inside a network that allows only outbound connections. Oracle Connection Manager creates a pool of connections, known as tunnels, that can be used to connect to a database inside the network.

To access a database inside a network that allows only egress connections, you must deploy CMAN at both the client site that is hosting the database and the server site that wants to access the database. The data transfer happens over an encrypted channel on public internet using TLS, if TLS is configured between the two CMANs.

When client CMAN is started, the gateways connects to the server CMAN and creates a pool of connections, known as tunnels. Reverse connections from the server to the client are routed through these tunnels. You can also configure the pool size.

In the following figure, the client CMAN uses tunnel service of the server CMAN to establish a tunnel connection. Once a client CMAN establishes a tunnel, the server CMAN offers client CMAN identifier as a service for clients in site A.

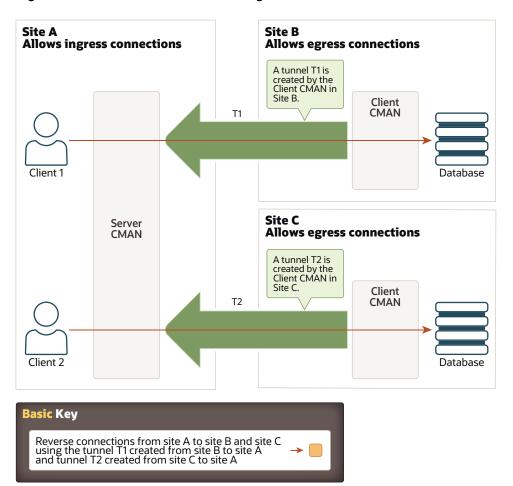

Figure 5-8 Reverse Connection Using CMAN Tunnels

Part II

Configuration and Administration of Oracle Net Services

Part II describes how to set up and configure Oracle Net Services.

This part contains the following chapters:

Quick Start to Oracle Net Services

Help novice users set up and test a simple but common network configuration, such as one between a client application and a database over a TCP/IP network.

Managing Oracle Net Services

Learn about the various administration tools of Oracle Net Services, and also explore the command-line control utilities.

Configuring Naming Methods

Find out how to configure connectivity information for client connections to the database server.

- Configuring and Administering Oracle Net Listener
- Configuring and Administering Oracle Connection Manager

Oracle Connection Manager is a proxy server that forwards connection requests to databases or other proxy servers. It operates at the session level, and usually resides on a computer separate from the database server and client computers.

Configuring a Shared Server Architecture

You can manage server loads on Oracle Database by managing dispatchers, and configuring your clients to take advantages of Oracle Net Services features.

Configuring Profiles

Learn how to configure client and server configuration parameters in profiles. A profile is a collection of parameters that specifies preferences for enabling and configuring Oracle Net features on the client or database server.

Enabling Advanced Features of Oracle Net Services

Understand how to configure the advanced features of Oracle Net Services, including advanced connect data parameters, load balancing, failover, and connections to non-database services.

Optimizing Performance

Learn how to optimize connection performance.

Quick Start to Oracle Net Services

Help novice users set up and test a simple but common network configuration, such as one between a client application and a database over a TCP/IP network.

Prerequisites for Establishing Connectivity

The tasks in this chapter show a TCP/IP connection between a database server and a client computer.

Confirming Network Availability

Before using Oracle Net to connect a client computer to a database server, confirm that the client computer can successfully communicate with the database server computer. Evaluating network connectivity can eliminate network-based errors.

Starting Oracle Net Listener and the Oracle Database Server

Oracle Net Listener and the Oracle Database server must be running in order for the database server to receive connections.

Starting Oracle Connection Manager

If Oracle Connection Manager is installed, then follow these steps to start Oracle Connection Manager.

Using Easy Connect to Connect to a Database

Easy Connect extends the functionality of the host naming method by enabling clients to connect to a database server with an optional port and service name in addition to the host name of the database.

Viewing Connection Strings Using the connstr Utility

You can run the Oracle Database Connection String command-line utility (connstr) to display Oracle Database connect strings for all the available network service names.

Connecting to the Database

There are several methods for connecting to Oracle Database.

6.1 Prerequisites for Establishing Connectivity

The tasks in this chapter show a TCP/IP connection between a database server and a client computer.

The following conditions are assumed about the database server and client computer:

- Database server
 - The server is running on a network that can access the client
 - An Oracle database is installed
 - A listener is configured
 - TCP/IP protocol support is installed
- Client computer
 - The client computer is running on a network that can access the database server
 - Oracle Client is installed
 - TCP/IP protocol support is installed

In a TCP/IP network, each computer has a unique IP address. A name resolution service, such as Domain Name System (DNS), can be used to map the IP address of a computer with its host name. If a name resolution service is not used, then the mapping is typically stored in a centrally maintained file called hosts. This file is located in the /etc directory on Linux and the \windows\system32\drivers\etc directory on Microsoft Windows. For example, an entry for a database server computer named sales-server may look like the following:

```
#IP address of server host name alias
192.0.2.203 sales-server sales.us.example.com
```

6.2 Confirming Network Availability

Before using Oracle Net to connect a client computer to a database server, confirm that the client computer can successfully communicate with the database server computer. Evaluating network connectivity can eliminate network-based errors.

The following procedure describes how to confirm network connectivity:

- Confirm that the database server computer can communicate with itself with a loopback test as follows:
 - a. To confirm hardware connectivity, enter the following command at the command line:

```
ping ip_address
```

In the preceding command, $ip_address$ is the IP address of the database server computer, such as the following:

```
ping 192.0.2.203
```

b. To confirm the DNS or host name is configured properly, enter the following command at the command line:

```
ping host name
```

In the preceding command, host name is the host name of the server.

c. To test the TCP/IP setup for the server, enter the following command:

```
ping 127.0.0.1
ping6 ::1
```

The IP address 127.0.0.1 is the standard IPv4 address for a loopback test. The IP address ::1 (0: 0: 0: 0: 0: 0: 1) is the standard IPv6 address for a loopback test.

Verify the client computer can successfully communicate with the database server computer.

The method for verification varies according to the network protocol. For TCP/IP, you can use PING, FTP or TELNET utilities.

If the client computer cannot reach the server, then verify that the network cabling and network interface cards are correctly connected. Contact your network administrator to correct these problems.

6.3 Starting Oracle Net Listener and the Oracle Database Server

Oracle Net Listener and the Oracle Database server must be running in order for the database server to receive connections.

The following procedure describes how to start Oracle Net Listener:

 Start the listener with the Listener Control utility. From the command line, enter the following:

```
lsnrctl
LSNRCTL> START [listener name]
```

In the preceding command, *listener_name* is the name of the listener defined in the listener.ora file. It is not necessary to identify the listener if you are using the default name LISTENER.

A status message indicating that the listener has successfully started appears.

- 2. Start the database as follows:
 - a. Start SQL*Plus without connecting to the database using the following command:

```
SQLPLUS /nolog
```

b. Connect to the database as SYSDBA using the following command:

```
SQL> CONNECT username as sysdba
```

You will be prompted to enter a password.

For simplicity, this example does not perform the password management techniques that a deployed system normally uses. In a production environment, follow the Oracle Database password management guidelines, and disable any sample accounts. See *Oracle Database Security Guide* for password management guidelines and other security recommendations.

c. Start the database using the following command:

```
SQL> STARTUP database_name
```

In the preceding command, database_name is the name of the database.

For additional information about starting the database, see *Oracle Database Administrator's Guide*.

3. Confirm that database service registration with the listener has completed using the Listener Control utility and the following command:

```
LSNRCTL> SERVICES [listener name]
```

The SERVICES command lists the services supported by the database, along with at least one available service handler. If the database service registration is not listed, then enter the following SQL command:

```
SQL> ALTER SYSTEM REGISTER;
```

Related Topics

Monitoring Services of a Listener

6.4 Starting Oracle Connection Manager

If Oracle Connection Manager is installed, then follow these steps to start Oracle Connection Manager.

 Start the Oracle Connection Manager Control utility (CMCTL) using the following commands:

```
cmctl
CMCTL> ADMINISTER [instance name]
```

In the preceding command, <code>instance_name</code> is the name of Oracle Connection Manager to administer. You can determine the name by viewing the <code>cman.ora</code> file. The file is located on the Oracle Connection Manager computer in the <code>ORACLE_BASE_HOME/network/admin</code> directory by default.

Oracle Connection Manager displays a status message indicating the name of the instance, and informs you that the instance has not yet been started.

If you do not provide an instance name as an argument, then provide Oracle Connection Manager with a fully qualified host name. This is the default. After you issue the ADMINISTER command, CMCTL displays the instance name as follows:

```
CMAN_fully_qualified_host_name
```

2. Start Oracle Connection Manager that you have chosen to administer using the following command:

```
cmctl> STARTUP
```

Oracle Connection Manager confirms that the instance has been started, and provides status for the instance.

Exit from the Oracle Connection Manager Control utility using the following command:

```
cmctl> EXIT
```

On Microsoft Windows, you can start Oracle Connection Manager through the Control Panel, as follows:

- Select Services in the Control Panel.
- 2. Select the Oracle HOME NAMECMan service, and then click Start.
- In the Services window, click Close.

6.5 Using Easy Connect to Connect to a Database

Easy Connect extends the functionality of the host naming method by enabling clients to connect to a database server with an optional port and service name in addition to the host name of the database.

After network connectivity has been verified, you can use the Easy Connect naming method to connect to the database. This naming method provides out-of-the-box TCP/IP connectivity to databases.

The following is the syntax to connect using Easy Connect:

CONNECT username/password@host[:port][/service name][:server type][/instance name]

In Oracle Call Interface documentation, server is referred to as connect_type.

If Oracle Database server installation was performed in Typical mode, then the default service name used by the Oracle instance is the database name, and the following Easy Connect syntax can be used to connect to that instance:

```
SQLPLUS /nolog
SQL> CONNECT username@"host/db_name"
SQL> Enter password: password
```

Related Topics

- Understanding the Easy Connect Naming Method
 The Easy Connect naming method provides out-of-the-box TCP/IP connectivity to databases.
- Confirming Network Availability
 Before using Oracle Net to connect a client computer to a database server, confirm that the
 client computer can successfully communicate with the database server computer.
 Evaluating network connectivity can eliminate network-based errors.

6.6 Viewing Connection Strings Using the connstr Utility

You can run the Oracle Database Connection String command-line utility (connstr) to display Oracle Database connect strings for all the available network service names.

You can use these strings in a client application or tool (such as SQL*Plus, Python, or JDBC Thin) to quickly connect to Oracle Database, or write these service name entries to the tnsnames.ora file for use with the local naming method.

The connstr script is included in a default installation. The utility displays connect strings for a single Oracle software installation, based on the available system configuration.

Note:

This utility is suitable for single-instance or Oracle Database Free installations but not for more complex configurations, such as Oracle Real Application Clusters (Oracle RAC) or Oracle Data Guard. It relies on the Listener Control utility (lsnrctl), and thus you must run this utility on a computer hosting your Oracle Database and listener. However, you can use the displayed connect strings on any supported client system.

1. Enter the following command at the command line:

```
connstr
```

This utility runs in an interactive mode with default options, without the need to specify any arguments.

An output appears with a list of service names and their corresponding connect strings in the Easy Connect format. The output displays sample strings to be used in SQL*Plus, Python, or JDBC Thin clients. See Example 6-1.

2. (Optional) If you want to run this utility with advanced configuration options, then use the h (or --help) option to access a list of additional arguments that you can enter at the command line:

```
connstr -h
```

Here are some commonly used arguments that you may use with connstr:

• This utility uses the default listener named LISTENER. If you are using a different listener or if multiple listeners are active, then use -L (or --listener) to specify the listener name:

```
connstr -L listener name
```

When run, an interactive dialog appears with various choices depending on the listener configuration.

To filter a list of available listener endpoints, use -e (or --endpoints):

```
connstr -e
```

For example:

```
connstr -e
PROTOCOL PORT HOST
tcp 1521 sales-server
tcp 1523 hr-server
tcps 1522 mktg-server
```

To filter a list of available listener services, use -s (or --services):

```
connstr -s
```

For example:

```
connstr -s
sales.us.example.com
hr.us.example.com
mktg.us.example.com
```

• By default, this utility displays strings in the Easy Connect format. If you want to connect using a JDBC Thin application, then use -j (or --jdbc) along with the service name to view a connect string in the JDBC Thin format:

```
connstr -j service name
```

For example:

```
connstr -j sales.us.example.com
jdbc:oracle:thin:@sales-server:1521/sales.us.example.com
```

To display a connect string in the connect descriptor format, use -d (or --descriptor):

```
connstr -d service name
```

For example:

```
connstr -d sales.us.example.com
(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
(CONNECT_DATA=(SERVICE_NAME=sales.us.example.com)))
```

To display a connect string in the default (Easy Connect) format, use -z (or -ezconnect):

```
connstr -z service_name
```

For example:

```
connstr -z sales.us.example.com
username@sales-server:1521/sales.us.example.com
```

3. The output prompts you to write connect strings to the tnsnames.ora file. If you want to create this file with the available service names and their connect descriptors, then enter Y.

The tnsnames.ora file is written in the directory specified by the TNS_ADMIN environment variable. If the TNS_ADMIN environment variable is not set, then the file is written either in the ORACLE_BASE_HOME/network/admin directory or in the ORACLE_HOME/network/admin directory.

If the tnsnames.ora file already exists, then you are prompted to either append these entries to the existing file or overwrite the file. Enter Y to append or O to overwrite.

Example 6-1 Sample connstr Utility Output in the Easy Connect Format

```
Using Listener: LISTENER with Oracle Home: /app/oracle/product/23ai/dbhome_1 Service Name: sales.us.example.com
```

```
Connection String: sales-server:1521/sales.us.example.com

Connection strings can be used to connect to the specified service name.

For SQL*Plus you can use:
    SQL> connect username@sales-server:1522/sales.us.example.com

For Python you can use:
    connection = cx_Oracle.connect(user="username", password="password",
    dsn="sales-server:1521/sales.us.example.com")

For JDBC Thin you can use:
    OracleDataSource ods = new OracleDataSource();
    ods.setURL("jdbc:oracle:thin:@sales-server:1521/sales.us.example.com");
    ods.setUser("username"); ods.setPassword("password");
    Connection conn = ods.getConnection();

Write connect strings to tnsnames.ora (Y/N)? (Default: N): y
```

Related Topics

Entering a Connection String

You can make a connection across the network after the network components are started. How you make a connection depends upon the naming method and the tool used for the connection.

6.7 Connecting to the Database

There are several methods for connecting to Oracle Database.

Table 6-1 Database Connection Methods and Syntax

Type of Connection	Connection Syntax	Description
From the command line	The general form of connecting an application to a database server from the command line is:	Most Oracle tools can use the operating system command line to connect, and some provide alternatives.
	tool username@connect_identifier	
	You are prompted to enter your password which is encrypted. For example:	
	SQLPLUS system@sales Enter password: password	
From a login screen	username@connect_identifier	Some tools provide a login screen as an alternative form to log in. A user can log in to a database server by identifying both the user name and connect identifier in the user name field of the tool login screen, and entering the password in the password field.

Table 6-1 (Cont.) Database Connection Methods and Syntax

Type of Connection	Connection Syntax	Description
From a 3GL application	exec sql connect : username identified by :password In the preceding connection request, :username and :password are 3GL variables that can be set within the program either statically or by prompting the user. When connecting to a database server, the value of the :username variable is in the form: username@net_service_name The :password variable contains the password	Applications written in 3GL, such as OCI and pre-compilers, are used by middle-tier and database application developers for direct database access from a client program.
	for the database account to which you are	
From within SQL*Plus	connecting. SQLPLUS /nolog SQL> CONNECT username@net_service_name	Some Oracle tools have commands for database connections to allow an alternative user name to be specified without leaving the tool.
	For example: SQLPLUS /nolog SQL> CONNECT scott@serverx Enter password: password	Other Oracle tools use slightly different methods specific to their function or interface. For example, Oracle CDE tools use login buttons with fields for the user name, password, and remote database ID.
	In the preceding commands, <i>username</i> and <i>password</i> are the database user and password, and <i>net_service_name</i> is the network service name.	
Using KERBEROS5_CC_NAME parameter	<pre>(DESCRIPTION=</pre>	Use this parameter to specify the complete path to the Kerberos credentials cache file for the Kerberos principal (user), when multiple Kerberos principals need to log in through the Database client.
	<pre>(CONNECT_DATA=(SERVICE_NAME=sales. example.com)) (SECURITY=(SQLNET.KERBEROS5_CC_NAM E=/usr/tmp/krbcache)))</pre>	If you are using Kerberos authentication to connect to a database, then specifying the complete path to the credential cache using KERBEROS5_CC_NAME is mandatory. For a single Kerberos principal, you can specify the credential cache path in the sqlnet.ora file. When a client needs to use more than one Kerberos Principal for making multiple database connections, specify KERBEROS5_CC_NAME parameter in either the CONNECT string for individual connections or in the tnsnames.ora file. KERBEROS5_CC_NAME supports multiple principals and the storage of credentials that are returned by the Key Distribution Center (KDC) in an encrypted form. See Oracle Database Security Guide.

Table 6-1 (Cont.) Database Connection Methods and Syntax

Type of Connection	Connection Syntax	Description
Using KERBEROS5 PRINCIPAL	(DESCRIPTION=	This parameter is used to specify Kerberos principals for a database client.
parameter	(ADDRESS=(PROTOCOL=tcp) (HOST=sales-svr)(PORT=1521))	This is an optional parameter. However, if you use this parameter, then ensure that the KERBEROS5 PRINCIPAL matches the
	<pre>(CONNECT_DATA=(SERVICE_NAME=sales. example.com)) (SECURITY=</pre>	principal retrieved from the Kerberos credential cache (specified using KERBEROS5_CC_NAME). The authentication fails if the principal name does not match.
	<pre>(KERBEROS5_PRINCIPAL=krbprincl@exa mple.com))</pre>	

Table 6-1 (Cont.) Database Connection Methods and Syntax

Type of Connection **Connection Syntax** Description Using IAM database If you have configured Oracle Cloud SQLPLUS /nolog password verifier Infrastructure (OCI) Identity and Access SQL> CONNECT username@net_service_name Management (IAM) for user authentication authentication Enter password: password and authorization, then IAM users can connect to OCI Database as a Service In this connection request, username is the (DBaaS) using the IAM user name and IAM IAM user name, net_service_name is the database password. With this connection network service name, and password is the method, an IAM database password verifier IAM database password. (an encrypted hash of password) is retrieved An IAM user can connect through a database from IAM to authenticate users. proxy user account using password-based This IAM database password is different from proxy authentication: the OCI console password. An IAM user can set this password from the OCI console SQLPLUS [user1]/password123\!@cdb1 pdb2 (watch the Create an OCI IAM Password SOL> SHOW USER; video). select sys context ('USERENV', 'AUTHENTICATION $_{_}^{M}$ After you are granted the required ETHOD') from dual; authorization, you can log in from any supported database client using on-premise sys context('USERENV', 'PROXY USER') client applications, such as SQL*Plus. from dual; Use of IAM user name and IAM database select password with the IAM database verifier is the sys context('USERENV','CURRENT USER') default configuration, and you do not need to from dual; set any additional parameters for the client. However, if PASSWORD AUTH is set to OCI TOKEN in the client-side sqlnet.ora file, then the database client tries to connect with OCI IAM to retrieve a database token using the IAM user name and IAM database password. In this case, you can override this setting for a particular connection by setting PASSWORD AUTH=PASSWORD VERIFIER. You can configure client connections (typically middle-tier environments) to use proxy authentication. In this case, you can alter an existing IAM user with necessary permissions to connect through a proxy database user account by using password-based proxy authentication. The proxy user session has all the privileges granted to the IAM user.

See Oracle Database Security Guide.

Table 6-1 (Cont.) Database Connection Methods and Syntax

Type of Connection Description **Connection Syntax** Using IAM token-based If you have configured IAM for user SQLPLUS /nolog authentication (bearer authentication and authorization, then IAM SQL> CONNECT /@connect identifier token) users can use an IAM database token (dbtoken) to connect to an Oracle DBaaS The PASSWORD AUTH setting enforces IAM instance. This type of token is a bearer token token-based authentication using a bearer and does not come with a private key. token: You can configure the database client to request the db-token using your IAM user (DESCRIPTION= name and IAM database password. An (ADDRESS=(PROTOCOL=tcps) application cannot pass this type of token to (HOST=salesserver1) (PORT=1522)) the client. In this case, set the (SECURITY= PASSWORD AUTH parameter to OCI TOKEN. (SSL SERVER DN MATCH=TRUE) An IAM user can set this IAM database password from the OCI console (watch the (SSL SERVER CERT DN="C=US,O=exampl Create an OCI IAM Password video). e,CN=OracleContext") The database client retrieves the token (PASSWORD AUTH=OCI TOKEN) directly from the OCI IAM endpoint. You must (OCI IAM URL=https:// set additional parameters so that the auth.us-region-1.example.com/v1/ database client can find the IAM endpoint actions/ along with additional metadata. The additional parameters are ${\tt OCI}\ {\tt IAM}\ {\tt URL}$ and generateScopedAccessBearerToken) OCI TENANCY with the optional OCI COMPARTMENT and OCI DATABASE to (OCI TENANCY=ocid1.tenancy..12345) limit the scope. When an IAM user logs in with the IAM user name and IAM database password using / (CONNECT DATA=(SERVICE NAME=sales. @connect identifier, the us.example.com)) PASSWORD AUTH=OCI TOKEN setting along with /@connect identifier instructs the database client to get the token directly from You can use the optional OCI COMPARTMENT an OCI IAM endpoint using a REST API and OCI DATABASE parameters to limit the request. scope of your token request. You can specify these parameters in the tnsnames.ora file, sqlnet.ora file, or (DESCRIPTION= directly as part of the connect string. (ADDRESS=(PROTOCOL=tcps) See Oracle Database Security Guide. (HOST=salesserver1) (PORT=1522)) (SECURITY= (SSL SERVER DN MATCH=TRUE) (SSL SERVER CERT DN="C=US,O=exampl e, CN=OracleContext") (PASSWORD AUTH=OCI TOKEN) (OCI IAM URL=https:// auth.us-region-1.example.com/v1/ actions/ generateScopedAccessBearerToken) (OCI TENANCY=ocid1.tenancy..12345) (OCI COMPARTMENT=ocid1.compartment

Table 6-1 (Cont.) Database Connection Methods and Syntax

Type of Connection	Connection Syntax	Description
	12345)	
	(OCI_DATABASE=ocid1.autonomousdata base.oc1.12345))	
	<pre>(CONNECT_DATA=(SERVICE_NAME=sales. us.example.com)))</pre>	

Table 6-1 (Cont.) Database Connection Methods and Syntax

Type of Connection

Connection Syntax

Using IAM token-based authentication (PoP token)

```
SQLPLUS /nolog
SQL> CONNECT /@connect_identifier
```

The TOKEN_AUTH setting enforces IAM token-based authentication using a PoP token:

You can use the optional <code>TOKEN_LOCATION</code> parameter to override the default directory where the database token and private key are stored:

An IAM user can connect through a database proxy user account using token-based proxy authentication:

```
SQLPLUS [user1]/@pop_token_connstr
SQL> SHOW USER;
select
sys_context('USERENV','AUTHENTICAT
```

Description

If you have configured IAM for user authentication and authorization, then IAM users can use an IAM database token (db-token) to connect to an Oracle DBaaS instance. This type of token is a proof-of-possession (PoP) token with an expiration time and scope. You can request the token from IAM using Oracle Cloud Infrastructure (OCI) Command Line Interface (CLI) or programmatically from the OCI Software Development Kit (SDK).

You can use one of the IAM user credentials, such as API-key, security token, resource principal, service principal, instance principal, or delegation token (delegation token is available only in the Cloud Shell) to retrieve the db-token and private key from IAM.

A client application can send a connection request in one of the following ways:

- When an IAM user logs in using / @connect_identifier (and TOKEN_AUTH is set to OCI_TOKEN), the database client gets the db-token and private key from either the default directory or the location specified by TOKEN_LOCATION (using IAM token-based authentication).
- If your client application is updated to retrieve tokens from IAM, then IAM directly passes the db-token and private key as attributes to the database client using the database client API. In this case, you do not need to specify the TOKEN_AUTH and TOKEN_LOCATION parameters.

You can specify these parameters in the tnsnames.ora file, sqlnet.ora file, or directly as part of the connect string.

You can configure client connections to use proxy authentication. In this case, you can alter an IAM user with necessary permissions to connect through a proxy database user account by using token-based proxy authentication. The proxy user session has all the privileges granted to the IAM user.

See Oracle Database Security Guide.

Table 6-1 (Cont.) Database Connection Methods and Syntax

Type of Connection	Connection Syntax	Description
	<pre>ION_METHOD') from dual;</pre>	
	select	
	sys_context('USERENV','PROXY_USER'	
) from dual;	
	select	
	<pre>sys_context('USERENV','CURRENT_USE</pre>	
	R') from dual;	

Table 6-1 (Cont.) Database Connection Methods and Syntax

Type of Connection

Connection Syntax

Using Azure token-based authentication

```
SQLPLUS /nolog
SQL> CONNECT /@connect identifier
```

The TOKEN_AUTH setting enforces Azure token-based authentication. You must also use the TOKEN_LOCATION parameter to specify the directory path where the access token is stored.

If the token file is named token, then the client automatically looks for the file in the specified directory path (for example, / home/dbuser1/access-token):

```
(DESCRIPTION=
```

```
(ADDRESS=(PROTOCOL=tcps)
(HOST=salesserver1) (PORT=1522))
    (SECURITY=
```

(SSL_SERVER_DN_MATCH=TRUE)

dbuser1/access-token"))

(CONNECT_DATA=(SERVICE_NAME=sales.
us.example.com))

If the token file name is different from token, then you must specify the file name (for example, mytoken) along with the directory path:

```
(DESCRIPTION=
          (ADDRESS=(PROTOCOL=tcps)
(HOST=salesserver1) (PORT=1522))
          (SECURITY=
                (SSL SERVER DN MATCH=TRUE)
```

```
(CONNECT_DATA=(SERVICE_NAME=sales.
us.example.com))
```

Description

If you have configured Microsoft Entra ID (previously called Microsoft Azure Active Directory) for user authentication and authorization, then Azure users can use the Entra ID OAuth2 access token to connect to an Oracle Database. This access token is a bearer token with an expiration time and scope, and follows the OAuth2.0 standard with Entra ID extensions.

The TOKEN_AUTH setting (TOKEN_AUTH=OAUTH) instructs the database client to get the access token from the directory specified by TOKEN_LOCATION if the token file is named token. Otherwise, you must use your token file name along with the directory location while specifying the TOKEN_LOCATION parameter.

The TOKEN_LOCATION parameter is mandatory for Azure token-based authentication. The database client gets the access token from this location and sends it to the database server.

You specify the TOKEN_AUTH and TOKEN_LOCATION parameters in the tnsnames.ora, sqlnet.ora file or directly as part of the connect string.

You can request the tokens from tools and scripts run on Linux, Microsoft PowerShell, or other environments. You can also request these tokens programmatically using the Microsoft SDKs.

A client application can send a connection request in one of the following ways:

- An Azure user can request the access token from Entra ID using one of the supported authentication flows (resource owner password credentials, authorization code, on-behalf-of (OBO) flow, or client credentials) and store it in a local file directory.
- If your client application is updated to retrieve tokens from Entra ID, then the application can also request the access token directly from Entra ID and pass it as an attribute to the database instance using a database client API. In this case, you do not need to specify the TOKEN_AUTH and TOKEN_LOCATION parameters.

See Oracle Database Security Guide.

Note:

If you have configured IAM token-based authentication, then you can enable the database client to directly retrieve the db-token with IAM Single-Sign On (SSO) credentials using OCI authentication flows, such as OCI_INTERACTIVE, OCI_API_KEY, OCI_INSTANCE_PRINCIPAL, OCI_DELEGATION_TOKEN, and OCI_RESOURCE_PRINCIPAL.

Similarly, if you have configured Azure token-based authentication, then you can enable the database client to directly retrieve the access token with Azure SSO credentials using authentication flows, such as <code>AZURE_INTERACTIVE</code>, <code>AZURE SERVICE PRINCIPAL</code>, <code>AZURE MANAGED IDENTITY</code>, and <code>AZURE DEVICE CODE</code>.

This feature is available in environments that use JDBC-thin clients, ODP.NET Core classes, or ODP.NET Managed Driver classes. To configure this feature for JDBC-thin clients, see *Oracle Database JDBC Developer's Guide* and for ODP.NET, see *Oracle Data Provider for .NET Developer's Guide*.

Managing Oracle Net Services

Learn about the various administration tools of Oracle Net Services, and also explore the command-line control utilities.

This involves the main administration applications, Oracle Enterprise Manager Cloud Control and Oracle Net Manager.

- Using the User Interface Tools
 - Oracle Net Services provides tools to help you perform configuration and administrative tasks.
- About the OracleNetAdmins Group
 - To use Oracle Net Manager, you must be a member of the <code>OracleNetAdmins</code> group or the <code>OracleContextAdmins</code> group.
- Using Listener Control Utility to Administer the Listener
 Oracle Net Services provides tools to help you start, stop, configure, and control each network component. The Listener Control utility enables you to administer the listener.
- Performing Common Network Tasks
 Learn how to perform network configuration and administration tasks, such as configuring directory server, naming methods, profiles, listener, and Oracle Connection Manager.

7.1 Using the User Interface Tools

Oracle Net Services provides tools to help you perform configuration and administrative tasks.

- Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services
- Using Oracle Net Manager to Configure Oracle Net Services
- Deciding When to Use Oracle Enterprise Manager Cloud Control and Oracle Net Manager
- Using Oracle Net Configuration Assistant to Configure Network Components

7.1.1 Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services

Oracle Enterprise Manager Cloud Control enables you to configure Oracle Net Services for any Oracle home across multiple file systems. It also provides common administration functions for listeners. Oracle Enterprise Manager Cloud Control provides an integrated environment for configuring and managing Oracle Net Services.

You can use Oracle Enterprise Manager Cloud Control to configure and administer the following from multiple Oracle homes:

- Listeners: Configure listeners to receive client connections.
- Naming: Define connect identifiers and map them to connect descriptors to identify the network location of a service. Oracle Net Manager supports configuration of connect descriptors in local tnsnames.ora files or a centralized directory service.

- File location: Specify the file location of the Oracle Net configuration files.
- Accessing the Net Services Administration Page

Oracle Enterprise Manager Cloud Control documentation set and online help for information about using Oracle Enterprise Manager Cloud Control

7.1.1.1 Accessing the Net Services Administration Page

The following procedure describes how to access the Net Services Administration page using Oracle Enterprise Manager Cloud Control:

- From the Login to Database page, enter the database credentials, and then click Login.
 The Select Enterprise Manager Home page appears.
- 2. Select All Targets from the Targets menu.
- 3. Select Listener from the Refine Search list.
- 4. Select the listener by double-clicking on the listener name.
- Select Net Services Administration from the Oracle Listener menu.

The Net Services Administration page appears.

From the Net Services Administration page, you can administer the listeners, naming methods, preferences, and so on. The administration procedures are described in other chapters of this book.

7.1.2 Using Oracle Net Manager to Configure Oracle Net Services

Oracle Net Manager enables you to configure Oracle Net Services for an Oracle home on a local client or server host.

You can use Oracle Net Manager to configure the following network components:

- Listeners: Create and configure listeners to receive client connections.
- Naming: Define connect identifiers and map them to connect descriptors to identify the
 network location and identification of a service. Oracle Net Manager supports configuration
 of connect descriptors in local tnsnames.ora files or a centralized directory service.
- Naming methods: Configure the ways connect identifiers are resolved to connect descriptors.
- Profiles: Configure preferences for enabling and configuring Oracle Net features on the client or server.

This section introduces the features of Oracle Net Manager. However, the primary documentation for using Oracle Net Manager is online help.

- Starting Oracle Net Manager
- Navigating Oracle Net Manager
- Using Oracle Net Manager Wizards

7.1.2.1 Starting Oracle Net Manager

To start Oracle Net Manager, do the following

- On Linux, run netmgr from the ORACLE HOME/bin directory.
- On Microsoft Windows, select Programs from the Start menu, and then select Oracle -HOME NAME. Next, select Configuration and Migration Tools, and then Net Manager.

7.1.2.2 Navigating Oracle Net Manager

The Oracle Net Manager interface includes a toolbar and menu options, as well as property sheets for configuring network components.

The navigator pane provides a tree view of network objects and the objects they contain, organized in a folder hierarchy. You can expand and collapse the folders to monitor or manage objects such as connect identifiers, listeners, and profiles. Click an object to make changes to it.

The following are the main folders in the navigator pane:

Local

Displays networking elements configured in local configuration files:

- Net service names in the tnsnames.ora file
- Listeners in the listener.ora file
- Profile in the sqlnet.ora file
- Directory

Displays connect identifiers configured in a directory server

7.1.2.3 Using Oracle Net Manager Wizards

The Oracle Net Manager wizards provide step-by-step guidance for tasks. The wizards simplify complex tasks by guiding you through the tasks in manageable steps. The wizards are not intended to provide all configuration options. After you have completed a task with a wizard, use the other components of Oracle Net Manager to modify the configuration.

- Using the Net Service Name Wizard
- Using the Directory Server Migration Wizard

7.1.2.3.1 Using the Net Service Name Wizard

The Net Service Name wizard guides you through creating a basic network service name in a directory server or a tnsnames.ora file.

The following procedure describes how to start the Net Service Name wizard to create network service names:

- 1. In the navigator pane, select **Directory** or **Local**, and then select **Service Naming**.
- Click the plus sign (+) on the toolbar, or select Create from the Edit menu.

Oracle Net Manager online help for detailed information about using the Net Service Name wizard to create a network service name

7.1.2.3.2 Using the Directory Server Migration Wizard

If a tnsnames.ora file already exists, then its network service names can be exported to a directory server with the Directory Server Migration wizard.

The following procedure describes how to use the Directory Server Migration wizard:

- 1. Select **Directory** from the Command menu.
- 2. Select **Export Net Service Names** from the Oracle Net Manager menu.

"Exporting Local Naming Entries to a Directory Naming Server"

7.1.3 Deciding When to Use Oracle Enterprise Manager Cloud Control and Oracle Net Manager

Much of the functionality previously available only in Oracle Net Manager has been integrated with Oracle Enterprise Manager Cloud Control. Oracle Enterprise Manager Cloud Control provides the ability to manage configuration for multiple Oracle homes across multiple file systems. Oracle Net Manager only enables you to manage configuration for one Oracle home on a local host computer. The following are the key differences between the tools.

Oracle Enterprise Manager Cloud Control

- Configure the following features:
 - Local naming (tnsnames.ora files)
 - Directory naming
 - Listeners
- Provide Oracle home support across multiple file system
- Provide the ability to search and sort local and directory naming entries
- Export directory naming entries to a tnsnames.ora file
- Perform the following administrative tasks for a selected listener:
 - Show current status
 - Change status
 - Change tracing level settings
 - Change logging settings
 - Set connect-time failover and load balancing methods when there is more than one listener

Oracle Net Manager

- Configure the following features:
 - Local naming (tnsnames.ora files)
 - Directory naming
 - Listeners
 - Profiles
- Provide Oracle home support for single host
- Set connect-time failover and load balancing methods when there is more than one listener
- Set the following options for clients and servers:
 - Tracing settings
 - Logging settings
 - Security, authentication and access rights
 - Routing

When Automatic Diagnostic Repository (ADR) is enabled, any changes to the tracing and logging settings using Oracle Enterprise Manager Cloud Control are ignored by the system.

7.1.4 Using Oracle Net Configuration Assistant to Configure Network Components

Oracle Net Configuration Assistant configures basic network components during installation, including:

- Listener names and protocol addresses
- Naming methods the client uses to resolve connect identifiers to connect descriptors
- Net service names in a tnsnames.ora file
- Directory server usage

Oracle Net Configuration Assistant runs automatically during software installation, as described in the Oracle Database installation guide. It can also be run after installation in standalone mode to configure naming methods, the listener, network service names in the tnsnames.ora file, and directory server usage.

To start Oracle Net Configuration Assistant do the following:

- On Linux and UNIX, run netca from the ORACLE HOME/bin directory.
- On Microsoft Windows, select Programs from the Start menu, and then select Oracle -HOME_NAME. Next, select Configuration and Migration Tools, and then Oracle Net Configuration Assistant.

- Oracle Net Configuration Assistant online help
- Oracle Grid Infrastructure Installation Guide for information on running Oracle
 Net Configuration Assistant in silent mode

The following are the configuration options on the Oracle Net Configuration Assistant Welcome page:

- Listener configuration Create, modify, delete, or rename a listener.
- Naming Methods configuration Configure the computer to resolve connect identifiers to connect descriptor with one or more of following naming methods:
 - Local naming
 - Directory naming
 - Easy Connect naming
 - External naming
- Local Net Service Name configuration
 - Create, modify, delete, rename, or test connectivity of a connect descriptor stored in a local tnsnames.ora file
- Directory Usage Configuration Configure a directory server for directory-enabled features.

7.2 About the OracleNetAdmins Group

To use Oracle Net Manager, you must be a member of the <code>OracleNetAdmins</code> group or the <code>OracleContextAdmins</code> group.

Oracle Net Configuration Assistant establishes these access rights for these groups during Oracle Context creation.

- Adding Users To the OracleNetAdmins Group
- Removing Users From the OracleNetAdmins Group
- Changing Ownership of the OracleNetAdmins Group

7.2.1 Adding Users To the OracleNetAdmins Group

The following procedure describes how to add a user to the <code>OracleNetAdmins</code> group using the <code>ldapmodify</code> command:

1. Create an Lightweight Directory Interchange Format (LDIF) file that specifies that you want to add a user to the <code>OracleNetAdmins</code> group.

You can use the following sample LDIF file. Use the appropriate DN for cn=OracleNetAdmins and the user that you want to add.

```
dn: cn=OracleNetAdmins,cn=OracleContext,...
changetype: modify
add: uniquemember
uniquemember: DN of user being added to group
```

2. Enter the following command at the command line to refresh the file:

```
$ ldapmodify -h directory host -p port -D binddn -q -f ldif file
```

In the preceding command, $directory_host$ is the directory server host, port is the listening TCP/IP port for the directory server, binddn is the directory administrator or user DN, and $ldif_file$ is the input file name. If the port is not specified, then the default port of 389 is used. The -q option prompts for a single bind password.

7.2.2 Removing Users From the OracleNetAdmins Group

The following procedure describes how to remove a user from the <code>OracleNetAdmins</code> group with the <code>ldapmodify</code> command:

1. Create an LDIF file that specifies that you want to delete a user to the OracleNetAdmins group.

You can use the following sample LDIF file. Enter the appropriate DN for cn=OracleNetAdmins and the user that you want to delete.

```
dn: cn=OracleNetAdmins,cn=OracleContext,...
changetype: modify
delete: uniquemember
uniquemember: DN of user being deleted from group
```

2. Enter the following command to delete the user:

```
$ ldapmodify -h directory_host -p port -D binddn -q -f ldif_file
```

In the preceding command, $directory_host$ is the directory server host, port is the listening TCP/IP port for the directory server, binddn is the directory administrator or user DN, and $ldif_file$ is the input file name. If the port is not specified, then the default port of 389 is used. The -q option prompts for a single bind password.

7.2.3 Changing Ownership of the OracleNetAdmins Group

The following procedure describes how to add a group as an owner of an OracleNetAdmins group:

- 1. Create an LDIF file, as follows:
 - a. Specify the group you want to add as an owner.

You can use the following sample LDIF file. Enter the appropriate DN for cn=OracleNetAdmins and the DN of the group that you want to add.

```
dn: cn=OracleNetAdmins,cn=OracleContext,...
    changetype: modify
    add: owner
    owner: DN of group to add
```

For example, the following LDIF syntax changes the ownership from the OracleNetAdmins group to another group named ExampleSecurityAdmins. The group can be either inside or outside Oracle Context.

b. (Optional) Specify the group to delete as an owner.

```
dn: cn=OracleNetAdmins,cn=OracleContext,...
    changetype: modify
    delete: owner
    owner: DN of group to delete
```

2. Enter the following command at the command line to refresh the file:

```
$ ldapmodify -h directory host -p port -D binddn -q -f ldif file
```

In the preceding command, $directory_host$ is the directory server host, port is the listening TCP/IP port for the directory server, binddn is the directory administrator or user DN, and $ldif_file$ is the input file name. If the port is not specified, then the default port of 389 is used. The -q option prompts for a single bind password to be entered.

7.3 Using Listener Control Utility to Administer the Listener

Oracle Net Services provides tools to help you start, stop, configure, and control each network component. The Listener Control utility enables you to administer the listener.

The utility is started by the user that owns the Oracle installation, or a member of the designated group, on the same machine where the listener is running. The basic syntax for this utility is as follows:

```
lsnrctl command [listener_name]
```

For example, the following command starts a listener named lsnr:

```
lsnrctl START lsnr
```

You can also issue Listener Control utility commands at the LSNRCTL> program prompt. To obtain the prompt, enter lsnrctl with no arguments at the operating system command line. When you run lsnrctl, the utility is started, and you can enter the necessary commands from the program prompt.

For example:

```
lsnrctl
LSNRCTL> START lsnr
```

See Also:

- "Customizing Oracle Net Listener Configuration" for additional information about the listener
- Oracle Database Net Services Reference for additional information about the Listener Control utility

7.4 Performing Common Network Tasks

Learn how to perform network configuration and administration tasks, such as configuring directory server, naming methods, profiles, listener, and Oracle Connection Manager.

Configuring Directory Server for Oracle Net Usage

Configure directory server usage.

Tool used to perform the task: Oracle Internet Directory Configuration Assistant. See *Oracle Fusion Middleware Administering Oracle Internet Directory*.

Add users to the OracleNetAdmins group.

Tool used to perform the task: ldapmodify. See Who Can Add or Modify Entries in the Directory Server.

Authenticate with the directory.

Tools used to perform the task: Oracle Enterprise Manager Cloud Control, Oracle Net Manager. See Online help in Oracle Enterprise Manager Cloud Control and Online help in Oracle Net Manager.

Change Oracle Context.

Tool used to perform the task: Oracle Net Manager. See Online help in Oracle Net Manager.

Configuring Naming Methods

Configure the local naming method.

Tool used to perform the task: Oracle Enterprise Manager Cloud Control, Oracle Net Manager, Oracle Net Configuration Assistant. See Configuring the Local Naming Method.

Configure the directory naming method.

Tool used to perform the task: Oracle Enterprise Manager Cloud Control, Oracle Net Manager. See Configuring the Directory Naming Method.

Configure the Easy Connect naming method.

Tool used to perform the task: Oracle Net Manager. See Understanding the Easy Connect Naming Method.

Configure the Centralized Config Provider naming method.

Tool used to perform the task: Microsoft Azure portal, Oracle Cloud Infrastructure console, or command line interface (CLI). See Configuring the Centralized Configuration Provider Naming Method.

Migrating to Directory Naming

Export from tnsnames.ora files.

Tools used to perform the task: Oracle Enterprise Manager Cloud Control, Oracle Net Manager. See Export Directory Naming Entries to the tnsnames.ora file.

Configuring Profiles

Prioritize naming methods.

Tool used to perform the task: Oracle Net Manager, Oracle Net Configuration Assistant. See Prioritizing Naming Methods.

 Configure a default domain that is automatically appended to any unqualified network service name.

Tool used to perform the task: Oracle Net Manager, Oracle Net Configuration Assistant. See About the Default Domain for Clients.

Route connection requests.

Tool used to perform the task: Oracle Net Manager, Oracle Net Configuration Assistant. See Routing Connection Requests to a Process.

Configure access control.

Tool used to perform the task: Oracle Net Manager. See Configuring Database Access Control.

Configure an authentication method.

Tool used to perform the task: Oracle Net Manager. See Configuring Oracle Network Security.

Configure connect request timeouts.

Tool used to perform the task: Manual configuration. See Limiting Resource Consumption by Unauthorized Users.

Configuring Listeners

Configure listening protocol addresses.

Tool used to perform the task: Oracle Enterprise Manager Cloud Control, Oracle Net Manager, Oracle Net Configuration Assistant. See Configuring Listening Protocol Addresses.

Configure dynamic service registration.

Tool used to perform the task: Automatic configuration. See Configuring Dynamic Service Registration.

Configure static service registration.

Tool used to perform the task: Oracle Enterprise Manager Cloud Control, Oracle Net Manager. See Configuring Static Service Registration.

Configure connect request timeouts.

Tool used to perform the task: Manual configuration. See Limiting Resource Consumption by Unauthorized Users.

Administering Listeners

Start and stop listeners.

Tool used to perform the task: Listener Control Utility. See Starting and Stopping a Listener.

View registered information.

Tool used to perform the task: Listener Control Utility. See Monitoring Services of a Listener.

Configuring Oracle Connection Manager

Configure session multiplexing.

Tool used to perform the task: Manual configuration. See Enabling Session Multiplexing for Oracle Connection Manager.

Configure access control.

Tool used to perform the task: Manual configuration. See Enabling Access Control.

Configuring Naming Methods

Find out how to configure connectivity information for client connections to the database server.

Configuring the Local Naming Method

The local naming method adds network service names to the tnsnames.ora file. Each network service name maps to a connect descriptor.

Configuring the Directory Naming Method

With this naming method, connect identifiers are mapped to connect descriptors contained in an LDAP-compliant directory server, such as Oracle Internet Directory, Oracle Unified Directory, or Microsoft Active Directory.

Configuring the Centralized Configuration Provider Naming Method

With this naming method, connect identifiers are mapped to connect descriptors contained in a Centralized Configuration Provider, such as Azure App Configuration store or Oracle Cloud Infrastructure (OCI) Object Storage as a JSON file.

Configuring the Easy Connect Naming Method

The Easy Connect naming method eliminates the need for service name lookup in tnsnames.ora files for TCP/IP environments. In fact, no naming or directory system is required when using this method.

Related Topics

Understanding Naming Methods

Oracle Net Services offers several types of naming methods that support localized configuration on each client, or centralized configuration that can be accessed by all clients in the network.

8.1 Configuring the Local Naming Method

The local naming method adds network service names to the tnsnames.ora file. Each network service name maps to a connect descriptor.

The following example shows the network service name sales mapped to the connect descriptor contained in DESCRIPTION. The DESCRIPTION section contains the protocol address and identifies the destination database service. In this example, the protocol is TCP/IP and the port is 1521.

Example 8-1 Connector Descriptor with Host Name

```
sales=
(DESCRIPTION=
   (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
(CONNECT_DATA=
        (SERVICE_NAME=sales.us.example.com)))
```

The following example shows a valid tnsnames.ora entry to connect to a host identified with an IPv6 address and a port number of 1522.

Example 8-2 Connect Descriptor with IPv6 Address

You can configure local naming during or after installation, as described in the following sections:

- Configuring the tnsnames.ora File During Installation
- Configuring the this names or a File After Installation
 You can add network service names to the this names or a file at any time after installation.

Related Topics

IPv6 Network Connectivity

8.1.1 Configuring the trsnames.ora File During Installation

Oracle Net Configuration Assistant enables you to configure network service names for clients. Oracle Universal Installer launches Oracle Net Configuration Assistant after software installation. The configuration varies depending on the installation mode.

- Administrator or runtime installation: Oracle Net Configuration Assistant prompts you to configure network service names in the tnsnames.ora file to connect to an Oracle Database service.
- Custom installation: Oracle Net Configuration Assistant prompts you to select naming methods to use. If local is selected, then Oracle Net Configuration Assistant prompts you to configure network service names in the tnsnames.ora file to connect to an Oracle Database service.

8.1.2 Configuring the thsnames.ora File After Installation

You can add network service names to the tnsnames.ora file at any time after installation.

To configure the local naming method, perform the following tasks:

- Task 1, Configure Net Services Names
- Task 2, Configure Local Naming as the First Naming Method
- Task 3, Copy the Configuration to the Other Clients
- Task 4, Configure the Listener
- Task 5, Connect to the Database

The underlying network connection must be operational before attempting to configure connectivity with Oracle Net.

Task 1 Configure Net Services Names

To configure the network services names, use one of the following methods:

- Net Services Names Configuration using Oracle Enterprise Manager Cloud Control
- Net Services Names Configuration using Oracle Net Manager
- Net Services Names Configuration using Oracle Net Configuration Assistant

Each method provides similar functionality. However, Oracle Net Manager has more configuration options for the sqlnet.ora file.

Net Services Names Configuration using Oracle Enterprise Manager Cloud Control

The following procedure describes how to configure network service names in the tnsnames.ora file with Oracle Enterprise Manager Cloud Control:

 Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

"Accessing the Net Services Administration Page"

- 2. Select **Local Naming** from the Administer list, and then select the Oracle home that contains the location of the configuration files.
- **3.** The Local Naming page appears. You may be prompted to log in to the database server.
- 4. Click Create Like.

The Create Net Service Name page appears.

5. Enter a name in the Net Service Name field.

You can qualify the network service name with the client's domain. The network service name is automatically domain qualified if the sqlnet.ora file parameter NAMES.DEFAULT DOMAIN is set.

"About the Default Domain for Clients"

- **6.** In the Database Information section, configure service support as follows:
 - a. Enter a destination service name.

"About Connect Descriptors" for additional information about the service name string to use

b. Select a database connection type.

The default setting of Database Default is recommended for the connection type. If dedicated server is configured in the initialization parameter file, then you can select Dedicated Server to force the listener to spawn a dedicated server, bypassing shared server configuration. If shared server is configured in the initialization parameter file and you want to guarantee the connection always uses shared server, then select Shared Server.

"Configuring a Shared Server Architecture " for additional information about shared server configuration

- 7. In the Addresses section, configure protocol support, as follows:
 - a. Click Add.

The Add Address page appears.

- **b.** From the Protocol list, select the protocol on which the listener is configured to listen. This protocol must also be installed on the client.
- Enter the appropriate parameter information for the selected protocol in the fields provided.

See Also:

Oracle Database Net Services Reference for additional information about protocol parameter settings

d. (Optional) In the Advanced Parameters section, specify the I/O buffer space limit for send and receive operations of sessions in the Total Send Buffer Size and Total Receive Buffer Size fields.

See Also:

"Configuring I/O Buffer Space " for additional information about buffer space

e. Click OK.

The protocol address is added to the Addresses section.

8. Click **OK** to add the network service name.

The network service name is added to the Local Naming page.

- 9. Select connect-time failover and client load balancing option for the addresses.
- 10. Click OK.

- "Creating a List of Listener Protocol Addresses" to configure multiple protocol addresses
- "About the Advanced Connect Data Parameters" to configure additional CONNECT_DATA options

Net Services Names Configuration using Oracle Net Manager

The following procedure describes how to configure network service names in the tnsnames.ora file with Oracle Net Manager:

1. Start Oracle Net Manager.

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, select **Service Naming** from Local.
- 3. Click the plus sign (+) from the toolbar, or select **Create** from the Edit menu. The Welcome page of the Net Service Name wizard appears.
- 4. Enter a name in the Net Service Name field.

You can qualify the network service name with the client's domain. The network service name is automatically domain qualified if the sqlnet.ora file parameter NAMES.DEFAULT_DOMAIN is set.

"About the Default Domain for Clients"

5. Click Next.

The Protocol page appears.

- 6. Select the protocol on which the listener is configured to listen. The protocol must also be installed on the client.
- 7. Click Next.

The Protocol Settings page appears.

Enter the appropriate parameter information for the selected protocol in the fields provided.

Oracle Database Net Services Reference for additional information about protocol parameter settings

9. Click Next.

The Service page appears.

10. Enter a destination service name, and optionally, select a database connection type.

Oracle recommends that you use the default setting of Database Default for the connection type. If dedicated server is configured in the initialization parameter file, then you can select Dedicated Server to force the listener to spawn a dedicated server, bypassing shared server configuration. If shared server is configured in the initialization parameter file and you want to guarantee the connection always uses shared server, then select Shared Server.

See Also:

- Configuring a Shared Server Architecture for additional information about shared server configuration
- "About Connect Descriptors" for additional information about the service name string to use

11. Click Next.

The Test page appears.

Click Test to verify that the network service name works, or click Finish to dismiss the Net Service Name wizard.

If you click Test, then Oracle Net connects to the database server by using the connect descriptor information you configured. Therefore, the listener and database must be running for a successful test. If they are not, then see "Starting Oracle Net Listener and the Oracle Database Server" to start components before testing. During testing, a Connection Test dialog box appears, providing status and test results. A successful test results in the following message:

The connection test was successful.

If the test was successful, then click **Close** to close the Connect Test dialog box, and proceed to Step 13.

If the test was not successful, then do the following:

- a. Ensure that the database and listener are running, and then click **Test**.
- **b.** Click **Change Login** to change the user name and password for the connection, and then click **Test**.
- 13. Click Finish to close the Net Service Name wizard.
- 14. Select Save Network Configuration from the File menu.

- "Creating a List of Listener Protocol Addresses" to configure multiple protocol addresses
- "About the Advanced Connect Data Parameters" to configure additional CONNECT_DATA options

Net Services Names Configuration using Oracle Net Configuration Assistant

The following procedure describes how to configure network service names in the tnsnames.ora file with Oracle Net Configuration Assistant:

1. Start Oracle Net Configuration Assistant.

"Using Oracle Net Configuration Assistant to Configure Network Components"

The Welcome page appears.

2. Select Local Net Service Name Configuration, and then click Next.

The Net Service Name Configuration page appears.

Click Add, and then click Next.

The Service Name Configuration page appears.

- 4. Enter a service name in the Service Name field.
- 5. Click Next.
- Follow the prompts in the wizard and online help to complete network service name creation.

Task 2 Configure Local Naming as the First Naming Method

Configure local naming as the first method specified in the NAMES.DIRECTORY_PATH parameter in the sqlnet.ora file. This parameter specifies the order of naming methods Oracle Net uses to resolve connect identifiers to connect descriptors.

To configure the local naming method as the first naming method, use one of the following methods:

- Local Naming Configuration using Oracle Enterprise Manager Cloud Control
- Local Naming Configuration using Oracle Net Manager

Each method provides the same functionality.

Local Naming Configuration using Oracle Enterprise Manager Cloud Control
The following procedure describes how to specify local naming as the first naming method using Oracle Enterprise Manager Cloud Control:

 Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

"Accessing the Net Services Administration Page"

- Select Network Profile from the Administer list.
- Click Go.
- 4. Select Naming Methods.
- 5. Select **TNSNAMES** from the Available Methods list.
- Click Move to move the selection to the Selected Methods list.
- 7. Use the **Promote** button to move TNSNAMES to the top of the list.
- 8. Click OK.

Local Naming Configuration using Oracle Net Manager

The following procedure describes how to specify local naming as the first naming method using Oracle Net Manager:

1. Start Oracle Net Manager.

See Also:

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, select **Profile** from the Local menu.
- 3. From the list in the right pane, select Naming.
- 4. Click the **Methods** tab.
- 5. From the Available Methods list, select **TNSNAMES**, and then click the right-arrow button.
- From the Selected Methods list, select TNSNAMES, and then use the Promote button to move the selection to the top of the list.
- 7. Choose Save Network Configuration from the File menu.

The sqlnet.ora file updates with the NAMES.DIRECTORY_PATH parameter, listing tnsnames first:

NAMES.DIRECTORY_PATH=(tnsnames, EZCONNECT)

Task 3 Copy the Configuration to the Other Clients

After one client is configured, copy the tnsnames.ora and sqlnet.ora configuration files to the same location on the other clients. This ensures that the files are consistent. Alternatively, you can use Oracle Net Assistant on every client.

Task 4 Configure the Listener

Ensure that the listener located on the server is configured to listen on the same protocol address configured for the network service name. By default, the listener is configured for the TCP/IP protocol on port 1521.

Configuring and Administering Oracle Net Listener for listener configuration details

Task 5 Connect to the Database

Clients can connect to the database using the following syntax:

CONNECT username@net service name

8.2 Configuring the Directory Naming Method

With this naming method, connect identifiers are mapped to connect descriptors contained in an LDAP-compliant directory server, such as Oracle Internet Directory, Oracle Unified Directory, or Microsoft Active Directory.

A directory provides central administration of database services and network service names, making it easier to add or relocate services.

You can specify the protocol-specific and directory usage parameters either in external configuration files (such as ldap.ora and sqlnet.ora) or directly in a database client connection identifier.

- Configure Net Service Name, Database Service, and Alias Entries
 You can use Oracle Enterprise Manager Cloud Control and Oracle Net Manager to
 configure network service names, network service alias entries, and database service
 entries. Clients can use these entries to connect to the database.
- Create Multiple Default Contexts in a Directory Naming Server
 To enable multiple default contexts, define the orclCommonContextMap with a list of associations between a domain and a DN to be used as the default oracleContext.
- Export Local Naming Entries to a Directory Naming Server
 If a tnsnames.ora file already exists, then you can export the network service names stored in that file to a directory server. These tasks assume the directory server has been installed and is running.
- Configure the LDAP Naming Adapter to Use Wallets
 The client LDAP naming adapter authenticates the LDAP bind while connecting to the LDAP directory to resolve connect string names. You can configure the adapter to use an Oracle wallet during the authentication.
- Specify LDAP Parameters Directly in a Connect Identifier
 The Directory Naming method provides an alternative way to specify LDAP name lookup, by using LDAP parameters in a database client connection identifier. With this feature, you do not need to configure external configuration files (ldap.ora or sqlnet.ora) to connect to the database.
- Export Directory Naming Entries to the tnsnames.ora file
 After you create the directory naming entries, consider exporting the entries to a local tnsnames.ora file and distributing that file to clients. Clients can use the locally saved file when the directory server is temporarily unavailable.

8.2.1 Configure Net Service Name, Database Service, and Alias Entries

You can use Oracle Enterprise Manager Cloud Control and Oracle Net Manager to configure network service names, network service alias entries, and database service entries. Clients can use these entries to connect to the database.

1. Verify Directory Compatibility:

On the computer from which you plan to create network service names, do the following verification steps:

- a. Ensure the computer has the latest release of Oracle Net Services software. The release information is located in the About Net Manager option on the help menu.
- Run Oracle Internet Directory Configuration Assistant to verify directory server, Oracle Context, and Oracle schema releases.

2. Create Net Service Names in the Directory:

You can configure clients to use a network service name rather than the database service entry.

Note:

- Only users that are members of either the OracleNetAdmins or
 OracleContextAdmins group can create network service name entries in a
 directory. To add or remove users from the OracleNetAdmins group, see Who
 Can Add or Modify Entries in the Directory Server.
- You can export existing network service names from a tnsnames.ora file.
 See Exporting Local Naming Entries to a Directory Naming Server.
- a. Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control. See Accessing the Net Services Administration Page.
- **b.** Select **Directory Naming** from the Administer list, and then select the Oracle home that contains the location of the directory server.
- c. Click Go.

The Directory Naming page appears.

- d. Click the Net Service Names tab.
- e. In the Results section, click Create.

The Create Net Service Name page with the General tab appears.

- f. Enter a name in the **Net Service Name** field.
- g. In the Database Information section, configure service support, as follows:
 - i. Enter a destination service name. See About Connect Descriptors.
 - ii. Select a database connection type. Oracle recommends that you use the Database Default for the connection type. If a shared server is configured in the initialization parameter file, then the following options are available:
 - Select Dedicated Server to force the listener to spawn a dedicated server, and bypass shared server configuration.
 - Select Shared Server to guarantee the connection always uses shared server.

See Configuring a Shared Server Architecture.

- h. In the Addresses section, configure protocol support:
 - Click Add.

The Add Address page appears.

- ii. From the Protocol list, select the protocol that the listener is configured to listen. This protocol must also be installed on the client.
- iii. Enter the appropriate parameter information for the selected protocol in the fields provided.

See Oracle Database Net Services Reference.

Note:

Optionally, you can specify LDAP parameters directly in the connect identifier, instead of configuring the sqlnet.ora file. See Specify LDAP Parameters Directly in a Connect Identifier.

- iv. (Optional) In the Advanced Parameters section, specify the I/O buffer space limit for send and receive operations of sessions in the Total Send Buffer Size and Total Receive Buffer Size fields. See Configuring I/O Buffer Space.
- v. Click OK.

The protocol address is added to the Addresses section.

i. Click **OK** to add the network service name.

The network service name is added to the Results section of the **Net Service Names** tab.

See Creating a List of Listener Protocol Addresses to configure multiple protocol addresses. See About the Advanced Connect Data Parameters to configure additional CONNECT DATA options.

3. Create or Modify Connectivity Information for Database Service Entries:

A database service entry is created during installation. When database registration with the directory naming completes, a database service entry is created in the directory. By default, this entry contains network route information with the location of the listener through a protocol address. You can re-create this information or modify the existing network route information.

Note:

Only users that are members of the <code>OracleNetAdmins</code> or <code>OracleContextAdmins</code> group can modify network information for a database service in a directory. To add or remove users from these groups, see Who Can Add or Modify Entries in the <code>Directory Server</code>.

- a. Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control. See Accessing the Net Services Administration Page.
- **b.** Select **Directory Naming** from the Administer list, and then select the Oracle home that contains the location of the directory server.
- c. Click Go. You may be prompted to log in to the database server and the directory server.

The Directory Naming page appears.

Click the Database Services tab.

e. In the Simple Search section, select **Oracle Context** and search criteria to see the network service names for Oracle Context.

The database service names display in the Results section.

f. In the Results section, select a database service, and then click **Edit**.

4. Create Net Services Aliases:

Net service aliases in a directory server enable clients to refer to a database service or a network service name by an alternative name. For example, a network service alias of salesalias can be created for a network service name of sales. When salesalias is used to connect to a database, as in CONNECT scott@salesalias, it resolves to and use the connect descriptor information for sales.

There are two main uses of network service aliases:

- Use a network service alias as a way for clients to refer to a database service or network service name by another name.
- Use a network service alias in one Oracle Context for a database service or network service name in a different Oracle Context. This enables a database service or network service name to be defined once in the directory server, and referred to by clients that use other Oracle Contexts. See <u>Understanding Net Service Alias Entries</u> for an overview of network service aliases.

Note:

- Only users that are members of either the OracleNetAdmins or
 OracleContextAdmins group can create or modify network service alias
 entries in a directory. To add or remove users from the OracleNetAdmins
 group, see Who Can Add or Modify Entries in the Directory Server.
- Net service aliases are not supported by Microsoft Active Directory.
- Ensure the NLS_LANG environment variable is set for the clients when using network service aliases.

To create a network service alias, use one of the following methods. Each method provides similar functionality:

Network Service Alias Configuration using Oracle Enterprise Manager Cloud Control

The following procedure describes how to configure a network service alias using Oracle Enterprise Manager Cloud Control:

- a. Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control. See Accessing the Net Services Administration Page.
- **b.** Select **Directory Naming** from the Administer list, and then select the Oracle home that contains the location of the directory server.
- c. Click Go.

The Directory Naming page appears.

- d. Click the Net Service Aliases tab.
- e. In the Results section, click Create.

The Create Net Service Alias page appears.

- Enter a name for the alias in the Net Service Alias Name field.
- g. In the Referenced Service Detail section, enter the following information in the fields:
 - Oracle Context: Select the Oracle Context of the database service or network service name from the list or enter one in the field.
 - Referenced Service Name: Select the DN of the database service or network service name.
- h. Click **OK** to add the network service alias.

The network service alias is added to the Directory Naming page.

Network Service Alias Configuration using Oracle Net Manager

The following procedure describes how to configure a network service alias using Oracle Net Manager:

- Start Oracle Net Manager. See Using Oracle Net Manager to Configure Oracle Net Services
- b. In the navigator pane, select Service Naming from Directory.
- c. Select Aliases.
- d. Select Create from the Edit menu.
- e. Enter the network service alias in the Net Service Alias field.
- f. Select Oracle Context and name.
- g. Click Create.
- h. Select Save Network Configuration from the File menu.

5. Configure LDAP as the First Naming Method for Client Lookups:

Configure directory naming as the first method to be used in the NAMES.DIRECTORY_PATH parameter in the sqlnet.ora file. This parameter specifies the order of naming methods Oracle Net uses to resolve connect identifiers to connect descriptors.

To configure LDAP as the first naming method you can use one of the following methods:

LDAP Configuration using Oracle Enterprise Manager Cloud Control

The following procedure describes how to specify directory naming as the first naming method using Oracle Enterprise Manager Cloud Control:

- Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control. See Accessing the Net Services Administration Page.
- Select Network Profile from the Administer list.
- c. Click Go.
- d. Select Naming Methods.
- e. Select LDAP from the Available Methods list.
- f. Click **Move** to move the selection to the Selected Methods list.
- g. Use the **Promote** button to move LDAP to the top of the list.
- h. Click OK.

LDAP Configuration using Oracle Net Manager

The following procedure describes how to specify directory naming as the first naming method using Oracle Net Manager:

- Start Oracle Net Manager. See Using Oracle Net Manager to Configure Oracle Net Services.
- b. In the navigator pane, select **Profile** from the Local menu.
- c. From the list in the right pane, select Naming.
- d. Click the Methods tab.
- From the Available Methods list, select LDAP, and then click the right-arrow button.
- f. From the Selected Methods list, select LDAP, and then use the Promote button to move the selection to the top of the list.
- g. Select Save Network Configuration from the File menu.

The sqlnet.ora file updates with the NAMES.DIRECTORY_PATH parameter, listing ldap first, such as the following:

```
NAMES.DIRECTORY PATH=(ldap, tnsnames, hostname)
```

6. Configure the Listener:

Ensure that the listener located on the server is configured to listen on the same protocol address configured for the network service name. By default, the listener is configured to listen on the TCP/IP protocol, port 1521. See Configuring and Administering Oracle Net Listener for listener configuration details.

7. Connect to the Database:

Clients that are configured with a default directory entry that matches the directory location of the database service or network service name can connect to the database using the following syntax:

```
CONNECT username@connect_identifier
```

Clients that are configured with a default directory entry that does not match the entry's directory location must use the entry's distinguished name or its fully-qualified name. See Understanding the Directory Information Tree for fully-qualified name usage.

8.2.2 Create Multiple Default Contexts in a Directory Naming Server

To enable multiple default contexts, define the orclCommonContextMap with a list of associations between a domain and a DN to be used as the default oracleContext.

If you want clients to use discovery in directories which have more than one Oracle Context, then you can define the <code>orclCommonContextMap</code> attribute in the base <code>admin</code> context. This attribute overrides the <code>orclDefaultSubscriber</code> attribute. During name lookup the discovery operation returns both values, and the client decides based on these which Oracle Context to use.

If the orclCommonContextMap attribute is not defined, then the orclDefaultSubscriber is used as the default. If orclCommonContextMap is defined, then the client finds the default Oracle Context which is associated with its DNS domain in the orclCommonContextMap.

Here is a sample LDIF file entry:

```
$ ldapmodify -v -h sales-server -p 1389 -D cn=orcladmin -q
dn: cn=Common,cn=Products,cn=OracleContext
replace: orclCommonContextMap
orclCommonContextMap:
(contextMap=
```

```
(domain_map=(domain=us.example.com) (DN="dc=example,dc=com"))
  (domain_map=(domain=uk.example.com) (DN="dc=sales,dc=com"))
```

You must enter a contextMap entry without line breaks.

8.2.3 Export Local Naming Entries to a Directory Naming Server

If a tnsnames.ora file already exists, then you can export the network service names stored in that file to a directory server. These tasks assume the directory server has been installed and is running.

The export procedure is performed for one domain at a time.

Task 1 Create Structure in the Directory Server

In the directory server, create the directory information tree (DIT) with the structure in which you want to import network service names. Create the structure leading to the top of the Oracle Context.

For example, if the tnsnames.ora file supports a domain structure example.com and you want to replicate this domain in the directory, then create domain component entries of dc=com and dc=example in the directory, as shown in the following figure.

Figure 8-1 example.com in Directory Server

You can replicate the domain structure you currently use with tnsnames.ora, or you can develop an entirely different structure. Introducing an entirely different structure can change the way clients enter the network service name in the connect string. Oracle recommends considering relative and fully-qualified naming issues before changing the structure.

Task 2 Create Oracle Contexts

Create an Oracle Context under each DIT location that you created in Task 1 using Oracle Internet Directory Configuration Assistant. Oracle Context has a relative distinguished name (RDN) of cn=OracleContext. Oracle Context stores network object entries, as well as other entries for other Oracle components. In the following figure, cn=OracleContext is created under dc=example, dc=com.

Figure 8-2 Oracle Context

Task 3 Configure Directory Server Usage

If not done as a part of creating Oracle Contexts, then configure the Oracle home for directory server use. The Oracle home you configure should be the one that performs the export.

Task 4 Export Objects to a Directory Server

To export network service names contained in a tnsnames.ora file to a directory, use either Oracle Enterprise Manager Cloud Controlr or Oracle Net Manager.

Export Objects using Oracle Enterprise Manager Cloud Control

The following procedure describes how to export objects using Oracle Enterprise Manager Cloud Control

- Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control. See Accessing the Net Services Administration Page.
- 2. Select **Directory Naming** from the Administer list, and then select the Oracle home that contains the location of the directory server.
- 3. Click Go.

The Directory Naming page appears.

- Click the Net Service Names tab.
- In the Related Links section, click Import Net Service Names To Directory Server.
 The Import Net Service Names To Directory Server page appears.
- From the Oracle Context list in the Oracle Internet Directory Server Destination section, select Oracle Context to which you want to export the selected network service names.
- 7. In the Net Service Names to Import section, select the network service names.
- Click Add to add the network service names to the directory.
 The network service name is added to the Directory Naming page.

Export Objects using Oracle Net Manager

The following procedure describes how to export objects using Oracle Net Manager:

- Start Oracle Net Manager. See Using Oracle Net Manager to Configure Oracle Net Services.
- 2. If the tnsnames.ora file you want to export is not loaded in Oracle Net Manager, then select **Open Network Configuration** from the File menu to select the tnsnames.ora file to export to the directory.
- Select Directory from the Command menu, and then select Export Net Service Names.

The Directory Server Migration wizard starts.

Click Next.

If network service names with multiple domain were detected in the tnsnames.ora file, then the Select Domain page appears. Continue to Step 5.

If the network service names are not domain qualified, then the Select Net Service Names page appears. Skip to Step 6.

Select the network domain whose network service names you want to export, and then click Next.

The Select Net Service Names page appears.

- 6. Select the network service names from the list to export, and then click Next.
 - The Select Destination Context page appears.
- 7. In the Select Destination Context page, do the following:
 - a. From the Directory Naming Context list, select the directory entry that contains the Oracle Context. The directory naming context is part of a directory subtree that contains one or more Oracle Contexts.
 - **b.** From the Oracle Context list, select the Oracle Context to which you want to export the selected network service names.
 - c. Click Next.

The Directory Server Update page appears with the status of the export operation.

8. Click **Finish** to close the Directory Server Migration wizard.

Related Topics

- Client Connections Using Directory Naming
 Most clients needing to perform name lookups in the directory server access the directory
 server using anonymous authentication.
- Managing Network Address Information
 Identify how the network address information for Oracle Net Services can be stored in local files or in a centralized directory server.

8.2.4 Configure the LDAP Naming Adapter to Use Wallets

The client LDAP naming adapter authenticates the LDAP bind while connecting to the LDAP directory to resolve connect string names. You can configure the adapter to use an Oracle wallet during the authentication.

- Obtain an LDAP server certificate, create an Oracle wallet, and store the certificate and LDAP user credentials in the wallet truststore:
 - a. Obtain an LDAP server certificate from the LDAP directory server using openssl s client:

```
openssl s client -connect LDAP server host:port -showcerts -outform PEM
```

The -connect LDAP server host:port option specifies the LDAP directory server host name and port for the connection. The -showcerts option displays the LDAP server certificate list sent by the server. The -outform PEM option extracts the server certificate to your file system directory (for example, /tmp/ldapservercert.txt) in a PEM format.

b. Create an empty Oracle wallet:

```
orapki wallet create -wallet wallet directory
```

The -wallet wallet_directory option specifies the location of the file system directory where you want to create the wallet.

c. Add the LDAP server certificate to the wallet:

```
orapki wallet add -wallet wallet_directory -trusted_cert -cert
```

The -cert option specifies the location of the file system directory (for example, / tmp/ ldapservercert.txt) where you have stored the LDAP server certificate.

d. Create an entry in the wallet with the DN of the LDAP user name:

```
mkstore -wrl wallet_directory -createEntry oracle.ldap.client.dn
dn of ldap username
```

For example:

```
mkstore -wrl /app/wallet -createEntry oracle.ldap.client.dn
cn=userinldap,dc=example,dc=com
```

For Microsoft Active Directory, you can also specify the userPrincipalName or down-level logon name (samaccountName) attribute.

e. Create an entry in the wallet with the LDAP password:

```
mkstore -wrl wallet_directory -createEntry oracle.ldap.client.password
ldap password
```

f. Enable auto-login for the wallet:

```
orapki wallet create -wallet wallet directory -auto login
```

Note:

- The mkstore wallet management command line tool is deprecated with Oracle Database 23ai, and can be removed in a future release.
 To manage wallets, Oracle recommends that you use the orapki command line tool.
- Auto-login wallets are protected by file system permissions. Use operating system utilities to protect the wallet directory by granting read and write permissions only to the client.
- Oracle has introduced a new auto-login wallet version (7) with Oracle Database 23ai. Version 6 of the Oracle local auto-login wallet is deprecated.

You can update your local auto-login wallet by modifying it with orapki.

2. Use the WALLET_LOCATION parameter to specify your wallet directory in the sqlnet.ora file:

For example:

For detailed information on configuring this parameter, see WALLET_LOCATION.

The parameter WALLET_LOCATION is deprecated for use with Oracle Database 23ai for the Oracle Database server. It is not deprecated for use with the Oracle Database client or listener.

For Oracle Database server, Oracle recommends that you use the WALLET_ROOT system parameter instead of using WALLET LOCATION.

- Configure authentication settings for your LDAP connection in the sqlnet.ora file:
 - Set NAMES.LDAP_AUTHENTICATE_BIND=TRUE to specify that the LDAP connection is
 authenticated using the wallet directory (defined by WALLET LOCATION).
 - Set NAMES.LDAP_AUTHENTICATE_BIND_METHOD=LDAPS_SIMPLE_AUTH to use simple authentication method over LDAPS (LDAP over TLS connection).

For detailed information on configuring these settings, see NAMES.LDAP_AUTHENTICATE_BIND and NAMES.LDAP_AUTHENTICATE_BIND_METHOD.

- 4. Using Oracle Net Manager, add one or more directory entries to the LDAP server.
- 5. Using SQL*Plus or any other database client, verify names resolution.

Authentication Methods

Clients use different methods of authentication depending upon the task to be performed, such as resolving connect string names and managing directory entries.

Oracle Database Security Guide

8.2.5 Specify LDAP Parameters Directly in a Connect Identifier

The Directory Naming method provides an alternative way to specify LDAP name lookup, by using LDAP parameters in a database client connection identifier. With this feature, you do not need to configure external configuration files (ldap.ora or sqlnet.ora) to connect to the database.

The values that are specified as part of ldap.ora and sqlnet.ora for LDAP name lookup are directly passed in the connect identifier. If ldap.ora or sqlnet.ora is present and you use LDAP parameters in the connect identifier, then the connect identifier values take precedence.

Syntax for the Connect Identifier

ldap[s]://host[:port]/name[,context][?parameter1=value1{¶meter2=value2}]

For example:

sqlplus "<user_name>/<password>@ldaps://<host_name>:<port>/
cn=sales,cn=oraclecontext?DIRECTORY_SERVER_TYPE=oid&WALLET_LOCATION=/oracle/
network/
admin&AUTHENTICATE BIND=true&AUTHENTICATE BIND METHOD=LDAPS SIMPLE AUTH"

Here, $<\!\!\mathit{user_name}\!\!>/<\!\!\mathit{password}\!\!>$ specify the database user name and password for the connection.

The following are protocol-specific parameters specified using ldap[s]://host[:port]/name[,context]:

Syntax Element	Description	Default Value
ldap[s]	This is a mandatory parameter. Specifies the protocol, such as LDAP or LDAPS.	Not applicable
	The LDAPS protocol uses a TLS connection.	
host	This is a mandatory parameter. Specifies the host name where your LDAP directory server is running.	Not applicable
port	This is an optional parameter. Specifies the port number for the LDAP connection.	389 for the LDAP protocol 636 for the LDAPS protocol
name	This is a mandatory parameter. Specifies the LDAP entry to resolve the service name in the connect string.	Not applicable
	This entry must be contained in the OracleContext container of a given context.	
context	This is an optional parameter. Specifies the directory naming context containing OracleContext.	cn=OracleContext
	For example, a context can be:	
	cn=OracleContext,dc=example,dc=com	

The following are directory usage parameters specified using parameter=value. All these are optional parameters:

Syntax Element	Description	Default Value
directory_server_type	Specifies the directory server to use for LDAP-based name lookup.	OID
	The value can be:	
	 OID for Oracle Internet Directory or Oracle Unified Directory AD for Microsoft Active Directory See DIRECTORY_SERVER_TYPE. 	
authenticate_bind	Specifies whether the LDAP naming adapter should use a wallet for authentication.	false
	The value can be true or false.	
	See AUTHENTICATE_BIND.	
wallet_location	Specifies the directory where Oracle wallet is stored. See WALLET_LOCATION.	Not applicable

Syntax Element	Description	Default Value
authenticate_bind_method	Specifies the authentication method for the client LDAP naming adapter.	NONE
	The value can be LDAPS_SIMPLE_AUTH or NONE.	
	See AUTHENTICATE_BIND_METHOD.	

Note:

The directory_server_type, wallet_location, authenticate_bind, and authenticate bind method parameters are position independent.

Sample Connect Identifiers

Let us look at some examples on how to specify a connect identifier with different values:

With all parameters:

All the required and optional parameters are specified in the string.

```
"scott/password@ldaps://ldapserver:636/
cn=orcl,cn=OracleContext,dc=example,dc=com?
DIRECTORY_SERVER_TYPE=oid&WALLET_LOCATION=/
wallet&AUTHENTICATE BIND=true&AUTHENTICATE BIND METHOD=LDAPS SIMPLE AUTH"
```

Without directory server:

The default directory server (OID) is used:

```
"scott/password@ldaps://ldapserver:636/
cn=orcl,cn=OracleContext,dc=example,dc=com?
WALLET_LOCATION=wallet&AUTHENTICATE_BIND=true&AUTHENTICATE_BIND_METHOD=LDAP
S_SIMPLE_AUTH"
```

Without authenticate_bind:

The default authenticate_bind value (false) is used, and thus authenticate_bind_method is ignored.

```
"scott/password@ldaps://ldapserver:636/
cn=orcl,cn=OracleContext,dc=example,dc=com?
DIRECTORY_SERVER_TYPE=oid&WALLET_LOCATION=wallet&AUTHENTICATE_BIND_METHOD=L
DAPS_SIMPLE_AUTH"
```

With admin context:

The context name value is specified as cn=OracleContext, dc=example, dc=com.

```
"scott/password@ldaps://ldapserver:636/
cn=orcl,cn=OracleContext,dc=example,dc=com?
DIRECTORY_SERVER_TYPE=oid&WALLET_LOCATION=/
wallet&AUTHENTICATE BIND=true&AUTHENTICATE BIND METHOD=LDAPS SIMPLE AUTH"
```

· Without admin context:

The context value (cn=OracleContext, dc=example, dc=com) is null.

```
"scott/password@ldaps://ldapserver:636/orcl?
DIRECTORY_SERVER_TYPE=oid&WALLET_LOCATION=/
wallet&AUTHENTICATE BIND=true&AUTHENTICATE BIND METHOD=LDAPS SIMPLE AUTH"
```

With minimal parameters:

A minimal set of protocol-specific parameters are specified (protocol as ldaps, host as ldapserver, port as 636, and context that varies in each string).

```
"scott/password@ldaps://ldapserver:636/
cn=orcl,cn=OracleContext,dc=example,dc=com"

"scott/password@ldaps://ldapserver:636/cn=orcl"

"scott/password@ldaps://ldapserver:636/orcl"
```

Uses system wallet:

The WALLET_LOCATION value is not specified in the connect identifier and sqlnet.ora file. In this case, the client uses wallet from the operating system's default certificate store.

```
"scott/password@ldaps://ldapserver:636/
cn=orcl,cn=OracleContext,dc=example,dc=com?DIRECTORY SERVER TYPE=oid"
```

With the LDAP protocol:

The LDAP protocol is specified for OID configuration in these strings.

```
"scott/password@ldap://ldapserver:2389/
cn=orcl,cn=OracleContext,dc=example,dc=com?
DIRECTORY_SERVER_TYPE=oid&AUTHENTICATE_BIND=false"

"scott/password@ldap://ldapserver:2389/
cn=orcl,cn=OracleContext,dc=example,dc=com"
```

With directory server along with user name and password authentication

The DIRECTORY_SERVER_TYPE value is specified as AD (to use Microsoft Active Directory). The AUTHENTICATE_BIND and AUTHENTICATE_BIND_METHOD values specify LDAPS SIMPLE AUTH, which provides user name and password-based authentication.

```
"scott/password@ldaps://ldapserver:636/cn=orcl?
DIRECTORY_SERVER_TYPE=AD&WALLET_LOCATION=/
wallet&AUTHENTICATE_BIND=true&AUTHENTICATE_BIND_METHOD=LDAPS_SIMPLE_AUTH"
```

With directory server along with Windows native authentication

The DIRECTORY_SERVER_TYPE value is specified as AD (to use Microsoft Active Directory). The AUTHENTICATE BIND value is specified as true, which implies the default

LDAPS_SIMPLE_AUTH=NONE setting. This provides Windows native authentication, using Windows login credentials.

"scott/password@ldap://ldapserver:389/cn=orcl? DIRECTORY SERVER TYPE=AD&AUTHENTICATE BIND=true"

8.2.6 Export Directory Naming Entries to the tnsnames.ora file

After you create the directory naming entries, consider exporting the entries to a local tnsnames.ora file and distributing that file to clients. Clients can use the locally saved file when the directory server is temporarily unavailable.

The following procedure describes how to export directory naming entries to a local tnsnames.ora file:

- 1. Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.
- 2. Select **Directory Naming** from the Administer list, and then select the Oracle home that contains the location of the directory server.
- 3. Click Go.

The Directory Naming page appears.

- Click the Net Service Names tab.
- 5. In the Simple Search section, select **Oracle Context** and search criteria to see the network service names for a particular Oracle Context.

The network service names display in the Results section.

6. In the Results section, click Save to tnsnames.ora.

The Processing: Create thsnames.ora File page appears, informing you of the creation process.

Accessing the Net Services Administration Page

8.3 Configuring the Centralized Configuration Provider Naming Method

With this naming method, connect identifiers are mapped to connect descriptors contained in a Centralized Configuration Provider, such as Azure App Configuration store or Oracle Cloud Infrastructure (OCI) Object Storage as a JSON file.

Optionally, you can also store database credentials (such as database user name and database password) and Oracle Call Interface attributes (such as statement_cache_size, prefetch_rows, or session_pool) in a Centralized Configuration Provider. You need to use Azure Key Vault or OCI Vault to store the database password, and then add a reference to that vault in your Centralized Configuration Provider. You can also store an Oracle wallet in Azure Key Vault or OCI Vault, and then add a reference to that vault in your Centralized Configuration Provider.

A connect identifier here includes instance-specific details of a Centralized Configuration Provider (such as server name or app configuration name), path, and authentication details. Database clients can securely look up the configuration data from your Centralized Configuration Provider and connect to the database.

In addition to the Azure App Configuration store and OCI Object Storage, JDBC supports built-in Centralized Configuration Providers such as HTTPS provider and File provider (see *Oracle Database JDBC Developer's Guide*). Also, ODP.NET supports local file system access for web and desktop apps (see *Oracle Data Provider for .NET Developer's Guide*).

Use one of the following Centralized Configuration Providers:

- Azure App Configuration Store
 Stores configuration data in the Azure App Configuration store as key-value pairs, which are accessible with network service name paths as URI.
- OCI Object Storage JSON File
 Stores configuration data in the Oracle Cloud Infrastructure (OCI) Object Storage as a
 JSON file.

Related Topics

Choosing a Naming Method
 Selecting the appropriate naming method for mapping names to connect descriptors depends upon the size of the organization.

8.3.1 Azure App Configuration Store

Stores configuration data in the Azure App Configuration store as key-value pairs, which are accessible with network service name paths as URI.

- Prerequisites for Using the Azure App Configuration Store
 Perform these steps in the Azure portal or using the Azure CLI or API, before beginning to use the Azure App Configuration store.
- Step 1: Create a Key-Value with the Connect Descriptor
 Create a key-value pair with the connect descriptor, which contains the protocol address of the listener and the connect information for the destination service.
- Step 2: Add the User Name and Password Vault Reference (Optional)
 Under the prefix that you used in Step 1, create key-value pairs with the database user name and password for authentication to Oracle Database. The password value is a vault reference.
- Step 3: Add the Wallet Vault Reference (Optional)
 Under the same prefix, create a key-value pair with the wallet location. The wallet location value is a vault reference.
- Step 4: Add Oracle Call Interface Parameters (Optional)
 Under the same prefix, create key-value pairs with Oracle Call Interface configuration parameters.
- Step 5: Use a Connect Identifier Containing Azure App Configuration Store Values
 Use the Azure App Configuration name, key path, and Azure authentication parameters in a database client connection identifier.

8.3.1.1 Prerequisites for Using the Azure App Configuration Store

Perform these steps in the Azure portal or using the Azure CLI or API, before beginning to use the Azure App Configuration store.

Register an OAuth application and grant authorization permissions:

The Azure App Configuration store's administrator must register an OAuth application with Microsoft Entra ID (previously called Microsoft Azure Active Directory) using App Registrations. The administrator must also give authorization permissions to this OAuth application for accessing the Azure App Configuration store.

(Optional) Create Azure Key Vault for secrets and grant authorization permissions:

You can store Oracle Database credentials and Oracle wallet data in Azure Key Vault.

To store Oracle Database credentials:

Create Azure Key Vault with the database password stored as a secret in that vault.

To store Oracle wallet data:

The SQLNET client applications running on multitenant cloud service environments can store wallets in remote stores. Because these applications may not have access to the wallets stored in a local system file, this feature is especially useful for Mutual Transport Layer Security (mTLS) connections that require file system access to keep the wallet.

To store wallet data, you first convert an auto-login wallet file (cwallet.sso) to a Base64 format, and then create Azure Key Vault with the Base64-formatted cwallet.sso value stored as a secret.

1. Convert your cwallet.sso file to a Base64 format.

A common way to convert <code>cwallet.sso</code> to <code>Base64</code> is by using the following <code>openssl</code> command on Linux:

```
cat cwallet.sso | base64 -w 0 > file to upload
```

Here, file to upload specifies the cwallet.sso file that you want to convert.

2. Create Azure Key Vault by pasting contents of the Base64-formatted string of the cwallet.sso file, as secret contents without any new lines.

You will later add a Key Vault reference to this vault in Azure App Configuration. The Azure App Configuration store's administrator must give authorization permissions to the registered OAuth application for accessing this vault.

For detailed information on how to perform these steps, see Azure Key Vault Documentation.

Understand how to organize keys in Azure App Configuration:

Keys ending with <code>connect_descriptor</code>, user, <code>password</code>, and <code>wallet_location</code> serve as identifiers for key-values, and are used to store and retrieve corresponding values for the database connection.

The connect_descriptor keys (keys ending with connect_descriptor) store connection descriptors, also known as TNS connection strings.

It is a common practice to organize keys into a hierarchical namespace by using a character delimiter, such as / (slash), & (ampersand), or : (colon). Use a convention that

suits your application. The examples here use / (slash) as a character delimiter to organize keys.

An application user can organize connect descriptors under a prefix as per application requirements, and set up authentication and authorization for all such keys in Azure App Configuration. Optionally, you can add database credentials (such as the user name and password of database user), wallet location, and Oracle Call Interface attributes under the same prefix:

- prefix/connect_descriptor (required)
- prefix/user (optional)
- prefix/password (optional)
- prefix/wallet location (optional)
- prefix/oci (optional)

The portion of a key without the <code>connect_descriptor</code> suffix is treated as a prefix for deriving the database user name, database password, and OCI attributes. Database clients look for a key ending with the <code>user</code> suffix after the derived prefix is used as the database user name, a key ending with the <code>password</code> suffix for the database password, a key ending with the <code>wallet_location</code> suffix for the wallet directory, and a key ending with the <code>oci</code> suffix for OCI attributes.

A connect identifier contains the part of a key without terminating <code>connect_descriptor</code> as a prefix. Database clients complete the key by appending <code>connect_descriptor</code>, <code>user</code>, <code>password</code>, <code>wallet_location</code>, or <code>oci</code>, and then search the Azure App Configuration store with that key.

Syntax for Azure Centralized Configuration Provider Naming:

```
config-azure://{appconfig-name}[?
key=prefix&label=value&option1=value1&option2=value2...]
```

For example:

```
sqlplus dbuser/@"config-azure://dbclient-appconfig?key=database/sales/
&azure_client_id=client
id&azure_client_secret=secret&azure_tenant_id=tenant_id"
```

This syntax is explained in details in the sections that follow.

Related Topics

Azure App Configuration Documentation

8.3.1.2 Step 1: Create a Key-Value with the Connect Descriptor

Create a key-value pair with the connect descriptor, which contains the protocol address of the listener and the connect information for the destination service.

- 1. In the Azure portal, search for App Configuration, and then navigate to the Configuration explorer page of your Azure App Configuration store.
- 2. Click Create and select Key-value to create a new key-value.
 - Key: Add a key with the connect descriptor suffix for your chosen prefix.

For example, for the database/sales/ prefix, add a key as:

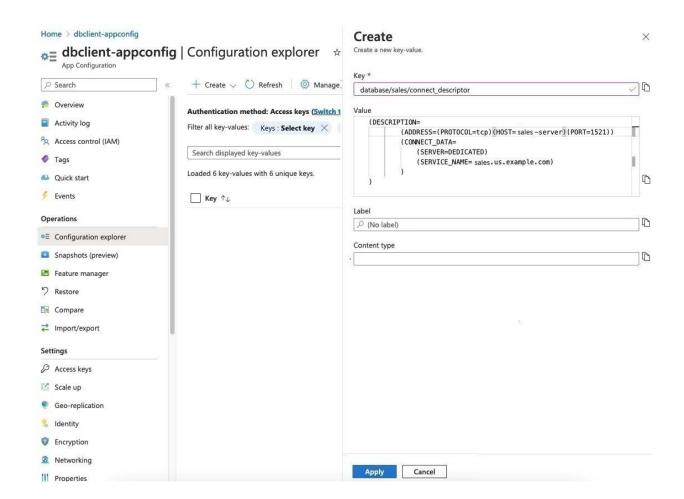

database/sales/connect descriptor

• **Value**: Store a value for your key by specifying the connect descriptor in either the Easy Connect syntax or the connect descriptor format.

The connect descriptor value must start with either (DESCRIPTION= or (DESCRIPTION_LIST=. The DESCRIPTION parameter defines connect descriptor containers. The DESCRIPTION_LIST parameter defines a list of connect descriptors for a service name.

Note:

There are some restrictions on the parameter names and values that can appear in connect descriptors. Ensure that you specify only the allowed parameters and values, as listed in *Oracle Database Net Services Reference*.

As shown in the preceding image, the suffix <code>connect_descriptor</code> in the <code>database/sales/connect_descriptor</code> key is paired with the following connect descriptor value:

Related Topics

Azure App Configuration Documentation: Quickstart

8.3.1.3 Step 2: Add the User Name and Password Vault Reference (Optional)

Under the prefix that you used in Step 1, create key-value pairs with the database user name and password for authentication to Oracle Database. The password value is a vault reference.

This step is optional. With this configuration, you can omit database credentials in the connect identifier for the database connection.

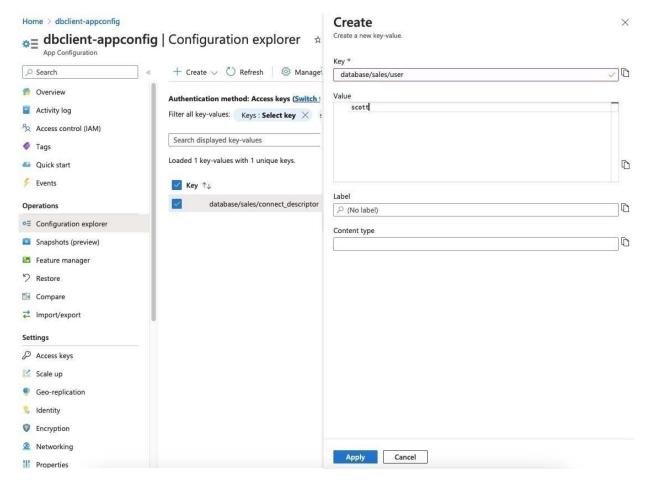

- Ensure that you have created Azure Key Vault with the database password stored as a secret, as explained in Prerequisites for Using the Azure App Configuration Store.
- 2. On the Configuration explorer page of your Azure App Configuration store, click **Create** and select **Key-value** to add a key-value pair with the database user name.
 - Key: Add a key with the user suffix to your chosen prefix.

For example, to the database/sales/ prefix, add a key as:

```
database/sales/user
```

• **Value**: Store a value for your key by specifying the database user name.

As shown in the following image, the suffix user in the database/sales/user key is paired with scott as its value:

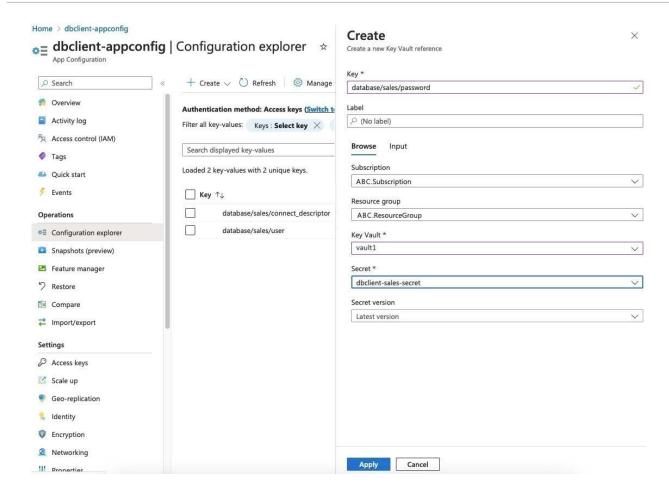

- Click Create and select Key Vault reference to add a key-value pair with the database password.
 - Key: Add a key with the password suffix to your chosen prefix.

For example, to the database/sales/ prefix, add a key as:

database/sales/password

 Value: Select the Key Vault and Secret values corresponding to the Azure Key Vault that you created for storing your database password.

As shown in the following image, the suffix password in the database/sales/password key is paired with dbclient-sales-secret (stored in vault1) as its value:

8.3.1.4 Step 3: Add the Wallet Vault Reference (Optional)

Under the same prefix, create a key-value pair with the wallet location. The wallet location value is a vault reference.

This step is optional. With this configuration, you can store an Oracle wallet in a remote store using Azure App Configuration.

- 1. Ensure that you have created Azure Key Vault with your wallet data stored as a secret, as explained in Prerequisites for Using the Azure App Configuration Store.
- On the Configuration explorer page of your Azure App Configuration store, click Create and select Key Vault reference to add a key-value pair with the wallet location.
 - Key: Add a key with the wallet_location suffix to your chosen prefix.

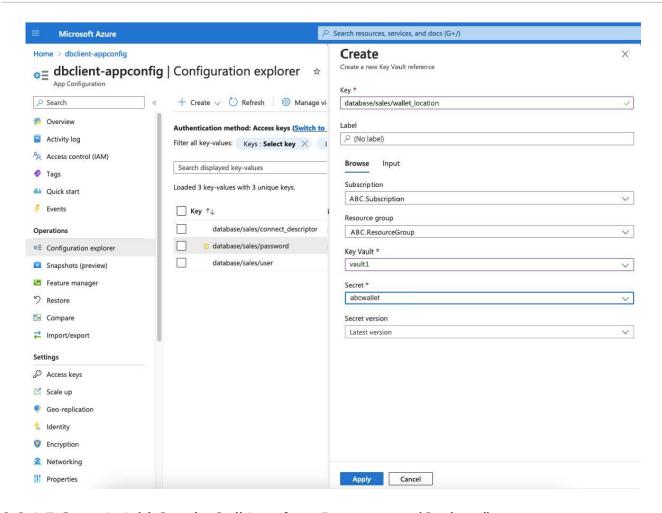

For example, to the database/sales/ prefix, add a key as:

database/sales/wallet location

 Value: Select the Key Vault and Secret values corresponding to the Azure Key Vault that you created for storing your wallet data.

As shown in the following image, the suffix wallet_location in the database/sales/wallet location key is paired with abcwallet (stored in vault1) as its value:

8.3.1.5 Step 4: Add Oracle Call Interface Parameters (Optional)

Under the same prefix, create key-value pairs with Oracle Call Interface configuration parameters.

This step is optional. With this configuration, you can override the Oracle Call Interface parameters configured in the oraccess.xml file or omit configuring the file. The oraccess.xml file is a client-side configuration file that lets you configure selected OCI parameters during deployment.

- On the Configuration explorer page of your Azure App Configuration store, click Create and select Key-value to add a key-value to your store.
 - Key: Add a key with the oci/oci parameter name suffix to your chosen prefix.

Ensure that you specify only the allowed Oracle Call Interface parameters, as listed in *Oracle Call Interface Developer's Guide*.

For example, to specify the prefetch_rows parameter for the database/sales/ prefix, add a key as:

database/sales/oci/prefetch_rows

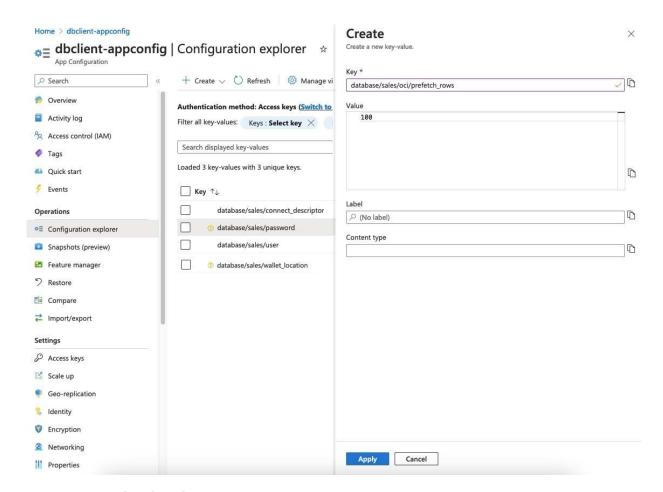

Similarly, to specify the <session_pool> inactivity_timeout parameter, add a key
as:

database/sales/oci/session pool/inactivity timeout

Value: Store a value for your key by specifying the required configuration parameter.

As shown in the following image, the suffix oci/prefetch_rows in the database/sales/oci/prefetch rows key is paired with the prefetch rows value of 100:

Oracle Call Interface Developer's Guide

8.3.1.6 Step 5: Use a Connect Identifier Containing Azure App Configuration Store Values

Use the Azure App Configuration name, key path, and Azure authentication parameters in a database client connection identifier.

Syntax:

```
config-azure://{appconfig-name}[?
key=prefix&label=value&option1=value1&option2=value2...]
```

The syntax details are:

Syntax Element	Description	
<pre>config-azure:// {appconfig-name}</pre>	Name of your Azure App Configuration store.	
key=prefix	Prefix of your key, without the connect_descriptor suffix in Azure App Configuration.	
label=value	Label to be used for the connect descriptor.	
	Labels are used to differentiate key-values with the same key. Refer to Microsoft Azure documentation for additional details.	
option=value	Both the authentication method and corresponding authentication parameters to access your Centralized Configuration Provider.	
	Authentication method:	
	Use the AUTHENTICATION parameter to set one of the following authentication methods:	
	 For Azure Service Principal (or OAuth 2.0 Client Credentials): AUTHENTICATION=AZURE_DEFAULT 	
	Note : This is the default setting, which means that the OAuth 2.0 Client Credentials authentication method is implied by default and you do not need to explicitly specify the AUTHENTICATION parameter. In this case, you can omit this setting.	
	• For Azure Service Principal: AUTHENTICATION=AZURE_SERVICE_PRINCIPAL	
	 For Azure Managed Identity (or Azure Managed User Identity): AUTHENTICATION=AZURE MANAGED IDENTITY 	
	Authentication parameters:	
	Set authentication parameters corresponding to your chosen authentication method, as described in AUTHENTICATION.	
	For example, if using the default OAuth 2.0 Client Credentials authentication method, then set authentication parameters such as AZURE_TENANT_ID, AZURE_CLIENT_ID, or AZURE_CLIENT_SECRET.	
	For detailed information on all authentication parameters, see Authentication Parameters for Azure App Configuration Store.	

Examples:

Let us look at some examples on how to specify a connect identifier string with different values:

With the default OAuth 2.0 Client Credentials authentication:

For multiple applications, such as sales and hr, you can store a connect descriptor for sales under the database/sales prefix and for hr under the database/hr prefix.

The following usage of naming looks up a <code>connect_descriptor</code> under the <code>database/sales</code> prefix. Here, the <code>AUTHENTICATION=AZURE_DEFAULT</code> setting is omitted. Authentication method for the default flow is implicit, so only the client credentials are specified using the <code>AZURE_CLIENT_ID</code>, <code>AZURE_CLIENT_SECRET</code>, and <code>AZURE_TENANT_ID</code> authentication parameters.

With database credentials specified in the string:

```
sqlplus dbuser@"config-azure://dbclient-appconfig?key=database/sales/
&azure_client_id=alabc12-ab12-lab1-
alb1-123a&azure_client_secret=A123B~AB123a~AB1234_abab&azure_tenant_id=1
23ab-12a12-la2b1-alb2"
```

With database credentials stored in Azure Key Vault:

```
alb1-123a&azure_client_secret=A123B~AB123a~AB1234_abab&azure_tenant_id=1 23ab-12a12-1a2b1-a1b2"
```

Similarly, the following usage of naming looks up a <code>connect_descriptor</code> under the <code>database/hr</code> prefix:

With database credentials specified in the string:

```
sqlplus dbuser@"config-azure://dbclient-appconfig?key=database/hr/
&azure_client_id=alabc12-ab12-lab1-
alb1-123a&azure_client_secret=A123B~AB123a~AB1234_abab&azure_tenant_id=1
23ab-12a12-la2b1-alb2"
```

With database credentials stored in Azure Key Vault:

```
sqlplus /@"config-azure://dbclient-appconfig?key=database/hr/
&azure_client_id=alabc12-ab12-lab1-
alb1-123a&azure_client_secret=A123B~AB123a~AB1234_abab&azure_tenant_id=1
23ab-12a12-la2b1-alb2"
```

With the Azure Service Principal authentication:

With database credentials specified in the string:

```
sqlplus dbuser@"config-azure://dbclient-appconfig?key=database/sales/ &authentication=azure_service_principal&azure_client_id=alabc12-ab12-lab1- alb1-123a&azure_client_secret=A123B~AB123a~AB1234_abab&azure_client_cert ificate_path=/app/dbclient/ certificate_for_authenticaion.txt&azure_tenant_id=123ab-12a12-1a2b1-alb2"
```

With database credentials stored in Azure Key Vault:

```
sqlplus /@"config-azure://dbclient-appconfig?key=database/sales/
&authentication=azure_service_principal&azure_client_id=alabc12-
ab12-lab1-
alb1-123a&azure_client_secret=A123B~AB123a~AB1234_abab&azure_client_cert
ificate_path=/app/dbclient/
certificate_for_authenticaion.txt&azure_tenant_id=123ab-12a12-1a2b1-
alb2"
```

With the Azure Managed Identity authentication:

With database credentials specified in the string:

```
sqlplus dbuser@"config-azure://dbclient-appconfig?key=database/sales/
&authentication=azure managed identity"
```

With database credentials stored in Azure Key Vault:

```
sqlplus /@"config-azure://dbclient-appconfig?key=database/sales/
&authentication=azure managed identity"
```

8.3.2 OCI Object Storage JSON File

Stores configuration data in the Oracle Cloud Infrastructure (OCI) Object Storage as a JSON file.

- Prerequisites for Using the OCI Object Storage JSON File
 Perform these steps in the Oracle Cloud Infrastructure (OCI) console or using the OCI CLI or API, before beginning to use the OCI Object Storage.
- Step 1: Create a JSON file with the Connect Descriptor
 Create a Centralized Configuration Provider JSON file with the connect descriptor and upload it to the Oracle Cloud Infrastructure (OCI) Object Storage.
- Step 2: Add the User Name and Password Vault Reference (Optional)

 To the JSON file that you created in Step 1, add the database user name and database password for authentication to Oracle Database. The password value is a vault reference.
- Step 3: Add the Wallet Vault Reference (Optional)
 To the same JSON file, add the wallet location. The wallet location value is a vault reference.
- Step 4: Add Oracle Call Interface Parameters (Optional)
 To the same JSON file, add Oracle Call Interface configuration parameters.
- Step 5: Use a Connect Identifier Containing OCI Object Storage Values
 Use the Oracle Cloud Infrastructure (OCI) Object Storage server name, key path, and authentication parameters in a database client connection identifier.

8.3.2.1 Prerequisites for Using the OCI Object Storage JSON File

Perform these steps in the Oracle Cloud Infrastructure (OCI) console or using the OCI CLI or API, before beginning to use the OCI Object Storage.

Create a bucket in the OCI Object Storage:

Use the OCI Object Storage service to create a bucket within a compartment of your Object Storage namespace. You will later upload a Centralized Configuration Provider JSON file as an object to this bucket.

Create a policy and assign it to database user:

The OCI administrator must grant security access in a policy. Create an OCI Identity and Access Management (IAM) policy, and assign it to database user for accessing Object Storage resources in the compartment.

(Optional) Create a vault for secrets and grant authorization permissions:

You can store Oracle Database credentials and Oracle wallet data in OCI Vault or Azure Key Vault.

To store Oracle Database credentials:

Create OCI Vault or Azure Key Vault with the database password stored as a secret in that vault.

To store Oracle wallet data:

The SQLNET client applications running on multitenant cloud service environments can store wallets in remote stores. Because these applications may not have access to the

wallets stored in a local system file, this feature is especially useful for Mutual Transport Layer Security (mTLS) connections that require file system access to keep the wallet.

To store wallet data, you first convert an auto-login wallet file (cwallet.sso) to a Base64 format, and then create OCI Vault or Azure Key Vault with the Base64-formatted cwallet.sso value stored as a secret.

1. Convert your cwallet.sso file to a Base64 format.

A common way to convert cwallet.sso to Base64 is by using the following openss1 command on Linux:

```
cat cwallet.sso | base64 -w 0 > file_to_upload
```

Here, file to upload specifies the cwallet.sso file that you want to convert.

2. Create OCI Vault or Azure Key Vault by pasting contents of the Base64-formatted string of the cwallet.sso file, as secret contents without any new lines.

You will later add a reference to these vaults in the JSON file. The OCI administrator must give authorization permissions to the database user for accessing the OCI Vault. Similarly, the Azure App Configuration store's administrator must give authorization permissions to the registered OAuth application for accessing the Azure Key Vault.

For detailed information on how to perform these steps, see OCI Vault Documentation or Azure Key Vault Documentation.

Understand the format of a Centralized Configuration Provider JSON file:

You can organize connect descriptors in a Centralized Configuration Provider JSON file based on your application requirements, in one of the following JSON formats:

- A single object with a connect descriptor sub-object
- Multiple objects (separated by a comma) with each object having its own connect descriptor sub-object

Optionally, you can add user and password sub-objects (to specify the database user name and database password), wallet_location sub-object (to specify the wallet directory), and oci sub-object (to specify Oracle Call Interface configuration parameters) in the same file.

Database clients look for specific network service names in a JSON object for deriving the connect descriptor, database user name and password, wallet data, and other Oracle Call Interface attributes. A connect identifier retrieves these JSON objects from the OCI Object Storage endpoint and uses it to locate the stored attributes. These values are used for the database connection.

The syntax for Centralized Configuration Provider JSON (CCJSON) is:

```
CCJSON_elements -> CCJSON_element

CCJSON_element -> CCJSON_element

CCJSON_element -> '{' members '}'

members -> member

-> member, member
```

```
-> cd
member
                      -> member, cd related
                      -> "connect_descriptor" : "<connect_descriptor>"
cd
                      -> "user" : "<database user name>"
cd related
                      -> "password" : '{' password data '}'
                      -> "wallet location" : '{' wallet data '}'
                      -> "oci" : '{' oci config members '}'
                      -> nul
                      -> '{' "type" : vault_type,
password data
                             "value" : vault value,
                             "authentication": authentication value '}'
                      -> '{' "type" : vault type,
wallet data
                             "value" : vault value,
                             "authentication": authentication value '}'
vault type
                      -> "ocivault"
                      -> "azurevault"
vault value
                     -> "<vault-specific identifier>"
authentication value -> '{' "azure client id" : "<client id>",
                             "azure client secret" : "<secret>",
                             "azure tenant id" : "<tenant id>"
1 } '
                      -> null
                     -> '{' oci_config_name : oci_config value '}'
oci config members
oci config value
                     -> json value
oci config name
                      -> prefetch rows
                      -> statement cache size
                      -> lob_prefetch_size
                      -> session pool
                     -> '{' "min" : value, "max" : value,
session pool
                             "increment" : value, "max lifetime session" :
value,
                             "max use session" : value,
"inactivity timeout" : value '}'
                     -> "prefetch_rows" : numeric_value
prefetch rows
statement_cache_size -> "statement_cache_size" : numeric_value
                     -> "lob prefetch size" : numeric value
lob prefetch size
numeric value
                     -> "<number>"
```

You will see how to create a JSON file with these values in the sections that follow.

Oracle Cloud Infrastructure Documentation

8.3.2.2 Step 1: Create a JSON file with the Connect Descriptor

Create a Centralized Configuration Provider JSON file with the connect descriptor and upload it to the Oracle Cloud Infrastructure (OCI) Object Storage.

- Create a JSON file in one of the following formats:
 - Single object specified with a connect_descriptor sub-object:

The following example shows a sample sales.json file, configured with a connect descriptor for the sales.myexample.com service:

 Multiple objects (separated by a comma), and each object with a separate connect_descriptor sub-object:

The following example shows a sample multi.json file, configured with multiple connect descriptors for the sales and hr objects.

```
"sales" : {
   "connect descriptor": "(DESCRIPTION=
                               (ADDRESS=
                                  (PROTOCOL=TCP)
                                  (HOST=my sales dbserver)
                                  (PORT=1521))
                               (CONNECT DATA=
                                  (SERVER=DEDICATED)
                                  (SERVICE NAME=sales.myexample.com))
                           ) "
},
"hr" : {
   "connect descriptor": "(DESCRIPTION=
                               (ADDRESS=
                                  (PROTOCOL=TCP)
                                  (HOST=my dbserver.my.example.com)
                                  (PORT=1521))
                               (CONNECT DATA=
                                  (SERVER=DEDICATED)
                                  (SERVICE NAME=hr.my.example.com))
                           ) "
```

}

Note:

There are some restrictions on the parameter names and values that can appear in connect descriptors. Ensure that you specify only the allowed parameters and values, as listed in *Oracle Database Net Services Reference*.

2. Store your JSON file in the OCI Object Storage:

In the OCI console, navigate to the Object Storage - Bucket Details page of your bucket and upload the file to that bucket under **Objects**.

8.3.2.3 Step 2: Add the User Name and Password Vault Reference (Optional)

To the JSON file that you created in Step 1, add the database user name and database password for authentication to Oracle Database. The password value is a vault reference.

This step is optional. With this configuration, you can omit database credentials in the connect identifier for the database connection.

- Ensure that you have created either OCI Vault or Azure Key Vault with the database password stored as a secret, as explained in Prerequisites for Using the OCI Object Storage JSON File.
- 2. Specify the user and password objects in your JSON file.
 - user: Database user name.
 - password:
 - type: Type of vault used. Specify ocivault for OCI Vault and azurevault for Azure Key Vault.
 - value: For OCI Vault, specify the Oracle Cloud Identifier (OCID) of the secret stored in your vault. You can get this value from the Secret Details page under Secret Information in the OCI console. For example: "ocid1.vaultsecret.mysecret-id"

For Azure Key Vault, specify the URI value of Azure Key Vault. You can get this value from the Azure portal or use REST API that gives details about vault. For example: "https://dbclients.vault.azure.net/secrets/salesappaswd"

 authentication: Authentication parameters to access the Azure Key Vault secrets store:

```
{
  "azure_client_id" : "<client id>",
  "azure_client_secret" : "<secret>",
  "azure_tenant_id" : "<tenant id>"
}
```

You can access OCI Vault using the authentication parameters set at the command line in the connect identifier.

The following sales.json file shows the user and password attributes along with connect_descriptor, configured for the sales.myexample.com service. The password is stored in Azure Key Vault.

```
"connect descriptor" : "(DESCRIPTION=
                           (ADDRESS=
                              (PROTOCOL=TCP)
                              (HOST=my sales dbserver)
                              (PORT=1521))
                           (CONNECT DATA=
                              (SERVER=DEDICATED)
                              (SERVICE NAME=sales.myexample.com))
                        ) "
"user" : "admin",
"password" : {
   "type" : "azurevault",
   "value" : "https://dbclient.vault.azure.net/secrets/salesdbpasswd",
   "authentication" : {
      "azure client id": "a12a1b12-ab12-1ab1-a1b2-12345a123aba",
      "azure client secret" : "A1B1A~ABCabc~ABaAbAb1223ABAB12abc abcd",
      "azure tenant id" : "1a123ab1-a1b2-1a12-a1b1-a12bcdab01234"
}
```

Similarly, the following multi.json file shows the user and password attributes along with connect_descriptor, specified for the sales and hr objects. The passwords are stored in OCI Vault.

```
"sales" : {
   "connect descriptor" : "(DESCRIPTION=
                               (ADDRESS=
                                  (PROTOCOL=TCP)
                                  (HOST=my sales dbserver)
                                  (PORT=1521))
                               (CONNECT DATA=
                                  (SERVER=DEDICATED)
                                  (SERVICE NAME=sales.myexample.com))
                            ) "
   "user" : "admin",
   "password" : {
     "type" : "ocivault",
     "value" : "ocid1.vaultsecret.my-secret-id"
},
"hr" : {
   "connect descriptor" : "(DESCRIPTION=
                               (ADDRESS=
                                  (PROTOCOL=TCP)
                                  (HOST=my dbserver.my.example.com)
                                  (PORT=1521))
                               (CONNECT DATA=
                                  (SERVER=DEDICATED)
```

```
(SERVICE_NAME=hr.my.example.com))

"user" : "admin",

"password" : {
    "type" : "ocivault",
    "value" : "ocid1.vaultsecret.my-secret-id"
    }
}
```

3. Store your updated JSON file in the OCI Object Storage:

In the OCI console, navigate to the Object Storage - Bucket Details page of your bucket and upload the file to that bucket under **Objects**.

Related Topics

- Oracle Database Net Services Reference
- Managing OCI Vault Secrets
- Managing Azure Key Vault Secrets

8.3.2.4 Step 3: Add the Wallet Vault Reference (Optional)

To the same JSON file, add the wallet location. The wallet location value is a vault reference.

This step is optional. With this configuration, you can store an Oracle wallet in a remote store using OCI Object Storage.

- Ensure that you have created either OCI Vault or Azure Key Vault with your wallet data stored as a secret, as explained in Prerequisites for Using the OCI Object Storage JSON File.
- 2. Specify the wallet location object with the wallet data.
 - type: Type of vault used. Specify ocivault for OCI Vault and azurevault for Azure Key Vault.
 - value: For OCI Vault, specify the OCID of the secret stored in your vault. You can get
 this value from the Secret Details page under Secret Information in the OCI console.
 For example: "ocid2.vaultsecret.my-wallet-secret-id"

For Azure Key Vault, specify the URI value of Azure Key Vault. You can get this value from the Azure portal or use REST API that gives details about vault. For example: "https://dbclients.vault.azure.net/secrets/saleswallet"

 authentication: Authentication parameters to access the Azure Key Vault secrets store:

```
{
  "azure_client_id" : "<client id>",
  "azure_client_secret" : "<secret>",
  "azure_tenant_id" : "<tenant id>"
}
```

You can access OCI Vault using the authentication parameters set at the command line in the connect identifier.

The following sales.json file shows the user, password, and wallet_location attributes along with connect_descriptor, configured for the sales.myexample.com service. The password and wallet data are stored in Azure Key Vault.

```
"connect descriptor" : "(DESCRIPTION=
                           (ADDRESS=
                              (PROTOCOL=TCP)
                              (HOST=my sales dbserver)
                              (PORT=1521))
                           (CONNECT DATA=
                              (SERVER=DEDICATED)
                              (SERVICE NAME=sales.myexample.com))
                        ) "
"user" : "admin",
"password" : {
   "type" : "azurevault",
   "value" : "https://dbclient.vault.azure.net/secrets/salesdbpasswd",
   "authentication" : {
      "azure client id": "a12a1b12-ab12-1ab1-a1b2-12345a123aba",
      "azure client secret" : "A1B1A~ABCabc~ABaAbAb1223ABAB12abc abcd",
      "azure tenant id" : "1a123ab1-a1b2-1a12-a1b1-a12bcdab01234"
},
"wallet location" : {
   "type" : "azurevault",
   "value" : "https://dbclient.vault.azure.net/secrets/saleswallet"
   "authentication" : {
      "azure client id" : "a12a1b12-ab12-1ab1-a1b2-12345a123aba",
      "azure client secret" : "A1B1A~ABCabc~ABaAbAb1223ABAB12abc abcd",
      "azure tenant id" : "1a123ab1-a1b2-1a12-a1b1-a12bcdab01234"
```

Similarly, the following multi.json file shows the user, password, and wallet_location attributes along with connect_descriptor, specified for the sales and hr objects. The passwords and wallet data are stored in OCI Vault.

```
"type" : "ocivault",
     "value" : "ocid2.vaultsecret.my-wallet-secret-id"
},
"hr" : {
   "connect descriptor" : "(DESCRIPTION=
                              (ADDRESS=
                                 (PROTOCOL=TCP)
                                  (HOST=my dbserver.my.example.com)
                                 (PORT=1521))
                              (CONNECT DATA=
                                  (SERVER=DEDICATED)
                                  (SERVICE NAME=hr.my.example.com))
                           ) "
   "user" : "admin",
   "password" : {
     "type" : "ocivault",
     "value" : "ocid1.vaultsecret.my-password-secret-id"
   "wallet location" : {
     "type" : "ocivault",
     "value" : "ocid2.vaultsecret.my-wallet-secret-id"
}
```

Store your updated JSON file in the OCI Object Storage:

In the OCI console, navigate to the Object Storage - Bucket Details page of your bucket and upload the file to that bucket under **Objects**.

- Managing Azure Key Vault Secrets

8.3.2.5 Step 4: Add Oracle Call Interface Parameters (Optional)

To the same JSON file, add Oracle Call Interface configuration parameters.

This step is optional. With this configuration, you can override the Oracle Call Interface parameters configured in the oraccess.xml file or omit configuring the file. The oraccess.xml file is a client-side configuration file that lets you configure selected OCI parameters during deployment.

1. Specify Oracle Call Interface parameters in the oci JSON object.

Ensure that you specify only the allowed Oracle Call Interface parameters, as listed in *Oracle Call Interface Developer's Guide*.

The following sales.json file shows Oracle Call Interface attributes along with the connect descriptor, database credentials, and wallet location values that are configured for the sales.myexample.com Service:

```
"connect descriptor": "(DESCRIPTION=
                          (ADDRESS=
                            (PROTOCOL=TCP)
                            (HOST=my sales dbserver)
                            (PORT=1521))
                          (CONNECT DATA=
                            (SERVER=DEDICATED)
                            (SERVICE NAME=sales.myexample.com))
                       )",
"user": "admin",
"password": {
   "type": "ocivault",
   "value": "ocid1.vaultsecret.my-password-secret-id"
},
"wallet location" : {
   "type" : "ocivault",
   "value" : "ocid2.vaultsecret.my-wallet-secret-id"
"oci": { "statement cache size" : 5,
         "prefetch rows" : 10,
         "lob prefetch size": 1024,
         "session pool" : { "min" : 4, "max" : 10, "increment" : 2 }
}
```

Similarly, the following multilison file shows Oracle Call Interface attributes along with the connect descriptor, database credentials, and wallet location values that are specified for the sales and hr objects:

```
"sales" : {
 "connect descriptor": "(DESCRIPTION=
                            (ADDRESS=
                              (PROTOCOL=TCP)
                              (HOST=my sales dbserver)
                              (PORT=1521))
                            (CONNECT DATA=
                              (SERVER=DEDICATED)
                              (SERVICE NAME=sales.myexample.com))
                         )",
 "user": "scott",
  "password": {
     "type": "ocivault",
     "value": "ocid1.vaultsecret.oc1.my-password-secret-id"
  "wallet location" : {
     "type" : "ocivault",
     "value" : "ocid2.vaultsecret.my-wallet-secret-id"
  "oci":{ "statement cache size" : 5,
```

```
"prefetch rows" : 10,
          "lob prefetch size": 1024,
          "session pool" : { "min" : 4, "max" : 10, "increment" : 2 }
  }
},
"hr" : {
  "connect descriptor": "(DESCRIPTION=
                            (ADDRESS=
                              (PROTOCOL=TCP)
                              (HOST=my dbserver.my.example.com)
                              (PORT=1521))
                            (CONNECT DATA=
                              (SERVER=DEDICATED)
                              (SERVICE NAME=hr.my.example.com))
  "oci":{
  "statement_cache_size" : 6,
  "prefetch rows" : 10
  }
```

Store your updated JSON file in the OCI Object Storage:

In the OCI console, navigate to the Object Storage - Bucket Details page of your bucket and upload the file to that bucket under **Objects**.

Related Topics

Oracle Call Interface Developer's Guide

8.3.2.6 Step 5: Use a Connect Identifier Containing OCI Object Storage Values

Use the Oracle Cloud Infrastructure (OCI) Object Storage server name, key path, and authentication parameters in a database client connection identifier.

Syntax:

```
config-ociobject://objectstorage-server-name/n/{namespaceName}/b/
{bucketName}/o/{objectName}/[c/{networkServiceName}]?
[option1=value1&option2=value2...]
```

The syntax details are:

Syntax Element	Description	
config-ociobject:// objectstorage-server-name	Server name of your OCI Object Storage. This is the URL Path (URI) value given on the Object Details page in the OCI console.	
	Specify this value without the https://prefix.	
n/{namespaceName}	OCI Object Storage namespace where you have stored the JSON file.	
b/{bucketName}	OCI Object Storage bucket name where you have stored the JSON file.	
o/{objectName}	JSON file to look up and resolve a network service name.	
c/{networkServiceName}	Network service name if the JSON file contains two or more network service names.	

Syntax Element	Description	
option=value	Both the authentication method and corresponding authentication parameters to access your Centralized Configuration Provider.	
	Authentication method:	
	Use the AUTHENTICATION parameter to set one of the following authentication methods:	
	 For OCI API Key: AUTHENTICATION=OCI_DEFAULT 	
	 Note: This is the default setting, which means that the OCI API Key authentication method is implied by default and you do not need to explicitly specify the AUTHENTICATION parameter. In this case, you can omit this setting. For OCI Instance Principal: AUTHENTICATION=OCI INSTANCE PRINCIPAL 	
	For OCI Resource Principal: AUTHENTICATION=OCI RESOURCE PRINCIPAL	
	For detailed information on these authentication methods, see AUTHENTICATION.	
	Authentication parameters:	
	Set authentication parameters corresponding to your chosen authentication method:	
	 If using the default OCI API Key authentication method, then set authentication parameters such as OCI_TENANCY, OCI_USER, OCI_FINGERPRINT, or OCI_KEY_FILE. See Authentication Parameters for OCI Object Storage. If using the OCI Instance Principal or the OCI Resource Principal 	
	authentication method, then you do not need to set any authentication parameter.	

Examples:

Let us look at some examples on how to specify a connect identifier string with different values:

Database credentials specified in the string:

```
sqlplus dbuser/@"config-ociobject://objectstorage.us-
region-1.example.com/n/myappnamespace/b/dbclientapps/o/sales.json?
oci_tenancy=ocid1.tenancy.oc1..aaabbbl234aaabbb&oci_user=ocid1.user.oc1..ab
ababl2121212&oci_fingerprint=a1:bc:a1:la:12:a1:a2:b1:b2:lb&oci_key_file=//a
pp/mykey.pem"
```

Database credentials stored in OCI Vault:

The vault reference is configured in the sales.json file:

```
sqlplus /@"config-ociobject://objectstorage.us-region-1.example.com/n/
myappnamespace/b/dbclientapps/o/sales.json?
oci_tenancy=ocid1.tenancy.oc1..aaabbb1234aaabbb&oci_user=ocid1.user.oc1..ab
abab12121212&oci_fingerprint=a1:bc:a1:1a:12:a1:a2:b1:b2:1b&oci_key_file=//a
pp/mykey.pem"
```

Network service name specified in the JSON file:

A network service name is given (as c/hr) to indicate a specific name among many network service names in the multi.json file:

sqlplus dbuser/@"config-ociobject://objectstorage.usregion-1.example.com/n/myappnamespace/b/dbclientapps/o/multi.json/c/hr?
oci_tenancy=ocid1.tenancy.oc1..aaabbb1234aaabbb&oci_user=ocid1.user.oc1..ab
abab12121212&oci_fingerprint=a1:bc:a1:1a:12:a1:a2:b1:b2:1b&oci_key_file=//a
pp/mykey.pem"

With the default OCI API Key authentication:

Here, the Authentication=oci_default setting is omitted. Authentication method for the default flow is implicit, so only the API key-related values are specified using the oci tenancy, oci user, oci fingerprint, and oci key file authentication parameters.

sqlplus dbuser/@"config-ociobject://objectstorage.usregion-1.example.com/n/myappnamespace/b/dbclientapps/o/sales.json?
oci_tenancy=ocid1.tenancy.oc1..aaabbb1234aaabbb&oci_user=ocid1.user.oc1..ab
abab12121212&oci_fingerprint=a1:bc:a1:1a:12:a1:a2:b1:b2:1b&oci_key_file=//a
pp/mykey.pem"

With the OCI Instance Principal authentication:

sqlplus dbuser/@"config-ociobject://objectstorage.usregion-1.example.com/n/myappnamespace/b/dbclientapps/o/multi.json/c/sales?
authentication=oci instance principal"

With the OCI Resource Principal authentication:

sqlplus dbuser/@"config-ociobject://objectstorage.us-region-1.example.com/n/myappnamespace/b/dbclientapps/o/multi.json/c/sales?authentication=oci resource principal"

8.4 Configuring the Easy Connect Naming Method

The Easy Connect naming method eliminates the need for service name lookup in this names or a files for TCP/IP environments. In fact, no naming or directory system is required when using this method.

- Understanding the Easy Connect Naming Method
 The Easy Connect naming method provides out-of-the-box TCP/IP connectivity to databases.
- Support for Easy Connect Plus

Starting with Oracle Database 19c, the Easy Connect syntax that applications use to connect to Oracle Database supports an enhanced functionality known as Easy Connect Plus.

- Examples of Easy Connect Naming Method
 - Review some example Easy Connect strings and how each string converts into a connect descriptor.
- Configuring Easy Connect Naming on the Client
 - Learn about the required conditions and configuration tasks that clients need to ensure before using the Easy Connect naming method.
- Configuring Easy Connect Naming to Use a DNS Alias
 You can optionally configure a DNS alias for the host name, as provided with the host
 naming method.

8.4.1 Understanding the Easy Connect Naming Method

The Easy Connect naming method provides out-of-the-box TCP/IP connectivity to databases.

Overview

This naming method extends the functionality of the host naming method by enabling clients to connect to a database server with an optional port and service name in addition to the host name of the database:

```
CONNECT username@[//]host[:port][/[service_name][:server_type][/
instance_name]]
Enter password: password
```

The connect identifier converts to the following connect descriptor:

```
(DESCRIPTION=
  (ADDRESS=(PROTOCOL=tcp) (HOST=host) (PORT=port))
  (CONNECT_DATA=
      (SERVICE_NAME=service_name)
      (SERVER=server_type)
      (INSTANCE_NAME=instance_name))
)
```

If the Oracle Database server installation was performed in Typical mode, then the default service name used by the Oracle instance is the database name, and the following Easy Connect syntax can be used to connect to that instance:

```
SQLPLUS /nolog
SQL> CONNECT username@host/db_name
SQL> Enter password: password
```

Easy Connect Syntax Examples

The connect strings in the following example connect the client to database service sales.us.example.com with a listening endpoint of 1521 on database server sales-server:

```
CONNECT scott@sales-server:1521/sales.us.example.com
CONNECT scott@//sales-server/sales.us.example.com
CONNECT scott@//sales-server.us.example.com/sales.us.example.com
```

After each of the connect strings, you must enter a password to connect to the database service.

These connect strings convert into the following connect descriptor:

```
(DESCRIPTION=
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
  (CONNECT_DATA=
        (SERVICE_NAME=sales.us.example.com)))
```

Connect Identifier for Easy Connect Naming

This is a list of the Easy Connect syntax elements and descriptions for each:

Syntax Element	Description	
//	Use // to specify a URL or JDBC connection.	
	Required for URL or JDBC connections. The connect identifier must be preceded by a double-slash $(//)$. For example:	
	<pre>scott@//sales-server Enter password: password</pre>	
	Optional for SQL connections. The connect identifier can preceded by a double-slash (//). For example, the following connect strings are semantically equivalent:	
	SQL> CONNECT scott@sales-server	
	SQL> CONNECT scott@//sales-server	
host	Required. Specify the host name or IP address of the database host computer.	
	The host name is domain-qualified if the local operating system configuration specifies a domain.	
	You may use an IPv4 or IPv6 address as a value. IPv6 addresses or host names that resolve to IPv6 addresses must be enclosed in square brackets, as in [2001:0db8:0:0::200C:417A] and [salesdb].	
port	Optional. Specify the listening port.	
-	The default is 1521.	
service name	Optional. Specify the service name of the database.	
_	If a user specifies a service name, then the listener connects the user to that specific database. Otherwise, the listener connects to the database specified by the DEFAULT_SERVICE_listener_name parameter in the listener.ora file. If DEFAULT_SERVICE_listener_name is not configured for the listener and a service name is not explicitly specified by the user as part of the Easy Connect syntax, then the listener returns an error.	
server type	Optional. Specify the database server type to use.	
	This parameter instructs the listener to connect the client to a specific type of service handler.	
	The values for the server_type parameter are dedicated, shared, and pooled. If server is not specified in the Easy Connect syntax, then the type of server is chosen by the listener (shared server if configured, otherwise a dedicated server is used).	
	Note : In Oracle Call Interface documentation, server is referred to as connect_type.	

Syntax Element	Description	
instance_name	Optional. Identify the database instance to access.	
	The instance name can be obtained from the <code>INSTANCE_NAME</code> parameter in the initialization parameter file.

- INSTANCE_NAME

8.4.2 Support for Easy Connect Plus

Starting with Oracle Database 19c, the Easy Connect syntax that applications use to connect to Oracle Database supports an enhanced functionality known as Easy Connect Plus.

With this enhancement, Easy Connect supports both the TCP and TCPS protocols (earlier, it supported only the TCP transport protocol). This simplifies the client configurations to Oracle Database Cloud Services that mandate TCPS connections for network security.

Syntax:

The enhanced Easy Connect syntax, using the Easy Connect Plus feature, is as follows:

```
[[protocol:]//]host1{,host12}[:port1]{,host2:port2}{;host1{,host12}[:port1]}
[/[service_name][:server][/instance_name]][?
parameter name=value{&parameter name=value}]
```

The question mark (?) indicates the start of name-value pairs and the ampersand (&) is the delimiter between the name-value pairs.

Here, the Easy Connect syntax includes:

- Protocol: Easy Connect adapter supports specification of protocol as part of the connect string. This protocol is applicable to each host in the connect string.
- Multihost or port: Easy Connect adapter can accept multiple hosts or ports in the connect string. This helps in load-balancing the client connections.
- Name-Value pairs: Easy Connect adapter can accept a list of name value pairs. Each name-value pair is added as a DESCRIPTION level parameter.

The following names are supported:

- ENABLE
- FAILOVER
- LOAD BALANCE
- RECV BUF SIZE
- SEND BUF SIZE
- SDU

- SOURCE ROUTE
- RETRY_COUNT
- RETRY DELAY
- CONNECT_TIMEOUT
- TRANSPORT CONNECT TIMEOUT
- Address lists: Starting with Oracle Database 23ai, you can specify one or more address lists of protocol addresses that share common characteristics.
- Security attributes: The following SECURITY attributes are supported for TLS:
 - SSL_SERVER_DN_MATCH=on/off
 - SSL_SERVER_CERT_DN=longDN
 - WALLET LOCATION=Wallet location

Note:

The parameter WALLET_LOCATION is deprecated for use with Oracle Database 23ai for the Oracle Database server. It is not deprecated for use with the Oracle Database client or listener.

For Oracle Database server, Oracle recommends that you use the WALLET_ROOT system parameter instead of using WALLET LOCATION.

Examples

With a single protocol address using the ADDRESS parameter:

The following syntax to specify the Session Data Unit (SDU)

```
salesserver1:1521/sales.us.example.com?sdu=16384
```

translates to the following connect descriptor:

```
(DESCRIPTION=
  (SDU=16384)
  (ADDRESS=(PROTOCOL=tcp) (HOST=saleserver1) (PORT=1521))
  (CONNECT_DATA=(SERVICE_NAME=sales.us.example.com))
)
```

Similarly, the following syntax to specify connect timeout, transport connect timeout, and retry count values

```
salesserver1:1521/sales.us.example.com?
connect_timeout=1min&transport_connect_timeout=30sec&retry_count=3&retry_delay
=2
```

translates to the following connect descriptor:

```
(DESCRIPTION=
   (retry_count=3) (retry_delay=2)
   (connect_timeout=1min) (transport_connect_timeout=30sec)
   (ADDRESS=(PROTOCOL=tcp) (HOST=salesserver1) (PORT=1521))
```

```
(CONNECT_DATA=(SERVICE_NAME=sales.us.example.com))
```

With multiple protocol addresses using the ADDRESS_LIST parameter:

The following syntax to specify the Session Data Unit (SDU)

```
salesserver1:1521;saleserver2:1522/sales.us.example.com?sdu=16384
```

translates to the following connect descriptor:

```
(DESCRIPTION=
  (SDU=16384)
  (ADDRESS_LIST=
        (ADDRESS=(PROTOCOL=tcp) (HOST=saleserver1) (PORT=1521))
)
  (ADDRESS_LIST=
        (ADDRESS=(PROTOCOL=tcp) (HOST=saleserver2) (PORT=1522))
)
  (CONNECT_DATA=(SERVICE_NAME=sales.us.example.com))
)
```

8.4.3 Examples of Easy Connect Naming Method

Review some example Easy Connect strings and how each string converts into a connect descriptor.

	Connect Descriptor
sales-server	(DESCRIPTION=
	(CONNECT DATA=
	(SERVICE_NAME=))
	(ADDRESS=
	(PROTOCOL=TCP)
	(HOST=sales-server)
	(PORT=1521)))
sales-server:3456	(DESCRIPTION=
56165 561761.6166	(CONNECT DATA=
	(SERVICE NAME=))
	(ADDRESS=
	(PROTOCOL=TCP)
	(HOST=sales-server)
	(PORT=3456)))
	sales-server sales-server:3456

Naming Option	Connect String	Connect Descriptor
With host and service name. The host name is sales- server and the service name is sales.	sales-server/sales	<pre>(DESCRIPTION= (CONNECT_DATA= (SERVICE_NAME=sales)) (ADDRESS= (PROTOCOL=TCP) (HOST=sales-server) (PORT=1521)))</pre>
With IPv6 address. The IPv6 address of the host is 2001:0db8:0:0::200C:417A, the port is 80, and the service name is sales.	[2001:0db8:0:0::200C:417A]:80/sales Square brackets are required around IPv6 host names.	<pre>(DESCRIPTION= (CONNECT_DATA= (SERVICE_NAME=sales) (ADDRESS= (PROTOCOL=TCP) (HOST=2001:0db8:0:0::200C:417A) (PORT=80)))</pre>
With IPv6 host address. The host is sales-server, the port is 80, and the service name is sales.	sales-server:80/sales	<pre>(DESCRIPTION= (CONNECT_DATA= (SERVICE_NAME=sales) (ADDRESS= (PROTOCOL=TCP) (HOST=sales-server) (PORT=80)))</pre>
With host, service name, and server. The host name is sales-server, the service name is sales, the server is dedicated, and the instance name is inst1	sales-server/sales:dedicated/inst1	<pre>(DESCRIPTION= (CONNECT_DATA=</pre>
With host and instance name. The host name is sales- server and the instance name is inst1.	sales-server//inst1	<pre>(DESCRIPTION= (CONNECT_DATA= (SERVICE_NAME=) (INSTANCE_NAME=inst1)) (ADDRESS= (PROTOCOL=TCP) (HOST=sales-server) (PORT=1521)))</pre>

Here are some sample Easy Connect strings using the Easy Connect Plus feature:

Naming Option	Connect String	Connect Descriptor
With a list of name value pairs (SDU, RETRY_COUNT, and CONNECT_TIMEOUT). The host is salesserver, the port is 1521, and the service name is sales.	<pre>salesserver1:1521/sales? SDU=8128&retry_count=3&connect_tim eout=10</pre>	<pre>(DESCRIPTION= (SDU=8128) (retry_count=3) (connect_timeout=10) (ADDRESS= (PROTOCOL=tcp) (HOST=saleserver1) (PORT=1521)) (CONNECT_DATA=(SERVICE_NAME=sales)))</pre>
With multiple hosts or ports.	salesserver1:1521, salesserver2, sal	
The host is salesserver, the port is 1521, and the service name is sales.	esserver3:1522/sales	<pre>((DESCRIPTION= (LOAD_BALANCE=ON) (ADDRESS= (PROTOCOL=tcp) (HOST=sales-server1) (PORT=1521)) (ADDRESS= (PROTOCOL=tcp) (HOST=sales-server2) (PORT=1522)) (ADDRESS= (PROTOCOL=tcp) (HOST=sales-server3) (HOST=sales-server3) (PORT=1522))) (CONNECT_DATA=(SERVICE_NAME=sales))))</pre>
With specification of protocol. The host is salesserver, the port is 1521, and the service name is sales.	tcps://salesserver1:1521/sales	(DESCRIPTION= (ADDRESS= (PROTOCOL=tcps) (HOST=salesserver1) (PORT=1521))
		(SECURITY=(SSL_SERVER_DN_MATCH=TR UE))
		(CONNECT_DATA=(SERVICE_NAME=sales)))

Naming Option	Connect String	Connect Descriptor
With SECURITY attributes supported for TLS. The host is sales-server, the port is 1521, and the service name is sales.	tcps://sales-server:1521/sales? ssl_server_cert_dn="cn=sales,cn=Or acleContext,dc=us,dc=example,dc=co m"&wallet_location="/tmp/oracle" Note: The parameter WALLET_LOCATION is deprecated for use with Oracle Database 23ai for the Oracle Database server. It is not deprecated for use with the Oracle Database client or listener. For Oracle Database server, Oracle recommends that you use the WALLET_ROOT system parameter instead of using WALLET_LOCATION.	<pre>(DESCRIPTION= (ADDRESS= (PROTOCOL=tcps) (HOST=salesserver) (PORT=1521)) (CONNECT_DATA=(SERVICE_NAME=sales)) (SECURITY= (SSL_SERVER_DN_MATCH=TRUE) (SSL_SERVER_CERT_DN=cn=sales,cn=0 racleContext,dc=us,dc=example,dc=com) (WALLET_LOCATION=/tmp/oracle)))</pre>
With ADDRESS_LIST to specify multiple protocol addresses.	<pre>salesserver1:1521; saleserver2:1522 /sales.us.example.com?sdu=16384</pre>	<pre>(DESCRIPTION= (SDU=16384) (ADDRESS_LIST= (ADDRESS=(PROTOCOL=tcp) (HOST=saleserver1) (PORT=1521))) (ADDRESS_LIST= (ADDRESS=(PROTOCOL=tcp) (HOST=saleserver2) (PORT=1522))) (CONNECT_DATA=(SERVICE_NAME=sales.us.example.com)))</pre>

- Configuring Listening Protocol Addresses
- Using Oracle Connection Manager as a Bridge for IPv4 and IPv6
 In some database connection environments, a client and database may use different versions of the IP protocol so that complete connectivity does not exist. In this case, at least two hops in the connection use different versions of the IP protocol.

8.4.4 Configuring Easy Connect Naming on the Client

Learn about the required conditions and configuration tasks that clients need to ensure before using the Easy Connect naming method.

Clients can connect to Oracle Database using Easy Connect naming if the following conditions are met:

Oracle Net Services software is installed on the client.

- Oracle TCP/IP protocol is supported on both the client and database server.
- No features require a more advanced connect descriptor.

Easy Connect naming is not suitable for large or complex environments with advanced features, such as external procedure calls, or Heterogeneous Services, that require additional connect information. In these cases, another naming method is recommended.

Easy Connect naming is automatically configured at installation. Before using it, you must ensure that EZCONNECT is specified by the NAMES.DIRECTORY_PATH parameter in the sqlnet.ora file. This parameter specifies the order of naming methods Oracle Net can use to resolve connect identifiers to connect descriptors.

Note:

If you use the Easy Connect naming method for TCPS connections (PROTOCOL=TCPS), then SSL_SERVER_DN_MATCH is set to TRUE by default. With the SSL_SERVER_DN_MATCH=TRUE setting, the client performs a partial DN matching to ensure that the server and listener certificates are valid.

If you want to check with the full DN (not partial DN), then you must also specify the DN in <code>SSL_SERVER_CERT_DN</code>. If you do not set <code>SSL_SERVER_CERT_DN</code>, then a partial DN match must succeed for the client to establish a connection to the server. If you set <code>SSL_SERVER_CERT_DN</code>, then a full DN match (with certificates for both the server and listener) must succeed for the client to establish a connection to the server.

The following procedure describes how to verify that the Easy Connect naming method is configured:

- Start Oracle Net Manager.
- 2. In the navigator pane, expand Local, and then select Profile.
- 3. From the list in the right pane, select **Naming**.
- Click the Methods tab.

Verify that EZCONNECT is listed in the Selected Methods list. If it is not, then proceed to Step 5. If it is listed, then proceed to Step 7.

- **5.** From the Available Methods list, select **EZCONNECT**, and then click the right-arrow button.
- 6. In the Selected Methods list, select **EZCONNECT**, and then use the **Promote** button to move the selection to the top of the list.
- Select Save Network Configuration from the File menu.

The sqlnet.ora file updates the NAMES.DIRECTORY_PATH parameter, listing hostname first:

NAMES.DIRECTORY PATH=(ezconnect, tnsnames)

- SSL SERVER DN MATCH
- SSL_SERVER_CERT_DN

8.4.5 Configuring Easy Connect Naming to Use a DNS Alias

You can optionally configure a DNS alias for the host name, as provided with the host naming method.

With host naming, clients use a connect string that uses the following pattern:

```
CONNECT username@DNS_alias
Enter password: password
```

The following procedure describes how to configure a DNS alias:

1. Ensure the database service is registered with the listener.

If the database can find the listener, then information about the database service is dynamically registered with the listener during service registration, including the service name. The listener is found if the following conditions are met:

- The default listener named LISTENER on TCP/IP, port 1521 is running.
- The LOCAL LISTENER parameter is set in the initialization file.

If the database cannot find the listener, then you can configure static registration for the listener.

2. Establish a host name resolution environment.

You can configure a mechanism such as DNS, NIS, or a centrally-maintained TCP/IP host file, /etc/hosts. For example, if a service name of sales.us.example.com for a database exists on a computer named sales-server, then the entry in the /etc/hosts file would look like the following:

```
#IP address of server host name alias
192.0.2.35 sales-server sales.us.example.com
```

The domain section of the service name must match the network domain.

3. Connect to the database using the DNS alias.

Using the example in the previous step, the client can use sales.example.com in the connect string:

```
CONNECT username@sales.us.example.com
Enter password: password
```

If the client and server are in the same domain such as us.example.com, then the client must enter only sales in the connect string.

Configuring and Administering Oracle Net Listener

Oracle Net Listener is a separate process that runs on the database server. It receives incoming client connection requests and manages the traffic of these requests to the database server. Find out how to configure the listener to accept client connections.

Overview of Oracle Net Listener

A listener is configured with one or more listening protocol addresses, information about supported services, and parameters that control its runtime behavior. The listener configuration is stored in a configuration file named listener.ora.

Configuring Dynamic Service Registration Service registration allows processes, such as an Oracle database, to identify their available services to the listener, which then acts as a port mapper for those services.

- Configuring Oracle Net Listener During Installation
 Oracle Universal Installer launches Oracle Net Configuration Assistant during installation.
 Oracle Net Configuration Assistant configures the listening protocol address and service information for Oracle Database.
- Customizing Oracle Net Listener Configuration
 If the default or installed configuration is not adequate for a particular environment, then you can use Oracle Net Manager to customize the listener.ora configuration.
- Administering the Listener

After the listener is configured, you can administer it with the Listener Control utility, Oracle Enterprise Manager Cloud Control, and the Server Control utility (SRVCTL).

Understanding Listener Redirects

The listener redirect feature allows a client to connect to a pluggable database (PDB) using an unchanged connect descriptor even after the PDB is migrated to a new location in the Oracle Public Cloud.

Related Topics

- Identifying and Accessing the Database
 Understand how databases are identified, and how clients access them.
- Understanding the Communication Layers
 The primary function of Oracle Net is to establish and maintain connections between a client application and an Oracle database server.

9.1 Overview of Oracle Net Listener

A listener is configured with one or more listening protocol addresses, information about supported services, and parameters that control its runtime behavior. The listener configuration is stored in a configuration file named listener.ora.

The release of the listener must be the same as or later than the latest release of all Oracle databases being serviced through the listener.

Because the configuration parameters have default values, it is possible to start and use a listener with no configuration. This default listener has a name of LISTENER, supports no services on startup, and listens on the following TCP/IP protocol address:

```
(ADDRESS=(PROTOCOL=tcp) (HOST=host name) (PORT=1521))
```

The listener forwards client requests to supported services. These services are dynamically registered with the listener. This dynamic registration feature is called service registration. The registration is performed by the Listener Registration (LREG) process. Dynamic service registration does not require any manual configuration in the listener.ora file.

Service registration offers the following benefits:

Connect-time failover

Because the listener always monitors the state of the instances, service registration facilitates automatic failover of a client connect request to a different instance if one instance is down.

Connection load balancing

Service registration enables the listener to forward client connect requests to the least-loaded instance and dispatcher or dedicated server. Service registration balances the load across the service handlers and nodes.

High-availability for Oracle Real Application Clusters and Oracle Data Guard

Related Topics

Understanding Oracle Net Architecture

The Oracle Net listener is an application positioned on top of the Oracle Net foundation layer. The database receives an initial connection from a client application through the listener.

Configuring Dynamic Service Registration

Service registration allows processes, such as an Oracle database, to identify their available services to the listener, which then acts as a port mapper for those services.

- About the Address List Parameters
- Understanding Connection Load Balancing

The connection load balancing feature improves connection performance by balancing the number of active connections among multiple dispatchers.

9.2 Configuring Dynamic Service Registration

Service registration allows processes, such as an Oracle database, to identify their available services to the listener, which then acts as a port mapper for those services.

The listener uses the dynamic service information about the database and instance received through service registration.

Dynamic service registration is configured in the database initialization file. It does not require any configuration in the listener.ora file. However, listener configuration must be set to listen

on the ports named in the database initialization file, and must not have parameters set that prevent automatic registration, such as COST parameters.

- Setting Initialization Parameters for Service Registration
- Registering Information with a Local Listener
- Registering Information with a Remote Listener
- · Registering Information with All Listeners in a Network
- Configuring a Naming Method

9.2.1 Setting Initialization Parameters for Service Registration

To ensure service registration works properly, the initialization parameter file should contain the following parameters:

- SERVICE_NAMES for the database service name
- INSTANCE NAME for the instance name
- LOCAL_LISTENER for the local listener
- REMOTE_LISTENER for the remote listener, if any
- FORWARD_LISTENER for the forward listener

For example:

SERVICE_NAMES=sales.us.example.com
INSTANCE NAME=sales

The value for the SERVICE_NAMES parameter defaults to the global database name, a name comprising the DB_NAME and DB_DOMAIN parameters in the initialization parameter file. The value for the INSTANCE NAME parameter defaults to the Oracle system identifier (SID).

Starting with Oracle Database 19c, customer use of the <code>SERVICE_NAMES</code> parameter is deprecated. To manage your services, Oracle recommends that you use the <code>SRVCTL</code> or <code>GDSCTL</code> command line utilities, or the <code>DBMS_SERVICE</code> package.

See Also:

Oracle Database Reference for additional information about the SERVICE_NAMES and INSTANCE_NAME parameters

9.2.2 Registering Information with a Local Listener

By default, the LREG process registers service information with its local listener on the default local address of TCP/IP, port 1521. If the listener configuration is synchronized with the database configuration, then LREG can register service information with a nondefault local listener or a remote listener on another node. Synchronization occurs when the protocol address of the listener is specified in the listener.ora file and the location of the listener is specified in the initialization parameter file.

To have the LREG process register with a local listener that does not use TCP/IP, port 1521, configure the LOCAL_LISTENER parameter in the initialization parameter file to locate the local listener.

For a shared server environment, you can use the LISTENER attribute of the DISPATCHERS parameter in the initialization parameter file to register the dispatchers with a nondefault local listener. Because the LOCAL_LISTENER parameter and the LISTENER attribute enable LREG to register dispatcher information with the listener, it is not necessary to specify both the parameter and the attribute if the listener values are the same.

LOCAL_LISTENER is a comma-delimited list parameter. If a comma appears in the string, then the entire string must be enclosed in double quotation marks. Set the LOCAL_LISTENER parameter as follows:

```
ALTER SYSTEM SET LOCAL_LISTENER=["]listener_address["][,...];
```

For example, if the listener address "ab, cd" is entered, then it resolves to one listener address. If the address is entered as ab, cd, then it resolves to two listener addresses, ab and

For shared server connections, set the LISTENER attribute as follows:

```
ALTER SYSTEM SET DISPATCHERS="(PROTOCOL=tcp)(LISTENER=listener address)";
```

In the preceding command, *listener_address* is resolved to the listener protocol addresses through a naming method, such as a tnsnames.ora file on the database server.

Note:

 To dynamically update the LOCAL_LISTENER parameter, use the SQL statement ALTER SYSTEM as follows:

```
ALTER SYSTEM SET LOCAL_LISTENER=["]listener_address["][,...]
```

If you set the parameter to null using the following statement, then the default local address of TCP/IP, port 1521 is assumed:

```
ALTER SYSTEM SET LOCAL_LISTENER=''
```

 The LISTENER attribute overrides the LOCAL_LISTENER parameter. As a result, the SQL statement ALTER SYSTEM SET LOCAL_LISTENER does not affect the setting of this attribute.

In Example 9-1, a database resides on host sales1-server. The listener on this host is named listener sales1 and is configured to listen on port 1421 instead of port 1521.

Example 9-1 Registering a Local Listener in a Dedicated Server Environment

- 1. On the host where the local listener resides, configure the listener.ora file with the protocol address of the listener using Oracle Net Manager.
- On the database, set the LOCAL_LISTENER parameter in the database initialization parameter file to the alias of the local listener. For example:

```
ALTER SYSTEM SET LOCAL LISTENER=listener sales1;
```

If the database is configured for shared server connections, then you could set the LISTENER attribute as follows:

```
ALTER SYSTEM SET DISPATCHERS="(PROTOCOL=tcp)(LISTENER=listener sales1)";
```

3. Resolve the listener name alias for the LOCAL_LISTENER setting through a tnsnames.ora file on the database host using a text editor, as follows:

```
listener_sales1=
  (DESCRIPTION =
          (ADDRESS = (PROTOCOL=tcp) (HOST=sales-server) (PORT=1421)))
```

Note:

- If you are registering a local listener and use Oracle Connection Manager, then do not include (DESCRIPTION = or its closing parenthesis.
- A network service name entry can be created for the protocol address without the CONNECT DATA section of the connect descriptor.

See Also:

- See Oracle Database SQL Reference for additional information about the ALTER SYSTEM statement.
- "Configuring Listening Protocol Addresses"
- "Configuring a Naming Method"

9.2.3 Registering Information with a Remote Listener

A **remote listener** is a listener residing on one computer that redirects connections to a database instance on another computer. Remote listeners are typically used in an Oracle Real Application Clusters (Oracle RAC) environment. You can configure registration to remote listeners, such as with Oracle RAC, for dedicated or shared server environments.

In a dedicated server environment, you must enable the LREG background process to register with a remote listener. You do this by configuring the REMOTE_LISTENER parameter, which is a comma-delimited list parameter, in the initialization parameter file. The syntax of REMOTE LISTENER is as follows:

```
ALTER SYSTEM SET REMOTE LISTENER=["]listener address["][,...];
```

In the preceding command, *listener_address* is resolved to the listener protocol addresses through a naming method such as a tnsnames.ora file on the database host. If a comma appears in the listener address, then the entire string must be enclosed in quotation marks.

In a shared server environment, you can use the same registration technique as for a dedicated server environment. Alternatively, you can set the LISTENER attribute of the DISPATCHERS parameter in the initialization parameter file to register the dispatchers with any listener. The syntax of the LISTENER attribute is as follows:

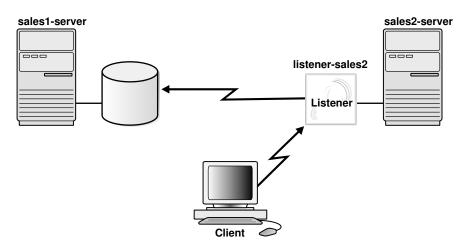

```
ALTER SYSTEM SET DISPATCHERS="(PROTOCOL=tcp)(LISTENER=listener address)";
```

Note:

The LISTENER attribute overrides the REMOTE_LISTENER initialization parameter. Because the REMOTE_LISTENER initialization parameter and the LISTENER attribute enable LREG to register dispatcher information with the listener, you do not need specify both the parameter and the attribute if the listener values are the same.

For example, assume that a remote listener named <code>listener-sales2</code> listens on port 1521 on host <code>sales2-server</code>, and a database resides on host <code>sales1-server</code>. You want the listener on <code>sales2-server</code> to redirect connection requests to this database. Figure 9-1 illustrates this scenario.

Figure 9-1 Remote Listener

See Also:

Oracle Database SQL Reference for additional information about the ALTER SYSTEM SET statement

Example 9-2 shows how to register a remote listener in a dedicated server environment. In the example, the remote listener is sales2-server.

Example 9-2 Registering a Remote Listener in a Dedicated Server Environment

- 1. On the host where the remote listener resides, use Oracle Net Manager to configure the listener.ora file with the protocol addresses of the remote listener.
- 2. On the database to which you want requests to be redirected, set the REMOTE_LISTENER parameter in the database initialization parameter file to the alias of the remote listener, for example:

ALTER SYSTEM SET REMOTE LISTENER=listener sales2;

For shared server connections, set the DISPATCHER parameter in the initialization file for the database on host sales1-server as follows:

ALTER SYSTEM SET DISPATCHERS="(PROTOCOL=tcp)(LISTENER=listeners sales2)";

To statically update the REMOTE_LISTENER initialization parameter, use a text editor to de-register the information with the remote listener which it had previously registered information.

3. Resolve the listener name alias for the remote listener through a tnsnames.ora file on the database host. For example:

```
listener_sales2=
(DESCRIPTION=
    (ADDRESS=(PROTOCOL=tcp) (HOST=sales2-server) (PORT=1521)))
```

See Also:

- "Configuring a Naming Method"
- "Configuring Listening Protocol Addresses"
- Oracle Database Reference to learn about the REMOTE_LISTENER initialization parameter
- Oracle Real Application Clusters Administration and Deployment Guide to learn how to configure remote listeners (also called SCAN listeners) in an Oracle RAC environment

9.2.4 Registering Information with All Listeners in a Network

A network may contain multiple local and remote listeners. By default, all listeners are cross-registered with each other. By specifying a set of listeners in the LISTENER_NETWORKS initialization parameter, you can designate a subset of local listeners with a subset of remote listeners. Listeners specified by the LISTENER_NETWORKS parameter should not be specified by the LOCAL_LISTENER and REMOTE_LISTENER parameters.

The syntax of LISTENER_NETWORKS parameter is as follows:

In the preceding syntax, *listener_address* is resolved according to the rules of LOCAL_LISTENER and REMOTE_LISTENER.

Example 9-3 Using Two Networks on a Subnet

Assume there are two distinct networks, <code>network1</code> and <code>network2</code>. On <code>network1</code>, there is a local listener named <code>local1</code>, and a remote listener named <code>remote1</code>. On <code>network2</code>, there is a local listener named <code>local2</code>, and a remote listener named <code>remote2</code>. The following syntax sets up registration so that the listeners only redirect connections to listeners on the same network.

```
LISTENER_NETWORKS =
   '((NAME=network1) (LOCAL_LISTENER=local1) (REMOTE_LISTENER=remote1))',
   '((NAME=network2) (LOCAL_LISTENER=local2) (REMOTE_LISTENER=remote2))'
```

In the preceding example, local1 is registered only with remote1, and remote1 only redirects connections to local1. The listener local2 is registered only with remote2, and remote2 only redirects connections to local2.

Example 9-4 Configuring Multiple Listeners

Assume that multiple listeners are listening on a network named sales-network. The following conditions are true:

- A database configured for dedicated server connections resides on host sales1-server. It
 is the only database in the network.
- A local listener resides on sales1-server and listens on nondefault port 1421.
- A remote listener named resides on host sales2-server and listens on port 1521.
- Another remote listener resides on host sales3-server and listens on port 1521.

The following procedure describes how to register information with all listeners in a dedicated server environment:

- 1. On the hosts where the remote listeners reside (in this example, sales2-server and sales3-server), configure the listener.ora file with the protocol addresses of the remote listener.
- On the database to which you want requests to be redirected, set the REMOTE_LISTENER parameter in the database initialization parameter file to the alias of the remote listeners, and the LOCAL_LISTENER parameter to the alias of the local listener.

Set the parameters in the initialization file for the database on host sales1-server as follows:

```
REMOTE_LISTENER="listener_sales2, listener_sales3"
LOCAL LISTENER=listener sales1
```

3. Resolve the listener name alias for the LOCAL_LISTENER and REMOTE_LISTENER setting through a tnsnames.ora file on the database host.

In the tnsnames.ora on sales1-server, resolve the local listener alias and remote listener aliases listener sales1, listener sales2, and listener sales3 as follows:

```
listener sales1=
 (DESCRIPTION=
  (ADDRESS=(PROTOCOL=TCP) (HOST=sales1-server) (PORT=1421)))
listener sales2=
 (DESCRIPTION=
  (ADDRESS=(PROTOCOL=TCP) (HOST=sales2-server) (PORT=1521)))
listener sales3=
 (DESCRIPTION=
  (ADDRESS=(PROTOCOL=TCP)(HOST=sales3-server)(PORT=1521)))
listener sales local=
 (DESCRIPTION=
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales1-server) (PORT=1421)))
listener sales remote=
(DESCRIPTION LIST=
  (DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=sales2-server)(PORT=1521)))
  (DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=sales3-server)(PORT=1521))))
```

See Also:

- "Configuring a Naming Method"
- "Configuring Listening Protocol Addresses"
- Oracle Database Reference for additional information about the REMOTE LISTENER initialization parameter

9.2.5 Configuring a Naming Method

The listener name alias specified for the LOCAL_LISTENER or REMOTE_LISTENER initialization parameters, or LISTENER attribute can be resolved using a thinnames.ora file. For example, a listener can be defined in the init.ora file as the following:

```
LOCAL LISTENER = (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1421))
```

To use an alias for the listener, it can be defined in the init.ora and the thshames.ora files as follows:

In the init.ora file:

```
LOCAL LISTENER = listener sales1
```

In the tnsnames.ora file:

```
listener sales1 = (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1421))
```

The CONNECT_DATA information should not be included in the network service entry in the tnsnames.ora file. However, Oracle Enterprise Manager Cloud Control and Oracle Net Manager cannot configure a tnsnames.ora file without the CONNECT_DATA information. To use listener name aliases, Oracle recommends you modify the tnsnames.ora file using a text editor.

Note:

- Multiple addresses are supported, but connect-time failover and client load balancing features are not supported.
- If the listener alias specified in the LOCAL_LISTENER parameter is invalid or not resolved, then the LREG process does not allow the database to start. The following errors occur:

```
ORA-00119: invalid specification for system parameter LOCAL_LISTENER ORA-00132: syntax error or unresolved network name '%s'
```

See Also:

Enabling Advanced Features of Oracle Net Services for additional information about multiple address configuration

9.3 Configuring Oracle Net Listener During Installation

Oracle Universal Installer launches Oracle Net Configuration Assistant during installation. Oracle Net Configuration Assistant configures the listening protocol address and service information for Oracle Database.

During an Enterprise Edition or Standard Edition installation on the database server, Oracle Net Configuration Assistant automatically configures a listener with a name of LISTENER that has a TCP/IP listening protocol address for Oracle Database. During a Custom installation, Oracle Net Configuration Assistant prompts for the listener name and protocol address.

A listening IPC protocol address for external procedure calls is automatically configured, regardless of the installation type. Oracle Net Configuration Assistant also automatically configures service information for the external procedures in the listener.ora file.

If you are using the IPC protocol, then you can improve performance by specifying the maximum number of concurrent IPC connection requests to match your expected connection requests.

9.4 Customizing Oracle Net Listener Configuration

If the default or installed configuration is not adequate for a particular environment, then you can use Oracle Net Manager to customize the listener.ora configuration.

- Configuring Listening Protocol Addresses
- Handling Large Volumes of Concurrent Connection Requests
- Managing Oracle Net Listener Security
 By default, Oracle Net Listener permits only local administration for security reasons. As a
 policy, the listener can be administered only by the user who started it. This is enforced
 through local operating system authentication.

9.4.1 Configuring Listening Protocol Addresses

Oracle Enterprise Manager Cloud Control and Oracle Net Manager can be used to configure protocol support for the listener.

The Oracle Net Listener endpoint address configuration accepts both IPv6 addresses and host names that resolve to IPv6 addresses, as explained in "IPv6 Interface and Address Configurations". This technique can create listening endpoints that service IPv6 clients.

- Configuring Listening Protocol Addresses Using Oracle Enterprise Manager Cloud Control Configure protocol addresses for the listener from the Net Services Administration page in Oracle Enterprise Manager Cloud Control.
- Configuring Listening Protocol Addresses Using Oracle Net Manager

9.4.1.1 Configuring Listening Protocol Addresses Using Oracle Enterprise Manager Cloud Control

Configure protocol addresses for the listener from the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

1. Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

2. Click **Edit**. You may be prompted to log in to the database server.

The Edit Listener page appears.

- 3. In the Addresses section, configure protocol support:
 - a. Click Add.

The Add Address page appears.

b. From the Protocol list, select the protocol on which the listener is configured to listen.

For TCP/IP, if the computer has more than one IP address and you want the listener to listen on all available IP addresses, then select **TCP/IP** or **TCP/IP** with **TLS** and enter the host name of the computer in the Host field.

c. In Port, enter the port number.

When configuring the listener to listen on TCP/IP, enter the default port of 1521. Otherwise, you must configure the LOCAL_LISTENER parameter in the initialization parameter file and the non-default port number must be specified for use by any naming method.

- d. In Host, enter the host address.
- e. (Optional) In the Advanced Parameters section, specify the I/O buffer space limit for send and receive operations of sessions in the Total Send Buffer Size and Total Receive Buffer Size fields.
- Click OK.

The protocol address is added to the Addresses section.

Repeat Step 3 for additional protocols.

Related Topics

- Accessing the Net Services Administration Page
- Configuring I/O Buffer Space

Reliable network protocols, such as TCP/IP, buffer data into send and receive buffers while sending and receiving to or from lower and upper layer protocols. The sizes of these buffers affect network performance by influencing flow control decisions.

Oracle Database Net Services Reference

9.4.1.2 Configuring Listening Protocol Addresses Using Oracle Net Manager

The following procedure describes how to configure protocol addresses for the listener using Oracle Net Manager:

Start Oracle Net Manager.

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, expand **Local**, and then select **Listeners**.
- 3. Select the listener.
- 4. From the list in the right pane, select **Listener Locations**.
- 5. Select the protocol from the Protocol list.

- 6. Enter the host name for the listener in the Host field.
- 7. Enter the port number in the Port field.
- 8. If you want to set send and receive buffer sizes, then click **Show Advanced**, and then enter the sizes in the appropriate fields.
- 9. Select Save Network Configuration from the File menu to save the changes.

9.4.2 Handling Large Volumes of Concurrent Connection Requests

If you expect the listener to handle large volumes of concurrent connection requests, then you can specify a listener queue size for its TCP/IP or IPC listening endpoints.

To specify the listener queue size, do the following:

• Specify the QUEUESIZE parameter at the end of the protocol address with its value set to the expected number of concurrent requests.

The following example sets the queue size to 20:

```
LISTENER=
(DESCRIPTION=
(ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521) (QUEUESIZE=20)))
```

Note:

The default number of concurrent connection requests is operating systemspecific. The defaults for TCP/IP on the Linux operating system and Microsoft Windows follow:

- Linux operating system: 128
- Microsoft Windows XP Professional SP2: 10
- Microsoft Windows Server Enterprise Edition: 200

9.4.3 Managing Oracle Net Listener Security

By default, Oracle Net Listener permits only local administration for security reasons. As a policy, the listener can be administered only by the user who started it. This is enforced through local operating system authentication.

For example, if user1 starts the listener, then only user1 can administer it. Any other user trying to administer the listener gets an error. The super user is the only exception.

Oracle recommends that you perform listener administration in the default mode (secure by means of local operating system authentication), and access the system remotely using a remote login. Oracle Enterprise Manager Cloud Control can also be used for remote administration.

Connections coming to listener on an IP (TCP, TCPS, and SDP) based endpoint with firewall functionality enabled, go through service ACL validation. The listener after receiving the service name validates the connection IP with ACL list.

A new attribute FIREWALL is added in the endpoint to enable firewall functionality.

```
(ADDRESS=(PROTOCOL=TCP) (HOST=) (PORT=1521) (FIREWALL=ON))
```

You can configure the FIREWALL parameter as follows:

- (FIREWALL=ON) is explicitly set in endpoint: This enables strict ACL validation of all
 connections coming on this endpoint. If no ACLs are configured for a service, all
 connections are rejected for that service.
- FIREWALL is not set in endpoint: This implies relaxed validation. If ACL is configured for a service, validation is done for that service. In the absence of ACLs, no validation is done and all connections for that service are accepted.
- (FIREWALL=OFF) is set in endpoint: No validation is done and all connections are accepted from this endpoint.

The server also enforces the ACLs.

The DBMS_SFW_ACL_ADMIN package provides interfaces for administering and managing the access control policies.

· Specifying Valid Nodes and Subnets

Related Topics

- Access Control Lists
 - Authentication is used with access control lists (ACLs) to determine whether clients can read, modify, or add information in the directory server.
- Firewall
- LOCAL_REGISTRATION_ADDRESS_listener_name
- DBMS SFW ACL ADMIN

9.4.3.1 Specifying Valid Nodes and Subnets

Listener registration should be restricted to valid nodes and subnets. Valid nodes and subnets can be specified for registration, and excluded nodes can also be specified for registration. By default, every incoming connection for registration at the listener is subjected to IP-based filtering. A connection is only allowed if it originates from the local machine. If the other nodes and subnets are specified for registration, then the local machine and the ones specified are allowed. The following parameters can be set in the <code>listener.ora</code> file to specify valid and restricted nodes and subnets:

- REGISTRATION_INVITED_NODES_listener_name: Specifies the nodes that can register with the listener. The list can be host names, or CIDR notation for IPv4 and IPv6 addresses. Presence of a host name in the list results in all IP addresses mapped to it being invited.
- REGISTRATION_EXCLUDED_NODES_listener_name: Specifies the nodes that cannot register with the listener. Nodes not specified on the list are allowed to register with the listener.

If both parameters are set, then <code>REGISTRATION_EXCLUDED_NODES_listener_name</code> is ignored.

By default, the SCAN listener agent sets REMOTE_ADDRESS_REGISTRATION_listener_name to a private IP endpoint. The SCAN listener accepts registration requests only from the private network. Remote nodes that are not accessible to the private network of the SCAN listener must be included in the list of valid nodes by using the registration_invited_nodes_alias parameter in the listener.ora file, or by modifying the SCAN listener using the command-line interface, SRVCTL.

Note:

Starting with Oracle Grid Infrastructure 12c, for a SCAN listener, if the VALID_NODE_CHECKING_REGISTRATION_listener_name and REGISTRATION_INVITED_NODES_listener_name parameters are set in the listener_ora file, then the listener agent overwrites these parameters.

If you use the SRVCTL utility to set the invitednodes and invited subnets values, then the listener agent automatically sets VALID_NODE_CHECKING_REGISTRATION_listener_name to SUBNET and sets REGISTRATION_INVITED_NODES_listener_name to the specified list in the listener.ora file.

For other listeners managed by CRS, the listener agent sets

VALID_NODE_CHECKING_REGISTRATION_listener_name to be SUBNET in the listener.ora file only if it is not already set in the listener.ora file. The SRVCTL utility does not support setting the invitednodes and invitedsubnets values for a non-SCAN listener. The listener agent does not update REGISTRATION_INVITED_NODES_listener_name in the listener.ora file for a non-SCAN listener.

See Also:

Oracle Database Net Services Reference for more information about the

VALID_NODE_CHECKING_REGISTRATION_listener_name,
REGISTRATION_INVITED_NODES_listener_name, and
REGISTRATION_EXCLUDED_NODES_listener_name parameters

9.5 Administering the Listener

After the listener is configured, you can administer it with the Listener Control utility, Oracle Enterprise Manager Cloud Control, and the Server Control utility (SRVCTL).

For a complete list of the Listener Control utility commands, see *Oracle Database Net Services Reference*. Also refer to the Oracle Enterprise Manager Cloud Control online help.

- Starting and Stopping a Listener
- Managing a Listener in an Oracle Restart Configuration
- Determining the Current Status of a Listener
- · Monitoring Services of a Listener
- Monitoring Service Registration Operations
 The SHOW STATS -REG command enables you to monitor database service registration operations that the listener handles, analyze the traffic or overhead of these operations, and diagnose registration-related issues.
- Monitoring Listener Log Files

9.5.1 Starting and Stopping a Listener

To stop or start a listener, use one of the following methods:

You can configure the listener to start automatically whenever the computer is running or is restarted. Refer to "Managing a Listener in an Oracle Restart Configuration" for additional information.

- Starting or Stopping a Listener Using the Listener Control Utility
- Starting or Stopping a Listener Using Oracle Enterprise Manager Cloud Control

9.5.1.1 Starting or Stopping a Listener Using the Listener Control Utility

To start the listener from the command line, enter:

```
lsnrctl START [listener name]
```

In the preceding command, *listener_name* is the name of the listener defined in the listener.ora file. It is not necessary to identify the listener if you are using the default listener name LISTENER.

In addition to starting the listener, the Listener Control utility verifies connectivity to the listener.

To stop a listener from the command line, enter:

```
lsnrctl STOP [listener name]
```

In the preceding command, *listener_name* is the name of the listener defined in the listener.ora file. It is not necessary to identify the listener if you are using the default listener name LISTENER.

When using the Oracle Home User, the listener control utility prompts for a password on Microsoft Windows systems. This password is the operating system password for the Oracle Home User. The password prompt is displayed only if the listener service does not exist and needs to be created as part of starting the listener.

See Also:

Oracle Database Platform Guide for Microsoft Windows for information about the Oracle Home User

9.5.1.2 Starting or Stopping a Listener Using Oracle Enterprise Manager Cloud Control

The following procedure describes how to start or stop a listener from Oracle Enterprise Manager Cloud Control:

1. Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

See Also:

"Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services"

- Select Listeners from the Administer list, and then select the Oracle home that contains the location of the configuration files.
- 3. Click Go.

The Listeners page appears.

- Select the listener.
- 5. From the Actions list, select **Start/Stop**.
- 6. Click Go.

The Start/Stop page appears.

Depending on the current status of the selected listener, select either Stop or Start, and then click OK.

9.5.2 Managing a Listener in an Oracle Restart Configuration

The Oracle Restart feature enhances availability for the processes and applications in a single-instance database environment. The Oracle Restart agents monitor the health of added components by periodically running check operations and restarting the components when necessary.

You can add the listener as a component to the Oracle Restart configuration. The listener is then automatically started by Oracle Restart when it fails or is not running. For example, if you restart the database instance after a planned restart of the computer, then Oracle Restart restarts the listener. Server Control (SRVCTL) is a command-line interface that you can use to manage listeners in an Oracle Restart configuration.

- Viewing Configured Listeners Using the SRVCTL Utility
- · Adding or Removing a Listener Using the SRVCTL Utility
- Starting or Stopping a Listener Using the SRVCTL Utility

9.5.2.1 Viewing Configured Listeners Using the SRVCTL Utility

To view all configured listeners, use the following command:

% srvctl config listener

Oracle Database Administrator's Guide to learn how to configure Oracle Restart and for SRVCTL syntax and semantics

9.5.2.2 Adding or Removing a Listener Using the SRVCTL Utility

Adding a listener as an entry to the grid infrastructure enables the agent to monitor the listener. Similarly, removing a listener removes as an entry. Use the <code>srvctl</code> command at the operating system command line as follows:

• To add the listener, enter srvctl add listener

The following command adds an entry for listener sales1 to the grid infrastructure:

```
% srvctl add listener -listener listener sales1
```

To remove the listener, enter srvctl remove listener

The following command removes the entry for <code>listener_sales1</code> from the grid infrastructure:

```
% srvctl remove listener -listener listener_sales1
```

9.5.2.3 Starting or Stopping a Listener Using the SRVCTL Utility

The SRVCTL utility enables you to stop and start the listener. If you do not specify the -listener parameter, then the SRVCTL utility starts and stops the default listener.

To start a listener, enter srvctl start listener

In the following example, the first command starts the default listener, and the second command starts <code>listener1</code> and <code>listener2</code>:

```
% srvctl start listener
% srvctl start listener -listener listener1,listener2
```

To stop a listener, enter srvctl stop listener

In the following example, the first command stops the default listener, and the second command stops listener1 and listener2:

```
% srvctl stop listener
% srvctl stop listener -listener listener1,listener2
```

9.5.3 Determining the Current Status of a Listener

To show the current status of a listener, use either the STATUS command of the Listener Control utility or Oracle Enterprise Manager Cloud Control. The status output provides basic status information about a listener, a summary of listener configuration settings, the listening protocol addresses, and a summary of services registered with the listener.

- Showing Status Using Listener Control Run the STATUS command to view status of the listener.
- Showing Status Using Oracle Enterprise Manager Cloud Control

9.5.3.1 Showing Status Using Listener Control

Run the STATUS command to view status of the listener.

At the command line, enter the following command:

```
lsnrctl STATUS [listener name]
```

In the preceding command, *listener_name* is the name of the listener defined in the listener.ora file. It is not necessary to identify the listener if you are using the default listener name LISTENER.

Example 9-5 shows example output of the STATUS command.

Example 9-5 Listener Control Utility's STATUS Command Output

```
Connecting to (DESCRIPTION=(ADDRESS=(PROTOCOL=ipc)(KEY=net)))
STATUS of the LISTENER
_____
Alias
                          LISTENER
                        TNSLSNR for Linux: Version 23.4.0.0.0

Listener Trace File /oracle/network/trace/listener.trc
Listening Endpoints Summary...
  (DESCRIPTION=(ADDRESS=(PROTOCOL=ipc)(KEY=net)))
  (DESCRIPTION=(ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521)))
  (DESCRIPTION=(ADDRESS=(PROTOCOL=tcps)(HOST=sales-server)(PORT=2484)))
Services Summary...
Service "sales.us.example.com" has 1 instance(s).
  Instance "sales", status READY, has 3 handler(s) for this service...
Service "hr.us.example.com" has 1 instance(s).
  Instance "hr", status READY, has 2 handler(s) for this service...
The command completed successfully
```

The STATUS command output includes the sections described in the following table:

Table 9-1 Listener Control Utility STATUS Command

Output Section	Description
STATUS of the LISTENER	Status of the listener, including the following:
	Alias of the listener
	Version of listener
	Start time and up time
	Trace level
	• listener.ora file being used
	 Logging and tracing configuration settings
Listening Endpoints Summary	The protocol addresses the listener is configured to listen on.
Services Summary	A summary of the services registered with the listener and the service handlers allocated to each service.
Service	The registered service.

Table 9-1 (Cont.) Listener Control Utility STATUS Command

Output Section	Description		
Instance	The name of the instance associated with the service.		
	The status field indicates if the instance can accept connections.		
	 READY means that the instance can accept connections. 		
	 BLOCKED means that the instance cannot accept connections. 		
	 READY/SECONDARY means that this is a secondary instance in an Oracle Real Application Clusters primary/secondary configuration, and is ready to accept connections. 		
	 RESTRICTED means the instance is in restricted mode. The listener blocks all connections to this instance. 		
	 UNKNOWN means that the instance is registered statically in the listener.ora file rather than dynamically with service registration. Therefore, the status is not known. 		

9.5.3.2 Showing Status Using Oracle Enterprise Manager Cloud Control

The following procedure describes how to show the status of a listener using Oracle Enterprise Manager Cloud Control:

1. Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

"Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services"

- 2. Select **Listeners** from the Administer list, and then select the Oracle home that contains the location of the configuration files.
- 3. Click **Go**. You may be prompted to log in to the database server.

The Listeners page appears.

- Select a listener.
- From the Actions list, select Show Listener Control Status.
- Click Go.

The Listener Control Status page appears.

7. After viewing the content, click the listener link at the top of the page.

9.5.4 Monitoring Services of a Listener

The SERVICES command of the Listener Control utility provides detailed information about the services and instances registered with a listener and the service handlers allocated to each instance. To show information about the services and instances from the command line, enter:

lsnrctl SERVICES [listener name]

Example 9-6 shows example output of the SERVICES command.

Example 9-6 Listener Control Utility's SERVICES Command Output

```
Connecting to (DESCRIPTION=(ADDRESS=(PROTOCOL=ipc)(KEY=net)))
Services Summary...
Service "sales.us.example.com" has 1 instance(s).
 Instance "sales", status READY, has 3 handler(s) for this service...
   Handler(s):
      "DEDICATED" established: 0 refused: 0 state:ready
        LOCAL SERVER
      "D000" established:0 refused:0 current:0 max:10000 state:ready
        DISPATCHER <machine: sales-server, pid: 1689>
         (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=52414))
      "D001" established:0 refused:0 current:0 max:10000 state:ready
        DISPATCHER <machine: sales-server, pid: 1691>
         (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=52415))
Service "hr.us.example.com" has 1 instance(s).
 Instance "hr", status READY, has 2 handler(s) for this service...
   Handler(s):
      "DEDICATED" established: 0 refused: 0 state:ready
        LOCAL SERVER
      "D000" established:0 refused:0 current:0 max:10000 state:ready
        DISPATCHER <machine: sales-server, pid: 11326>
         (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=58361))
The command completed successfully
```

This output shows that two database services, sales.us.example.com and hr.us.example.com, are registered with the listener.

Client connection requests to sales.us.example.com are handled by two dispatchers named D000 and D001 and one dedicated server. All handlers have a status of ready, indicating that they are ready to receive connections.

Client connection requests to hr.us.example.com are handled by one dispatcher named D001 and one dedicated server.

The SERVICES command generates output with the following information as described in Table 9-2.

Table 9-2 Listener Control Utility SERVICES Command

Output Section	Description
Services	The registered service.
Instance	The name of the instance associated with the service The status field indicates if the instance can accept connections.
	 READY means the instance can accept connections. BLOCKED means the instance cannot accept connections. READY/SECONDARY means the is a secondary instance in an Oracle Real Application Clusters primary/secondary configuration and is ready to accept connections. RESTRICTED means the instance is in restricted mode. The listener blocks all connections to this instance. UNKNOWN means the instance is registered statically in the listener.ora file rather than dynamically with service registration. Therefore, the status is non known.

Table 9-2 (Cont.) Listener Control Utility SERVICES Command

Output Section	Description
Handlers	The name of the service handler. Dispatchers are named D000 through D999. Dedicated servers have the name of DEDICATED.
	This section also identifies the following about the service handler:
	 established: The number of client connections this service handler has established.
	refused: The number of client connections it has refused.
	 current: The number of client connections it is handling, that is, its current load.
	 max: The maximum number of connections for the service handler, that is, its maximum load.
	state: The state of the handler:
	- READY means the service handler can accept new connections.
	- BLOCKED means the service handler cannot accept new connections.

9.5.5 Monitoring Service Registration Operations

The SHOW STATS -REG command enables you to monitor database service registration operations that the listener handles, analyze the traffic or overhead of these operations, and diagnose registration-related issues.

An Oracle Database instance registers or updates its services and related information with the listener through service registration operations, such as REGISTER, UPDATE, RE-REGISTER, or UN-REGISTER. The listener keeps a record (count) of all these registration operations. You can query statistics about this data either periodically or for a particular period. Monitoring these statistics is especially helpful in Oracle Autonomous Database environments, where the listener continuously receives registration and update information from multiple instances.

To display statistics about database service registration operations, run the following command at the Listener Control (LSNRCTL) utility prompt:

LSNRCTL SHOW STATS -REG

You can also run this command from the Oracle Connection Manager Control (CMCTL) utility for the Oracle Connection Manager listener.

For a list of all the arguments that you can use with SHOW STATS, see *Oracle Database Net Services Reference*.

The SHOW STATS command generates an output that typically includes these sections:

Output Section	Description
Instance Name, Service Name, and	The output fields display statistics at these levels, depending on the arguments that you enter with SHOW STATS:
Global Level statistics	instances associated with the service
	 Service Name: Statistics for the specified service name or for all services registered with the listener
	 Global Level: Statistics for all instances, registered services, handlers allocated to these services, listening endpoints, and access control lists (ACLs)
Command summary	Registration operations through which an instance registers or updates its services and related information (such as handlers, endpoints, or ACLs) with the listener:
	• REGISTER
	• UPDATE
	• RE-REGISTER
	• UN-REGISTER
	Counters showing the number of commands received by the listener:
	• Instance: Number of instance registration, instance update, instance re- registration, and instance un-registration commands received.
	 Service: Number of service registration, service update, service re- registration, and service un-registration commands received.
	 ENDP (listening endpoint): Number of endpoints registration, endpoints update, endpoints re-registration, and endpoints un-registration commands received.
	 Handler: Number of handlers registration, handlers update, handlers reregistration, and handlers un-registration commands received. INF (related ACL information): Number of ACL registration, ACL update,
	ACL re-registration, and ACL un-registration commands received.
Recent count	Periodic count of all commands received by the listener from the last reset, that is, from the time you cleared the Recent section using -clear. If you have not used -clear till now, then this field displays a cumulative count of all registration commands received since the listener started.
	The Recent Duration field specifies a cumulative time (in days, hours, minutes, and seconds) from the last reset (if used -clear) or since the listener started (if not used -clear).
Cumulative count	Total number of commands received by the listener, collected since the listener started.
Flags, Goodness, and Delta summary	Summary of service update metrics for all services registered with the listener. These fields appear only for service-level queries.

Example 9-7 Sample SHOW STATS Command Output

LSNRCTL:lsnr1> sho	w stats -	reg			
Global Level:					
	Recent				
Recent Duration: 5	days 17	hr. 15	min. 25	sec	
Command Instanc	e Service	ENDP	Handler	INF

9.5.6 Monitoring Listener Log Files

When you notice any of the following conditions, review the listener log file for error information:

- Long connection establishment times
- Connectivity problems and refusals
- Unexpected shutdown of the listener that could indicate a denial-of-service attack

"Analyzing Listener Log Files"

9.6 Understanding Listener Redirects

The listener redirect feature allows a client to connect to a pluggable database (PDB) using an unchanged connect descriptor even after the PDB is migrated to a new location in the Oracle Public Cloud.

The Listener Registration (LREG) process registers a new handler with the local listener for the PDB or the service which is in the process of migration. This handler contains the new listener address of the database where the PDB or the service is migrated. The new listener address can be that of a Single Client Access Name (SCAN) listener in case of an Oracle RAC database or a local listener in case of a single-instance database. The listener then redirects the client to the new address.

If a local listener redirects to a SCAN listener in an Oracle RAC configuration, then this listener may need to further redirect the client connection request to another cluster node. Such multiple redirects are not supported by Oracle Net listeners by default. To allow the SCAN listener to forward the already redirected client connection request, add the ALLOW_MULTIPLE_REDIRECTS_listener_name parameter to its listener.ora file. Set the parameter to TRUE. Do not set this parameter for node listeners because it may allow infinite redirection loops in certain network configurations.

Configuring and Administering Oracle Connection Manager

Oracle Connection Manager is a proxy server that forwards connection requests to databases or other proxy servers. It operates at the session level, and usually resides on a computer separate from the database server and client computers.

Oracle Connection Manager is available for installation with Oracle Database Enterprise Edition. It is a custom installation option on the client system. Starting with Oracle Database Client 23ai, Oracle Connection Manager is available as an image file for installation and configuration. Refer to your platform-specific Oracle Database installation guide for additional information.

- Setting Up Oracle Connection Manager
 In order to set up Oracle Connection Manager, you must configure the proxy server, database, and clients.
- Configuring Oracle Connection Manager in Traffic Director Mode
 A current Oracle Database Client Interface (OCI) client or a supported older version OCI client (Oracle Database 11g Release 2 (11.2) and later) can connect to Oracle Connection Manager in Traffic Director Mode.
- Configuring Oracle Connection Manager in Tunneling Mode for Reverse Connection
 Oracle Connection Manager in tunnelling mode establishes tunnel connections between
 server CMAN and client CMAN. Clients can make reverse connections over tunnels by
 connecting to server cman.
- Using Oracle Connection Manager as a Bridge for IPv4 and IPv6
 In some database connection environments, a client and database may use different versions of the IP protocol so that complete connectivity does not exist. In this case, at least two hops in the connection use different versions of the IP protocol.
- Using Oracle Connection Manager to Prevent Denial-of-Service Attacks
 You can enforce a limit on the number of client connections that Oracle Connection
 Manager (CMAN) can handle from an IP address in a specific time interval.
- Starting and Stopping Oracle Connection Manager
 After configuring Oracle Connection Manager, you can start and administer it using the Oracle Connection Manager Control (CMCTL) utility.
- About CMCTL REST Interface
 CMCTL REST interface helps you manage Oracle Connection Manager (Oracle CMAN)
 instance from remote machines using REST interface. A client that supports HTTPS can
 issue CMCTL equivalent commands. Each REST API call must have www-Authenticate
 HTTPS header with Basic authentication method.
- Migrating CMAN Sessions During Patching
 You can migrate the established client/server sessions from one Oracle Connection
 Manager (CMAN) instance to another Oracle CMAN instance during a planned upgrade or
 patching of Oracle CMAN with zero downtime.
- Oracle Connection Manager Enhancements
 Oracle Connection Manager proxies and screens request for Oracle Database Server.

Related Topics

- Introducing Oracle Net Services
 Understand the basic elements of Oracle Net Services architecture and the Oracle Net foundation layer.
- Understanding the Communication Layers
 The primary function of Oracle Net is to establish and maintain connections between a client application and an Oracle database server.

10.1 Setting Up Oracle Connection Manager

In order to set up Oracle Connection Manager, you must configure the proxy server, database, and clients.

- About the cman.ora File
 You can set parameters in the cman.ora file to configure the computer that hosts Oracle
 Connection Manager.
- · Configuring the cman.ora file for the Oracle Connection Manager Host
- Configuring Transport Layer Security on Oracle Connection Manager
 Create a wallet on the Oracle Connection Manager (CMAN) server, and then specify the
 TCP/IP with Transport Layer Security (TLS) listening endpoint and wallet location in the
 cman.ora file.
- Enabling Access Control
- Configuring Clients for Oracle Connection Manager
- Configuring the Oracle Database Server for Oracle Connection Manager
 Configuring the database server involves registering database information remotely with Oracle Connection Manager and, optionally, configuring the server for multiplexing.

10.1.1 About the cman.ora File

You can set parameters in the cman.ora file to configure the computer that hosts Oracle Connection Manager.

The cman.ora file resides on the computer that hosts Oracle Connection Manager, and is located in the <code>ORACLE_BASE_HOME/network/admin</code> directory. If the cman.ora file is not present in the <code>ORACLE_BASE_HOME/network/admin</code> directory, then look for the file in <code>ORACLE_HOME/network/admin</code> directory.Oracle Connection Manager will not start if the cman.ora file does not exist. This file includes the following components:

- Listening endpoint
- Access control rule list
- Parameter list

Each Oracle Connection Manager configuration is encapsulated within a single name-value (NV) string, which consists of the preceding components.

One computer can host any number of Oracle Connection Managers, each with its own entry in the cman.ora file. When defining more than one Oracle Connection Manager in the file, you can assign a default by giving only one a fully qualified host name.

You can specify multiple rules for both client and Oracle Connection Manager Control utility (CMCTL) connections. The following guidelines apply when making changes:

- You must enter at least one rule for client connections and one rule for CMCTL connections. Omitting a rule results in the rejection of all connections for the rule type omitted.
- Oracle Connection Manager does not support wildcards for partial IP addresses. If you use a wildcard, then use it in place of a full IP address. The IP address of the client may be, for example, (SRV=*).
- Oracle Connection Manager supports only the /nn notation for subnet addresses. In Example 10-1, in the first rule, /24 represents a subnet mask that comprises 24 left-most bits. Only the first 24 bits in the client's IP address are compared with the IP address in the rule.

Oracle Connection Manager supports IPv6 addressing. See "Using Oracle Connection Manager as a Bridge for IPv4 and IPv6".

Example 10-1 shows a cman.ora file that contains a configuration entry for an Oracle Connection Manager called CMAN1.

Example 10-1 Sample cman.ora File

```
CMAN1=
  (CONFIGURATION=
        (ADDRESS=(PROTOCOL=tcp) (HOST=proxysvr) (PORT=1521))
  (RULE_LIST=
        (RULE=(SRC=192.0.2.32/24) (DST=sales-server) (SRV=*) (ACT=accept)
            (ACTION_LIST=(AUT=on) (MCT=120) (MIT=30)))
        (RULE=(SRC=192.0.2.32) (DST=proxysvr) (SRV=cmon) (ACT=accept)))
        (PARAMETER_LIST=
            (MAX_GATEWAY_PROCESSES=8)
            (MIN_GATEWAY_PROCESSES=3)))
```

Example 10-1 shows the following rules:

- In the first rule in the example, the following parameters are set:
 - SRC=192.0.2.32/24 is for client connections. It designates the IP address of the client, or source.
 - DST=sales-server designates the destination host name. The ACT parameter specifies the action, that is, accept, reject, or drop. The ACTION_LIST parameter sets attributes for a connection if it is accepted, enabling you to override default parameter settings on a connection-by-connection basis.
- In the second rule, the following parameters are set:
 - SRC=192.0.2.32 and DST=proxysvr represent the same server, indicating that Oracle
 Connection Manager and CMCTL must reside on the same computer.

"Enabling Access Control"

Table 10-1 describes the rule-level parameters in the cman.ora file.

Table 10-1 Rule-Level Parameters in cman.ora File

Parameter	Description
SRC	The source host name or IP address of the client. The IP address can be a subnet, such as 192.0.2.62/24.
DST	The destination host name or IP address of the database server. The IP address can be a subnet, such as 192.0.2.62/24.
SRV	The service name of the Oracle database obtained from the SERVICE_NAMES parameter in the initialization parameter file (init.ora).
	The service name is given by the client as part of the connect descriptor when connecting to the listener. This service name is compared to the service name specified in the rule list.
ACT	To accept, reject, or drop incoming requests based on the preceding three parameters.

You can define multiple rules in the RULE_LIST. The action (ACT) in the first matched RULE is applied to the connection request. If no rules are defined, then all connections are rejected.

In the following example, client computer client1-pc is denied access to the service sales.us.example.com, but client 192.0.2.45 is granted access to the service db1.

```
(RULE_LIST=
   (RULE=(SRC=client1-pc) (DST=sales-server) (SRV=sales.us.example.com)
(ACT=reject))
   (RULE=(SRC=192.0.2.45) (DST=192.0.2.200) (SRV=db1) (ACT=accept)))
```

Oracle Database Net Services Reference for additional information about Oracle Connection Manager parameters

10.1.2 Configuring the cman.ora file for the Oracle Connection Manager Host

You make changes to the cman.ora file manually. The following procedure describes how to set parameters in the cman.ora file:

- 1. Navigate to the cman.ora file in the ORACLE_BASE_HOME/network/admin directory. If the cman.ora file is not present in the ORACLE_BASE_HOME/network/admin directory, then look for the file in ORACLE HOME/network/admin directory.
- 2. Open the cman.ora file with a text editor.
- Configure the listening endpoint (ADDRESS).
 The listening endpoint specifies the protocol address for the Oracle Connection Manager listener. CMON, the Oracle Connection Manager monitoring process, uses this address to

register information about gateway processes with the listener. The database uses the address to register service information at the Oracle Connection Manager node.

The Oracle Connection Manager listener always listens on the TCP/IP protocol.

(ADDRESS=(PROTOCOL=tcp) (HOST=proxysvr) (PORT=1521))

Oracle Connection Manager can connect to the database using protocols such as TCP/IP (version 4 and version 6). Starting with Oracle Database 12c release 2 (12.2), the TCPS protocol is also supported

- Configure the access control rule list (RULE_LIST).
 The access control rule list specifies which connections are accepted, rejected, or dropped by the listener.
- 5. Configure the parameter list (PARAMETER_LIST). The parameter list sets attributes for an Oracle Connection Manager. Parameters take the following forms:
 - If global, then the parameter applies to all Oracle Connection Manager connections unless a rule-level parameter overrides it. To change a global parameter default setting, enter it into the PARAMETER_LIST with an allowable value.
 - If a rule-level parameter is enabled in the ACTION_LIST section of the RULE_LIST, then it applies only to connections specified by the rule. It overrides its global counterpart.

10.1.3 Configuring Transport Layer Security on Oracle Connection Manager

Create a wallet on the Oracle Connection Manager (CMAN) server, and then specify the TCP/IP with Transport Layer Security (TLS) listening endpoint and wallet location in the cman.ora file.

Starting with Oracle Database 23ai, the Oracle Wallet Manager (OWM) is desupported.

Oracle recommends using the orapki command line tool to replace OWM.

- 1. Confirm that a CMAN wallet has been created and that it has a certificate:
 - a. Log in to the Oracle Connection Manager server where the CMAN wallet resides.
 - b. Run the following command using the orapki command-line tool:

```
orapki wallet display -wallet wallet location
```

Where, wallet_location is the path to the directory where the wallet is stored.

If your wallet directory contains the <code>cwallet.sso</code> file (auto-login wallet) and it contains a user certificate, then this command displays a user certificate without asking for a password.

Ensure that <code>cwallet.sso</code> contains a user certificate. If the wallet does not contain a user certificate, create a wallet that contains a user certificate, and then run the following command to create <code>cwallet.sso</code> in your wallet directory:

```
orapki wallet create -wallet wallet location -auto login
```

2. In the cman.ora file, create a listening endpoint that uses TCP/IP with TLS (TCPS) and set the WALLET LOCATION parameter to specify the wallet location on the CMAN side.

For example, this is a sample cman.ora file configured with the TCPS protocol address and WALLET LOCATION parameter settings:

```
CMAN 1=
    (CONFIGURATION=
            (ADDRESS LIST=
               (ADDRESS=(PROTOCOL=tcps) (HOST=proxysvr) (PORT=1522))
               (ADDRESS=(PROTOCOL=tcp) (HOST=proxysvr) (PORT=1523))
        (RULE LIST=
               (RULE=(SRC=*)(DST=*)(SRV=*)(ACT=accept))
            (PARAMETER LIST=
               (MAX GATEWAY PROCESSES=8)
               (MIN GATEWAY PROCESSSES=3)
WALLET LOCATION=
    (SOURCE=
        (METHOD=File)
        (METHOD DATA=
             (DIRECTORY=wallet location)
SQLNET.WALLET OVERRIDE = TRUE
```

Note:

The parameter WALLET_LOCATION is deprecated for use with Oracle Database 23ai for the Oracle Database server. It is not deprecated for use with the Oracle Database client or listener.

For Oracle Database server, Oracle recommends that you use the WALLET_ROOT system parameter instead of using WALLET LOCATION.

10.1.4 Enabling Access Control

Use the RULE_LIST parameter to control client access to designated database servers in a TCP/IP environment. By entering filtering rules under this parameter, you can allow or restrict specific clients access to a database server.

The following procedure describes how to configure access control:

- Open the cman.ora file with a text editor.
- Update the RULE_LIST parameter using the following format:

10.1.5 Configuring Clients for Oracle Connection Manager

To route clients to the database server through Oracle Connection Manager, configure the tnsnames.ora file with a connect descriptor that specifies the protocol address of Oracle Connection Manager. This address enables clients to connect to the Oracle Connection Manager computer. The connect descriptor looks similar to the following:

The following procedure describes how to configure a protocol address for Oracle Connection Manager:

Start Oracle Net Manager.

```
See Also:

"Using Oracle Net Manager to Configure Oracle Net Services"
```

- In the navigator pane, select Service Naming from Directory or Local menus.
- Click the plus sign (+) on the toolbar, or select Create from the Edit menu.The Welcome page of the Net Service Name wizard appears.
- 4. Enter a name in the Net Service Name field.

Click Next.

The Protocol page appears.

- Select the TCP/IP protocol for Oracle Connection Manager.
- Click Next.

The Protocol Settings page appears.

8. Specify the Oracle Connection Manager port and protocol. The default port number for Oracle Connection Manager is 1521, and the protocol is TCP/IP.

Oracle Database Net Services Reference for protocol parameter settings

Click Next.

The Service page appears.

10. Enter a service name in the **Service Name** field, and then select the connection type.

"About Connect Descriptors" for additional information about setting the service name string

11. Click Next.

Do not click **Test**, because a connection cannot be tested at this point.

12. Click Finish to save your configuration and close the Net Service Name wizard.

The new network service name and the Oracle Connection Manager protocol address is added to the Service Naming folder.

10.1.6 Configuring the Oracle Database Server for Oracle Connection Manager

Configuring the database server involves registering database information remotely with Oracle Connection Manager and, optionally, configuring the server for multiplexing.

If the database that you want to register with Oracle Connection Manager is located on a remote node, then you must configure the cman.ora parameter VALID NODE CHECKING REGISTRATION to allow remote registration.

- Configuring Service Registration for Use with Oracle Connection Manager
 To enable the database server to communicate with Oracle Connection Manager, the
 - tnsnames.ora file must include the service name entry, and the initialization parameter file (init.ora) must contain a descriptor that specifies the listening address of Oracle Connection Manager.
- Enabling Session Multiplexing for Oracle Connection Manager

 To enable Oracle Connection Manager to take advantage of session multiplexing, set the

 DISPATCHERS parameter in the initialization parameter file (init.ora) with the PROTOCOL and

 MULTIPLEX attributes.

Related Topics

VALID_NODE_CHECKING_REGISTRATION

10.1.6.1 Configuring Service Registration for Use with Oracle Connection Manager

To enable the database server to communicate with Oracle Connection Manager, the <code>tnsnames.ora</code> file must include the service name entry, and the initialization parameter file <code>(init.ora)</code> must contain a descriptor that specifies the listening address of Oracle Connection Manager.

The following procedure describes how to configure service registration:

 Resolve the Oracle Connection Manager alias to a service name entry in the tnsnames.ora file as follows:

For example, the alias <code>listener_cman</code> would be resolved to the following entry in the <code>tnsnames.ora</code> file:

```
listener_cman=
(DESCRIPTION=
  (ADDRESS_LIST=
      (ADDRESS=(PROTOCOL=tcp) (HOST=proxyserver1) (PORT=1521))))
```

2. Specify an alias for Oracle Connection Manager in the init.ora file as follows. This alias is the one specified in the tnsnames.ora file in step 1.

```
REMOTE_LISTENER=cman_listener_address
```

The alias must be specified because this address is TCP, port 1521 but it is not the default local listening address of TCP, port 1521 of the database server.

For example, the alias for the Oracle Connection Manager listener running on host, proxyserver1, specified in step 1, might look like the following in the init.ora file:

```
REMOTE LISTENER=listener cman
```

3. Configure REGISTRATION_INVITED_NODES in cman.ora if the database resides on a remote node. For example:

```
(registration invited nodes=sales.us.example.com, 10.245.129.60)
```

4. After the initialization parameter file is configured with the alias of Oracle Connection Manager, the Listener Registration (LREG) process can register database information with the Oracle Connection Manager listener. Use the following command to register the change:

SQL> ALTER SYSTEM REGISTER

10.1.6.2 Enabling Session Multiplexing for Oracle Connection Manager

To enable Oracle Connection Manager to take advantage of session multiplexing, set the DISPATCHERS parameter in the initialization parameter file (init.ora) with the PROTOCOL and MULTIPLEX attributes.

For example:

DISPATCHERS="(PROTOCOL=tcp)(MULTIPLEX=on)"

The following table lists the parameters to set different levels of multiplexing:

Table 10-2 Session Multiplexing Parameters

Attribute	Description	
PROTOCOL	The network protocol for which the dispatcher generates a listening endpoint.	
MULTIPLEX	 This parameter is used to enable session multiplexing, as follows: If 1, on, yes, true, or both is specified, then multiplexing is enabled for both incoming and outgoing network sessions. If in is specified, then multiplexing is enabled for incoming network sessions from the client. If out is specified, then multiplexing is enabled for outgoing network sessions. If 0, off, no, or false is specified, then multiplexing is disabled for 	
	both incoming and outgoing network sessions.

10.2 Configuring Oracle Connection Manager in Traffic Director Mode

A current Oracle Database Client Interface (OCI) client or a supported older version OCI client (Oracle Database 11g Release 2 (11.2) and later) can connect to Oracle Connection Manager in Traffic Director Mode.

- About Oracle Connection Manager in Traffic Director Mode
 Oracle Connection Manager in Traffic Director Mode is a proxy that is placed between supported database clients and database instances.
- Configuring cman.ora File for Oracle Connection Manager in Traffic Director Mode You can set up Oracle Connection Manager in Traffic Director Mode using the TDM=YES setting in the cman.ora configuration file.

 Configuring a Wallet for Oracle Connection Manager in Traffic Director Mode Proxy Authentication

Oracle Connection Manager in Traffic Director Mode connects to the databases using the wallet that must be configured with cman.ora file.

 Enabling Oracle Connection Manager in Traffic Director Mode to Use External Password Store

Steps involve creating an Oracle wallet and creating database connection credentials in that wallet for each database service.

 Configuring Databases for Oracle Connection Manager in Traffic Director Mode Proxy Authentication

Every database to which an application connects through Oracle Connection Manager in Traffic Director Mode must have a user, for example, tdm.

- Configuring Service Registration with Oracle Connection Manager in Traffic Director Mode
 To configure service registration, include the service name entry in the tnsnames.ora file.
 Also, include a descriptor that specifies the listening address of Oracle Connection
 Manager in the init.ora file.
- Configuring Proxy Resident Connection Pooling in Oracle Connection Manager in Traffic Director Mode

Oracle Connection Manager in Traffic Director Mode (CMAN-TDM) supports Proxy Resident Connection Pooling (PRCP). You can configure PRCP either for each database service (default setting) or for an entire PDB.

- Configuring Oracle Connection Manager in Traffic Director Mode for Unplanned Events
 Oracle Connection Manager in Traffic Director Mode implicitly subscribes to Fast
 Application Notification (FAN) events. For this events must be enabled in oraccess.xml.
- Configuring Oracle Connection Manager in Traffic Director Mode for Planned Down Events
 Oracle Connection Manager in Traffic Director Mode implicitly subscribes to Fast
 Application Notification (FAN) events. For this events must be enabled in oraccess.xml.
- Configuring Oracle Connection Manager in Traffic Director Mode for Service Affinity
 Configure Oracle Connection Manager in Traffic Director Mode to modify the default load
 distribution mechanism for routing incoming connection requests.
- Configuring Transport Layer Security on Oracle Connection Manager in Traffic Director Mode

Create a wallet on the Oracle Connection Manager in Traffic Director Mode server (CMAN-TDM), and then specify the TCP/IP with Transport Layer Security (TLS) listening endpoint and wallet location in the cman.ora file.

Oracle Connection Manager in Traffic Director Mode Restrictions
 These features are not supported with Oracle Connection Manager in Traffic Director Mode (CMAN-TDM) for all drivers.

10.2.1 About Oracle Connection Manager in Traffic Director Mode

Oracle Connection Manager in Traffic Director Mode is a proxy that is placed between supported database clients and database instances.

- Connection Modes
 - Oracle Connection Manager in Traffic Director Mode supports pooled and non-pooled modes of operation.
- Performance and Security
 Orgale Connection Manager in

Oracle Connection Manager in Traffic Director Mode allows client connections to be routed to databases, providing high availability and connection multiplexing capabilities. It also

supports enhanced security features, and provides zero application downtime for planned and unplanned database outages.

Database Links

Oracle Connection Manager in Traffic Director Mode supports database links, which extends high availability and failover to databases.

Per-Service and Per-PDB Connection Pools

Proxy Resident Connection Pooling (PRCP) provides connection pools on the Oracle Connection Manager in Traffic Director Mode (CMAN-TDM) server. You can configure CMAN-TDM to establish either per-service or per-PDB pooled connections.

Implicit Connection Pooling

Client applications that do not use an application connection pool can leverage connection pooling capabilities without making any application-level change or calling the pooling APIs.

Related Topics

Oracle Database Security Guide

10.2.1.1 Connection Modes

Oracle Connection Manager in Traffic Director Mode supports pooled and non-pooled modes of operation.

Pooled connection mode:

Supports applications using the following database client releases:

- OCI and Open Source Drivers (11.2.0.4 and later)
- JDBC (12.1 and later)
- ODP.NET (12.2 and later)

In addition, applications must be Database Resident Connection Pool (DRCP) aware. This means specifying (SERVER=POOLED) in the application connect string.

Non-pooled connection (or dedicated) mode:

Supports applications using database client releases 11.2.0.4 and later. In this mode, some capabilities such as connection multiplexing are not available.

For a connection from a client to the database using Oracle Connection Manager in Traffic Director Mode, the client and database versions should be a supported combination.

10.2.1.2 Performance and Security

Oracle Connection Manager in Traffic Director Mode allows client connections to be routed to databases, providing high availability and connection multiplexing capabilities. It also supports enhanced security features, and provides zero application downtime for planned and unplanned database outages.

Transparent Performance and Connection Multiplexing

 Statement caching, rows prefetching and result set caching are auto-enabled for all mode of operations.

 Database connection multiplexing (pooled mode only) using Proxy Resident Connection Pooling (PRCP, a proxy mode of Database Resident Connection Pooling). PRCP uses the Oracle Call Interface (OCI) Session Pooling feature.

PRCP provides connection services for a large number of client connections that are routed using a connection pool, which comprises a fewer number of server connections to target databases. PRCP reduces connection load (connection memory usage) on the database tier, and provides runtime load balancing between database and Oracle Connection Manager in Traffic Director Mode.

High Availability

- Multiple Oracle Connection Manager in Traffic Director Mode instances: Applications get increased scalability through client-side connect time load balancing or with a load balancer (BIG-IP, NGINX, and others).
- Rolling upgrade of Oracle Connection Manager in Traffic Director Mode instances.
- Closure of existing connections from client to Oracle Connection Manager in Traffic Director Mode for planned outages.
- In-band notifications to Oracle Database release 18c and later clients. For earlier release clients, notifications are sent with the response of the current request.

Security and Isolation

- Database proxy supporting TCP/TCPS and protocol conversion.
- Firewall based on IP address, service name, and TLS wallets.
- Tenant isolation in a multitenant environment.
- Protection against denial-of-service and fuzzing attacks.
- Secure tunneling of database traffic across on-premises database and Oracle Cloud.

Zero Application Downtime

- Planned database maintenance or pluggable database (PDB) relocation:
 - In a pooled mode, Oracle Connection Manager in Traffic Director Mode responds to Oracle Notification Service (ONS) events for planned outages and redirects work. The connections are drained from the pool on Oracle Connection Manager in Traffic Director Mode when the request completes. It also supports service relocation.
 - Oracle Connection Manager in Traffic Director Mode responds to in-band notifications when a PDB is relocated, even when ONS is not configured (for server only).
 - In a non-pooled or dedicated mode, no request boundary information is received from the client. Oracle Connection Manager in Traffic Director Mode supports planned outage for many applications (as long as only simple session state and cursor state need to be preserved across the request or transaction boundaries). This involves the following:
 - * Stop Service or PDB at a transaction boundary or leverage Continuous Application Availability to stop service at a request boundary.
 - Oracle Connection Manager in Traffic Director Mode leverages TAF Failover Restore to reconnect and restore simple states.
- Unplanned database outages:
 - For both pooled and non-pooled (dedicated) modes, Oracle Connection Manager in Traffic Director Mode supports unplanned outage for read—mostly applications by leveraging TAF Failover Restore to restore simple session state or cursor state and replay SELECT statements and first DML statement.

10.2.1.3 Database Links

Oracle Connection Manager in Traffic Director Mode supports database links, which extends high availability and failover to databases.

Starting with Oracle Database 21c, Oracle Connection Manager in Traffic Director Mode (TDM) supports the following types of database links:

- Fixed User: The user connects to the remote database using the username and password specified during the creation of the database link.
- Connected User: The user connects to the remote database using the credentials of the
 user accessing the database link. These credentials can either be a username and
 password, or external, such as Kerberos ticket.

You can use database links with Traffic Director Mode in the following scenarios:

Scenario 1:

When a client connects directly to the database

In this scenario, both fixed user and connected user database links work.

Scenario 2:

When a client connects to the database through the Traffic Director Mode

In this scenario, only fixed user database link works. The connected user database link does not work as the session between TDM and the database is a proxy user session. Proxy user sessions are not allowed over a database link for security reasons.

For the database links to work with TDM, the TDM should not be running in Proxy Resident Connection Pool (PRCP) mode for the particular database service.

10.2.1.4 Per-Service and Per-PDB Connection Pools

Proxy Resident Connection Pooling (PRCP) provides connection pools on the Oracle Connection Manager in Traffic Director Mode (CMAN-TDM) server. You can configure CMAN-TDM to establish either per-service or per-PDB pooled connections.

Per-Service PRCP

In per-service PRCP, CMAN-TDM creates a single, dedicated pool for the requested database service based on the <code>SERVICE_NAME</code> parameter specified in the connect string. When a client application requests a new connection, CMAN-TDM establishes a pooled connection from this service pool. Every time the application requests a connection to this service, CMAN-TDM returns a matching connection from its service pool.

For example, for incoming connection requests with the specified service names as Service1_PDB1 and Service2_PDB1, CMAN-TDM creates two service pools, that is, PRCP_for_Service1_PDB1 to support the Service1_PDB1 connections and PRCP for Service2 PDB1 to support the Service2 PDB1 connections.

Per-PDB PRCP

Per-PDB PRCP works in a similar manner as per-service PRCP. In this mode, when a client application requests a new connection, CMAN-TDM again establishes a pooled connection to the requested service based on the SERVICE_NAME parameter value specified in the connect string. However, instead of creating a dedicated pool for this service, it creates a multi-service PDB pool that supports connections across all services registered with that PDB. Any available Oracle Connection Manager Gateway (CMGW) can accept a connection request to the service or PDB, based on load balancing.

For example, for incoming connection requests to <code>Service1_PDB1</code> and <code>Service2_PDB1</code> (both running on <code>PDB1</code>), CMAN-TDM creates a single PDB pool, that is, <code>PRCP_for_PDB1</code> to support both the <code>Service1_PDB1</code> and <code>Service2_PDB1</code> connections.

Per-PDB PRCP has the following advantages over per-service PRCP:

- Reduces the number of connection pools on CMGW by consolidating multiple service pools into a single PDB pool. This helps in optimizing the database performance.
- Dynamically determines and refreshes the maximum size of a PDB pool based on the TDM PERPDB PRCP CONNFACTOR value and the OCPU count allocated to each PDB.

The per-PDB PRCP configuration is especially useful in multitenant environments like Autonomous Databases, where PDB administrators can configure and monitor PRCP on the database side instead of having to access CMAN-TDM hosts for PRCP configuration.

Oracle does not recommend switching between the per-service and per-PDB modes. If you do so, then the changes are applied only to the gateways that start after the reconfiguration.

Pool Size Configuration Settings

- For per-service PRCP, CMAN administrators specify the <session_pool> MAX_SIZE value in the orangeess.xml on the CMAN-TDM host during the initial PRCP configuration.
- In the per-PDB PRCP mode, pool sizing is more autonomous. CMAN administrators
 specify a connection factor in the cman.ora file using the TDM_PERPDB_PRCP_CONNFACTOR
 parameter.

The per-PDB PRCP setting determines the maximum size of a per-PDB PRCP pool based on the <code>TDM_PERPDB_PRCP_CONNFACTOR</code> parameter value and the Oracle Compute Unit (OCPU) count allocated to each PDB automatically. A background process automatically fetches these values and resizes the pool. This derived maximum size value overrides the <code><session_pool> MAX_SIZE</code> parameter configured in the <code>oraaccess.xml</code> file.

You must set the sqlnet.ora parameter TCP.ALLOWED_PROXIES on the Oracle Database server to list the allowed CMAN instances that can fetch the OCPU count.

V\$TDM_STATS View

In the per-PDB PRCP mode, PDB administrators can query the V\$TDM_STATS view on the database to display usage statistics for CMAN-TDM. In this view, you can analyze an aggregated data for all inbound connections, such as the number of client requests that have retrieved a session in the pool, the number of active client connections, the number of busy

and free server connections, the maximum number of connections reached, and so on. This view helps in the monitoring and tuning of CMAN-TDM.

A separate background thread fetches the statistical data from each CMGW and uploads to PDB at regular intervals. You can configure this time interval using the cman.ora parameter TDM STATS FREQUENCY.

Related Topics

 Configuring Proxy Resident Connection Pooling in Oracle Connection Manager in Traffic Director Mode

Oracle Connection Manager in Traffic Director Mode (CMAN-TDM) supports Proxy Resident Connection Pooling (PRCP). You can configure PRCP either for each database service (default setting) or for an entire PDB.

- TDM_PERPDB_PRCP_CONNFACTOR
- TCP.ALLOWED_PROXIES
- TDM_STATS_FREQUENCY
- V\$TDM_STATS

10.2.1.5 Implicit Connection Pooling

Client applications that do not use an application connection pool can leverage connection pooling capabilities without making any application-level change or calling the pooling APIs.

Overview

Starting with Oracle Database 23ai, Proxy Resident Connection Pooling (PRCP) supports implicit connection pooling. This feature enables the automatic assignment of PRCP servers to and from an application connection at runtime when the application starts and finishes database operations, even if the application does not explicitly release the connection.

With implicit connection pooling, a database session from PRCP automatically gets mapped to and unmapped from an application connection without the explicit session pool API calls from the client. PRCP implicitly detects an end of request boundary (statelessness of the session) and releases the session back to the connection pool. For example, for a transaction, the application can implicitly use or reuse an available session from a pool of stateless sessions and then release the session back to the pool after the transaction is complete.

Implicit connection pooling helps in reducing the size of PRCP pools required. It provides better scalability and an efficient use of database resources for applications that do not use connection pools, such as Oracle Call Interface (OCI) Session Pool or Java Database Connectivity (JDBC) Oracle Universal Connection Pool (UCP).

Statement and Transaction Boundaries

Implicit connection pooling uses time boundaries to release a session back to the connection pool. A time boundary is a point in time in the life-cycle of the application when an application session is released back to the pool.

You can enable implicit connection pooling by setting the POOL_BOUNDARY parameter in the connect string, Easy Connect syntax, or tnsnames.ora file. Using this parameter, you specify one of these time boundaries:

 STATEMENT: To release a session back to the PRCP pool when the session is implicitly stateless.

• TRANSACTION: To release a session back to the PRCP pool when a transaction ends implicitly or explicitly, or when a transaction is not available and the session is stateless.

Note the following:

- A session is implicitly stateless when all open cursors in a session have been fetched through to completion and there are no active transactions, temporary tables, or temporary LOBs. The release to the pool closes any active cursors, temporary tables, and temporary LOBs.
- After executing a statement or creating a temporary LOB, if you perform a commit or rollback within the TRANSACTION boundary, then:
 - Subsequent fetch operations may encounter an invalid cursor-related error, such as ORA-01001.
 - Subsequent use of a temporary LOB may encounter an ORA-22922.
 - Working with a persistent LOB can continue even after an implicit release. However, if an implicit operation lands on a different instance, then an ORA-43887 error may occur. In such cases, you must attempt the operation again.

- Oracle Database Development Guide
- Configuring Proxy Resident Connection Pooling in Oracle Connection Manager in Traffic Director Mode
 - Oracle Connection Manager in Traffic Director Mode (CMAN-TDM) supports Proxy Resident Connection Pooling (PRCP). You can configure PRCP either for each database service (default setting) or for an entire PDB.
- POOL_BOUNDARY

10.2.2 Configuring cman.ora File for Oracle Connection Manager in Traffic Director Mode

You can set up Oracle Connection Manager in Traffic Director Mode using the TDM=YES setting in the cman.ora configuration file.

Oracle Connection Manager (CMAN) is the standard Oracle Net proxy for both Oracle Real Application Clusters (Oracle RAC) and non-RAC databases. To configure CMAN to act as Oracle Connection Manager in Traffic Director Mode, you must add the tdm and tdm threading model parameters in the cman.ora file.

The databases that Oracle Connection Manager in Traffic Director Mode connects to must have a user, for example, *tdm* with the CONNECT THROUGH privilege granted to connect as application users. Oracle Connection Manager in Traffic Director Mode uses proxy authentication and connects as this user.

Note:

The parameter WALLET_LOCATION is deprecated for use with Oracle Database 23ai for the Oracle Database server. It is not deprecated for use with the Oracle Database client or listener.

For Oracle Database server, Oracle recommends that you use the WALLET_ROOT system parameter instead of using WALLET LOCATION.

10.2.3 Configuring a Wallet for Oracle Connection Manager in Traffic Director Mode Proxy Authentication

Oracle Connection Manager in Traffic Director Mode connects to the databases using the wallet that must be configured with cman.ora file.

This wallet has the user name and the password information for the *tdm* user used by Oracle Connection Manager in Traffic Director Mode for proxy authentication. This *tdm* user must exist on all the databases that the Oracle Connection Manager in Traffic Director Mode connects to.

The following setting causes all outbound connections from Oracle Connection Manager in Traffic Director Mode to use the credentials in the wallet at the specified location for proxy authentication:

Note:

The parameter WALLET_LOCATION is deprecated for use with Oracle Database 23ai for the Oracle Database server. It is not deprecated for use with the Oracle Database client or listener.

For Oracle Database server, Oracle recommends that you use the WALLET_ROOT system parameter instead of using WALLET LOCATION.

The wallet must be configured for each service. If a new service is added, then you must supply the credentials for the new service using the same wallet.

Whenever a new service is added and the credentials for the new service are added to the wallet, the Oracle Cloud Traffic Manager should be restarted for the changes to take effect.

Related Topics

 Configuring Databases for Oracle Connection Manager in Traffic Director Mode Proxy Authentication

Every database to which an application connects through Oracle Connection Manager in Traffic Director Mode must have a user, for example, tdm.

10.2.4 Enabling Oracle Connection Manager in Traffic Director Mode to Use External Password Store

Steps involve creating an Oracle wallet and creating database connection credentials in that wallet for each database service.

Step 1: Create a wallet on Oracle Connection Manager in Traffic Director Mode by using the following syntax at the command line:

```
mkstore -wrl wallet_location -create
```

wallet location is the path to the directory where you want to create and store the wallet.

This command creates an Oracle wallet with the auto-login feature enabled at the specified location:

```
orapki wallet create -wallet wallet_location -auto_login
Enter password: password
Enter password again: password
```

The auto-login feature enables Oracle Connection Manager in Traffic Director Mode to access the wallet contents without supplying a password.

Step 2: Create database connection credentials in the wallet by using the following syntax at the command line:

mkstore -wrl wallet_location -createCredential db_service_name username
password

wallet_location is the path to the directory where you created the wallet in Step 1. The db_service_name is the service name used by the application in its connect string while connecting to Oracle Connection Manager. The username and password are the tdm user name and password.

Note:

The mkstore wallet management command line tool is deprecated with Oracle Database 23ai, and can be removed in a future release.

To manage wallets, Oracle recommends that you use the orapki command line tool.

Repeat this step for each database service that must be accessed by using Oracle Connection Manager in Traffic Director Mode.

For TCP/IP with TLS (TCPS) configuration, Oracle Connection Manager in Traffic Director Mode wallet is already created. In this case, you can skip Step 1 and specify wallet_location in mkstore as the same location used for TCPS configuration.

Note:

- The same tdm user can be used across all services for a given database.
 However, if required, a different tdm user can also be associated for each service.
- For pluggable database (PDB) services, there are two choices for setting up the tdm user:

Common *tdm* user: *tdm* user can be a common user, in which case Oracle Connection Manager in Traffic Director Mode uses a single set of credentials for proxy authenticating users from different PDBs in a multitenant container database (CDB).

Per PDB *tdm* user: *tdm* user can be a PDB–specific user, in which case Oracle Connection Manager in Traffic Director Mode uses PDB–specific proxy user for proxy authenticating users in a specific PDB.

10.2.5 Configuring Databases for Oracle Connection Manager in Traffic Director Mode Proxy Authentication

Every database to which an application connects through Oracle Connection Manager in Traffic Director Mode must have a user, for example, tdm.

Oracle Connection Manager in Traffic Director Mode uses proxy authentication and connects to the database as the tdm user. All the users that must connect through Oracle Connection Manager in Traffic Director Mode must be granted CONNECT THROUGH tdm privilege as follows:

ALTER user SCOTT GRANT CONNECT THROUGH tdm

10.2.6 Configuring Service Registration with Oracle Connection Manager in Traffic Director Mode

To configure service registration, include the service name entry in the tnsnames.ora file. Also, include a descriptor that specifies the listening address of Oracle Connection Manager in the init.ora file.

The procedure to configure service registration with Oracle Connection Manager in Traffic Director Mode is similar to how you configure service registration for use with Oracle Connection Manager.

Related Topics

Configuring Service Registration for Use with Oracle Connection Manager
 To enable the database server to communicate with Oracle Connection Manager, the
 tnsnames.ora file must include the service name entry, and the initialization parameter file
 (init.ora) must contain a descriptor that specifies the listening address of Oracle

 Connection Manager.

10.2.7 Configuring Proxy Resident Connection Pooling in Oracle Connection Manager in Traffic Director Mode

Oracle Connection Manager in Traffic Director Mode (CMAN-TDM) supports Proxy Resident Connection Pooling (PRCP). You can configure PRCP either for each database service (default setting) or for an entire PDB.

Optionally, you can enable implicit connection pooling with PRCP.

- Configure PRCP in either per-service or per-PDB mode.
 - Per-service PRCP:

This is the default PRCP configuration.

The <session_pool> parameters in the oraccess.xml file (available in the TNS_ADMIN directory of the CMAN-TDM server) enable you to configure per-service PRCP and specify the associated connection parameters.

You can specify the following <code><session_pool></code> parameters in the <code><default_parameters></code> section or in the <code><config_descriptions></code> section. When specified in the <code><default_parameters></code> section, the setting applies to all connection pools in the application.

Parameter	Description
<enable></enable>	You must set <enable> to true (default setting) to make the session pool configuration effective.</enable>
	This is a mandatory parameter, that means, if <pre><session_pool> is configured, then <enable> must also be configured.</enable></session_pool></pre>

Parameter	Description
<min_size></min_size>	Minimum number of connections in the pool.
	The default value is 0. CMAN-TDM is a heterogeneous pool scenario, so all other values are ignored.
<max_size></max_size>	Maximum number of connections in the pool.
	This is a mandatory parameter, that means, if <pre><session_pool> is configured, then <max_size> must also be configured.</max_size></session_pool></pre>
	The default value is 0.
<increment></increment>	Amount of increase in the number of connections in the pool as the pool expands.
	The default value is 1.
<pre><inactivity_timeout></inactivity_timeout></pre>	Maximum time in seconds for which a connection stays idle in the pool, after which it is terminated.
	The default value is 0. It means that there is no limit.
<max_use_session></max_use_session>	Maximum number of times a connection can be retrieved and released to the pool.
	The default value is θ . It means that there is no limit.
<max_life_time_session></max_life_time_session>	Time, in seconds, a connection must stay after it has been created in the pool.
	The default value is $\ensuremath{\mathbb{0}}$. It means that there is no limit.

The orangess.xml file allows you to configure a connection pool for each required connection service.

The following example shows two groups of connection parameters associated with its respective <code>config_alias</code>, the <code>sales_config</code> and the <code>hr_config</code>, where each connection string that the application uses is mapped with its respective <code>config_alias</code>, thus providing two proxy resident connection pools.

```
<oraaccess xmlns="http://xmlns.example.com/oci/oraaccess"</pre>
            xmlns:oci="http://xmlns.example.com/oci/oraaccess"
            schemaLocation="http://xmlns.example.com/oci/oraaccess
            http://xmlns.example.com/oci/oraaccess.xsd">
  <default parameters>
  </default parameters>
    <!--
         Create configuration descriptions, which are
        groups of connection parameters associated with
         a config alias.
  <config descriptions>
    <config description>
      <config alias> sales config </config alias>
      <parameters>
         <session pool>
            <enable>true</enable>
            <min size> 10 </min size>
            <max size> 100 </max size>
            <increment> 5 </increment>
         </session pool>
      </parameters>
    </config description>
```

```
<config description>
      <config alias> hr config </config alias>
      <parameters>
         <session pool>
          <enable>true</enable>
          <max size> 10 </max size>
         </session pool>
      </parameters>
    </config description>
  </config descriptions>
  <!--
         Now map the connection string used by the application
        with a config alias.
  -->
  <connection_configs>
    <connection config>
      <connection string>sales.us.example.com</connection string>
      <config alias>sales config</config alias>
    </connection config>
    <connection config>
      <connection string>hr.us.example.com</connection string>
      <config alias>hr config</config alias>
    </connection config>
  </connection configs>
</oraaccess>
```

Per-PDB PRCP:

Instead of creating dedicated pools for all requested services, you can configure a single multi-service PDB pool to support connections across all the services registered with that PDB. Based on the Oracle Compute Unit (OCPU) count allocated to your PDB and the specified connection factor, PRCP dynamically computes the maximum pool size.

a. On the database server, set the sqlnet.ora parameter TCP.ALLOWED_PROXIES to specify one or more CMAN instances (IP addresses or host names) that you want to allow for fetching the OCPU count.

For example:

```
TCP.ALLOWED PROXIES=(10.1.1.1/24, cmanhost1.example.com)
```

b. On the CMAN-TDM host, set the cman.ora parameter

TDM PERPDB PRCP CONNFACTOR to the required connection factor value.

Any value equal to or greater than 1 enables per-PDB PRCP.

For example:

```
TDM PERPDB PRCP CONNFACTOR=10
```

Note:

Ensure that you set the connection factor value within the maximum connections limit defined by the cman.ora parameter MAX CONNECTIONS.

c. (Optional) To monitor the behavior of these pools, you can query the dynamic database view V\$TDM_STATS. To do so, first enable statistics upload by setting the cman.ora parameter TDM STATS FREQUENCY to the required time interval value.

Any value equal to or greater than 1 (up to the defined maximum value) enables statistics upload.

For example:

```
TDM STATS FREQUENCY=300
```

Based on the specified frequency, CMAN-TDM fetches the data from each CMAN-TDM gateway and uploads to PDB.

d. (Optional) You can specify the associated connection parameters in the <default parameters> section of the oraaccess.xml file.

For example:

```
<default_parameters>
  <events>true</events>
   <session_pool>
        <enable>true</enable>
        <max_size> 5 </max_size>
        <max_life_time_session> 50 </max_life_time_session>
        <max_use_session> 5 </max_use_session>
        <inactivity_timeout> 5 </inactivity_timeout>
        </session_pool>
</default_parameters>
```

If you specify the <default_parameters> section with <enable> set to true, then all the specified parameters are effective except for the <max_size> parameter. PRCP automatically derives the maximum size of a pool (using TDM_PERPDB_PRCP_CONNFACTOR and OCPU count). This derived maximum size value overrides the <session_pool> <max_size> parameter configured in the oraaccess.xml file.

If you do not specify the <default_parameters> section or if you specify it with <enable> set to false, then all other parameters in the section are ignored.

The <code>config_alias</code>, which maps each service name used by the application to the connection parameters, does not function because the pool is not limited to a single service in the per-PDB PRCP mode.

 (Optional) To enable implicit connection pooling with either per-service or per-PDB PRCP, on the client side, set the POOL_BOUNDARY parameter in the tnsnames.ora file, Easy Connect syntax, or directly as part of the command-line connect string.

Implicit connection pooling automatically performs session mapping or unmapping based on the session state. This can help maximize the pooled server usage and reduce the server resource usage.

Specify one of these time boundaries to release the session back to the PRCP pool:

STATEMENT: To release the session when the session is implicitly stateless.

For example:

 TRANSACTION: To release the session when a transaction ends implicitly or explicitly, or when a transaction is not available and the session is stateless.

For example:

The release to the pool closes any active cursors, temporary tables, and temporary LOBs.

You must set the POOL_BOUNDARY parameter along with the SERVER=POOLED setting. Otherwise, implicit connection pooling is disabled and the POOL_BOUNDARY directive is ignored.

Related Topics

- Per-Service and Per-PDB Connection Pools
 Proxy Resident Connection Pooling (PRCP) provides
 - Proxy Resident Connection Pooling (PRCP) provides connection pools on the Oracle Connection Manager in Traffic Director Mode (CMAN-TDM) server. You can configure CMAN-TDM to establish either per-service or per-PDB pooled connections.
- Implicit Connection Pooling
 Client applications that do not use an application connection pool can leverage connection pooling capabilities without making any application-level change or calling the pooling APIs.

10.2.8 Configuring Oracle Connection Manager in Traffic Director Mode for Unplanned Events

Oracle Connection Manager in Traffic Director Mode implicitly subscribes to Fast Application Notification (FAN) events. For this events must be enabled in oraccess.xml.

Use <code>DBMS_SERVICE</code> or <code>SRVCTL</code> (for an Oracle RAC database) to specify <code>COMMIT_OUTCOME</code> for this specific service.

- Oracle Clusterware Administration and Deployment Guide

10.2.9 Configuring Oracle Connection Manager in Traffic Director Mode for Planned Down Events

Oracle Connection Manager in Traffic Director Mode implicitly subscribes to Fast Application Notification (FAN) events. For this events must be enabled in oraccess.xml.

For planned down events, use DBMS_SERVICE or SRVCTL to configure the service and set failover_mode to select, commit_outcome to TRUE, and failover_restore to LEVEL1.

Related Topics

- Oracle Database PL/SQL Packages and Types Reference
- Oracle Clusterware Administration and Deployment Guide

10.2.10 Configuring Oracle Connection Manager in Traffic Director Mode for Service Affinity

Configure Oracle Connection Manager in Traffic Director Mode to modify the default load distribution mechanism for routing incoming connection requests.

By default, Oracle Connection Manager in Traffic Director Mode uses service affinity to select a gateway for routing incoming connection requests. All new connection requests are routed to the gateways associated with database services.

Use the cman.ora parameter SERVICE_AFFINITY to modify the default behavior and set the parameter to ON or OFF.

When using Proxy Resident Connection Pooling (PRCP), Oracle recommends that you set the SERVICE_AFFINITY parameter to OFF for better performance and resource utilization of gateway processes.

Related Topics

- Oracle Database Net Services Reference

10.2.11 Configuring Transport Layer Security on Oracle Connection Manager in Traffic Director Mode

Create a wallet on the Oracle Connection Manager in Traffic Director Mode server (CMANTDM), and then specify the TCP/IP with Transport Layer Security (TLS) listening endpoint and wallet location in the cman.ora file.

Starting with Oracle Database 23ai, the Oracle Wallet Manager (OWM) is desupported.

Oracle recommends using the orapki command line tool to replace OWM.

- Confirm that a wallet has been created and that it has a certificate:
 - Log in to the Oracle Connection Manager in Traffic Director Mode server where the wallet resides.
 - b. Run the following command using the orapki command-line tool:

```
orapki wallet display -wallet wallet location
```

Where, wallet location is the path to the directory where the wallet is stored.

If your wallet directory contains the <code>cwallet.sso</code> file (auto-login wallet) and it contains a user certificate, then this command displays a user certificate without asking for a password.

Ensure that <code>cwallet.sso</code> contains a user certificate. If the wallet does not contain a user certificate, create a wallet that contains a user certificate, and then run the following command to create <code>cwallet.sso</code> in your wallet directory:

```
orapki wallet create -wallet wallet_location -auto_login
```

2. In the cman.ora file, create a listening endpoint that uses TCP/IP with TLS (TCPS) and set the WALLET LOCATION parameter to specify the wallet location on the CMAN-TDM side.

For example, this is a sample $\mathtt{cman.ora}$ file configured with the \mathtt{TCPS} protocol address and $\mathtt{WALLET_LOCATION}$ parameter settings:

```
CMAN_1=

(CONFIGURATION=

(ADDRESS_LIST=

(ADDRESS=(PROTOCOL=tcps) (HOST=proxysvr) (PORT=1522))

(ADDRESS=(PROTOCOL=tcp) (HOST=proxysvr) (PORT=1523))

)

(RULE_LIST=

(RULE=(SRC=*) (DST=*) (SRV=*) (ACT=accept))

)

(PARAMETER_LIST=

(MAX_GATEWAY_PROCESSES=8)

(MIN_GATEWAY_PROCESSES=3)
```

```
)
)
WALLET_LOCATION=
(SOURCE=
(METHOD=File)
(METHOD_DATA=
(DIRECTORY=wallet_location)
)
)
SQLNET.WALLET OVERRIDE = TRUE
```

Note:

The parameter WALLET_LOCATION is deprecated for use with Oracle Database 23ai for the Oracle Database server. It is not deprecated for use with the Oracle Database client or listener.

For Oracle Database server, Oracle recommends that you use the <code>WALLET_ROOT</code> system parameter instead of using <code>WALLET_LOCATION</code>.

10.2.12 Oracle Connection Manager in Traffic Director Mode Restrictions

These features are not supported with Oracle Connection Manager in Traffic Director Mode (CMAN-TDM) for all drivers.

- Java Database Connectivity (JDBC) objects for Transparent Application Continuity (TAC)
- Advanced Queuing (AQ)
- Database Links
- Database Startup or Database Shutdown calls
- Sharding (or Oracle Globally Distributed Database)
- SQL Translation
- Dual session proxy authentication
- OS authentication
- Authentication as SYSDBA, SYSOPER, and so on
- SSL external authentication (such as DN) without explicitly passing user name and password
- Object REF
- Session switching
- · Session migration
- OCIObject* calls for navigational access
- OCIPickerImage* calls
- OCIAnyData* calls

- OCISubscription* calls: Client-side subscriptions for Application Continuity (AC), TAC, Runtime Load Balancing (RLB), and Fast Application Notification (FAN)
- OCILCR*, OCIXStream* calls
- OCIStmtExecute:
 - Server-side scrollable cursor support
 - Implicit Results
- Change Notification (CQN)
- Client Result Cache
- Database Resident Connection Pool (DRCP): Multi-property tag and PLSQL callback
- OCIConnectionPool
- Real Application Security (only in Java)
- Bulk Copy (ODP.Net only)
- Self-Tuning (ODP.Net only)
- MultiThreadedServer (MTS) distributed transactions (ODP.Net only)
- Oracle Advanced Security (ASO) encryption and supported algorithms (ASO only)
- Usage of Application Context attributes

In addition, the following tasks are not supported:

- Using SID instead of SERVICE NAME in application-provided connect strings
- Pipelining statement executions
- Altering table's metadata

This is because statements are always cached by CMAN-TDM.

- Changing password with Proxy Resident Connection Pool (PRCP) connections
- Application Continuity with Implicit Connection Pooling

When connected to a TAC or AC service using PRCP or DRCP with Implicit Connection Pooling enabled, CMAN-TDM internally disables support for Application Continuity.

10.3 Configuring Oracle Connection Manager in Tunneling Mode for Reverse Connection

Oracle Connection Manager in tunnelling mode establishes tunnel connections between server CMAN and client CMAN. Clients can make reverse connections over tunnels by connecting to server cman.

Complete the tasks in the following topics to configure Oracle Connection Manager in tunneling mode:

- Configure cman.ora for Oracle Connection Manager in Server Tunneling Mode
 Use the tunneling parameter to set up Oracle Connection Manager in server tunnelling
 mode
- Configure cman.ora for Oracle Connection Manager in Client Tunnelling Mode
 You must set the tunnel_address parameter in the cman.ora file to set up Oracle
 Connection Manager in client tunnelling mode.

- Configure Clients to Make Reverse Connection
 When connecting to the server CMAN, the clients must specify client CMAN identifier.
- Configure Rules in Server CMAN for Tunnel Registration and Client Access
 The client CMAN connects to the server CMAN using tunnel service.
- Configure Oracle Database Server for Client Oracle Connection Manager
 You must register the database with client Oracle Connection Manager.

10.3.1 Configure cman.ora for Oracle Connection Manager in Server Tunneling Mode

Use the tunneling parameter to set up Oracle Connection Manager in server tunnelling mode.

Set the tunneling parameter to ON in the cman.ora file.

A sample cman.ora configuration for Oracle Connection Manager in server tunnelling mode.

10.3.2 Configure cman.ora for Oracle Connection Manager in Client Tunnelling Mode

You must set the tunnel_address parameter in the cman.ora file to set up Oracle Connection Manager in client tunnelling mode.

A sample cman.ora configuration for Oracle Connection Manager in client tunnelling mode.

```
)
(PARAMETER_LIST=
(MAX_TUNNELS=2)
(GATEWAY_PROCESSES=16)
(NON_TUNNEL_GATEWAYS=8)
)
```

The default name for tunnel id is RC.

10.3.3 Configure Clients to Make Reverse Connection

When connecting to the server CMAN, the clients must specify client CMAN identifier.

Use the TUNNEL SERVICE NAME parameter to specify the client CMAN identifier.

A sample tnsnames.ora configuration for client.

Note:

source route is not supported for reverse connection.

10.3.4 Configure Rules in Server CMAN for Tunnel Registration and Client Access

The client CMAN connects to the server CMAN using tunnel service.

The tunnel ID of client CMAN is registered as a service in server CMAN.

- Configure Rules in Server CMAN using rule_list Syntax
 You must add a rule for each client CMAN as source, and service as tunnel. To allow client connections to a client CMAN, add a rule for service that identifies the client CMAN.
- Configure Rules in Server CMAN Using rule_group Syntax
 Add a group for each tunnel ID. The rule list in the group grants access to the required source addresses.

10.3.4.1 Configure Rules in Server CMAN using rule_list Syntax

You must add a rule for each client CMAN as source, and service as tunnel. To allow client connections to a client CMAN, add a rule for service that identifies the client CMAN.

You must set destination as * or localhost.

A sample ${\tt cman.ora}$ configuration for server Oracle Connection Manager in tunnelling mode using ${\tt rule}$ list.

10.3.4.2 Configure Rules in Server CMAN Using rule_group Syntax

Add a group for each tunnel ID. The rule list in the group grants access to the required source addresses.

You must set destination as * or localhost.

A sample cman.ora configuration for server Oracle Connection Manager in tunnelling mode using rule group.

```
CMAN SERVER=
    (CONFIGURATION=
    (ADDRESS=(PROTOCOL=TCP) (HOST=SERVERCMAN) (PORT=1522))
       (RULE GROUP=
         (GROUP=
           (DESCRIPTION=(NAME=south))
           (RULE LIST=(RULE=(SRC=CLIENTCMAN)(DST=*)(SRV=*)(ACT=accept)))
        (RULE LIST=(RULE=(SRC=CLIENTHOST)(DST=*)(SRV=*)(ACT=accept)))
         (GROUP=
           (DESCRIPTION=(NAME=cmon))
           (RULE LIST=(RULE=(SRC=*)(DST=*)(SRV=*)(ACT=accept)))
       (PARAMETER LIST=
        (TUNNELING=ON)
        (GATEWAY PROCESSES=16)
        (NON TUNNEL GATEWAYS=8)
        (TUNNEL CAPACITY=32)
        (TUNNEL PROBE INTERVAL=7)
```

10.3.5 Configure Oracle Database Server for Client Oracle Connection Manager

You must register the database with client Oracle Connection Manager.

Section Configuring the Oracle Database Server for Oracle Connection Manager of this guide explains how to register the database with Oracle Connection Manager.

Static routing is not supported by Oracle connection manager in tunnelling mode.

Related Topics

Configuring the Oracle Database Server for Oracle Connection Manager
 Configuring the database server involves registering database information remotely with Oracle Connection Manager and, optionally, configuring the server for multiplexing.

10.4 Using Oracle Connection Manager as a Bridge for IPv4 and IPv6

In some database connection environments, a client and database may use different versions of the IP protocol so that complete connectivity does not exist. In this case, at least two hops in the connection use different versions of the IP protocol.

For example, a request passes from an IPv4 source to an IPv6 destination, from an IPv6 source to an IPv4 destination, or from IPv6 to IPv6 through an IPv4 network.

You can use Oracle Connection Manager as a network bridge between IPv4 and IPv6. To serve as a bridge, Oracle Connection Manager must run on a dual-stack host configured with at least one IPv4 interface and at least one IPv6 interface.

Use the Oracle Connection Manager filtering feature to filter based on an IPv6 address. You can base rules on complete or partial IP addresses. The following figure shows the format of an IPv6 address:

Figure 10-1 IPv6 Address Format

The numbers at the top of the diagram indicate the number of bits in the address. Each hexadecimal character in an IPv6 address represents 4 bits. Bits 4-16 are the Top-Level Aggregation Identifier (TLA ID) portion of the address. Bits 25-49 are the Next-Level Aggregation Identifiers (NLA ID).

For example, in the address 2001:0db8::203:BAFF:FE0F:C74B, the binary representation of the first four hexademical characters (2001) is as follows:

00100000000000001

Thus, the first 3 bits in the address are 001. The TLA ID portion of the address is 000000000001.

The following procedure describes how to create a rules filter for IPv6 address:

- 1. Navigate to the cman.ora file located in the ORACLE_BASE_HOME/network/admin directory. If the cman.ora file is not present in the ORACLE_BASE_HOME/network/admin directory, then check for the file in the ORACLE HOME/network/admin directory.
- Open the cman.ora file with a text editor.
- 3. Create a RULE in the RULE_LIST based on IPv6 address format.
 For example, assume that the source host is an IPv6-only host with address 2001:0db8::203:BAFF:FE0F:C74B, whereas the destination is an IPv4-only host named SALESL1593. You configure Oracle Connection Manager as an IPv6-to-IPv4 bridge by creating one of the following rules:

Type of Rule	Description	Example
Filter based on subnet ID	Filtering is based on the 64 bits up to and including the subnet ID	<pre>(RULE = (SRC = 2001:0db8::203:BAFF:FE0F:C74B/64) (DST = SALESL1593) (SRV = SALES) (ACT = ACCEPT) (ACTION_LIST = (AUT=ON) (MOCT=10) (MIT=30) (CONN_STATE=YES)))</pre>
Filter based on NLA ID	Filtering is based on the 48 bits up to and including the NLA ID	<pre>(RULE = (SRC = 2001:0db8::203:BAFF:FE0F:C74B/48) (DST = SALESL1593) (SRV = SALES) (ACT = ACCEPT) (ACTION_LIST = (AUT=ON) (MOCT=10) (MIT=30) (CONN_STATE=YES)))</pre>
Filter based on TLA ID	Filtering is based on the 16 bits up to and including the TLA ID	<pre>(RULE = (SRC = 2001:0db8::203:BAFF:FE0F:C74B/16) (DST = SALESL1593) (SRV = SALES) (ACT = ACCEPT) (ACTION_LIST = (AUT=ON) (MOCT=10) (MIT=30) (CONN_STATE=YES)))</pre>

Type of Rule	Description	Example
Filter based on number of bits	Filtering is based on the first 60 bits of the address	<pre>(RULE = (SRC = 2001:0db8::203:BAFF:FE0F:C74B/60) (DST = SALESL1593) (SRV = SALES) (ACT = ACCEPT) (ACTION_LIST = (AUT=ON) (MOCT=10) (MIT=30) (CONN_STATE=YES)))</pre>

- About TCP/IP Protocol
 - TCP/IP (Transmission Control Protocol/Internet Protocol) is the standard communication protocol suite used for client/server communication over a network.
- About IPv6 Addresses in Connect Descriptors
 A host can use IP version 4 (IPv4) and IP version 6 (IPv6) interfaces. IPv6 addresses and host names that resolve to IPv6 addresses are usable in the HOST parameter of a TNS connect address, which can be obtained through any of the supported net naming methods.
- Configuring Listening Protocol Addresses

10.5 Using Oracle Connection Manager to Prevent Denial-of-Service Attacks

You can enforce a limit on the number of client connections that Oracle Connection Manager (CMAN) can handle from an IP address in a specific time interval.

Malicious clients can send excessive connection requests to the server node. This can saturate the capacity of CMAN to handle new connections per second, and thus cause denial-of-service (DoS) attacks on your database. Using the IP rate limit feature, you can limit the maximum number of new connections allowed from an IP address. This helps to prevent DoS attacks by detecting malicious clients early and rejecting those connections.

To enforce IP rate limit, set the IP_RATE_COUNT parameter in the cman.ora configuration file. This parameter specifies the number of connections that are allowed from a single IP address. The specified IP rate limit is enforced at the CMAN endpoint level.

If required, you can also set the following optional parameters in the cman.ora file:

- IP_RATE_INTERVAL: Specifies the time interval, in seconds, for which IP_RATE_COUNT connections are accepted from the IP address.
- IP_RATE_BLOCK: Specifies the duration, in minutes, for which the IP address is blocked after exceeding the specified IP rate limit.

If a connection exceeds the <code>IP_RATE_COUNT</code> per <code>IP_RATE_INTERVAL</code> limit, then CMAN rejects the <code>IP</code> address and blocks it for <code>IP_RATE_BLOCK</code> minutes. CMAN records an <code>IP</code> rate <code>limit</code> enforced for <code>ip</code> address error message in the Oracle Connection Manager log file.

Related Topics

- IP_RATE_COUNT
- IP_RATE_INTERVAL

IP RATE BLOCK

10.6 Starting and Stopping Oracle Connection Manager

After configuring Oracle Connection Manager, you can start and administer it using the Oracle Connection Manager Control (CMCTL) utility.

At the operating system command line, the basic syntax for this utility is:

```
cmctl [command] [argument1 . . . argumentN] [-c instance name]
```

The -c parameter specifies the Oracle Connection Manager instance that you want to administer. Instances are defined in the cman.ora file.

Note:

The use of password access to Oracle Connection Manager parameters is desupported in Oracle Database 23ai.

Oracle provides an enhanced connection method, Local Operating System Authentication" (LOSA), which permits only the user who started CMAN to perform admin operations. This method is consistent with other operating system authentication methods used with Oracle Database. If you are currently using password access to CMAN, then Oracle recommends that you remove the CMAN password, and instead rely on LOSA.

To start and stop Oracle Connection Manager using the Oracle Connection Manager Control utility:

1. Create the cman.ora file.

A sample file is located in the <code>ORACLE_BASE_HOME/network/admin/samples</code> directory after installation of Oracle Connection Manager.

- 2. Start Oracle Connection Manager using one of the following methods:
 - At the command line:

Run the STARTUP command. For example:

```
cmctl STARTUP -c [cman example instance]
```

The command starts the listener, Connection Manager Administration (CMADMIN), and gateway processes for an instance named cman example instance.

At the CMCTL prompt:

At the command line, enter <code>cmctl</code> with no arguments to obtain the <code>CMCTL</code> prompt, and then run the <code>ADMINISTER</code> and <code>STARTUP</code> commands. For example:

```
cmctl
CMCTL> ADMINISTER [cman_example_instance]
CMCTL> STARTUP
```

- Stop a running instance of Oracle Connection Manager using one of the following methods:
 - At the command line:

Run the Shutdown command. For example:

```
cmctl SHUTDOWN -c [cman example instance]
```

At the CMCTL prompt:

At the command line, enter <code>cmctl</code> with no arguments to obtain the <code>CMCTL</code> prompt, and then run the <code>ADMINISTER</code> and <code>SHUTDOWN</code> commands. For example:

```
cmctl
CMCTL> ADMINISTER [cman_example_instance]
CMCTL> SHUTDOWN
```

10.7 About CMCTL REST Interface

CMCTL REST interface helps you manage Oracle Connection Manager (Oracle CMAN) instance from remote machines using REST interface. A client that supports HTTPS can issue CMCTL equivalent commands. Each REST API call must have www-Authenticate HTTPS header with Basic authentication method.

Configuring CMCTL REST Interface

Use the cman.ora REST_ADDRESS parameter to configure REST endpoint hostname and port. The CMCTL REST interface authentication uses user name and password available in an Oracle CMAN wallet.

REST APIs for CMCTL Commands

Use CMCTL REST interface to automate CMAN tasks in cloud deployments. This functionality is similar to the CMAN <code>cmctl</code> control utility.

10.7.1 Configuring CMCTL REST Interface

Use the cman.ora REST_ADDRESS parameter to configure REST endpoint hostname and port. The CMCTL REST interface authentication uses user name and password available in an Oracle CMAN wallet.

- 1. Add the REST ADDRESS attribute under the parameters section of the cman.ora file.
- 2. Create an Oracle wallet.

An Oracle wallet is a file that stores certificates and authentication credentials. Use the orapki utility to create an Oracle wallet.

You can import a certificate from a recognized authority into an Oracle Wallet or you can create your own authorized and signed certificate and use it with CMAN Oracle wallet. You can also use a self-signed Oracle wallet.

For example, to create a wallet with a self-signed certificate, run the following commands:

```
$ORACLE_HOME/bin/orapki wallet create -wallet wallet directory
$ORACLE_HOME/bin/orapki wallet add -wallet wallet directory -dn
'cn=root test, c=US' -keysize 2048 -self signed -validity 365
```

Where wallet directory is the file system directory location where the wallet is created.

Ensure that this directory is not readable by any group or other users.

3. Add CMAN REST client user name to the wallet.

CMCTL REST interface process supports only HTTPS protocol. HTTP protocol is not supported. This wallet file must not have read permission to any group or other users. It should have read permissions only to the user owning the CMAN instance.

Use the mkstore utility to store user name and password in an Oracle CMAN wallet.

For example:

mkstore -wrl wallet directory -createEntry myusername my password

The mkstore wallet management command line tool is deprecated with Oracle Database 23ai, and can be removed in a future release.

To manage wallets, Oracle recommends that you use the \mathtt{orapki} command line tool.

4. Create an auto-login wallet.

Oracle CMAN requires auto-login wallet to start HTTPS endpoint. Run the following command to create an auto-login wallet:

```
$ORACLE_HOME/bin/orapki wallet create -wallet wallet_location -auto_login
```

where wallet location is the directory where you have created the CMAN wallet.

Note:

Oracle has introduced a new auto-login wallet version (7) with Oracle Database 23ai. Version 6 of the Oracle local auto-login wallet is deprecated.

You can update your local auto-login wallet by modifying it with orapki.

5. Specify the wallet location in the cman.ora file. Update the cman.ora file with wallet directory outside of cman alias:

```
CMAN=
(CONFIGURATION=
....
(RULE_LIST=
...)
(PARAMETER_LIST=
...))
Wallet location= ...
```

For example:

Note:

The parameter WALLET_LOCATION is deprecated for use with Oracle Database 23ai for the Oracle Database server. It is not deprecated for use with the Oracle Database client or listener.

For Oracle Database server, Oracle recommends that you use the WALLET_ROOT system parameter instead of using WALLET LOCATION.

- Uses of orapki Utility
- Managing Oracle Wallets with orapki Utility
- Oracle Database Net Services Reference

10.7.2 REST APIs for CMCTL Commands

Use CMCTL REST interface to automate CMAN tasks in cloud deployments. This functionality is similar to the CMAN <code>cmctl</code> control utility.

CMCTL REST interface uses local operating system authentication between REST interface process and Oracle CMAN listener.

After you start an Oracle CMAN instance with REST configuration, you can make a REST call with HTTPS basic authentication.

Use the curl command line tool to verify CMAN REST API. For example to list the services that are running, use the following command:

Note:

The curl command is used for testing and verification purposes only.

curl -X GET -u username:password https://cmanhostname:rest port/show/services

10.8 Migrating CMAN Sessions During Patching

You can migrate the established client/server sessions from one Oracle Connection Manager (CMAN) instance to another Oracle CMAN instance during a planned upgrade or patching of Oracle CMAN with zero downtime.

You can migrate live sessions with data in-transit without disrupting the service. Any operations that are running either on a client or on a server continue to run seamlessly during the migration without loss of service. You can also add new client connections during the migration.

Perform the following steps to migrate client/server sessions:

You must have either upgraded Oracle CMAN to the latest release or applied the latest patch.

- 1. Install the upgraded Oracle CMAN or the patched Oracle CMAN in a new ORACLE HOME.
- 2. Use the same cman.ora file that you used for configuring Oracle CMAN to configure the new Oracle CMAN instance.
- 3. Start the new Oracle CMAN instance from the new ORACLE_HOME in migration mode. Use the following command:

```
cmctl startup -migrate -c cman_alias
```

This command starts a new Oracle CMAN instance and initiates migrating of sessions from old Oracle CMAN instances. An old Oracle CMAN instance will exit as soon as the migration is complete or after 7 minutes timeout.

The address of the old Oracle CMAN instance is added in the cman.ora file with the alias, cman_alias_old. You can use this alias to control and check the status of old Oracle CMAN instance during migration.

You can migrate sessions in the following scenarios:

- If both client to Oracle CMAN and Oracle CMAN to server use TCP.
- If either a client or a server uses TCPS (TLS) on one end and TCP on the other end. You
 must install Oracle Database 21c or later on both, the client using TCPS and the server
 using TCPS.

Unsupported connections remain connected till the timeout duration.

Note

- Session migration is supported only for Oracle CMAN in regular mode and not for Oracle CMAN in Traffic Director Mode.
- If both client to Oracle CMAN and Oracle CMAN to server use TCPS, then migration is not supported.
- Currently, session migration is not supported on Microsoft Windows.

10.9 Oracle Connection Manager Enhancements

Oracle Connection Manager proxies and screens request for Oracle Database Server.

Oracle Connection Manager provides a more secure access to the server by supporting the Transport Layer Security (TLS) protocol. With this support, the database client can communicate to the server through Oracle Connection Manager over TCPS protocol. You can also configure the Oracle Connection Manager to have TLS connection on one side and non-TLS connection on the other side. This also acts as a secure way to hide the internal database servers for the outside clients connecting from the internet.

Multiplexing: If the gateway already has the TCPS connection to the endpoint requested by the database client, then it multiplexes the new connect request on the same connection.

 It can listen on multiple protocol addresses. With multiple listening endpoints, Oracle Connection Manager is now able to support both TCP and TCPS at the same time. The existing single protocol address configuration is still supported. For example:

```
CMAN_ALIAS=
  (configuration=
   (address_list=
        (address=(protocol=TCP) (host=a.b.c.d) (port=12522))
        (address=(protocol=TCPS) (host=a.b.c.d) (port=12523))
)
...
)
```

It has the addition of network data compression facility to improve network throughput and
make data transfer faster between the Oracle Database Client and the Oracle Database
Server. This is done in different ways according to the database client, database server,
and the next hop compression ability. Compression is enabled between any two nodes if it
is negotiated by them

If more than two consecutive nodes support and negotiate compression, such case is handled in a way that the intermediate node just relays the compressed data to the next node without performing decompression.

Compression is supported between the Oracle Connection Manager and the server, even if the Oracle Database Client is earlier than the Oracle Database 12c release and cannot support compression.

- It supports up to 2 MB SDU enabling the Oracle Database Client and the Oracle Database Server to negotiate higher SDU when establishing connection through Oracle Connection Manager.
- Starting with this release, valid node checking for registration is enabled by default in Oracle Connection Manager. By default, only the databases on local node are allowed to register with Oracle Connection Manager. The databases on remote node can be permitted or denied to register with Oracle Connection Manager through the use of parameters REGISTRATION INVITED NODES and REGISTRATION EXCLUDED NODES.
- Starting with Oracle Database 21c, you can manage distribution of bandwidth across services using Oracle Connection Manager.

Oracle Connection Manager has the following enhancements:

- REST APIs for CMCTL Commands
- GROUP syntax for rules
- BANDWIDTH in bytes per second at service level

Configuring a Shared Server Architecture

You can manage server loads on Oracle Database by managing dispatchers, and configuring your clients to take advantages of Oracle Net Services features.

- How Oracle Net Manages Client Loads
 Learn how Oracle Net manages system resource loads using shared server architecture.
- About Dispatchers
- Enabling Session Multiplexing
- Configuring Clients for Environments with Both Shared and Dedicated Servers

11.1 How Oracle Net Manages Client Loads

Learn how Oracle Net manages system resource loads using shared server architecture.

When client loads cause a strain on memory and other system resources, you can alleviate load issues by starting shared server resources. The **shared server** architecture enables a database server to allow many client processes to share very few server processes, so the number of users that the database can support is increased. With the shared server architecture, many client processes connect to a **dispatcher**. The dispatcher directs multiple incoming network session requests to a common queue. An idle shared server process from a shared pool of server processes picks up a request from the queue. This means a small pool of server processes can serve a large number of clients. This is useful when a system is overloaded or has limited memory.

11.2 About Dispatchers

Shared memory resources for dispatchers, virtual circuits, and shared servers are preconfigured enable shared servers at runtime. Database administrators can start dispatchers and shared servers with the SQL ALTER SYSTEM statement without having to restart the instance. When shared server mode is turned on, a dispatcher is started automatically on the TCP/IP protocol even if the DISPATCHERS parameter has not been set. Using a shared server is equivalent to setting the DISPATCHERS parameter in the database initialization parameter file as follows:

DISPATCHERS=" (PROTOCOL=tcp) "

Configure the DISPATCHERS parameter directly if either of the following conditions apply:

- You need to configure a protocol other than TCP/IP.
- You want to configure one or more of the optional dispatcher attributes, such as multiplexing.

You can specify the following attributes for the DISPATCHERS parameter. The PROTOCOL attribute is required, and the others are optional. The ADDRESS attribute is used to set a specify port number, such as when using a firewall.

- ADDRESS
- CONNECTIONS

- DESCRIPTION
- DISPATCHERS
- LISTENER
- MULTIPLEX
- PROTOCOL (required)
- SERVICE
- SESSIONS

You change the dispatcher configuration using the SQL statement ALTER SYSTEM. You do not need to restart the instance after setting the parameters.

- Grouping Services by Dispatcher
- Monitoring Dispatchers

Oracle Database Administrator's Guide for additional information about configuring dispatchers

11.2.1 Grouping Services by Dispatcher

An Oracle database can be represented by multiple service names. A pool of dispatchers can be allocated exclusively for clients requesting a particular service. This way, the mission critical requests may be given more resources and in effect increase their priority.

For example, the following initialization parameter file shows two dispatchers. The first dispatcher services requests for clients requesting sales.us.example.com. The other dispatcher services requests only for clients requesting adminsales.us.example.com.

```
SERVICE_NAMES=sales.us.example.com
INSTANCE_NAME=sales
DISPATCHERS="(PROTOCOL=tcp)"
DISPATCHERS="(PROTOCOL=tcp) (SERVICE=adminsales.us.example.com)"
```

You must manually start services on pluggable databases.

11.2.2 Monitoring Dispatchers

Use the following views to check configurations and monitor dispatchers:

- V\$QUEUE: Contains information about the shared server message queues. This view is
 only available to the SYS user, and users who have SELECT ANY TABLE system privilege,
 such as SYSTEM.
- V\$DISPATCHER: Provides information about the dispatcher processes, including name, network address, status, various usage statistics, and index number.

- V\$DISPATCHER_CONFIG: Provides configuration information about the dispatchers.
- V\$DISPATCHER RATE: Provides rate statistics for the dispatcher processes.

See Also:

- Oracle Database Performance Tuning Guide and Oracle Database Reference for additional information these views
- Oracle Database Administrator's Guide for additional information about shared server configuration
- Oracle Database Reference for additional information about configuring the DISPATCHERS parameter and supported attributes
- Oracle Database SQL Reference for additional information about the ALTER SYSTEM statement

11.3 Enabling Session Multiplexing

Session multiplexing, available with Oracle Connection Manager, enables multiple client sessions to funnel through a single protocol connection. For example, several client processes can connect to one dispatcher by way of a single connection from Oracle Connection Manager.

Oracle Connection Manager allows communication by users to the dispatcher by way of a shared connection. At any one time, users might need the connection, while other client processes linked to the dispatcher by way of the connection manager process are idle. Session multiplexing is beneficial because it maximizes use of the dispatcher process connections.

Session multiplexing is also useful for database link connections between dispatchers. The limit on the number of sessions for each dispatcher is operating system specific.

To enable session multiplexing, set the attribute MULTIPLEX in the DISPATCHERS parameter to on or an equivalent value.

DISPATCHERS="(PROTOCOL=tcp)(MULTIPLEX=on)"

See Also:

"Enabling Session Multiplexing for Oracle Connection Manager" for configuration details

11.4 Configuring Clients for Environments with Both Shared and Dedicated Servers

If a shared server is configured on the server side, and a client connection request arrives when no dispatchers are registered, then the request is processed by a dedicated server

process. If you want a particular client always to use a dispatcher, then configure (SERVER=shared) in the CONNECT DATA section of the connect descriptor. For example:

```
sales=
(DESCRIPTION=
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
(CONNECT_DATA=
        (SERVICE_NAME=sales.us.example.com)
        (SERVER=shared)))
```

If the (SERVER=shared) attribute is configured and a dispatcher is not available, then the client connection request is rejected, and a message is sent to the client.

If the database is configured for a shared server and a particular client requires a dedicated server, then you can configure the client to use a dedicated server in one of the following ways:

 You can configure a network service name with a connect descriptor that contains (SERVER=dedicated) in the CONNECT DATA section. For example:

```
sales=
(DESCRIPTION=
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
(CONNECT_DATA=
        (SERVICE_NAME=sales.us.example.com)
        (SERVER=dedicated)))
```

• You can configure the client profile file, sqlnet.ora, with USE_DEDICATED_SERVER=on. This adds (SERVER=dedicated) to the CONNECT_DATA section of the connect descriptor the client uses.

Note:

If $use_dedicated_server$ is set to on, then existing (server=value) entries in connect descriptors are overwritten with (server=dedicated).

See Also:

- "About the Advanced Connect Data Parameters" to set the SERVER parameter
- "Routing Connection Requests to a Process" to set the USE_DEDICATED_SERVER parameter

Configuring Profiles

Learn how to configure client and server configuration parameters in profiles. A profile is a collection of parameters that specifies preferences for enabling and configuring Oracle Net features on the client or database server.

A profile is stored and implemented through the sqlnet.ora file.

- Overview of Profile Configuration
- · Configuring the Profile During Installation
- Understanding Client Attributes for Names Resolution
- Configuring Database Access Control
- Setting the Advanced Features in the sqlnet.ora File Using Oracle Net Services
- Configuring External Naming Methods
- Configuring Oracle Network Security
 Oracle network security features enable data encryption, integrity checking, enhanced
 authentication, and single sign-on. The features also provide centralized user management
 on LDAP-compliant directory servers and certificate-based single sign-on. This
 functionality relies on the Transport Layer Security (TLS) protocol.

12.1 Overview of Profile Configuration

You can use a profile to do the following:

- Specify the client domain to append to unqualified names
- Prioritize naming methods
- Enable logging and tracing features
- Route connections through specific processes
- Configure parameters for an external procedure
- Configure Oracle Advanced Security
- Use protocol-specific parameters to restrict access to the database

12.2 Configuring the Profile During Installation

Oracle Universal Installer launches Oracle Net Configuration Assistant after software installation on the client and server. Oracle Net Configuration Assistant configures the order of the naming methods that the computer uses to resolve a connect identifier to a connect descriptor.

Configuration with the Oracle Net Configuration Assistant during installation results in an entry in the sqlnet.ora file similar to the following:

NAMES.DIRECTORY PATH=(ezconnect,tnsnames)

The NAMES.DIRECTORY_PATH parameter specifies the priority order of the naming methods to use to resolve connect identifiers. If the installed configuration is not adequate, then use Oracle Net Manager to change the sqlnet.ora configuration.

12.3 Understanding Client Attributes for Names Resolution

The following sections describe available client configuration options:

- About the Default Domain for Clients
- Prioritizing Naming Methods
- Routing Connection Requests to a Process
 Clients and servers can be configured so connection requests are directed to a specific process. Learn how to route connection requests to a process.

12.3.1 About the Default Domain for Clients

In environments where the client often requests names from a specific domain, it is appropriate to set a default domain in the client sqlnet.ora file with the NAMES.DEFAULT_DOMAIN parameter. This parameter is available to the local and external naming methods.

When a default domain is set, it is automatically appended to any unqualified network service name given in the connect string, and then compared to network service names stored in a tnsnames.ora file.

For example, if the client tnsnames.ora file contains a network service name of sales.us.example.com, and the default domain is us.example.com, then the user can enter the following connect string:

```
CONNECT scott@sales
Enter password: password
```

In the preceding example, sales gets searched as sales.us.example.com.

If the connect string includes the domain extension, such as in CONNECT scott@sales.us.example.com, then the domain is not appended.

If a network service name in a tnsnames.ora file is not domain qualified and the NAMES.DEFAULT_DOMAIN parameter is set, then the network service name must be entered with a period (.) at the end of the name. For example, if the domain is set to us.example.com and the client tnsnames.ora file contains a network service name of sales2, then the user would enter the following connect string:

```
CONNECT scott@sales2.
Enter password: password
```

In the preceding example, the client would connect to sales2, not sales2.us.example.com.

Specifying a Default Domain

12.3.1.1 Specifying a Default Domain

The following procedure describes how to specify a default domain:

1. Start Oracle Net Manager.

See Also:

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, select **Profile** from the Local menu.
- 3. From the list in the right pane, select Naming.
- Click the Methods tab.
- 5. In the Default Domain field, enter the domain.
- 6. Select Save Network Configuration from the File menu.

The sqlnet.ora file should contain an entry that looks similar to the following:

NAMES.DEFAULT DOMAIN=us.example.com

12.3.2 Prioritizing Naming Methods

After naming methods are configured, as described in Configuring Naming Methods, they must be prioritized. Naming methods to resolve a connect identifier are tried in the order they appear in the list. If the first naming method in the list cannot resolve the connect identifier, then the second method in the list is used, and so on.

The following procedure describes how to specify the order of naming methods:

1. Start Oracle Net Manager.

See Also:

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, select **Profile** from the Local menu.
- 3. From the list in the right pane, select **Naming**.
- Click the Methods tab.

Table 12-1 describes the naming method values listed in the Methods tab.

Table 12-1 Naming Method Values

Naming Method Value	Description
TNSNAMES	Resolve a network service name through the tnsnames.ora file on the client.
	See Also: "Configuring the Local Naming Method"
LDAP	Resolve a database service name, network service name, or network service alias through a directory server.
	See Also: "Configuring the Directory Naming Method"
EZCONNECT	Enable clients to use a TCP/IP connect identifier, consisting of a host name and optional port and service name, or resolve a host name alias through an existing names resolution service or centrally maintained set of /etc/hosts files.
	See Also: "Understanding the Easy Connect Naming Method"

Table 12-1 (Cont.) Naming Method Values

Naming Method Value Description	
NIS	Resolve service information through an existing network information service (NIS).

Select naming methods from the Available Methods list, and then click the right-arrow button.

The selected naming methods move to the Selected Methods list.

- 6. Order the naming methods according to the order in which you want Oracle Net to try to resolve the network service name or database service name. Select a naming method in the Selected Methods list, and then click **Promote** or **Demote** to move the selection up or down in the list.
- Select Save Network Configuration from the File menu.

The sqlnet.ora file updates with the NAMES.DIRECTORY_PATH parameter, such as the following:

NAMES.DIRECTORY PATH=(ldap, tnsnames)

12.3.3 Routing Connection Requests to a Process

Clients and servers can be configured so connection requests are directed to a specific process. Learn how to route connection requests to a process.

- 1. Start Oracle Net Manager.
- 2. In the navigator pane, select **Profile** from the Local menu.
- 3. From the list in the right pane, select General.
- Click the Routing tab.
- Select the preferred way for routing connections.

To configure all connections to use a particular server, you select the **Always Use Dedicated Server** option in Oracle Net Manager. This sets the

USE_DEDICATED_SERVER parameter in the sqlnet.ora file to force the listener to spawn a dedicated server for all network sessions from the client. The result is a dedicated server connection, even if a shared server is configured.

6. Choose Save Network Configuration from the File menu.

Related Topics

Using Oracle Net Manager to Configure Oracle Net Services

12.4 Configuring Database Access Control

The following procedure describes how to configure database access control:

Start Oracle Net Manager.

See Also:

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, select **Profile** from the Local menu.
- 3. From the list in the right pane, select **General**.
- 4. Click the Access Rights tab.
- 5. Select the Check TCP/IP client access rights option.
- 6. In the Clients allowed to access fields and Clients excluded from access field, enter either a host name or an IP address for a client that you want to include or exclude, using commas to delimit entries placed on the same line.

12.5 Setting the Advanced Features in the sqlnet.ora File Using Oracle Net Services

The following procedure describes how to set advanced features in the sqlnet.ora file:

1. Start Oracle Net Manager.

See Also:

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, select **Profile** from the Local menu.
- 3. From the list in the right pane, select **General**.
- Click the Advanced tab.
- 5. Enter the values for the fields or options you want to set.
- Select Save Network Configuration from the File menu.

12.6 Configuring External Naming Methods

The sqlnet.ora file is used to configure required client parameters needed for Network Information Service (NIS) external naming. The following procedure describes how to configure the NIS parameter in the sqlnet.ora file:

Start Oracle Net Manager.

✓ See Also:

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, select **Profile** from the File menu.
- 3. From the list in the right pane, select Naming.
- 4. Click the External tab.

- 5. Enter NAMES.NIS.META_MAP in the Meta Map field.
- 6. Select Save Network Configuration from the File menu.

12.7 Configuring Oracle Network Security

Oracle network security features enable data encryption, integrity checking, enhanced authentication, and single sign-on. The features also provide centralized user management on LDAP-compliant directory servers and certificate-based single sign-on. This functionality relies on the Transport Layer Security (TLS) protocol.

The following procedure describes how to configure a client or server to use Oracle network security features:

- Start Oracle Net Manager.
- 2. In the navigator pane, select **Profile** from the Local menu.
- 3. From the list in the right pane, select **Network Security**.

Each Network Security tab page enables you to configure a separate set of parameters. The tab pages are as follows:

 Authentication: For configuration of available authentication methods, such as KERBEROS5 and RADIUS.

Note:

Starting with Oracle Database 23ai, users authenticating to the database using the legacy RADIUS API no longer are granted administrative privileges.

In previous releases, users authenticating with RADIUS API could be granted administrative privileges such as SYSDBA or SYSBACKUP. In Oracle Database 23ai, Oracle introduces a new RADIUS API that uses the latest standards. To grant administrative privileges to users, ensure the database connection to the database uses the new RADIUS API, and that you are using the Oracle Database 23ai client to connect to the Oracle Database 23ai server.

- Other Params: For configuration of the authentication service.
- Integrity: For configuration of the type of integrity, checksum level and available methods.
- Encryption: For configuration of the encryption type and method.
- TLS: For setting the use of TLS.
- Select or edit options as applicable.
- Select Save Network Configuration from the File menu.

Note:

For additional details, refer to the help button on a tab page or the network security topics in the Oracle Net Manager online help. To access the network security topics, select **Network Security**, and then select the **How To** option.

Enabling Advanced Features of Oracle Net Services

Understand how to configure the advanced features of Oracle Net Services, including advanced connect data parameters, load balancing, failover, and connections to non-database services.

- Configuring Advanced Network Address and Connect Data Information
 A database service can be accessed by several routes and protocol addresses. You configure which routes to use by setting a list of protocol addresses. You configure order addresses by specifying address parameters.
- Understanding Connection Load Balancing
 The connection load balancing feature improves connection performance by balancing the number of active connections among multiple dispatchers.
- Configuring Transparent Application Failover
 Transparent Application Failover (TAF) instructs Oracle Net to transparently reconnect a
 failed connection to a different listener in the event of the failure of a database instance.
 This enables you to continue your work using the new connection as if the original
 connection never failed.
- Specifying the Instance Role for Primary and Secondary Instance Configurations

 The INSTANCE_ROLE parameter is an optional parameter for the CONNECT_DATA section of a connect descriptor. It enables you to specify a connection to the primary or secondary instance of Oracle RAC configurations.
- Configuring Static Service Registration
 The listener uses the dynamic service information about the database and instance before using statically configured information in the listener.ora file.
- Configuring Connections to Third-Party Database Services
 Learn about external procedures settings in the listener.ora file, changing the default
 configuration for external procedures, configuring the Oracle database server for
 connecting to Heterogeneous Services agents, and configuring clients for connecting to
 the Oracle Rdb database.

13.1 Configuring Advanced Network Address and Connect Data Information

A database service can be accessed by several routes and protocol addresses. You configure which routes to use by setting a list of protocol addresses. You configure order addresses by specifying address parameters.

- Creating a List of Listener Protocol Addresses
- About the Address List Parameters
- About the Advanced Connect Data Parameters

13.1.1 Creating a List of Listener Protocol Addresses

A database service may be accessed by more than one network route, or protocol address. In the following example, sales.us.example.com can connect to the sales.us.example.com service using listeners on either sales1-server or sales2-server.

```
sales.us.example.com=
(DESCRIPTION=
    (ADDRESS_LIST=
         (ADDRESS=(PROTOCOL=tcp) (HOST=sales1-server) (PORT=1521))
         (ADDRESS=(PROTOCOL=tcp) (HOST=sales2-server) (PORT=1521)))
(CONNECT_DATA=
         (SERVICE NAME=sales.us.example.com)))
```

To add a network protocol address to an existing network service name or database service, use one of the following procedures:

- Adding a Network Protocol Using Oracle Enterprise Manager Cloud Control
- · Adding a Network Protocol Using Oracle Net Manager

Adding a Network Protocol Using Oracle Enterprise Manager Cloud Control

The following procedure describes how to add a network protocol to an existing network service name or database service using Oracle Enterprise Manager Cloud Control:

- Access the Directory Naming or Local Naming page in Oracle Enterprise Manager Cloud Control:
 - Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

"Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services"

- b. Select Local Naming or Directory Naming from the Administer list, and then select the Oracle home for the directory server or the location of the local configuration files.
- c. Click Go.

The Local Naming or Directory Naming page appears.

- 2. Select the directory service or network service name.
 - For Local Naming, select a network service from the list, and then click Edit.
 - For Directory Naming, perform a search of the network service name in the Simple Search section, then select the network service or database service from the Results list, and then click Edit.
- 3. In the Addresses section, click Add.

The Add Address page appears.

- **4.** From the Protocol list, select the protocol which the listener is configured to listen. This protocol must also be installed on the client.
- 5. Enter the appropriate parameter information for the selected protocol in the fields provided.

Oracle Database Net Services Reference for protocol parameter settings

(Optional) In the Advanced Parameters section, specify the I/O buffer space limit for send and receive operations of sessions in the Total Send Buffer Size and Total Receive Buffer Size fields.

"Configuring I/O Buffer Space " for additional information about buffer space

7. Click OK.

The protocol address is added to the Addresses section.

8. Click **OK** to update the address information.

Adding a Network Protocol Using Oracle Net Manager

The following procedure describes how to add a network protocol to an existing network service name or database service using Oracle Net Manager:

1. Start Oracle Net Manager.

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, select **Service Naming** from the Directory or Local menus.
- 3. Select either the network service name or a database service.

The right pane displays the current destination service and address list.

In the Address Configuration box, click the plus sign (+) to add a new address.

A new Address tab appears:

a. Select the protocol and enter appropriate address information.

Oracle Database Net Services Reference for details about protocol address parameters

b. (Optional) On the Address tab, click Advanced to specify the I/O buffer space limit for send and receive operations of sessions in the Total Send Buffer Size and Total Receive Buffer Size fields.

See Also:

"Configuring I/O Buffer Space" for additional information about buffer space

- c. Order the protocol addresses using the left-arrow and right-arrow buttons. This will order the addresses in the protocol address list. Unless multiple address options are configured, the first address in the list is contacted.
- 5. Select Save Network Configuration from the File menu.

13.1.2 About the Address List Parameters

When a database service is accessible by multiple listener protocol addresses, specify the order in which the addresses are to be used, such as chosen randomly or tried sequentially. The following table lists the parameters used with multiple protocol addresses.

Table 13-1 Address List Parameters in the tnsnames.ora File

Parameter	Description
FAILOVER	At connect time, this parameter instructs Oracle Net to fail over to a different listener if the first listener fails when set to on. The number of addresses in the list determines how many addresses are tried. When set to off, instructs Oracle Net to try one address.
	Connect-time failover is turned on by default for multiple address lists (ADDRESS_LIST), connect descriptors (DESCRIPTION), and multiple connect descriptors (DESCRIPTION_LIST).
LOAD_BALANCE	When set to on, this parameter instructs Oracle Net to progress through the list of protocol addresses in a random sequence, balancing the load on the various listeners. When set to off, instructs Oracle Net to try the addresses sequentially until one succeeds. Client load balancing is turned on by default for multiple connect
	descriptors (DESCRIPTION_LIST).
SOURCE_ROUTE	When set to on, this parameter instructs Oracle Net to use each address in the order presented until the destination is reached. This parameter is required for reaching the destination using a specific route, that is, by specific computers. This parameter is used to enable connections to Oracle Connection Manager.

Note:

You cannot set source routing (SOURCE_ROUTE) at the same level as connect-time failover (FAILOVER) or client load balancing (LOAD_BALANCE). Source routing connects to each address in the list sequentially whereas connect-time failover and client load balancing select a single address from a list.

When a connect descriptor in a thinsnames.ora file contains at least two protocol addresses for an Oracle Connection Manager hop, then parameters for connect-time failover and load balancing within the hop can be included in the file.

The following table describes the address list options.

Table 13-2 Address List Options Dialog Box

Option	Parameter Setting
Try each address, in order, until one succeeds.	FAILOVER=on
Try each address, randomly, until one succeeds.	LOAD_BALANCE=on FAILOVER=on
Try one address, selected at random.	LOAD_BALANCE=on
Use each address in order until destination reached.	SOURCE_ROUTE=on
Use only the first address.	LOAD_BALANCE=off FAILOVER=off SOURCE_ROUTE=off

The following example shows a tnsnames.ora file configured for client load balancing:

The following example shows a tnsnames.ora file configured for connect-time failover:

```
sales.us.example.com=
(DESCRIPTION=
  (ADDRESS_LIST=
    (LOAD_BALANCE=off)
    (FAILOVER=on)
    (ADDRESS=(PROTOCOL=tcp) (HOST=sales1-server) (PORT=1521))
    (ADDRESS=(PROTOCOL=tcp) (HOST=sales2-server) (PORT=1521)))
    (CONNECT_DATA=
        (SERVICE_NAME=sales.us.example.com)))
```

The following example shows a trsnames.ora file configured for Oracle Connection Manager and load balancing:

```
sales.us.example.com=
(DESCRIPTION=
    (SOURCE_ROUTE=ON)
    (ADDRESS=(PROTOCOL=tcp) (HOST=cman-pc1) (PORT=1630))
    (ADDRESS=
        (LOAD_BALANCE=ON)
        (ADDRESS=(PROTOCOL=tcp) (HOST=cman-pc2) (PORT=1521))
        (ADDRESS=(PROTOCOL=tcp) (HOST=cman-pc3) (PORT=1521)))
        (CONNECT_DATA=
        (SERVICE_NAME=sales.us.example.com)))
```

Configuring Address List Parameters

"Configuring Clients for Oracle Connection Manager" for additional information about configuring clients for source routing

13.1.2.1 Configuring Address List Parameters

The following procedure describes how to configure address list parameters:

- 1. Perform the procedure in "Creating a List of Listener Protocol Addresses".
- 2. Use Oracle Enterprise Manager Cloud Control or Oracle Net Manager to configure address list options.
 - For Oracle Enterprise Manager Cloud Control, select the appropriate option in the Connect-time Failover and Client Load Balancing section.
 - For Oracle Net Manager, click **Advanced** in the Address Configuration box. The Address List Options dialog box appears. Select the appropriate option.

13.1.3 About the Advanced Connect Data Parameters

Starting with Oracle Database 12c release 2 (12.2), data compression can be set in the sqlnet.ora file. The parameters that set compression are SQLNET.COMPRESSION and SQLNET.COMPRESSION_LEVELS. Setting these parameters in the sqlnet.ora file affects all the connections using the sqlnet.ora file, except for Oracle Data Guard streaming redo and SecureFiles LOBs (Large Objects). The following example shows how to set compression:

```
SQLNET.COMPRESSION = on
SQLNET.COMPRESSION LEVELS = (low, high)
```

The CONNECT_DATA section of a connect descriptor in the tnsnames.ora file defines the destination database service. In the following example, SERVICE_NAME defines a service called sales.us.example.com:

In addition to the service name, you can optionally configure the connect data information with the parameters described in Table 13-3.

Table 13-3 Advanced Connect Data Settings in the tnsnames.ora File

Oracle Enterprise Manager Cloud Control/Oracle Net Manager Option	tnsnames.ora File Parameter	Description
Instance Name	INSTANCE_NAME	The database instance to access. The instance name can be obtained from the INSTANCE_NAME parameter in the initialization parameter file.

Table 13-3 (Cont.) Advanced Connect Data Settings in the tnsnames.ora File

Oracle Enterprise Manager Cloud Control/Oracle Net Manager Option	tnsnames.ora File Parameter	Description
Session Data Unit Size	SDU	The transfer rate of data packets being sent across the network. You can specify the session data unit (SDU) size to change the performance characteristics having to do with the packets sent across the network. The SDU size limit is 2 MB.
Use for Heterogeneous Services	HS	If you want an Oracle database server to access a third-party system through Heterogeneous Services, then set this option to on.
Oracle RDB Database	RDB_DATABASE	The file name of the Oracle Rdb database.
Type of Service	TYPE_OF_SERVICE	The type of service to use for the Oracle Rdb database.
Global Database Name	GLOBAL_NAME	Oracle Rdb database identifier.

In the following example, the transfer rate for data packets is set:

```
sales.us.example.com=
(DESCRIPTION=
   (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
   (CONNECT_DATA=
        (SERVICE_NAME=sales.us.example.com)
        (SDU=8192)))
```

Use Oracle Enterprise Manager Cloud Control or Oracle Net Manager to configure advanced CONNECT_DATA parameters for either a network service name or a database service.

Configuring Advanced Connect Descriptor Parameters Using Oracle Enterprise Manager Cloud Control

The following procedure describes how to configure advanced connect descriptor parameters using Oracle Enterprise Manager Cloud Control:

- Access the Directory Naming or Local Naming page in Oracle Enterprise Manager Cloud Control, as follows:
 - Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

"Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services"

- **b.** Select **Local Naming** or **Directory Naming** from the **Administer** list, and then select the Oracle home for the directory server or the location of the local configuration files.
- c. Click Go.

The Directory Naming or Local Naming pages appear.

- 2. Select the directory service or network service name.
 - For Local Naming, select a network service from the list, and then click Edit.

- For Directory Naming, search the network service name in the Simple Search section by selecting the network service or database service from the Results list, and then clicking Edit.
- 3. Click the Advanced tab.
- 4. Enter fields or select options as appropriate, and then click **OK**.
- 5. Click **OK** to update the connect data information.

Configuring Advanced Connect Descriptor Parameters Using Oracle Net Manager

The following procedure describes how to configure advanced connect descriptor parameters using Oracle Net Manager:

Start Oracle Net Manager.

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, select **Service Naming** from Directory or Local menus.
- 3. Select either the network service name or a database service.

The right pane displays the current destination service and address list.

- 4. In the Service Identification box, click **Advanced**.
 - The Advanced Service Options dialog box appears.
- 5. Enter fields or select options as appropriate, and then click **OK**.
- If you are making these changes to the Local folder, then select Save Network
 Configuration from the File menu. Changes to the Directory folder are saved
 automatically.

13.2 Understanding Connection Load Balancing

The connection load balancing feature improves connection performance by balancing the number of active connections among multiple dispatchers.

In an Oracle Real Application Clusters (Oracle RAC) environment, connection load balancing can also balance the number of active connections among multiple instances.

Because the Listener Registration (LREG) process can register with remote listeners, a listener can always be aware of all instances and dispatchers, regardless of their location. Depending on the load information, a listener decides which instance and, if shared server is configured, which dispatcher to send the incoming client request.

In a shared server configuration, a listener selects a dispatcher in the following order:

- Least loaded node.
- Least loaded instance.
- 3. Least loaded dispatcher for that instance.

In a dedicated server configuration, a listener selects an instance in the following order:

Least loaded node.

Least loaded instance.

Load Balancing across nodes for HTTP presentation is introduced in this release. The remote listener can load balance across instances that are on different nodes for HTTP presentation using HTTP redirect.

An Oracle RAC environment requires that the dispatchers on each instance be cross-registered with the other listeners on the other nodes. This is achieved by the use of the LISTENER attribute of the DISPATCHERS parameter.

Note:

For optimum connection load balancing results, the instances that belong to the same database service should be on equivalent hardware and software configurations.

- Example of Connection Load Balancing for Shared Server Configuration
- Example of Connection Load Balancing for Dedicated Server Configuration
- COLOCATION_TAG of Client Connections
 The COLOCATION_TAG parameter is an alphanumeric string that you can use with the CONNECT DATA parameter of the TNS connect string.

See Also:

- "Registering Information with a Remote Listener" for additional information about cross-registration
- Oracle Database Reference for complete information about the SERVICE NAMES and INSTANCE NAME parameters
- Configuring a Shared Server Architecture for additional information about the LISTENER attribute
- Oracle Database Global Data Services Concepts and Administration Guide for information about management of global services

13.2.1 Example of Connection Load Balancing for Shared Server Configuration

Figure 13-1 shows an Oracle RAC shared server database with two instances, sales1 and sales2, of the same service, sales.us.example.com. The instances sales1 and sales2 reside on computers sales1-server and sales2-server, respectively. Instance sales1 has one dispatcher and instance sales2 has two dispatchers. Listeners named listener run on nodes 1 and 2. The listener attribute in the DISPATCHERS parameter has been configured to allow for service registration of information to both listeners.

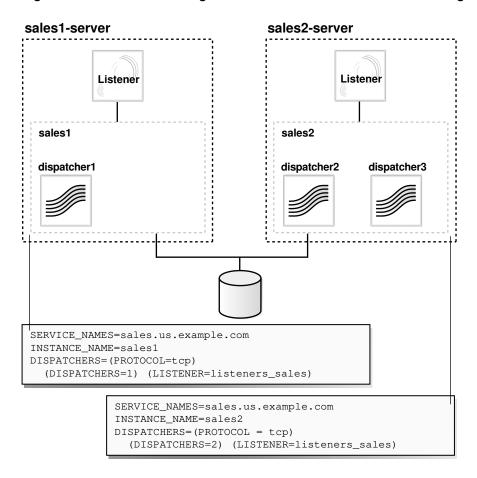

Figure 13-1 Load Balancing Environment for a Shared Server Configuration

In this example, sales2-server is the least loaded node, sales2 is the least loaded instance, and dispatcher2 is the least loaded dispatcher. The following load information is registered.

- The one minute load average for each instance is 600 for sales1 and 400 for sales2. This can happen if more processing is required on sales1-server.
- The number of connections to each instance is 200 for sales1 and 300 for sales2.
- The number of dispatcher connections to each instance is 200 for dispatcher1, 100 for dispatcher2, and 200 for dispatcher3.
- The number of connections to sales1 (200) is the same as that of its only dispatcher, dispatcher1.
- The number of connections on sales2 (300) is the sum of the connections on its two dispatchers, dispatcher2 (100) and dispatcher3 (200).

The listeners_sales value in (LISTENER=listeners_sales) is resolved through a local tnsnames.ora file on both servers as follows:

```
listeners_sales=
(DESCRIPTION=
    (ADDRESS_LIST=
         (ADDRESS=(PROTOCOL=tcp) (HOST=sales1-server) (PORT=1521))
         (ADDRESS=(PROTOCOL=tcp) (HOST=sales2-server) (PORT=1521))))
```

Based on the environment, the following actions occur. The numbered actions correspond to the arrows shown in Figure 13-2:

- **1.** LREG processes for instances sales1 and sales2 register with both listeners. The listeners are updated dynamically on the load of the instances and dispatchers.
- 2. The client sends a connect request. A connect descriptor is configured to try each protocol address randomly until one succeeds:

```
sales.us.example.com=
(DESCRIPTION=
  (LOAD_BALANCE=on)
  (FAILOVER=on)
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales1-server) (PORT=1521))
  (ADDRESS=(PROTOCOL=tcp) (HOST=sales2-server) (PORT=1521))
  (CONNECT_DATA=(SERVICE_NAME=sales.us.example.com)))
```

The listener on sales1-server was randomly chosen to receive the client connect request.

The listener on sales1-server compares the load of the instances sales1 and sales2. The comparison takes into account the load on nodes sales1-server and sales2-server, respectively. Because sales2-server is less loaded than sales1-server, the listener selects sales2-server over sales1-server.

- 3. The listener compares the load on dispatchers dispatcher2 and dispatcher3. Because dispatcher2 is less loaded than dispatcher3, the listener redirects the client connect request to dispatcher2.
- 4. The client connects directly to dispatcher2.

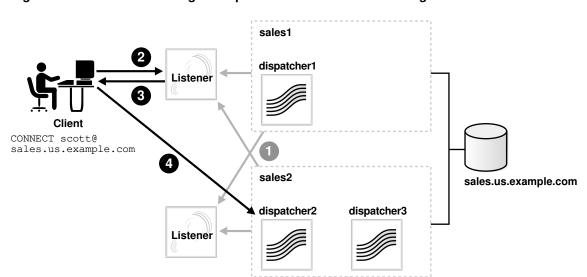

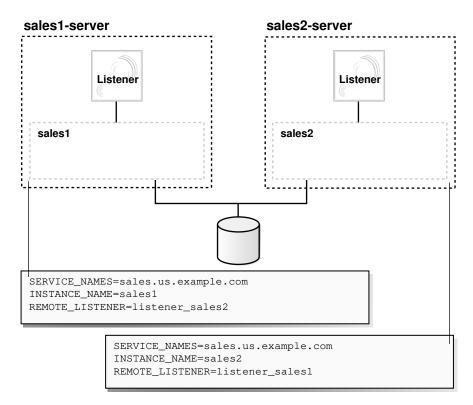

Figure 13-2 Load Balancing Example for a Shared Server Configuration

13.2.2 Example of Connection Load Balancing for Dedicated Server Configuration

Figure 13-3 shows an Oracle RAC dedicated server database with two instances, sales1 and sales2, of the same service, sales.us.example.com. The instances sales1 and sales2 reside on computers sales1-server and sales2-server, respectively. Listeners named listener run

on nodes 1 and 2. The REMOTE_LISTENER initialization parameter has been configured to allow for service registration of information to both listeners.

Figure 13-3 Load Balancing Environment for a Dedicated Server Configuration

In this example, the following load information is registered:

- sales1-server has a node load average of 450 per minute.
- sales2-server has a node load average of 200 per minute.
- sales1 has 200 connections.
- sales2 has 150 connections.

The listener_sales1 value in (REMOTE_LISTENER=listener_sales1) is resolved through a local tnsnames.ora file on the sales2-server as follows:

```
listener_sales1=
  (DESCRIPTION=
          (ADDRESS=(PROTOCOL=tcp) (HOST=sales1-server) (PORT=1521)))
```

The listener_sales2 value in (REMOTE_LISTENER=listener_sales2) is resolved through a local tnsnames.ora file on the sales1-server as follows:

```
listener_sales2=
(DESCRIPTION=
    (ADDRESS=(PROTOCOL=tcp) (HOST=sales2-server) (PORT=1521)))
```

Based on the environment, the following actions occur. The numbered actions correspond to the arrows shown in Figure 13-4:

 LREG processes for instances sales1 and sales2 register with both listeners. The listeners are dynamically updated on the load of the instances. Based on the preceding information, sales2-server is the least loaded node and sales2 is the least loaded instance.

2. The client sends a connect request.

A connect descriptor is configured to try each protocol address randomly until one succeeds:

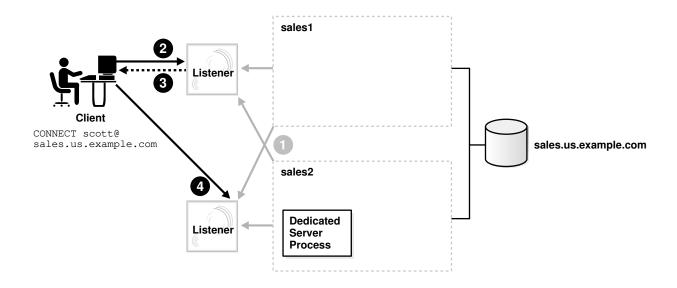

```
sales.us.example.com=
(DESCRIPTION=
  (ADDRESS_LIST=
        (LOAD_BALANCE=on)
        (FAILOVER=on)
        (ADDRESS=(PROTOCOL=tcp) (HOST=sales1-server) (PORT=1521))
        (ADDRESS=(PROTOCOL=tcp) (HOST=sales2-server) (PORT=1521)))
        (CONNECT_DATA=(SERVICE_NAME=sales.us.example.com)))
```

The listener on sales1-server was randomly chosen to receive the client connect request.

The listener on sales1-server compares the load of the instances sales1 and sales2. The comparison takes into account the load on nodes sales1-server and sales2-server, respectively. Because sales2-server is less loaded than sales1-server, the listener selects sales2-server over sales1-server.

- 3. The listener on sales1-server redirects the client connect request to the listener on sales2-server.
- 4. The client connects to the listener on sale2-server. The listener starts a dedicated server process, and the dedicated server process inherits the connection request from the listener.

Figure 13-4 Load Balancing Example for a Dedicated Server Configuration

13.2.3 COLOCATION_TAG of Client Connections

The ${\tt COLOCATION_TAG}$ parameter is an alphanumeric string that you can use with the ${\tt CONNECT_DATA}$ parameter of the TNS connect string.

When you set the <code>colocation_tag</code> within the <code>CONNECT_DATA</code> parameter, load balancing is ignored. The listener makes an effort to send all connections that have the same <code>colocation_tag</code> to the same database instance. The instance selection algorithm is based on the <code>colocation_tag</code>, and the list of available instances for the specified service.

For example, the listener will try to route all clients to the same database instance that have the COLOCATION TAG set to interactive in the connection descriptor.

```
sales.us.example.com=
  (DESCRIPTION=
          (ADDRESS=(PROTOCOL=tcp) (HOST=sales-scan) (PORT=1521))
          (CONNECT_DATA=(SERVICE_NAME=sales.us.example.com)
(COLOCATION TAG=interactive)))
```

Under certain conditions, such as, when maximum load of an instance is reached or when new instances are added or deleted for a service, the colocation of client connections that have the same <code>colocation_tag</code> to the same database instance may not be consistent.

COLOCATION TAG

13.3 Configuring Transparent Application Failover

Transparent Application Failover (TAF) instructs Oracle Net to transparently reconnect a failed connection to a different listener in the event of the failure of a database instance. This enables you to continue your work using the new connection as if the original connection never failed.

TAF involves manual configuration of a network service name that includes the FAILOVER_MODE parameter included in the CONNECT DATA section of the connect descriptor.

Note:

For TAF and Application Continuity, Oracle recommends that you configure failover on the connected service. It overrides the client-side settings.

Learn about the TAF functionality and how to configure it in the connect string.

- About Transparent Application Failover
 - Transparent Application Failover enables a client to automatically reconnect to a database instance if the current instance to which the connection is made fails. Notifications are used by the server to trigger TAF callbacks on the client-side.
- What Transparent Application Failover Restores

TAF automatically restores some or all of these elements associated with active database connections. Other elements may need to be embedded in the application code to enable TAF and recover a connection.

About the FAILOVER MODE Parameters

The FAILOVER_MODE parameter supports these additional parameters. You can specify these in the CONNECT DATA section of a connect descriptor.

Implementing Transparent Application Failover

Depending on the FAILOVER_MODE parameters, you can implement TAF in several ways. Oracle recommends these methods.

Verifying Transparent Application Failover

You can query the FAILOVER_TYPE, FAILOVER_METHOD, and FAILED_OVER columns in the V\$SESSION view to verify that TAF is correctly configured.

Related Topics

- Connection Load Balancing
- Ensuring Application Continuity

13.3.1 About Transparent Application Failover

Transparent Application Failover enables a client to automatically reconnect to a database instance if the current instance to which the connection is made fails. Notifications are used by the server to trigger TAF callbacks on the client-side.

You can configure TAF using server-side service attributes. This is the preferred method. Alternatively, you can configure TAF in the application connect string. The server-side service attributes take precedence over the values specified in the connect string.

TAF operates in one of the following modes:

- Session Failover: Re-creates lost connections and sessions.
- Select Failover: Replays in-progress queries.

When there is a failure, callback functions are initiated on the client-side using Oracle Call Interface (OCI) callbacks. This works with standard OCI connections as well as connection pool and session pool connections.

TAF operates with Oracle Data Guard to provide automatic failover. TAF works with the following database configurations to effectively mask a database failure:

- Oracle Real Application Clusters
- Replicated systems
- Standby databases
- Single instance Oracle database

- Oracle Real Application Clusters Administration and Deployment Guide
- Oracle Call Interface Developer's Guide

13.3.2 What Transparent Application Failover Restores

TAF automatically restores some or all of these elements associated with active database connections. Other elements may need to be embedded in the application code to enable TAF and recover a connection.

- Client-server database connections: TAF automatically reestablishes the connection using the same connect string or an alternate connect string that you specify when configuring failover.
- Users' database sessions: TAF automatically logs a user in with the same user ID as was
 used before the failure. If multiple users were using the connection, then TAF automatically
 logs them in as they attempt to process database commands. Unfortunately, TAF cannot
 automatically restore other session properties. These properties can be restored by
 invoking a callback function.
- Completed commands: If a command was completed at the time of connection failure, and
 it changed the state of the database, then TAF does not resend the command. If TAF
 reconnects in response to a command that may have changed the database, then TAF
 issues an error message to the application.
- Open cursors used for fetching: TAF allows applications that began fetching rows from a
 cursor before failover to continue fetching rows after failover. This is called select failover. It
 is accomplished by re-running a SELECT statement using the same snapshot, discarding
 those rows already fetched and retrieving those rows that were not fetched initially. TAF
 verifies that the discarded rows are those that were returned initially, or it returns an error
 message.
- Active transactions: Any active transactions are rolled back at the time of failure because
 TAF cannot preserve active transactions after failover. The application instead receives an
 error message until a ROLLBACK command is submitted.
- Server-side program variables: Server-side program variables, such as PL/SQL package states, are lost during failures, and TAF cannot recover them. They can be initialized by making a call from the failover callback.

Oracle Call Interface Developer's Guide

13.3.3 About the FAILOVER_MODE Parameters

The FAILOVER_MODE parameter supports these additional parameters. You can specify these in the CONNECT DATA section of a connect descriptor.

Table 13-4 Additional Parameters of the FAILOVER MODE Parameter

Parameter	Description
BACKUP	A different network service name for backup connections. A backup should be specified when using preconnect to pre-establish connections.
DELAY	The amount of time in seconds to wait between connect attempts. If RETRIES is specified, then DELAY defaults to one second.
	If a callback function is registered, then this parameter is ignored.
METHOD	 The setting for fast failover from the primary node to the backup node: basic: Set to establish connections at failover time. This option requires almost no work on the backup server until failover time. preconnect: Set to pre-established connections. This provides faster failover but requires that the backup instance be able to support all connections from every supported instance.
RETRIES	The number of times to attempt to connect after a failover. If <code>DELAY</code> is specified, then <code>RETRIES</code> defaults to five retry attempts. If a callback function is registered, then this parameter is ignored.

Table 13-4 (Cont.) Additional Parameters of the FAILOVER_MODE Parameter

Parameter	Description
TYPE	The type of failover. Three types of Oracle Net failover functionality are available by default to Oracle Call Interface (OCI) applications:
	 session: Set to fail over the session. If the user's connection is lost, then a new session is automatically created for the user on the backup. This type of failover does not attempt to recover select operations. select: Set to enable users with open cursors to continue fetching on them after failure. However, this mode involves overhead on the client side in normal select operations.
	 none: This is the default. No failover functionality is used. This can also be explicitly specified to prevent failover from happening.

Oracle Net Manager does not provide support for TAF parameters. These parameters must be set manually.

13.3.4 Implementing Transparent Application Failover

Depending on the FAILOVER_MODE parameters, you can implement TAF in several ways. Oracle recommends these methods.

🧪 Important:

Do not set the <code>GLOBAL_DBNAME</code> parameter in the <code>SID_LIST_listener_name</code> section of the <code>listener.ora</code> file. A statically configured global database name disables TAF.

- TAF with Connect-Time Failover and Client Load Balancing
 Implement TAF with connect-time failover and client load balancing for multiple addresses.
- TAF Retrying a Connection
 TAF enables you to automatically retry connecting if the first connection attempt fails with
 the RETRIES and DELAY parameters.
- TAF Pre-establishing a Connection
 TAF enables you to pre-establish a backup connection. You must explicitly specify the initial and backup connections.

13.3.4.1 TAF with Connect-Time Failover and Client Load Balancing

Implement TAF with connect-time failover and client load balancing for multiple addresses.

In the following example, Oracle Net connects randomly to one of the protocol addresses on sales1-server or sales2-server. If the instance fails after the connection, then the TAF application fails over to the other node's listener, reserving any SELECT statements in progress.

sales.us.example.com=
 (DESCRIPTION=

Although the preceding example has multiple addresses, the optional ADDRESS_LIST parameter is not used.

13.3.4.2 TAF Retrying a Connection

TAF enables you to automatically retry connecting if the first connection attempt fails with the RETRIES and DELAY parameters.

In the following example, Oracle Net tries to reconnect to the listener on sales1-server. If the failover connection fails, then Oracle Net waits 15 seconds before trying to reconnect again. Oracle Net attempts to reconnect up to 20 times.

13.3.4.3 TAF Pre-establishing a Connection

TAF enables you to pre-establish a backup connection. You must explicitly specify the initial and backup connections.

In the following example, clients that use network service name <code>sales1.us.example.com</code> to connect to the listener on <code>sales1-server</code> are also preconnected to <code>sales2-server</code>. If <code>sales1-server</code> fails after the connection, then Oracle Net fails over to <code>sales2-server</code>, preserving any <code>SELECT</code> statements in progress. Similarly, Oracle Net preconnects to <code>sales1-server</code> for those clients that use <code>sales2.us.example.com</code> to connect to the listener on <code>sales2-server</code>.

```
(SERVICE NAME=sales.us.example.com)
     (INSTANCE NAME=sales1)
     (FAILOVER MODE=
       (BACKUP=sales2.us.example.com)
       (TYPE=select)
       (METHOD=preconnect) ) )
sales2.us.example.com=
 (DESCRIPTION=
  (ADDRESS=
       (PROTOCOL=tcp)
       (HOST=sales2-server)
       (PORT=1521))
  (CONNECT DATA=
     (SERVICE NAME=sales.us.example.com)
     (INSTANCE NAME=sales2)
     (FAILOVER MODE=
       (BACKUP=sales1.us.example.com)
       (TYPE=select)
       (METHOD=preconnect))))
```

13.3.5 Verifying Transparent Application Failover

You can query the FAILOVER_TYPE, FAILOVER_METHOD, and FAILED_OVER columns in the V\$SESSION view to verify that TAF is correctly configured.

To view the columns, use a query similar to the following:

```
SELECT MACHINE, FAILOVER_TYPE, FAILOVER_METHOD, FAILED_OVER, COUNT(*) FROM V$SESSION
GROUP BY MACHINE, FAILOVER TYPE, FAILOVER METHOD, FAILED OVER;
```

The output before failover looks similar to the following:

MACHINE	FAILOVER_TYPE	FAILOVER_METHOD	FAILED_OVER	COUNT(*)
sales1	NONE	NONE	NO	11
sales2	SELECT	PRECONNECT	NO	1

The output after failover looks similar to the following:

FAILOVER_TYPE	FAILOVER_METHOD	FAILED_OVER	COUNT(*)
NONE	NONE	NO	10
SELECT	PRECONNECT	YES	1
	NONE	NONE NONE	NONE NONE NO

You can monitor each step of TAF using an appropriately configured ${\tt OCI}$ TAF CALLBACK function.

13.4 Specifying the Instance Role for Primary and Secondary Instance Configurations

The INSTANCE_ROLE parameter is an optional parameter for the CONNECT_DATA section of a connect descriptor. It enables you to specify a connection to the primary or secondary instance of Oracle RAC configurations.

This parameter is useful when:

- You want to explicitly connect to a primary or secondary instance. The default is the primary instance.
- You want to use TAF to preconnect to a secondary instance.

Table 13-5 describes the INSTANCE_ROLE parameters.

Table 13-5 INSTANCE ROLE Parameters

INSTANCE_ROLE Parameter	Description
PRIMARY	Specifies a connection to the primary instance.
SECONDARY	Specifies a connection to the secondary instance.
ANY	Specifies a connection to whichever instance has the lowest load, regardless of primary or secondary instance role.

Connection to Instance Role Type

In the following example of the tnsnames.ora file, network service name sales_primary enables connections to the primary instance, and network service name sales_secondary enables connections to the secondary instance.

```
sales primary=
 (DESCRIPTION=
  (ADDRESS LIST=
    (ADDRESS=
       (PROTOCOL=tcp)
       (HOST=sales1-server)
       (PORT=1521))
    (ADDRESS=
       (PROTOCOL=tcp)
       (HOST=sales2-server)
       (PORT=1521)))
  (CONNECT DATA=
     (SERVICE NAME=sales.us.example.com)
     (INSTANCE ROLE=primary)))
sales secondary=
 (DESCRIPTION=
  (ADDRESS LIST=
    (ADDRESS=
       (PROTOCOL=tcp)
       (HOST=sales1-server)
       (PORT=1521))
    (ADDRESS=
       (PROTOCOL=tcp)
       (HOST=sales2-server)
       (PORT=1521)))
  (CONNECT DATA=
```

```
(SERVICE_NAME=sales.us.example.com)
(INSTANCE ROLE=secondary)))
```

Connection to a Specific Instance

There are times when Oracle Enterprise Manager Cloud Control and other system management products need to connect to a specific instance regardless of its role to perform administrative tasks. For these types of connections, configure

(INSTANCE_NAME=instance_name) and (INSTANCE_ROLE=any) to connect to the instance regardless of its role.

In the following example, network service name sales1 enables connections to the instance on sales1-server and sales2 enables connections to the instance on sales2-server. (SERVER=dedicated) is specified to force a dedicated server connection.

```
sales1=
 (DESCRIPTION=
  (ADDRESS=
       (PROTOCOL=tcp)
       (HOST=sales1-server)
      (PORT=1521))
  (CONNECT DATA=
     (SERVICE NAME=sales.us.example.com)
     (INSTANCE ROLE=any)
     (INSTANCE NAME=sales1)
     (SERVER=dedicated)))
sales2=
 (DESCRIPTION=
  (ADDRESS=
       (PROTOCOL=tcp)
       (HOST=sales2-server)
       (PORT=1521))
  (CONNECT DATA=
     (SERVICE NAME=sales.us.example.com)
     (INSTANCE ROLE=any)
     (INSTANCE NAME=sales2)
     (SERVER=dedicated)))
```

Failover is incompatible with the preceding settings.

TAF Pre-establishing a Connection

If TAF is configured, then a backup connection can be pre-established to the secondary instance. The initial and backup connections must be explicitly specified. In the following example, Oracle Net connects to the listener on sales1-server and preconnects to sales2-server, the secondary instance. If sales1-server fails after the connection, then the TAF application fails over to sales2-server, the secondary instance, preserving any SELECT statements in progress.

13.5 Configuring Static Service Registration

The listener uses the dynamic service information about the database and instance before using statically configured information in the listener.ora file.

Configuration of static service information is necessary in the following cases:

- Use of external procedure calls
- Use of Oracle Heterogeneous Services
- Use of Oracle Data Guard
- Remote database startup from a tool other than Oracle Enterprise Manager Cloud Control
- Connections to Oracle databases earlier than Oracle8i release 2 (8.1)
- Parameters for Static Service Registration
 Understand the static service settings in the listener.ora file for static service registration.
- Configuring Static Service Information for the Listener
 Learn how to statically configure database service information for the listener using Oracle
 Enterprise Manager Cloud Control.

13.5.1 Parameters for Static Service Registration

Understand the static service settings in the listener.ora file for static service registration.

Example listener.ora File

This example shows a <code>listener.ora</code> file configured for static service registration. The <code>LISTENER</code> entry defines the listening protocol address for a listener named <code>Listener</code>, and the <code>SID_LIST_LISTENER</code> entry provides information about the external services statically supported by the <code>Listener</code> listener.

LISTENER=

```
(DESCRIPTION=
    (ADDRESS_LIST=
          (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
          (ADDRESS=(PROTOCOL=ipc) (KEY=extproc) (queuesize=50))))

SID_LIST_listener=
    (SID_LIST=
          (SID_DESC=
                (SID_DESC=
                 (SID_NAME=plsextproc)
```

```
(ORACLE_HOME=/oracle8)
(PROGRAM=extproc)))
```

The SID_LIST_listener_name parameter setting in the listener.ora file specifies information about the databases served by the listener. When services are configured statically, a listener starts a dedicated server process when it receives a client request. If the instance is not up, then the server returns an Oracle not available error message.

If a database cannot find the listener, then configure the <code>listener.ora</code> file with the <code>GLOBAL_DBNAME</code> parameter, as shown in the following example

```
SID_LIST_listener=
(SID_LIST=
  (SID_DESC=
  (GLOBAL_DBNAME=sales.example.com)
  (SID_NAME=sales)
  (ORACLE_HOME=/u01/app/oracle))
```

A statically-configured global database name disables TAF. To use TAF, do not set the GLOBAL_DBNAME parameter in the SID_LIST_listener_name section of the listener.ora file.

Static Service Settings in listener.ora

Oracle Net Manager Field	listener.ora File Parameter	Description
SID	SID_NAME	The Oracle system identifier (SID) of the instance. You can obtain the SID value from the INSTANCE_NAME parameter in the initialization parameter file.
Service Name	GLOBAL_DBNAME	The database service.
		While processing a client connection request, the listener tries to match the value of this parameter with the value of the SERVICE_NAME parameter in the client connect descriptor. If the client connect descriptor uses the SID parameter, then the listener does not attempt to map the values. This parameter is primarily intended for configurations with Oracle8 databases (where dynamic service registration is not supported for dedicated servers). This parameter may also be required for use with Oracle8 <i>i</i> and later database services by some configurations. The value for this parameter is typically obtained from the combination of the DB_NAME and DB_DOMAIN parameters (DB_NAME.DB_DOMAIN) in the initialization parameter file, but the value can also contain any valid name used by clients to identify the service.
		When using a connect descriptor with a SERVICE_NAME parameter, ensure that any SID_DESC entry does not have the value GLOBAL_DBNAME.
Oracle Home Directory	ORACLE_HOME	The Oracle home location of the instance. Without this setting, the listener assumes its Oracle home for the instance.
		On Linux and UNIX, this setting is optional.
		On Microsoft Windows, this setting is ignored. The Oracle home specified by the ORACLE_HOME parameter in https://home.oracle.home.id of the Microsoft Windows registry is used.

Oracle Net Manager Field	listener.ora File Parameter	Description
Not applicable	SID_LIST_listener_nam e	The section of the listener.ora file that defines the database served by the listener.

13.5.2 Configuring Static Service Information for the Listener

Learn how to statically configure database service information for the listener using Oracle Enterprise Manager Cloud Control.

If you are using connect-time failover or TAF, such as in an Oracle Real Application Clusters environment, then do not set the GLOBAL_DBNAME parameter.

- 1. Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.
- 2. Select **Listeners** from the Administer list, and then select the Oracle home that contains the configuration files.
- 3. Click **Go**. You may be prompted to log in to the database server.

The Listeners page appears.

4. Select a listener, and then click **Edit**.

The Edit Listener page appears.

Click the Static Database Registration tab, and then click Add.
 The Add Database Service page appears. Enter the required information in the fields.

6. Click OK.

You can also configure static service information with Oracle Net Manager. See **Statically Configure Database Service Information** in the online help for additional information.

Related Topics

- Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services
- Configuring Dynamic Service Registration
 Service registration allows processes, such as an Oracle database, to identify their available services to the listener, which then acts as a port mapper for those services.

13.6 Configuring Connections to Third-Party Database Services

Learn about external procedures settings in the listener.ora file, changing the default configuration for external procedures, configuring the Oracle database server for connecting to

Heterogeneous Services agents, and configuring clients for connecting to the Oracle Rdb database.

- Default Configuration for External Procedures
- About Oracle Net Services for Oracle Heterogeneous Services
- Configuring Oracle Net Services for an Oracle Rdb Database
 Oracle Rdb is a database for Digital 64-bit operating systems. Because Oracle Rdb has its
 own listener, the client interacts with Rdb in the same manner as it does with an Oracle
 database.

13.6.1 Default Configuration for External Procedures

An external procedure is a procedure called from another program, written in a different language. An example is a PL/SQL program calling one or more C routines that are required to perform special-purpose processing.

When an application calls an external procedure, Oracle Database starts an external procedure agent named extproc. Using the network connection established by Oracle Database, the application passes the following information to the agent:

- DLL or shared library name
- External procedure name
- Any parameters

The agent then loads the DLL or the shared library, and runs the external procedure and passes back to the application any values returned by the external procedure. The agent must reside on the same computer as the application making the external procedure call.

When you use the default configuration for external procedures, the <code>extproc</code> agent is spawned directly by Oracle Database. There are no configuration changes required for either the <code>listener.ora</code> or <code>tnsnames.ora</code> file. However, you must define the environment variables to be used by external procedures in the <code>extproc.ora</code> file located in the <code>ORACLE_BASE_HOME/hs/admin</code> directory. If the default configuration for external procedures is not used, then the parameters listed in Table 13-6 must be set.

Table 13-6 External Procedures Settings in listener.ora

Oracle Enterprise Manager Cloud Control Field	listener.ora Parameter	Description
Program Name	PROGRAM	The name of the external procedure agent executable.
		Note: On Microsoft Windows, the executable must reside in the ORACLE_HOME\bin directory.

Table 13-6 (Cont.) External Procedures Settings in listener.ora

Oracle Enterprise Manager Cloud Control Field	listener.ora Parameter	Description
Environment Variables	ENVS	The environment variables to be used by external procedures in the extproc.ora file located in the ORACLE_BASE_HOME/hs/admin directory.
		Note: When extproc.ora is in use, it precedes the same environment variables of ENVS in listener.ora.
		Syntax: SET name=value
		Example: SET EXTPROC DLLS=ANY
		Specify the EXTPROC_DLLS environment variable to restrict the DLLs that the extproc agent is allowed to load. Without the EXTPROC_DLLS environment variable, the extproc agent loads DLLs from the ORACLE_HOME/lib directory on UNIX operating systems and the ORACLE_HOME\bin directory on Microsoft Windows.
		Set EXTPROC_DLLS to one of the following values:
		Colon-separated list of DLLs ¹
		Syntax: "DLL: DLL"
		This value allows the extproc agent to load the specified DLLs and the DLLs from the <code>ORACLE_HOME/lib</code> directory on UNIX operating systems and the <code>ORACLE_HOME/bin</code> directory on Microsoft Windows. You must enter the complete directory path and file name of the DLLs. • ONLY (Recommended for maximum security) ¹
		Syntax: "ONLY: DLL: DLL"
		This value allows the extproc agent to load only the specified DLLs. You must enter the complete directory path and file name of the DLLs. ANY
		Syntax: "ANY"
		Description: This value allows the extproc agent to load any DLL. ANY disables DLL checking.
		Examples:
		"EXTPROC_DLLS=/home/xyz/mylib.so:/home/abc/urlib.so, LD_LIBRARY_PATH=/private/xpm/lib:/private/mylibs, MYPATH=/usr/ucb:/usr/local/packages,APL_ENV_FILE=/apl/conf/env.txt" "EXTPROC_DLLS=ONLY:/home/xyz/mylib.so:/home/abc/urlib.so, LD_LIBRARY_PATH=/private/xpm/lib:/private/mylibs,
		MYPATH=/usr/ucb:/usr/local/packages,APL_ENV_FILE=/apl/conf/env.txt" "EXTPROC_DLLS=ANY,LD_LIBRARY_PATH=/private/xpm/lib:/private/mylibs, MYPATH=/usr/ucb:/usr/local/packages,APL_ENV_FILE=/apl/conf/env.txt"
		Note: If effective user and real user, or effective group and real group are different, then LD_LIBRARY_PATH environment setting is ignored.
Oracle Home Directory	ORACLE_HOME	The Oracle home location of the agent.

Table 13-6 (Cont.) External Procedures Settings in listener.ora

Oracle Enterprise Manager Cloud Control Field	listener.ora Parameter	Description
Oracle System Identifier (SID)	SID_NAME	A system identifier for the external procedure agent by any name.
		See the examples in Configuring Oracle Net Services for External Procedures for more information about how to work with the external procedure agent spawned by Oracle listener.

¹ The DLLs are separated by semi-colons (;) on Microsoft Windows.

The default configuration for external procedures does not require a network listener to work with Oracle Database and the <code>extproc</code> agent. The <code>extproc</code> agent is spawned directly by Oracle Database and eliminates the risks that the <code>extproc</code> agent might be spawned by Oracle Listener unexpectedly. This default configuration is recommended for maximum security.

You can change the default configuration for external procedures and have the <code>extproc</code> agent spawned by Oracle Listener. To do this, you must perform additional network configuration steps.

Having the extproc agent spawned by Oracle Listener is necessary if you use:

- Multi-threaded agent
- Oracle Database in MTS mode on Microsoft Windows
- The AGENT clause of the LIBRARY specification or the AGENT IN clause of the PROCEDURE specification such that you can redirect external procedures to a different extproc agent.
- Configuring Oracle Net Services for External Procedures

Oracle Database Security Guide for additional information about securing external procedures

13.6.1.1 Configuring Oracle Net Services for External Procedures

You can change the default configuration for external procedures and have the extproc agent spawned by the listener similar to earlier releases of Oracle Database. Here is the process:

1. Configure an existing listener or create a new listener to serve external procedures.

Example 13-1 shows a sample configuration in the listener.ora file.

Example 13-1 listener.ora File with an External Procedure

```
LISTENER=

(DESCRIPTION=

(ADDRESS_LIST=

(ADDRESS=(PROTOCOL=tcp) (HOST=sale-server) (PORT=1521))

(ADDRESS=(PROTOCOL=ipc) (KEY=extproc))))

SID_LIST_LISTENER=

(SID_LIST=

(SID_DESC=

(GLOBAL_DBNAME=sales.us.example.com)

(ORACLE_HOME=/oracle)

(SID_NAME=sales))

(SID_DESC=

(SID_NAME=plsextproc)

(ORACLE_HOME=/oracle)

(PROGRAM=extproc)))
```

2. Add a new entry in this names.ora.

Example 13-2 shows a sample configuration in the tnsnames.ora file.

Example 13-2 tnsnames.ora File with an External Procedure

```
EXTPROC_CONNECTION_DATA_1=
  (DESCRIPTION=
     (ADDRESS=(PROTOCOL=ipc) (KEY=extproc))
     (CONNECT_DATA=
     (SID=plsextproc)))
```

3. Use AGENT clause of the LIBRARY specification or AGENT IN clause of the PROCEDURE specification such that you can redirect external procedures to a different extproc agent (for example, extproc spawned by Oracle listener).

```
$ cat test.c
#include <stdlib.h>
int negative(char* db, int n)
{
        return -1*n;
}
char* mygetenv(const char* env)
{
        return getenv(env);
}
$ gcc -shared -fPIC -o test.so test.c
$ cp test.so $ORACLE_HOME/lib

In SQL*PLUS, run:

DROP DATABASE LINK extproclink;
CREATE DATABASE LINK extproclink USING 'extproc_connection_data_1';
CREATE OR REPLACE LIBRARY test1 AS '$ORACLE_HOME/lib/test.so';
```

```
-- Use 'AGENT' clause in LIBRARY SPEC
CREATE OR REPLACE LIBRARY test2 AS '$ORACLE HOME/lib/test.so' AGENT
'extproclink';
-- Use 'AGENT IN' clause in FUNCTION
CREATE OR REPLACE FUNCTION ftest1 (x VARCHAR2, y BINARY INTEGER)
RETURN BINARY INTEGER
AS LANGUAGE C
LIBRARY test1
NAME "negative"
PARAMETERS (x STRING, y INT)
AGENT IN (x);
CREATE OR REPLACE FUNCTION ftest2 (x VARCHAR2)
RETURN VARCHAR2
AS LANGUAGE C
LIBRARY test2
NAME "mygetenv";
$ select ftest1('extproclink', 123) from dual;
$ select ftest2('LD LIBRARY PATH') from dual;
```

The listener for external procedures should have a user account that does not have general access to the files owned by the oracle user. Specifically, this user should not have permission to read or write to database files or to the Oracle server address space. In addition, this user should have read access to the listener.ora file, but must not have write access to it.

Running the listener with lower privileges also prevents using the Listener Control SET commands to alter the configuration of the listener in the listener.ora file. For this reason, Oracle recommends that you complete listener.ora file configuration before running the listener.

- Modifying the Default Configuration for External Procedures
- Creating a New Listener to Run External Procedures

13.6.1.1.1 Modifying the Default Configuration for External Procedures

To modify the default configuration for external procedures, configure and run a separate or existing listener to serve external procedures. The following procedure describes how to modify the default configuration:

- 1. Configure an existing listener to serve external procedures using Oracle Net Configuration Assistant as follows. For most installation types, this listener is named LISTENER.
 - Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

- b. Select Listeners from the Administer list, and then select the Oracle home that contains the location of the configuration files.
- c. Click Go.

The Listeners page appears.

 Select the existing listener created by Oracle Net Configuration Assistant, and then click Edit.

The Edit Listeners page appears.

- In the Addresses section, select the protocol address for external procedures, and then click Add.
- Click the Other Services tab.
- g. Select the row representing the service information for external procedures, and then click Add.
- Add service information about the extproc agent in the listener.ora file, including the parameters described in Table 13-6.

13.6.1.1.2 Creating a New Listener to Run External Procedures

To configure and run a separate listener to serve external procedures, create the external procedure entries for a different listener using Oracle Net Configuration Assistant. The following procedure describes how to create a new listener:

- 1. Create a listener to exclusively handle external procedures, as follows:
 - a. Navigate to the Listeners page.
 - b. Click Create.

The Create Listener page appears.

- c. In the Listener Name field, enter a unique listener name, such as LISTENEREXTPROC, in the Listener Name field.
- 2. In the Addresses section, configure an IPC protocol address, as follows:
 - a. Click Add.

The Add Address page appears.

- b. From the Protocol list, select IPC.
- c. In the Key field, enter a key value of the extproc agent.
- d. Click OK.

"Configuring Listening Protocol Addresses" for additional information about configuring listener protocol addresses

- 3. Add service information about the extproc agent in the listener.ora file, including the parameters described in Table 13-6, as follows:
 - a. Click the Other Services tab.
 - b. Click Add.

The Create Other Service page appears.

- c. Enter the following values in the fields:
 - extproc in the Program Name field.
 - The Oracle home where the extproc executable resides in the Oracle Home Directory field.
 - System identifier, such as extproc, in the SID field.
- d. In the Environment Variables section, click Add Another Row.
- e. Enter the EXTPROC_DLLS environment variable in the Name field, and the directory path and file name of the DLLs in the Value field.
- Click OK.

The Create Listener page appears.

q. Click **OK** to add the listener.

The listener is added to the Listeners page.

The listener.ora file updates with information for external procedures, as shown in the following output:

Start the listener for external procedures from a user account with lower privileges than the oracle user.

See Also:

- "Starting Oracle Net Listener and the Oracle Database Server" for instructions on using the Listener Control utility START command to start the listener
- Oracle Database Development Guide for instruction on enabling external procedure calls

13.6.2 About Oracle Net Services for Oracle Heterogeneous Services

Heterogeneous Services is an integrated component within the Oracle database server, and provides the generic technology for accessing third-party systems from the Oracle database server. Heterogeneous Services enables you to:

- Use Oracle SQL to transparently access data stored in third-party systems as if the data resides within an Oracle database server.
- Use Oracle procedure calls to transparently access third-party systems, services, or application programming interfaces (APIs) from your Oracle distributed environment.

While Heterogeneous Services provides the generic technology in the Oracle database server, a Heterogeneous Services agent is required to access a particular third-party system.

Configuring Oracle Database to Connect to Agents
 To initiate a connection to the third-party system, the Oracle database server starts an agent process through the listener on the gateway.

13.6.2.1 Configuring Oracle Database to Connect to Agents

To initiate a connection to the third-party system, the Oracle database server starts an agent process through the listener on the gateway.

The following procedure describes how to configure the Oracle database server to be able to connect to the agents:

- 1. Configure the listener on the gateway to listen for incoming requests from the Oracle database server and spawn Heterogeneous Services agents by configuring the following parameters in the listener.ora file:
 - PROGRAM: The name of the agent executable
 - ORACLE HOME: The Oracle home location of the agent executable
 - SID NAME: The Oracle system identifier (SID)
- 2. Configure the PROGRAM, ORACLE_HOME, and SID parameters in Oracle Enterprise Manager Cloud Control.
 - Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

See Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services.

- **b.** Select **Listeners** from the Administer list, and then select the Oracle home that contains the location of the configuration files.
- c. Click Go.

The Listeners page appears.

- d. Select the listener created by Oracle Net Configuration Assistant, and then click Edit. The Edit Listeners page appears.
- e. Click the Other Services tab.
- f. Click Add.

The Create Other Service page appears.

- g. Enter the program name in the Program Name field that will be run to create a gateway, the Oracle home where the agent executable resides in the Oracle Home Directory field, and the Oracle System Identifier (SID) or service name of the thirdparty system in the SID field.
- h. Click OK.

The Edit Listener page appears.

i. Click **OK** to modify the listener.

The Listeners page appears.

The listener.ora file updates information about the Heterogeneous Services, as shown in the following:

```
SID_LIST_LISTENER=
(SID_LIST=
  (SID_DESC=
   (SID_NAME=sybasegw)
   (ORACLE_HOME=/oracle12c)
   (PROGRAM=tq4sybs)))
```

- 3. On the computer where the Oracle database resides, set up a network service name to connect to the listener on the gateway. The connect descriptor must include the HS=ok clause to ensure the connection uses Heterogeneous Services, as follows:
 - a. Create a network service name that can be used for connections from the Oracle database server to a third-party system.
 - See Task 1, Configure Net Services Names for local naming instructions and Create Net Service Names in the Directory for directory naming instructions.
 - **b.** Use either Oracle Enterprise Manager Cloud Control or Oracle Net Manager to configure HS=0k.

 - For Oracle Net Manager, click Advanced in the Service Identification box. The Advanced Service Options dialog box appears. Click Use for Heterogeneous Services.
 - c. Click **OK** to confirm the change.

The tnsnames.ora file updates with the new network service name configured for Heterogeneous Services, as shown in the following:

Related Topics

Oracle Database Heterogeneous Connectivity Administrator's Guide

13.6.3 Configuring Oracle Net Services for an Oracle Rdb Database

Oracle Rdb is a database for Digital 64-bit operating systems. Because Oracle Rdb has its own listener, the client interacts with Rdb in the same manner as it does with an Oracle database.

To initiate a connection to an Oracle Rdb, set up a network service name to connect to the Oracle Rdb database using the parameters described in Table 13-7.

Table 13-7 Oracle RDB Database Settings in a Connect Descriptor

Oracle Enterprise Manager Cloud Control Field	tnsnames.ora Parameter	Description
Rdb Database	RDB_DATABASE	The file name of an Oracle Rdb database.
Type of Service	TYPE_OF_SERVICE	The type of service to use for an Oracle Rdb database. It is used by Rdb interface tools. This feature should only be used if the application supports both Oracle Rdb and Oracle database services, and you want the application to load balance between the two.
Global Database Name	GLOBAL_NAME	The Oracle Rdb database. Optional.

The following procedure describes how to configure a client for an Oracle Rdb database:

1. Create a network service name that can be used for connections from the Oracle server to a third-party system.

See Task 1, Configure Net Services Names for local naming instructions and Create Net Service Names in the Directory for directory naming instructions.

- 2. Use either Oracle Enterprise Manager Cloud Control or Oracle Net Manager to set the Oracle Rdb parameters.
 - For Oracle Enterprise Manager Cloud Control, access the Net Services
 Administration page, select Local Naming for the listener, and then click the
 Advanced tab in the Create Net Service Name page.
 - For Oracle Net Manager, click Advanced in the Service Identification section. The Advanced Service Options dialog box appears.
- 3. Enter the file name of an Oracle Rdb database in the Rdb Database field.
- 4. (Optional) Specify the type of service in the Type of Service field, if needed, and enter the global database name in the Global Database Name field, and then click **OK.**

The tnsnames.ora file updates with the new network service name configured for the Oracle Rdb database, similar to the following:

In the following example, the TYPE_OF_SERVICE parameter is used to load balance between an Oracle Rdb database service and an Oracle database service:

Optimizing Performance

Learn how to optimize connection performance.

- Understanding the Benefits of Network Data Compression
- Configuring Session Data Unit
 Under typical database configuration, Oracle Net encapsulates data into buffers the size of the Session Data Unit (SDU) before sending the data across the network.
- Determining the Bandwidth-Delay Product
- Configuring I/O Buffer Space

Reliable network protocols, such as TCP/IP, buffer data into send and receive buffers while sending and receiving to or from lower and upper layer protocols. The sizes of these buffers affect network performance by influencing flow control decisions.

- Configuring SDP Support for InfiniBand Connections
 Oracle Net Services provides support for the Sockets Direct Protocol (SDP) for InfiniBand
 high-speed networks. These sections describe how to set up Oracle Net support of SDP
 for middle tier and database server communication.
- Configuring Exadirect Support for InfiniBand Connections
 Oracle Net Services provides support for the Exadirect for InfiniBand high-speed
 networks.. Use the new transport to improve latency and throughput by leveraging Remote
 Direct Memory Access (RDMA) in an InfiniBand environment
- Limiting Resource Consumption by Unauthorized Users
- Configuring Key-Based Routing for Client-Server Connections
 Learn how to establish client-server connections in a sharded database by using key-based (or direct) routing. In key-based routing to a shard, a connection is established to a single, relevant shard that contains the data pertinent to the required transaction using a sharding key.
- Configuring SNI for TLS connections
 Oracle Net Services supports Server Name Indication (SNI) in order to minimize the time
 taken to establish client-server connection. When SNI is set, the listener forwards the
 connection request from client to an appropriate server without performing a TLS
 handshake, thereby reducing the overall connection establishment time.

14.1 Understanding the Benefits of Network Data Compression

Network data compression reduces the size of the session data unit (SDU) transmitted over a data connection. Reducing the size of data reduces the time required to transmit a SQL query and result across the network. In addition, compressed data uses less bandwidth which allows transmission of larger data in less time. The data compression process is transparent to the application layer.

The following are some of the benefits of using data compression:

- Increased network throughput means constrained bandwidth environments can utilize compression to reduce query response time.
- Reduced bandwidth utilization allows other applications to use the bandwidth.

Reduction in the amount of data transferred between sites.

14.2 Configuring Session Data Unit

Under typical database configuration, Oracle Net encapsulates data into buffers the size of the Session Data Unit (SDU) before sending the data across the network.

Oracle Net sends each buffer when it is filled, flushed, or when an application tries to read data. Adjusting the size of the SDU buffers relative to the amount of data provided to Oracle Net to send at any one time can improve performance, network utilization, and memory consumption. When large amounts of data are being transmitted, increasing the SDU size can improve performance and network throughput. SDU size can be adjusted lower or higher to achieve higher throughput for a specific deployment.

The amount of data provided to Oracle Net to send at any one time is referred to as the message size.

The SDU size can range from 512 bytes to 2 MB. The wide range of sizes allows the network administrator to tune the SDU size for optimal network performance for a given deployment. A high SDU size value requires more memory.

The default SDU size for the client is 8192 bytes and the server is 65536 bytes.

The actual SDU size used is negotiated between the client and the server at connect time and is the smaller of the client and server values. Configuring an SDU size different from the default requires configuring the SDU on both the client and server computers, unless you are using shared servers.

You should consider changing the SDU size when the predominant message size is smaller or larger than 8192. The SDU size should be 70 bytes more than the predominant message size. If the predominant message size plus 70 bytes exceeds the maximum SDU, then the SDU should be set such that the message size is divided into the smallest number of equal parts where each part is 70 bytes less than the SDU size. To change the default, change the DEFAULT SDU SIZE parameter in the sglnet.ora file.

For example, if the majority of the messages sent and received by the application are smaller than 8 KB, taking into account the 70 bytes for overhead, then setting the SDU to 8 KB will likely produce good results. If sufficient memory is available, then using the maximum value for the SDU minimizes the number of system calls and overhead for Oracle Net Services.

- Setting the SDU Size for the Database
- Setting the SDU Size for the Client

Related Topics

- Session Data Unit Size for Data Transfer Optimization
- Statistics Example

14.2.1 Setting the SDU Size for the Database

To set the SDU size for the database server, configure the following files:

sqlnet.ora

Configure the DEFAULT_SDU_SIZE parameter in the sqlnet.ora file, such as the following:

DEFAULT_SDU_SIZE=32767

Initialization parameter file

If using shared server processes, then set the SDU size in the DISPATCHERS parameter in the initialization parameter file, as follows:

```
DISPATCHERS="(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp))(SDU=8192))"
```

listener.ora

If the listener was configured with a list of targets in the listener.ora file, then the value for SDU in the SID_LIST parameter overrides the current setting in the sqlnet.ora file when using dedicated server processes.

14.2.2 Setting the SDU Size for the Client

To set the SDU size for the client, configure the following files:

sqlnet.ora

For global configuration on the client side, configure the DEFAULT_SDU_SIZE parameter in the sqlnet.ora file, such as the following:

```
DEFAULT_SDU_SIZE=32767
```

tnsnames.ora

For a particular connect descriptor, you can specify the SDU parameter in the DESCRIPTION parameter.

The SDU size applies to all Oracle Net protocols for the particular connect descriptor.

14.3 Determining the Bandwidth-Delay Product

Bandwidth-delay product is the product of network bandwidth and the round trip time of data going over the network. A simple way to determine the round trip time, is to use a command such as ping from one host to another and use the response times returned by ping.

For example, if a network has a bandwidth of 100 Mbps and a round trip time of 5ms, then the send and receive buffers should be at least (100*10^6) * (5/10^3) bits or approximately 62.5 Kilobytes.

The following equation shows the relationships between the units and factors involved:

```
100,000,000 bits 1 byte 5 seconds

----- x ----- x ----- = 62,500 bytes

1 second 8 bits 1000
```

Setting the SEND_BUF_SIZE and RECV_BUF_SIZE parameters to at least the bandwidth-delay product insures that when large amounts of data are being sent that the network bandwidth will be optimally utilized.

Based on the preceding equation, the bandwidth-delay product of this network link is approximately 64 KB. If the largest message used to transfer redo data between a primary

database and a standby database is 1 MB, then the value for the SEND_BUF_SIZE and RECV_BUF_SIZE parameters could be 1 MB. However, if the average message is less, then a setting of 64 KB should be sufficient to optimize use of the available bandwidth.

For most network protocols, ensure that the RECV_BUF_SIZE parameter at one end of the network connection, typically at the client, equals the value of the SEND_BUF_SIZE parameter at the other end, typically at the server.

See Also:

"Statistics Example" for additional information about determining messages sizes

14.4 Configuring I/O Buffer Space

Reliable network protocols, such as TCP/IP, buffer data into send and receive buffers while sending and receiving to or from lower and upper layer protocols. The sizes of these buffers affect network performance by influencing flow control decisions.

The RECV_BUF_SIZE and SEND_BUF_SIZE parameters specify sizes of socket buffers associated with an Oracle Net connection. To ensure the continuous flow of data and better utilization of network bandwidth, specify the I/O buffer space limit for receive and send operations of sessions with the RECV_BUF_SIZE and SEND_BUF_SIZE parameters. The RECV_BUF_SIZE and SEND_BUF_SIZE parameter values do not have to match, but should be set according to your environment.

For best performance, the size of the send and receive buffers should be set large enough to hold all the data that may be sent concurrently on the network connection. For optimal network performance, these buffers should be set to at least the bandwidth-delay product.

Use these parameters with caution as they affect network and system performance. The default values for these parameters are operating system specific. The following are the defaults for the Linux operating system:

- SEND BUF SIZE: 131,072 bytes (128k)
- RECV BUF SIZE: 174,700 bytes

These parameters are supported for TCP, TCP/IP with TLS, and SDPs. Additional protocols may support these parameters on certain operating systems. The recommended values for these parameters are specified in the installation guide. Refer to operating system specific documentation for additional information.

Note:

- The actual value of the SEND_BUF_SIZE and RECV_BUF_SIZE parameters may be less than the value specified because of limitations in the host operating system or due to memory constraints.
- It is important to consider the total number of concurrent connections that your system must support and the available memory resources. The total amount of memory consumed by these connections depends on the number of concurrent connections and the size of their respective buffers.

- Configuring I/O Buffer Size on the Server
- Configuring I/O Buffer Space on the Client

Related Topics

Oracle Call Interface Developer's Guide

14.4.1 Configuring I/O Buffer Size on the Server

Because the database server writes data to clients, setting the SEND_BUF_SIZE parameter on the server-side is typically adequate. If the database server is receiving large requests, then also set the RECV_BUF_SIZE parameter. To configure the database server, set the buffer space size in the listener.ora and sqlnet.ora files.

In the listener.ora file, specify the buffer space parameters for a particular protocol address or for a description. The following is an example of the settings:

```
LISTENER=
(DESCRIPTION=
(ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521)
(SEND_BUF_SIZE=11784)
(RECV_BUF_SIZE=11784))
(ADDRESS=(PROTOCOL=ipc) (KEY=extproc)
(SEND_BUF_SIZE=11784)
(RECV_BUF_SIZE=11784)))
LISTENER2=
(DESCRIPTION=
(SEND_BUF_SIZE=8192)
(RECV_BUF_SIZE=16384)
(ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521)))
```

Although the preceding example has multiple addresses, the <code>ADDRESS_LIST</code> parameter was not used. This is because the <code>ADDRESS_LIST</code> parameter is not mandatory.

The following is an example of the settings in the sqlnet.ora file:

```
RECV_BUF_SIZE=65536
SEND_BUF_SIZE=65536
```

Setting the Buffer Size Parameter for Shared Server Processes

14.4.1.1 Setting the Buffer Size Parameter for Shared Server Processes

If using shared server processes, then you can override the current settings obtained from the server sqlnet.ora file by setting the buffer space parameters in the DISPATCHERS initialization parameter as follows:

```
DISPATCHERS="(ADDRESS=(PROTOCOL=tcp)(SEND BUF SIZE=65536))"
```

14.4.2 Configuring I/O Buffer Space on the Client

To configure the client, set the buffer space size in the following locations in the specified file:

 Setting only the RECV_BUF_SIZE parameter is typically adequate. If the client is sending large requests, then also set the SEND_BUF_SIZE parameter. These parameters are set in the client's sqlnet.ora file. • For a particular connect descriptor, you can override the current settings in the client sqlnet.ora file. You can specify the buffer space parameters for a particular protocol address or description in the tnsnames.ora file similar to the following:

```
sales.us.example.com=
 (DESCRIPTION=
   (ADDRESS LIST=
     (ADDRESS=(PROTOCOL=tcp) (HOST=sales1-server) (PORT=1521)
        (SEND BUF SIZE=11784)
        (RECV BUF SIZE=11784))
     (ADDRESS=(PROTOCOL=tcp) (HOST=sales2-server) (PORT=1521)
        (SEND BUF SIZE=11784)
        (RECV BUF SIZE=11784))
   (CONNECT DATA=
     (SERVICE NAME=sales.us.example.com)))
hr.us.example.com=
 (DESCRIPTION=
   (SEND BUF SIZE=8192)
   (RECV BUF SIZE=8192)
     (ADDRESS=(PROTOCOL=tcp)(HOST=hr1-server)(PORT=1521))
   (CONNECT DATA=
     (SERVICE NAME=hr.us.example.com)))
```

14.5 Configuring SDP Support for InfiniBand Connections

Oracle Net Services provides support for the Sockets Direct Protocol (SDP) for InfiniBand highspeed networks. These sections describe how to set up Oracle Net support of SDP for middle tier and database server communication.

SDP is a standard communication protocol for clustered server environments. SDP is an interface between a network interface card and the application. By using SDP, applications place most of the messaging burden upon the network interface card, freeing the CPU for other tasks. As a result, SDP decreases network latency and CPU utilization.

SDP is designed specifically for System Area Networks (SANs). A SAN is characterized by short-distance, high-performance communications between multiple server systems, such as Oracle WebLogic Server or any other third-party middle-tier client and database servers clustered on one switch.

Note:

Check with your individual vendor for their version compatibility with Oracle Database 23ai.

Visit the Oracle Technology Network for additional information about SDP support at:

http://www.oracle.com/technetwork/index.html

Understanding Performance

14.5.1 Prerequisites for Using SDP

Prior to configuring support for SDP, install the required hardware, and set up InfiniBand hardware and software compatible with OpenFabrics Enterprise Distribution (OFED) 1.4 or 1.5 from a designated vendor on both the application web server and database server.

During installation of the InfiniBand software, identify the constant that defines SDP or the address family for the system. This can be obtained from the operating system or OFED documentation.

Vendor documentation for installation information

14.5.2 Configuring SDP on the Server

To configure the database server, configure an SDP address in the listener.ora file on the database server.

If the SDP or address protocol family constant is not 27, the default value for Oracle Net Services, then define the constant in the SDP.PF_INET_SDP parameter in the sqlnet.ora file.

The following example shows an SDP endpoint that uses port number 1521 on the computer sales-server.

LISTENER=

"Creating a List of Listener Protocol Addresses"

14.5.3 Configuring SDP on the Client

Learn how to configure the Oracle WebLogic Server servers or third-party middle-tier client.

If the SDP or address protocol family constant is not 27, the default value for Oracle Net Services, then define the constant in the $SDP.PF_INET_SDP$ parameter in the sqlnet.ora file.

- 1. If configuring third-party middle-tier client, then upgrade the clients to use Oracle Database 23ai client software, as follows:
 - a. Run Oracle Universal Installer.
 - b. Select Oracle Database 23ai Client from the Available Products page.
- For both Oracle WebLogic Server servers and third-party middle-tier client, create a network service name to connect to the database server, as follows:
 - For Oracle WebLogic Server servers, specify a network service name that uses the same TCP/IP protocol address configured in the tnsnames.ora file. For example:

 For third-party middle-tier clients, specify a network service name that uses the same SDP address configured in the tnsnames.ora file.

14.6 Configuring Exadirect Support for InfiniBand Connections

Oracle Net Services provides support for the Exadirect for InfiniBand high-speed networks.. Use the new transport to improve latency and throughput by leveraging Remote Direct Memory Access (RDMA) in an InfiniBand environment

Exadirect protocol uses TCP for control communication and IB RC transport for data. The Exadirect protocol adapter is supported only on Oracle Linux in this release.

Exadirect does not support DRCP.

The following sections describe how to set up Oracle Net support of Exadirect for middle tier and database server communication.

- Prerequisites for Using Exadirect
- Configuring Exadirect on the Server

 To configure the database server configure an Evadirect address.

To configure the database server, configure an Exadirect address in the listener.ora file on the database server.

Configuring Exadirect on the Client
 Specify a network service name that uses the same Exadirect address that is configured in
 the tnsnames.ora file.

14.6.1 Prerequisites for Using Exadirect

Exadirect can be used as a transport protocol between Exadata nodes. The Exadata version must be 12.1.2.3.3 or higher for Exadirect to work.

14.6.2 Configuring Exadirect on the Server

To configure the database server, configure an Exadirect address in the listener.ora file on the database server.

Configure <code>enable_exadirect_listener_name=on</code> parameter in <code>listener.ora</code> file. The following example shows an Exadirect endpoint that uses port number <code>1522</code> on the computer having IB interface as <code>192.168.10.1</code>.

```
LISTENER

=
(DESCRIPTION=
(ADDRESS_LIST=
(ADDRESS=(PROTOCOL=exadirect) (HOST=192.168.10.1) (PORT=1522))
(ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
(ADDRESS=(PROTOCOL=ipc) (KEY=extproc))))

ENABLE EXADIRECT LISTENER=on
```

Note:

To enable Exadirect flow control, set <code>exadirect_flow_control=on</code> in <code>sqlnet.ora</code> file. This is a negotiated parameter and should be set in both the server and the client <code>sqlnet.ora</code> file. <code>EXADIRECT_RECVPOLL</code> parameter specifies the time that a receiver polls for incoming data. Exadirect adapter uses <code>HugePages</code>.

14.6.3 Configuring Exadirect on the Client

Specify a network service name that uses the same Exadirect address that is configured in the tnsnames.ora file.

Enable Exadirect flow control by setting exadirect flow control=on in sqlnet.ora file.

```
(DESCRIPTION=
(ADDRESS=(PROTOCOL=exadirect)(HOST=192.168.10.1)(port=1522))
```

(CONNECT_DATA=
(SERVICE NAME=sales.us.example.com)))

14.7 Limiting Resource Consumption by Unauthorized Users

Unauthorized access to the listener or database server can result in denial-of-service attacks, whereby an unauthorized client attempts to block authorized users' ability to access and use the system when needed. Malicious clients may attempt to flood the listener or database server with connect requests that have the sole purpose of consuming resources, such as connections, processes, or threads. To mitigate these types of attacks, configure limits that constrain the time in which resources can be held prior to authentication. Client attempts to exceed the configured limits result in connection terminations and an audit trail containing the IP address of the client being logged.

To limit the resource consumption by unauthorized users and enable the audit trail, set timelimit values for the parameters described in the following table. These parameters do not have default values.

Table 14-1 Connect-Timeout Parameters

Parameter	File	Description
INBOUND_CONNECT_TIMEOUTlistener_name	listener.ora	The time, in seconds, for the client to complete its connect request to the listener after the network connection had been established.
		If the listener does not receive the client request in the time specified, then it terminates the connection. In addition, the listener logs the IP address of the client and an ORA-12525: Listener has not received client's request in time allowed error message to the listener.log file.
SQLNET.INBOUND_CONNECT_ TIMEOUT	sqlnet.ora on the database server	The time, in seconds, for a client to connect with the database server and provide the necessary authentication information. If the client fails to establish a connection and complete authentication in the time specified, then the database server terminates the connection. The database server logs the IP address of the client and an ORA-12170 error message to the database alert log file.
		The client receives either an ORA-12547: TNS:lost contact, or an ORA-12637: Packet receive failed error message.

When specifying values for these parameters, consider the following recommendations:

- Set both parameters to an initial low value.
- Set the value of the INBOUND_CONNECT_TIMEOUT_listener_name parameter to a lower value than the SQLNET.INBOUND CONNECT TIMEOUT parameter.

For example, you can set <code>INBOUND_CONNECT_TIMEOUT_listener_name</code> to 2 seconds and <code>INBOUND_CONNECT_TIMEOUT</code> parameter to 3 seconds. If clients are unable to complete connections within the specified time due to system or network delays that are normal for the particular environment, then increment the time as needed.

Related Topics

Analyzing Listener Logs

The listener log file records information about audit trails, service registration-related events, direct hand-off events, subscriptions for Oracle Notification Service (ONS) nodedown events, and Oracle Clusterware notifications.

Resolving the Most Common Error Messages for Oracle Net Services
 Due to the complexity of network communications, network errors may originate from a
 variety of sources, for a variety of reasons. If an error occurs, then applications such as
 SQL*Plus, that depend on network services from Oracle Net Services, normally generate
 an error message.

14.8 Configuring Key-Based Routing for Client-Server Connections

Learn how to establish client-server connections in a sharded database by using key-based (or direct) routing. In key-based routing to a shard, a connection is established to a single, relevant shard that contains the data pertinent to the required transaction using a sharding key.

- About Key-Based Routing
 With key-based or direct routing, a database connection is established directly from the
 client to a shard according to the value of the sharding key specified in the connect string.
- Specifying a Sharding Key in the Connect String
 You can directly connect to shards by specifying a sharding key in the CONNECT_DATA
 section of a connect string or tnsnames.ora file. You can also specify shard directors (as
 endpoints), global service name, and region name for your Oracle Globally Distributed
 Database deployment.

14.8.1 About Key-Based Routing

With key-based or direct routing, a database connection is established directly from the client to a shard according to the value of the sharding key specified in the connect string.

Oracle Globally Distributed Database enables you to horizontally partition data across multiple, independent Oracle databases. Each physical database in such a configuration is called a shard. Sharded table partitions are distributed across shards at the tablespace level, based on a sharding key. Examples of keys include customer ID, account number, and country ID.

A shard director is a specific implementation of a Global Service Manager (GSM) that acts as a regional listener for clients that connect to a sharded database. Based on the sharding key passed during a connection request, the shard director establishes a connection to an appropriate shard as follows:

- The shard director performs a lookup for the service and key value, and then redirects the client to a shard containing the data.
- The client runs a SQL statement and receives results directly from the shard.

Direct routing assumes that all the database requests that are issued within a connection are related to the data associated with the specified key value. If a client needs to access data with a different key value, then it must establish a new database connection.

The connect string contains a single sharding key if an Oracle Database is sharded by consistent hash, list, or range. Oracle Database also supports composite sharding that enables two levels of sharding. First the data is sharded by list or range and then it is further sharded by consistent hash. In composite sharding method, the connect string contains both a sharding key (for sharding by consistent hash) and a super sharding key (for sharding by list or range).

14.8.2 Specifying a Sharding Key in the Connect String

You can directly connect to shards by specifying a sharding key in the <code>CONNECT_DATA</code> section of a connect string or <code>tnsnames.ora</code> file. You can also specify shard directors (as endpoints), global service name, and region name for your Oracle Globally Distributed Database deployment.

Specify a shard (partition) key value using one of the following parameters:

- SHARDING KEY: To specify a sharding key for a particular shard in simplified text format.
- SHARDING_KEY_ID: To specify the unique SHA-256 ID of a sharding key in simplified text
 format. This allows clients that have already calculated the SHA-256 hash value of a
 sharding key to pass it directly in the connect string. You use this parameter for directorybased sharding.
- SUPER_SHARDING_KEY: To specify a shardspace key for a collection of shards in simplified text format.
- SHARDING_KEY_B64: To specify a sharding key for a particular shard in base64-encoded binary format.
- SUPER_SHARDING_KEY_B64: To specify a shardspace key for a collection of shards in base64-encoded binary format.

The connect string must be in the format required to connect to a global service.

```

14.9 Configuring SNI for TLS connections

Oracle Net Services supports Server Name Indication (SNI) in order to minimize the time taken to establish client-server connection. When SNI is set, the listener forwards the connection request from client to an appropriate server without performing a TLS handshake, thereby reducing the overall connection establishment time.

Client can use Server Name Indication (SNI) which is a TLS extension to send the relevant CONNECT_DATA information such as the SERVICE_NAME to listener. The listener then obtains the requested connect data from SNI field of the first packet and forwards the connection request to an appropriate service handler to service the request without doing a TLS handshake with the client. The client then performs a full TLS handshake with the server and establishes the connection directly.

This optimization saves one TLS handshake between the client and the listener which otherwise involves 1-RTT data transfer and certain amount of processing, hence minimizing the overall time taken to establish connection with the server.

You can enable SNI in the client by setting the <code>USE_SNI</code> parameter in sqlnet.ora. When SNI is enabled, the <code>CONNECT_DATA</code> parameter in the client's connect string can be used to set the SNI value. The list of supported <code>CONNECT_DATA</code> parameters for setting the connection's SNI value include:

- SERVICE NAME
- INSTANCE NAME
- SERVER
- COLOCATION TAG

If client's connect string has any of these parameters as part of <code>CONNECT_DATA</code>, then those parameters are used to set the SNI value. If none of the parameters from the supported list are part of <code>CONNECT_DATA</code>, then SNI value will not be set for the connection and the listener will perform the usual TLS handshake with the client to get the connect request.

SNI is enabled by default in listener and Oracle Connection Manager (CMAN). Hence, you need not set USE_SNI parameter explicitly in listener.ora or cman.ora. In case you set the

 ${\tt USE_SNI}$ parameter explicitly in cman.ora, then the gateway process will also set the SNI value in outgoing connection.

Under certain cases where additional security of DN matching is required or configured in CMAN, SNI will be disabled and CMAN's listener will follow the usual process of performing TLS handshake with the client.

Support for SNI is available in all versions starting 23.7, but not in earlier versions.

Oracle Database Net Services Reference

Part III

Testing and Troubleshooting Oracle Net Services

Part III describes how to establish connections, and identify and diagnose problems with Oracle Net Services.

- Testing Connections
- Troubleshooting Oracle Net Services

Oracle Net Services provides methods for understanding, testing and resolving network problems. Oracle Database includes utilities, and log and trace files for testing and diagnosing network connection and problems.

Testing Connections

After you have configured the network, you should connect and test each component to ensure that the network is functioning properly. Oracle Net Services provides tools to help you test the listener, database, and Oracle Connection Manager.

- Testing the Network
 - This is the recommended sequence for testing the network.
- Using the TNSPING Utility to Test Connectivity from the Client
 The TNSPING utility determines whether the listener for a service on an Oracle Net network
 can be reached successfully.
- Using the TRCROUTE Utility to Test Connectivity from the Client
 The Trace Route Utility (TRCROUTE), in Linux and UNIX environments, enables
 administrators to discover the path or route that a connection takes from the client to the
 server.

15.1 Testing the Network

This is the recommended sequence for testing the network.

 Start and test each listener. To start the listener, use the procedure described in Starting Oracle Net Listener and the Oracle Database Server.

To test a listener, initiate a connection from a client to any active database controlled by that listener.

2. Start and test each Oracle Connection Manager, if included in your network. To start Oracle Connection Manager, use the procedure described in Starting Oracle Connection Manager.

To test Oracle Connection Manager, initiate a connection from a client to any active database that has been registered with Oracle Connection Manager.

3. Test the server with a loopback test or Oracle Net Manager.

A loopback test uses Oracle Net to go from the database server back to itself, bypassing the Interprocess Communication (IPC). Performing a successful loopback verifies that Oracle Net is functioning on the database server. The following procedure describes how to perform a loopback test using Oracle Net Manager:

a. Start Oracle Net Manager.

Using Oracle Net Manager to Configure Oracle Net Services

- b. In the navigator, expand **Directory** or **Local**, and then select **Service Naming**.
- Select the network service name or database service.
- Choose Command, and then select Test Net Service.

Testing assumes the listener and database are running. If they are not, then see Starting Oracle Net Listener and the Oracle Database Server to start components.

During testing, a Connection Test dialog box appears, providing status and test results. A successful test results in the following message:

```
The connection test was successful.
```

If the test was successful, then proceed to step 3.e.

If the test was not successful, then use the error message to determine further action. For example, if the error message is the following:

```
Attempting to connect using userid: scott
The test did not succeed.
ORA-28000: the account is locked
There may be an error in the fields entered,
or the server may not be ready for a connection.
```

Change the user name to an account known to be unlocked. To change the user name, click **Change Login**. You are prompted for the password.

- e. Click Close to close the Connect Test dialog box.
- 4. Test client with a connection.

To test several different clients in your network, initiate a connection to a database server from each of them using the following command:

```
CONNECT username@connect identifier
```

15.2 Using the TNSPING Utility to Test Connectivity from the Client

The TNSPING utility determines whether the listener for a service on an Oracle Net network can be reached successfully.

If you can connect successfully from a client to a server (or a server to another server) using the ${\tt TNSPING}$ utility, then it displays an estimate of the round trip time (in milliseconds) it takes to establish a ${\tt SQLNET}$ connection to the Oracle listener corresponding to the server.

If it fails, then it displays a message describing the error that occurred. This enables you to see the network error that is occurring without the overhead of a database connection.

Use the following command to test connectivity:

```
tnsping net service name count
```

In the preceding command, the following arguments are used:

- net_service_name must exist in tnsnames.ora file or the name service in use, such as NIS.
- *count* determines how many times the program attempts to reach the server. This argument is optional.

If the network service name specified is a database name, then TNSPING attempts to contact the corresponding listener. It does not actually determine whether the database is running. Use SQL*Plus to attempt a connection to the database.

The following are some examples of TNSPING.

Different platforms may have different interfaces, but the program accepts the same arguments. Invoke TNSPING for the display of the proper interface requirements.

Example 15-1 is an example of checking a listener for a database using a network service name of sales using the TNSPING command.

Example 15-1 Checking a Listener with TNSPING

TNSPING sales

This produces the following message:

```
TNS Ping Utility for Linux: Version 23.4.0.0.0 - Production on 21-MAR-2024

Copyright (c) 1997, 2024 Oracle Corporation. All rights reserved.

Used parameter files:

Used TNSNAMES adapter to resolve the alias

Attempting to contact (DESCRIPTION = (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP) (HOST = sales-server) (PORT = 1521))) (CONNECT_DATA = (SERVICE_NAME = sales.us.example.com)))

OK (10 msec)
```

To determine whether the listener for the sales database is available, and to specify that TNSPING try to connect eight times and then give up, use the following syntax:

```
tnsping sales 8
```

This command produces the following message:

```
TNS Ping Utility for Linux: Version 23.4.0.0.0 - Production on 21-MAR-2024

Copyright (c) 1997, 2024 Oracle Corporation. All rights reserved.

Used parameter files:

Used TNSNAMES adapter to resolve the alias

Attempting to contact (DESCRIPTION = (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP) (HOST = sales-server) (PORT = 1521))) (CONNECT_DATA = (SERVICE_NAME = sales.us.example.com)))

OK (10 msec)

OK (0 msec)

OK (10 msec)
```

Example 15-2 is an example of TNSPING attempting to check using an invalid network service name.

Example 15-2 Checking an Invalid Net Service Name with TNSPING

tnsping badname

This attempt produces the following message:

```
TNS Ping Utility for Linux: Version 23.4.0.0.0 - Production on 21-MAR-2024 Copyright (c) 1997, 2024 Oracle Corporation. All rights reserved.

Used parameter files:

TNS-03505: Failed to resolve name
```

Example 15-3 is an example of output when using TNSPING to check a name that is valid, but resolves to an address where no listener is located, for example, the listener may not be started.

Example 15-3 Checking Valid Net Service Name but No Listener with TNSPING

```
tnsping sales
TNS Ping Utility for Linux: Version 23.4.0.0.0 - Production on 21-MAR-2024
Copyright (c) 1997, 2024 Oracle Corporation. All rights reserved.
Used parameter files:
Used TNSNAMES adapter to resolve the alias
Attempting to contact (DESCRIPTION = (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP) (HOST = 10.9.7.5) (PORT = 1521))) (CONNECT_DATA = (SERVICE_NAME = sales.us.example.com)))
TNS-12541: TNS:Cannot connect. No Listener at host 10.9.7.5 port 1521
```

15.3 Using the TRCROUTE Utility to Test Connectivity from the Client

The Trace Route Utility (TRCROUTE), in Linux and UNIX environments, enables administrators to discover the path or route that a connection takes from the client to the server.

If TRCROUTE encounters a problem, then it returns an error stack to the client instead of a single error. These additional error messages make troubleshooting easier.

TRCROUTE is different from TNSPING in that it travels as a special type of connect packet, and is routed as such. As it travels toward its destination, the TRCROUTE connect packet collects the TNS addresses of every node it travels through. If an error occurs, then TRCROUTE collects error information that shows where the error occurred. The TRCROUTE displays the information collected on the client screen. You can redirect the TRCROUTE output to a file, and print it.

The TRCROUTE uses minimal resources. It gathers information in the connect data of a special connect packet. Standard connect packets are not affected.

The server is not affected by TRCROUTE. The listener receives and processes the TRCROUTE connect packet. It returns the information to the client by putting it into a refuse packet. The server does not need to start any new processes or deal with dummy connections.

To use the TRCROUTE utility, enter the following command:

```
trcroute net_service_name
```

Example 15-4 shows a successful trace route packet that traveled from a client to a listener.

Example 15-4 Successful Trace Route

Example 15-5 shows an unsuccessful trace route packet that could not reach the listener because the listener was not up.

Example 15-5 Trace Route with Error

Troubleshooting Oracle Net Services

Oracle Net Services provides methods for understanding, testing and resolving network problems. Oracle Database includes utilities, and log and trace files for testing and diagnosing network connection and problems.

The TNSPING and TRCROUTE utilities test connectivity. The log and trace files keep track of the interaction between network components as errors occur. Evaluating this information helps to diagnose and troubleshoot network problems.

Understand the common testing procedures and network errors, and outline procedures for resolving problems. Also, learn methods for logging and tracing error information to diagnose and troubleshoot more complex network problems.

- Understanding Automatic Diagnostic Repository
 The Automatic Diagnostic Repository (ADR) (ADR) is a system-wide tracing and logging central repository.
- Diagnosing Oracle Net Services
 Any underlying fault, noticeable or not, is reported by Oracle Net Services with an error number or message. The error number and message provide useful information for diagnosing the problem, but may not always identify the actual problem.
- Resolving the Most Common Error Messages for Oracle Net Services
 Due to the complexity of network communications, network errors may originate from a
 variety of sources, for a variety of reasons. If an error occurs, then applications such as
 SQL*Plus, that depend on network services from Oracle Net Services, normally generate
 an error message.
- Troubleshooting Suggestions for Oracle Net Services
 These are the suggestions for diagnosing network problems and troubleshooting Oracle Connection Manager in Traffic Director Mode.
- Example of Troubleshooting a TNS-12154 Error

 This section offers some solutions for the TNS-12154 error. The TNS-12154 error is
 encountered when SQL*Net cannot find the connect identifier specified for a connection in
 the tnsnames.ora file or other naming adapter.
- Logging Error Information for Oracle Net Services
 All errors encountered by Oracle Net Services are appended to a log file for evaluation by
 a network or database administrator. The log file provides additional information for an
 administrator about on-screen error messages. The error stack in the log file shows the
 state of the software at various layers.
- Tracing Error Information for Oracle Net Services
 Tracing produces a detailed sequence of statements that describe network events as they are run. Tracing an operation enables you to obtain more information about the internal operations of the components of Oracle Net Services than is provided in a log file.
- Contacting Oracle Support Services
 Some messages recommend contacting Oracle Support Services to report a problem.
 When you contact Oracle Support Services, have this information available.

16.1 Understanding Automatic Diagnostic Repository

The Automatic Diagnostic Repository (ADR) (ADR) is a system-wide tracing and logging central repository.

The repository is a file-based hierarchical data store for depositing diagnostic information, including network tracing and logging information.

The ADR home is the unit of the ADR directory that is assigned to an instance of an Oracle product. Each database instance has its own ADR home. Similarly, each listener, Oracle Connection Manager, and client instance has its own ADR home.

In case of a process failure, an incident is generated. The incident dump files are located in the ADR_BASE/ADR_HOME/incident/ directory, By default, ADR_BASE is ORACLE_BASE if the ORACLE_BASE variable is set. If the variable is not set, then ADR_BASE is ORACLE_HOME/log. ADR BASE can be set to any location.

The incident dump file location can be found inside the process trace file.

The location of an ADR home is given by the following path, which starts at the ADR base directory:

diag/product type/product id/instance id

The following table lists the values of the path components for an Oracle Net Listener instance.

Table 16-1 ADR Home Path Components for an Oracle Net Listener Instance

Path Component	Value for Oracle Net Listener
product_type	tnslsnr
product_id	host name
instance_id	listener alias name

The following figure illustrates the directory hierarchy of the ADR for an Oracle Net Listener instance. Other ADR homes for other Oracle products or components, such as Automatic Storage Management (ASM) or Oracle Database, can exist within this hierarchy, under the same ADR base.

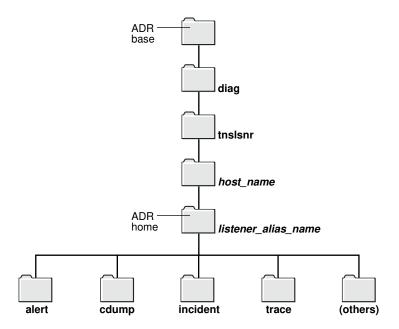

Figure 16-1 Directory Structure for an Oracle Net Listener Instance

The following table lists the values of the path components for an Oracle Connection Manager instance.

Table 16-2 ADR Home Path Components for an Oracle Connection Manager Instance

Path Component	Value for Oracle Connection Manager
product_type	netcman
product_id	host name
instance_id	Oracle Connection Manager instance name

The following figure illustrates the directory hierarchy of the ADR for an Oracle Connection Manager instance. Other ADR homes for other Oracle products or components, such as Oracle ASM or Oracle Database, can exist within this hierarchy, under the same ADR base.

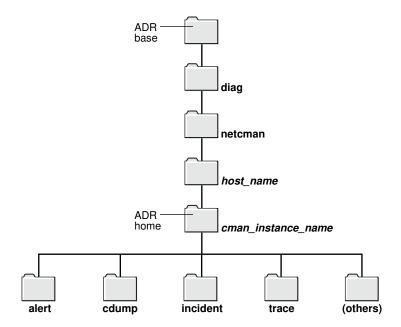

Figure 16-2 Directory Structure for an Oracle Connection Manager Instance

Within the ADR home directory are subdirectories where each instance, such as the database, listener, Oracle Connection Manager, or client, stores diagnostic data. The following table lists all the subdirectories shown in the preceding figure and their contents.

Table 16-3 ADR Home Subdirectories

Subdirectory Name	Contents
alert	The XML-formatted log named log.xml.
cdump	Core files.
incident	Multiple subdirectories, in which each subdirectory is named for a particular incident, and each contains dumps pertaining only to that incident.
trace	Background and server process trace files, SQL trace files, and text version of the log.xml file in the alert directory.
(others)	Other subdirectories of ADR home, which store incident packages, health monitor reports, and other information.

The ADR_BASE directory is the physical location in which one or more ADR homes are placed. Conceptually, it is the root directory of ADR.

Non-ADR (meaning that the <code>DIAG_ADR_ENABLED</code> parameter is set to <code>OFF</code>) diagnostic and tracing methods are still current and applicable but the parameters are ignored if ADR is enabled. ADR is enabled by default.

Diagnostic parameters are found in the following configuration files:

- sqlnet.ora for clients
- listener.ora for listeners
- cman.ora for Oracle Connection Managers

The following table compares usage of diagnostic parameters found in the sqlnet.ora file, which is used in both ADR-based and non-ADR-based diagnostics.

Table 16-4 sqlnet.ora File Diagnostic Parameter Comparison

Parameter	DIAG_ADR_ENABLE D=ON	DIAG_ADR_ENABLE D=OFF
ADR_BASE	Enabled	Disabled
ENABLE_CONCISE_LOGS	Enabled	Enabled
LOG_SUPPRESSED_COUNT	Enabled	Enabled
LOG_SUPPRESSED_TIME	Enabled	Enabled

TRACE_TIMESTAMP_listener_name	Enabled	Enabled
LOG_DIRECTORY_CLIENT_listener_name	Disabled	Enabled
LOG_FILE_CLIENT_listener_name	Disabled	Enabled
TRACE_DIRECTORY_CLIENT_listener_name	Disabled	Enabled
TRACE_FILELEN_listener_name	Disabled	Enabled
TRACE_FILENO_listener_name	Disabled	Enabled

The following table compares usage of diagnostic parameters found in the cman.ora file, which is used in both ADR-based and non-ADR-based diagnostics.

Parameter	DIAG_ADR_ENABLE D=ON	DIAG_ADR_ENABLE D=OFF
ADR_BASE	Enabled	Disabled
LOG_LEVEL	Enabled	Enabled
TRACE_LEVEL	Enabled	Enabled
TRACE_TIMESTAMP	Enabled	Enabled
LOG_DIRECTORY	Disabled	Enabled
TRACE_DIRECTORY	Disabled	Enabled
TRACE_FILELEN	Disabled	Enabled
TRACE_FILENO	Disabled	Enabled

Table 16-6 cman.ora File Diagnostic Parameter Comparison

- For additional information about the location of the client ADR Home, see Oracle Call Interface Programmer's Guide.
- For additional information about ADR, see Oracle Database Administrator's Guide.
- For descriptions of the diagnostic parameters, see Oracle Database Net Services Reference.
- ADRCI: ADR Command Interpreter

16.1.1 ADRCI: ADR Command Interpreter

ADRCI is a command-line tool that is part of the fault diagnosability infrastructure. ADRCI enables you to do the following:

- View diagnostic data within ADR
- Package incident and problem information into a zip file for transmission to Oracle Support Services

Diagnostic data includes incident and problem descriptions, trace files, dumps, health monitor reports, alert log entries, and so on.

ADRCI has a rich command set, and can be used in interactive mode or within scripts. In addition, ADRCI can run scripts of ADRCI commands in the same way that SQL*Plus runs scripts with SQL and PL/SQL commands.

To view trace files using ADRCI, enter ADRCI at a command line. The following are common ADRCI commands used to check a client:

Client Side

```
adrci> SHOW ALERT
adrci> SHOW BASE -product client
adrci> SET BASE -product client
adrci> SHOW TRACEFILE
adrci> SHOW TRACE trace_file.trc
adrci> SHOW SPOOL
```

In the preceding commands, the SHOW ALERT command shows the log.xml file in a text editor, such as VI. The SHOW BASE -product client command displays the value of the ADR_BASE directory for the client. Use that value for *client* in the SET BASE command.

The following are common ADRCI commands used to check a server:

Server Side

```
adrci> SHOW BASE
adrci> SHOW TRACEFILE
adrci> SHOW TRACE trace file.trc
```

Other ADRCI command options are available for a more targeted Oracle Net trace file analysis. Type HELP at the ADRCI prompt for help documentation.

Oracle Database Utilities for additional information about ADRCI

16.2 Diagnosing Oracle Net Services

Any underlying fault, noticeable or not, is reported by Oracle Net Services with an error number or message. The error number and message provide useful information for diagnosing the problem, but may not always identify the actual problem.

This section helps you determine the parts of Oracle Net Services that function properly. You can also determine one of the following categories to which the fault belongs:

- Oracle software
- Operating system layer
- Other network layers

Testing the various network layers progressively should, in most cases, uncover any problem.

Starting with Oracle Database 21c, a connection identifier is available for each network connection. The connection identifier uniquely identifies a connection in trace and logs of different network elements and helps in correlating diagnostic data from these elements.

When a SQL*Net connection has multiple hops, such as from a client to Oracle Connection Manager (CMAN) and then to a server, correlating diagnostic information from the existing logs and traces becomes difficult. However, with the availability of a connection identifier, you can correlate diagnostics, track network data traffic, and resolve connectivity errors.

The connection identifier consists of two components, namely, <code>connection_id</code> and <code>connection_id_prefix</code>. The <code>connection_id</code> parameter contains a unique value, which is generated when the connection originates at the client. The <code>connection_id_prefix</code> is an application specific prefix parameter that is added to the connection identifier.

- Diagnosing Server Problems
- Diagnosing Client Problems

16.2.1 Diagnosing Server Problems

To start diagnosing server problems, you should answer the following questions:

 Is any other system such as a workstation or server able to connect to the server using Oracle Net? Has the server, database, or listener configuration remained the same for some time?

If you answered yes to either of the preceding questions, then go to "Diagnosing Client Problems".

If you are unsure, or answered no to any of the preceding questions, then use the tasks in this section to diagnose the problem. Diagnosing Oracle Net Services on the server involves the following tasks:

- Task 1, Verify the Database is Running
- Task 2, Perform a Loopback Test

Task 1 Verify the Database is Running

To check that the database is up, log in to the database and connect with a valid username and password. For example:

```
SQLPLUS system
Enter password: password
```

A message appears, confirming that you are connected with the database. If you receive the following errors, then ask the database administrator to assist you:

- ORA-1017: invalid U/P
- ORA-1034: Oracle not available

Task 2 Perform a Loopback Test

A loopback test uses Oracle Net to go from the database server back to itself, bypassing the Interprocess Communication (IPC) protocol. Many network protocols provide a means of testing network connections. The PING utility can be used with a TCP/IP network. Performing a successful loopback verifies that Oracle Net is functioning on the database server. The following procedure describes how to perform a loopback test from the server to the database:

- 1. Ensure that the listener.ora, thshames.ora, and sqlnet.ora files exist in the correct locations, as described in "Using Localized Management".
- Start Oracle Net Manager.

"Using Oracle Net Manager to Configure Oracle Net Services"

- 3. In the navigator, expand the **Directory** or **Local** option.
- 4. Expand **Service Naming** to view the available network service and database names.
- Select the network service name or database service.
- **6.** Choose **Command**, and then select **Test Net Service**.

Testing assumes the listener and database are running. If they are not, then see "Starting Oracle Net Listener and the Oracle Database Server" to start components.

During testing, a Connection Test dialog box appears, providing status and test results. A successful test results in the following message:

The connection test was successful.

If the test was successful, then proceed to step 7.

If the test was not successful, then do the following:

- a. Ensure the database and listener are running, and then click **Test**.
- Click Change Login to change the username and password for the connection, and then click Test.
- If the loopback test passes, then go to "Diagnosing Client Problems".
- If the loopback test continues to fail, then contact Oracle Support Services.
- Click Close to close the Connect Test dialog box.

16.2.2 Diagnosing Client Problems

Verify at least one of the following statements. This will help you decide if it is a client problem.

- The database server passed a loopback test, showing the connection worked.
- Other computers connect using Oracle Net Services to the same database.
- Connections from this workstation worked before making changes on this computer, such as the installation of a new product or modification to the network configuration.

The following procedure describes how to perform diagnostics on the client:

 Check that you have installed the same protocol support that was installed on the database server.

On Linux and UNIX platforms you can use the ADAPTERS utility to verify protocol support. On the database server, run the following command from the <code>ORACLE_HOME/bin</code> directory to display the protocol support, naming methods, and security options linked with the <code>oracle</code> executable:

```
adapters ./oracle
```

The adapters utility displays output similar to the following:

```
Installed Oracle Net transport protocols are:
    TPC
    BEQ
   TCP/IP
    SSL
    RAW
    SDP/IB
Installed Oracle Net naming methods are:
    Local Naming (tnsnames.ora)
   Oracle Directory Naming
   Oracle Host Naming
   NIS Naming
Installed Oracle Advanced Security options are:
   RC4 40-bit encryption
   RC4 56-bit encryption
   RC4 128-bit encryption
   RC4 256-bit encryption
   DES40 40-bit encryption
    DES 56-bit encryption
    3DES 112-bit encryption
```

```
3DES 168-bit encryption
AES 128-bit encryption
AES 192-bit encryption
AES 256-bit encryption
MD5 crypto-checksumming
SHA crypto-checksumming (for FIPS)
SHA-1 crypto-checksumming
Kerberos v5 authentication
RADIUS authentication
```

Installed Oracle Net transport protocols are:

On the client, run the adapters command from the ORACLE_HOME/bin directory to display the configured Oracle protocol support, naming methods, and security options. The ADAPTERS utility displays output similar to the following:

```
IPC
   BEO
    TCP/IP
    SSL
    RAW
   SDP/IB
   Exadirect
Installed Oracle Net naming methods are:
   Local Naming (tnsnames.ora)
   Oracle Directory Naming
   Oracle Host Naming
Installed Oracle Advanced Security options are:
   RC4 40-bit encryption
   RC4 56-bit encryption
   RC4 128-bit encryption
   RC4 256-bit encryption
   DES40 40-bit encryption
   DES 56-bit encryption
    3DES 112-bit encryption
    3DES 168-bit encryption
   AES 128-bit encryption
   AES 192-bit encryption
   AES 256-bit encryption
   MD5 crypto-checksumming
   SHA-1 crypto-checksumming
   Kerberos v5 authentication
    RADIUS authentication
```

Note:

• The DES, DES40, 3DES 112, 3DES 168, RC4 40, RC4 56, RC4 128, RC4 256, and MD5 algorithms are deprecated in this release.

To transition your Oracle Database environment to use stronger algorithms, download and install the patch described in My Oracle Support note 2118136.2.

RAW is an internal protocol used by Oracle Net.

See Also:

Oracle Database Administrator's Reference for additional information about the adapters utility

2. Check base connectivity for underlying network transport. Oracle Net technology depends on the underlying network for a successful connection.

Table 16-7 Verify Base Connectivity for Network Transport

Protocol	Verify that you can
TCP/IP	Use terminal emulation or file transfer utilities, (PING, FTP, TELNET) from the client to the database server.
Named Pipes	See other computers or servers on the Microsoft network.Ensure that you are able to share drives within the network.

- Ensure that the Oracle Net foundation layer and the appropriate Oracle protocol support are present by verifying that all Oracle Net Services software has been installed for the client.
- 4. Ensure that the client computer has the tnsnames.ora and the sqlnet.ora files in the correct locations.

"Using Localized Management"

If any other working client computers are connecting to the selected Oracle Database, then back up your existing files and copy both the working this names or a and sqlnet ora files from the working client computer to the non-working clients. This eliminates the possibility of errors in the files.

5. Test the Oracle Net foundation layer. You can test using the following command to connect to SQL*Plus:

SQLPLUS user/password@connect_string

Do not use the TNSPING utility. The TNSPING utility works like the TCP/IP ping utility and does not create and open a socket, nor does it connect with the listener. It only shows that the listener is present on the database server.

- 6. If the connection still fails, then do the following:
 - Use tracing, as described in section "Tracing Error Information for Oracle Net Services".
 - Check the Oracle Support Services website for a specific diagnostics bulletin on the error received.
 - c. Contact Oracle Support Services.

16.3 Resolving the Most Common Error Messages for Oracle Net Services

Due to the complexity of network communications, network errors may originate from a variety of sources, for a variety of reasons. If an error occurs, then applications such as SQL*Plus, that depend on network services from Oracle Net Services, normally generate an error message.

For information about the specific error messages, use the Oracle error tool oerr, by entering the following command at any command line:

```
oerr code error number
```

In the preceding command, *code* is the type of message, such as ORA and TNS, and *error number* is the number associated with the error message.

The following is a list of the most common network error messages:

ORA-03113

Indicates that an error has occurred on the database server.

ORA-12154

Indicates that the specified connection alias cannot be resolved.

ORA-12170

Indicates that the connection failed with a timeout, such as Transmission Control Protocol (TCP) connect timeout, Outbound connect timeout, or Receive timeout.

ORA-12241

Appears on Microsoft Windows systems to indicate that a particular service is either not available or not running.

ORA-12261

Indicates that the specified connection alias cannot be resolved due to errors in the Easy Connect syntax.

ORA-12262

Indicates that the specified connection alias cannot be resolved due to invalid host name in the Easy Connect syntax.

ORA-12500

Indicates that the listener failed to start the Oracle program.

ORA-12505

Indicates that the listener cannot identify the system identifier (SID) specified in the connect descriptor.

ORA-12514

Indicates that the listener cannot identify the service requested in the connect descriptor.

ORA-12516

Indicates that the listener is unable to find an available handler with the matching protocol stack.

ORA-12520

Indicates that the listener cannot find an available handler for the requested server type.

ORA-12521

Indicates that the listener cannot identify the instance requested in the connect descriptor.

ORA-12525

Indicates that the client failed to complete its connect request in the time specified by the INBOUND_CONNECT_TIMEOUT_listener_name parameter in the listener.ora file.

ORA-12533

Indicates that the ADDRESS section parameters are incorrect.

ORA-12540 and TNS-00510

Indicate that an internal limit has been exceeded.

ORA-12541

Indicates that the listener cannot be reached.

ORA-12549 and TNS-00519

Indicate that a quota or hard limit imposed by the operating system has been exceeded.

ORA-12560

Indicates that a lower-level communication protocol adapter error has occurred.

Directory Naming Errors

See Also:

Oracle Database Error Messages for a complete listing of error messages

16.3.1 ORA-03113

Indicates that an error has occurred on the database server.

Message

ORA-03113: End-of-file on communication channel

Cause

An unexpected end of file is processed on the communication channel. This may be an indication that the communications link may have gone down at least temporarily, or it may indicate that the server has gone down.

Action

Check the <code>alert_sid.log</code> file on the server. You may need to modify your retransmission count.

16.3.2 ORA-12154

Indicates that the specified connection alias cannot be resolved.

Message

ORA-12154: Cannot connect to database. Could not find alias string in string.

For example:

With the LDAP naming adapter:

```
ORA-12154: Cannot connect to database. Could not find alias sales in LDAP.
```

With the TNSNAMES naming adapter:

• When only one (system or local) tnsnames.ora file is used:

```
ORA-12154: Cannot connect to database.

Could not find alias sales in
/u01/app/oracle/product/21.3.0/dbhome 1/network/admin/tnsnames.ora.
```

When both the system and local tnsnames.ora files are used:

```
ORA-12154: Cannot connect to database. Could not find alias sales in path to file 1, path to file 2.
```

With the TNSNAMES and LDAP naming adapters:

When only one (system or local) tnsnames.ora file is used:

```
ORA-12154: Cannot connect to database.

Could not find alias sales in
/u01/app/oracle/product/21.3.0/dbhome_1/network/admin/tnsnames.ora and
LDAP.
```

When both the system and local tnsnames.ora files are used:

```
ORA-12154: Cannot connect to database.

Could not find alias sales in

path to file 1, path to file 2 and LDAP.
```

Cause

A connection to the database or other service is requested using a connection alias, but the specified alias cannot be resolved into a connect descriptor using one of the configured naming methods. For example, if you have used a network service name as the connect identifier, then the network service name cannot be found in a naming method repository or the repository cannot be located.

By default, the client tries all naming methods in an order: starting with local (TNSNAMES), followed by LDAP, and then Easy Connect Plus. A failure to resolve an alias through all of these naming methods returns in an error.

Action

- Check for mistakes in the specified connection string.
- 2. If your sqlnet.ora file contains the NAMES.DIRECTORY_PATH parameter, then ensure that the parameter contains valid values.
- 3. If you are using an alias from the tnsnames.ora file, then perform these steps:
 - Verify that the tnsnames.ora file exists, is in the correct directory, and is accessible.
 You can find the tnsnames.ora file in any of the following locations:

- The directory specified by the TNS ADMIN environment variable, if it is set.
- The ORACLE_BASE_HOME/network/admin directory. If the file is not present in the
 ORACLE_BASE_HOME/network/admin directory, then look for the file in ORACLE_HOME/
 network/admin directory.
- Ensure that the alias, given in the connect string, exists in one of the tnsnames.ora files.

This network service name should match the name in the tnsnames.ora file exactly if the name is simple and there is not NAMES_DEFAULT_DOMAIN in the sqlnet.ora file, or the network service name is a fully-qualified name. If the network service name in the connect string is simple, then check the NAMES_DEFAULT_DOMAIN parameter in the sqlnet.ora file. Its value is appended to the network service name given in the connect string. This fully-qualified name should be the entry in the tnsnames.ora file.

- Ensure that there are no syntax errors anywhere in the tnsnames.ora files. Look for unmatched parentheses or stray characters. Ensure that magic quotes are not used.
- If you are connecting from a Login dialog box, then verify that you are not placing an at sign (@) before the connect network service name. Activate client tracing, and repeat the operation.
- 4. If you are using LDAP directory naming, then perform these steps:
 - Verify that the net service name or database name used as the connect identifier is configured in the directory.
 - Verify that the LDAP directory server is up and accessible.
 - Verify that the default context used is correct by specifying a fully-qualified net service name or a full LDAP DN as the connect identifier.
 - Verify that the ldap.ora file exists and is in the correct location. The following directories are searched for the ldap.ora file in an order:
 - The directory specified by the TNS ADMIN environment variable.
 - The ORACLE_BASE_HOME/network/admin directory. If the file is not present in the ORACLE_BASE_HOME/network/admin directory, then the file is searched in the ORACLE HOME/network/admin directory.
 - The directory specified by the LDAP ADMIN environment variable.
 - The ORACLE BASE HOME/network/admin directory for a read-only Oracle home.
 - The ORACLE HOME/network/admin directory for a read/write Oracle home.
 - Verify that the parameters defined in the ldap.ora file are correct, as follows:
 - The DIRECTORY_SERVERS parameter defines the correct host and port for one or more valid LDAP servers.
 - The DEFAULT_ADMIN_CONTEXT parameter defines the location of the Oracle Context
 in this directory that should include the network service entry.

If the ldap.ora file does not exist, then these parameters are resolved using automatic discovery.

- Verify that the LDAP server host and port are defined in DNS.
- Verify that the directory has the default Oracle Context defined.

 Use the ldapsearch utility or a directory administration tool to verify that the network service object exists in the Oracle Context at the location given by the value of the DEFAULT_ADMIN_CONTEXT parameter.

16.3.3 ORA-12170

Indicates that the connection failed with a timeout, such as Transmission Control Protocol (TCP) connect timeout, Outbound connect timeout, or Receive timeout.

Message

```
ORA-12170: Cannot connect. string timeout of string for string. (CONNECTION ID=string)
```

For example:

TCP-level connect timeout:

```
ORA-12170: Cannot connect.

TCP connect timeout of 30s for host 10.9.7.5 port 1522.

(CONNECTION ID=1ABcDEabCd1aB+AbCdE1aB==)
```

Outbound connect timeout:

```
ORA-12170: Cannot connect.

Outbound connect timeout of 30s for host 10.9.7.5 port 1522.

(CONNECTION ID=1ABcDEabCdlaB+AbCdElaB==)
```

Receive timeout:

```
ORA-12170: Cannot connect.

Receive timeout of 30s for host 10.9.7.5 port 1522.

(CONNECTION ID=1ABcDEabCd1aB+AbCdE1aB==)
```

Cause

The connection request cannot be completed within the allotted time interval. This may be a result of network or system delays, or may indicate a denial-of-service (DoS) attack on the database server.

Action

- If the error occurred in your application, then perform these tasks:
 - If you have used the CONNECT_TIMEOUT or TRANSPORT_CONNECT_TIMEOUT parameters in an Easy Connect or thinnames.ora connection string, then set these parameters to a larger value.

Alternatively, set one or all of these parameters in the client sqlnet.ora file to a larger value:

```
SQLNET.OUTBOUND_CONNECT_TIMEOUT
```

SQLNET.RECV TIMEOUT

TCP.CONNECT TIMEOUT

The connection string parameters take precedence over the corresponding sqlnet.ora parameters.

2. In the languages that support programmatic driver settings, adjust the settings equivalent to your specified timeout parameter values.

For example:

```
With JDBC, adjust oracle.net.OUTBOUND_CONNECT_TIMEOUT, oracle.net.CONNECT_TIMEOUT, or use setLoginTimeout().
```

With Python, python-oracledb, adjust the tcp_connect_timeout parameter when calling connect() or create pool().

- If the error occurred in the database alert log file, then set one or both of these parameters in the database sqlnet.ora file to a larger value:
 - SQLNET.INBOUND CONNECT TIMEOUT
 - SQLNET.RECV_TIMEOUT
- If you suspect a malicious client, then use the database alert log to identify the source address and then restrict the access.
- Use the CONNECTION_ID value to track this connection attempt in trace files for further diagnosis.

Related Topics

- Tracing Error Information for Oracle Net Services
 Tracing produces a detailed sequence of statements that describe network events as they are run. Tracing an operation enables you to obtain more information about the internal operations of the components of Oracle Net Services than is provided in a log file.
- Limiting Resource Consumption by Unauthorized Users

16.3.4 ORA-12241

Appears on Microsoft Windows systems to indicate that a particular service is either not available or not running.

Message

ORA-12241: Windows service string is either not available or not running.

For example:

ORA-12241: Windows service OracleServiceSID1 is either not available or not running.

Cause

The operation cannot be completed because the requested Windows service is either not available or not running.

Action

Create and start the Windows service before the operation to be performed.

For further details, turn on tracing and run the operation again. If error persists, contact Oracle Support Services.

16.3.5 ORA-12261

Indicates that the specified connection alias cannot be resolved due to errors in the Easy Connect syntax.

Message

```
ORA-12261: Cannot connect to database.

Syntax error in Easy Connect connection string string.
```

For example:

```
ORA-12261: Cannot connect to database.

Syntax error in Easy Connect connection string sales1.example.com:1522/sales.
```

Cause

A connection to the database or other service is requested using an incorrect Easy Connect connection string.

Action

- 1. Check for mistakes in the specified connection string.
- 2. Ensure that the specified host, port, and service name values are correct.
- Try enclosing the connect identifier in quotation marks.

16.3.6 ORA-12262

Indicates that the specified connection alias cannot be resolved due to invalid host name in the Easy Connect syntax.

Message

```
ORA-12262: Cannot connect to database.

Could not resolve hostname string

in Easy Connect connection string string.
```

For example:

```
ORA-12262: Cannot connect to database.

Could not resolve hostname sales1.example.com
in Easy Connect connection string sales1.example.com:1522/sales.
```

Cause

A connection to the database or other service is requested using a host name or Easy Connect connection string, but the host name is invalid and cannot be resolved.

Action

- Check for mistakes in the specified connection string.
- 2. Ensure that the specified host name value is correct.
- Try enclosing the connect identifier in quotation marks.

16.3.7 ORA-12500

Indicates that the listener failed to start the Oracle program.

Message

ORA-12500: Listener failed to start a dedicated server process

Cause

Possible reasons include:

- The maximum number of processes allowed for a single user has exceeded
- The listener does not have execute permission on the Oracle program
- The associated Microsoft Windows service is not started

In some cases, these errors may be caused by the same conditions that cause the following errors:

- TNS-12549 or ORA-12549
- TNS-00519
- TNS-12540 or ORA-12540
- TNS-00510
- TNS-12560 or ORA-12560

Action

- Increase the number of processes by setting the PROCESSES parameter in the database initialization file to a larger value.
- Check the listener.log file for the detailed error stack information.

16.3.8 ORA-12505

Indicates that the listener cannot identify the system identifier (SID) specified in the connect descriptor.

Message

```
ORA-12505: Cannot connect to database. SID string is not registered with the listener at string. (CONNECTION ID=string)
```

For example:

```
ORA-12505: Cannot connect to database.
SID sales_sid is not registered with the listener at host 10.9.7.5 port 1522.
(CONNECTION ID=1ABcDEabCdlaB+AbCdE1aB==)
```

Cause

A listener process initially handles all connections to Oracle Database. The connection request received by the listener specified SID for an instance (usually a database instance) that either has not yet been dynamically registered with the listener or has not been statically configured in the listener's listener.ora configuration file. This error may be a temporary condition that occurs after the listener has started but before the database instance registers with the listener.

Action

- 1. Check for mistakes in the specified connection string.
- 2. Ensure that the SID parameter in the connection string or that the thisnames.ora file connect descriptor specifies an instance known by the listener.
- 3. Wait a moment, and then try to connect again. The database instance registration may not be complete yet.
- 4. Use the CONNECTION_ID value to track this connection attempt in trace files for further diagnosis.
- 5. Check which instances are currently known by the listener by performing one of these tasks:
 - Ask your database administrator.
 - Review the connection string in the cloud service console.
 - If you have access to the machine where the listener is running, then run one of the following:
 - lsnrctl services
 - If a listener is named in the listener.ora file, then run:

```
lsnrctl services listener name
```

 If an Oracle Connection Manager (Oracle CMAN) proxy listener is named in the cman.ora file, then run:

```
cmctl show services -c cman name
```

Related Topics

Monitoring Services of a Listener

16.3.9 ORA-12514

Indicates that the listener cannot identify the service requested in the connect descriptor.

Message

```
ORA-12514: Cannot connect to database. Service string is not registered with the listener at string. (CONNECTION ID=string)
```

For example:

When the client connects by specifying the service name:

```
ORA-12514: Cannot connect to database.

Service sales_service.example.com is not registered with the listener at host 10.9.7.5 port 1522.

(CONNECTION ID=1ABcDEabCd1aB+AbCdE1aB==)
```

When the client connects without specifying the service name:

```
ORA-12514: Cannot connect to database.
Service Default is not registered with the listener
  at host 10.9.7.5 port 1522.
(CONNECTION ID=1ABcDEabCd1aB+AbCdE1aB==)
```

Cause

A listener process initially handles all connections to Oracle Database. The connection request received by the listener specified a service name (usually for a database service) that either has not been dynamically registered with the listener or that has not been statically configured in the listener's listener.ora configuration file. This error may be a temporary condition that occurs after the listener has started but before the database instance registers with the listener.

Action

- Check for mistakes in the specified connection string.
- 2. Check that the database or pluggable database (PDB) is running. If you are using a cloud service, ensure that the database service is running.
- Ensure that the SERVICE_NAME parameter in the connection string or that the tnsnames.ora file connect descriptor specifies a service known by the listener.
- **4.** If using an Easy Connect connection string, then check that the specified service name is known by the listener.
- Wait a moment, and then try to connect again. The database instance registration may not be complete yet.
- Use the CONNECTION_ID value to track this connection attempt in trace files for further diagnosis.
- Check which services are currently known by the listener by performing one of these tasks:
 - Ask your database administrator.

- Review the connection string in the cloud service console.
- If you have access to the machine where the listener is running, then run one of the following:
 - lsnrctl services
 - If a listener is named in the listener.ora file, then run:

```
lsnrctl services listener_name
```

 If an Oracle Connection Manager (Oracle CMAN) proxy listener is named in the cman.ora file, then run:

```
cmctl show services -c cman_name
```

If an Oracle Global Service Manager (Oracle GSM) listener is named in the gsm.ora file, then run:

```
gdsctl services -raw -gsm gsm_name
```

Related Topics

Monitoring Services of a Listener

16.3.10 ORA-12516

Indicates that the listener is unable to find an available handler with the matching protocol stack.

Message

```
ORA-12516: Cannot connect to database.

Listener at string does not have a protocol handler for string ready or registered for service string.

(CONNECTION ID=string)
```

For example:

```
ORA-12516: Cannot connect to database.

Listener at host 10.9.7.5 port 1522 does not have protocol handler for tcp ready or registered for service sales_service.example.com. (CONNECTION ID=1ABcDEabCdlaB+AbCdElaB==)
```

Cause

The connection is refused by the Oracle Database listener process. None of the known and available service handlers for the specified service name support the client's requested protocol stack.

Action

- 1. Check for mistakes in the specified connection string.
- If you are using a cloud service, then review the connection string shown in the cloud service console.

- 3. Wait a moment, and then try to connect again. The service handler may be in a blocked state and not accepting new connections.
- Use the CONNECTION_ID value to track this connection attempt in trace files for further diagnosis.
- 5. Check which handlers are currently known by the listener and are accepting connections by performing one of these tasks:
 - Ask your database administrator.
 - Review the connection string in the cloud service console.
 - If you have access to the machine where the listener is running, then run one of the following:
 - lsnrctl services
 - If a listener is named in the listener.ora file, then run:

```
lsnrctl services listener name
```

 If an Oracle Connection Manager (Oracle CMAN) proxy listener is named in the cman.ora file, then run:

```
cmctl show services -c cman name
```

 If an Oracle Global Service Manager (Oracle GSM) listener is named in the gsm.ora file, then run:

```
gdsctl services -raw -gsm gsm name
```

 Ensure that the registered handlers are configured to support the required protocol stack. For example, to match the protocol, session, and presentation used in the connection string.

Related Topics

Monitoring Services of a Listener

16.3.11 ORA-12520

Indicates that the listener cannot find an available handler for the requested server type.

Message

```
ORA-12520: Cannot connect to database. Listener at string does not have handler for string server type ready or registered for service string. (CONNECTION_ID=string)
```

For example:

```
ORA-12520: Cannot connect to database.
Listener at host 10.9.7.5 port 1522 does not have handler
for pooled server type
```

```
ready or registered for service sales_service.example.com.
(CONNECTION ID=1ABcDEabCd1aB+AbCdE1aB==)
```

Cause

The connection is refused by the Oracle Database listener process. None of the known and available handlers for the requested server type (dedicated, shared, or pooled) is appropriate for the client connection.

Action

- Check for mistakes in the specified connection string.
- 2. Ensure that the SERVER parameter in the connection string or that the tnsnames.ora file connect descriptor specifies a server type (dedicated, shared, or pooled) that is supported by handlers known by the listener.
- If using an Easy Connect connection string, then check that the specified server type is supported by handlers known by the listener.
- 4. Wait a moment, and then try to connect again. The service handler may be in a blocked state and not accepting new connections.
- Use the CONNECTION_ID value to track this connection attempt in trace files for further diagnosis.
- **6.** Check which handlers are currently known by the listener and are accepting connections by performing one of these tasks:
 - Ask your database administrator.
 - Review the connection string shown in the cloud service console.
 - If you have access to the machine where the listener is running, then run one of the following:
 - lsnrctl services
 - If a listener is named in the listener.ora file, then run:

```
lsnrctl services listener_name
```

 If an Oracle Connection Manager (Oracle CMAN) proxy listener is named in the cman.ora file, then run:

```
cmctl show services -c cman name
```

 If an Oracle Global Service Manager (Oracle GSM) listener is named in the gsm.ora file, then run:

```
gdsctl services -raw -gsm gsm_name
```

Related Topics

Monitoring Services of a Listener

16.3.12 ORA-12521

Indicates that the listener cannot identify the instance requested in the connect descriptor.

Message

```
ORA-12521: Cannot connect to database.

Instance string for service string
is not registered with the listener at string.

(CONNECTION ID=string)
```

For example:

```
ORA-12521: Cannot connect to database.
Instance sales_instance for service sales_service.example.com
  is not registered with the listener at host 10.9.7.5 port 1522.
(CONNECTION ID=1ABcDEabCd1aB+AbCdE1aB==)
```

Cause

A listener process initially handles all connections to Oracle Database. In addition to the service name, the connection request received by the listener specified an instance name for an instance (usually a database instance) that either has not been dynamically registered with the listener or has not been statically configured in the listener's listener.ora configuration file. This error may be a temporary condition that occurs after the listener has started but before the database instance registers with the listener.

Action

- Check for mistakes in the specified connection string.
- 2. Ensure that the INSTANCE_NAME parameter in the connection string or that the tnsnames.ora file connect descriptor specifies an instance known by the listener.
- 3. If using an Easy Connect connection string, then check that the specified instance name is known by the listener.
- Wait a moment, and then try to connect again. The database instance registration may not be complete yet.
- Use the CONNECTION_ID value to track this connection attempt in trace files for further diagnosis.
- 6. Check which instances are currently known by the listener by performing one of these tasks:
 - Ask your database administrator.
 - Review the connection string in the cloud service console.
 - If you have access to the machine where the listener is running, then run one of the following:
 - lsnrctl services
 - If a listener is named in the listener.ora file, then run:

```
lsnrctl services listener name
```

If an Oracle Connection Manager (Oracle CMAN) proxy listener is named in the cman.ora file, then run:

```
cmctl show services -c cman_name
```

 If an Oracle Global Service Manager (Oracle GSM) listener is named in the gsm.ora file, then run:

```
gdsctl services -raw -gsm gsm name
```

Related Topics

Monitoring Services of a Listener

16.3.13 ORA-12525

Indicates that the client failed to complete its connect request in the time specified by the INBOUND_CONNECT_TIMEOUT_listener_name parameter in the listener.ora file.

Message

```
ORA-12525: Listener has not received client's request in time allowed
```

Cause

This error may be a result of network or system delays, or it may indicate that a malicious client is trying to cause a denial-of-service (DoS) attack on the listener.

Action

- If the error occurred due to system or network delays that are normal for the particular environment, then reconfigure the INBOUND_CONNECT_TIMEOUT_listener_name parameter in listener.ora to a larger value.
- If you suspect a malicious client, then perform the following steps:
 - Locate the IP address of the client in the listener.log file to identify the source. Keep in mind that an IP address can be forged.

For example, the following listener.log file excerpt shows a client IP address of 192.0.2.35.

```
03-MAY-2023 16:42:35 * <unknown connect data> * (ADDRESS=(PROTOCOL=tcp) (HOST=192.0.2.35) (PORT=53208)) * establish * <unknown sid> * 12525
TNS-12525: TNS:listener has not received client's request in time allowed
TNS-12604: TNS: Application timeout occurred
```

2. Restrict access to the client. You can configure parameters for access rights in the sqlnet.ora file.

Related Topics

Limiting Resource Consumption by Unauthorized Users

16.3.14 ORA-12533

Indicates that the ADDRESS section parameters are incorrect.

Message

ORA-12533: Illegal address parameters

Cause

This message appears if the protocol specific parameters in the ADDRESS section of the designated connect descriptor are incorrect. This error is often caused by hand-editing of the tnsnames.ora file.

Action

Correct the protocol address in the tnsnames.ora file. Only edit the tnsnames.ora file using Oracle Enterprise Manager Cloud Control or Oracle Net Manager.

Related Topics

Oracle Database Net Services Reference

16.3.15 ORA-12540 and TNS-00510

Indicate that an internal limit has been exceeded.

Message

```
ORA-12540: TNS:Internal limit restriction exceeded
TNS-00510: Internal limit restriction exceeded
```

Cause

Possible limits include:

- Number of open connections that Oracle Net can process simultaneously
- Number of memory buffers that can be used simultaneously
- Number of processes a particular database instance is allowed

The first two are examples of hard limits. The third is an example of a limit which can be increased by setting the PROCESSES parameter in the database initialization file to a larger value. In this case, a TNS-12500 or ORA-12500 error is also returned.

In some cases, these errors can be caused by the same conditions that cause TNS-12549 or ORA-12549, and TNS-00519 errors.

Action

Wait for the open connections to close and retry. If the error persists, then check the sqlnet.log or listener.log file for the detailed error stack information.

16.3.16 ORA-12541

Indicates that the listener cannot be reached.

Message

```
ORA-12541: Cannot connect. No listener at string.
```

For example:

When using the TCP, TCPS, Exadirect, or Websocket protocol:

```
ORA-12541: Cannot connect.
No Listener at host 10.9.7.5 port 1522
```

In this case, the last tried IP address of the client appears. In case of re-direct, the re-direct IP address appears.

When using the IPC protocol:

```
ORA-12541: Cannot connect. No Listener at key EXTPROC
```

Cause

The connection request cannot be completed in the following cases:

- The database listener process is not running on the specified host and port.
- An Interprocess Communication (IPC) protocol connection is attempted, but there is no listener for the specified key running on the local machine.

The PL/SQL applications using \mathtt{UTL} packages can also get this error if the external server process is not listening at the specified address.

Action

- 1. If the error displays the host and port that the connection tried to use, then ensure that a listener process is running on that host and is listening on that port. If the message indicates that there is no listener at the specified key, then ensure that the listener is running on the local machine and is listening for the specified key. The listener process is used to initially handle all connections to Oracle Database.
- Check for mistakes in the specified connection string.
- 3. If you are using an alias from a tnsnames.ora file, then verify the correctness of the host and port.

Alternatively, verify the correctness of the key if you are using an IPC connection.

- 4. If using an Easy Connect connection string, then ensure that the host and port are correct.
- 5. Use lsnrctl to check that the listener is running and also verify the port or key that the listener is listening to. To do so, run one of the following:
 - lsnrctl status

If a listener is named in the listener.ora file, then run:

```
lsnrctl status listener name
```

• If an Oracle Connection Manager (Oracle CMAN) proxy listener is named in the cman.ora file, then run:

```
cmctl show status -c cman name
```

16.3.17 ORA-12549 and TNS-00519

Indicate that a quota or hard limit imposed by the operating system has been exceeded.

Message

```
ORA-12549: TNS:Operating system resource quota exceeded
TNS-00519: Operating system resource quota exceeded
```

Cause

Possible limits include:

- The maximum number of processes allowed for a single user
- The operating system is running low on paging space

Action

- Increase the number of processes by setting the PROCESSES parameter in the database initialization file to a larger value.
- Check the sqlnet.log or listener.log file for the detailed error stack information, such as an operating system error code to help identify which quota has been exceeded.

16.3.18 ORA-12560

Indicates that a lower-level communication protocol adapter error has occurred.

Message

```
ORA-12560: Database communication protocol error.
```

Cause

This error may be due to incorrect configuration of an ADDRESS parameter, or may occur due to errors returned from the underlying protocol or operating system interface.

In some cases, these errors are caused by the same conditions that cause TNS-00510, TNS-00519, TNS-12540, ORA-12540, TNS-12549, or ORA-12549 errors.

Action

1. Check for lower-level network transport errors in the error stack for additional information.

- Ensure that the protocol specification used in the address for the connection is correct.
- 3. For further details, turn on network tracing and rerun the operation. Turn off tracing when the operation is complete.
- 4. Contact Oracle Support Services.

16.3.19 Directory Naming Errors

Directory naming issues associated with connectivity errors for database service or network service name entries in a directory server require analysis of the data. You can analyze the data contained within a directory server with the <code>ldifwrite</code> command line tool. The <code>ldifwrite</code> tool is an Oracle Internet Directory tool.

The ldifwrite tool can be used to convert all or part of the information residing in a directory server to LDIF. The ldifwrite tool performs a subtree search, including all entries following the specified distinguished name (DN), including the DN itself.

The ldifwrite tool syntax is as follows:

```
ldifwrite -c net service name/database service -b base DN -f ldif file
```

The following table lists ldifwrite tool arguments and descriptions for each.

Table 16-8 Idifwrite Arguments

Argument	Description
-c net_service_name/ database_service	The network service name or database service name that connects to the directory server.
-b base_DN	The base of the subtree to be written out in LDIF format.
-f ldif_file	The output file name.

The following example writes all the directory naming entries under dc=us, dc=example, dc=com to the output1.ldi file:

ldifwrite -c ldap -b "dc=us,dc=example,dc=com" -f output.ldif

Check the ldap.ora file to determine the base_DN value. It is the same as the DEFAULT_ADMIN_CONTEXT entry in the ldap.ora file.

16.4 Troubleshooting Suggestions for Oracle Net Services

These are the suggestions for diagnosing network problems and troubleshooting Oracle Connection Manager in Traffic Director Mode.

Suggestions for Diagnosing Network Problems
 These suggestions may be useful when diagnosing and resolving network connectivity errors.

- Troubleshooting Oracle Connection Manager in Traffic Director Mode

 Learn how to resolve errors that you may encounter while executing Select statements using Oracle Connection Manager in Traffic Director Mode.
- Questions to Consider When Troubleshooting Oracle Net Services
 These questions help you in diagnosing network problems.

16.4.1 Suggestions for Diagnosing Network Problems

These suggestions may be useful when diagnosing and resolving network connectivity errors.

- Use the node or network address during configuration instead of the name of the server computer. This eliminates any internal lookup problems and make the connection slightly faster.
- If you are using TCP/IP addresses, then use the IP address rather than the host name. For example, change the <code>HOST=server_name</code> line in the <code>tnsnames.ora</code> file to the IP address, such as <code>HOST=192.0.2.5</code>.
- Perform a loopback test on the server as described in Task 2, Perform a Loopback Test. If the test passes, then use FTP to send the tnsnames.ora and sqlnet.ora files to the client.
- Check the systems between the client and the server. If it is a wide area network (WAN), then identify any intermediate systems that may not work correctly. If all computers are fine, then the problem may be a timing issue.
- Verify whether there is a timing issue. Timing issues are associated with an ORA-12535 error in the client log files.
 - To resolve a timing issue, try speeding up the connection by using exact addresses instead of names and increase the INBOUND_CONNECT_TIMEOUT_listener_name parameter in the listener.ora file. The default value for this parameter is 10 seconds.
- Determine which Oracle applications are failing. SQL*Plus may work, but CASE tools may
 not. If you determine the problem is a data volume issue, then try to transfer a large (5 MB)
 file with the base connectivity.

16.4.2 Troubleshooting Oracle Connection Manager in Traffic Director Mode

Learn how to resolve errors that you may encounter while executing SELECT statements using Oracle Connection Manager in Traffic Director Mode.

If an application runs a SELECT statement using Oracle Connection Manager in Traffic Director Mode, then the ORA-24449 error message may appear in the following scenarios:

- If you modify data type or maximum length of a select list column on the database server side while Oracle Connection Manager is running.
 - To resolve the error, applications need to close or return the \mathtt{SELECT} statements and run the query again.
- If you select columns with different formats (for example, TO_CHAR (<datecolumn>) with different NLS_DATE_FORMAT values) and modify the session property either in the same connection or with different connections having different format settings, using Proxy Resident Connection Pooling (PRCP).

To resolve the error, use column aliases to distinguish statements in the same connection. For PRCP connections, use connection classes or tags.

16.4.3 Questions to Consider When Troubleshooting Oracle Net Services

These questions help you in diagnosing network problems.

Do all computers have a problem, or is it just one?

If one computer works and another does not, and the same software (Oracle and third-party products) is installed on each computer, then, if possible, swap out the network cables to see if the problem occurs on the second client. If it does occur, then it indicates that the problem has something to do with the client/server connection and is not local to the client.

 What kind of connections exist between the client and the server, for example, X.25, ISDN, or leased line?

Sniffers and LAN analyzers are useful for locating intermittent connection failures, and detecting time outs and resent packets. You can also see which side is waiting for a response.

16.5 Example of Troubleshooting a TNS-12154 Error

This section offers some solutions for the TNS-12154 error. The TNS-12154 error is encountered when SQL*Net cannot find the connect identifier specified for a connection in the tnsnames.ora file or other naming adapter.

Before attempting to resolve the problem, it may be helpful to print out or view the tnsnames.ora file and the sqlnet.ora file. Looking at these files at the same time is helpful because references are made to both.

In this example, the tnsnames.ora and sqlnet.ora files are located in the default network administration directory on the client system.

Be sure that the tnsnames.ora file and the sqlnet.ora file resemble the following examples.

The following is an example of a tnsnames.ora file:

Example 16-1 tnsnames.ora Sample

The following is an example of a sqlnet.ora file:

Example 16-2 sqlnet.ora Sample

```
TRACE_LEVEL_CLIENT = OFF
SQLNET.AUTHENTICATION_SERVICES = (NONE)
NAMES.DIRECTORY_PATH = (TNSNAMES)
AUTOMATIC_IPC = OFF
```

The alias in Example 16-1 is DEV1.WORLD. However, the NAMES.DEFAULT_DOMAIN = WORLD parameter does not exist in Example 16-2. To fix this problem, add the NAMES.DEFAULT_DOMAIN = WORLD parameter anywhere in the sqlnet.ora file. Save the file, and try the connection again.

16.6 Logging Error Information for Oracle Net Services

All errors encountered by Oracle Net Services are appended to a log file for evaluation by a network or database administrator. The log file provides additional information for an administrator about on-screen error messages. The error stack in the log file shows the state of the software at various layers.

To ensure that all errors are recorded, logging cannot be disabled on clients or name servers. Furthermore, only an administrator may replace or erase log files. The log file for the listener includes audit trail information about every client connection request, and most listener control commands.

Oracle Net Error Stacks

Log files provide information contained in an error stack. An error stack refers to the information that is produced by each layer in an Oracle communications stack as the result of a network error.

Understanding Error Stack Messages

Although the application displays only a one-line error message, an error stack that is much more informative is recorded in the log file by the network layer.

Oracle Net Services Log File Names

Each Oracle Net Services component produces its own log file. When using ADR, the default, the log file names are log.xml in the appropriate alert directory.

Oracle Network Log File Segmentation

The maximum size and number of text log files can be configured for Oracle Network components such as Oracle Net Listener, Oracle Connection Manager, and Global Service Manager.

About the Logging Parameters

Parameters that control logging, including the type and amount of information logged, and the location where the files are stored, are set in the configuration file of each network component.

Setting Logging Parameters in Configuration Files

You configure logging parameters for the sqlnet.ora file with Oracle Net Manager and for the listener.ora file with either Oracle Enterprise Manager Cloud Control or Oracle Net Manager.

Setting Logging During Control Utilities Runtime

You can set logging during control utility runtime. Setting logging with a control utility does not set parameters in the \star .ora files, and the setting is only valid for the control utility session.

Using Log Files

This procedure describes how to use a log file to diagnose a network error.

Analyzing Listener Logs

The listener log file records information about audit trails, service registration-related events, direct hand-off events, subscriptions for Oracle Notification Service (ONS) nodedown events, and Oracle Clusterware notifications.

Analyzing Oracle Connection Manager Logs

Oracle Connection Manager (CMAN) generates the <code>cman_alias.log</code> file in the specified log directory. This log file records messages related to the CMAN listener, gateway, CMADMIN processes, and alerts.

16.6.1 Oracle Net Error Stacks

Log files provide information contained in an error stack. An error stack refers to the information that is produced by each layer in an Oracle communications stack as the result of a network error.

Table 16-9 Error Stack Components

Error Stack Component	Description
NI	Network Interface. This layer provides a generic interface for Oracle clients, servers, or external processes to access Oracle Net functions. The NI layer handles the "break" and "reset" requests for a connection.
NS	Network Session (main and secondary layers). These layers receive requests from NI, and settle all generic computer-level connectivity issues, such as:
	 The location of the server or destination (open, close functions). Whether one or more protocols are involved in the connection (open, close functions).
	 How to handle interrupts between client and server based on the capabilities of each (send, receive functions).
NA	Network Authentication. This layer negotiates authentication and encryption requirements.
NT	Network Transport (main, secondary, and operating system layers). These layers map Oracle Net foundation layer functionality to industry-standard protocols.

16.6.2 Understanding Error Stack Messages

Although the application displays only a one-line error message, an error stack that is much more informative is recorded in the log file by the network layer.

Suppose that a user of a client application tries to establish a connection with the database server using Oracle Net and TCP/IP, by entering the following commands:

```
SQLPLUS scott@example.com Enter password: password
```

When the commands are entered, the following error appears:

```
ORA-12543: TNS:Unable to connect to destination
```

This message indicates that the connection to the server failed because the database could not be contacted.

On the client side, the sqlnet.log file contains an error stack corresponding to the ORA-12543 error. As shown in the following example logs, the messages can appear in a concise format (default setting) or in a more detailed long format:

Concise format: This format displays all the relevant information in a single line. This
helps in reducing the size of the log file and makes it easier to understand.

The sqlnet.ora setting ENABLE CONCISE LOGS=TRUE enables logging in a concise format.

 Long format: This is the regular longer format that includes multiple lines, with additional details such as Version information.

The sqlnet.ora setting ENABLE_CONCISE_LOGS=FALSE disables concise logging and prints the message in a long format.

Example 16-3 sqlnet.log File: Concise Format

This log file uses the default, concise format to display the message:

```
Fatal NI connect error 12514 [Time: 06-AUG-2024 06:33:17] [NS errors [12564:TNS-12564: TNS:connection refused] 0] [NT errors [0 0] 0] [Oracle errors [0 ] 0] [Connecting to: (DESCRIPTION=(ADDRESS=(PROTOCOL=TCP) (HOST=sales-sever) (PORT=6513)) (CONNECT_DATA=(service_name=sales.example.com) (CID=(PROGRAM=oracle) (HOST=sales-server) (USER=scott)) (CONNECTION_ID=labcAB1+ABcabAB1aBCab12A==)))] [PID: 1122110]
```

Example 16-4 sqlnet.log File: Long Format

This sample log file uses a longer, detailed format to display the message:

```
Fatal NI connect error 12514, connecting to:
 (DESCRIPTION=
  (ADDRESS=(PROTOCOL=TCP) (HOST=sales-server) (PORT=6513))
  (CONNECT DATA=
    (service name=sales.oracle,.com)
    (CID=(PROGRAM=ora cle)(HOST=sales-server)(USER=scott))
    (CONNECTION ID=945VpOeGXR/gU0tBRmTdxw==)))
VERSION INFORMATION:

   nt secondary err code: 0
    nt OS err code: 0
```

16.6.3 Oracle Net Services Log File Names

Each Oracle Net Services component produces its own log file. When using ADR, the default, the log file names are log.xml in the appropriate alert directory.

The following table lists the default log file names and the components that generate the log files that appear in the ADR/diag/instance name/trace directory.

Table 16-10 Log File Names When Using ADR

Component	Log File
Listener	listener.log
Client or database server	sqlnet.log
Oracle Connection Manager listener	instance-name_pid.log
Oracle Connection Manager CMGW (Oracle Connection Manager Gateway) process	instance- name_cmgw_pid.log
Oracle Connection Manager CMADMIN (Oracle Connection Manager Administration) process	instance- name_cmadmin_pid.log
Oracle Connection Manager alert log	instance-name_alert.log

16.6.4 Oracle Network Log File Segmentation

The maximum size and number of text log files can be configured for Oracle Network components such as Oracle Net Listener, Oracle Connection Manager, and Global Service Manager.

This feature allows better management of log files, particularly in Cloud environments. This is an ADR only feature and applicable to both text and XML log files.

16.6.5 About the Logging Parameters

Parameters that control logging, including the type and amount of information logged, and the location where the files are stored, are set in the configuration file of each network component.

Table 16-11 Location of Log Parameters

Network Component	Configuration File
Oracle Connection Manager processes	cman.ora
Listener	listener.ora
Client	sqlnet.ora
Database server	sqlnet.ora

If the ADR_ENABLED parameter is set to ON, then all logging parameters are set by ADR. Using Oracle Net Manager to change the parameters will not work.

- sqlnet.ora Log Parameters
 You can set these log parameters in the sqlnet.ora file.
- listener.ora Log Parameters
 You can set these log parameters in the listener.ora file.

cman.ora Log Parameters

You can set these log parameters in the cman.ora file.

Related Topics

Oracle Database Net Services Reference

16.6.5.1 sqlnet.ora Log Parameters

You can set these log parameters in the sqlnet.ora file.

Table 16-12 sqlnet.ora Log Parameters

sqlnet.ora Parameter	Oracle Net Manager Field	Description
ADR_BASE	Tracing: ADR Base Directory	Specifies the base directory for storing tracing and logging incidents.
		Use this parameter when <code>DIAG_ADR_ENABLED</code> is set to <code>ON</code> .
DIAG_ADR_ENABLED	You must set this	Indicates whether ADR tracing is enabled.
	parameter manually.	When the <code>DIAG_ADR_ENABLED</code> parameter is set to <code>OFF</code> , non-ADR file tracing is used.
ENABLE_CONCISE_LOGS	You must set this parameter manually.	Enables or disables the logging in a concise format, which displays all the relevant information of a failure in a single line.
LOG_SUPPRESSED_COUNT	You must set this parameter manually.	Controls suppression of a log message on the database server side, based on the number of occurrences.
LOG_SUPPRESSED_TIME	You must set this parameter manually.	Controls suppression of a log message on the database server side, based on the time interval.
LOG_DIRECTORY_CLIENT	Client Information: Log Directory	Specifies the destination directory for the client log file. By default, the client directory is the current working directory. This parameter is disabled when ADR_ENABLED is set to ON.
LOG_DIRECTORY_SERVER	Server Information: Log Directory	Specifies the destination directory for the database server log files. By default, the server directory is <code>ORACLE_HOME/network/log</code> . This parameter is disabled when <code>ADR_ENABLED</code> is set to <code>ON</code> .
LOG_FILE_CLIENT	Client Information: Log	Specifies the name of the log file for the client.
_ _	File	By default, the log name is sqlnet.log.
LOG_FILE_SERVER	You must set this	Specifies the name of the log file for the database server.
parameter manually.	By default, the log name is sqlnet.log.	

16.6.5.2 listener.ora Log Parameters

You can set these log parameters in the listener.ora file.

Table 16-13 listener.ora Log Parameters

listener.ora Parameter	Oracle Net Manager Field	Description
ADR_BASE_listener_name	You must set this parameter manually.	The ADR_BASE_listener_name parameter specifies the base directory for storing which tracing and logging incidents.
		Use when DIAG_ADR_ENABLED_listener_name is set to ON.

Table 16-13 (Cont.) listener.ora Log Parameters

listener.ora Parameter	Oracle Net Manager Field	Description
DIAG_ADR_ENABLED_listener_name	You must set this parameter manually.	The DIAG_ADR_ENABLED_listener_name parameter indicates whether ADR tracing is enabled. When DIAG ADR ENABLED listener name is set to
IOC DIDECTION 1: otonom nome	Log Eilo	OFF, non-ADR file tracing is used.
LOG_FILE_listener_name LOG_FILE_listener_name	Log File	The destination directory and file for the log file that is automatically generated for listener events. By default the directory is <code>ORACLE_HOME/network/log</code> , and the file name is <code>listener.log</code> . These parameters are disabled when <code>ADR_ENABLED</code> is set to <code>ON</code> .

16.6.5.3 cman.ora Log Parameters

You can set these log parameters in the ${\tt cman.ora}$ file.

Table 16-14 cman.ora Log Parameters

cman.ora Parameter	Description	
ADR_BASE	The ADR_BASE parameter specifies the base directory for storing tracing and logging incidents.	
	Use this parameter when <code>DIAG_ADR_ENABLED</code> is set to <code>ON</code> .	
DIAG_ADR_ENABLED	The <code>DIAG_ADR_ENABLED</code> parameter indicates whether ADR tracing is enabled.	
	When the <code>DIAG_ADR_ENABLED</code> parameter is set to <code>OFF</code> , non-ADR file tracing is used.	
EVENT_GROUP	The event groups that are logged. Multiple events may be designated using a comma-delimited list. This parameter accepts the following values:	
	 INIT_AND_TERM: initialization and termination 	
	 MEMORY_OPS: memory operations 	
	 CONN_HDLG: connection handling 	
	 PROC_MGMT: process management 	
	 REG_AND_LOAD: registration and load update 	
	 WAKE_UP: events related to CMADMIN wakeup queue 	
	TIMER: gateway timeouts	
	 CMD_PROC: command processing 	
	 RELAY: events associated with connection control blocks 	
LOG_DIRECTORY	The destination directory for log files.	
	By default, the directory is <code>ORACLE_HOME/network/log</code> .	
	This parameter is disabled when ADR_ENABLED is set to ON.	
LOG_LEVEL	The level of logging. Four levels are supported:	
	 off (default): no logging 	
	user: user log information	
	 admin: administrative log information 	
	 support: Oracle Support Services information 	

16.6.6 Setting Logging Parameters in Configuration Files

You configure logging parameters for the sqlnet.ora file with Oracle Net Manager and for the listener.ora file with either Oracle Enterprise Manager Cloud Control or Oracle Net Manager.

You must manually configure cman.ora file logging parameters.

- · Setting Parameters for the sqlnet.ora File Using Oracle Net Manager
- Setting Parameters for the listener.ora File Using Oracle Enterprise Manager Cloud Control
- Setting Parameters for the listener.ora File Using Oracle Net Manager

16.6.6.1 Setting Parameters for the sqlnet.ora File Using Oracle Net Manager

The following procedure describes how to set the logging parameters in the sqlnet.ora file.

Start Oracle Net Manager.

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, expand **Profile** under the Local heading.
- 3. From the list in the right pane, select **General**.
- Click the Logging tab.
- Specify the settings.
- 6. Choose Save Network Configuration from the File menu.

The name of the log file is sqlnet.log.

16.6.6.2 Setting Parameters for the listener.ora File Using Oracle Enterprise Manager Cloud Control

The following procedure describes how to set the logging parameters in the listener.ora file using Oracle Enterprise Manager Cloud Control:

Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

"Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services"

- Select Listeners from the Administer list, and then select the Oracle home that contains the location of the configuration files.
- 3. Click Go to display the Listeners page.
- 4. Select a listener, and then click **Edit** to display the Edit Listeners page.
- 5. Click the **Logging & Tracing** tab.

- Specify the settings.
- 7. Click OK.

The name of the log file is listener.log.

16.6.6.3 Setting Parameters for the listener.ora File Using Oracle Net Manager

The following procedure describes how to set the logging parameters in the listener.ora file using Oracle Net Manager:

1. Start Oracle Net Manager.

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, expand **Listeners** under the Local heading.
- Select a listener.
- 4. From the list in the right pane, select **General**.
- 5. Click the Logging and Tracing tab.
- 6. Specify the settings.
- Choose Save Network Configuration from the File menu.

The name of the log file is listener.log.

See Also:

Oracle Database Net Services Reference

16.6.7 Setting Logging During Control Utilities Runtime

You can set logging during control utility runtime. Setting logging with a control utility does not set parameters in the *.ora files, and the setting is only valid for the control utility session.

The following settings can be set for a control utility:

- For a listener, use the SET LOG_FILE and SET LOG_DIRECTORY commands from the Listener Control utility.
- For an Oracle Connection Manager, use the SET LOG_DIRECTORY, SET LOG_LEVEL, and SET EVENT commands from the Oracle Connection Manager control utility.

Note:

If the ADR_ENABLED parameter is set to ON, then all logging parameters are set by ADR. Using Oracle Connection Manager to change the parameters will not work.

Related Topics

Oracle Database Net Services Reference

16.6.8 Using Log Files

This procedure describes how to use a log file to diagnose a network error.

- 1. Review the log file for the most recent error number received from the application. This is usually the last entry in the log file.
- 2. Starting from the bottom of the file, locate the first nonzero entry in the error report. This is usually the actual cause.
- 3. If that error does not provide the information, then review the next error in the log until you locate the correct error information.
- 4. If the cause of the error is still not clear, then turn on tracing and repeat the command that produced the error message.

16.6.9 Analyzing Listener Logs

The listener log file records information about audit trails, service registration-related events, direct hand-off events, subscriptions for Oracle Notification Service (ONS) node-down events, and Oracle Clusterware notifications.

Listener Log Audit Trails

The audit trail information in the listener log file enables you to analyze network usage statistics, client connection requests, commands issued by the Listener Control utility, and so on.

Listener Service Registration Events

The service registration events information in the listener log file enables you to analyze registration-related statistics, such as service names for instances, instance names, service handlers, load information, dynamic listening endpoints, and so on.

Listener Handler Block Information

The listener handler block information in the listener log file enables you to analyze events about blocked and unblocked handlers.

Listener Direct Hand-Off Information

The direct hand-off information in the listener log file enables you to analyze direct hand-off events to dispatchers.

Listener Subscription for ONS Node-Down Event Information

The listener subscribes to the Oracle Notification Service (ONS) node-down event on startup if the ONS configuration file is available. The ONS node-down event information in the listener log file enables you to analyze these messages.

• Listener Oracle Clusterware Notification Information

If the required Oracle Clusterware libraries are installed and Oracle Clusterware is started on the host, then the listener notifies Oracle Clusterware about its status during start and stop processes. The Oracle Clusterware notification information in the listener log file enables you to analyze these messages.

16.6.9.1 Listener Log Audit Trails

The audit trail information in the listener log file enables you to analyze network usage statistics, client connection requests, commands issued by the Listener Control utility, and so on.

Listener Log Audit Trail Information

The audit trail information comprises statistics about network usage, client connection requests, and commands issued by the Listener Control utility (such as RELOAD, START, STOP, STATUS, or SERVICES).

Format of the Listener Log Audit Trail
 This is the format in which audit trail text fields are captured in the listener log file.

16.6.9.1.1 Listener Log Audit Trail Information

The audit trail information comprises statistics about network usage, client connection requests, and commands issued by the Listener Control utility (such as RELOAD, START, STOP, STATUS, or SERVICES).

You can use the audit trail information to view trends and user activity by first storing it in a table and then collating it in a report format. To import the data into a table, use an import utility such as SQL*Loader.

16.6.9.1.2 Format of the Listener Log Audit Trail

This is the format in which audit trail text fields are captured in the listener log file.

```
Timestamp * Connect Data [* Protocol Info] * Event [* SID | Service] * Return Code
```

Properties for the audit trail are:

- Each field is delimited by an asterisk (*).
- Protocol address information and service name or SID information appear only when a connection is attempted.
- A successful connection or command returns a code of zero.
- A failure produces a code that maps to an error message.

Example 16-5 shows a log file excerpt with RELOAD command request.

Example 16-5 Listener Log Event for Successful RELOAD Request

```
14-OCT-2022 00:29:54 * (connect_data=(cid=(program=) (host=sales-server) (user=jdoe)) (command=reload) (arguments=64) (service=listener) (version=135290880)) * reload * 0
```

Example 16-6 shows a log file excerpt with a successful connection request.

Example 16-6 Listener Log Events for a Successful Connection Request

```
14-OCT-2022 15:28:58 *
(connect_data=(service_name=sales.us.example.com) (cid=(program=) (host=sales-server) (user=jdoe)) (CONNECTION_ID=abcdefgtx42abCde6V/aB602xAbCDe==)) (TARGET_INSTANCE=sales) * (address=(protocol=tcp) (host=192.0.2.35) (port=41349)) * establish * sales.us.example.com * 0
```

Example 16-7 shows a log file excerpt with a successful execution of the STATUS command by host sales-server. It is followed by an unsuccessful connection attempt by a client with an IP address of 192.0.2.35. This connection attempt results in an ORA-12525: Listener Has Not Received Client's Request in Time Allowed error message. This error occurs when a client fails to complete its connection request in the time specified by the

INBOUND_CONNECT_TIMEOUT_listener_name parameter in the listener.ora file. This client could be attempting a denial-of-service attack on the listener.

Example 16-7 Listener Log Events for an Unsuccessful Connection Request

```
03-OCT-2022 16:41:57 *
(CONNECT_DATA=(CID=(PROGRAM=) (HOST=sales-server) (USER=jdoe)) (COMMAND=status)
(ARGUMENTS=64) (SERVICE=LISTENER) (VERSION=153092352)) * status * 0
03-OCT-2022 16:42:35 * <unknown connect data> *
(ADDRESS=(PROTOCOL=tcp) (HOST=192.0.2.35) (PORT=53208)) * establish *
<unknown sid> * 12525
TNS-12525: TNS:listener has not received client's request in time allowed
TNS-12604: TNS: Application timeout occurred
```

16.6.9.2 Listener Service Registration Events

The service registration events information in the listener log file enables you to analyze registration-related statistics, such as service names for instances, instance names, service handlers, load information, dynamic listening endpoints, and so on.

- Listener Service Registration Event Information
 The service registration information comprises statistics related to database service registration events, such as service register, service update, and service died.
- Format of the Listener Service Registration Information
 This is the format for each of the service registration event messages captured in the listener log file.

16.6.9.2.1 Listener Service Registration Event Information

The service registration information comprises statistics related to database service registration events, such as service_register, service_update, and service_died.

During service registration, the Listener Registration (LREG) process provides the listener with information about:

- Service names for each running instance of the database
- Instance names of the database
- Service handlers (dispatchers or dedicated servers) available for each instance
- Dispatcher, instance, and node load information
- Dynamic listening endpoints

Table 16-15 Service Registration Event Log Information

Event	Description
service_registe r	Registration information that the listener receives for an instance.
service_update	Updated registration information that the listener receives for a particular instance, such as dispatcher or instance load information.
	These messages also display all the update operations performed during this service_update.
service_died	Lost connection information for the connections that the listener is unable to establish with LREG. All registration information for the instance is discarded. Clients are unable to connect to the instance until LREG registers it again.

16.6.9.2.2 Format of the Listener Service Registration Information

This is the format for each of the service registration event messages captured in the listener log file.

Table 16-16 Service Registration Events Format

```
      Event
      Format

      service_register
      Timestamp * Address * Event * Instance Name * Return Code

      service_update
      Timestamp * Event * Registration Update Operation * Instance Name * Return Code

      service_died
      Timestamp * Event * Instance Name * Return Code
```

Properties of service registration fields are:

- Each field is delimited by an asterisk (*).
- It is normal for the events to appear multiple times in a row for one instance.
- A successful registration returns a code of zero, meaning the client can connect to the instance.
- A failure produces a code that maps to an error message.

Example 16-8 shows a log file with service registration events. The listener is able to receive a client request after a successful service_register event, but is unable to receive client requests after a service_died event.

Example 16-8 Listener Log with Service Registration Events

```
01-OCT-2022 11:40:06 * (ADDRESS=(PROTOCOL=tcp) (HOST=192.0.2.35) (PORT=46750)) *
service_register * sales * 0
01-OCT-2022 11:40:26 * (connect data=(service name=sales.us.example.com) (cid=(program=)
(host=sales-server) (user=jdoe)))
* (address=(protocol=tcp)(host=192.0.2.35)(port=41349)) * establish *
sales.us.example.com * 0
01-OCT-2022 11:41:51 * service_update * inst_upd=1 handler_upd=2 * sales * 0
01-OCT-2022 11:41:57 * service update * inst upd=1 handler upd=2 * sales * 0
01-OCT-2022 11:42:06 * service update * inst upd=1 handler upd=2 * sales * 0
01-OCT-2022 11:42:08 * (connect data=(service name=sales.us.example.com) (cid=(program=)
(host=sales-server) (user=jdoe)))
* (address=(protocol=tcp)(host=192.0.2.35)(port=41365)) * establish *
sales.us.example.com * 0
01-OCT-2022 11:57:02 * service died * sales * 12537
01-OCT-2022 11:57:10 * (connect data=(service name=sales.us.example.com) (cid=(program=)
(host=sales-server) (user=jdoe)))
* (address=(protocol=tcp)(host=192.0.2.35)(port=41406)) * establish *
sales.us.example.com * 12514
TNS-12514: TNS:Cannot connect to database. Service sales.us.example.com is not
registered with the listener at host 192.0.2.35 port 41365.
```

```
(CONNECTION_ID=4VIdFEpcSe3gU+FoRmR0aA==)
```

Oracle Database Error Messages Reference

16.6.9.3 Listener Handler Block Information

The listener handler block information in the listener log file enables you to analyze events about blocked and unblocked handlers.

When a service handler is blocked or unblocked by a database instance or listener, the log message displays blocked or unblocked handler details along with load information in the following format:

```
Timestamp * Handler Blocked or Unblocked by Instance or Listener: Load Information * Instance Name
```

Example 16-9 Listener Log for Handler Block Events

```
19-OCT-2022 06:13:51 * dedicated handler blocked by instance : load = 79 * sales 19-OCT-2022 06:13:51 * dedicated handler blocked by listener : load = 79 * sales 19-OCT-2022 06:15:05 * dedicated handler unblocked: load = 74 * sales 19-OCT-2022 07:51:13 * dedicated handler blocked by instance * sales 19-OCT-2022 07:51:13 * dedicated handler unblocked by instance * sales
```

16.6.9.4 Listener Direct Hand-Off Information

The direct hand-off information in the listener log file enables you to analyze direct hand-off events to dispatchers.

These events are formatted into the following fields:

```
Timestamp * Presentation * Handoff * Error Code
```

Properties of direct hand-off fields are as follows:

- Each field is delimited by an asterisk (*).
- A successful connection or command returns a code of zero.
- A failure produces a code that maps to an error message.

The following example shows a direct hand-off event in the log file.

Example 16-10 Listener Log Event for Direct Hand-Off

```
21-MAY-2012 10:54:55 * oracle.aurora.net.SALESHttp2 * handoff * 0
```

16.6.9.5 Listener Subscription for ONS Node-Down Event Information

The listener subscribes to the Oracle Notification Service (ONS) node-down event on startup if the ONS configuration file is available. The ONS node-down event information in the listener log file enables you to analyze these messages.

The subscription enables the listener to remove the affected service when it receives nodedown event notification from ONS. The listener uses asynchronous subscription for the event notification. The following warning message is recorded to the listener log file on each STATUS command if the subscription has not completed, such as the ONS daemon is not running on the host.

```
WARNING: Subscription for node down event still pending
```

The listener cannot receive the ONS event while subscription is pending. Other than that, no other listener functionality is affected.

16.6.9.6 Listener Oracle Clusterware Notification Information

If the required Oracle Clusterware libraries are installed and Oracle Clusterware is started on the host, then the listener notifies Oracle Clusterware about its status during start and stop processes. The Oracle Clusterware notification information in the listener log file enables you to analyze these messages.

After a successful notification to Oracle Clusterware (shown as CRS in the following log messages), listeners record the event in the log. No message is recorded if the notification fails.

```
Listener completed notification to CRS on start Listener completed notification to CRS on stop
```

16.6.10 Analyzing Oracle Connection Manager Logs

Oracle Connection Manager (CMAN) generates the <code>cman_alias.log</code> file in the specified log directory. This log file records messages related to the CMAN listener, gateway, CMADMIN processes, and alerts.

The alert log entry is a chronological list of all critical errors. In addition to logging critical errors, it captures information about instance startup and shutdown. It also records values of all configuration parameters at the beginning and end of a session.

Each log entry consists of a timestamp and an event. You can configure the cman.ora file to log events for the following categories:

- Initialization and termination
- Memory operations
- Connection handling
- Process management
- Registration and load update
- Events related to CMADMIN wakeup queue
- Gateway timeouts
- Command processing
- Events associated with connection control blocks

Use the SET EVENT command to specify the type of events that you want to log.

Table 16-17 CMADMIN and Gateway Log Entry Details

Log Entry	Event	Description
CMADMIN	Failed to get procedure ID	The CMCTL session connected to CMADMIN has disconnected.

Table 16-17 (Cont.) CMADMIN and Gateway Log Entry Details

Log Entry	Event	Description
CMADMIN	GMON attributes validated	Informational message. The parameters needed for CMADMIN to come up are specified correctly.
CMADMIN	Invalid connect data	An unknown client is trying to connect to CMADMIN. This is most likely a denial of service attack.
CMADMIN	No connect data	An unknown client is trying to connect to CMADMIN. This is most likely a denial of service attack.
Gateway	Connected to monitor	The gateway has connected to CMADMIN.
Gateway	Housekeeping	Informational message. Internal housekeeping for the gateway process is in order. The gateway process is properly connected to the CMADMIN process.
Gateway	Idle timeout	The connection is disconnected because it was idle longer than the time specified in the cman.ora file.
Gateway	Out of connection control block (CCB)	CMADMIN cannot process a connection request. There could be two reasons:
		 Faulty load update between CMADMIN and listener.
		 Someone is trying to connect to CMADMIN directly (possibly a denial of service attack).
Gateway	Session timeout	The connection is disconnected because it exceeded the session timeout specified in the cman.ora file.
Gateway	State change from Empty to Init	State change message from the gateway. After it reaches the Init state, the gateway begins some internal data initialization.
Gateway	State change from Init to Ready	State change message from the gateway. After it reaches the Ready state, the gateway begins accepting connections from the client.

Example 16-11 Sample CMADMIN Log Messages

```
(LOG RECORD=(TIMESTAMP=01-MAY-2024 08:46:40) (EVENT=Parameter list)
    (listener address=(address=(protocol=tcp) (host=sales1) (port=1574)))
    (aso authentication filter=OFF)
    (connection statistics=ON)
    (log directory=/home/user/network/admin/log)
    (log level=support)
    (max connections=256)
    (idle_timeout=5)
    (inbound_connect_timeout=0)
    (session_timeout=20)
    (outbound_connect_timeout=0)
    (max_gateway_processes=1)
    (min_gateway_processes=1)
    (trace directory=/home/user/network/admin/log)
    (trace level=off)
    (trace_timestamp=OFF)
    (trace_filelen=0)
    (trace_fileno=0)
(LOG_RECORD=(TIMESTAMP=01-MAY-2024 08:46:40)(EVENT=Shared Memory Size)
```

```
(BYTES=82524))
(LOG RECORD=(TIMESTAMP=01-MAY-2024 08:46:40) (EVENT=GMON Attributes validated)
(Type=Information))

16.7 Tracing Error Information for Oracle Net Services

Tracing produces a detailed sequence of statements that describe network events as they are run. Tracing an operation enables you to obtain more information about the internal operations of the components of Oracle Net Services than is provided in a log file.

This information is output to files that can be evaluated to identify the events that led to an error.

Tracing uses a large amount of disk space and may have a significant impact upon system performance. Therefore, you should enable tracing only when necessary.

- Understanding Oracle Net Services Trace File Names
- · Setting Tracing Parameters
- Setting Tracing During Control Utilities Runtime
- Evaluating Oracle Net Services Trace Files
- Using the Trace Assistant to Examine Trace Files

16.7.1 Understanding Oracle Net Services Trace File Names

Each Oracle Net Services component produces its own trace file. Table 16-18 provides the default trace file names and lists the components that generate the trace files.

Table 16-18 Trace Files Names

Trace File	Component
instance-name_pid.trc	Oracle Connection Manager listener
instance-name_cmgw_pid.trc	Oracle Connection Manager CMGW process
instance-name_cmadmin_pid.trc	Oracle Connection Manager CMADMIN process
listener.trc	Listener
sqlnet.trc	Client
svr_pid.trc	Database server
tnsping.trc	TNSPING utility

16.7.2 Setting Tracing Parameters

Parameters that control tracing, including the type and amount of information trace, and the location where the files are stored, are set in the configuration file of each network component as described in Table 16-19.

Table 16-19 Location of Trace Parameters

Configuration File	Component
cman.ora	Oracle Connection Manager processes
listener.ora	Listener
sqlnet.ora	Client
	Database server
	TNSPING utility

This section contains the following topics:

cman.ora Trace Parameters

Review the trace parameter settings for Oracle Connection Manager that can be set in the cman.ora file.

listener.ora Trace Parameters

Review the trace parameter settings for the listener that can be set in the listener.ora file.

sglnet.ora Trace Parameters

Review the trace parameter settings that can be set in the sqlnet.ora file.

Setting Tracing Parameters in Configuration Files

Oracle Database Net Services Reference for additional information about these parameters

16.7.2.1 cman.ora Trace Parameters

Review the trace parameter settings for Oracle Connection Manager that can be set in the cman.ora file.

Table 16-20 cman.ora Trace Parameters

cman.ora Parameter	Description
TRACE_DIRECTORY	The destination directory for trace files. By default, the directory is ORACLE_HOME/network/trace.
TRACE_FILELEN	The size of the trace file in KB. When the size is reached, the trace information is written to the next file. The number of files is specified with the TRACE_FILENO parameter.

Table 16-20 (Cont.) cman.ora Trace Parameters

cman.ora Parameter	Description			
TRACE_FILENO	The number of trace files for tracing. When this parameter is set along with the <code>TRACE_FILELEN</code> parameter, trace files are used in a cyclical fashion. The first file is filled, then the second file, and so on. When the last file has been filled, the first file is reused, and so on.			
	The trace file names are distinguished from one another by their sequence number. For example, if this parameter is set to 3, then the Oracle Connection Manager trace files for the gateway processes would be named <code>instance-name_cmgw1_pid.trc</code> , <code>instance-name_cmgw2_pid.trc</code> and <code>instance-name_cmgw3_pid.trc</code> .			
	In addition, trace events in the trace files are preceded by the sequence number of the file.			
TRACE_LEVEL	The level of detail the trace facility records for the listener. Specify one of the following trace level values:			
	off (equivalent to 0) provides no tracing.			
	 user (equivalent to 4) traces to identify user-induced error conditions. 			
	 admin (equivalent to 10) traces to identify installation-specific problems. 			
	 support (equivalent to 16) provides trace information for troubleshooting by Oracle Support Services. 			
	The Oracle Connection Manager listener, gateway, and CMADMIN processes create trace files on both Linux and Microsoft Windows.			
TRACE_TIMESTAMP	If the TRACING parameter is enabled, then a time stamp in the form of dd -mon-yyyy $hh:mi:ss:mil$ is created for every trace event in the listener trace file.			

16.7.2.2 listener.ora Trace Parameters

Review the trace parameter settings for the listener that can be set in the listener.ora file.

Table 16-21 listener.ora Trace Parameters

listener.ora Parameter	Oracle Enterprise Manager Cloud Control/Oracle Net Manager Field	Description
TRACE_LEVEL_listener_ name	Select a trace level/ Trace Level	 The level of detail the trace facility records for the listener. The trace level value can either be a value within the range of 0 (zero) to 16 where 0 is no tracing and 16 represents the maximum amount of tracing or one of the following values: off (equivalent to 0) provides no tracing. user (equivalent to 4) traces to identify user-induced error conditions. admin (equivalent to 6) traces to identify installation-specific problems. support (equivalent to 16) provides trace information for troubleshooting by Oracle Support Services.

Table 16-21 (Cont.) listener.ora Trace Parameters

listener.ora Parameter	Oracle Enterprise Manager Cloud Control/Oracle Net Manager Field	Description
TRACE_DIRECTORY_liste ner_name TRACE_FILE_listener_n ame	Trace File	The destination directory and file for the trace file. By default, the directory is <code>ORACLE_HOME/network/trace</code> , and the file name is <code>listener.trc</code> .
TRACE_FILEAGE_listene r_name	You must set this parameter manually.	The maximum age of listener trace files in minutes. When the age limit is reached, the trace information is written to the next file. The number of files is specified with the TRACE_FILENO_listener_name parameter.
TRACE_FILEAGE_SERVER	You must set this parameter manually.	Specifies the maximum age of server trace files in minutes. When the age limit is reached, the trace information is written to the next file. The number of files is specified with the TRACE_FILENO_SERVER parameter.
TRACE_FILELEN_listene r_name	You must set this parameter manually.	The size of the listener trace files in KB. When the size is reached, the trace information is written to the next file. The number of files is specified with the <code>TRACE_FILENO_listener_name</code> parameter
TRACE_FILENO_listener _name	You must set this parameter manually.	The number of trace files for listener tracing. When this parameter is set along with the <code>TRACE_FILELEN_listener_name</code> parameter, trace files are used in a cyclical fashion. The first file is filled, then the second file, and so on. When the last file has been filled, the first file is re-used, and so on.
		The trace file names are distinguished from one another by their sequence number. For example, if the default trace file of listener.trc is used, and this parameter is set to 3, then the trace files would be named listener1.trc, listener2.trc and listener3.trc.
		In addition, trace events in the trace files are preceded by the sequence number of the file.
		When this parameter is set with the <code>TRACE_FILEAGE_listener_name</code> parameter, trace files are cycled based on the age of the trace file. The first file is used until the age limit is reached, then the second file is use, and so on. When the last file's age limit is reached, the first file is re-used, and so on.
		When this parameter is set with both the TRACE_FILELEN_listener_name and TRACE_FILEAGE_listener_name parameters, trace files are cycled when either the size limit or the age limit is reached.
TRACE_TIMESTAMP_liste ner_name	You must set this parameter manually.	A time stamp in the form of dd-mon-yyyy hh:mi:ss:mil for every trace event in the listener trace file.

16.7.2.3 sqlnet.ora Trace Parameters

Review the trace parameter settings that can be set in the sqlnet.ora file.

Table 16-22 sqlnet.ora Trace Parameters

sqlnet.ora Parameter	Oracle Net Manager Field	Description
TRACE_DIRECTORY_CLIENT	Client Information: Trace Directory	The destination directory for the client trace output. By default, the client directory is <code>ORACLE_HOME/network/trace</code> .
TRACE_DIRECTORY_SERVER	Server Information: Trace Directory	The destination directory for the database server trace output. By default, the server directory is <code>ORACLE_HOME/network/trace</code> .
TRACE_FILE_CLIENT	Client Information: Trace File	The name of the trace file for the client. By default, the trace file name is sqlnet.trc.
TRACE_FILE_SERVER	Server Information: Trace File	The name of the trace file for the database server. By default the trace file name is $svr_pid.trc$.
TRACE_FILEAGE_CLIENT	You must set this parameter manually.	Specifies the maximum age of client trace files in minutes. When the age limit is reached, the trace information is written to the next file. The number of files is specified with the TRACE_FILENO_CLIENT parameter.
TRACE_FILEAGE_SERVER	You must set this parameter manually.	Specifies the maximum age of server trace files in minutes. When the age limit is reached, the trace information is written to the next file. The number of files is specified with the TRACE_FILENO_SERVER parameter.
TRACE_FILELEN_CLIENT	You must set this parameter manually.	The size of the client trace files in KB. When the size is reached, the trace information is written to the next file. The number of files is specified with the <code>TRACE_FILENO_CLIENT</code> parameter.
TRACE_FILELEN_SERVER	You must set this parameter manually.	The size of the database server trace files in KB. When the size is reached, the trace information is written to the next file. The number of files is specified with the TRACE_FILENO_SERVER parameter.

Table 16-22 (Cont.) sqlnet.ora Trace Parameters

sqlnet.ora Parameter	Oracle Net Manager Field	Description
TRACE_FILENO_CLIENT	You must set this parameter manually.	The number of trace files for client tracing. When this parameter is set along with the TRACE_FILELEN_CLIENT parameter, trace files are used in a cyclical fashion. The first file is filled, then the second file, and so on. When the last file has been filled, the first file is re-used, and so on.
		The trace file names are distinguished from one another by their sequence number. For example, if the default trace file of sqlnet.trc is used, and this parameter is set to 3, then the trace files would be named sqlnet1_pid.trc, sqlnet2_pid.trc and sqlnet3_pid.trc.
		In addition, trace events in the trace files are preceded by the sequence number of the file.
		When this parameter is set with the TRACE_FILEAGE_CLIENT parameter, trace files are cycled based on the age of the trace file. The first file is used until the age limit is reached, then the second file is use, and so on. When the last file's age limit is reached, the first file is reused, and so on.
		When this parameter is set with both the TRACE_FILELEN_CLIENT and TRACE_FILEAGE_CLIENT parameters, trace files are cycled when either the size limit or age limit is reached.
TRACE_FILENO_SERVER	You must set this parameter manually.	The number of trace files for database server tracing. When this parameter is set along with the <code>TRACE_FILELEN_SERVER</code> parameter, trace files are used in a cyclical fashion. The first file is filled, then the second file, and so on. When the last file has been filled, the first file is re-used, and so on.
		The trace file names are distinguished from one another by their sequence number. For example, if the default trace file of svr_pid.trc is used, and this parameter is set to 3, then the trace files would be named svr1_pid.trc, svr2_pid.trc and svr3_pid.trc.
		In addition, trace events in the trace files are preceded by the sequence number of the file.
		When this parameter is set with the TRACE_FILEAGE_SERVER parameter, trace files are cycled based on the age of the trace file. The first file is used until the age limit is reached, then the second file is use, and so on. When the last file's age limit is reached, the first file is reused, and so on.
		When this parameter is set with both the TRACE_FILELEN_SERVER and TRACE_FILEAGE_SERVER parameters, trace files are cycled when either the size limit or age limit is reached.

Table 16-22 (Cont.) sqlnet.ora Trace Parameters

sqlnet.ora Parameter	Oracle Net Manager Field	Description		
TRACE_LEVEL_CLIENT	Client Information: Trace	The level of detail the trace facility records for the client.		
	Level	The trace level value can either be a value within the range of 0 (zero) to 16 where 0 is no tracing and 16 represents the maximum amount of tracing or one of the following values:		
		 off (equivalent to 0) provides no tracing. 		
		 user (equivalent to 4) traces to identify user-induced error conditions. 		
		 admin (equivalent to 6) traces to identify installation- specific problems. 		
		 support (equivalent to 16) provides trace information for troubleshooting by Oracle Support Services. 		
TRACE_LEVEL_SERVER	Server Information: Trace Level	The level of detail the trace facility records for the database server. The trace level value can either be a value within the range of 0 (zero) to 16 where 0 is no tracing and 16 represents the maximum amount of tracing or one of the following values:		
		 off (equivalent to 0) provides no tracing. 		
		 user (equivalent to 4) traces to identify user-induced error conditions. 		
		 admin (equivalent to 6) traces to identify installation- specific problems. 		
		 support (equivalent to 16) provides trace information for troubleshooting by Oracle Support Services. 		
TRACE_TIMESTAMP_CLIENT	You must set this parameter manually.	A time stamp in the form of dd-mon-yyyy hh:mi:ss:mil for every trace event in the client trace file, sqlnet.trc.		
TRACE_TIMESTAMP_SERVER	You must set this parameter manually.	A time stamp in the form of dd-mon-yyyy hh:mi:ss:mil for every trace event in the client trace file, sqlnet.trc.		
TRACE_UNIQUE_CLIENT	Client Information: Unique Trace File Name	When the value is set to on, Oracle Net creates a unique file name for each trace session by appending a process identifier to the name of each trace file generated, and enabling several files to coexist. For example, trace files named $sqlnetpid.trc$ are created if default trace file name $sqlnet.trc$ is used. When the value is set to off, data from a new client trace session overwrites the existing file.		

You can manually add the TNSPING utility tracing parameters described in Table 16-23 to the sqlnet.ora file. The TNSPING utility determines whether a service, such as a database or other TNS services on an Oracle Net network can be successfully reached.

Table 16-23 TNSPING Trace Parameters

sqlnet.ora Parameter	Description
TNSPING.TRACE_DIRECTOR Y	The destination directory for TNSPING trace file, tnsping.trc. By default, the directory is ORACLE HOME/network/trace.

Table 16-23 (Cont.) TNSPING Trace Parameters

sqlnet.ora Parameter	Description
TNSPING.TRACE_LEVEL	The level of detail the trace facility records for the TNSPING utility. The trace level value can either be a value within the range of 0 (zero) to 16 where 0 is no tracing and 16 represents the maximum amount of tracing or one of the following values:
	 off (equivalent to 0) provides no tracing.
	 user (equivalent to 4) traces to identify user-induced error conditions.
	 admin (equivalent to 6) traces to identify installation-specific problems.
	 support (equivalent to 16) provides trace information for troubleshooting by Oracle Support Services.

16.7.2.4 Setting Tracing Parameters in Configuration Files

Configure tracing parameters for the sqlnet.ora file with Oracle Net Manager and listener.ora file with either Oracle Enterprise Manager Cloud Control or Oracle Net Manager. You must manually configure cman.ora file tracing parameters.

- Setting Tracing Parameters for sqlnet.ora File Using Oracle Net Manager
- Setting Tracing Parameters for the Listener Using Oracle Enterprise Manager Cloud Control
- Setting Tracing Parameters for the Listener Using Oracle Net Manager

16.7.2.4.1 Setting Tracing Parameters for sqlnet.ora File Using Oracle Net Manager

The following procedure describes how to set the tracing parameters for the sqlnet.ora file using Oracle Net Manager:

Start Oracle Net Manager.

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, expand **Profile** under the Local heading.
- 3. From the list in the right pane, select **General**.
- Click the Tracing tab.
- Specify the settings.
- 6. Choose Save Network Configuration from the File menu.

The name of the trace file for the client is sqlnet.trc. The name of the trace file for the server is svr pid.trc.

16.7.2.4.2 Setting Tracing Parameters for the Listener Using Oracle Enterprise Manager Cloud Control

The following procedure describes how to set the tracing parameters for the listener using Oracle Enterprise Manager Cloud Control:

1. Access the Net Services Administration page in Oracle Enterprise Manager Cloud Control.

"Using Oracle Enterprise Manager Cloud Control to Configure Oracle Net Services"

- Select Listeners from the Administer list, and then select the Oracle home that contains the location of the configuration files.
- Click Go to display the Listeners page.
- 4. Select a listener, and then click **Edit** to display the Edit Listeners page.
- 5. Click the Logging & Tracing tab.
- Specify the settings.
- Click OK.

The name of the trace file is listener.trc.

16.7.2.4.3 Setting Tracing Parameters for the Listener Using Oracle Net Manager

The following procedure describes how to set the tracing parameters for the listener using Oracle Net Manager:

Start Oracle Net Manager.

"Using Oracle Net Manager to Configure Oracle Net Services"

- 2. In the navigator pane, expand **Listeners** from the Local heading.
- Select a listener.
- 4. From the list in the right pane, select **General**.
- Click the Logging and Tracing tab.
- Specify the settings.
- Choose Save Network Configuration from the File menu.

16.7.3 Setting Tracing During Control Utilities Runtime

You can set tracing during control utility runtime. Setting tracing with a control utility does not set parameters in the *.ora files. The setting is only valid for the session of the control utility:

- For the listener, use the SET TRC_DIRECTORY, SET TRC_FILE, and SET TRC_LEVEL
 commands from the Listener Control utility.
- For Oracle Connection Manager, use the SET TRACE_DIRECTORY and SET TRACE_LEVEL, and SET TRACE TIMESTAMP commands from the Oracle Connection Manager control utility.

16.7.4 Evaluating Oracle Net Services Trace Files

Trace files can help Oracle Support Services diagnose and troubleshoot network problems. This section explains how to perform basic analysis of trace files.

- Flow of Data Packets Between Network Nodes
- Oracle Net Data Packet Formats
- Pertinent Oracle Net Trace Error Output
 When there is a problem, the error code is logged to the trace file. This example illustrates a typical trace file output for a failed SQL*Plus connection to the database server.

16.7.4.1 Flow of Data Packets Between Network Nodes

Oracle Net performs its functions by sending and receiving data packets. You can view the actual contents of the Oracle Net packet in your trace file by specifying a trace level of support. The order of the packet types sent and received help to determine how the connection was established.

16.7.4.2 Oracle Net Data Packet Formats

Each line in the trace file begins with a procedure followed by a message. Following each procedure is a line of hexadecimal data representing actual data. The actual data that flows inside the packet is sometimes viewable to the right of the hexadecimal data.

Each packet has a keyword that denotes the packet type. All packet types begin with the prefix "nsp". This is helpful when reviewing trace files for specific packet information. The following keywords are used in a trace file:

- NSPTCN: Used with connect packet types.
- NSPTAC: Used with accept packet types.
- NSPTRF: Used with refuse packet types.
- NSPTRS: Used with resend packet types.
- NSPTDA: Used with data packet types.
- NSPCNL: Used with control packet types.
- NSPTMK: Used with marker packet types.

Example 16-13 shows typical packet information. In the example, the nscon procedure sends an NSPTCN packet over the network.

Example 16-13 Packet Information

```
nscon: entry
nscon: doing connect handshake...
nscon: sending NSPTCN packet
nspsend: entry
nspsend: plen=187, type=1
nspsend: 187 bytes to transport
nspsend:packet dump
```

```
nspsend:00 BB 00 00 01 00 00 00 |.....

```

Note:

An operating system error code appears in the error stack. Each operating system has its own error codes, refer to your system documentation for information about operating system error codes.

The most efficient way to evaluate error codes is to find the most recent nserror entry logged, as the session layer controls the connection. The most important error messages are the ones at the bottom of the file. They are the most recent errors and the source of the problem with the connection.

For information about the specific return codes, use the Oracle error tool oerr, by entering the following at any command line:

```
oerr tns error number
```

As an example, consider the following nserror entry logged in the trace file shown in Example 16-14:

```
[22-MAY-2022 13:35:09:625] nserror: nsres: id=0, op=68, ns=12537, ns2=12560; nt[0]=507, nt[1]=0, nt[2]=0; ora[0]=0, ora[1]=0, ora[2]=0
```

In the preceding example, the main TNS error is 12537, and its secondary error is 12560. The protocol adapter error is 507. Using oerr, you can find out more information about return codes 12537, 12560, and 507. User input is shown in bold in the following examples.

```
oerr tns 12537
12537, 00000, "TNS:connection closed"
// *Cause: "End of file" condition has been reached; partner has disconnected.
// *Action: None needed; this is an information message.
oerr tns 12560
12560, 00000, "TNS:Database communication protocol error."
// *Cause: A lower level communication protocol adapter error occurred.
// *Action:
   - Check for lower level network transport errors in the error stack
       for additional information.
     - Ensure the protocol specification used in the address for the
      connection is correct.
    - For further details, turn on network tracing and rerun the
      operation. Turn off tracing when the operation is complete.
     - Contact Oracle Support.
oerr tns 507
00507, 00000, "Connection closed"
// *Cause: Normal "end of file" condition has been reached; partner has
// disconnected.
// *Action: None needed; this is an information message.
```

16.7.5 Using the Trace Assistant to Examine Trace Files

Oracle Net Services provides a tool called the **Trace Assistant** to help understand the information provided in trace files by converting existing lines of trace file text into a more readable paragraph. The Trace Assistant works only with level 16 (support) Oracle Net Services trace files.

The Trace Assistant can only be used when the DIAG_ADR_ENABLED parameter is set to off. See "Understanding Automatic Diagnostic Repository".

Trace Assistant Syntax

To run the Trace Assistant, enter the treasst command at the command line.

Packet Examples

Trace Assistant enables you to view data packets from both the Oracle Net and TTC communication layers.

Two-Task Common (TTC) Packet Examples

TTC handles requests, such as open cursor, select rows, and update rows that are directed to the database server.

Connection Example

These are the sample outputs using the treasst -la and -li options.

Statistics Example

16.7.5.1 Trace Assistant Syntax

To run the Trace Assistant, enter the treasst command at the command line.

trcasst [options] filename

Table 16-24 Trace Assistant Syntax Options

Option	Description
-elevel	Displays error information. After the -e, use 0, 1, or 2 error decoding level may follow:
	• 0 or nothing translates the NS error numbers dumped from the nserror function plus lists all other errors
	1 displays only the NS error translation from the nserror function
	2 displays error numbers without translation
-la	If a connection ID exists in the NS connect packet, then the output displays the connection IDs. Connection IDs are displayed as hexadecimal, eight-byte IDs. A generated ID is created by Trace Assistant if the packet is not associated with any connection, that is, the connect packet is overwritten in the trace file. This can occur with cyclic trace files.
	For each ID, the output lists the following:
	Socket ID, if the connection has one.
	Connect packet send or receive operation.
	 Current setting of the MULTIPLEX attribute of the DISPATCHERS parameter in the initialization parameter file. When MULTIPLEX is set to ON, session multiplexing is enabled.
	Session ID, if MULTIPLEX is set to ON.
	Connect data information.
	Notes:
	Do not use this option with other options.
	 The IDs generated by the Trace Assistant do not correlate with client/server trace files.
-li ID	Displays the trace for a particular ID from the -la output
	Note: Only use this option with output from the -la option.
-otype	Displays the amount and type of information to be output. After the -o the following options can be used:
	c to display summary connectivity information.
	• d to display detailed connectivity information.
	 u to display summary Two-Task Common (TTC) information.
	t to display detailed TTC information.
	• q to display SQL commands enhancing summary TTC information. Use this option with u, such as $-ouq$.
	Note: As output for d contains the same information as displayed for c, do not submit both c and d. If you submit both, then only output d is processed.

Table 16-24 (Cont.) Trace Assistant Syntax Options

Option	Description
-s	Displays the following statistical information:
	Total number of bytes sent and received.
	Maximum open cursors.
	Currently open cursors.
	Count and ratio of operations.
	 Parsing and execution count for PL/SQL.
	Total calls sent and received.
	 Total, average, and maximum number of bytes sent and received.
	 Total number of transports and sessions present.
	Timestamp information, if any.
	Sequence numbers, if any.

If no options are provided, then the default is -odt -e0 -s, which provides detailed connectivity and TTC events, error level zero (0), and statistics in the trace file.

The following example shows how the Trace Assistant converts the trace file information into a more readable format using the -e1 option.

Example 16-15 trcasst -e1 Output

```
******************
                         Trace Assistant
   ******************
ntus2err: exit

-<ERROR>- nserror: nsres: id=0, op=65, ns=12541, ns2=12560; nt[0]=511, nt[1]=2, nt[2]=0
Error found. Error Stack follows:
            id:0
 Operation code:65
     NS Error 1:12541
     NS Error 2:12560
NT Generic Error:511
 Protocol Error:2
       OS Error:0
NS & NT Errors Translation
12541, 00000 "TNS:Cannot connect. No listener at %s."
 // *Cause: The connection request could not be completed because either the
 // database listener process was not running on the specified host
 // and port, or an Interprocess Communication (IPC) protocol
 \ensuremath{//} connection was attempted but there was no listener for the
 // specified key running on the local machine. PL/SQL applications
 // using UTL packages can also get this error if the external server
 // process is not listening on the specified address.
 // *Action:
 // - If the error shows the host and port that the connection tried to
 //
    use, then ensure that a listener process is running on that host
 //
    and is listening on that port. If the message indicates that there
 //
    was no listener at the specified key, then ensure that the listener
 //
     is running on the local machine and listening for the specified
      key. The listener process is used to initially handle all
```

```
connections to Oracle Database.
// - Check for mistakes in the specified connection string.
// - If you are using an alias from a thsnames.ora file, then verify
     the correctness of the host and port. Alternatively, verify the
     correctness of the key if you are using an IPC connection.
//\,\, - If using an Easy Connect connection string, then ensure that the
     host and port are correct.
// - Use lsnrctl to check that the listener is running and to verify
     the port or key it listens to. Run one of the following:
       * lsnrctl status
//
//
       * Or, when a listener is named in the listener.ora file, run:
//
                  lsnrctl status <listener name>
//
        * Or, if an Oracle Connection Manager (Oracle CMAN) proxy
//
                  listener is named in the cman.ora file, run:
//
                  cmctl show status -c <cman name>
12560, 00000 "TNS:Database communication protocol error."
// *Cause: A lower level communication protocol adapter error occurred.
// *Action:
// - Check for lower level network transport errors in the error stack
    for additional information.
// - Ensure the protocol specification used in the address for the
// connection is correct.
//\,\, - For further details, turn on network tracing and rerun the
    operation. Turn off tracing when the operation is complete.
// - Contact Oracle Support.
00511, 00000 "No listener"
// *Cause: The connect request could not be completed because no application
// is listening on the address specified, or the application is unable to
// service the connect request in a sufficiently timely manner.
// *Action: Ensure that the supplied destination address matches one of
// the addresses used by the listener - compare the TNSNAMES.ORA entry with
// appropriate LISTENER.ORA file (or TNSNAV.ORA if the connection is to go
// by way of an Interchange. Start the listener on the remote machine.
********************
                      Trace Assistant has completed
```

However, other errors may also exist within the trace file that were not logged from the nserror function.

16.7.5.2 Packet Examples

Trace Assistant enables you to view data packets from both the Oracle Net and TTC communication layers.

You can view the packets using the following options:

- Summary connectivity (using option -oc)
- Detailed connectivity (using option -od)

Example 16-16 shows summary information from the -oc option.

Example 16-16 Summary Information from treasst -oc Output

```
---> Send 198 bytes - Connect packet
Connect data length: 140
Connect Data:
    (DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=sales-server)(PORT=1521))
    (CONNECT DATA=(SERVICE NAME=sales.us.example.com) (CID=(PROGRAM=)
    (HOST=sales-server)(USER=joe))))
<--- Received 76 bytes - Redirect packet
Redirect data length: 66
Redirect Data:
   (ADDRESS=(PROTOCOL=tcp) (HOST=sales-server) (PORT=1521))
---> Send 198 bytes - Connect packet
Connect data length: 140
Connect Data:
   (DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=sales-server)(PORT=1521))
   (CONNECT DATA=(SERVICE NAME=sales.us.example.com)(CID=(PROGRAM=)
   (HOST=sales-server) (USER=joe))))
<--- Received 32 bytes - Accept packet
Connect data length: 0
---> Send 153 bytes - Data packet
      Native Services negotiation packet
<--- Received 127 bytes - Data packet
      Native Services negotiation packet
---> Send 32 bytes - Data packet
<--- Received 140 bytes - Data packet
   Trace Assistant has completed
   **********************
```

The packets being sent or received have a prefix of ---> Send nnn bytes or <--- Received nnn bytes showing that this node is sending or receiving a packet of a certain type and with nnn number of bytes. This prefix enables you to determine if the node is the client or the database server. The connection request is always sent by the client, and received by the database server or listener.

Example 16-17 shows detailed information from the -od option. The output shows all of the details sent along with the connect data in negotiating a connection.

Example 16-17 Detailed Information from treasst -od Output

16.7.5.3 Two-Task Common (TTC) Packet Examples

TTC handles requests, such as open cursor, select rows, and update rows that are directed to the database server.

All requests are answered by the database server. If you request to log on, then a response is returned from the database server that the request was completed.

Summary information for TTC from the -ou option is different from other displays in that it shows two packets on each line, rather than one. This is done to mirror the request/response pairings process by which TTC operates.

Output is displayed in the following format:

description TTC_message cursor_number SQL_statement bytes_sent bytes_received

Example 16-18 shows all of the details sent along with the connect data in negotiating a connection.

Example 16-18 treasst -ou Output

Example 16-20 shows detailed SQL information from the <code>-ouq</code> option. On each line of the output, the first item displayed is the actual request made. The second item shows on what cursor that operation has been performed. The third item is either a listing of the SQL command or flag that is being answered. The number of bytes sent and received are displayed at the far right. A flag can be one of the following:

- !PL/SQL = Not a PL/SQL request
- COM = Commit
- IOV = Get I/O Vector
- DEFN = Define
- EXEC = Execute
- FETCH = Fetch
- CAN = Cancel
- DESCSEL = Describe select
- DESCBND = Describe Bind
- BND = Bind
- PARSE = Parse
- EXACT = Exact

16.7.5.4 Connection Example

These are the sample outputs using the treasst -la and -li options.

Example 16-21 shows output from the -la option. The output shows the following information:

- Connect IDs received
- Socket ID for the connection
- Operation
 - Receive identifies the trace as a database server trace. In this example, Receive is the operation.
 - Send identifies the trace as a client trace.
- MULTIPLEX attribute of the DISPATCHERS parameter is set to ON
- 32-bit session ID
- Connect data information received

Example 16-21 trcasst -la Output

```
******************
                           Trace Assistant
Connection ID: 00000B27000000B

16.7.5.5 Statistics Example

The type of statistics gathered is approximately the number of TTC calls, packets, and bytes sent and received between the network partners. Example 16-23 shows typical trace file statistics from the -s option.

Example 16-23 treasst -s Output

```
Trace File Statistics:
_____
Total number of Sessions: 3
DATABASE:
 Operation Count: 0 OPENS, 21 PARSES, 21 EXECUTES,
                                                                  9 FETCHES
   Parse Counts:

9 PL/SQL, 9 SELECT, 0 INSERT, 0 UPDATE, 0 DELETE,
0 LOCK, 3 TRANSACT, 0 DEFINE, 0 SECURE, 0 OTHER
   Execute counts with SQL data:

9 PL/SQL, 0 SELECT, 0 INSERT, 0 UPDATE, 0 DELETE,
0 LOCK, 0 TRANSACT, 0 DEFINE, 0 SECURE, 0 OTHER
 Packet Ratio: 6.142857142857143 packets sent per operation
 Currently opened Cursors: 0
 Maximum opened Cursors : 0
ORACLE NET SERVICES:
 Total Calls : 129 sent, 132 received, Total Bytes : 15796 sent, 13551 received
                                       132 received, 83 oci
   Average Bytes: 122 sent per packet, 102 received per packet Maximum Bytes: 1018 sent, 384 received
  Grand Total Packets: 129 sent, 132 received

16.8 Contacting Oracle Support Services

Some messages recommend contacting Oracle Support Services to report a problem. When you contact Oracle Support Services, have this information available.

- The hardware, operating system, and release number of the operating system running Oracle Database.
- The complete release number of Oracle Database, such as release 23.4.0.0.0.
- All Oracle programs (with release numbers) in use when the error occurred, such as SQL*Plus release 23.4.0.0.0.
- If you encountered one or more error codes or messages, then the exact code numbers and message text, in the order in which they appeared.
- The problem severity, according to the following codes:
 - 1: Program not usable. Critical effect on operations.
 - 2: Program usable. Operations severely restricted.
 - 3: Program usable with limited functions. Not critical to overall operations.
 - 4: Problem circumvented by customer. Minimal effect, if any, on operations.

You will also be expected to provide the following:

- Your name
- The name of your organization
- Your Oracle Support ID number

Your telephone number
