# About This Document

## Scope

The scope of this document includes all the information required to install, configure and administer the Voucher and Wallet Server (VWS) application.

## Audience

This guide was written primarily for system administrators and persons installing, configuring and administering the VWS application. However, sections of the document may be useful to anyone requiring an introduction to the application.

## Prerequisites

Although there are no prerequisites for using this guide, familiarity with the target platform would be an advantage.

A solid understanding of UNIX and a familiarity with IN concepts are an essential prerequisite for safely using the information contained in this technical guide. Attempting to install, remove, configure or otherwise alter the described system without the appropriate background skills, could cause damage to the system; including temporary or permanent incorrect operation and complete loss of service.

This manual describes system tasks that should only be carried out by suitably trained operators.

## Related Documents

The following documents are related to this document:

- *Service Logic Execution Environment Technical Guide*
- *Service Management System Technical Guide*
- *Service Management System User's Guide*
- *Event Detail Record Reference Guide*

If this Voucher and Wallet Server is installed with Charging Control Services, these documents are also related to this document:

- *Charging Control Services Technical Guide*
- *Charging Control Services User's Guide*
- *Feature Nodes Reference Guide*

# Document Conventions

## Typographical Conventions

The following terms and typographical conventions are used in the Oracle Communications Convergent Charging Controller documentation.

Formatting Convention	Type of Information
<b>Special Bold</b>	Items you must select, such as names of tabs. Names of database tables and fields.
<i>Italics</i>	Name of a document, chapter, topic or other publication. Emphasis within text.
<b>Button</b>	The name of a button to click or a key to press. <b>Example:</b> To close the window, either click <b>Close</b> , or press <b>Esc</b> .
<b>Key+Key</b>	Key combinations for which the user must press and hold down one key and then press another. <b>Example:</b> <b>Ctrl+P</b> or <b>Alt+F4</b> .
Monospace	Examples of code or standard output.
<b>Monospace Bold</b>	Text that you must enter.
<i>variable</i>	Used to indicate variables or text that should be replaced with an actual value.
<b>menu option &gt; menu option &gt;</b>	Used to indicate the cascading menu option to be selected. <b>Example:</b> <b>Operator Functions &gt; Report Functions</b>
<a href="#">hypertext link</a>	Used to indicate a hypertext link.

Specialized terms and acronyms are defined in the glossary at the end of this guide.

# System Overview

## Overview

### Introduction

This chapter provides a high-level overview of the application. It explains the basic functionality of the system and lists the main components.

It is not intended to advise on any specific Oracle Communications Convergent Charging Controller network or service implications of the product.

### In this Chapter

---

This chapter contains the following topics.

Introduction to VWS.....	1
Wallets, Balances and Buckets .....	4
Request handling.....	7
Data Management .....	17
Synchronization .....	20
Wallet and Bucket Expiry.....	23
BE States.....	26
EDR Processing .....	28
MFile Updates .....	30
Statistics .....	32

## Introduction to VWS

### Introduction

The Voucher and Wallet Server (VWS) provides high-performance, real-time charging and subscriber account management functions.

The VWS solution maintains voucher, wallet and reservation details in the E2BE database on the Voucher and Wallet Server. It enables call processing applications to bill mobile customers.

Billing information is kept logically separate from call processing on the SLCs, allowing it to be used by multiple clients.

### Functions

The role of the VWS is to manage all the billing/charging information associated with call processing.

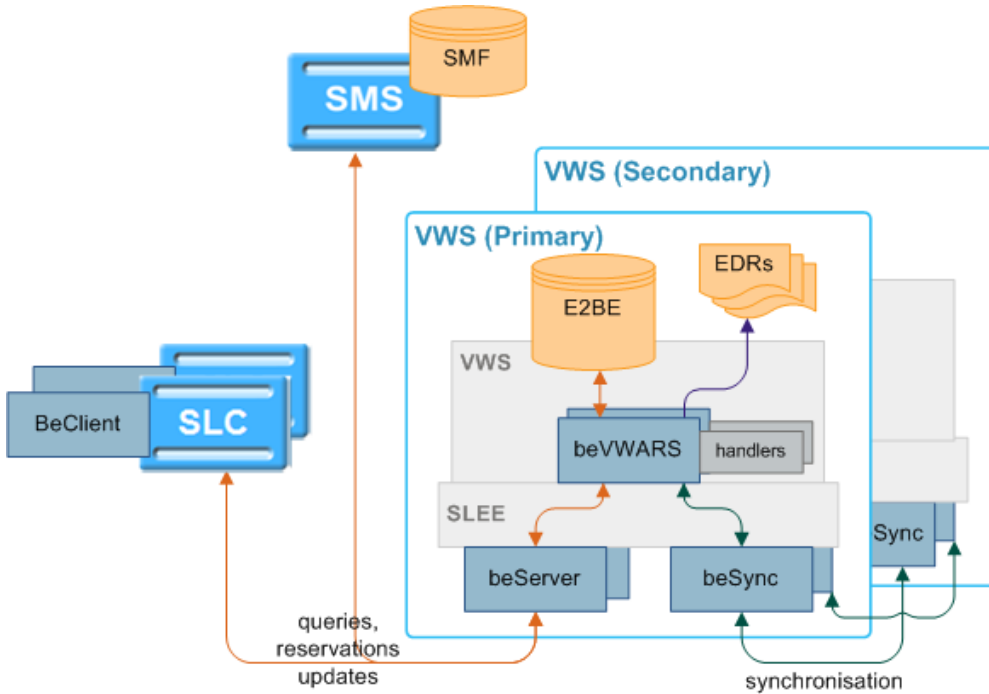

The VWS provides:

- Subscriber account management
- Management of multiple wallets and balance types
- Real-time rating of services
- Structure for tariffing on transactions
- Reservation, debit and credit requests

- Voucher management, including voucher query and redemption requests
- Failover and machine redundancy
- EDRs and EDR archiving

### Main components diagram

This diagram shows the main components of VWS. They mostly run as separate processes on the SLEE, as illustrated below. Their operation needs to be coordinated, as the state of the entire VWS affects their behavior.

### Main components

This table describes the main components in VWS.

Process	Role	Further information
BeClient	The BeClient is a SLEE interface that runs on the SLC and handles any process that uses the libBeClientIF library to connect to the beServer.  The main BeClient is the BeClient provided by VWS for the SLC. (Other applications can provide other processes to handle other activities such as ccsBeOrb, which handles interaction between the SMS UI and the Voucher and Wallet Server nodes.)	BeClient (on page 50)
beServer	Handles connections from client processes (including BeClient processes) and controls routing to beVWARS processes.  You can run more than one beServer process to improve performance on Sun CMT hardware.	beServer (on page 65)
beVWARS	beVWARS is the core of the VWS. More than one beVWARS will usually be running on a VWS. It: <ul style="list-style-type: none"> <li>• Reads and caches wallet and voucher</li> </ul>	beVWARS (on page 92)

Process	Role	Further information
	information from the E2BE database <ul style="list-style-type: none"> <li>• Manages all queries, reservations and updates against wallets</li> <li>• Manages all queries, redemptions and state changes for vouchers</li> <li>• Writes files used to synchronize data</li> <li>• Writes EDRs.</li> </ul>	
beVWARS plug-in handlers	Perform business-case specific operations on wallets and vouchers. Some plug-in handlers are provided by VWS, but other applications can extend VWS logic by providing additional plug-ins. <b>Examples:</b> CCS beVWARS plug-in handlers manage monthly: <ul style="list-style-type: none"> <li>• Spend accumulation and upgrade</li> <li>• Account activation</li> </ul>	<i>beVWARS plugins</i> (on page 7)
beSync	Synchronizes data between the Voucher and Wallet Servers in a VWS pair. You can run more than one beSync process to improve performance on Sun CMT hardware.	<i>beSync</i> (on page 76)
E2BE database	The databases on the VWSs. They hold a subset of the data from the SMF database on SMS.	

## Billing Interfaces

VWS supports external interfaces to bill for third-party services, such as:

- Calling card services
- Data charging services
- SMS charging services
- Universal Parlay Gateway

## VWS Domains

Each VWS domain is made up of a pair of Voucher and Wallet Server. For more information about Voucher and Wallet Server pairs, see *Data redundancy* (on page 17).

Domains can provide a full set of functions, or can be configured to offer a specific set of functions.

Domains are configured in the Service Management screen in CCS. For more information about configuring domains, see *CCS User's Guide*.

## About improving performance

If the VWS server will be processing high volumes of traffic, you can improve performance by configuring the SLEE to run multiple instances of the beServer and beSync processes. Running multiple instances of these processes enables the VWS server to load-share:

- beServer client connections over multiple process spaces
- beSync synchronization connections over multiple process spaces

For information on configuring beServer, see *beServer* (on page 65). For information on configuring beSync, see *beSync* (on page 76).

**Note:** In the diagrams in the following sections in this guide that show the beServer and beSync processes, only one instance of each is shown.

## Wallets, Balances and Buckets

### Wallets

Each subscriber account is linked to one or two wallets.

A wallet is a group of balances owned by the subscriber and available to pay for prepaid services offered by the platform.

**Example:** A subscriber could have a “General Cash” balance and a “Free Notification” balance in their wallet. Each balance has its own expiry date, which means that any value left in the balance after this date will be removed.

### Wallet states

The wallet has a state which:

- Indicates what phase of the life cycle the associated subscriber account currently is in
- Determines whether the subscriber can use his or her services

This table describes the available wallet states.

State	Description
Pre-use	The first state after the subscriber account/wallet is created.
Active	The state during which normal wallet operations are handled. All services can be used. When a subscriber uses their account for the first time (via any paid service), the wallet moves from the Pre-use state into the Active state. The initial expiry dates for the balances and the wallet are set when the wallet is activated.
Dormant	If the subscriber does not use any services for a configurable period of time, the account/wallet is put in the Dormant state. The Dormant state is useful for reporting inactive subscribers. All services are still accessible.
Frozen	If fraudulent activity is detected on the subscriber account, the subscriber account/wallet is changed into the Frozen state. All services are disabled until manual intervention by an operator.
Suspended	The suspended state can be used by the operator to temporarily disable a subscriber's account.
Terminated	When the wallet's expiry date is reached, the subscriber account/wallet is moved into the terminated state.

**Note:** Wallets may also be affected by expiry dates. For more information about wallet and bucket expiry, see *Wallet and Bucket Expiry* (on page 23).

## Wallet lifecycle

This diagram shows the states in a standard life cycle of a wallet.

## Wallet life cycle plans

A wallet life cycle plan comprises a set of wallet life cycle periods. The plan can be associated with a subscriber's wallet through the subscriber's product type.

The plan is used to extend the existing states of the wallet with customizable sub-states called periods. The beginning of each period can be configured as an offset of days before or after the wallet expiration date. A period ends when the next one, if defined, starts or when the wallet expires.

For each period in the wallet life cycle you can define the features that will be available. This includes:

- Session charges
- Available named event operations
- Enabled general charges and recharges

For information on configuring wallet life cycle plans, see the *Wallet Management* section in *CCS User's Guide*.

## VWS associations

When a wallet is created, it is created on a specific VWS Voucher and Wallet Server pair. This Voucher and Wallet Server pair handles all the updates and information queries for that wallet.

Processes which send a wallet request will usually check to which VWS to send the request before the request is sent. If the wallet request is sent to the wrong VWS, the VWS will return an error.

## Migrating wallets

If the Voucher and Wallet Server (VWS) pair is storing CCS wallets, the wallets can be migrated from one VWS to another using the **UBE Account Balancing** tab. For more information about this tab, see *CCS User's Guide*. For more information about how CCS migrates wallets between VWSs, see *CCS Technical Guide*.

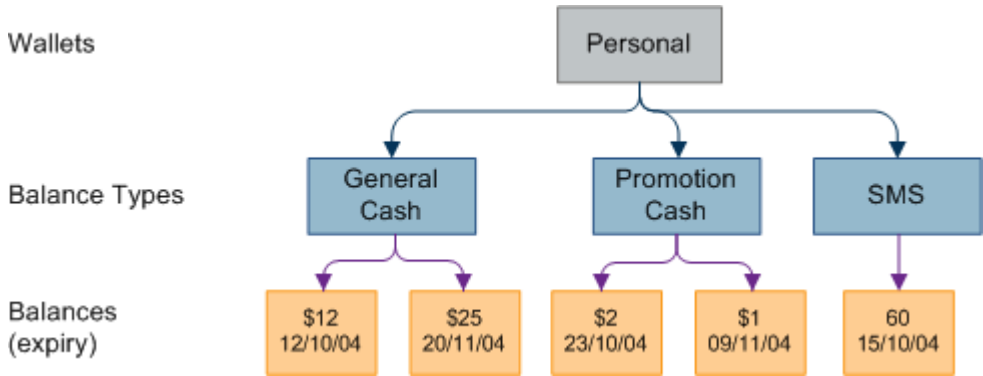

## Balances

Balances record a value in a wallet by collecting buckets into a group. Each bucket records a specific value with an optional expiry date. There are two main types of balances:

- Chargeable balances which record value that can be used for services
- Internal balances which are used for internal values and triggers within the system

### Wallets, balances and buckets relationship

This diagram shows how buckets are collected into a balance value, and balances are connected to a wallet.

**Note:** Internal balances have the same structure.

### Wallet and bucket events

When beVWARS receives a request which involves a wallet, it will load the wallet and all the wallet's buckets. This includes loading a wallet for a query, update or charging operation. When the wallet is loaded, wallet load event plug-ins are triggered. These event plug-ins will take any required actions on the wallets and buckets as necessary.

### Background processing

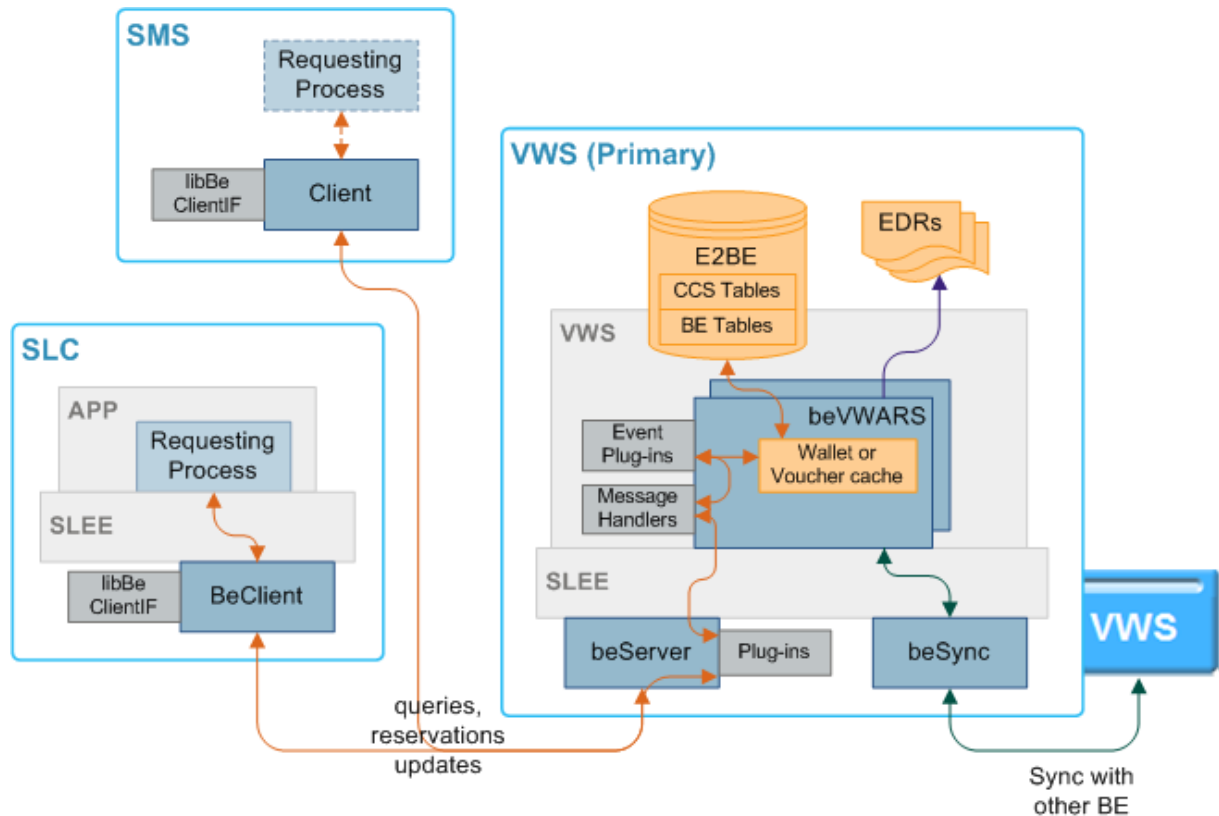

In normal processing, events are triggered only when a subscriber or customer care representative interacts with the wallet. Some events (such as expiries and periodic charges) should be triggered regardless of whether the wallet has been used by a subscriber or customer care representative. In order to process these events, beGroveller sends lists of wallet IDs to beVWARS for processing. This processing triggers any events which are due to occur in the same way a normal interaction would, except wallet events triggered from beGroveller lists do not trigger any message handlers.

For more information about how wallets and buckets are expired, see *Wallet and Bucket Expiry* (on page 23).

## Request handling

### Reservations and billing diagram

This diagram shows how VWS handles requests.

### beVWARS plugins

beVWARS plug-ins can trigger on any event which requires reading data about a wallet or voucher (including maintenance through SMS UI, call charges, or named events).

Because the plug-ins run before the original request is processed, any action such as expiring a bucket or wallet is executed before any charges are applied. This means expired wallets or buckets are never available, even if they still exist in the database.

Applications which are using the VWS for charging or voucher redemption usually provide beVWARS plug-ins to handle the specific application logic required by the application. VWS provides these plug-ins as standard:

- *beVWARSExpiry* (on page 114)
- *beVWARSMergeBuckets* (on page 117)
- *libbeEventFactory* (on page 126)

### Request processing

This table describes how VWS handles requests from service applications.

**Note:** For information about how CCS handles charging for calls or SMS and the CCS plug-ins mentioned in the process, see *CCS Technical Guide*.

Stage	Description
1	<p>Requesting process sends a request to the BeClient process (usually BeClient on the SLC, but also PlbeClient and ccsBeOrb on the SMS).</p> <p><b>Note:</b> Other applications and specific functions can use other BeClient processes, but the ones mentioned are the most common.</p>
2	<p>BeClient process checks for plug-ins to handle this message. Plug-ins are specified in the <code>plugins</code> (on page 57) parameter in <code>eserv.config</code>.</p> <p><b>Example:</b> <code>libBeClientIF</code> (on page 125) will usually be triggered in addition to any application-specific plug-ins such as <code>libccsClientPlugins</code> which applies CCS logic.</p>
3	<p>If the message has a BE ID of 0, <code>libclientBcast</code> will send the request to all VWS Voucher and Wallet Servers to locate the Voucher and Wallet Server which holds the details which are relevant to the request.</p> <p>If the message has a BE ID other than 0, BeClient will send the request to the VWS pair with that id.</p> <p><b>Note:</b> The BE ID of a VWS is set by the <code>serverId</code> (on page 42) parameter.</p> <p><b>Example:</b> If the request is a voucher redeem, the <code>libclientBcast</code> library will cause the BeClient to send a request to all Voucher and Wallet Server pairs to locate the Voucher and Wallet Server pair which holds the data for the voucher which is about to be redeemed.</p>
4	<p><code>beServer</code> receives the request from the BeClient process via FOX over TCP/IP. It determines the message type and checks whether there are any handlers for this message. Handlers are configured in the <code>handlers</code> (on page 69) parameter in <code>eserv.config</code>.</p>
5	<p><code>beServer</code> creates a context to store information for the request. The information includes:</p> <ul style="list-style-type: none"> <li>• The original request</li> <li>• The BeClient</li> <li>• Any message handler that is handling the request</li> <li>• The state the message handler is in</li> <li>• The beVWARS process which will handle the request</li> </ul>
6	<p><code>beServer</code> checks for and executes routing plug-ins configured in the <code>messageRoutingPlugins</code> (on page 70) parameter in <code>eserv.config</code>.</p> <p><b>Note:</b> If this message is part of a sequence (but not the first), <code>beServer</code> will send the message to the same beVWARS as the other parts of the sequence.</p>
7	<p><code>beServer</code> forwards the message across the SLEE to the correct beVWARS.</p>
8	<p>beVWARS determines whether there is a message handler for this message type. Message handlers are configured in the <code>handlers</code> (on page 96) parameter in <code>eserv.config</code>.</p> <p><b>Note:</b> If there is no message handler for this type, beVWARS will log an error.</p>
9	<p>When the initial message handler is triggered, it will query either the wallet or the voucher cache. If the cache does not contain the details or the details in the cache are stale, beVWARS reads the details from the database.</p>
10	<p>Depending on the message type, different event and message plug-ins will be triggered. Plug-ins (including event handlers) are configured in the <code>plugins</code> (on page 98) parameter in <code>eserv.config</code>.</p>

Stage	Description
	<p><b>Example:</b> If a wallet is interacted with, beVWARSExpiry will check the expiry dates on all buckets in the wallet, and will expire any buckets which are overdue. For more information about expiry handling, see <i>Wallet and Bucket Expiry</i> (on page 23).</p> <p><b>Note:</b> At least one plug-in must be provided to process requests from an application which is using VWS for charging. For more information about the specific plug-ins which are triggered, what order they are triggered in, and what they do, see the technical guide for that application.</p>
11	<p>For updates and reservations (but not queries), beVWARS starts the synchronization process by writing the change to the sync files. Synchronization enables the VWS to replay operations in the event of a failure and maintain redundancy in the event of a failure. For more information about how the synchronization process works, see <i>Data synchronization</i>.</p> <p>For updates only, beVWARS also flushes the data. It:</p> <ul style="list-style-type: none"> <li>• Updates the wallet cache from the database</li> <li>• Updates the database (this update will be held in a queue until the next flush of COMMITs to the E2BE database)</li> <li>• Writes the changes to the EDR file (these updates are also queued for bulk writing)</li> </ul> <p><b>Note:</b> The EDRs will be written by the beVWARS which executed the update. This avoids duplicate EDRs being written in the event of a failover.</p> <p>For more information about how beVWARS writes data, see <i>Queuing and flushing updates</i> (on page 18).</p> <p>For more information about EDRs, see <i>EDR Processing</i> (on page 28).</p>
12	beVWARS on the primary VWS sends the acknowledgment back to BeClient via beServer.
13	BeClient passes the acknowledgment back to the requesting process.

## Wallet and voucher caches

beVWARS maintains a wallet cache and a voucher cache to store up to date information about the wallets and vouchers it maintains. beVWARS updates the cache record for a wallet or voucher whenever one of the following occurs:

- Wallet or voucher is queried
- Wallet reservation or update is received
- Voucher is redeemed

A wallet or voucher record is removed from the cache if the record for it expires before a new request for that record is retrieved.

## Supported requests

This table describes the types of messages VWS supports.

Message Type	Code	Description
Initial Reservation	IR	Reserve a charge amount.
Subsequent Reservation	SR	Reserve another charge amount.
Commit Reservation	CR	Apply reserved charge.

Message Type	Code	Description
Revoke Reservation	RR	Abandon a reservation.
Named Event	NE	Attempt to charge a named event.
Named Event Rate	NER	Used by Named Event feature node.
Apply Tariffed Charge	ATC	Used by DUCR feature node.
Initial Named Event Reservation	INER	Attempt to reserve a named event.
Subsequent Named Event Reservation	SNER	Named event reservation which follows on from an Initial Events Reservation (INER).
Confirm Named Event Reservation	CNER	Apply reserved named event.
Revoke Named Event Reservation	RNER	Abandon a named event reservation.
Voucher Information	VI	Query a voucher.
Voucher Update	VU	Update voucher details.
Voucher Redeem	VR	Reserves a voucher.
Commit Voucher Redeem	CVR	Wallet changed successfully, redeem voucher.
Revoke Voucher Redeem	RVR	Abandon a voucher reservation.
Voucher Redeem Wallet	VRW	Tells BeClient to start a Voucher Redemption.
Voucher Type Recharge	VTR	Recharge a wallet using a voucher type name.
Voucher Type Recharge Confirm	VTRC	Perform product type swap.
Wallet General Recharge	WGR	Recharge wallet and buckets.
Wallet Update	WU	Update wallet details (not buckets/balances).
Wallet Create	WC	Create a new wallet.
Wallet Delete	WD	Delete an existing wallet.
Wallet Information	WI	Query a wallet and its buckets/balances.
Bad PIN	BPIN	Increase the Bad PIN balance.
Reload the MFile	LDMF	Reload an updated MFile.

#### walletDeleteBufferSize

**Syntax:** `walletDeleteBufferSize = num`

**Description:** The number of wallet deletes in a buffer before beVWARS will flush it.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 1000

**Notes:**

**Example:** `walletDeleteBufferSize = 1000`

#### walletIds

**Syntax:** `walletIds = [ID1, ID2, ...]`

**Description:** List of subscriber wallet ids we want to trace.

**Type:** Array, Integer

**Optionality:** Optional if beClient parameter supplied, mandatory if beClient not supplied.

**Allowed:** Any valid wallet ID.  
**Default:** None  
**Notes:** To obtain the wallet id(s) for a given CLI/subscriber use the showCLI.sh script on the BE where tracing is to occur.  
**Example:**

```
walletIds = [
    382,
    385
]
```

#### walletLowWaterMark

**Syntax:** `walletLowWaterMark = num`  
**Description:** The number of outstanding wallet IDs to grovel, before sending a request to beGroveler for another batch of wallet IDs to grovel.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 100  
**Notes:**  
**Example:** `walletLowWaterMark = 100`

## Wallets

Each subscriber account is linked to one or two wallets.

A wallet is a group of balances owned by the subscriber and available to pay for prepaid services offered by the platform.

**Example:** A subscriber could have a “General Cash” balance and a “Free Notification” balance in their wallet. Each balance has its own expiry date, which means that any value left in the balance after this date will be removed.

#### writerIfName

**Syntax:** `writerIfName = "name"`  
**Description:** The SLEE name for the VWS component - beWriter.  
**Type:** String  
**Optionality:**  
**Allowed:**  
**Default:** "beWriter"  
**Notes:** For more information about the SLEE, see *SLEE Technical Guide*.  
**Example:** `writerIfName = "beWriter"`

## XmITcap Parameters

beServiceTrigger/XmITcap is configured by the following parameters from the `triggering` section in the `eserv.config` file on the VWS:

```
triggering = {
    Control_Plan = "cpname"
    Service_Handle = "handle"
    scps = [ "ip:port" ]
```

```

}
triggering = {
    Control_Plan = "Reward"
    Service_Handle = "CCS_BPL"
    CCSNamespace = "http://eng-prf-zone01-z1/wsdl/ON/CCSNotifications.wsdl"
    edr = false
    scps = [ "cmxdevscp1:3072", "cmxdevscp2:3072" ]
    osd_scps = [ "cmxdevscp1:3072", "cmxdevscp2:3072" ]
    failureRetryTime = 60
    storageInterface = beEventStorageIF
    triggerInterface = beServiceTrigger
    operationSet = CMX ON
    operation = Invoke OSD
    responseTag = Result
    maxRatePerUAS = 0
    throttleLife = 30
    timeBetweenThrottles 10
} # triggering

```

## Example eserv.config configuration

This is an example of the BE section of an **eserv.config** file (comments have been removed). It is not intended to be used in a production environment, but only to illustrate the configurations available.

Details on the configurations in this file are located in various sections later in this guide.

```

BE = {
    serverId = 11
    amPrimary = true
    oracleUserAndPassword="/"
    beLocationPlugin = "libGetccsBeLocation.so"

    soloBE = true

    timerIfName = "Timer"

    enableGroveling = true

    freeDiskSpaceWarningThres = 100
    freeDiskSpaceShutdownThres = 10
    freeDiskSpaceCheckInterval = 300
    lowDiskSpaceNotificationInterval = 30

    beServer = {
        clientSelectTime = 1000000
        quiesceLength = 100000
        serverPortOverride = 1500
        clientSocketBufferSize = 10240
        maxDownstreamQueueLength = 1000
        downstreamOverloadSleepUSec = 100000
        dbConnCheckTime = 5
        recoveryReportInterval = 60
        shutdownDelayTime = 4
        startupRetryPeriodSeconds = 2

        notEndActions = [
            {type="IR ", action="ACK "}
            {type="SR ", action="ACK "}
            {type="SR ", action="NACK"}
            {type="INER", action="ACK "}
            {type="SNER", action="ACK "}
            {type="SNER", action="NACK"}
        ]
    }
}

```

```

handlers = [
    "libbeServerPingPlugin.so"
]

messageRoutingPlugins = [
    "libbeMsgRouterDefault.so"
]

msgRouterDefault = {
    roundRobinTypes = [
        "VI "
    ]
    routeOnVoucherNumber = true
}

purge = {
    purgeInterval = 300

## Wallet life cycle period checks

Before processing a request, the request handler will check that the corresponding feature in the current wallet life cycle plan period is enabled. If the feature is disabled for the subscriber's wallet, then the request will fail.

This table lists the request handler and the feature it checks for when processing requests.

Request Handler	Wallet Life Cycle Period Features Checked
IR	Session Charge

Request Handler	Wallet Life Cycle Period Features Checked
IARR	Session Charge
NE	General Charge and First Named Event Class if the amount is greater than or equal to 0 (debit) General Recharge and First Named Event Class if the amount is less than 0 (credit)
INER	Session Charge and First Named Event Class
ATC	General Charge if the amount is greater than or equal to 0 (debit) General Recharge if the amount is less than 0 (credit)
DA	General Charge if the amount is greater than or equal to 0 (debit) General Recharge if the amount is less than 0 (credit)
WGR	General Recharge

## Merging wallets processes

This table describes the main components involved in merging wallets.

Process	Role	Further information
beServer	Handles connections from client processes (including BeClient processes) and controls routing to beVWARS processes.	<i>beServer</i> (on page 65)
beVWARS	beVWARS is the core of the VWS. More than one beVWARS will usually be running on a VWS. It: <ul style="list-style-type: none"> <li>• Reads and caches wallet and voucher information from the E2BE database</li> <li>• Manages all queries, reservations and updates against wallets</li> <li>• Manages all queries, redemptions and state changes for vouchers</li> <li>• Writes EDRs.</li> </ul>	<i>beVWARS</i> (on page 92)
beVWARSMergeBuckets	This beVWARS plug-in merges buckets in the same balance when there are too many buckets in the wallet.	<i>beVWARSMergeBuckets</i> (on page 117) <i>beVWARS plugins</i> (on page 7)
E2BE database	The databases on the VWSs. They hold a subset of the data from the SMF.	

## Data Management

### Data redundancy

In a redundant configuration there are two Voucher and Wallet Servers in each VWS domain: a primary and a secondary. The primary is the node with:

- 'true' specified in the *amPrimary* (on page 41) parameter
- The highest node number

In normal conditions, the primary VWS performs all subscriber account, wallet and balance actions for the pair. The secondary VWS maintains a duplicate set of data.

If a single Voucher and Wallet Server in a pair is down, the system will work as normal. When the other peer comes back up:

- 1 It will resynchronize with the uninterrupted peer without prompting
- 2 Service will continue as if nothing happened

If the network link between BeClients and beServers, or between peer servers in a redundant pair, is disconnected, those BeClients that can see at least one member of a VWS pair should be able to keep running. When connectivity is restored, changes made to records held on the peers are resynchronized.

If the primary VWS fails, the secondary VWS performs the functions of a primary VWS until the primary VWS becomes available again.

For more information about failover and recovery, see *BE States* (on page 26).

### BeClients and connection failure

If a BeClient process cannot connect to the beServer on the primary VWS, it will retransmit any outstanding messages to the secondary VWS for processing. Subsequent messages will go to the secondary VWS, until the primary VWS recovers. When the primary VWS recovers, BeClient sends new transactions to the primary VWS.

This prevents call crossover conditions, where the beginning of a call could start on one VWS and end on another.

### Throttling

If one beVWARS process is throttling, the beServer will stop accepting any new requests on the client sockets.

### Database update consistency

The E2BE database seldom reflects the complete state of the running system, because updates are almost always pending. To maintain a single consistent view of the state of records in the database, all wallet or voucher accesses are executed through beVWARS. beVWARS is responsible for all updates to resynchronized database fields.

Because beVWARS sends updates to beSync before confirmation of the update on the local VWS has happened, updates can be applied to the remote VWS and not the local VWS. If the local VWS fails before updates have been applied, then the updates are retrieved and applied during resynchronization.

### beVWARS data updates

Each beVWARS performs the following data update tasks:

- Buffering database updates and EDRs (for performance reasons)
- Applying database updates to the database in the order they were produced
- Writing EDR data to flat files
- Writing updates to sync files
- Informing beSync there is a sync file to process

### Queuing and flushing updates

Updates fall into one of these categories:

- Bucket creations, updates or deletions
- Balance creations, updates or deletions

- Wallet creations, updates or deletions
- Voucher creations, updates or deletions

A buffer is maintained for each of these categories to store updates for later binding to the database via a bulk bind operation. Each buffer has a configurable maximum size.

beVWARS also maintains an EDR cache to queue EDR details for later writing to disk.

Each time beVWARS processes a transaction, it checks the following criteria to determine if it should perform a flush:

- One of the buffers is full
- The configurable buffer/cache flush period has been reached
- The writer subsystem is told to flush and commit (on shutdown, for example)

If a flush is triggered, all buffers are written to the E2BE database and the EDR cache is written to the EDR files.

## Flush process

This describes the stages involved in a flush operation.

Stage	Description
1	beVWARS writes all EDR records in the cache to a new file.
2	beVWARS records the EDR file name in the E2BE database (BE_CDR_FILE).
3	Update the BE_VWARS_SEQ_NUM table entry for the current beVWARS process. Sets: <ul style="list-style-type: none"> <li>• 'last local sequence number' to the sequence number of the last update in the buffers, and</li> <li>• 'remote sequence number' to the last value sent from the remote beSync).</li> </ul>
4	Bulk bind and execute the database statement associated with each database buffer. The buffers are flushed in this order: <ul style="list-style-type: none"> <li>• BE_WALLET, BE_BALANCE, BE_BUCKET, then BE_VOUCHER Inserts</li> <li>• BE_WALLET, BE_BALANCE, BE_BUCKET, then BE_VOUCHER Updates</li> <li>• BE_BUCKET, BE_BALANCE, BE_WALLET, then BE_VOUCHER Deletes</li> </ul>
5	Commit the changes to the E2BE database.
6	Generate and send a COMMIT message to the beSync process containing the last local and remote sequence numbers.
7	Update the last committed local update sequence number.
8	Perform a wallet cache flush. This frees up space in the wallet cache by releasing any entries which were protected until a flush applied the transaction.

## Changing number of beVWARS

Because of the method used to keep the VWS pairs synchronised, you must run the same number of beVWARS on both Voucher and Wallet Server nodes.

Follow these steps to change the number of beVWARS to run on the VWS.

**Note:** If you reduce the number of beVWARS on a pair, any transactional updates that are incomplete when the change is made will be lost.

Step	Action 14.25
1	Set the number of beVWARS interface instances to run by editing the INTERFACE line for beVWARS in <b>SLEE.cfg</b> for each VWS in the pair.

Step	Action
2	Stop the SLEE on both VWSs in the pair. The VWS will move to the disabled state.
3	Start the SLEE on both VWSs in the pair. <ul style="list-style-type: none"> <li>The SLEE will start the number of beVWARS instances specified in the updated <b>SLEE.cfg</b> file.</li> <li>The VWS will move to a running state.</li> </ul>

For more information about configuring SLEE interfaces, stopping the SLEE, and starting the SLEE, see *SLEE Technical Guide*.

## Synchronization

### Data synchronization

Synchronization is used to ensure database updates and EDRs are not lost. This is achieved by beVWARS recording a stream of updates to flat files, so the updates can:

- Be replayed in the event of a failure (for example, a hardware fault, power failure, software failure)
- Provide a persistent stream of updates to be delivered to the secondary VWS for application to a remote E2BE database in the interests of redundancy and failover

It is possible for the remote beSync to drop the connection and later connect and request older updates at any point. The sync files are only removed when both VWSs have committed the updates.

The current position in the transaction stream for each VWS within a pair is recorded as a pair of sequence numbers. These numbers record the last locally sourced update and the last remotely sourced update received and written to the database.

Sequence numbers are managed for each beVWARS, so lost updates are visible as gaps in the sequence numbers for the beVWARS handling that traffic.

Synchronization between two VWSs in a VWS domain can be viewed as two continuous streams containing all reservations, updates, and deletions made on one VWS to the other. The two streams are connections from:

- Primary beSync source to secondary beSync sink.
- Secondary beSync sink to primary beSync source.

The two stream connections between the beSync processes on the primary and secondary VWS nodes are maintained using the internal port that you specify when you configure the VWS domain. If you are running more than one instance of beSync on the VWS nodes, then two stream connections will be maintained for each instance. The internal port number is incremented by 1 (one) for each additional instance of beSync.

For information on configuring VWS domains, see the section on Service Management in *CCS User's Guide*.

#### Example

If you are running two instances of beSync and the internal port number is 1500 then the connections between:

- beSync0 on VWS1 and beSync0 on VWS2 use port 1500
- beSync1 on VWS1 and beSync1 on VWS2 use port 1501

### Sync files

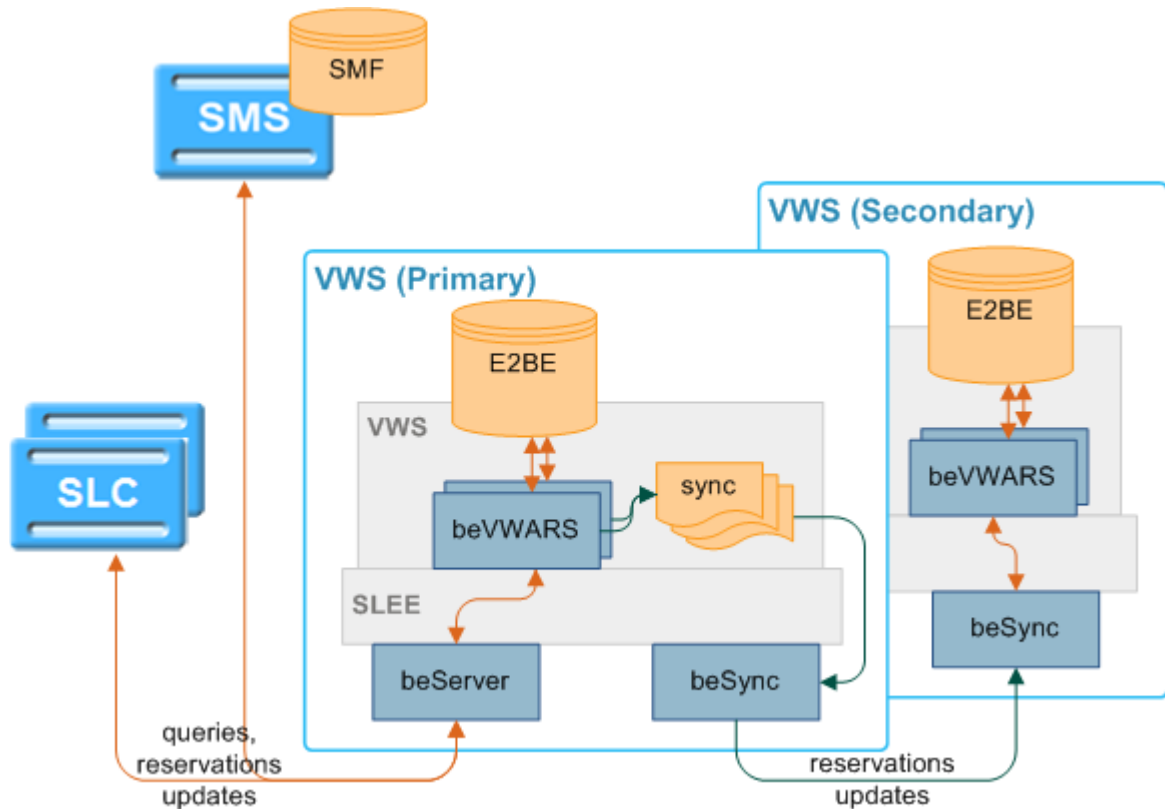

Files are named with the form "sync-VWARS-YYYYMMDDHHMMSS-*UUU*" where:

- UUU is a unique number used to differentiate when two or more files are produced in a second
- VWARS is the beVWARS number to distinguish between beVWARS instances.

The files are stored in numbered directories within the main sync file directory. The name of the subdirectories follows the beVWARS number which wrote the sync file. This is to aid the beSync during recovery of individual beVWARS instances.

## Synchronization diagram

This diagram shows the processes and data involved in the synchronization.

## Synchronization process

This table describes how the VWS keeps the Voucher and Wallet Servers in a pair in sync during an update or reservation.

**Note:** This process starts at the point the beVWARS has triggered all the configured event plug-ins and message handlers and is ready to start a reservation or update.

Stage	Description
1	For each reservation or update, beVWARS: <ul style="list-style-type: none"> <li>• Updates the cache</li> <li>• Writes the update or reservation to the sync file</li> <li>• Updates the sync file sequence number</li> </ul> If there is no sync file, the beVWARS creates one.
2	If the request is an update, the beVWARS on the primary VWS writes the EDR to record the transaction.
3	beVWARS closes its sync file after a configurable period or a configurable number of

Stage	Description
	entries, or force-closes it (if a commit message is received). It writes the current transaction set to the file and performs a file flush on the current file to ensure the last transaction set is written safely to disk.
4	<p>beVWARS sends a new file notification to beSync containing the name of the file.</p> <p>beSync receives the notification and starts to read the new sync file.</p> <p>The notification contains the name of the sync file and the beVWARS number. The beSync process queues received sync file names, so it knows the order in which to process them without performing expensive directory searching operations.</p>
5	The beSync sink function on the secondary VWS opens a TCP connection to the corresponding source function on the beSync on the primary VWS and requests updates.
6	The beSync source function on the primary VWS listens on a defined TCP port, for connections from the corresponding beSync sink. When it receives a request, it reads the updates and reservations from a transaction set in the sync file and sends them to beSync on the secondary VWS. A transaction set is a specific sequence number range from a single beVWARS's sync file. It then waits for another request.
	<b>Note:</b> If the number of commands exceeds a configured maximum, outstanding updates are queued until the number is reduced. This helps to prevent surges of activity that may stress the VWSs and delay the synchronization.
7	beSync on the secondary VWS sends the update or reservation to a local beVWARS process.
8	<p>The beVWARS on the secondary VWS updates the:</p> <ul style="list-style-type: none"> <li>• Cache</li> <li>• Sync file sequence number</li> </ul> <p>The beVWARS on both the primary and secondary VWSs flush the reservations or updates. They:</p> <ul style="list-style-type: none"> <li>• Update the database</li> <li>• Send a COMMIT message to the local beSync.</li> </ul>
9	The beSync on the secondary VWS sends the COMMIT to the beSync on the primary VWS.
10	The beSyncs on both VWSs verify the updates and reservations in their sync files against the updates and reservations in the COMMIT message(s) they have received.
11	When all the updates and reservations in a sync file have been verified by a COMMIT message, beSync deletes the file.

## Resynchronizations

This table describes the stages involved in resynchronizations.

**Note:** The running VWS refers to the Voucher and Wallet Server which has been running as a primary. It also refers to the other VWS if the two Voucher and Wallet Servers have been running in isolation. The recovering VWS refers to the Voucher and Wallet Server which has been disabled.

Stage	Description
1	If a resynchronization is triggered, the beSync on the recovering VWS queries a local beVWARS for its last update numbers (both local and remote update numbers).
2	beSync on the recovering compares the sequence number from the local beVWARS with the last local update sequence number to check whether any local updates have been missed. If the numbers do not match, beSync streams all local uncommitted transactions to the recovering beVWARS.
3	When all local updates have been sent, beSync sends a "request all reservations"

Stage	Description
	message to the beSync on the running VWS specifying which beVWARS instance to update.
4	The running VWS sends updated beVWARS context and reservations for the recovering beVWARS number from the beServer on the running VWS to the beServer on the recovering VWS via the beSync processes.
5	The beVWARS on the running VWS indicates all contexts have been sent correctly and the beSync on the recovering VWS requests the beSync on the recovering VWS to start streaming updates.
6	As remote updates are received by the beSync on the recovering VWS, they are delivered to the appropriate beVWARS instance for application to the database. When streamed updates are close enough to real-time relative to the running VWS, which is still actively processing traffic, the beSync process will notify the recovering beVWARS to move into running state.
7	After the recovering beVWARS has been enabled, it sends a message to the beServer to move into running state.

For more information about the different failure scenarios which can trigger a resynchronization, see *Failure scenarios* (on page 139).

## Wallet and Bucket Expiry

### Introduction

Like most functions, wallet expiry and bucket expiry and removal are triggered when a wallet is loaded. VWS uses beVWARSExpiry to control when wallet expiry events are triggered. Additional wallet expiry processing can be done by plug-ins and processes provided by other applications. VWS provides basic bucket handling, though this functionality can be extended by plug-ins which are triggered on bucket expiry or bucket delete/removal events.

**Note:** Expiry handling is optional. If no expiry dates are configured for wallets and/or buckets, no expiry handling will be executed.

### Wallet management processes

This table describes the main components in VWS.

Process	Role	Further information
beServer	Handles connections from client processes (including BeClient processes) and controls routing to beVWARS processes.	<i>beServer</i> (on page 65)
beGroveler	beGroveler triggers processing on wallets which have not been triggered by a subscriber action. This enables VWS to ensure required actions are taken against all wallets and buckets.	<i>beGroveler</i> (on page 59)
beVWARS	beVWARS is the core of the VWS. More than one beVWARS will usually be running on a VWS. It does the following: <ul style="list-style-type: none"> <li>• Reads and caches wallet and voucher information from the E2BE database</li> <li>• Manages all queries, reservations and updates against wallets</li> </ul>	<i>beVWARS</i> (on page 92)

Process	Role	Further information
	<ul style="list-style-type: none"> <li>Manages all queries, redemptions and state changes for vouchers</li> <li>Writes sync files</li> <li>Writes EDRs</li> </ul>	
beVWARSExpiry	beVWARSExpiry monitors wallets and buckets, checking for wallets and buckets which have passed their expiry date. If it finds a wallet or bucket which requires expiring, it processes the record as configured and triggers any Expiry plug-ins with a Wallet Event or Bucket Event.	<i>beVWARSExpiry</i> (on page 114) <i>beVWARS plugins</i> (on page 7)
Expiry plug-ins	beVWARSExpiry starts an expiry event when it finds an expired wallet or bucket. Each expiry event can trigger one or more expiry plug-ins. Each expiry plug-in will take its own action.	Technical guide for the application using VWS. For an example, see <i>CCS Technical Guide</i> .
E2BE database	The databases on the VWSs. They hold a subset of the data from the SMF.	

### Expiry diagram

This diagram shows the basic processes, communication and relationships for expiring wallets and buckets.

## Wallet and bucket expiry processing

This table describes how wallets and buckets are expired when they have passed their expiry date.

Stage	Description
1	<p><i>beVWARS</i> (on page 92) loads a wallet.</p> <p>Loading a wallet can be triggered by one of the following:</p> <ul style="list-style-type: none"> <li>• A query, request or reservation from a requesting process as part of normal processing</li> <li>• <i>beVWARS</i> processing a wallet from a list of wallet IDs to grovel from <i>beGroveler</i> (on page 59).</li> </ul>
2	Loading the wallet triggers <i>beVWARSExpiry</i> (on page 114).
3	<p>For wallets which are Active or Dormant, <i>beVWARSExpiry</i> checks whether the wallet has passed its expiry date.</p> <p><b>Tip:</b> Wallet expiry date checking is defined by <code>expireAtMidnightTZ</code> (on page 114). If <code>expireAtMidnightTZ</code> is set, <i>beVWARSExpiry</i> will expire the wallet and buckets the next time they are loaded after the midnight in the specified time zone which follows the expiry date.</p> <p>If the wallet has not expired, <i>beVWARSExpiry</i> checks whether any of the buckets in the wallet have passed their expiry date. For each bucket which has passed its expiry date, <i>beVWARSExpiry</i> deletes the bucket. If two buckets expire at exactly the same time, the buckets will be processed in bucket ID order.</p> <p>This triggers any <i>beVWARS</i> event plug-ins which are designed to handle Bucket Expiry events.</p> <p><b>Note:</b> If a bucket is expired, it will be deleted unless an event plug-in provides specific logic which retains the bucket.</p> <p><b>Example:</b> <code>ccsVWARSPeriodicCharge</code> processes expiring periodic charge buckets. It keeps the periodic charge bucket and sets the expiry date to a point in the future.</p>
4	<p>If the wallet has passed its expiry date, <i>beVWARSExpiry</i> sets the wallet's state to terminated and fires a Wallet Expiry event. This triggers any <i>beVWARS</i> event plug-ins which are designed to handle Wallet Expiry events.</p> <p>Expiry plug-ins which handle Wallet Expiry events can be provided as part of another application such as CCS.</p> <p><b>Example:</b> When triggered by a Wallet Expiry event, <code>ccsVWARSExpiry</code> writes an EDR and adds the wallet to a list of expired wallets which is used to update the HLR records.</p>
5	<p><i>beVWARSExpiry</i> checks the configuration.</p> <p>If <code>expireBucketsForExpiredWallets</code> (on page 115) is set to true, it deletes all buckets with a positive or zero value. If <code>expireNegativeBuckets</code> (on page 115) is also set to true, <i>beVWARSExpiry</i> will also delete buckets with negative values.</p> <p>This triggers any <i>beVWARS</i> event plug-ins which are designed to handle Bucket Expiry events.</p>
6	<p>If <code>removeEmptyBuckets</code> (on page 116) is set to true, <i>beVWARSExpiry</i> deletes all buckets with a 0 balance from the E2BE.</p> <p><b>Exception:</b> If the last bucket in a wallet which has not expired has a value of 0, that bucket will be left.</p>

For more information about the expiry plug-ins provided with other applications, see the application's technical guide.

## BE States

### Introduction

In a VWS domain, there are two Voucher and Wallet Servers, in a redundant configuration.

If one VWS in a pair is down, the system will work as normal. When the other peer comes back up:

- 1 It will resynchronize with the uninterrupted peer without prompting
- 2 Service will continue as if nothing happened.

If the network link between BeClients and beServers (or between VWSs in a domain) is disconnected, the BeClients that can see at least one member of a VWS pair should be able to keep running. When connectivity is restored, changes made to records held on the VWSs are resynchronized.

### BE states

The beVWARS is responsible for maintaining the current state of a Voucher and Wallet Server. There are three possible states for a VWS:

- Running
- Recovering
- Disabled

### Running

This is the normal state of a VWS.

In this state:

- beSync is streaming updates and receiving streamed updates
- beServer is accepting connections from BeClients and processing requests

beSync listens on a defined TCP port, for connections from the beSync on the peer VWS. When this connection is open and streaming, all reservations and transactions are sent to the other VWS.

### Disabled

This is the initial state of a VWS, and it can return to this state in a variety of failure scenarios.

In this state:

- beServer does not accept any connections from BeClients
- beSync does not accept any connections from the peer VWS
- The beGroveler does not run
- No internal processing is performed

### beVWARS failure

When the SLEE watchdog notices a beVWARS process has failed, the beServer will:

- Cease to read new work from the client sockets
- Allow the remaining active beVWARS instances to quiesce
- Close all client connections (when all beVWARS instances are idle)

When all connections are closed, the BeClient processes will failover to the secondary Voucher and Wallet Server. The local beServer removes all existing context and beVWARS routes for the failed beVWARS. These are recovered during the beVWARS recovery, which delivers all context from the remote VWS.

## Recovering

In this state:

- The beGroveller does not run
- Synchronization can be in any state
- beServer should not be accepting new connections from the BeClients.

beServer begins in a recovery state expecting to receive all of its contexts from the beServer on the peer, and getting the OK from all local beVWARS indicating they are in sync before accepting client connects and client requests.

On VWS recovery/startup, the local sync files are processed to ensure there are no lost local updates. Then a connection is made to the peer VWS, to request all updates since the last remote update received. For more information about this process, see *Resynchronizations* (on page 22).

If one VWS is disabled for an extended period of time, its peer will amass a significant number of updates in the sync directory specified by *spoolDirectory* (on page 78) (typically in the */IN/service\_packages/E2BE/sync/* directory). When the VWS is re-enabled, the updates will be requested and the VWSs will return to a synchronized state.

## beVWARS recovery

Individual beVWARS processes recover independently. If a beVWARS process fails, the other beVWARS processes do not detect this, and continue to function (though, due to the beServer disabling connections, they will only be processing remote transactions from the now active secondary VWS).

The failed beVWARS independently goes through its recovery process along with the beSync process, until it is able to move back into running state. The beServer asks the remote beServer for all contexts for the beVWARS which failed.

## State transitions

Here is what a user can expect to see, in the transition of a Voucher and Wallet Server from one state to another.

**Note:** The initial state of the VWS should be disabled.

Transition	Description
Disabled to Recovering	beServer should prepare to accept contexts. beVWARS should prepare to send contexts to the beServer, and should prepare to receive Operations. This should include a complete new Reservation load, so all existing reservations should be erased. beVWARS will not request work from beGroveller. beGroveller will not return wallet IDs for groveling to beVWARS. beSync should initiate recovery.
Disabled to Running	Not a possible transition.
Recovering to Running	beServer should start accepting connections. beVWARS can start to accept new requests and can start to send requests to beGroveller for lists of wallet IDs to grovel. beGroveller will determine if it should run. If it should, it will start to return wallet IDs to grovel to beVWARS. For more information about the beGroveller, see <i>beGroveller</i> (on page 59). beSync should proceed as it was (it usually leads the recovery process).
Recovering to Disabled	beServer should terminate all connections.

Transition	Description
	beVWARS should disable the beGroveller. beVWARS should stop requesting work from beGroveller. beGroveller will stop accepting requests from beVWARS for wallet IDs to grovel. an inactive state.
Running to Recovering	beServer should terminate all connections. beVWARS should stop requesting work from beGroveller. beGroveller will stop accepting requests from beVWARS for wallet IDs to grovel. beSync should disconnect open connections and initiate recovery.
Running to Disabled	beServer should terminate all connections. beVWARS should stop requesting work from beGroveller. beGroveller will stop accepting requests from beVWARS for wallet IDs to grovel. beSync should close all open connections and return to an inactive state.

## EDR Processing

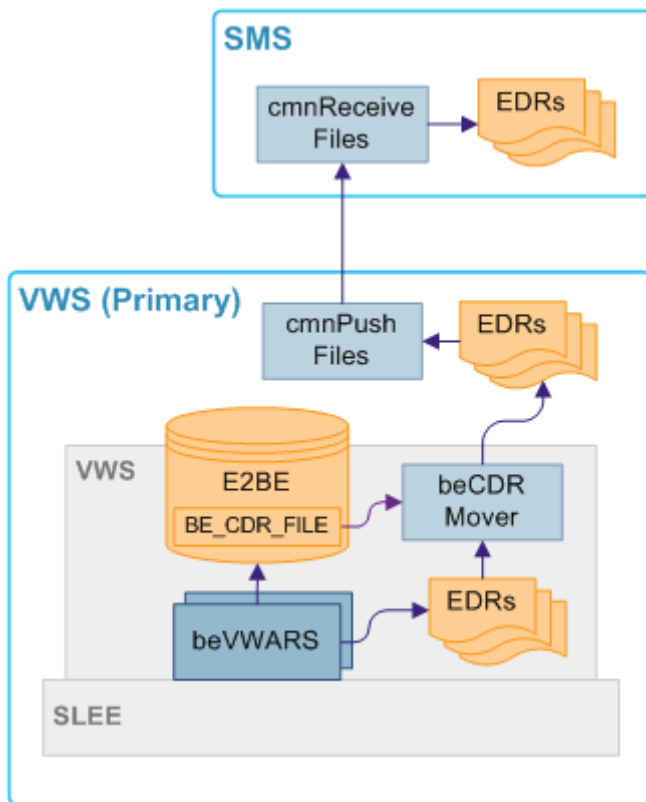

### Introduction

Each Voucher and Wallet Server in a domain logs EDRs for all actions which are successfully completed on the local VWS.

### EDR processing diagram

This diagram shows how EDRs are processed by VWS.

**Note:** EDRs can be post-processed on the SMS.

## VWS EDR processing

This process describes how VWS processes EDRs.

Stage	Description
1	beVWARS receives an update request from the local beServer.
2	beVWARS updates the relevant cache and queues the EDR write until the next flush. For more information about queuing and flushing, see <i>Queuing and flushing updates</i> (on page 18).
3	When the next flush is triggered, beVWARS: <ul style="list-style-type: none"> <li>• Writes all queued EDR records to a new EDR file</li> <li>• Records the EDR file name in the E2BE database (in the BE_CDR_FILE table).</li> </ul> <p><b>Note:</b> Entering the EDR file name in the BE_CDR_FILE table indicates that the EDRs in the file should be:</p> <ul style="list-style-type: none"> <li>• Accepted by the rest of the system</li> <li>• Transmitted to the SMS for consolidation into the SMF database.</li> </ul>
4	beCDRMover moves completed EDR files from the working directory to the output directory.
5	cmnPushFiles transfers the EDR file to the SMS.

### EDR triggers

EDRs are written on the Voucher and Wallet Servers when a wallet or voucher is modified. The following messages, among others, cause the beVWARS to write EDRs:

- Call End Notification
- Wallet Recharge Request
- Named Event

## MFile Updates

### Introduction

The MFile contains a subset of the Voucher and Wallet Server data, used to reduce network traffic on the system. Some of the information held within the VWS changes less frequently, such as Tariffs. It is this data which is copied to the MFile and held on the VWS. The system reads this MFile, enabling it to retrieve data quickly, thereby reducing network traffic to the Voucher and Wallet Servers.

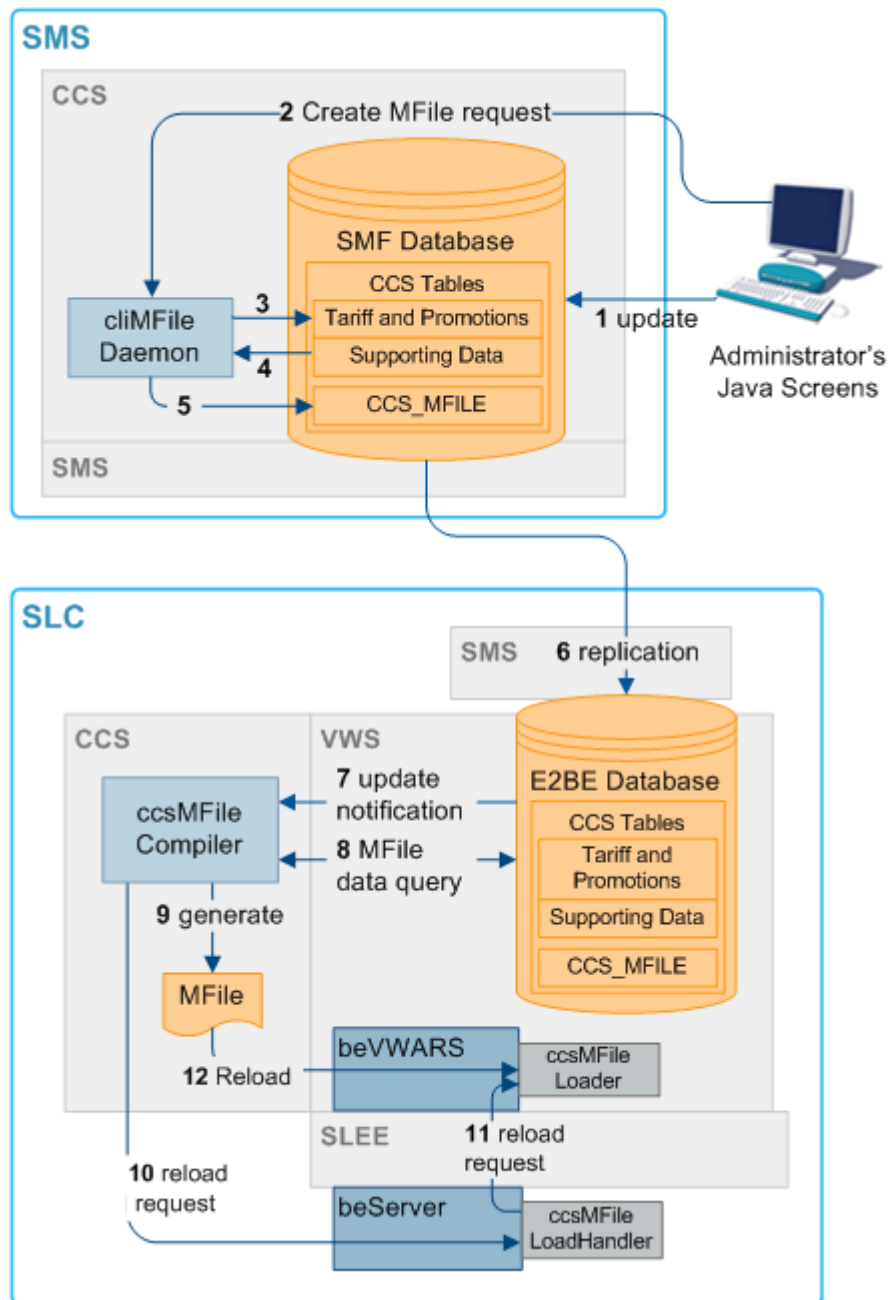

### MFile data types

A MFile will need to be recompiled if any of the following data types are changed:

- Discount Period
- Discount Sets
- Geography Sets
- Billing Periods
- CLIXDN Mappings
- Tariff Plans
- Product Types
- Tariff Plans
- Currency

## Update process diagram

Here is an example showing an update to an MFile.

## Update process - mfile

This table describes the process through which MFiles are updated.

Stage	Description
1 - 4	Through the Prepaid Charging user interface (UI) on the SMS node, the system administrator updates the details contained in the MFile and clicks <b>Save</b> .
5	A new entry is added to the CCS_MFILE table in the SMF database.

Stage	Description
6	The relevant tables in the SMF are updated and the data is transferred to the VWS nodes using replication.
7	When the new CCS_MFILE entry arrives on the BE, VWS sends a notification to the ccsMFileCompiler.
8	The ccsMFileCompiler updates the MFile file name table (CCS_MFILE) in the BE database.
9	ccsMFileCompiler then generates a new MFile from the updated data in the E2BE database.
10	If ccsMFileCompiler has not already connected to the beServer, it uses the <code>beLocationPlugin</code> (on page 41) to extract the location of the beServer from the BE database. After establishing the connection, or if it is already connected, ccsMFileCompiler sends a request to the beServer to reload the MFile.
11	The ccsMFileLoadHandler message handler on the beServer forwards the reload request to the ccsMFileLoader message handler in beVWARS.
12	beVWARS uses ccsMFileLoader to reload the new MFile.

For more information about the ccsMFile processes, see *CCS Technical Guide*.

## Statistics

### Introduction

VWS statistics are generated by each VWS VWS, and then transferred at periodic intervals to the SMS for permanent storage and analysis.

VWS also records statistics for applications which use the VWS, such as CCS. For more information about these statistics, see the application's technical guide.

### SMS statistics subsystem

The statistics system provided by SMS provides the functionality which collects the statistical events logged by VWS processes.

For more information about the SMS statistics subsystem, see *SMS Technical Guide*.

### Collected statistics

This table describes the statistics produced by VWS processes.

Statistic	Description
NUM_TOTAL_REQ	Total number of requests sent to the VWS.

**Note:** All statistics are collected with a period of 1800 seconds.

For more information about the request messages these statistics measure, see *Supported requests* (on page 9).

# Configuration

## Overview

### Introduction

This chapter explains how to configure the Oracle Communications Convergent Charging Controller application.

### In this chapter

This chapter contains the following topics.

Configuration Overview .....	33
Configuring the Environment .....	34
eserv.config Configuration .....	34
BE Shared Parameters.....	40
User Interface-Based Configuration Tasks .....	44
SLEE.cfg.....	45

## Configuration Overview

### Introduction

This topic provides a high level overview of how the VWS application is configured.

**Note:** There are several configuration options that are not explained in this chapter. These options should not be changed by the user without first consulting Oracle for technical support.

### Configuration process overview

This table describes the steps involved in configuring a VWS for the first time.

Stage	Description
1	The environment that VWS will run in must be configured correctly. This includes: <ul style="list-style-type: none"> <li>• If the directory VWS was installed into was not the recommended directory (/IN/service_packages/E2BE), setting the root directory</li> <li>• Configuring the location of the EDR directories</li> </ul>
2	The <b>eserv.config</b> file must be configured for the following machines: <ul style="list-style-type: none"> <li>• SMS nodes</li> <li>• SLC nodes</li> <li>• VWS nodes</li> </ul> <p>The example file should be copied into the main <b>eserv.config</b>, and any mandatory parameters configured. The parameters which must be set are listed at the top of the <b>eserv.config</b> file. For more information, see <b>eserv.config Configuration</b> (on page 34).</p>
3	The screen-based configuration tasks must be completed through the CCS User Interface (UI).
4	The <b>SLEE.cfg</b> file must contain references to the VWS SLEE applications and interfaces.

## Configuration components

VWS is configured by the following components:

Component	Locations	Description	Further Information
<b>eserv.config</b>	all SMSs and VWSs	VWS is configured by the <code>BE</code> section of <b>eserv.config</b> .	<i>eserv.config Configuration</i> (on page 34)
<b>SLEE.cfg</b>	all VWSs	<b>SLEE.cfg</b> sets up SLEE interfaces and applications.	<i>SLEE.cfg</i> (on page 45)
Domains screen	SMF database	Domains must be set up which define the Voucher and Wallet Servers, and available services in the Domain screen in the CCS UI.	<i>User Interface-Based Configuration Tasks</i> (on page 44)

## Configuring the Environment

### Oracle environment variables

The VWS UNIX system account `ebe_oper` requires the standard ORACLE environment variables to be present.

## eserv.config Configuration

### Introduction

The **eserv.config** file is a shared configuration file, from which many Oracle applications read their configuration. Each Oracle machine (SMS, SLC and VWS) has its own version of the configuration file, containing configuration relevant to that machine. The configuration file contains many different parts or sections; each application reads the parts of the **eserv.config** file that contains data relevant to it.

It is located in the following directory:

```
/IN/service_packages/
```

The **eserv.config** file format allows hierarchical groupings, and most applications make use of this to divide up the options into logical groupings.

### Configuration File Format

To organize the configuration data within the **eserv.config** file, some sections are nested within other sections. Configuration details are opened and closed using either `{ }` or `[ ]`.

- Groups of parameters are enclosed with curly brackets – `{ }`
- An array of parameters is enclosed in square brackets – `[ ]`
- Comments are prefaced with a `#` at the beginning of the line

To list things within a group or an array, elements must be separated by at least one comma or at least one line break. Any of the following formats can be used, as in this example:

```
{ name="route6", id = 3, prefixes = [ "00000148", "0000473" ] }
{ name="route7", id = 4, prefixes = [ "000001049" ] }
```

or

```
{ name="route6"
```

```

        id = 3
        prefixes = [
            "00000148"
            "0000473"
        ]
    }
    { name="route7"
      id = 4
      prefixes = [
          "000001049"
      ]
    }
}

```

or

```

{ name="route6"
  id = 3
  prefixes = [ "00000148", "0000473" ]
}
{ name="route7", id = 4
  prefixes = [ "000001049" ]
}

```

## eserv.config Files Delivered

Most applications come with an example **eserv.config** configuration in a file called **eserv.config.example** in the root of the application directory, for example, `/IN/service_packages/eserv.config.example`.

## Editing the File

Open the configuration file on your system using a standard text editor. Do not use text editors, such as Microsoft Word, that attach control characters. These can be, for example, Microsoft DOS or Windows line termination characters (for example, `^M`), which are not visible to the user, at the end of each row. This causes file errors when the application tries to read the configuration file.

Always keep a backup of your file before making any changes to it. This ensures you have a working copy to which you can return.

## Loading eserv.config Changes

If you change the configuration file, you must restart the appropriate parts of the service to enable the new options to take effect.

## Example eserv.config configuration

This is an example of the `BE` section of an **eserv.config** file (comments have been removed). It is not intended to be used in a production environment, but only to illustrate the configurations available.

Details on the configurations in this file are located in various sections later in this guide.

```

BE = {
    serverId = 11
    amPrimary = true
    oracleUserAndPassword="/"
    beLocationPlugin = "libGetccsBeLocation.so"

    soloBE = true

    timerIfName = "Timer"

    enableGroveling = true

```

## BE Shared Parameters

### Purpose

The BE section of the `eserv.config` file for the VWS contains parameters that are shared by various VWS background processes. These parameters define the settings that are common to the background processes.

### Configuration

VWS accepts these parameters from `eserv.config`.

```

serverId = int
amPrimary = true|false
oracleUserAndPassword="/"
beLocationPlugin = "lib"

soloBE = true|false

timerIfName = "str"

enableGroveling = true|false

freeDiskSpaceWarningThres = MB
freeDiskSpaceShutdownThres = MB
freeDiskSpaceCheckInterval = secs
lowDiskSpaceNotificationInterval = secs

```

### Example BE shared parameters configuration

The following section sets the shared BE configuration parameters.

**Note:** The comments have been removed.

```

BE = {
  serverId = 11
  amPrimary = true
  oracleUserAndPassword="/"
  beLocationPlugin = "libGetccsBeLocation.so"

  soloBE = true

  timerIfName = "Timer"

  enableGroveling = true

  freeDiskSpaceWarningThres = 100

```

```

freeDiskSpaceShutdownThres = 10
freeDiskSpaceCheckInterval = 300
lowDiskSpaceNotificationInterval = 30
}

```

## Parameters

Here are the available shared VWS parameters.

### amPrimary

**Syntax:** amPrimary = true|false  
**Description:** True if this is the primary VWS in the pair.  
**Type:** Boolean  
**Optionality:** Optional, default used if not set  
**Allowed:**  
**Default:** true  
**Notes:**  
**Example:** amPrimary = false

### beLocationPlugin

**Syntax:** beLocationPlugin = "lib"  
**Description:** The plug-in library that finds the Voucher and Wallet Server details of the Voucher and Wallet Servers to connect to.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** libGetccsBeLocation.so  
**Notes:** This library must be in the LD\_LIBRARY\_PATH.  
**Example:** beLocationPlugin = "libGetccsBeLocation.so"

### enableGroveling

**Syntax:** enableGroveling = true|false  
**Description:** Whether or not to process wallets when spare resources are available.  
**Type:** Boolean  
**Optionality:** Optional (default used if not set)  
**Allowed:**

- true – Use beGroveler to trigger events on wallets and balances that are not used often.
- false – Do not do background triggering of events on wallets and balances.

**Default:** true  
**Notes:**  
**Example:** enableGroveling = true

### oracleUserAndPassword

**Syntax:** oracleUserAndPassword = "usr/pwd"  
**Description:** The Oracle user and password for the connections to the E2BE database for VWS processes.  
**Type:** String

**Optionality:** Optional, default used if not set  
**Allowed:**  
**Default:** "/"  
**Notes:** The default sets no user and password.  
**Example:** `oracleUserAndPassword = "/"`

### `serverId`

**Syntax:** `serverId = id`  
**Description:** The ID of the VWS pair.  
**Type:** Integer  
**Optionality:**  
**Allowed:**  
**Default:** 1  
**Notes:** Set to 1 if this is not a VWS  
**Example:** `serverId = 11`

### `soloBE`

**Syntax:** `soloBE = true|false`  
**Description:** Set to true if there is no peer VWS node to synchronize with in this billing engine domain.  
**Type:** Boolean  
**Optionality:** Optional (default used if not set)  
**Allowed:** true, false  
**Default:** false  
**Notes:**  
**Example:** `soloBE = true`

### `timerIfName`

**Syntax:** `timerIfName = "name"`  
**Description:** The name for the SLEE Timer interface component.  
**Type:** String  
**Optionality:** Optional, default used if not set  
**Allowed:**  
**Default:** Timer  
**Notes:** Must match the handle of the timer interface in **SLEE.cfg**. For more information about the SLEE, see *SLEE Technical Guide*.  
**Example:** `timerIfName = "Timer"`

### `freeDiskSpaceCheckInterval`

**Syntax:** `freeDiskSpaceCheckInterval = seconds`  
**Description:** How often (in seconds) `beServer` checks whether there is more than *freeDiskSpaceWarningThres* (on page 43) space free on the disk. If there is less than *freeDiskSpaceShutdownThres* (on page 43), `beServer` closes its connections and stops accepting requests.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)

- Allowed:**
- 0 – Disables the disk space check
  - Positive Integer – Checks the available disk space at the specified interval

**Default:** 300

**Notes:** If a shutdown is triggered, beServer logs a critical-level error to the syslog.

**Example:** `freeDiskSpaceCheckInterval = 300`

#### `freeDiskSpaceShutdownThres`

**Syntax:** `freeDiskSpaceShutdownThres = MB`

**Description:** When free disk space in MB is below this threshold, beServer closes its connections and stops taking new requests.

Threshold applies to the partitions containing the directories set by the following parameters:

- `spoolDirectory` (on page 78)
- `cdrOutputDirectory` (on page 109)

**Type:** Integer

**Optionality:** Optional (default used if not set)

- Allowed:**
- 0 – Disables the threshold shutdown
  - Positive Integer – The MB threshold

**Default:** 10

**Notes:** When the disk space has come back above the threshold, beServer re-enables and returns to running state.

If beServer stops taking requests, it will log a critical-level error to the syslog.

Disk space is checked by beServer at the frequency set by `freeDiskSpaceCheckInterval` (on page 42).

**Example:** `freeDiskSpaceShutdownThres = 10`

#### `freeDiskSpaceWarningThres`

**Syntax:** `freeDiskSpaceWarningThres = MB`

**Description:** Low disk space threshold, in Megabytes, for the partitions containing the directories set by the following parameters:

- `spoolDirectory` (on page 78)
- `cdrOutputDirectory` (on page 109)

**Type:** Integer

**Optionality:** Optional (default used if not set)

- Allowed:**
- 0 – Disables the threshold warning
  - Positive Integer – The MB threshold

**Default:** 100

**Notes:** If the threshold is reached, an error-level warning is logged to the syslog.

Disk space is checked by beServer at the frequency set by `freeDiskSpaceCheckInterval` (on page 42).

**Example:** `freeDiskSpaceWarningThres = 200`

#### `lowDiskSpaceNotificationInterval`

**Syntax:** `lowDiskSpaceNotificationInterval = seconds`

**Description:** The number of seconds between logging the error triggered by the low disk space

warning or shutdown thresholds being triggered.

**Type:** Integer

**Optionality:** Optional (default used if not set)

**Allowed:**

**Default:** 30

**Notes:** The threshold is set by `freeDiskSpaceWarningThres` (on page 43) and `freeDiskSpaceShutdownThres` (on page 43).  
The notification interval should be set to a value higher than `freeDiskSpaceCheckInterval` (on page 42), as it will only log an error if the check interval has recorded a low disk space condition since the last error was logged.

**Example:** `lowDiskSpaceNotificationInterval = 30`

## Deprecated SLEE Name Definitions

The parameters listed in this section have been deprecated and should not be used. You should delete them from the BE section of `eserv.config` if they are currently defined.

`grovellerIfNamePrefix`

**Syntax:** `grovellerIfNamePrefix = "name"`

**Default:** `beGroveller`

**Example:** `grovellerIfNamePrefix = "beGroveller"`

`serverIfName`

**Syntax:** `serverIfName = "name"`

**Default:** `beServer`

**Example:** `serverIfName = "beServer"`

`syncIfName`

**Syntax:** `syncIfName = "name"`

**Default:** `beSync`

**Example:** `syncIfName = "beSync"`

`vwarsIfNamePrefix`

**Syntax:** `vwarsIfNamePrefix = "name"`

**Default:** `beVWARS`

**Example:** `vwarsIfNamePrefix = "beVWARS"`

## User Interface-Based Configuration Tasks

### Introduction

These procedures are normally performed only once, after the installation and initial configuration of the system.

For more information about accessing the CCS screens, see *CCS User's Guide*.

## Defining VWS locations

The system requires the location of VWS machines to be defined. These are defined using the New Domain or Edit Domain screens, accessed from the Service Management screen.

For more information about configuring domains, see *CCS User's Guide*.

## SLEE.cfg

### About Configuring VWS SLEE Interfaces

The VWS includes the beVWARS, beSync, and beServer SLEE interfaces that run on the VWS nodes. For these processes to run correctly, they must be configured in the **SLEE.cfg** file. The SLEE is automatically configured during installation to run one or more instances of each by the following lines in **SLEE.cfg**:

```
INTERFACE=beVWARS  beVWARSStartup.sh /IN/service_packages/E2BE/bin instance_count EVENT
INTERFACE=beSync   beSyncStartup.sh  /IN/service_packages/E2BE/bin instance_count EVENT
INTERFACE=beServer beServerStartup.sh /IN/service_packages/E2BE/bin instance_count EVENT
```

Where *instance\_count* is the number of instances of the interface process to run.

**Note:** The actual startup script names can vary.

You should only update this configuration if you want to change the number of instances to run any of these processes. For example, if there is a high volume of traffic on the VWS, you can improve performance by running additional instances of these processes.

For more information about configuring SLEE interfaces, see the discussion about configuring the SLEE in *SLEE Technical Guide*.

### About Configuring MAXEVENTS

The value of MAXEVENTS sets the maximum number of event objects that the system can hold in shared memory. If MAXEVENTS is exceeded when the system is running, no more events or calls will be accepted and alarm messages will be sent. This means that you should set MAXEVENTS to a value that is big enough to handle an overload situation. You can estimate this value by using the following formula:

$$(num\_beServers * max\_beServer\_queue) + (num\_beVWARS * max\_beVWARS\_queue) + (num\_beSyncs * max\_beSync\_queue) + contingency$$

Where:

- *num\_beServers* is the number of instances of the beServer interface defined in the **SLEE.cfg** configuration file.
- *max\_beServer\_queue* is the maximum number of beVWARS response events that can be queued up for the beServer. This is the value specified for the `BE.beVWARS.maxDownstreamQueueLength` parameter in the **eserv.config** configuration file.
- *num\_beVWARS* is the number of instances of the beVWARS interface defined in the **SLEE.cfg** configuration file.
- *max\_beVWARS\_queue* is the value specified in the **eserv.config** configuration file for either `BE.beSync.maxDownstreamQueueLength` or `BE.beServer.maxDownstreamQueueLength`, whichever value is greater.
- *num\_beSyncs* is the number of instances of the beSync interface defined in the **SLEE.cfg** configuration file.

- *max\_beSync\_queue* is the maximum number of beVWARS events that can be queued up for the beSync. This is the value specified for the `BE.beVWARS.maxDownstreamQueueLength` parameter in the `eserv.config` configuration file.
- *contingency* is an estimated value for any additional VWS events such as VWS control messages. A typical value for contingency would be 5000.

### Example

This example shows how to calculate the value for MAXEVENTS for one beServer interface, six instances of the beVWARS interface, and two instances of the beSync interface, and where:

- `BE.beVWARS.maxDownStreamQueueLength = 10000`
- `BE.beSync.maxDownStreamQueueLength = 50000`
- `BE.beServer.maxDownStreamQueueLength = 50000`
- `contingency = 5000`

$\text{MAXEVENTS} = (1 * 10000) + (6 * 5000) + (2 * 10000) + 5000 = 65000$

You configure MAXEVENTS in the `SLEE.cfg` configuration file. For more information about configuring MAXEVENTS, see the discussion about configuring the SLEE in *SLEE Technical Guide*.

### Loading SLEE.cfg changes

If you change the `SLEE.cfg` file, you must restart the SLEE to enable the new options to take effect.

For more information about restarting the SLEE, see *SLEE Technical Guide*.

# Background Processes

## Overview

### Introduction

This chapter explains the processes that are started automatically by Service Logic Execution Environment (SLEE).

**Note:** This chapter also includes some plug-ins to background processes which do not run independently.

### In this chapter

---

This chapter contains the following topics.

beCDRMover .....	47
BeClient .....	50
beGroveler .....	59
beServer .....	65
beSync.....	76
beServiceTrigger .....	82
beVWARS.....	92
beVWARSCCDDRHandler .....	113
beVWARSExpiry .....	114
beVWARSMergeBuckets .....	117
cmnPushFiles .....	118
Event Storage Interface.....	121
libbeMsgRouterDefault .....	124
libBeClientIF .....	125
libclientBcast.....	125
libbeEventFactory.....	126

## beCDRMover

### Purpose

beCDRMover moves completed EDR files from the working directory to a directory from which they are copied to the SMS. The inter-machine transfer is completed by cmnPushFiles.

### Startup

This task is started by entry be\_1 in the inittab, via the shell script:

```
/IN/service_packages/E2BE/bin/beCDRMoverStartup.sh
```

**Note:** The above is a default and may vary as per configuration.

### Configuration

beCDRMover accepts the following parameters from **eserv.config**.

## Chapter 3

```
beCDRMover = {  
    oracleService = "str"  
    oracleUser = "name"  
    oraclePassword = "str"  
    outDirectory = "dir"  
    destinationDirectory = "dir"  
    timeout = int  
    numberOfRecordsToCommit = num  
    commitTimeSeconds = num  
}
```

### Parameters

Here are the available beCDRMover parameters.

#### destinationDirectory

**Syntax:** destinationDirectory = "dir"  
**Description:** The destination directory into which EDRs are moved.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** /IN/service\_packages/E2BE/logs/CDR  
**Notes:** Must be a valid directory  
**Example:** destinationDirectory = "/var/edr/UBE/dest"

#### commitTimeSeconds

**Syntax:** commitTimeSeconds = num  
**Description:** The maximum amount of time, in seconds, to leave transactions uncommitted.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 10  
**Notes:**  
**Example:** commitTimeSeconds = 5

#### numberOfRecordsToCommit

**Syntax:** numberOfRecordsToCommit = num  
**Description:** EDRs are moved in batches. This parameter defines the number of records in each batch.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 10  
**Notes:**  
**Example:** numberOfRecordsToCommit = 10

#### oraclePassword

**Syntax:** oraclePassword = "str"  
**Description:** The Oracle password VWS processes to connect to the E2BE database.

**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** e2be\_admin  
**Notes:**  
**Example:** `oraclePassword = "password"`

#### oracleService

**Syntax:** `oracleService = "name"`  
**Description:** The Oracle service.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** ""  
**Notes:**  
**Example:** `oracleService = ""`

#### oracleUser

**Syntax:** `oracleUser = "name"`  
**Description:** The Oracle user that VWS uses to connect to the E2BE.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** "e2be\_admin"  
**Notes:**  
**Example:** `oracleUser = "e2be_admin"`

#### outDirectory

**Syntax:** `outDirectory = "dir"`  
**Description:** The directory from which EDRs are moved.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** IN/service\_packages/E2BE/logs/CDR  
**Notes:**  
**Example:** `outDirectory = "/var/edr/UBE"`

#### timeout

**Syntax:** `timeout = seconds`  
**Description:** Time (in seconds) before the EDR move is regarded as failed.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 4

## Chapter 3

**Notes:** The `timeout` value should be set to 4 seconds or less. If it is set to higher than 4 seconds, multiple "file cannot be deleted" messages will appear in the syslog.

**Example:** `timeout = 4`

### Example configuration

This is an example of the `beCDRMover` section of an `eserv.config` file on a VWS (comments have been removed).

```
beCDRMover = {
    oracleService = ""
    oracleUser = "e2be_admin"
    oraclePassword = "password"
    outDirectory = "/IN/service_packages/E2BE/logs/CDR"
    destinationDirectory = "/IN/service_packages/E2BE/logs/CDR-out"
    timeout = 4
    numberOfRecordsToCommit = 10
    commitTimeSeconds = 10
} # BE.beCDRMover
```

### Failure

If `beCDRMover` fails, no EDR files will be moved from the input directory until it is restarted.

### Output

The `beCDRMover` writes error messages to the system messages file, and also writes additional output to:

`/IN/service_packages/E2BE/tmp/beCDRMover.log`

**Note:** Above is default and can vary if configured differently to the default values.

## BeClient

### Purpose

BeClient is a SLEE interface that runs on the SLC. It communicates with the Voucher and Wallet Server using FOX over TCP/IP.

BeClient maintains connections to all primary nodes within all of the configured VWS domains. It switches from the primary to the secondary Voucher and Wallet Server if the TCP connection breaks or if a failure to detect Voucher and Wallet Server heartbeat occurs.

BeClient is designed to be mostly ignorant of the messages it routes. This enables it to be used with enhanced protocols without requiring upgrades.

### Startup

The BeClient is a SLEE interface and is started during SLEE initialization by the following line in `SLEE.cfg`:

```
INTERFACE=BeClient BeClientStartup.sh /IN/service_packages/BE/bin/ instance_count
EVENT
```

Where `instance_count` is the number of instances to run of the BeClient process.

**Note:** If you are running multiple BeClient instances, then each BeClient process will have the value of `instance_count - 1` appended to its name. So the first BeClient process will be named BeClient0 and subsequent BeClient processes will be named BeClient1, BeClient2 and so on. Nothing will be appended to the process name when you configure only one beClient instance to run.

For more information about starting and stopping BeClient processes, see *SLEE Technical Guide*.

## Configuration

In order to operate, BeClient plug-in reads the BeClient section of the `eserv.config` file. The BeClient section is listed below.

```
BeClient = {

    clientName = "str"

    heartbeatPeriod = microsecs
    messageTimeoutSeconds = seconds
    maxOutstandingMessages = int
    reportPeriodSeconds = seconds
    primaryFailbackIntreval = seconds
    connectionRetryTime = seconds

    plugins = [
        {
            config="confStr",
            library="lib",
            function="str"
        }
        [...]
    ]

    confStr = {
        plugin configuration
    }

    notEndActions = [
        {type="str", action="[ACK |NACK]"}
        [...]
    ]

    billingEngines = [
        { id = int,
          primary = { ip="ip", port=port },
          secondary = { ip="ip", port=port }
        }
        [...]
    ]
}
```

## Parameters

BeClient has no command line parameters.

The BeClient supports the following parameters from the BE section of `eserv.config`.

### billingEngines

<b>Syntax:</b>	<pre>billingEngines = [     { id = int       primary = { ip="ip", port=port },       secondary = { ip="ip", port=port }     }     [...] ]</pre>
<b>Description:</b>	Overrides connection details that <code>beLocationPlugin</code> (on page 41) obtains from the database.
<b>Type:</b>	Parameter array.
<b>Optionality:</b>	Optional ( <code>beLocationPlugin</code> finds connection details if not set).
<b>Allowed:</b>	
<b>Default:</b>	
<b>Notes:</b>	Identifies the Voucher and Wallet Servers and assigns their Internet connection details.
<b>Example:</b>	<pre>billingEngines = [     { id = 1,       primary = { ip="192.0.2.0", port=1500 },       secondary = { ip="192.0.2.1", port=1500 }     } ]</pre>

### id

<b>Syntax:</b>	<pre>id = int</pre>
<b>Description:</b>	This unique identifier for this Voucher and Wallet Server configuration.
<b>Type:</b>	Integer
<b>Optionality:</b>	Required, if this section is used
<b>Allowed:</b>	
<b>Default:</b>	
<b>Notes:</b>	This parameter is part of the <code>billingEngines</code> parameter array.
<b>Example:</b>	<pre>id = 1</pre>

### primary

<b>Syntax:</b>	<pre>primary = { ip="ip", port=port }</pre>
<b>Description:</b>	The <code>primary</code> parameter group defines the Internet Protocol (IP) address and associated port number of the primary Voucher and Wallet Server.
<b>Type:</b>	Parameter array
<b>Optionality:</b>	Required if this section is used
<b>Allowed:</b>	
<b>Default:</b>	
<b>Notes:</b>	This parameter is part of the <code>billingEngines</code> parameter array.
<b>Examples:</b>	<pre>primary = { ip="192.0.2.0", port=1500 } primary = { ip = "2001:db8:0000:1050:0005:0600:300c:326b", port=1500 } primary = {ip = "2001:db8:0:0:0:500:300a:326f", port=1500 } primary = { ip = "2001:db8::c3", port=1500 }</pre>

## secondary

<b>Syntax:</b>	<code>secondary = { ip="ip", port=port }</code>
<b>Description:</b>	The <code>secondary</code> parameter group defines the Internet Protocol (IP) address and associated port number of the secondary Voucher and Wallet Server.
<b>Type:</b>	Array
<b>Optionality:</b>	Required, if this section is used
<b>Allowed:</b>	
<b>Default:</b>	
<b>Notes:</b>	This parameter is part of the <code>billingEngines</code> parameter array.
<b>Examples:</b>	<pre>secondary = { ip="192.0.2.1", port=1500 } secondary = { ip = "2001:db8:0000:1050:0005:0600:300c:326b", port=1500 } secondary = {ip = "2001:db8:0:0:0:500:300a:326f", port=1500 } secondary = { ip = "2001:db8::c3", port=1500 }</pre>

## ip

<b>Syntax:</b>	<code>ip = "ip"</code>
<b>Description:</b>	The Internet Protocol (IP) address of the Voucher and Wallet Server.
<b>Type:</b>	String
<b>Optionality:</b>	Required
<b>Allowed:</b>	IP version 4 (IPv4) addresses, IP version 6 (IPv6) addresses
<b>Default:</b>	None
<b>Notes:</b>	This parameter is part of either the primary, or the secondary parameter group of the <code>billingEngines</code> parameter array. You can use the industry standard for omitting zeros when specifying IPv6 addresses.
<b>Examples:</b>	<pre>ip = "192.0.2.0" ip = "2001:db8:0000:1050:0005:0600:300c:326b" ip = "2001:db8:0:0:0:500:300a:326f" ip = "2001:db8::c3"</pre>

## port

<b>Syntax:</b>	<code>port = port</code>
<b>Description:</b>	The port number associated with the address of the Voucher and Wallet Server.
<b>Type:</b>	Integer
<b>Optionality:</b>	Required
<b>Allowed:</b>	
<b>Default:</b>	None
<b>Notes:</b>	This parameter is part of either the primary or secondary parameter group of the <code>billingEngines</code> parameter array.
<b>Example:</b>	<code>port = 1500</code>

### broadcastOptions

<b>Syntax:</b>	<pre>broadcastOptions = {     aggregateNAckCodes = [<i>config</i>] }</pre>
<b>Description:</b>	Name of configuration section for the BeClient Broadcast plug-in libclientBcast.
<b>Type:</b>	Parameter array
<b>Optionality:</b>	
<b>Allowed:</b>	
<b>Default:</b>	
<b>Notes:</b>	libclientBcast is used by a range of processes which connect to the beServer, including: <ul style="list-style-type: none"><li>• BeClient</li><li>• PlbeClient</li><li>• ccsBeOrb</li></ul> For more information about libclientBcast, see libclientBcast (on page 125).
<b>Example:</b>	<pre>broadcastOptions = {     aggregateNAckCodes = [ ] }</pre>

### aggregateNAckCodes

<b>Syntax:</b>	<pre>aggregateNAckCodes = [     "NVOU" ]</pre>
<b>Description:</b>	When this parameter is set, the BeClient waits for a response from all the VWS pairs in use and filters the responses from the broadcast request using the configured NAck codes.
<b>Type:</b>	Parameter array
<b>Optionality:</b>	
<b>Allowed:</b>	NVOU
<b>Default:</b>	
<b>Notes:</b>	When a voucher recharge request is broadcast, this ensures that all the available VWS pairs are checked for the required voucher before a voucher not found message is returned to the requesting process.
<b>Example:</b>	

### clientName

<b>Syntax:</b>	<pre>clientName = "<i>name</i>"</pre>
<b>Description:</b>	The unique client name of the process.
<b>Type:</b>	String
<b>Optionality:</b>	Required
<b>Allowed:</b>	Must be unique.
<b>Default:</b>	The host name of the local machine.
<b>Notes:</b>	The server generates clientId from a hash of <i>str</i> . If more than one client attempts to connect with the same name, then some connections will be lost. This parameter is used by libBeClientIF.
<b>Example:</b>	<pre>clientName = "scpClient"</pre>

`connectionRetryTime`

**Syntax:** `connectionRetryTime = seconds`

**Description:** The maximum number of seconds the client process will wait for a connection to succeed before attempting a new connection.

**Type:** Integer

**Optionality:** Required

**Allowed:**

**Default:** 5

**Notes:** This parameter is used by `libBeClientIF`.

**Example:** `connectionRetryTime = 2`

`heartbeatPeriod`

**Syntax:** `heartbeatPeriod = microsecs`

**Description:** The number of microseconds during which a Voucher and Wallet Server heartbeat message must be detected, or the BeClient process will switch to the other VWS in the pair.

**Type:** Integer

**Optionality:** Required

**Allowed:** 0 Disable heartbeat detection.  
positive integer Heartbeat period.

**Default:** 3000000

**Notes:** 1 000 000 microseconds = 1 second.  
If no heartbeat message is detected during the specified time, client process switches to the other Voucher and Wallet Server in the pair.  
This parameter is used by `libBeClientIF`.

**Example:** `heartbeatPeriod = 10000000`

`maxOutstandingMessages`

**Syntax:** `maxOutstandingMessages = num`

**Description:** The maximum number of messages allowed to be waiting for a response from the Voucher and Wallet Server.

**Type:** Integer

**Optionality:** Required

**Allowed:**

**Default:** If this parameter is not set, the maximum is unlimited.

**Notes:** If more than this number of messages are waiting for a response from the Voucher and Wallet Server, the client process assumes the Voucher and Wallet Server is overloaded. In this event, the client process refuses to start new calls but continues to service existing calls.  
The messages are queued until the Voucher and Wallet Server has reduced its outstanding load.  
This parameter is used by `libBeClientIF`.

**Example:** `maxOutstandingMessages = 100`

### messageTimeoutSeconds

<b>Syntax:</b>	<code>messageTimeoutSeconds = seconds</code>
<b>Description:</b>	The time that the client process will wait for the server to respond to a request.
<b>Type:</b>	Integer
<b>Units:</b>	Seconds
<b>Optionality:</b>	Required
<b>Allowed:</b>	1-604800 Number of seconds to wait. 0 Do not time out.
<b>Default:</b>	2
<b>Notes:</b>	After the specified number of seconds, the client process will generate an exception and discard the message associated with the request. This parameter is used by libBeClientIF.
<b>Example:</b>	<code>messageTimeoutSeconds = 2</code>

### notEndActions

<b>Syntax:</b>	<pre>notEndActions = [     {type="str", action="[ACK NACK]"}     [...] ]</pre>
<b>Description:</b>	The <code>notEndActions</code> parameter array is used to define the messages associated with dialogs that should not have their dialog closes, because the dialog is closed by default. This facilitates failover.
<b>Type:</b>	Parameter array.
<b>Optionality:</b>	Required
<b>Allowed:</b>	
<b>Default:</b>	
<b>Notes:</b>	If the incoming dialog for a call closes and the last response received was of the <code>notEndActions</code> type, the client process sends an ABRT message. The ABRT message allows the VWS to remove the reservation. An example of this situation would be where <code>slee_acs</code> has stopped working. This parameter is used by libBeClientIF. For more information about <code>slee_acs</code> , see <i>ACS Technical Guide</i> .
<b>Example:</b>	<pre>notEndActions = [     {type="IR ", action="ACK "}     {type="SR ", action="ACK "}     {type="SR ", action="NACK"}     {type="INER", action="ACK "}     {type="SNER", action="ACK "}     {type="SNER", action="NACK"} ]</pre>

`plugins`

<b>Syntax:</b>	<pre>plugins = [   {     config=""     library="lib"     function="str"   }   ... ]</pre>
<b>Description:</b>	Defines any client process plug-ins to run. Also defines the string which maps to their configuration section.
<b>Type:</b>	Parameter array
<b>Optionality:</b>	Optional (as plug-ins will not be loaded if they are not configured here, this parameter must include any plug-ins which are needed to supply application functions; for more information about which plug-ins to load, see the <code>BeClient</code> section for the application which provides the <code>BeClient</code> plug-ins).
<b>Allowed:</b>	
<b>Default:</b>	Empty (that is, do not load any plug-ins).
<b>Notes:</b>	The <code>libclientBcast</code> plug-in must be placed last in the plug-ins configuration list. For more information about the <code>libclientBcast</code> plug-in, see <i>libclientBcast</i> (on page 125). This parameter is used by <code>libBeClientIF</code> .
<b>Example:</b>	<pre>plugins = [   {     config="broadcastOptions"     library="libclientBcast.so"     function="makeBroadcastPlugin"   } ]</pre>

`primaryFailbackInterval`

<b>Syntax:</b>	<code>primaryFailbackInterval = seconds</code>
<b>Description:</b>	<code>seconds</code> defines the failback interval. If the number of seconds since the VWS sent the last request for a session running on the secondary BE is greater than the specified failback interval, then all subsequent requests for the session will be sent to the primary BE. During the failback interval, the secondary BE will synchronize requests to the primary BE.
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	<ul style="list-style-type: none"> <li>• 0 – For immediate failback</li> <li>• -1 – To disable primary failback</li> <li>• A positive integer</li> </ul>
<b>Default:</b>	-1
<b>Notes:</b>	Setting this parameter will not affect failover behavior. A session will failover to the other BE if a communications error means that it cannot continue processing on the current BE.
<b>Example:</b>	<code>primaryFailbackInterval = 10</code>

### reportPeriodSeconds

<b>Syntax:</b>	<code>reportPeriodSeconds = seconds</code>
<b>Description:</b>	The number of seconds separating reports of failed messages.
<b>Type:</b>	Integer
<b>Units:</b>	Seconds
<b>Optionality:</b>	Required
<b>Allowed:</b>	
<b>Default:</b>	10
<b>Notes:</b>	<p>BeClient issues a failed message report:</p> <ul style="list-style-type: none"><li>• For timed-out messages</li><li>• For unrequested responses</li><li>• For new calls rejected because of congestion</li><li>• For messages with invalid Voucher and Wallet Server identifiers</li><li>• If new and subsequent requests fail because both Voucher and Wallet Servers have stopped working</li></ul> <p>VWS heartbeat detection must be enabled for the parameter to work. Set <code>reportPeriodSeconds</code> to more than <code>heartbeatPeriod</code>.</p> <p>This parameter is used by <code>libBeClientIF</code>.</p>
<b>Example:</b>	<code>reportPeriodSeconds = 10</code>

### Example configuration

The following configuration is an example BeClient section of `eserv.config` on a Voucher and Wallet Server node. Comments have been removed.

```
BeClient = {
  clientName = "scpClient"
  heartbeatPeriod = 3000000
  messageTimeoutSeconds = 2
  maxOutstandingMessages = 100
  reportPeriodSeconds = 10
  primaryFailbackIntreval = 10
  connectionRetryTime = 2

  plugins = [
    {
      config="broadcastOptions",
      library="libclientBcast.so",
      function="makeBroadcastPlugin"
    }
  ]

  broadcastOptions = {
    aggregateNAckCodes = [
      "NVOU"
    ]
  }

  notEndActions = [
    {type="IR ", action="ACK "}
    {type="SR ", action="ACK "}
    {type="SR ", action="NACK"}
    {type="INER", action="ACK "}
    {type="SNER", action="ACK "}
    {type="SNER", action="NACK"}
  ]
}
```

```

]
billingEngines = [
  {
    id = 1,
    primary   = { ip="192.0.2.0", port=1500 },
    secondary = { ip="192.0.2.1", port=1500 }
  }
]
}

```

## Output

The BeClient writes error messages to the system messages file, and also writes additional output to:

```

//N/service_packages/CCS/tmp/BeClient.log

```

**Note:** The above are defaults and can vary.

## beGroveler

### Purpose

The beGroveler processes wallets daily on the primary VWS (while the VWS is active) and performs wallet inquiries. This triggers all beVWARS plug-ins that are activated on wallet inquiry (for example, beVWARSExpiry). This activity catches up on due events for wallets that have not been accessed for some time. This keeps the E2BE database relatively up to date and means operations such as MSC deactivation for removed accounts always happen (although later than they are scheduled to occur).

Additionally, the beGroveler executes a night time run to process all the wallets that have not been accessed during the day.

The beGroveler is designed to run on the primary VWS, although it will failover to the secondary if necessary. For more information about which VWS the beGroveler runs on, see *beGroveler quorum* (on page 142).

Tuning the beGroveler is a balance between the need to keep the database running smoothly for business purposes, and the load imposed by the process. Configuring the beGroveler for less than 100 ms per wallet (= 10 wallets/second) is not recommended.

### Process

The beGroveler maintains multiple asynchronous connections to the VWS database; a single connection for each beVWARS requesting grovel activity.

Here is the beGroveler process.

Stage	Description
1	A connection is assigned to the first beVWARS instance requiring grovel activity and a buffer is opened for it.
2	The wallets with currently expired buckets are retrieved and stored to the buffer in a collection set for the beVWARS. The buffer is then closed.
3	The beVWARS requests are then processed directly from the set instead of being continuously fetched from the database.
4	The beGroveler is responsible for maintaining the set of wallets in the beVWARS buffer. When it is empty, or it drops below a configured threshold, then the buffer is automatically reopened and more wallet details are collected.

Stage	Description
5	Successive beVWARS instances perform one of the following: <ul style="list-style-type: none"> <li>• Use an existing connection that is not currently managing a buffer</li> <li>• Open a new connection if all the current connections are in operation</li> </ul>
6	At the end of the day the beGroveler creates a list of all the wallets that have not been accessed during the day, and these are processed during the overnight run.

## Startup

This task is started by the SLEE, by the following line in **SLEE.cfg**:

```
INTERFACE=beGroveler beGroveler /IN/service_packages/E2BE/bin instance_count
EVENT
```

Where *instance\_count* is the number of instances to run of the beGroveler process.

### Notes:

- To enable beGroveler to run, you must set the `enableGroveling` (on page 41) parameter to true.
- If you configure the SLEE to run multiple instances of the beGroveler, then each beGroveler process will have the value of *instance\_count* - 1 appended to the process name. So the master beGroveler process will be named beGroveler0 and subsequent slave beGroveler processes will be named beGroveler1, beGroveler2 and so on. If you configure only one instance of the beGroveler, then nothing will be appended to the process name.

For more information about configuring SLEE interfaces, see *SLEE Technical Guide*.

## Configuration

The beGroveler uses parameters from these parameter groups in the **eserv.config** file on VWS nodes:

- beGroveler
- beVWARS *groveler parameters* (on page 102)

beGroveler also uses the `enableGroveling` (on page 41) shared parameter from the BE section of **eserv.config**.

The `beGroveler` group contains parameters in the structure shown below.

```
beGroveler = {
  quorumHost = "host"
  maxIDsPerResponse = ids
  retrySeconds = seconds
  processExpiredBuckets = true|false
  consecutiveFetch = num
  noProcessingTimes = [
    { startsAt = "HH:MM", endsAt = "HH:MM" }
    ...
  ]
  connectionRetryTime = seconds
  heartbeatPeriod = microseconds
  filledBufferThreshold = num
  ludProcessingTime = "HH:MM"
}
```

## Example configuration

This is an example of the beGroveler section of an `eserv.config` file on a VWS (comments have been removed).

```
beGroveler = {
  quorumHost = "produsms-cluster"
  maxIDsPerResponse = 160
  retrySeconds = 60
  processExpiredBuckets = true
  noProcessingTimes = [
    { startsAt = "06:00", endsAt = "09:30" }
    { startsAt = "11:30", endsAt = "14:00" }
    { startsAt = "16:00", endsAt = "21:00" }
  ]
  connectionRetryTime = 60
  heartbeatPeriod = 300000000
  filledBufferThreshold = 480
  ludProcessingTime = "14:04"
}
```

## Parameters

Parameters of the beGroveler group are listed below.

`connectionRetryTime`

<b>Syntax:</b>	<code>connectionRetryTime = <i>seconds</i></code>
<b>Description:</b>	The number of seconds between attempts to establish a connection to the beServer on the local VWS and the remote VWS in this pair.
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	
<b>Default:</b>	60
<b>Notes:</b>	The connection to beServer establishes whether or not the local and remote VWSs are in the running state. If it fails to make a connection, beGroveler will log an error to the syslog. For more information about states, see <i>BE States</i> (on page 26).
<b>Example:</b>	<code>connectionRetryTime = 60</code>

`consecutiveFetch`

<b>Syntax:</b>	<code>consecutiveFetch = <i>num</i></code>
<b>Description:</b>	Maximum number of consecutive fetches between other priority checks.
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	
<b>Default:</b>	3000
<b>Notes:</b>	This number is hard coded in versions prior to 2.4.0.22.
<b>Example:</b>	<code>consecutiveFetch = 3000</code>

### filledBufferThreshold

<b>Syntax:</b>	<code>filledBufferThreshold = num</code>
<b>Description:</b>	Threshold for the minimum number of wallet ID entries stored in the buffer. A refill is needed when the number of entries in the buffer falls below this number.
<b>Type:</b>	Integer
<b>Optionality:</b>	Required
<b>Allowed:</b>	
<b>Default:</b>	320
<b>Notes:</b>	A separate buffer will be used for each beGroveler client. The beGroveler will continue to fetch wallets until all the client buffers are full. It will then wait until the number of entries in one of the buffers falls below the minimum before fetching more wallets.
<b>Example:</b>	<code>filledBufferThreshold = 400</code>

### heartbeatPeriod

<b>Syntax:</b>	<code>heartbeatPeriod = microsecs</code>
<b>Description:</b>	The heartbeat period for the beGroveler connection to the beServer through beClientIF.
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	
<b>Default:</b>	300000000 (300 seconds)
<b>Notes:</b>	
<b>Example:</b>	<code>heartbeatPeriod = 300000000</code>

### ludProcessingTime

<b>Syntax:</b>	<code>ludProcessingTime = "HH:MM"</code>
<b>Description:</b>	Defines the hour of the day when the last used date logic will execute. If the beGroveler starts at a later time in the day, then the last used date logic processing will be delayed until the next day. If this hour occurs in a no processing period, then the last used date logic processing will be delayed until the end of the no processing period.
<b>Type:</b>	String
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	A valid time in the format <i>HH:MM</i>
<b>Default:</b>	00:00
<b>Notes:</b>	
<b>Example:</b>	<code>ludProcessingTime = "10:00"</code>

### maxIDsPerResponse

<b>Syntax:</b>	<code>maxIDsPerResponse = ids</code>
<b>Description:</b>	The number of wallet IDs to send to a beVWARS process when it requests wallets to grovel.
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	
<b>Default:</b>	160

**Notes:** beVWARS processes request IDs when they run out other work to do. Setting too low will make groveling slow. Setting it too high will make the response exceed the SLEE event size. 1k events will fit in about 160. 2k events will fit in ~330. Fit in as many as your event size will allow.

For more information about SLEE event sizes, see *SLEE Technical Guide*.

**Example:** `maxIDsPerResponse = 160`

`noProcessingTimes`

**Syntax:**

```
noProcessingTimes = [
  { startsAt = "HH:MM", endsAt = "HH:MM" }
  ...
]
```

**Description:** The time periods during each day when beGroveler should not return any wallet IDs to beVWARS which are requesting wallet IDs to grovel.

**Type:** Array

**Optionality:** Optional (default used if not set)

**Allowed:**

**Default:** No time restrictions.

**Notes:**

**Example:**

```
noProcessingTimes = [
  { startsAt = "06:00", endsAt = "09:30" }
  { startsAt = "11:30", endsAt = "14:00" }
  { startsAt = "16:00", endsAt = "21:00" }
]
```

`startsAt`

**Syntax:** `startsAt = "HH:MM"`

**Description:** The hour and minute to start a period of not sending wallets to be groveled beVWARS processes.

**Type:** String

**Optionality:** Required if `noProcessingTimes` is set

**Allowed:**

**Default:** No default

**Notes:** The period is finished by the `endsAt` (on page 63) parameter paired with this `startsAt` parameter in the `{}` set.

This parameter is part of the `noProcessingTimes` (on page 63) parameter array.

**Example:** `startsAt = "06:00"`

`endsAt`

**Syntax:** `endsAt = "HH:MM"`

**Description:** The hour and minute to finish a period of not sending wallets to be groveled beVWARS processes.

**Type:** String

**Optionality:** Required if `noProcessingTimes` is set

**Allowed:**

**Default:** No default

**Notes:** The period is started by the `startsAt` (on page 63) parameter paired with this `endsAt` parameter in the `{}` set.

This parameter is part of the `noProcessingTimes` (on page 63) parameter array.

**Example:** `endsAt = "09:30"`

### `processExpiredBuckets`

**Syntax:** `processExpiredBuckets = true|false`

**Description:** Activates or deactivates expired bucket processing.

**Type:** Boolean

**Optionality:** Optional (default used if not set)

**Allowed:**

<code>true</code>	Activate expired bucket processing. The <code>beGroveler</code> will fetch wallets as often as required and process buckets based on the bucket expiry date.
<code>false</code>	Deactivate expired bucket processing. The <code>beGroveler</code> will fetch wallets for processing once per day at the time set by the <code>ludProcessingTime</code> parameter.

**Default:** `true`

**Notes:**

**Example:** `processExpiredBuckets = true`

### `quorumHost`

**Syntax:** `quorumHost = "host"`

**Description:** The host name or IP address of a machine on the same VWS subnet to use as a quorum device. The quorum machine is used to break a tie when trying to decide if `beGroveler` should allow the `beVWARS` processes to process wallets.

**Type:** String

**Optionality:** Required. If this is not set, or if the specified machine is not on the same VWS subnet, `groveling` may not start (see Notes).

**Allowed:**

**Default:** Not specified

**Notes:** This value is used when a `beGroveler` cannot see the other VWS in a pair (that is, it cannot ping the other VWS). In this case, `beGroveler` needs to decide which VWS is partitioned from the rest of the network. If this `beGroveler` can see `quorumHost` but not the other VWS, it will `grovel`. This means that `quorumHost` must be another device on the same subnet that the VWS nodes use for communication.

A good value for `quorumHost` may be the logical address of a SMS cluster, or the IP address of a non-clustered SMS, but you should confirm this with the network administrator.

**Example:** `quorumHost = "produsms-cluster"`

### `retrySeconds`

**Syntax:** `retrySeconds = seconds`

**Description:** How many seconds to tell `beVWARS` to wait before sending another request for wallet IDs to process. Used when `beGroveler` cannot find any wallets which need `groveling` to send to a `beVWARS` which has requested wallets to `grovel`.

<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	0      beGroveler will attempt to calculate a useful delay to set. Either: <ul style="list-style-type: none"> <li>• the time that a wallet for the requesting beVWARS will expire + 1 minute (up to a maximum of 1 hour), or</li> <li>• 300 (five minutes).</li> </ul>
	positive integer      The number of seconds beVWARS should wait before asking for more wallet IDs to grovel.
<b>Default:</b>	0
<b>Notes:</b>	
<b>Example:</b>	<code>retrySeconds = 60</code>

## beServer

### Purpose

Handles connections from client processes (including BeClient processes) and controls routing to beVWARS processes.

It maintains a list of connected clients, and loads plug-ins to handle different request types.

The beServer is a finite state machine, handling one request at a time until either a response can be sent back, or more information is needed and a further request is sent to the beVWARS.

The beServer deals with:

- Multiple client connections (via be protocol)
- Pluggable message handlers (per message type x message version)
- Call context for call state for plug-ins
- SLEE event message passing
- Switchable accepting messages from client
- Resynchronizable call context.

### Plug-ins

beServer can be extended by:

- Routing handlers specified in the `messageRoutingPlugins` (on page 70) parameter (such as `libbeMsgRouterDefault` (on page 124))
- Message handlers specified in the `handlers` (on page 69) parameter.

The beServer will attempt to process messages using its own handlers; if no handler is found the message will be sent to the beVWARS for processing. Message handlers are generally provided by other applications such as CCS to provide application-specific functions such as asking the beVWARS (through the SLEE) for account information, reservations, and billing.

For more information about the plug-ins provided by CCS, see *CCS Technical Guide*.

## About running multiple beServer processes

You can run multiple instances of the beServer to improve performance. The first beServer process (beServer0) is the master beServer and all other instances of the beServer are its slave processes. The master beServer determines which slave beServer to use for each new VWS client connection. It checks the status of the slave beServers and load balances client connections across all slave beServers on the VWS (the master beServer also acts as a slave in this respect and will assign connections to itself as required by the connection loading). After a VWS client connection has been assigned to a slave beServer, it will remain attached to that slave beServer for the lifetime of the connection.

**Note:** You can configure the master beServer process to always handle specific VWS client interface connections itself. By default, this includes the beGroveler and ccsMfileCompiler connections. See *clientLoadWeightings* (on page 67) for more information.

## Startup

This task is started by the SLEE, by the following line in **SLEE.cfg**:

```
INTERFACE=beServer beServerStartup.sh /IN/service_packages/E2BE/bin instance_count EVENT
```

Where *instance\_count* is the number of instances to run of the beServer process.

**Note:** If you configure the SLEE to run multiple instances of the beServer, then each beServer process will have the value of *instance\_count* - 1 appended to the process name. So the first beServer process will be named beServer0 and subsequent beServer processes will be named beServer1, beServer2 and so on. If you configure only one instance of the beServer, then nothing will be appended to the process name.

For more information about configuring SLEE interfaces, see *SLEE Technical Guide*

## Configuration

The beServer is configured by the parameters in the following section of **eserv.config** file:

```
beServer = {
  clientSelectTime = microsecs
  quiesceLength = microsecs
  serverPortOverride = port
  clientSocketBufferSize = bytes
  maxDownstreamQueueLength = int
  downstreamOverloadSleepUSec = microsecs
  dbConnCheckTime = seconds
  recoveryReportInterval = seconds

  notEndActions = [
    {type="str", action="[ACK|NACK]"}
    [...]
  ]

  handlers = [
    "lib"
    [...]
  ]

  messageRoutingPlugins = [
    "lib"
    ...
  ]

  msgRouterDefault = {
    roundRobinTypes = [
      "TYPE"
    ]
  }
}
```

```

    ...
  ]
  routeOnVoucherNumber = true|false
}

purge = {
  purgeInterval = seconds
  vwarTimeout = seconds
  expectedKeep = seconds
  noExpectedKeep = seconds
}

routingVoucherNumberLength = int
slaveLocalSocketDirectory = "directory"

clientLoadWeightings = [
  {name="client_name", weighting=value}
  {...}
]
}

```

## Parameters

Parameters of the `beServer` group are listed below.

### `clientLoadWeightings`

**Syntax:**

```

clientLoadWeightings = [
  {name="client_name", weighting=value}
  {name="client_name", weighting=value}
  ...
]

```

**Description:**

Defines the load weighting value to assign to each type of client connected to the `beServer`. This improves load sharing over multiple `beServer` interfaces.

- `client_name` is the name of a client interface configured in **SLEE.cfg**.
- `value` is the load weighting value and indicates the expected traffic load from the specified client interface. A larger value indicates a greater expected load.

The weighting value for the `beGroveler` and `ccsMFileCompiler` clients should be zero (0) and you should not change their value. Setting the weighting value to zero forces the master `beServer` to always handle the connection itself.

**Type:**

Array

**Optionality:**

Optional (default used if not set)

**Allowed:**

**Default:**

100 except `ccsMfileCompiler` (default 0), and `beGroveler` (default 0)

**Notes:**

The `clientLoadWeightings` configuration is used when there are multiple instances of the `beServer` interface running. It is not used if only one `beServer` interface is running.

**Example:**

```

clientLoadWeightings = [
  {name="ccsBeClient", weighting=200}
  {name="ccsMFileCompiler", weighting=0}
  {name="ccsBeGroveler", weighting=0}
  {name="ccsBeOrb", weighting=10}
  {name="ccsBeResync", weighting=100}
  {name="ccsBatchCharge", weighting=10}
  {name="ccsDomainMigration", weighting=50}
  {name="ccsAccount", weighting=10}
  {name="ccsPeriodicCharge", weighting=100}
  {name="ccsChangeDaemon", weighting=50}
  {name="ccsSLEEChangeDaemon", weighting=50}
  {name="PIbeClient", weighting=10}
]

```

`clientSelectTime`**Syntax:** `clientSelectTime = microsecs`**Description:** The number of microseconds between each instant where beServer checks the SLEE for events.**Type:** Integer**Optionality:** Optional (default used if not set)**Allowed:****Default:** 1000000**Notes:**

- 1 000 000 microseconds = 1 second.
- If an event is waiting on the SLEE, beServer ignores this setting and makes the next check immediately afterwards. This allows a second event to be detected without delay.
- If the **eserv.config** file is reloaded, beServer will re-read the `clientSelectTime` parameter.

**Example:**`clientSocketBufferSize`**Syntax:** `clientSocketBufferSize = bytes`**Description:** The maximum message size in bytes expected from the BeClients connected to the beServer.**Type:** Integer**Optionality:** Optional (default used if not set)**Allowed:****Default:** 10240**Notes:** A message larger than this value will not be constructed properly.**Example:** `clientSocketBufferSize = 10240``dbConnCheckTime`**Syntax:** `dbConnCheckTime = seconds`**Description:** The number of seconds between each check that beServer is connected to, and logged on to, the Oracle database.**Type:** Integer**Optionality:** Optional**Allowed:****Default:** 1**Notes:** If the Oracle database is not available, the current Voucher and Wallet Server is

disabled and BeClient routes calls to the other Voucher and Wallet Server.

**Example:** `dbConnCheckTime = 1`

`downstreamOverloadSleepUsec`

**Syntax:** `downstreamOverloadSleepUsec = microsecs`

**Description:** If a downstream process like beVWARS is overloaded, this parameter sets the number of microseconds that beServer will wait before rechecking the process.

**Type:** Integer

**Optionality:** Required

**Allowed:**

**Default:**

- Notes:**
- 1 000 000 microseconds = 1 second.
  - This value must be shorter than the SLEE watchdog timeout period.

**Example:** `downstreamOverloadSleepUsec = 100000`

`handlers`

**Syntax:**

```
handlers = [
    "lib"
    [...]
]
```

**Description:** The handlers parameter array contains plug-in library files that beServer must load.

**Type:** Parameter array

**Optionality:** Optional

**Allowed:**

**Default:**

- Notes:**
- Plug-in library files contain message handlers for requests from clients. A typical file might be libbeServerPingPlugin.so.
  - The order that plug-in files are listed in the array is important. A handler can be loaded twice, causing the last handler to be the one used.
  - If the **eserv.config** file is reloaded, beServer will re-read the plug-in library files in the handlers parameter array.

**Example:**

```
handlers = [
    "libbeServerPingPlugin.so"
]
```

`quiesceLength`

**Syntax:** `quiesceLength = microsecs`

**Description:** The number of microseconds that the beServer will restrict traffic to only sending responses to outstanding requests from clients.

**Type:** Integer

**Optionality:** Optional (default used if not set)

**Allowed:**

**Default:** 100000 (1/10 second)

**Notes:** beServer will not read any new work during a quiesced interval so the Voucher and Wallet Server has a chance to confirm the result of requests to the clients. This minimizes failing over requests to the other VWS in the pair that have been

successfully processed on this VWS, but the confirmation has not been sent to the client.

Client requests that have yet to be read will build up during this time, and when they exceed the maximum queue length, BFT will kick in on the client. The beServer will close the socket after quiesceLength has passed, and all traffic will be directed at the other VWS in this pair.

This value should be set to the maximum time it takes to process all outstanding requests currently on the SLEE. Any longer and outstanding requests on the sockets will be delayed unnecessarily.

For more information about VWS error states and recovery, see *Process Failure Recovery* (on page 141).

**Example:** `quiesceLength = 100000`

#### maxDownStreamQueueLength

**Syntax:** `maxDownStreamQueueLength = len`  
**Description:** The maximum number of pending events on any beVWARS.  
**Type:** Integer  
**Optionality:** Required  
**Allowed:**  
**Default:**  
**Notes:** If pending events exceed this number, beServer refers to the `downstreamOverloadSleepUsec` parameter.  
**Example:** `maxDownStreamQueueLength = 1000`

#### messageRoutingPlugins

**Syntax:** `messageRoutingPlugins = [ "lib" ]`  
**Description:** Which message routing plug-ins to load.  
**Type:** Array  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:**  
**Notes:** These plug-ins tell the beServer which beVWARS to pass requests to. Requests based on a wallet or a voucher must continue to be serviced by the same beVWARS so it can keep the wallet or voucher cached.  
 For more information, see *libbeMsgRouterDefault* (on page 124).  
**Example:** `messageRoutingPlugins = [ "libbeMsgRouterDefault.so" ]`

#### msgRouterDefault

**Syntax:** `msgRouterDefault = { roundRobinTypes = [] }`  
**Description:** Defaults for the message routing plug-ins loaded by `messageRoutingPlugins` (on page 70).  
**Type:** Array  
**Optionality:**

**Allowed:****Default:****Notes:** Includes the `roundRobinTypes` (on page 71) parameter**Example:**`roundRobinTypes`

**Syntax:**

```
roundRobinTypes = [
    "type"
    ...
]
```

**Description:** Default routing for `libbeMsgRouterDefault.so`.**Type:** Array of four-character strings.**Optionality:** Optional (default used if not set)**Allowed:****Default:** VI

**Notes:** If a message does not have a [WALT] or [VNUM] tag and its message type is in this array, it will be round robin around beVWARS to share load. The CCS VI message may or may not have a [VNUM] field. You can also organize the elements in this array in one line, using a comma ',' to separate the types.

**Example:**

```
roundRobinTypes = [
    "VI "
]
```

`routeOnVoucherNumber`

**Syntax:** `routeOnVoucherNumber = true|false`

**Description:** What method to use to determine which beVWARS process to route voucher redeem requests to.**Type:** Boolean**Optionality:** Optional (default used if not set)

**Allowed:**

- `true` Use a hash of the Voucher Number to route to beVWARS. Compatible with CCS 3.1.4 and earlier.
- `false` Use Voucher ID to route to beVWARS. Compatible with CCS 3.1.5 and later.

**Default:** true**Notes:** This parameter is used by the `libbeMsgRouterDefault` library.**Example:** `routeOnVoucherNumber = false``notEndActions`

**Syntax:**

```
notEndActions = [
    {type="type", action="ACK|NACK"}
    [...]
]
```

**Description:** This parameter array identifies messages that will be followed by subsequent message.**Type:** Parameter array**Optionality:** Required

**Allowed:**

**Default:**

**Notes:**

**Example:**

```
notEndActions = [  
    {type="IR  ", action="ACK "  
    {type="SR  ", action="ACK "  
    {type="SR  ", action="NACK"  
    {type="INER", action="ACK "  
    {type="SNER", action="ACK "  
    {type="SNER", action="NACK"  
]
```

purge

**Syntax:**

```
purge = {  
    purgeInterval = seconds  
    vwarTimeout = seconds  
    expectedKeep = seconds  
    noExpectedKeep = seconds  
}
```

**Description:** The purge parameter group contains parameters that control purges.

**Type:** Parameter group.

**Optionality:** Optional

**Allowed:**

**Default:**

**Notes:** Running purge stresses the system with high loads.

**Example:**

expectedKeep

**Syntax:** `expectedKeep = seconds`

**Description:** A plug-in can specify the number of seconds it will wait for a request for a context that it wants to keep. This parameter sets additional time, after the plug-in's time, that beServer keeps a context if (during this period) no request for the context is made.

**Type:** Integer

**Optionality:** Optional

**Allowed:**

**Default:** 60

**Notes:**

- This parameter is part of the `purge` parameter group.
- If the `eserv.config` file is reloaded, beServer will re-read the parameter.

**Example:** `expectedKeep = 60`

noExpectedKeep

**Syntax:** `noExpectedKeep = seconds`

**Description:** If the plug-in does not specify a time it will wait for a request for a wanted context, this parameter defines the number of seconds that beServer will keep the context.

**Type:** Integer

**Optionality:** Optional

**Allowed:**

**Default:** 3600

**Notes:**

- This parameter is part of the `purge` parameter group.

- If the **eserv.config** file is reloaded, beServer will re-read the parameter.
- This parameter should be set to the equivalent value in seconds as the CCS `volumeReservationLength` value. See *CCS Technical Guide*

**Example:** `volumeReservationLength = 2 (days)`  
`noExpectedKeep = 172800 (number of seconds in 2 days)`

#### `purgeInterval`

**Syntax:** `purgeInterval = seconds`

**Description:** The number of seconds between purges.

**Type:** Integer

**Optionality:** Optional

**Allowed:**

**Default:** 300

**Notes:**

- This parameter is part of the `purge` parameter group.
- If the **eserv.config** file is reloaded, beServer will re-read the parameter.

**Example:** `purgeInterval = 300`

#### `vwarTimeout`

**Syntax:** `vwarTimeout = seconds`

**Description:** The number of seconds between the moment that beServer sends a request to the beVWARS and the moment that beServer fabricates an exception response.

**Type:** Integer

**Units:** Seconds

**Optionality:** Optional

**Allowed:**

**Default:** 10

**Notes:**

- This parameter is read during a purge.
- This parameter is part of the `purge` parameter group.
- If the **eserv.config** file is reloaded, beServer will re-read the parameter.

**Example:** `vwarTimeout = 10`

#### `recoveryReportInterval`

**Syntax:** `recoveryReportInterval = seconds`

**Description:** The number of seconds between logging each recovery report to the syslog while in recovery mode.

**Type:** Integer

**Optionality:** Optional (default used if not set)

**Allowed:**

**Default:** 60

**Notes:** The recovery report records how many beVWARS processes beServer is waiting to go into running state before it will go into running state.  
 For more information about the different states, see *Process Failure Recovery* (on page 141).

**Example:** `recoveryReportInterval = 60`

`routingVoucherNumberLength`

<b>Syntax:</b>	<code>routingVoucherNumberLength = len</code>
<b>Description:</b>	The length of the prefix of the voucher number to use for routing voucher messages to beVWARS processes.
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	
<b>Default:</b>	10
<b>Notes:</b>	For CCS vouchers, this should match the length of the voucher number, not the length of the voucher signature. For more information about voucher numbers and voucher signatures, see <i>Voucher Manager User's Guide</i> .
<b>Example:</b>	<code>routingVoucherNumberLength = 10</code>

`serverPortOverride`

<b>Syntax:</b>	<code>serverPortOverride = port</code>
<b>Description:</b>	The port number beServer uses as an alternative to the one defined by the beLocationPlugin (on page 41).
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional
<b>Allowed:</b>	-1                    Do not override beLocationPlugin. any valid port    Port for beServer to use.
<b>Default:</b>	-1
<b>Notes:</b>	This parameter is usually used for testing.
<b>Example:</b>	<code>serverPortOverride = 1500</code>

`slaveLocalSocketDirectory`

<b>Syntax:</b>	<code>slaveLocalSocketDirectory = "directory_name"</code>
<b>Description:</b>	Specifies the directory to use for files created by interprocess communication (IPC) objects, such as sockets, semaphores, and shared memory. The IPC objects enable communication between master and slave beServer interfaces.
<b>Type:</b>	String
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	A valid directory location.
<b>Default:</b>	/tmp
<b>Notes:</b>	None
<b>Example:</b>	<code>slaveLocalSocketDirectory = "/tmp"</code>

## Example configuration

This is an example of the beServer section of the `eserv.config` file on a VWS node (comments have been removed).

```
beServer = {
    clientSelectTime = 1000000
    quiesceLength = 100000
    serverPortOverride = 1500
    clientSocketBufferSize = 10240
    maxDownstreamQueueLength = 1000
    downstreamOverloadSleepUSec = 100000
    dbConnCheckTime = 5
}
```

```

recoveryReportInterval = 60

notEndActions = [
    {type="IR  ", action="ACK "}
    {type="SR  ", action="ACK "}
    {type="SR  ", action="NACK"}
    {type="INER", action="ACK "}
    {type="SNER", action="ACK "}
    {type="SNER", action="NACK"}
]

handlers = [
    "libbeServerPingPlugin.so"
]

messageRoutingPlugins = [
    "libbeMsgRouterDefault.so"
]

msgRouterDefault = {
    roundRobinTypes = [
        "VI  "
    ]
    routeOnVoucherNumber = true
}

purge = {
    purgeInterval = 300
    vvarsTimeout = 10
    expectedKeep = 60
    noExpectedKeep = 3600
}

routingVoucherNumberLength = 10
slaveLocalSocketDirectory = "/tmp"

clientLoadWeightings = [
    {name="ccsBeClient", weighting=200}
    {name="ccsMFileCompiler", weighting=0}
    {name="ccsBeGroveler", weighting=0}
    {name="ccsBeOrb", weighting=10}
    {name="ccsBeResync", weighting=100}
    {name="osaChamScs", weighting=100}
    {name="ccsBatchCharge", weighting=10}
    {name="ccsDomainMigration", weighting=50}
    {name="ccsAccount", weighting=10}
    {name="ccsPeriodicCharge", weighting=100}
    {name="ccsChangeDaemon", weighting=50}
    {name="ccsSLEEChangeDaemon", weighting=50}
    {name="PIbeClient", weighting=10}
]

} # BE.beServer

```

## Output

The beServer writes error messages to the system messages file, and also writes additional output to the following location by default:

**/IN/service\_packages/E2BE/tmp/beServer.log**

## beSync

### Purpose

Synchronizes data between the Voucher and Wallet Servers in a VWS pair.

beSync collects all updates and reservations being made, and writes them to disk. It then reads them from disk and sends them to the other VWS, as and when it can.

For more information on beSync and how it interacts with other VWS components, see *Synchronization* (on page 20).

### Startup

This task is started by the SLEE, by the following line in **SLEE.cfg**:

```
INTERFACE=beSync  beSyncStartup.sh  /IN/service_packages/E2BE/bin instance_count
EVENT
```

Where *instance\_count* is the number of instances to run of the beSync process.

**Note:** If you configure the SLEE to run multiple instances of the beSync process, then each beSync process will have the value of *instance count* - 1 appended to the process name. So the first beSync process will be named beSync0 and subsequent beSync processes will be named beSync1, beSync2 and so on. If you configure only one instance of beSync then nothing is appended to the process name.

For more information about configuring SLEE interfaces, see *SLEE Technical Guide*.

### Configuration

beSync accepts the following parameters from **eserv.config**.

```
beSync = {
    shared = {
        noWorkSleepTime = seconds

        spoolDirectory = "dir"
        spoolChunkSize = num
        badFileDirectory = "dir"

        maxDownstreamQueueLength = num
        downstreamOverloadSleepUsec = int
    }

    sink = {
        inSyncThresholdSeconds = seconds
        inSyncReportingPeriodRecords = records

        maxSecsToWaitForRemoteOperations = seconds

        remoteBEhostname="host"
        remoteBEport=port

        retryConnectionDelaySeconds = seconds
        maxRetriesBeforeStart = num

        localUpdateChunkSize = size
        heartbeatPeriodSeconds = seconds
    }

    source = {
        listenInterface="ip"
```

```

listenPort = port

recordSendingChunkSize = num
maxQueueLength = num
}
}

```

## Parameters

Here are the parameters in the `beSync` section.

### shared parameters

The `shared` sub-section of `beSync` defines the `beSync` shared items.

#### `badFileDirectory`

**Syntax:** `badFileDirectory = "dir"`  
**Description:** Directory to move corrupted resync files to.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:** Any directory path.  
**Default:** `"/IN/service_packages/E2BE/tmp"`  
**Notes:** Files in this directory will be called **file.bad**.  
**Example:** `badFileDirectory = "/IN/service_packages/E2BE/tmp"`

#### `downstreamOverloadSleepUsec`

**Syntax:** `downstreamOverloadSleepUsec = int`  
**Description:** When a downstream process, a `beVWARS` is overloaded, sleep for this period before rechecking.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 100000  
**Notes:** This value must be shorter than the `SLEE` watchdog timeout period.  
**Example:** `downstreamOverloadSleepUsec = 100000`

#### `maxDownstreamQueueLength`

**Syntax:** `maxDownstreamQueueLength = num`  
**Description:** The maximum number of pending events on any `beVWARS`. When more than this number of events are queued on any of the processes, `beSync` will sleep.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 10000  
**Notes:** See *maxQueueLength* (on page 81) for throttling based on the remote `beSync`.

**Important:** Care should be taken when setting `BE.beSync.maxDownstreamQueueLength` as this is the value that slows a full resync by keeping each of the `beVWARS` processes busy. If you allow a full resync to run as fast as possible, it will use up all of the events.

**Example:** `maxDownstreamQueueLength = 10000`

### `noWorkSleepTime`

**Syntax:** `noWorkSleepTime = seconds`

**Description:** The sleep time in seconds.

**Type:** Integer

**Optionality:** Optional (default used if not set)

**Allowed:**

**Default:** 0.2

**Notes:** Should be small (0.x) in production, and larger in test (2.0). Lower values will cause more CPU usage.

**Example:** `noWorkSleepTime = 0.2`

### `spoolChunkSize`

**Syntax:** `spoolChunkSize = num`

**Description:** The number of records to read and send in one cycle.

**Type:** Integer

**Optionality:** Optional (default used if not set)

**Allowed:**

**Default:** 16

**Notes:**

**Example:** `spoolChunkSize = 16`

### `spoolDirectory`

**Syntax:** `spoolDirectory = "dir"`

**Description:** This is where all transactions are written to disk by beVWARS so they can be replayed to one of the following:

- The remote VWS in the pair
- If there has been a failure, the local VWS in the pair

**Type:** String

**Optionality:** Optional (default used if not set)

**Allowed:**

**Default:** `/IN/service_packages/E2BE/sync`

**Notes:** Available space in the directory set by this parameter is checked by the beSync against the limits set in the Disk space parameters.

**Example:** `spoolDirectory = "/var/logs/sync"`

## **sink parameters**

The `sink` sub-section of `beSync` defines the sink parameters for `beSync`. This is the component that *receives* operations from the remote `beSync`.

### `heartbeatPeriodSeconds`

**Syntax:** `heartbeatPeriodSeconds = seconds`

**Description:** How often in seconds heartbeat packets are sent on a connection.

**Type:** Integer

**Optionality:** Optional (default used if not set)

**Allowed:**  
**Default:** 10  
**Notes:**  
**Example:** `heartbeatPeriodSeconds = 10`

#### `inSyncThresholdSeconds`

**Syntax:** `inSyncThresholdSeconds = seconds`  
**Description:** How close (in seconds) to real-time before the beSync is enabled.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 5  
**Notes:**  
**Example:** `inSyncThresholdSeconds = 5`

#### `inSyncReportingPeriodRecords`

**Syntax:** `inSyncReportingPeriodRecords = records`  
**Description:** The number of records between checks against real-time.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 10000  
**Notes:**  
**Example:** `inSyncReportingPeriodRecords = 10000`

#### `localUpdateChunkSize`

**Syntax:** `localUpdateChunkSize = size`  
**Description:** Tuning parameter.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 100  
**Notes:**  
**Example:** `localUpdateChunkSize = 100`

#### `maxRetriesBeforeSeconds`

**Syntax:** `maxRetriesBeforeSeconds = num`  
**Description:** The number of attempts to contact the other VWS in the pair before we start regardless.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 5  
**Notes:**  
**Example:** `maxRetriesBeforeSeconds = 5`

### maxSecsToWaitForRemoteOperations

**Syntax:** `maxSecsToWaitForRemoteOperations = seconds`  
**Description:** During the synchronization process, the maximum number of seconds beSync waits for a remote operation message before enabling beVWARS to move to the Running state.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:** 0 – beSync does not wait before enabling beVWARS to move to the Running state.  
Positive integer – Specifies the number of seconds beSync waits for a remote operation message.  
**Default:** 5  
**Notes:**  
**Example:** `maxSecsToWaitForRemoteOperations = 5`

### remoteBEhostname

**Syntax:** `remoteBEhostname = "host"`  
**Description:** Overrides the DB configuration of the remote VWS host.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** The name of the remote BE host.  
**Notes:**  
**Example:**

### remoteBEport

**Syntax:** `remoteBEport = port`  
**Description:** Overrides the DB configuration of the remote VWS port  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:** Valid port number  
**Default:** 2001  
**Notes:**  
**Example:** `remoteBEport = 2001`

### retryConnectionDelaySeconds

**Syntax:** `retryConnectionDelaySeconds = seconds`  
**Description:** The maximum number of seconds between connection attempts  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 30  
**Notes:**  
**Example:** `retryConnectionDelaySeconds = 30`

**source parameters**

The `source` sub-section `beSync` defines the source parameters for `beSync`. This is the component that *sends* operations to the remote `beSync`.

`listenInterface`

**Syntax:** `listenInterface = "ip"`  
**Description:** Overrides the DB configuration for what we listen to.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:** Internet Protocol version 4 (IPv4) addresses, IP version 6 (IPv6) addresses  
**Default:** 0.0.0.0  
**Notes:** You can use the industry standard for omitting zeros when specifying IPv6 addresses.  
**Examples:** `listenInterface = "192.0.2.0"`  
`listenInterface = "2001:db8:0000:1050:0005:0600:300c:326b"`  
`listenInterface = "2001:db8:0:0:0:500:300a:326f"`  
`listenInterface = "2001:db8::c3"0"`

`listenPort`

**Syntax:** `listenPort = port`  
**Description:** Overrides the DB configuration.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 2001  
**Notes:**  
**Example:** `listenPort = 2001`

`maxQueueLength`

**Syntax:** `maxQueueLength = num`  
**Description:** How many messages can queue on the socket before we stop sending and stop getting work from the `beVWARS`.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 50  
**Notes:**  
**Example:** `maxQueueLength = 50`

`recordSendingChunkSize`

**Syntax:** `recordSendingChunkSize = num`  
**Description:** The number of records to send in one poll cycle.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**

**Default:** 50  
**Notes:**  
**Example:** recordSendingChunkSize = 50

### Example configuration

This is an example of the `beSync` section of the `eserv.config` file on a VWS (comments have been removed).

```
beSync = {
  shared = {
    noWorkSleepTime = 0.2

    spoolDirectory = "/IN/service_packages/E2BE/sync"
    spoolChunkSize = 16
    badFileDirectory = "/IN/service_packages/E2BE/tmp"

    maxDownstreamQueueLength = 10000
    downstreamOverloadSleepUsec = 100000
  }

  sink = {
    inSyncThresholdSeconds = 5
    inSyncReportingPeriodRecords = 10000
    maxSecsToWaitForRemoteOperations = 5
    retryConnectionDelaySeconds = 30
    maxRetriesBeforeStart = 5
    localUpdateChunkSize = 100
    heartbeatPeriodSeconds = 10
  }

  source = {
    recordSendingChunkSize = 50
    maxQueueLength = 50
  }
}
```

### Output

The `beSync` writes error messages to the system messages file, and also writes additional output to:

`/IN/service_packages/E2BE/tmp/beSync.log`

**Note:** The above are defaults and can vary.

## beServiceTrigger

### Purpose

`beServiceTrigger` sends BPL requests to instances of the `xmlTcapIF` and Convergent Charging Controller Open Services Development (OSD) requests to the `osdInterface` running on separate SLC nodes within the same IN platform. It runs as a SLEE interface on the primary VWS only.

`beServiceTrigger` accepts `beServiceTrigger` events from other BE SLEE interfaces running on the same VWS. For each `beServiceTrigger` event received, it first checks whether an `operationSetName` is defined in the event. If an `operationSetName` is:

- Defined, it sends the related OSD operation to the OSD interface running on a separate SLC node

- Not defined, it creates and sends a new BPL request to an available instance of an XML TCAP interface running on a separate SLC node.

## About the beServiceTrigger User

The beServiceTrigger user allows beServiceTrigger to access external systems, such as a client ASP that is accessed through the OSD component during event processing. beServiceTrigger retrieves the user credentials (username and password) from a secure credentials vault on the SMS node. The credentials vault is used for storing user names and passwords securely and for authorizing users.

You can set the beServiceTrigger user and password by using the beServiceTriggerUser utility. See *Setting the beServiceTrigger User and Password* (on page 138) for more information.

## Example

An example of the use of the beServiceTrigger is the Rewards plug-in in the beVWARS. The Rewards plug-in sends a beServiceTrigger request to execute a control plan to apply rewards to subscribers on non-VWS charging domains.

## Characteristics

beServiceTrigger has the following characteristics:

- It only accepts beServiceTrigger events sent by other SLEE interfaces running on the same (primary) VWS
- When processing beServiceTrigger events, a new BPL or OSD request is issued to the next available XML TCAP or OSD interface without any acknowledgment to the requesting interface. The traffic between the beServiceTrigger and each particular xmlTcaplf / osdInterface is handled synchronously. No BPL / OSD request will be sent to the same xmlTcaplf / osdInterface instance until the processing of the previous BPL / OSD request has finished.
- Apart from processing incoming beServiceTrigger events, the beServiceTrigger interface communicates with the beVWARS interfaces in order to produce EDRs as a result of processing BPL / OSD responses
- Overall, the processing of beServiceTrigger events and connections to different xmlTcaplf / osdInterface instance is done asynchronously. This allows events to be processed and requests to different xmlTcaplf / osdInterface instances to be handled in parallel.

## Process

This section describes how beServiceTrigger processes a beServiceTrigger event from the Rewards plug-in of beVWARS.

Stage	Description
1	beServiceTrigger receives a beServiceTrigger event from the Rewards plug-in and immediately creates a new BPL request ready to be sent to the next available xmlTcaplf. <b>Note:</b> The Rewards plug-in is not notified about the events received or the BPL requests being sent.
2	When an xmlTcaplf becomes available, the enqueued BPL request is sent and the xmlTcaplf then becomes unavailable until a response is received or the request times out.
3	Incoming beServiceTrigger events and BPL responses are handled asynchronously to allow new BPL requests to be sent to available xmlTcaplf instances.
4	After a BPL response arrives, the corresponding xmlTcaplf becomes available to process further requests. A request to create a Control Plan Service Invoke EDR (type 7) is sent to the appropriate beVWARS interface.

## Startup

This task is started by the following line in `SLEE.cfg`:

```
INTERFACE=beServiceTrigger beSerTrigStartup.sh
/IN/service_packages/E2BE/bin EVENT
```

**Note:** Only one instance of the `beServiceTrigger` interface is allowed per VWS SLEE.

## Valid interfaces

The `beServiceTrigger` requires and uses slightly different configuration depending on the interface used.

`XmlTcap` is the default interface unless the operation set is defined in the request, in which case the OSD interface is used.

### XmlTcap parameters

- Control\_Plan
- Service\_Handle
- scps

### OSD parameters

- CCSNamespace
- osd\_scps
- operationSet
- operation

### Parameters common to both interfaces

- edr
- failureRetryTime
- storageInterface
- triggerInterface
- responseTag
- maxRatePerUAS
- throttleLife
- timeBetweenThrottles
- maxConnections

## XmlTcap Parameters

`beServiceTrigger/XmlTcap` is configured by the following parameters from the `triggering` section in the `eserv.config` file on the VWS:

```
triggering = {
  Control_Plan = "cpname"
  Service_Handle = "handle"
  scps = [ "ip:port" ]
}
triggering = {
  Control_Plan = "Reward"
  Service_Handle = "CCS_BPL"
  CCSNamespace = "http://eng-prf-zone01-z1/wsdl/ON/CCSNotifications.wsdl"
  edr = false
  scps = [ "cmxdevscp1:3072", "cmxdevscp2:3072" ]
  osd_scps = [ "cmxdevscp1:3072", "cmxdevscp2:3072" ]
  failureRetryTime = 60
}
```

```

storageInterface = beEventStorageIF
triggerInterface = beServiceTrigger
operationSet = CMX ON
operation = Invoke OSD
responseTag = Result
maxRatePerUAS = 0
throttleLife = 30
timeBetweenThrottles 10
} # triggering

```

### Control\_Plan

**Syntax:** Control\_Plan = "*cpname*"

**Description:** The default control plan name that will be used in BPL requests if none is present in the SLEE event.

**Type:** String

**Optionality:** Optional

**Allowed:**

**Default:** Empty

**Notes:**

**Example:** Control\_Plan = "Reward"

### scps

**Syntax:**

```

scps = [
    "ip:port"
    ...
]

```

**Description:** Lists the host name or Internet Protocol (IP) address, and port of each xmlTcapInterface SLC to which beServiceTrigger connects. If you specify an IP version 6 (IPv6) address and port combination, then you must enclose the IPv6 address in square brackets [], see example for details.

**Type:** Array

**Optionality:** Required. In any row of the array, *ip* must be specified but *port* is optional.

**Allowed:**

- *ip* – An IP address or symbolic host name
- *port* – Integer in the range 0 to 65535

**Default:** *port* defaults to 3072

**Notes:** An example of an IPv4 address is **192.0.2.1**.  
An example of an IPv6 address is **2001:db8:n:n:n:n:n:n** where *n* is a group of 4 hexadecimal digits. The industry standard for omitting zeros is also allowed.  
An example of an address in symbolic name format is **primary\_smc**.

**Example:**

```

scps = [
    "198.51.100.1"
    "192.0.2.1:4000"
    "[2001:db8:0000:1050:0005:0600:300c:326b]:3004"
    "[2001:db8:0:0:0:500:300a:326f]:1234:SMF"
    "[2001:db8::c3]:1234:SMF"
    "2001:db8:1050:0:0:300a:0300:126c"
    "primary_smc"
    "secondary_smc:3006"
]

```

## Service\_Handle

<b>Syntax:</b>	<code>Service_Handle = "handle"</code>
<b>Description:</b>	The default service handle that will be used in BPL requests if none is present in the SLEE event.
<b>Type:</b>	String
<b>Optionality:</b>	Optional
<b>Allowed:</b>	
<b>Default:</b>	Empty
<b>Notes:</b>	
<b>Example:</b>	<code>Service_Handle = "CCS_BPL"</code>

## OSD Parameters

beServiceTrigger/OSD is configured by the following parameters from the triggering section in the `eserv.config` file on the VWS:

```
triggering = {
  CCSNamespace = "URL"
  osd_scps = [ "ip:port" ]
  operationSet = "name"
  operation = "name"
}
```

## CCSNamespace

<b>Syntax:</b>	<code>CCSNamespace = "URL"</code>
<b>Description:</b>	The default Namespace that will be put into OSD requests if none is present in the SLEE event.
<b>Type:</b>	String
<b>Optionality:</b>	Optional
<b>Allowed:</b>	
<b>Default:</b>	Empty
<b>Notes:</b>	
<b>Example:</b>	<code>CCSNamespace = "http://eng-prf-zone01-z1/wsdls/ON/CCSNotifications.wsdl"</code>

## osd\_scps

<b>Syntax:</b>	<pre>scps = [   "ip:port"   ... ]</pre>
<b>Description:</b>	Lists the host name or Internet Protocol (IP) address, and port of each xmlITcapInterface SLC to which beServiceTrigger connects. If you specify an IP version 6 (IPv6) address and port combination, then you must enclose the IPv6 address in square brackets [], see example for details.
<b>Type:</b>	Array
<b>Optionality:</b>	Required. In any row of the array, <i>ip</i> must be specified but <i>port</i> is optional.
<b>Allowed:</b>	<ul style="list-style-type: none"> <li>• <i>ip</i> – An IP address or symbolic host name</li> <li>• <i>port</i> – Integer in the range 0 to 65535</li> </ul>
<b>Default:</b>	<i>port</i> defaults to 3072

**Notes:** An example of an Internet protocol address is `192.0.2.1`.  
 An example of an IPv6 address is `2001:db8:n:n:n:n:n` where `n` is a group of 4 hexadecimal digits  
 An example of an address in symbolic name format is `primary_smc`.

**Example:**

```
osd_scps = [
  "192.0.2.2"
  "192.0.2.1:4000"
  "[2001:db8:0000:1050:0005:0600:300c:326b]:3004"
  "[2001:db8:0:0:0:500:300a:326f]:1234:SMF"
  "[2001:db8::c3]:1234:SMF"
  "2001:db8:300c:0:600:300c:0:126b"
  "primary_smc"
  "secondary_smc:3006"
]
```

operation

**Syntax:** operation = "name"  
**Description:** The name of the OSD operation to invoke the service when none is set in the SLEE event.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** Empty  
**Notes:**  
**Example:** operation = "Notification"

operationSet

**Syntax:** operationSet = "name"  
**Description:** The name of the operation set that contains the template used to invoke the service when none is set in the SLEE event.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** Empty  
**Notes:**  
**Example:** operationSet = "NotificationSet"

## Common parameters

beServiceTrigger common parameters are configured by the following from the triggering section in the `eserv.config` file on the VWS:

```
triggering = {
  edr = true | false
  failureRetryTime = seconds
  storageInterface = "name"
  triggerInterface = "name"
  responseTag = name
  maxRatePerUAS = num
  throttleLife = seconds
  timeBetweenThrottles = millisecs
  maxConnections = integer
```

## Chapter 3

```
}
```

```
edr
```

**Syntax:** `edr = true|false`  
**Description:** Should an EDR be produced when a response is received.  
**Type:** Boolean  
**Optionality:** Optional (default used if not set)  
**Allowed:** true, false  
**Default:** false  
**Notes:**  
**Example:** `edr = false`

```
failureRetryTime
```

**Syntax:** `failureRetryTime = seconds`  
**Description:** The length of time in seconds between attempts to send the message to the SLC.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 60  
**Notes:**  
**Example:** `failureRetryTime = 60`

```
maxConnections
```

**Syntax:** `maxConnections = integer`  
**Description:** The maximum number of connections from beServiceTrigger to interfaces on the SLC.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:** 0 or any positive integer. 0 indicates no maximum.  
**Default:** 25  
**Notes:** Increase the value of *maxConnections* as the number of rows in the `be_event_storage` table increases.  
**Example:** `maxConnections = 25`

```
maxRatePerUAS
```

**Syntax:** `maxRatePerUAS = num`  
**Description:** The maximum rate (messages/second) each SLC is able to handle before throttling.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 0  
**Notes:** 0 means unlimited.  
**Example:** `maxRatePerUAS = 0`

`responseTag`

**Syntax:** `responseTag = name`  
**Description:** The name of the tag in the response message to use to populate the EDR.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** Result  
**Notes:**  
**Example:** `responseTag = Result`

`storageInterface`

**Syntax:** `storageInterface = "name"`  
**Description:** The name of the interface used to store events for sending later, either due to a failure, or a request for a delayed send.  
**Type:** String  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** `beEventStorageIF`  
**Notes:**  
**Example:** `storageInterface = "beEventStorageIF"`

`throttleLife`

**Syntax:** `throttleLife = seconds`  
**Description:** The length of time in seconds a throttle will exist for before the attempts to back it off.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 30  
**Notes:**  
**Example:** `throttleLife = 30`

`timeBetweenThrottles`

**Syntax:** `timeBetweenThrottles = millisecs`  
**Description:** The length of time in milliseconds between throttle messages being sent to the storage interface.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**  
**Default:** 10  
**Notes:**  
**Example:** `timeBetweenThrottles 10`

### triggerInterface

<b>Syntax:</b>	<code>triggerInterface = "name"</code>
<b>Description:</b>	The name of the triggering interface itself.
<b>Type:</b>	String
<b>Optionality:</b>	Optional (default used if not set)
<b>Allowed:</b>	
<b>Default:</b>	<code>beServiceTrgger</code>
<b>Notes:</b>	
<b>Example:</b>	<code>triggerInterface = "beServiceTrigger"</code>

## Output

beServiceTrigger writes error messages to the system messages file, and also writes additional output to the location indicated in the startup script, which will usually be set to:

```
/IN/service_packages/E2BE/tmp/beServiceTrigger.log
```

## Notification requests

The VWS directs all notification requests to a SLC OSD interface through the beServiceTrigger (flow 2 in diagram).

## Notification overview

The OSD interface triggers ACS, which loads a control plan containing the notification node in order to perform delivery (flow 6 in diagram).

If no OSD nodes are available, are unresponsive, or the notification has a Time of Day associated, then it will be stored locally for subsequent delivery.

**Note:** The Wallet Information will be omitted from this, as it will be stale before the notification is sent.

The Time Daemon will poll the Time Dependant notifications stored on the VWSs and trigger OSD requests according to the time. These requests will be throttled and load balanced in order to not overload SLC nodes with large numbers of Control Plan requests.

The VWSs will operate in isolation within the pair, therefore if notifications are delayed and stored on the Primary VWS, they will not be synchronized to the secondary.

If there is a failure or outage in the primary, notifications to be generated will be stored locally on the secondary during the outage. After the primary is operational again it will process all relevant notifications, while the secondary retains responsibility for notifications generated during the primary outage.

### Notification flows

This diagram shows the various notification flows across the Convergent Charging Controller platform.

#### Flow 1

The beVWARS plug-ins send SMS information to the beServiceTrigger.

### Flow 2

Notification XML messages from the beServiceTrigger to the OSD interface on the SLC.

### Flow 3

If a notification cannot be delivered immediately, either because it has an associated time period when it can be delivered, or because the delivery attempt failed, then persistent storage of the notification is provided in a database table.

### Flow 4

When the time notification daemon examines the notification entries in the database, it retrieves the notifications that can now be sent either because their allowable delivery time has been met or because it is a message retry.

### Flow 5

The time notification daemon deletes the active entries from the database and sends delivery request messages to the beServiceTrigger for each of the active entries.

### Flow 6

The OSD interface triggers ACS, which then loads the control plan containing the notification feature node that will perform delivery of the notification.

### Flow 7

The notification template to use is determined by the notification feature node, based on:

- Language ID
- Template ID
- Customer ID

### Flow 8

The notification feature node delivers a USSD notification through the TCAP interface.

If the message class is "USSD push", then an internal message is sent through the USSD push action handler to the TCAP interface after the notification feature node has performed all the parameter substitutions.

### Flow 9

Chassis action to construct message from template.

### Flow 10

Other send message feature nodes use new chassis actions to deliver notifications using Messaging Manager.

## beVWARS

### Purpose

beVWARS caches and holds the state of:

- Wallets and their associated reservations
- Vouchers and their associated reservations

The database cannot reflect the state of the running system, because updates are usually pending in the Writer. To maintain a single consistent view of an individual record's state in the database, use a beVWARS instance to access all wallets or vouchers. beVWARS is responsible for all updates to database fields changed during a resync.

beVWARS also handles COMMITting the database updates and writing EDRs. For more information, see *beVWARS data updates* (on page 18).

## Plug-ins

beVWARS can be extended by:

- Event handlers specified in the `plugins` (on page 98) parameter
- Message handlers specified in the `handlers` (on page 96) parameter

VWS provides a set of standard beVWARS plug-ins to handle standard interactions. These include *beVWARSMergeBuckets* (on page 117).

Other handlers are provided by other applications such as CCS to provide application-specific functions such as named event charges. For more information about the plug-ins provided by CCS, see *CCS Technical Guide*.

## Activating Used Units Confirmation (UUC) Features

Follow these steps to activate Used Units Confirmation (UUC) features. The installation instructions tell you when to perform these steps.

**Note:** Perform this procedure on the Primary BE only. Under normal operation, a reservation expires at exactly the same time on both VWSSs. Installing the `ccsvWARSReservationExpiry` plug-in on the Secondary BE causes the user to be double-charged.

Step	Action
1	On the primary BE, open the <code>/IN/service_packages/eserv.config</code> file in a text editor.
2	In the <code>plugins</code> section, add the <code>ccsvWARSReservationExpiry.so</code> entry. <pre>BE = {   beVWARS = {     plugins = [       # ... Existing plug-ins here ...       "ccsvWARSReservationExpiry.so" # &lt;-- New plugin entry     ]   } }</pre>
3	Save and close the file.

## Startup

The SLEE starts this task through the following line in `SLEE.cfg`:

```
INTERFACE=beVWARS beVWARSStartup.sh /IN/service_packages/E2BE/bin
instance_count EVENT
```

Where `instance_count` is the number of instances to run of the beVWARS process.

**Note:** beVWARS usually uses more than one beVWARS process. Each beVWARS process has the value of `instance_count - 1` appended to the process name. Thus, the first beVWARS process is `beVWARS0`, and subsequent beVWARS processes are named `beVWARS1`, `beVWARS2`, and so on. If you configure only one instance of beVWARS, nothing is appended to the process name.

For more information about configuring SLEE interfaces, see *SLEE Technical Guide*

## Wallet Time Configuration

By default, beVWARS applies the OS time to every wallet as transactions are applied. You can configure beVWARS to read the time from a wallet time configuration file (`/IN/service_packages/E2BE/etc/VWARS_sysdate.cfg`). The file contains a mapping of times to wallet IDs. This allows you to manually change the time for a wallet ID on the fly.

**Note:** beVWARS uses the time zone of the VWS host on which the beVWARS process is running.

The following shows the format for each line in the `VWARS_sysdate.cfg` file:

```
WalletID YYYY/MM/DD HH:MM:SS
```

For example:

```
12345 2011/11/01 12:00:00
```

To configure beVWARS to read times from `VWARS_sysdate.cfg`, set the `useTimeFromConfigFile` parameter to `true` in the `eserv.config` file.

## Configuration

beVWARS accepts the following parameters from `eserv.config`.

```
beVWARS = {
    voucherReservationPeriodSeconds = seconds
    useTimeFromClient = true|false
    maxTransactionsPerSet = num
    maxOpenDialogTime = seconds
    maxDownstreamQueueLength = num
    downstreamOverloadSleepUSec = microsecs
    minResyncReservationLength = seconds
    createBucketExpiryDays = days
    maxSendReservationsToSync = num
    reservationExpiryCheckMilliseconds = millisecs
    walletConfigFileReReadTime = seconds
    setLastUseDateOnActivation = true|false
    useTimeFromConfigFile = true|false
    waltResvsnExpiryToleranceSeconds = num

    walletCache = {
        maxSize = num
        maxLoopSize = num
        checkBeforeFlush = true|false
    }

    voucherCache = {
        maxSize = num
        maxLoopSize = num
        checkBeforeFlush = true|false
    }

    groveller = {
        periodMsec = millisecs
        requestHighWaterMark = num
        walletLowWaterMark = num
        requestTimeout = seconds
        peerDatabaseLogin = "login"
        peerWalletCheckRetrySeconds = seconds
        secondaryConnectionDelaySeconds = seconds
    }

    duplicateDetection = {
```

```

        keepDirectSeconds = seconds
        keepSyncSeconds = seconds
        directMaxDelaySeconds = seconds
        syncMaxDelaySeconds = seconds
    }

    setLastActivationDateStates = [states]

    plugins = [
        "lib"
        [...]
    ]

    handlers = [
        "lib"
        [...]
    ]

    syncWriter = {
        maxRecordsPerFile = num
        maxSecondsPerFile = seconds
    }

    dbWriter = {
        flushPeriod = seconds
        cdrOutputDirectory = "dir"

        balanceCreateBufferSize = num
        balanceUpdateBufferSize = num
        balanceDeleteBufferSize = num
        bucketCreateBufferSize = num
        bucketUpdateBufferSize = num
        bucketDeleteBufferSize = num
        walletCreateBufferSize = num
        walletUpdateBufferSize = num
        walletDeleteBufferSize = num
        voucherCreateBufferSize = num
        voucherUpdateBufferSize = num
        voucherDeleteBufferSize = num
    }
}

```

## Parameters

Here are the available parameters in the `beVWARS` section of `eserv.config`.

`createBucketExpiryDays`

**Syntax:** `createBucketExpiryDays = days`

**Description:** In rare cases, `beVWARS` must spontaneously create a new bucket to preserve a wallet's last use date. This occurs, for example, when:

- The last bucket is deleted.
- A call is made when a wallet does not contain any buckets.
- A recharge occurs against a Balance Type with no buckets.

This parameter defines the new bucket's Balance Expiry Date.

**Type:** Integer

**Units:** Days

**Optionality:** Optional (default used if not set).

## Chapter 3

- Allowed:**
- 0 – Creates the bucket with no expiry date.
  - A positive integer – Sets the bucket's Balance Expiry Date to this many days in the future.

**Default:** 30

**Notes:**

**Example:** `createBucketExpiryDays = 30`

### `downstreamOverloadSleepUsec`

**Syntax:** `downstreamOverloadSleepUsec = microsecs`

**Description:** When a downstream process (beSync or beServer) is overloaded, this parameter specifies the amount of time to sleep, in microseconds, before rechecking the downstream process.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 100000

**Notes:** This value must be shorter than the SLEE watchdog timeout period.

**Example:** `downstreamOverloadSleepUsec = 100000`

### `handlers`

**Syntax:**

```
handlers = [  
    "lib"  
    [...]  
]
```

**Description:** Lists the beVWARS message handler plug-ins to load.

**Type:** Array

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:**

**Notes:** This array must include handlers for messages from processes requesting billing actions.

For more information about handlers from other applications, see the associated technical guide.

**Example:**

```
handlers = [  
    "beVWARSCCDRHandler.so"  
]
```

### `maxDownstreamQueueLength`

**Syntax:** `maxDownstreamQueueLength = num`

**Description:** Specifies the maximum number of pending events on beSync or beServer.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 10000

**Notes:** When this number is exceeded, if events are queued on either of the processes, beVWARS sleeps.

**Example:** `maxDownstreamQueueLength = 10000`

`maxOpenDialogTime`

**Syntax:** `maxOpenDialogTime = seconds`  
**Description:** Specifies how long, in seconds, to try to open dialogs to the other SLEE processes.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 5.0  
**Notes:**  
**Example:** `maxOpenDialogTime = 5.0`

`maxSendReservationsToSync`

**Syntax:** `maxSendReservationsToSync = num`  
**Description:** When `beSync` has requested all reservations, this is the number to send in one pass.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 1000  
**Notes:**  
**Example:** `maxSendReservationsToSync = 1000`

`maxTransactionsPerSet`

**Syntax:** `maxTransactionsPerSet = num`  
**Description:** Specifies the number of transactions and EDRs to try initially to fit into a `TransactionSet` written to the sync files.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 7  
**Notes:** This `TransactionSet` will be passed across the SLEE on the other VWS, so must fit inside a SLEE event.  
 If this number of transactions does not fit the message, the message is re-encoded with fewer and fewer Transactions and EDRs per `TransactionSet`.  
 7 is used because 7.75 132 byte Transactions fit into a 1024 bytes `SleeEvent`.  
**Example:** `maxTransactionsPerSet = 7`

`minResyncReservationLength`

**Syntax:** `minResyncReservationLength = seconds`  
**Description:** Minimum reservation length (in seconds) before passing the reservation to the other Voucher and Wallet Server in a pair.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:** positive integer Minimum  
 0 Resync all reservations.  
**Default:** 5

## Chapter 3

**Notes:** Set this parameter to reduce the amount of reservations which are sent where they will have expired by the time they are received by the other VWS.

**Example:** `minResyncReservationLength = 5`

### plugins

**Syntax:**

```
plugins = [  
    "lib"  
    [...]  
]
```

**Description:** Lists the beVWARS event handler plug-ins to load.

**Type:** Parameter array

**Optionality:**

**Allowed:**

**Default:**

**Notes:** Where plug-ins are triggered by the same event, they will operate in the order they appear in this list.  
For more information about plug-ins from other applications, see the associated technical guide.

**Example:**

```
plugins = [  
    "beVWARSExpiry.so"  
]
```

### reservationExpiryCheckMilliseconds

**Syntax:** `reservationExpiryCheckMilliseconds = milliseconds`

**Description:** The frequency (milliseconds) that the reservation expiry check occurs.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 10000

**Notes:**

**Example:** `reservationExpiryCheckMilliseconds = 5000`

### setLastActivationDateStates

**Syntax:** `setLastActivationDateStates = [states]`

**Description:** A list of all old wallet states which will cause the 'Last Activation Date' for the wallet to be updated. The new wallet state in all these cases will be "ACTV" after the call has completed.

**Type:** String

**Optionality:** Optional (default used if not set).

**Allowed:** Valid values are: PREU, FROZ, DORM, SUSP, and TERM

**Default:** PREU

**Notes:**

**Example:** `setLastActivationDateStates = [PREU,DORM]`

### setLastUseDateOnActivation

**Syntax:** `setLastUseDateOnActivation = true | false`

**Description:** Specifies whether beVWARs creates a new bucket for all balance types.

**Type:** Boolean

**Optionality:** Optional (default used if not set)  
**Allowed:**

- true – When a wallet is activated, beVWARs stores balances in one bucket and sets each balance's last use date.
- false – When a wallet is activated, beVWARs creates a new bucket for all balance types and sets the wallet's last use date.

**Default:** true  
**Notes:**  
**Example:** `setLastUseDateOnActivation = true`

#### `useTimeFromClient`

**Syntax:** `useTimeFromClient = true|false`  
**Description:** Specifies whether beVWARs retrieves the time for every wallet from either the incoming message or the OS.  
**Type:** Boolean  
**Optionality:** Optional (default used if not set).  
**Allowed:**

- true – Uses the time from the incoming message (client date and usec).
- false – Applies the OS time to every wallet as transactions are applied.

**Default:** true  
**Notes:** This ensures that a given client message is treated identically on both VWSSs, when it is re-sent. Otherwise, duplicate detection will cause the VWSSs to get out of sync.  
**Example:** `useTimeFromClient = true`

#### `useTimeFromConfigFile`

**Syntax:** `useTimeFromConfigFile = true|false`  
**Description:** Specifies whether beVWARs reads the time from the `useTimeFromClient` parameter or the **VWARS\_sysdate.cfg** file.  
 This parameter allows beVWARs to read a configuration file on disk for every call to detect time mapping changes and apply them. This allows you to change the time applied to wallets on the fly without an application restart.  
**Type:** Boolean  
**Optionality:** Optional (default used if not set)  
**Allowed:**

- true – Use the time from the `/IN/service_packages/E2BE/etc/VWARS_sysdate.cfg` file.
- false – Use the time set in the `useTimeFromClient` parameter. See *useTimeFromClient*.

**Default:** false  
**Notes:** Set this parameter to true for functional tests only. This parameter should be disabled for performance tests and production systems.  
**Example:** `useTimeFromConfigFile = true`

#### `voucherReservationPeriodSeconds`

**Syntax:** `voucherReservationPeriodSeconds = seconds`  
**Description:** The number of seconds that vouchers remain 'reserved'.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**

**Default:** 120  
**Notes:**  
**Example:** `voucherReservationPeriodSeconds = 120`

### walletConfigFileReReadTime

**Syntax:** `walletConfigFileReReadTime = seconds`  
**Description:** Specifies how often, in seconds, beVWARS reads/parses the wallet time configuration file (`VWARS_sysdate.cfg`). beVWARS saves parsed values in a map, which is then queried until the time specified in `walletConfigFileReReadTime` elapses.  
To use this parameter, the `useTimeFromConfigFile` parameter must be set to `true`.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**

- 0 – beVWARS does not read/parse the wallet time configuration file.
- A positive integer – beVWARS reads/parses the wallet time configuration file at the specified interval. A value between 30 and 300 is recommended.

**Default:** 300  
**Notes:**  
**Example:** `walletConfigFileReReadTime = 300`

### waltResvnxpiryToleranceSeconds

**Syntax:** `waltResvnxpiryToleranceSeconds = num`  
**Description:** Specifies the number of seconds to add to the expiration time of wallet reservations during the data synchronization process.  
The data synchronization process introduces a slight delay between the time a wallet reservation is sent from the remote VWS server to the local VWS server. This means a wallet reservation could expire before it is received by the local VWS server. Use this parameter to ensure that wallet reservations expire sometime after the data synchronization process completes.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:**

- 0 – Does not add any time to wallet reservation expirations.
- A positive integer – The number of seconds to add to the expiration time of wallet reservations.

**Default:** 30  
**Notes:**  
**Example:** `waltResvnxpiryToleranceSeconds = 20`

### duplicateDetection parameters

Duplicate messages are possible, as the BeClient can switch to the auxiliary beServer after the original beServer has processed the message, but failed to return a response. The beVWARS detects duplicates by keeping a list of the client, `clientMessageId` and `clientMsgTimestamps` from messages received directly from the local beServer or received via beSync.

It is not necessary to store message identifiers permanently, as the BeClient switchover time is finite. For a given stream of messages, it is possible to tell that the client has not switched over.

**Example:** If the client is set to switch over at 1:00, but a message is received dated 3:00 from the beServer, we know that the BeClient has not switched over (or messages would not continue to be received via the beServer).

If we receive a message through the beServer dated 2:00, we know that we will not receive any other messages (from the beClient) through the beServer dated 1:30 or earlier. Due to wallet locks, messages are not always received exactly in the beClientMessageTimestamp order.

#### directMaxDelaySeconds

**Syntax:** `directMaxDelaySeconds = seconds`

**Description:** The maximum delay (in seconds) before IDs received directly are removed from the main stream. IDs are kept for this time, in order to compare them with IDs from the converse stream.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 1.0

**Notes:** It is recommended that the delay be kept to a minimum, so that the timestamp order is not affected too greatly.

**Example:** `directMaxDelaySeconds = 1.0`

#### keepDirectSeconds

**Syntax:** `keepDirectSeconds = seconds`

**Description:** The time (in seconds) to keep IDs from messages received directly (through beServer), for comparison later with IDs from messages received through sync (through beSync).

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 60.0

**Notes:** If a message has been kept much longer than the latest message received, we know that the BeClient has not switched beServers, so duplicates are not possible.

**Example:** `keepDirectSeconds = 60.0`

#### keepSyncSeconds

**Syntax:** `keepSyncSeconds = seconds`

**Description:** The time (in seconds) to leave the IDs in the duplicate map, to wait for a duplicate.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 60.0

**Notes:**

**Example:** `keepSyncSeconds = 60.0`

#### syncMaxDelaySeconds

**Syntax:** `syncMaxDelaySeconds = seconds`

**Description:** The maximum delay (in seconds) before IDs are removed from the duplicate map. IDs are kept for this time, in order to compare them with IDs from the converse stream.

**Type:** Integer

<b>Optionality:</b>	Optional (default used if not set).
<b>Allowed:</b>	
<b>Default:</b>	1.0
<b>Notes:</b>	It is recommended that the delay be kept to a minimum, so that the timestamp order is not affected too greatly.
<b>Example:</b>	<code>syncMaxDelaySeconds = 1.0</code>

### groveller parameters

The `groveller` sub-section of the `beVWARS` provides the configuration for the `groveller` subsystem in `beVWARS` to query wallets and run plug-ins against them. Wallets are supplied by wallet ID from `beGroveller`. For more information about how wallets are groveled, see *Background processing* (on page 6).

#### `peerDatabaseLogin`

<b>Syntax:</b>	<code>peerDatabaseLogin = "login"</code>
<b>Description:</b>	If <code>peerDatabaseLogin</code> is not "", the <code>groveller</code> will perform a remote database query on the other VWS's database for information on the wallet. If inconsistent, another check is attempted after the number of seconds configured in <code>peerWalletCheckRetrySeconds</code> . This gives the remote VWS time to process and commit transactions. If the wallets are still inconsistent, a syslog message is produced.
<b>Type:</b>	
<b>Units:</b>	
<b>Optionality:</b>	Optional (default used if not set).
<b>Allowed:</b>	
<b>Default:</b>	""
<b>Important:</b>	This should not be used in production due to impact on performance.
<b>Example:</b>	<code>peerDatabaseLogin = ""</code>

#### `peerWalletCheckRetrySeconds`

<b>Syntax:</b>	<code>peerWalletCheckRetrySeconds = seconds</code>
<b>Description:</b>	How long (in seconds) to wait after the peer VWS's information on a wallet, if found to be inconsistent. If the wallet is still inconsistent after this period a syslog message is produced.
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set).
<b>Allowed:</b>	
<b>Default:</b>	60
<b>Notes:</b>	This period should be long enough for locally generated operation message to be sent to the remote VWS, and committed to the database.
<b>Example:</b>	<code>peerWalletCheckRetrySeconds = 60</code>

#### `periodMsec`

<b>Syntax:</b>	<code>periodMsec = millisecs</code>
<b>Description:</b>	The minimum number of milliseconds between groveling wallets.
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set).

**Allowed:** 0 Send a new request as soon as possible.  
positive integer

**Default:** 1000

**Notes:** This parameter is restricted by `requestHighWaterMark` (on page 103). Setting request frequency to 0 will impact the normal VWS processing speed. This parameter will have no effect if `enableGroveling` (on page 41) is set to false).

**Example:** `periodMsec = 1200`

#### `requestHighWaterMark`

**Syntax:** `requestHighWaterMark = num`

**Description:** The maximum number of outstanding requests queued on the SLEE waiting on this beVWARS instance before no requests are sent to beGroveler for wallets to grovel.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 1

**Notes:** If the number of outstanding requests in the SLEE queue is less than or equal to half of `requestHighWaterMark`, then this beVWARS instance will try to grovel a wallet between every request it processes.

If the number of outstanding requests in the SLEE queue is more than half of `requestHighWaterMark`, wallets will be groveled with decreasing frequency proportional to the queue length, until only one wallet is groveled every for every 10 requests from beServer. The proportion is calculated to approximately increase the total number of requests (SLEE queue + grovel requests) to `requestHighWaterMark`.

**Examples:** These examples assume `requestHighWaterMark = 100`.

- If queue length = 25, beVWARS will process one grovel request for each SLEE queue request (that is, 50 of every 100 requests will be grovel requests).
- If queue length = 50, beVWARS will process one grovel request for each SLEE queue request (that is, 50 of every 100 requests will be grovel requests).
- If queue length = 80, beVWARS will process two grovel requests for every eight SLEE queue requests (that is, 20 of every 100 requests will be grovel requests).
- If queue length = 90, beVWARS will process one grovel request for every 10 SLEE queue requests (that is, 10 of every 100 requests will be grovel requests).
- If queue length = 100, beVWARS will not process any grovel requests.

**Example:** `requestHighWaterMark = 100`

#### `requestTimeout`

**Syntax:** `requestTimeout = seconds`

**Description:** The maximum number of seconds to wait for a response after sending a request to beGroveler for another batch of wallet IDs to grovel, before timing out the request.

**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:** positive integer  
-1 Do not time out requests.  
**Default:** 30  
**Notes:** If a request is timed out, beVWARS will log a Warning level error to syslog and will resend the request.  
If errors are being logged to the syslog indicating timeouts, try:

- Setting *walletLowWaterMark* (on page 11) to a higher value
- Setting *requestTimeout* to a higher value
- If there are not as many beGroveler processes as beVWARS processes, adding the number of beGroveler processes (this can be done until there are as many beGroveler processes as beVWARS processes)
- Setting *maxIDsPerResponse* (on page 62) to a higher value

**Example:** `requestTimeout = 30`

#### `secondaryConnectionDelaySeconds`

**Syntax:** `secondaryConnectionDelaySeconds = seconds`  
**Description:** The number of seconds to wait before enabling the beGroveler to process wallets on the secondary VWS if the primary VWS cannot be contacted. Ensures that wallet processing by the beGroveler is not started on the secondary VWS if the primary VWS is down for a short period of time only.

**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 900  
**Notes:** The configured delay is applied when the secondary VWS beGroveler is started and when the client connection from the secondary VWS beGroveler to the primary beServer is lost.

**Example:** `secondaryConnectionDelaySeconds = 900`

#### `walletLowWaterMark`

**Syntax:** `walletLowWaterMark = num`  
**Description:** The number of outstanding wallet IDs to grovel, before sending a request to beGroveler for another batch of wallet IDs to grovel.

**Type:** Integer  
**Optionality:** Optional (default used if not set).

**Allowed:**  
**Default:** 100

**Notes:**  
**Example:** `walletLowWaterMark = 100`

### **voucherCache parameters**

The `voucherCache` sub-section of the beVWARS parameters defines the voucher cache.

`checkBeforeFlush`

<b>Syntax:</b>	<code>checkBeforeFlush = true false</code>
<b>Description:</b>	If true, vouchers are checked against the database before flushing. If they are different, an error is sent to syslog.
<b>Type:</b>	Boolean
<b>Units:</b>	
<b>Optionality:</b>	Optional (default used if not set).
<b>Allowed:</b>	true, false
<b>Default:</b>	false
<b>Important:</b>	This should not be used in production due to impact on performance.
<b>Example:</b>	<code>checkBeforeFlush = false</code>

`maxLoopSize`

<b>Syntax:</b>	<code>maxLoopSize = num</code>
<b>Description:</b>	The number of vouchers in the voucher cache for beVWARS to process at one time before pausing. This enables beVWARS to pause and respond to other requests, instead of attempting to process the whole cache at once.
<b>Type:</b>	Integer
<b>Optionality:</b>	Optional (default used if not set).
<b>Allowed:</b>	Positive integers    Number of vouchers to process in a batch. -1                            Process whole cache at once.
<b>Default:</b>	10000
<b>Notes:</b>	This parameter should be set if <code>maxSize</code> and <code>maxAgeSeconds</code> are set to -1 (which is likely to cause a large cache). If this number is set too high (or to -1) the SLEE watchdog can restart beVWARS unnecessarily. Too low, and beVWARS will waste CPU polling the SLEE unnecessarily.
<b>Example:</b>	<code>maxLoopSize = 5000</code>

`maxSize`

<b>Syntax:</b>	<code>maxSize = MB</code>
<b>Description:</b>	The maximum size of the beVWARS voucher cache.
<b>Type:</b>	Integer
<b>Units:</b>	MB
<b>Optionality:</b>	Optional (default used if not set).
<b>Allowed:</b>	0 or a positive integer.
<b>Default:</b>	10000
<b>Notes:</b>	
<b>Example:</b>	<code>maxSize = 10000</code>

**walletCache parameters**

The `walletCache` sub-section of the beVWARS parameters defines the wallet cache.

`checkBeforeFlush`

<b>Syntax:</b>	<code>checkBeforeFlush = true false</code>
<b>Description:</b>	If true, wallets are checked against the database before flushing. If they are

different, an error is sent to syslog.

**Type:** Boolean

**Units:**

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** false

**Important:** This should not be used in production due to impact on performance.

**Example:** `checkBeforeFlush = false`

### `maxLoopSize`

**Syntax:** `maxLoopSize = num`

**Description:** The number of wallets in the wallet cache for beVWARS to process at one time before pausing. This enables beVWARS to pause and respond to other requests, instead of attempting to process the whole cache at once.

**Type:** Integer

**Optionality:** Optional, default value will be used if not set.

**Allowed:** Positive integers    Number of wallets to process in a batch.  
-1                            Process whole cache at once.

**Default:** 100000

**Notes:** This parameter should be set if `maxSize` and `maxAgeSeconds` are set to -1 (which is likely to cause a large cache).  
If this number is set to high (or to -1) the SLEE watchdog can restart beVWARS unnecessarily. Too low, and beVWARS will waste CPU polling the SLEE unnecessarily.

**Example:** `maxLoopSize = 5000`

### `maxSize`

**Syntax:** `maxSize = MB`

**Description:** The maximum size of the beVWARS wallet cache.

**Type:** Integer

**Units:** MB

**Optionality:** Optional (default used if not set).

**Allowed:** 0 or a positive integer.

**Default:** 100000

**Notes:**

**Example:** `maxSize = 100000`

## syncWriter parameters

The `syncWriter` sub-section of the beVWARS parameters defines how the beVWARS syncWriter writes sync files.

### `maxRecordsPerFile`

**Syntax:** `maxRecordsPerFile = num`

**Description:** The maximum number of records in a sync file.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**  
**Default:** 100  
**Notes:**  
**Example:** `maxRecordsPerFile = 200`

`maxSecondsPerFile`

**Syntax:** `maxSecondsPerFile = seconds`  
**Description:** The maximum number of seconds to hold a sync file open.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 2  
**Notes:**  
**Example:** `maxSecondsPerFile = 4`

## dbWriter parameters

The `dbWriter` sub-section of the `beVWARS` parameters defines how the `beVWARS` `dbWriter` buffers and writes:

- Data updates to the E2BE database
- EDRs to the filesystem

**Note:** All buffers and the EDR cache are flushed whenever one of the following conditions occurs:

- One of the buffers is full
- The EDR cache is full
- The current flush period has ended
- The `beVWARS` writer subsystem is told to flush and commit (on shutdown for example)

`balanceCreateBufferSize`

**Syntax:** `balanceCreateBufferSize = num`  
**Description:** The number of items in a buffer before `beVWARS` will flush it.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 1000  
**Notes:**  
**Example:** `balanceCreateBufferSize = 1500`

`balanceDeleteBufferSize`

**Syntax:** `balanceDeleteBufferSize = num`  
**Description:** The number of deletes in a buffer before `beVWARS` will flush it.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 1000

## Chapter 3

### Notes:

**Example:** `balanceDeleteBufferSize = 1000`

### `balanceUpdateBufferSize`

**Syntax:** `balanceUpdateBufferSize = num`

**Description:** The number of updates in a buffer before beVWARS will flush it.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 1000

### Notes:

**Example:** `balanceUpdateBufferSize = 1000`

### `bucketCreateBufferSize`

**Syntax:** `bucketCreateBufferSize = num`

**Description:** The number of bucket creates in a buffer before beVWARS will flush it.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 1000

### Notes:

**Example:** `bucketCreateBufferSize = 1000`

### `bucketDeleteBufferSize`

**Syntax:** `bucketDeleteBufferSize = num`

**Description:** The number of bucket deletes in a buffer before beVWARS will flush it.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 1000

### Notes:

**Example:** `bucketDeleteBufferSize = 1000`

### `bucketUpdateBufferSize`

**Syntax:** `bucketUpdateBufferSize = num`

**Description:** The number of bucket updates in a buffer before beVWARS will flush it.

**Type:** Integer

**Optionality:** Optional (default used if not set).

**Allowed:**

**Default:** 1000

### Notes:

**Example:** `bucketUpdateBufferSize = 1000`

`cdrOutputDirectory`

**Syntax:** `cdrOutputDirectory = "dir"`  
**Description:** Directory where EDRs are written to.  
**Type:** String  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** `"/IN/service_packages/E2BE/logs/CDR"`  
**Notes:** EDRs will be stored in this directory until they are moved by another process.  
**Example:** `cdrOutputDirectory = "/var/EDRs/UBE/"`

`flushPeriod`

**Syntax:** `flushPeriod = seconds`  
**Description:** The maximum number of seconds between flushes.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 10  
**Notes:**  
**Example:** `flushPeriod = 20`

`voucherUpdateBufferSize`

**Syntax:** `voucherUpdateBufferSize = num`  
**Description:** The number of voucher updates in a buffer before beVWARS will flush it.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 1000  
**Notes:**  
**Example:** `voucherUpdateBufferSize = 1000`

`voucherCreateBufferSize`

**Syntax:** `voucherCreateBufferSize = num`  
**Description:** The number of voucher creates in a buffer before beVWARS will flush it.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 1000  
**Notes:**  
**Example:** `voucherCreateBufferSize = 1000`

`voucherDeleteBufferSize`

**Syntax:** `voucherDeleteBufferSize = num`  
**Description:** The number of voucher deletes in a buffer before beVWARS will flush it.  
**Type:** Integer

## Chapter 3

**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 1000  
**Notes:**  
**Example:** `voucherDeleteBufferSize = 1000`

### walletCreateBufferSize

**Syntax:** `walletCreateBufferSize = num`  
**Description:** The number of wallet creates in a buffer before beVWARS will flush it.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 1000  
**Notes:**  
**Example:** `walletCreateBufferSize = 1000`

### walletDeleteBufferSize

**Syntax:** `walletDeleteBufferSize = num`  
**Description:** The number of wallet deletes in a buffer before beVWARS will flush it.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 1000  
**Notes:**  
**Example:** `walletDeleteBufferSize = 1000`

### walletUpdateBufferSize

**Syntax:** `walletUpdateBufferSize = num`  
**Description:** The number of wallet updates in a buffer before beVWARS will flush it.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 1000  
**Notes:**  
**Example:** `walletUpdateBufferSize = 1000`

## Tracing parameters

The tracing parameters allow tracing to be performed for individual wallet IDs on selected be clients.

Where more than one criteria (wallet and client) is configured for tracing then the message must satisfy all criteria (logical AND) for tracing/debug to activate.

### beClients

**Syntax:** `beClients = ["client1", "client2", ...]`  
**Description:** List of BE client names to trace.  
**Type:** Array, String

**Optionality:** Optional if walletIDs parameter supplied, mandatory if walletIDs not supplied.  
**Allowed:** Any beClient.  
**Default:** None  
**Notes:** The names are converted to a unique BE client hash ID - which is the same mechanism employed by the beVWARS for referencing BE clients.  
**Example:**

```
beClients = [
    "ccsBeOrb",
    "PIbeClient"
]
```

debugLevel

**Syntax:** debugLevel = "level"  
**Description:** The debug level/filter, is equivalent to DEBUG environment variable.  
**Type:** String  
**Optionality:** Optional (default used if not set).  
**Allowed:** Any of the DEBUG options.  
**Default:** "all"  
**Notes:** This is a comma separated string. See traceDebugLevel in *ACS Technical Guide* for more information.  
**Example:**

```
debugLevel = "all"
```

enabled

**Syntax:** enabled = true|false  
**Description:** The tracing activation switch to allow tracing of selected wallet and/or be client activity.  
**Type:** Boolean  
**Optionality:** Optional (default used if not set).  
**Allowed:** true, false  
**Default:** false  
**Notes:**  
**Example:**

```
enabled = true
```

walletIds

**Syntax:** walletIds = [ID1, ID2, ...]  
**Description:** List of subscriber wallet ids we want to trace.  
**Type:** Array, Integer  
**Optionality:** Optional if beClient parameter supplied, mandatory if beClient not supplied.  
**Allowed:** Any valid wallet ID.  
**Default:** None  
**Notes:** To obtain the wallet id(s) for a given CLI/subscriber use the showCLI.sh script on the BE where tracing is to occur.  
**Example:**

```
walletIds = [
    382,
    385
]
```

## Example configuration

This is an example `beVWARS` section `eserv.config` on a VWS node (comments have been removed).

```
beVWARS = {

    voucherReservationPeriodSeconds = 120
    useTimeFromClient = true
    maxTransactionsPerSet = 7
    maxOpenDialogTime = 5.0
    maxDownstreamQueueLength = 10000
    downstreamOverloadSleepUsec = 100000
    minResyncReservationLength = 5
    createBucketExpiryDays = 30
    maxSendReservationsToSync = 1000
    reservationExpiryCheckMilliseconds = 10000
    setLastUseDateOnActivation = true

    walletCache = {
        maxSize = 10000
        checkBeforeFlush = false
        maxLoopSize = 500
    }

    voucherCache = {
        maxSize = -100000
        checkBeforeFlush = false
        maxLoopSize = 500
    }

    groveller = {
        periodMsec = 1200
        requestHighWaterMark = 1
        walletLowWaterMark = 100
        requestTimeout = 300
        peerDatabaseLogin = ""
        peerWalletCheckRetrySeconds = 60
        secondaryConnectionDelaySeconds = 900
    }

    duplicateDetection = {
        keepDirectSeconds = 60.0
        keepSyncSeconds = 60.0
        directMaxDelaySeconds = 1.0
        syncMaxDelaySeconds = 1.0
    }

    setLastActivationDateStates = [
        [PREU]
    ]

    plugins = [
        "beVWARSExpiry.so"
    ]

    handlers = [
        "beVWARSCCDRHandler.so"
    ]

    syncWriter = {
        maxRecordsPerFile = 100
        maxSecondsPerFile = 2
    }
}
```

```

dbWriter = {
    flushPeriod = 10
    cdrOutputDirectory = "/IN/service_packages/E2BE/logs/CDR"

    balanceCreateBufferSize = 1000
    balanceUpdateBufferSize = 1000
    balanceDeleteBufferSize = 1000
    bucketCreateBufferSize = 1000
    bucketUpdateBufferSize = 1000
    bucketDeleteBufferSize = 1000
    walletCreateBufferSize = 1000
    walletUpdateBufferSize = 1000
    walletDeleteBufferSize = 1000
    voucherCreateBufferSize = 1000
    voucherUpdateBufferSize = 1000
    voucherDeleteBufferSize = 1000
}
tracing = {
    enabled = true
    debugLevel = "all"
    walletIds = [
        382,
        385
    ]
    beClients = [
        "ccsBeOrb",
        "PIbeClient"
    ]
}

setLastActivationDateStates = [
    "PREU"
]

} # BE.beVWARS

```

## Output

Each beVWARS writes error messages to the system messages file, and also writes additional output to its own log file. By default this is:

```
/IN/service_packages/E2BE/tmp/beVWARS0.log
```

**Note:** The actual name will be different for each beVWARS process.

## beVWARSCCDRHandler

### Purpose

The beVWARSCCDRHandler provides a specific EDR-generating function. This is generally used where no other process in an interaction will produce an EDR, but an EDR should still be generated.

**Example:** If a voucher redeem fails because the voucher cannot be found on any Voucher and Wallet Server, the client process will send a request to the beVWARSCCDRHandler to write an EDR for the failed voucher redeem.

### Startup

beVWARSCCDRHandler.so is included in the beVWARS by specifying it in the handlers array.

For more information about the handlers array, see *handlers* (on page 96).

### Configuration

This binary has no specific configuration.

## beVWARSEpiry

### Purpose

beVWARSEpiry monitors subscriber accounts and wallets, checking for subscriber accounts and wallets which have passed their expiry date. If it finds a subscriber account or wallet which requires expiring, it processes the record as configured.

### Startup

If beVWARSEpiry is configured in **eserv.config**, it is started by beVWARS when beVWARS is initialized. It is included in the beVWARS handlers section.

```
handlers = [  
    "beVWARSEpiry.so"  
]
```

For more information about beVWARS:

- Plug-ins, see *Plug-ins* (on page 93).
- Handlers section, see *handlers* (on page 96)

**Note:** Other handlers can also be included in the handlers list.

### Configuration

beVWARSEpiry accepts the following parameters from **eserv.config**.

```
beVWARSEpiry = {  
    expireNegativeBuckets = true|false  
    removeEmptyBuckets = true|false  
    expireBucketsForExpiredWallets = true|false  
    expireAtMidnightTZ = "timezone"  
    terminatedWalletConsistencyCheck = true|false  
}
```

### Parameters

Here are the available parameters in the beVWARSEpiry section of the **eserv.config**.

expireAtMidnightTZ

<b>Syntax:</b>	expireAtMidnightTZ = "timezone"
<b>Description:</b>	Sets wallets and buckets to expire at midnight for the time zone specified.
<b>Type:</b>	String
<b>Optionality:</b>	Optional (default used if not set)

- Allowed:** The time zone part of the parameter must be typed in a form that the operating system recognizes.  
Alternatively you can select a time zone from the operating system's list. To view top-level time zone names, type `ls /usr/share/lib/zoneinfo` from a shell. To see second-level time zone names type `ls /usr/share/lib/zoneinfo TopLevelName/`. For example, to verify that the operating system recognizes a time zone name for DeNORANHA, in Brazil, you would type `ls /usr/share/lib/zoneinfo/Brazil/`. DeNORANHA is listed, so the time zone name would be "Brazil/DeNORANHA".
- Default:** GMT
- Notes:** A list of time zones can be found in the Time Zones appendix of *ACS Technical Guide*.  
This parameter does not affect the expiry calculations of periodic charge buckets.
- Example:** An account is created at 2 p.m. on 5 September 2014 and is set to have a life span of 24 days.  
If `expireAtMidnightTZ = "Asia/Vladivostok"` is included, the account will expire on 29 September 2014 at midnight, Vladivostok time.  
If this parameter is omitted, the account will expire on 29 September 2014 at 2:00 PM GMT.

#### `expireBucketsForExpiredWallets`

- Syntax:** `expireBucketsForExpiredWallets = true|false`
- Description:** Controls whether wallet expiry triggers bucket expiry.  
If true, any buckets under the wallet will be expired when the wallet expires.
- Type:** Boolean
- Optionality:** Optional (default used if not set).
- Allowed:**
- |                    |  |
|--------------------|--|
| <code>true</code>  | All buckets with a positive or zero value in a wallet will be expired when the wallet is expired, even if the buckets are not due to expire yet. |
| <code>false</code> | Buckets are expired when their own expiry date passes.   |
- Note:** This means the wallet will not be deleted from the system, but will instead be set to Removed state and kept until the last bucket is expired.
- Default:** false
- Notes:** If `expireNegativeBuckets` (on page 115) is set to false, buckets with a negative value will not be deleted, regardless of the value of this parameter.  
Using this parameter will remove any positive value the wallet holds when the wallet expires.
- Example:** `expireBucketsForExpiredWallets = false`

#### `expireNegativeBuckets`

- Syntax:** `expireNegativeBuckets = true|false`
- Description:** Whether or not to expire buckets which have a negative value.
- Type:** Boolean
- Optionality:** Optional (default used if not set).

<b>Allowed:</b>	true	Buckets with negative values are expired when their expiry date passes.
		Buckets with negative values (where the subscriber is in debit), are expired when their expiry date passes.
	false	Buckets are expired when their expiry date passes and they have a positive or 0 balance.

**Note:** This means wallets with negative balances will not be deleted from the system, but will instead be set to Removed state and kept until the last bucket is expired.

<b>Default:</b>	false
<b>Notes:</b>	This parameter is designed to enable the Telco to keep the wallet until all outstanding money has been recovered from the subscriber.
<b>Example:</b>	<code>expireNegativeBuckets = false</code>

#### `removeEmptyBuckets`

<b>Syntax:</b>	<code>removeEmptyBuckets = true false</code>				
<b>Description:</b>	Whether or not to remove buckets when they have a value of 0.				
<b>Type:</b>	Boolean				
<b>Optionality:</b>	Optional (default used if not set).				
<b>Allowed:</b>	<table> <tr> <td>false</td> <td>Leave buckets to expire as normal.</td> </tr> <tr> <td>true</td> <td>If true, any buckets with 0 value will be removed.</td> </tr> </table>	false	Leave buckets to expire as normal.	true	If true, any buckets with 0 value will be removed.
false	Leave buckets to expire as normal.				
true	If true, any buckets with 0 value will be removed.				
<b>Default:</b>	false				
<b>Notes:</b>	Setting this to false does not stop beVWARSExpiry removing buckets for expired wallets if <code>expireBucketsForExpiredWallets</code> (on page 115) is set to true.				
<b>Example:</b>	<code>removeEmptyBuckets = false</code>				

#### `terminatedWalletConsistencyCheck`

<b>Syntax:</b>	<code>terminatedWalletConsistencyCheck = true false</code>				
<b>Description:</b>	Whether to check the wallet cache against the database for terminated wallets. If <code>terminatedWalletConsistencyCheck</code> is set to true, then beVWARSExpiry checks for terminated wallets in the wallet cache and if the status is different in the database, updates the wallet status to terminated in the database.				
<b>Type:</b>	Boolean				
<b>Optionality:</b>	Optional (default used if not set)				
<b>Allowed:</b>	<table> <tr> <td>true</td> <td>(perform database consistency check on terminated wallets)</td> </tr> <tr> <td>false</td> <td>(do not perform database consistency check)</td> </tr> </table>	true	(perform database consistency check on terminated wallets)	false	(do not perform database consistency check)
true	(perform database consistency check on terminated wallets)				
false	(do not perform database consistency check)				
<b>Default:</b>	false				
<b>Notes:</b>	Set this parameter to true if wallet expiry transactions are incorrectly synchronized with the database; for example, if the database failed when a wallet expired for the first time.				
<b>Example:</b>	<code>terminatedWalletConsistencyCheck = true</code>				

## Example configuration

This is an example of the `beVWARSExpiry` section of an `eserv.config` file from a VWS (comments have been removed).

```
beVWARSExpiry = {
    expireNegativeBuckets = false
    removeEmptyBuckets = false
```

```

    expireBucketsForExpiredWallets = false
    expireAtMidnightTZ = "Asia/Vladivostok"
}

```

## Failure

If beVWARSExpiry fails, it will not trigger expiry events for any Expiry plug-in. When beVWARSExpiry recovers, it will process as normal, and will catch up with any expired wallets or buckets.

## Output

The beVWARSExpiry writes error messages to the system messages file, and also writes additional output to the following default (can vary as per configuration):

```
/IN/service_packages/E2BE/tmp/beVWARSExpiry.log
```

## beVWARSMergeBuckets

### Purpose

beVWARSMergeBuckets is a plug-in library for beVWARS.

This beVWARS plug-in merges buckets in the same balance when there are too many buckets in the wallet. If there are too many buckets the message detailing the wallet contents will not fit in a 1024 byte SLEE event and can cause errors.

Merging begins with the balances that have the most buckets. In each balance, the bucket with the earliest expiry has its value added to the next bucket, then it is removed. This is repeated until the wallet has the maximum allowed number of buckets left.

### Configuration

beVWARSMergeBuckets accepts the following parameters from **eserv.config**.

```

maxBuckets = num
triggerPlugins = true|false

```

### Parameters

Here are the available parameters in the `beVWARSMergeBuckets` section of the **eserv.config**.

`maxBuckets`

<b>Syntax:</b>	<code>maxBuckets = num</code>
<b>Description:</b>	The maximum number of buckets a wallet can have.
<b>Type:</b>	Integer
<b>Units:</b>	
<b>Optionality:</b>	Optional (default used if not set).
<b>Allowed:</b>	-1                    No maximum. positive integer    Maximum number of buckets.
<b>Default:</b>	-1
<b>Notes:</b>	
<b>Example:</b>	<code>maxBuckets = -1</code>

## triggerPlugins

<b>Syntax:</b>	<code>triggerPlugins = true false</code>
<b>Description:</b>	When we merge buckets (update the value of one and delete the other), should we trigger other beVWARS plug-in.
<b>Type:</b>	Boolean
<b>Units:</b>	
<b>Optionality:</b>	Optional (default used if not set).
<b>Allowed:</b>	
<b>Default:</b>	false
<b>Notes:</b>	
<b>Example:</b>	<code>triggerPlugins = false</code>

## Example configuration

This is an example of the `beVWARSExpiry` section of an `eserv.config` file on a VWS (comments have been removed).

```
beVWARSMergeBuckets = {
    maxBuckets = -1
    triggerPlugins = false
}
```

## cmnPushFiles

### Purpose

`cmnPushFiles` transfers files to specific directories on the SMS from SLCs and VWSs. The files transferred include:

- EDRs
- PIN logs

**Note:** Other Oracle applications also use their own instances of this process.

### Startup

This task is started by entry `scp1` in the `inittab`, using the shell script:

```
/IN/service_packages/SMS/bin/cmnPushFilesStartup.sh
```

### Configuration

`cmnPushFiles` accepts the following command-line options:

#### Usage:

```
cmnPushFiles -d dir [-o dir [-a age]] [-f dir] [-F] [-P prefix] [-S suffix] -h host
[-r prefix] [-p port] [-s seconds] [-R seconds] [-M seconds] [-C seconds] [-t
bitrate] [-T] [-x] [-e] [-w seconds]
```

The available parameters are:

Parameter	Default	Description
<code>-d</code>		Destination directory for files on remote machine. <b>Example:</b> The directory on SLC where the <code>cmnPushFiles</code> looks for the files to be sent to the SMS.

Parameter	Default	Description
-o	File deleted	Transferred directory.
-a	Never delete files	Age of transferred files before being deleted. This parameter only relevant when -o option is specified.
-f	none	Retry directory.
-F	Do not use	Use fuser to not move files in use.
-P	none	File prefix.
-S	none	File suffix.
-h	none	Remote hostname.
-r	none	Remote directory prefix. <b>Note:</b> Required if -d is relative directory.
-p	2027	Port on remote machine on which the cmnReceiveFiles will listen for receiving files. <b>Note:</b> -1 for stdin/stdout.
-s	15	Sleep period in seconds.
-R	15	Seconds before Initial retry period in seconds.
-M	900	Maximum retry period in seconds.
-C	1800	Cleanup period in seconds.
-t	none (no throttling)	Throttles transfer to <i>nnn</i> bits per second.
-T	off (non-recursive)	Tree move: recursive into subdirectories.
-x	On (use prefixing)	Do not use hostname-prefixing on remote filenames.
-e	Daemon mode	Non-daemon mode. Execute file transfer only once, then exit.
-w	30	Time to wait for success in seconds.

**Example:**

```
cmnPushFiles -d /IN/service_packages/SMS/cdr/closed -f
/IN/service_packages/SMS/cdr/retry -r /IN/service_packages/SMS/cdr/received -h
prodsmpl.telcoexample.com -s 10 -p 2028 -S cdr -w 20
```

**Parameters**

Here are the available parameters in the `cmnPushFiles` section of the `eserv.config` file.

CDR

**Syntax:** CDR = [  
    "param" [, "value"]  
    [...]  
]

**Description:** Arguments to `cmnPushFiles` when used to send EDRs to SMS.

**Type:** Array

**Optionality:** Optional (default used if not set).

**Allowed:** See `cmnPushFiles` documentation in *SMS Technical Guide*.

**Default:**

### Notes:

**Example:**

```
CDR = [  
    "-d", "/IN/service_packages/E2BE/logs/CDR-out"  
    "-r", "/IN/service_packages/CCS/logs/CDR-in"  
    "-h", "smp1prod"  
    "-F"  
]
```

-d

**Syntax:** "-d", "*dir*"

**Description:** Local source directory.

**Type:** String

**Optionality:**

**Allowed:**

**Default:**

**Notes:**

**Example:** "-d", "/IN/service\_packages/E2BE/logs/CDR-out"

-r

**Syntax:** "-r", "*dir*"

**Description:** Remote destination directory.

**Type:** String

**Optionality:**

**Allowed:**

**Default:**

**Notes:**

**Example:** "-r", "/IN/service\_packages/CCS/logs/CDR-in"

-h

**Syntax:** "-h", "*host*"

**Description:** Full host name and domain of the SMS machine.

**Type:** String

**Optionality:**

**Allowed:**

**Default:**

**Notes:**

**Example:** "-h", "smp1prod"

-F

**Syntax:** -F

**Description:** Do not send the file if a process is currently using it.

**Type:** Boolean

**Optionality:** Optional (file sent if not set).

**Allowed:**

**Default:**

**Notes:****Example:** -F**Example configuration**

This is an example of the `cmnPushFiles` section of an `eserv.config` file on a VWS (comments have been removed).

```
cmnPushFiles = {
  CDR = [
    "-d", "/IN/service_packages/E2BE/logs/CDR-out"
    "-r", "/IN/service_packages/CCS/logs/CDR-in"
    "-h", "smp1hostname"
    "-F"
  ]
}
```

**Failure**

If `cmnPushFiles` fails, EDRs will accumulate in:

`/IN/service_packages/SMS/cdr/current/`

`cmnPushFiles` will send error messages to the syslog and the `cmnPushFiles` log.

**Output**

The `cmnPushFiles` writes error messages to the system messages file, and also writes additional output to this default location:

`/IN/service_packages/SMS/tmp/cmnPushFiles.log`

## Event Storage Interface

**Overview**

The event storage interface stores events to be sent to a different SLEE interface at a future time.

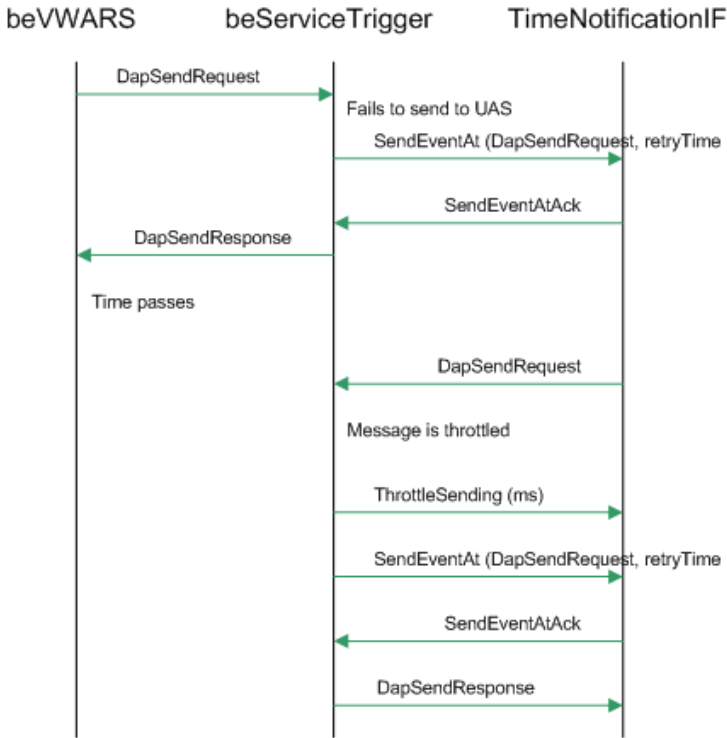

When it is time to send an event, the event storage interface sends the event to the specified SLEE interface and waits for a response. The response can be one of the following:

- `DIALOG_CLOSED`: An error occurred, and the event will be retried later.
- Any event other than `DIALOG_CLOSED`: The event was delivered successfully. The event storage interface removes the event from the queue.

To prevent it from spamming the outbound interface with events, the storage interface accepts a throttle message, which inserts a gap between events sent to the interface.

### Error and throttle flow

Here is an example flow showing the interaction between the plug-in and beServiceTrigger when an event that is to be sent immediately encounters multiple failures: first the SLC is down, and then a second failure occurs due to throttling.

### Send later flow

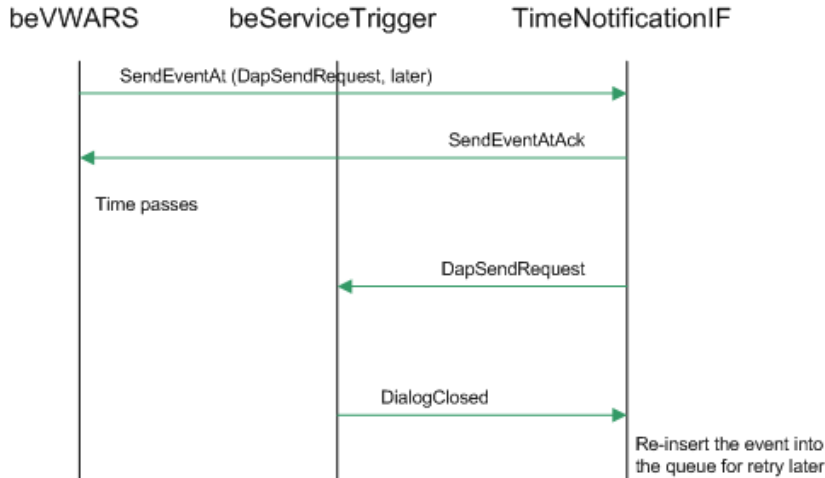

Here is an example flow showing the interaction between the plug-in and beServiceTrigger for an event that is to be sent later.

## Crash flow

Here is an example flow showing the interaction between the plug-in and beServiceTrigger when an event that is to be sent immediately encounters a beServiceTrigger failure.

## Event Storage SLEE Events

Trigger events for event storage, plus parameters are:

- `SenSendEventAt`:  
When  
InterfaceName  
EventToSend
- `SendEventAck`  
Success
- `ThrottleSending`  
TimeBetweenEvents  
InstanceToThrottledEventAt

## Configuration

The event storage interface accepts the following parameters from `eserv.config`.

```

eventStorage = {
    nextEventWindowTime = milliseconds
    NumberOfRows = num
    sleepTime = milliseconds
}
  
```

## Parameters

Parameters of the `eventStorage` group are listed below.

`nextEventWindowTime`

**Syntax:** `nextEventWindowTime = milliseconds`

**Description:** The timeout interval, in milliseconds, for the next event that is sent. This allows time for the event storage interface to check for further events, rather than get caught processing timeouts.

**Type:** Integer

**Optionality:** Optional (default used if not set)  
**Allowed:** A positive integer  
**Default:** 100  
**Notes:** The event timeout is set to one of the following, depending on whichever is greatest:

- The current time plus `nextEventWindowTime`
- Next event time

**Example:** `nextEventWindowTime = 75`

### NumberOfRows

**Syntax:** `NumberOfRows = num`  
**Description:** The number of rows that the event storage interface returns from a single re-read iteration, before the SLEE is checked for a management event.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:** A positive integer  
**Default:** 10  
**Notes:**  
**Example:** `NumberOfRows = 15`

### sleepTime

**Syntax:** `sleepTime = millisecs`  
**Description:** The amount of time, in milliseconds, that the event storage interface sleeps when waiting for new events. This time is used when no new events are due before the specified time interval elapses.  
**Type:** Integer  
**Optionality:** Optional (default used if not set)  
**Allowed:** Any positive integer  
**Default:** 1  
**Notes:** The amount of time that the event storage interface sleeps is set to one of the following, depending on whichever is shortest:

- `sleepTime`
- Next event time

**Example:** `sleepTime = 2`

## libbeMsgRouterDefault

### Purpose

`libbeMsgRouterDefault` is a `beServer` plug-in which determines which `beVWARS` to direct ESCHER messages to.

### Startup

`libclientBcast` is used by `beServer` process if its configuration includes the library. To be used, it must be included in the `messageRoutingPlugins` array as shown:

```
messageRoutingPlugins = [  
    "libbeMsgRouterDefault.so"
```

For more information about the `beServer` `messageRoutingPlugins` section, see *messageRoutingPlugins* (on page 70).

## Configuration

The `libbeMsgRouterDefault`'s configuration is read from the `beServer` section of `eserv.config`. `libbeMsgRouterDefault` supports the following parameters:

- All parameters in `msgRouterDefault` (on page 70)
- `routingVoucherNumberLength` (on page 74)

## libBeClientIF

### Purpose

The `libBeClientIF` provides an interface to one or more VWS Voucher and Wallet Servers.

### Startup

The `libBeClientIF` is a runtime dependency of processes which need to talk to the VWS Voucher and Wallet Servers.

### Configuration

The `libBeClientIF`'s configuration is usually read from the section which configures the process which is using it. `libBeClientIF` supports the following parameters.

- `beLocationPlugin` (on page 41)
- `clientName` (on page 54)
- `heartbeatPeriod` (on page 55)
- `messageTimeoutSeconds` (on page 56)
- `maxOutstandingMessages` (on page 55)
- `reportPeriodSeconds` (on page 58)
- `connectionRetryTime` (on page 55)
- `plugins` (on page 57)
- `notEndActions` (on page 56)

#### Notes:

- Any process which is using the `libBeClientIF` can use these parameters.
- `beLocationPlugin` is located in the shared parameters section.

## libclientBcast

### Purpose

`libclientBcast` is used by `BeClient` processes to send messages which may be answered by any Voucher and Wallet Server. The request is sent to one of the VWSs in all Voucher and Wallet Server pairs at once. The plug-in is activated by sending a message to BE ID 0.

This process is specifically used to redeem vouchers, and vouchers cannot be redeemed if this library is not loaded.

### Startup

libclientBcast is used by BeClient processes if their configuration includes the library.

If libclientBcast is used by BeClient and ccsBeOrb, it is included in the `plugins` array as shown:

```
plugins = [  
  {  
    config=""  
    library="libclientBcast.so"  
    function="makeBroadcastPlugin"  
  }  
]
```

For more information about the BeClient `plugins` section, see *plugins* (on page 57).

### Configuration

The libBeClientIF's configuration is usually read from the section which configures the process which is using it. libBeClientIF supports the `aggregateNAckCodes` (on page 54) parameter.

## libbeEventFactory

### Purpose

libbeEventFactory is the common library used to create SLEE events from ESCHER messages. It is required by the system and should not be removed.

### Startup

libbeEventFactory is used by a number of processes on the VWS. No startup configuration is required for this library to be used.

### Configuration

This binary has no specific configuration.

# Tools and Utilities

## Tools and Utilities Overview

### Introduction

This chapter provides a description of the operational programs or executables that can be used on the VWS. You can run these processes as needed.

### In this chapter

---

This chapter contains the following topics.

VWS Correction Tool.....	127
beEventStorageIFDump.....	135
beServiceTriggerUser.....	137

## VWS Correction Tool

### Purpose

Use the correction tool to restore consistent data in the system following a software fault or configuration error, without causing further outage or lost service for any node in the system.

Use the correction tool for making a small number of changes to fields that cannot be maintained via the User Interface or Provisioning Interface.

### Rollback

There is no rollback as such. The commands can be run again with pre-corrected data to reach the previous state.

### About minimizing tool impact

Any changes to the VWS database will affect the performance of the server. To mitigate performance degradation, several of the configuration parameters can be used to effectively throttle the tool.

The operator can:

- Limit number of concurrent commands executing in one binary by using the **maxQueueSize** configuration parameter. The tool will not issue new requests unless there are currently less than or equal to maxQueueSize commands in flight.
- Impose time delay between successive commands by using the **maxCommandsPerSecond** configuration parameter. The tool will issue this maximum number of commands per second. When used in conjunction with the maxQueueSize parameter, allows an even tighter throttle if required. For example, with a maxQueueSize of 1, the tool can still direct a strong volume commands, but if it is further moderated by a setting such as maxCommandsPerSecond=(say) 2 or even 1, then the traffic can be brought under tighter control.
- Queue or reject concurrent requests to same business object by using the **queueUpdatesToSameObject** configuration parameter. The tool can either allow concurrent or serial commands to run against the

same business object. The default is **false**, which means that a file of commands for the same wallet will be executed serially, **true**, the commands are executed in parallel.

### Starting the commands

For individual changes, the commands can be typed directly into the command line.

For many changes, the command lines can be entered into a batch file which is then executed from the command line.

### eserv.config parameters

clientName

**Syntax:** `clientName = "value"`  
**Description:** The unique client name to connect to the database with.  
**Type:** String  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** "ccsAccount"  
**Notes:** Only one connections with the same name is allowed.  
**Example:** `clientName = "nccdemo-dev-ccsVWSCorrection"`

heartbeatPeriod

**Syntax:** `heartbeatPeriod = value`  
**Description:** The number of microseconds since previous message before fail over to the other VWS.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:** 0 for no heartbeating.  
**Default:** 30000000 (30 seconds)  
**Notes:** If no heartbeat or other messages received in this period we switch to the other VWS in the pair on the assumption that the current VWS has failed.  
**Example:** `heartbeatPeriod = 10000000`

connectionRetryTime

**Syntax:** `connectionRetryTime = value`  
**Description:** The number of seconds before we try to reconnect.  
**Type:** Integer  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** 5  
**Notes:**  
**Example:** `connectionRetryTime = 2`

plugins

**Syntax:** `plugins = value`  
**Description:** Identifies which plugins to load.

**Type:** Array  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** [] (empty, no plugins)  
**Notes:** Not currently used, for future potential use.  
**Example:** `plugins = []`

**Syntax:** `billingEngines = value`  
**Description:** beLocationPlugin values override.  
**Type:** Array  
**Optionality:** Optional (default used if not set).  
**Allowed:**  
**Default:** beLocationPlugin billing engine values  
**Notes:** Used to override the beLocationPlugin that would normally load the connection details from the DB.  
**Example:**

```

billingEngines = [
  {id = 1,primary = { ip="PRIMARY_BE_IP", port=1500 },secondary
    = { ip="SECONDARY_BE_IP", port=1500 }
}
]

```

#### maxQueueSize

**Syntax:** `maxQueueSize = value`  
**Description:** Number of concurrent commands executing in one binary.  
**Type:** Integer  
**Optionality:** Mandatory.  
**Allowed:**  
**Default:**  
**Notes:** The tool will not issue new requests unless there are currently less than or equal to maxQueueSize commands in flight. In conjunction with maxCommandsPerSecond can be used to control impact on the VWS.  
**Example:** `maxQueueSize = 10`

#### queueUpdatesToSameObject

**Syntax:** `queueUpdatesToSameObject = value`  
**Description:** Controls whether multiple updates to a single business object are done in parallel or serially.  
**Type:** Boolean  
**Optionality:** Optional (default used if not set).  
**Allowed:**

- true – Allow parallel updates
- false – Serial updates only

**Default:** false  
**Notes:**  
**Example:** `queueUpdatesToSameObject = true`

**Syntax:** `notificationInterval = value`  
**Description:** The number of seconds between reporting progress status to the log file.

**Type:** Integer  
**Optionality:** Mandatory  
**Allowed:**  
**Default:**  
**Notes:**  
**Example:** notificationInterval = 6

**Syntax:** maxCommandsPerSecond = *value*  
**Description:** The maximum number of commands allowed in flight per second.  
**Type:** Integer  
**Optionality:** Mandatory  
**Allowed:**  
**Default:**  
**Notes:**  
**Example:** maxCommandsPerSecond = 10

**Syntax:** pollTimeUsecs = *value*  
**Description:** The number of microseconds to wait for a message from a Billing Engine client before polling.  
**Type:** Integer  
**Optionality:** Mandatory  
**Default:** 1000000 (one second)  
**Example:** pollTimeUsecs = 100000

## Example of VWS correction tool section

This is an example of the `eserv.config` file correction tool section.

```
ccsVWSCorrection = {  
    ClientIF = {  
        clientName = "nccdemo-dev-ccsVWSCorrection"  
        heartbeatPeriod = 10000000  
        connectionRetryTime = 2  
        plugins = []  
        billingEngines = [  
            {id = 1,  
            primary = { ip="PRIMARY_BE_IP", port=1500 },  
            secondary = { ip="SECONDARY_BE_IP", port=1500 }  
            }  
        ]  
    }  
  
    maxQueueSize = 10  
    queueUpdatesToSameObject = false  
    notificationInterval = 6  
    maxCommandsPerSecond = 10  
    pollTimeUsecs = 100000
```

```
} # CCS.ccsVWSCorrection section
```

## Command line parameters

The commands that can be used are:

- `delete_balance`:  
This deletes the balance from the wallet ID and balance type ID.
- `delete_bucket`:  
This updates the supplied bucket ID by zeroing the current value of the bucket. The mechanism to physically delete the bucket is up to other (pr-existing) configuration on the VWS as to whether or not zero value buckets are retained or deleted.
- `update_balance`:  
This updates the supplied balance fields with the new values.
- `update_bucket`:  
This updates supplied bucket fields with the new values.
- `update_wallet`:  
This updates the supplied wallet fields with the new values.

See Command line examples.

## Update balance parameters

The `update_balance` command has the ability to modify the following fields to schema and business rule acceptable values against a specified balance for a specified wallet:

- `limit_type`
- `minimum_credit`

The balance and wallet key data is supplied in these fields:

- `wallet_id`
- `balance_type`

An example of the `update_balance` command is:

```
update_balance:wallet_id=4,balance_type=9,limit_type=LCRD,minimum_credit=888
81000
```

## Update bucket parameters

The `update_bucket` command has the ability to modify the following fields to schema and business rule acceptable values against a specified bucket for a specified balance and wallet:

- `expiry`
- `value`
- `value_delta`
- `reference`
- `start_date`
- `last_use`
- `never_expires`
- `never_used`

The balance and wallet key data is supplied in these fields:

- `wallet_id`
- `balance_type`

## Chapter 4

- bucket\_id

Examples of the update\_bucket command is:

```
update_bucket:wallet_id=4,balance_type=9,bucket_id=2,expiry=20160101115500
```

```
update_bucket:wallet_id=4,balance_type=9,bucket_id=2,value=5,value_delta=1
```

### Update wallet parameters

The **update\_wallet** command has the ability to modify the following fields to schema and business rule acceptable values against a specified wallet:

- max\_concurrent state
- never\_expires
- expiry
- never\_activated
- activation\_date
- state

The wallet key data is supplied in this field:

- wallet\_id

Examples of the update\_wallet command is:

```
update_wallet:wallet_id=4,never_expires=true,expiry=20110101115600
```

```
update_wallet:wallet_id=47,state=ACTV
```

### Delete balance parameters

The **delete\_balance** command deletes the balance.

The balance key data is supplied in these fields:

- wallet\_id
- balance\_type

Example of the delete\_balance command is:

```
delete_balance:wallet_id=4,balance_type=99
```

### Delete bucket parameters

The **delete\_bucket** command modifies the bucket value field to zero, allowing the VWS to retain or delete the bucket.

The bucket key data is supplied in these fields:

- wallet\_id
- balance\_type
- bucket\_id

Example of the delete\_bucket command is:

```
delete_bucket:wallet_id=44,balance_type=13,bucket_id=30
```

### Command line examples

The commands can be run singularly by typing in at the command line prompt, or as a batch in a file.

This is an example of a file of commands that will do a set of updates (picture a file with 450 lines of the following) that generated the Progress reporting and Audit reporting examples.

```
update_bucket:wallet_id=4,balance_type=9,bucket_id=2,value=5,value_delta=1
```

```
update_bucket:wallet_id=4,balance_type=9,bucket_id=2,value=5,value_delta=1
```

lots of lines (447) deleted for conciseness.

```
update_bucket:wallet_id=4,balance_type=9,bucket_id=2,value=5,value_delta=1
```

Other examples are:

- update\_wallet:wallet\_id=4,never\_expires=true
- update\_balance:wallet\_id=4,balance\_type=9,limit\_type=LCRD
- delete\_balance:wallet\_id=44,balance\_type=9
- delete\_bucket:wallet\_id=4,balance\_type=13,bucket\_id=30

## Progress reporting

The tool sends report information to the logfile, including, the parameters at the start, the status periodically as it executes, and the details of each command processed.

Here is an example showing the expected reporting. The tool is executing a series of commands that add 5c to a particular bucket repeatedly (450 times).

To see the report, on the command line type (for example):

```
-bash-3.00$ ./ccsvWSCorrection -i commandFile -o logfile
```

The logfile report will look something like this:

```
Aug 2 14:54:37.208548 ccsvWSCorrection(29583) NOTICE: ccsvWSCorrection processing starting

## Audit reporting

The audit log contains structured fields (keyed by command number, time stamp and log record type. This is to permit convenient grepping, filtering, sorting and analysis of the log records after the run.

A log record can be of type:

- **COMMAND:** dumping the command being called
- **INFO:** displaying any informational message
- **WARNING:** displaying some warning condition
- **ERROR:** displaying an error in order to explain why the command did not run
- **AUDIT:** for commands that got as far as an update request, one or more of these show what fields were modified. Commands that delete business objects will display the current value of that object and any children it contains, to assist with recovery should it be necessary.

This is the log from the Command line examples and Progress reporting examples.

```

Total commands = 450
Update acks received = 450
Wallet Info Requests sent to Primary BE = 450

```

ccsVWSCorrection stopped at Tue Aug 2 14:55:54 2011

The log report shows that all commands were (eventually, there were some cases of the tool waiting for a previous update for the same wallet ID to finish, but this is normal in a file with multiple commands against the same wallet) successful, and the bucket value grew from an initial balance of 6330 (old value on first audit record) to 8580 (new value on last audit record). The difference is 450 x 5, so all updates were applied correctly.

## beEventStorageIFDump

### Purpose

The beEventStorageIFDump utility is a diagnostic tool for finding bottlenecks in the BE\_EVENT\_STORAGE database table. It parses through the table and lists the number, type, and contents of the storage events. The utility parses data exported from the database

To use the utility, you must use the new tool added to 5.0.1 codebase allows decoding of notifications

..in the BE\_EVENT\_STORAGE table. Decoding can occur via (i) direct query

..of the database, or (ii) by parsing of the exported table.

### Location

The beEventStorageIFDump utility is located on the SMS node.

### Syntax

You start the beEventStorageIFDump utility from the command line by using the following syntax:

```

beEventStorageIFDump -a|-m Value [-b FieldFile] [-c EventFieldName] [-d] [-f
DumpFile] [-g] [-h] [-l ListFile] [-n] [-r MSISDN] [-R Date] [-s StartEvent]
[-v 1|2|3]

```

The following table describes the beEventStorageIFDump command line parameters.

Parameter	Description
-a	Lists all events that are in the BE_EVENT_STORAGE table.
-m Value	Writes all events that match the specified value to a file. <ul style="list-style-type: none"> <li>ALL – Writes all events from the BE_EVENT_STORAGE table to a file named <b>BE_EVENT_STORAGE_EventFieldName_allevents</b>.</li> <li>FieldValue – Finds all events that have a matching event field value and writes them to a file named <b>BE_EVENT_STORAGE_EventFieldNameValue</b>.</li> </ul> <p>where <i>EventFieldName</i> is the name of a field in the BE_EVENT_STORAGE table, and <i>FieldValue</i> is the value of any field in the BE_EVENT_STORAGE table.</p>

-b <i>FieldFile</i>	The default file name is <b>beEventHeaders.txt</b> .
-c <i>EventFieldName</i>	Finds all events in the table that have a matching event field name. <b>Note:</b> You can further narrow the results by adding the -m <i>FieldValue</i> option to specify the required value of the field.
-f <i>DumpFile</i>	Specifies to write the event contents to the specified file. The default file name is <b>BE_EVENT_STORAGE.dmp</b> .
-g	Displays all event details.
-h	Displays the command-line syntax and parameters.
-l <i>ListFile</i>	Specifies to write the output of the utility to the specified file. The default file name is <b>beEventHeaders.txt</b> .
-n	Don't show event data as it finds it????
-r <i>MSISDN</i>	Match all entries based on <msisdn> in RequestTime window, use with -R
-R <i>Value</i>	match all entries with request times that occur in the interval  <date> - <n> days to <date>  where <date> is the value specified by -m<value>  An msisdn match can be specified with -r<msisdn> this option requires -c <time based event field name> e.g. -cRequestTime
-s <i>StartEvent</i>	Use eventFieldName <startEvent> as the start of the event dump file, default='beServiceTrigger' use in conjunction with -m
-v 1 2 3	Verbose: 1 (minimum), 2(mid), 3 (max)

## Command line examples

The commands can be run singularly by typing in at the command line prompt, or as a batch in a file.

The following example shows the syntax to list all MSISDN in exported table.

- show all MSISDN in exported table
- (i) show all msisdn in exported table
  - (a) list event field names to match against : `../beEventStorageIFDump -l`
  - (b) list Calling\_Party\_id for all events, show frequency: `../beEventStorageIFDump -cCalling_Party_id`
  - (c) list matched events, e.g.: `../beEventStorageIFDump -cCalling_Party_id -m12345678`
  - (d) to reduce display, add -n

To show all MSISDN in an exported table

Step	Action
1	List all events and their field names from the BE_EVENT_STORAGE table by entering the following command: <code>beEventStorageIFDump -l</code>
2	List the value of each event's CALLING_PARTY_ID field by entering the following command: <code>beEventStorageIFDump -c CALLING_PARTY_ID</code>
3	List all events that have a value of 12345678 in the CALLING_PARTY_ID field: <code>beEventStorageIFDump -c CALLING_PARTY_ID -m 12345678</code>

`beEventStorageIFDump -l -c CALLING_PARTY_ID -m 12345678 -n`

The following example shows the syntax

- (a) `./beEventStorageIFDump -cCalling_Party_id -m12345678 -g`
- (b) to reduce display, add `-n`
- (c) to show all events, regardless of `-c/-m` match, add `-a`

```
beEventStorageIFDump -c Calling_Party_id -m 12345678 -g
```

(iii) match all MSISDN with direct read from database

- (a) `./beEventStorageIFDump -cCalling_Party_id -m12345678 -S`  
generates result in `BE_EVENT_STORAGE_Calling_Party_id12345678`
- (b) to output to debug, rather than file, add `-d`

(iv) match all events on, or previous to <date> in DB dump

- (a) `./beEventStorageIFDump -fBE_EVENT_STORAGE2.dmp -cRequestTime -m2012-02-01 -r<> -n`
- (b) to match all events between `-m<date>` and the previous `n` days, add `-R<n>`

Note: date is expected to be 'YYYY-MM-DDTHH-MM-SSZ'

e.g.: `-mYYYY`, `-mYYYY-MM`, `-mYYYY-MM-DD` etc accepted

```
beEventStorageIFDump -f BE_EVENT_STORAGE2.dmp -cRequestTime -m2016-02-01 -r -n
```

## beServiceTriggerUser

### Purpose

The `beServiceTriggerUser` utility sets the user name and password that `beServiceTrigger` uses to log in to external systems remotely; for example, when sending service requests to a client ASP through the Convergent Charging Controller Open Services Development (OSD) component. The `beServiceTriggerUser` utility stores the user name and password in a secure credentials vault on the SMS node.

### Location

The `beServiceTriggerUser` utility is located on the SMS node.

### Startup

You start the `beServiceTriggerUser` utility from the command line by using the following syntax:

```
beServiceTriggerUser [-d user/password] [-u STUsername] [-p STpassword] [-r]
```

The following table describes the `beServiceTrigger` command line parameters.

Parameter	Description
<code>-d user/password</code>	(Optional) The oracle user and password to use to log in to the database on the SMS. If you omit the <code>-d</code> option, then <code>beServiceTriggerUser</code> uses the database login specified in the <code>oracleUserAndPassword</code> parameter in the BE section of <code>eserv.config</code> . Defaults to <code>'/'</code> if <code>-d</code> is not specified and <code>oracleUserAndPassword</code> is not set.
<code>-u STUsername</code>	(Optional) The name of the <code>beServiceTrigger</code> user. If you omit the <code>-u</code> option, <code>beServiceTriggerUser</code> prompts for a name.
<code>-p STpassword</code>	(Optional) The password for the <code>beServiceTrigger</code> user. If you omit the <code>-p</code> option, <code>beServiceTriggerUser</code> prompts for a password.
<code>-r</code>	(Optional) Specifies to delete the password.

## Setting the beServiceTrigger User and Password

Follow these steps to set the username and password for the `beServiceTrigger` process by using the `beServiceTriggerUser` utility.

Step	Action
1	Log in to the SMS as user <code>smf_oper</code> .
2	Go to the directory where <code>beServiceTriggerUser</code> is located.
3	Enter the following command to set the username and password for <code>beServiceTrigger</code> : <pre>beServiceTriggerUser [-d user/password] [-u STusername] [-p ST_password]</pre> Where: <ul style="list-style-type: none"><li>• <code>user/password</code> is the login ID for the Oracle database. The login specified in the <code>oracleUserAndPassword</code> parameter is used if you omit the <code>-d</code> option. If this is not set, then <code>/"</code> is used.</li><li>• <code>STusername</code> is the remote login name for the <code>beServiceTrigger</code> user. If you omit the <code>-u</code> option, then <code>beServiceTriggerUser</code> prompts for a name.</li><li>• <code>ST_password</code> is the new password for the <code>beServiceTrigger</code> user. If you omit the <code>-p</code> option, then <code>beServiceTriggerUser</code> prompts for a password.</li></ul>
	<b>Tip:</b> To remove the <code>beServiceTrigger</code> user and password, enter the following command: <pre>beServiceTriggerUser -r</pre>

# Troubleshooting

## Overview

### Introduction

This chapter explains the important processes on each of the server components in Convergent Charging Controller, and describes a number of example troubleshooting methods that can help aid the troubleshooting process before you raise a support ticket.

### In this chapter

---

This chapter contains the following topics.

Common Troubleshooting Procedures.....	139
Possible Problems.....	139
Process Failure Recovery .....	141

## Common Troubleshooting Procedures

### Introduction

Refer to *System Administrator's Guide* for troubleshooting procedures common to all Convergent Charging Controller components.

## Possible Problems

### Introduction

This topic lists common problems and actions you can take to investigate or solve them. This list enables you to check for alarms based on the overall behavior you are experiencing.

### Database failure

Upon network failure, any request or response may be lost. Pending Database (DB) write and EDRs will be lost.

### Failure scenarios

This table lists a range of failure scenarios and a description of the events that will happen as a result. For more information about resynchronization, see *Resynchronizations* (on page 22).

Scenario	Resulting Events
VWS is running. beServer core dumps, losing all contexts and BeClient connections.	<ol style="list-style-type: none"> <li>1 beServer recovers, finds the current state from beVWARS, determines that the VWS should be in Recovery state and makes it so.</li> <li>2 beServer prepares to receive contexts from beServer on the other VWS.</li> </ol>

Scenario	Resulting Events
	<ol style="list-style-type: none"> <li>3 beGroveler detects the dropped connection and a failover is triggered.</li> <li>4 beSync starts attempting recovery.</li> <li>5 Remote beServer starts sending contexts to the local beServer (and receives Operations from beSync).</li> <li>6 beSync should complete its recovery quickly (it should have already been in Sync). beSync will tell beVWARS to move to Running state, when the beVWARS has finished sending contexts it will move to Running.</li> <li>7 beServer starts accepting connections from BeClient processes.</li> <li>8 beGroveler establishes connection with beServer and starts grovelling.</li> </ol>
beVWARS core dumps, loses all reservations and cached wallets, then restarts.	<ol style="list-style-type: none"> <li>1 beServer and beSync are informed that the beVWARS process had died.</li> <li>2 beServer closes all open connections as nicely as it can.</li> <li>3 beVWARS restarts, prepares to send contexts to beServer (and receive Operations from beSync).</li> <li>4 beServer and beSync recognise beVWARS recovery.</li> <li>5 beSync initiates recovery (includes getting all reservation details from other VWS).</li> <li>6 beGroveler detects the dropped connection and a failover is triggered.</li> <li>7 When beSync completes recovery, the process completes as above (in beServer failure).</li> </ol>
VWS state is running. beSync core dumps and restarts.	<ol style="list-style-type: none"> <li>1 beSync restarts, gets current status from beVWARS.</li> <li>2 If the beVWARS is in Recovery or Running state it starts recovery.</li> <li>3 beSync processes as normal, but does not force the system into Recovery (which would deny connections, and this is not required) groveller proceeds as it was.</li> <li>4 beSync proceeds, when the inSync threshold is reached it tells the beVWARS to go to Running state (which it may already be in).</li> </ol>
Primary VWS has power turned off. BeClient detects failure of primary VWS.	<ol style="list-style-type: none"> <li>1 Primary VWS is turned back on.</li> <li>2 SLEE starts up, all SLEE processes start.</li> <li>3 beServer starts disabled, refuses BeClient connections.</li> <li>4 beGroveler attempts to connect to beServer and fails. It doesn't start processing.</li> <li>5 beSync starts, reads in existing sync file repository. At this point beSync source will not accept connections from the remote beSync sink as we do not want to send anything.</li> <li>6 BeClient swaps to sending messages to Secondary VWS, resending any it does not have responses for (and marks them as duplicates).</li> <li>7 beSync asks each local beVWARS for their last written Sequence Number.</li> <li>8 beSync looks to see if it needs to process files locally to write updates that are in the sync files but not in the database. This is done by looking to see if there is any later sequence numbers in the files.</li> <li>9 If later sequence numbers are found, they are read and sent to the beVWARS.</li> <li>10 While this is proceeding, the beSync source will start accepting connections from the remote beSync sink.</li> <li>11 When all local updates have been performed, beSync sink requests all reservations from the remote VWS to populate the beVWARS. <b>Note:</b> This is an extra step only performed on full recovery.</li> </ol>

Scenario	Resulting Events
	<p><b>12</b> The local beSync sink establishes a link to the remote VWS and requests all updates since the last remote update we have recorded on our database.</p> <p><b>13</b> Updates stream to us, and we confirm them in chunks.</p> <p><b>14</b> The timestamp on every update is checked against the wall clock. If the difference is less than the (configurable) inSyncThreshold then we consider ourselves to be inSync and tell beServer to start accepting connections again.</p> <p><b>15</b> beServer starts accepting connections again.</p> <p><b>16</b> beGroveler establishes connection with beServer and starts grovelling.</p>

For more information about beGroveler failover, see *beGroveler quorum* (on page 142).

## Process Failure Recovery

### Startup checks

On startup, or failure (and restart) of the beServer or beVWARS, we must get all reservations and server contexts from the peer VWS. Both the beServer and beVWARS must be present if this is to be successful.

### Startup process

After you start the SLEE, the following events occur.

Stage	Description
1	All processes startup in disabled/startup state.
2	beSync waits until it can contact beVWARS.
3	Once beSync can, it starts local recovery, by sending updates to the beVWARS.
4	The local beSync establishes a connection to the beSync on the remote VWS, and asks for contexts and reservations.
5	After the local beSync has all the remote contexts and updates, it requests the remote updates from beSync.
6	After remote updates are within a couple of seconds of the current time, beSync tells the beVWARS to change to running state.
7	beVWARS passes the state change message to beServer.
8	After beServer has Running messages from all beVWARS, it goes into running mode, and opens for client connections.
9	If grovelling is available at this time, beGroveler can now grovel, and will respond to requests for more wallets to grovel from each of the beVWARS processes.

### Restarts while in state Recovery

If you restart while in state recovery, the following events will occur.

For beSync:

- Queries the beVWARS, finds it is recovering, and starts requesting everything from the other beSync again.
- Reservations in the beVWARS are overwritten.

- Contexts in the beServer are overwritten.

For beVWARS:

- Comes up in disabled state.
- beServer gets a dialog closed event and disables itself, then it tries to contact beVWARS to put it in Recovery mode.

For beServer:

- Same as SLEE startup; contacts the beVWARS and resets Recovery mode.

### Restarts while in state Running

If you restart while in state running, the following events will occur.

- beSync queries the beVWARS and starts up running.
- beVWARS comes up disabled.
- beServer will get a dialog closed, disable itself, and then same as SLEE startup. Then it will follow the same process as a SLEE restart.
- beGroveler will start disabled, and will start processing when beServer starts accepting connections.
- We have lost all of the updates between the committed database's sequence number and those in the beVWARS, however the sync files still record all of these (they have not been removed as beSync hasn't received a COMMIT message yet).
- Each beVWARS clears its cache, reads the local and remote sequence number from the database, goes into recovery mode - broadcasting these SSEQ numbers.
- beVWARS will then ignore all operations from beSync until it sees one with the SessionNumber set to the ID of the control message it sent to set the VWS state to Recovery - beSync may have operations queued on the beVWARS with SSEQs AFTER those of the database (we do not want to skip those in between).
- beSync sees these new SSEQ numbers and sends all of the local and remote transactions it has to the beVWARS. The first operation message has the SessionNumber set to the ID of the control message that set the state to Recovery.

### beGroveler quorum

beGroveler is designed to only run on the primary Voucher and Wallet Server in a pair. However, groveling activity will failover to the secondary Voucher and Wallet Server if the Voucher and Wallet Server fails.

beGroveler determines whether it should pass groveling work to beVWARS processes, by checking whether it is on the primary and whether it can connect to the:

- Local beServer process
- beServer on the other VWS in the pair
- SMS specified in *quorumHost* (on page 64)

### Establishing quorum on primary VWS

beGroveler determines whether it is running on a primary VWS by checking the value of `amPrimary` (on page 41). If `amPrimary` is set to true, the beGroveler is running on a primary VWS.

If the beGroveler on a primary VWS can connect to the local beServer, beGroveler will respond to beVWARS grovel requests with lists of wallet IDs to grovel. If beGroveler cannot connect to the local beServer, it assumes the VWS is disabled or recovering and will not return work to beVWARS processes.

### Establishing quorum on secondary VWS

beGroveller determines whether it is running on a secondary VWS by checking the value of `amPrimary` (on page 41). If `amPrimary` is set to false, the beGroveller is running on a secondary VWS.

If beGroveller:

- Cannot connect to the local beServer, it assumes the VWS is disabled or recovering and will not return work to beVWARS processes.
- On a secondary VWS can connect to the local beServer, beGroveller will check whether it can connect to the beServer on the other VWS in the pair. If it can connect to the remote beServer, it will assume the primary is running and will not respond to beVWARS grovel requests with lists of wallet IDs to grovel.
- Can connect to the local beServer, but cannot connect to the beServer on the VWS, it will check whether it can ping the remote VWS. If it can ping the remote VWS it assumes the remote VWS is disabled and will start groveling.
- Cannot ping the remote VWS it will attempt to ping the SMS specified in `quorumHost` (on page 64). If it can ping `quorumHost`, it will assume the VWS pair has failed over, and will start to respond to beVWARS requests with lists of wallet IDs to grovel. If it cannot ping `quorumHost`, it will assume it is not on the main network, and will not respond to beVWARS requests with lists of wallet IDs to grovel.

# About Installation and Removal

## Overview

### Introduction

This chapter provides information about the installed components for the Oracle Communications Convergent Charging Controller application described in this guide. It also lists the files installed by the application that you can check for, to ensure that the application installed successfully.

### In this Chapter

---

This chapter contains the following topics.

Installation and Removal Overview .....	145
Configuring for Raw Device Support .....	145
Checking the Installation .....	149

## Installation and Removal Overview

### Introduction

For information about the following requirements and tasks, see *Installation Guide*:

- Convergent Charging Controller system requirements
- Pre-installation tasks
- Installing and removing Convergent Charging Controller packages

### Voucher and Wallet Server packages

An installation of Voucher and Wallet Server includes the following packages, on the:

- SMS:
  - beSms
- SLC:
  - beScp
- VWS:
  - beBe

## Configuring for Raw Device Support

### Introduction

This section details how to configure the VWS packages on the Voucher and Wallet Servers for raw device support.

CCS and BE can allocate tablespace storage based on raw (without a file system) partitions in order to enhance the performance of the VWS database.

When using the raw devices option, the raw partitions must be created by the user prior to continuing the installation of the database using tools such as the system's format command.

The raw devices file (of which the user is prompted to complete before continuing the installation) must contain the full paths of the device files for the appropriate partitions.

## System Device Configuration

To configure the Voucher and Wallet Server to use raw devices as datafiles, after installation is complete edit the following file:

```
/IN/service_packages/E2BE/db/install/create/BE/scripts/be_system_devices.sh
```

The `be_system_devices.sh` file contains entries for:

- 3 control file datafiles
- 1 system tablespace datafile
- 2 groups of 8 redo log datafiles
- 8 temporary tablespace datafiles
- 1 tools tablespace datafile
- 1 users tablespace datafile
- 5 undo tablespace datafiles
- 4 rollback segment datafiles (which will be unused for a 9i or post-9i database)

## Configuring the file

Follow these steps to configure the entries in `be_system_devices.sh`.

Step	Action
1	<p>Configure the control file entries.</p> <p>Create a raw device of size 301 MB (consult the partitioning guide).</p> <p>Append the line <code>CONTROL_FILE_X=</code> with the full path of the raw device node, for example:</p> <pre>CONTROL_FILE_1=/dev/rdisk/c1t4d3s0</pre>
2	<p>Configure the system tablespace datafile.</p> <p>Create a raw device of size 451 MB (consult the partitioning guide).</p> <p>Append the line <code>SYSTEM_TABLESPACE_DATAFILE=</code> with the full path of the raw device node, for example:</p> <pre>SYSTEM_TABLESPACE_DATAFILE=/dev/rdisk/c1t4d3s0</pre>
3	<p>Configure the redo logs.</p> <p>Create two raw devices. Either:</p> <ul style="list-style-type: none"> <li>• one each of size 11 MB if you wish to use the test sizing, or</li> <li>• two raw devices, each of size 41 MB (consult the partitioning guide).</li> </ul> <p><b>Note:</b> The redo logs are split into two groups of eight. There eight logs each with a backup. Follow these steps for each redo log.</p> <p>Append the line <code>REDO_LOGX_FILEA=</code> with the full path of the first raw device node, for example:</p> <pre>REDO_LOG1_FILEA=/dev/rdisk/c1t4d3s0</pre> <p>Append the line <code>REDO_LOGX_FILEB=</code> with the full path of the second raw device node, that is:</p> <pre>REDO_LOG1_FILEB=/dev/rdisk/c1t4d3s1</pre>
4	<p>Configure the temporary tablespace datafile entries.</p> <p>Create a raw device of size 102 MB if you wish to use the test sizing, otherwise create a</p>

Step	Action
	raw device of size 2042 MB (consult the partitioning guide). Append the line TEMP_DATAFILEX= with the full path of the raw device node, for example: TEMP_DATAFILE1=/dev/rdisk/c1t4d3s0
5	Configure the tools tablespace datafiles. Create a raw device of size 16 MB (consult the partitioning guide below). Append the line TOOLS_DATAFILE= with the full path of the raw device node, for example: TOOLS_DATAFILE=/dev/rdisk/c1t4d3s0
6	Configuring the users tablespace datafiles. Create a raw device of size 101 MB (consult the partitioning guide). Append the line USERS_DATAFILE= with the full path of the raw device node, for example: USERS_DATAFILE=/dev/rdisk/c1t4d3s0
7	Configure the undo tablespace datafiles. Create a raw device of size 201 MB if you wish to use the test sizing, otherwise create a raw device of size 1991 MB (consult the partitioning guide). <b>Note:</b> If installing on a pre-9i system, these entries should be skipped. Append the line UNDOTBS1_DATAFILE_X= with the full path of the raw device node, for example: UNDOTBS1_DATAFILE_1=/dev/rdisk/c1t4d3s0
8	Configure the rollback segment datafiles. Create a raw device of size 102 MB if you wish to use the test sizing, otherwise create a raw device of size 2042 MB (consult the partitioning guide). <b>Note:</b> If installing on a post-9i system, these entries should be skipped. Append the line RBS_DATAFILEX= with the full path of the raw device node, for example: RBS_DATAFILE1=/dev/rdisk/c1t4d3s0
9	Save and backup the newly populated device file (because it may be removed by the un-installation process later).

## E2BE\_ADMIN Schema Device Configuration

To configure the Voucher and Wallet Server to use Raw Devices as datafiles, once installation is complete edit the following file:

`//IN/service_packages/E2BE/db/install/create/BE/scripts/autogen_be_devices.sql`

The `autogen_be_devices.sql` file contains a number of repeated entries of the form:

```

/*
# Datafiles for tablespace: BE_DATA
*/

/* Datafile 1 partition size should be 10M + 1M */
define DEVICE_BE_DATA1 =
/* Datafile 2 partition size should be 10M + 1M */
define DEVICE_BE_DATA2 =

/*
#####
*/

```

**Note:** The comment for each datafile listed per tablespace, contains a size in mb of the form XM + 1M, for example:

```
/* Datafile 2 partition size should be 10M + 1M */
```

## Configuring the file

Follow these steps to configure the entries in `autogen_be_devices.sql`.

Step	Action
1	Edit the file: <code>!N/service_packages/E2BE/db/install/create/BE/scripts/autogen_be_devices.sql</code>
2	For each individual datafile listed create a raw device of the size specified in the comment (consult the partitioning guide). For the above example create two raw devices, each of 11 mb.
3	For each created datafile append the line of the form <code>DEVICE_BE_DATAX=</code> with the full path of the new device node <b>Example:</b> <code>DEVICE_BE_DATA1=/dev/rdisk/c1t4d3s0</code> <code>DEVICE_BE_DATA2=/dev/rdisk/ct14d3s1</code>
4	Save and backup the newly populated device file (because it may be removed by the un-installation process later)

## Raw Device Setup

Raw devices can be created on Solaris 11 using the `format` command (for additional information, run the command `man format`) as follows:

Step	Action
1	Start the <code>format</code> program by running the command <code>format</code> . <b>Result:</b> You will be presented with a list of disks.
2	Specify a disk to place the new partition. Type the option number of the applicable disk, and press <b>Enter</b> . <b>Result:</b> You will be presented with a list of format options.
3	Define a partition table for the applicable disk. Type <code>partition</code> and press <b>Enter</b> . <b>Result:</b> You will be presented with a list of 8 partitions (labeled 0 – 7), as well as some supporting options.
4	Type <code>print</code> and press <b>Enter</b> to list the current partition table for this disk. <b>Result:</b> Details of each currently defined partition (and those that are not defined) are displayed on the screen.
5	Choose a partition that is not defined already (one that has a size of 0 defined). Type the partition number and press <b>Enter</b> . <b>Result:</b> You will be asked to enter the partition ID tag.
6	Press <b>Enter</b> . <b>Result:</b> You will be asked for the partition permissions option.
7	Type <code>wm</code> and press <b>Enter</b> . <b>Result:</b> You will be asked for the starting cylinder of the partition.
8	If this is not the first partition, choose a cylinder that follows on from the last defined partition. For example: if there is a last partition defined between cylinders 1-1024, choose the cylinder 1025 as the starting cylinder.

Step	Action
9	<p>Each partition will have a corresponding file system node in the directory <code>/dev/rdisk</code>.</p> <p>The device nodes for the new partitions will start with the name of the disk, and end with the number of the partition. For example: if <code>c1t4d3</code> is the disk, and the partition is number 3, then the device file will be <code>/dev/rdsk/c1t4d3s3</code>.</p> <p>The above device file will be a soft link. Please ensure that the linked to file is readable and writable by the Oracle user.</p>

## Checking the Installation

### Introduction

Refer to this checklist to ensure that VWS has installed correctly.

The end of the package installation process specifies a script designed to check the installation just performed. They must be run from the command line.

### Checklist

Follow these steps in this checklist to ensure VWS has been installed on an VWS machine correctly.

Step	Action
1	Log into the VWS machine as root.
2	Check the following directory structure exists with the subdirectory: <code>/IN/service_packages/E2BE</code>
3	Check the directory contains subdirectories and that all are owned by: ebe_oper user (group esg)
4	Log into the system as ebe_oper.
	<b>Note:</b> This step is to check that the ebe_oper user is valid.
5	Type <code>sqlplus /</code> No password is required.
	<b>Note:</b> This step is to check that the ebe_oper user has valid access to the database.
	Ensure that the ORACLE_SID is set.
6	Ensure that VWS and CCS tables have been added to the database.
7	Check the entries of the following file: <code>/etc/inittab</code>
	Inittab Entries Reserved for VWS on VWS:
	a. <code>be_1 bin/beCDRMoverStartup.sh</code> (Runs <code>beCDRMoverStartup</code> , which moves completed EDR files into an output directory for later processing.)
	b. <code>be_2 bin/cmnPushFilesStartup.sh</code> (Runs <code>cmnPushFiles</code> , which moves the EDRs to a configured destination machine (usually the SMS).)

# Glossary of Terms

## AAA

Authentication, Authorization, and Accounting. Specified in Diameter RFC 3588.

## ACS

Advanced Control Services configuration platform.

## ANI

Automatic Number Identification - Term used in the USA by long-distance carriers for CLI.

## API

Application Programming Interface

## ASP

- Application Service Provider, or
- Application Server Process. An IP based instance of an AS. An ASP implements a SCTP connection between 2 platforms.

## BFT

Billing Failure Treatment - the process that is applied if the system has lost all connections to a billing engine. It allows for limited continuation of call processing functions, if configured.

## CC

Country Code. Prefix identifying the country for a numeric international address.

## CCS

- 1) Charging Control Services component.
- 2) Common Channel Signalling. A signalling system used in telephone networks that separates signalling information from user data.

## CDR

Call Data Record

**Note:** The industry standard for CDR is EDR (Event Detail Record).

## CLI

Calling Line Identification - the telephone number of the caller. Also referred to as ANI.

## Connection

Transport level link between two peers, providing for multiple sessions.

## **Convergent**

Also “convergent billing”. Describes the scenario where post-paid and pre-paid calls are handed by the same service platform and the same billing system. Under strict converged billing, post-paid subscribers are essentially treated as “limited credit pre-paid”.

## **CORBA**

Common Object Request Broker Architecture. It is a framework that provides interoperability between objects built in different programming languages, running on different physical machines perhaps on different networks. It specifies an Interface Definition Language, and API that allows client / server interaction with the ORB.

## **CPU**

Central Processing Unit

## **DB**

Database

## **Diameter**

A feature rich AAA protocol. Utilises SCTP and TCP transports.

## **DTMF**

Dual Tone Multi-Frequency - system used by touch tone telephones where one high and one low frequency, or tone, is assigned to each touch tone button on the phone.

## **FOX**

Fast OSA eXtensions. A TCP/IP billing protocol intended for use with external vendors. Based on OSA, it fills in functional gaps missing in OSA, and defines “combined” OSA operations to increase platform throughput. Uses a non-CORBA transport layer in order to provide enhanced fail-over and connection redundancy.

## **GPRS**

General Packet Radio Service - employed to connect mobile cellular users to PDN (Public Data Network- for example the Internet).

## **GSM**

Global System for Mobile communication.

It is a second generation cellular telecommunication system. Unlike first generation systems, GSM is digital and thus introduced greater enhancements such as security, capacity, quality and the ability to support integrated services.

## **HLR**

The Home Location Register is a database within the HPLMN (Home Public Land Mobile Network). It provides routing information for MT calls and SMS. It is also responsible for the maintenance of user subscription information. This is distributed to the relevant VLR, or SGSN (Serving GPRS Support Node) through the attach process and mobility management procedures such as Location Area and Routing Area updates.

## **HPLMN**

Home PLMN

## **HTML**

HyperText Markup Language, a small application of SGML used on the World Wide Web.

It defines a very simple class of report-style documents, with section headings, paragraphs, lists, tables, and illustrations, with a few informational and presentational items, and some hypertext and multimedia.

## **IN**

Intelligent Network

## **IP**

1) Internet Protocol

2) Intelligent Peripheral - This is a node in an Intelligent Network containing a Specialized Resource Function (SRF).

## **IP address**

Internet Protocol Address - network address of a card on a computer.

## **IPC**

Interprocess Communication

## **ISDN**

Integrated Services Digital Network - set of protocols for connecting ISDN stations.

## **MAP**

Mobile Application Part - a protocol which enables real time communication between nodes in a mobile cellular network. A typical usage of the protocol would be for the transfer of location information from the VLR to the HLR.

## **Messaging Manager**

The Messaging Manager service and the Short Message Service components of Oracle Communications Convergent Charging Controller product. Component acronym is MM (formerly MMX).

## **MM**

Messaging Manager. Formerly MMX, see also *XMS* (on page 156) and *Messaging Manager* (on page 153).

## **MSC**

Mobile Switching Centre. Also known as a switch.

## **MSISDN**

Mobile Station ISDN number. Uniquely defines the mobile station as an ISDN terminal. It consists of three parts; the country code (CC), the national destination code (NDC) and the subscriber number (SN).

## **MT**

Mobile Terminated

## **ORB**

Object Request Broker. Within an Object based communication system, an ORB keeps track of the actual addresses of all defined objects and thus is used to route traffic to the correct destination. The CORBA defines the ORB in a series of standards enabling different platforms to share common information.

## **OSA**

Open Service Access provides a standard interface through which developers can design services that may interact with functions within the network.

## **PI**

Provisioning Interface - used for bulk database updates/configuration instead of GUI based configuration.

## **PIN**

Personal Identification Number

## **PLMN**

Public Land Mobile Network

## **SCTP**

Stream Control Transmission Protocol. A transport-layer protocol analogous to the TCP or User Datagram Protocol (UDP). SCTP provides some similar services as TCP (reliable, in-sequence transport of messages with congestion control) but adds high availability.

## **Session**

Diameter exchange relating to a particular user or subscriber access to a provided service (for example, a telephone call).

## **SGML**

Standard Generalized Markup Language. The international standard for defining descriptions of the structure of different types of electronic document.

## **SGSN**

Serving GPRS Support Node

## **SLC**

Service Logic Controller (formerly UAS).

## **SLEE**

Service Logic Execution Environment

## **SMS**

Depending on context, can be:

- Service Management System hardware platform
- Short Message Service
- Service Management System platform
- Convergent Charging Controller Service Management System application

## **SN**

Service Number

## **SRF**

Specialized Resource Function – This is a node on an IN which can connect to both the SSP and the SLC and delivers additional special resources into the call, mostly related to voice data, for example play voice announcements or collect DTMF tones from the user. Can be present on an SSP or an Intelligent Peripheral (IP).

## **SSP**

Service Switching Point

## **System Administrator**

The person(s) responsible for the overall set-up and maintenance of the IN.

## **TCAP**

Transaction Capabilities Application Part – layer in protocol stack, message protocol.

## **TCP**

Transmission Control Protocol. This is a reliable octet streaming protocol used by the majority of applications on the Internet. It provides a connection-oriented, full-duplex, point to point service between hosts.

## **Telco**

Telecommunications Provider. This is the company that provides the telephone service to customers.

## **Telecommunications Provider**

See Telco.

## **URL**

Uniform Resource Locator. A standard way of specifying the location of an object, typically a web page, on the Internet.

## **USSD**

Unstructured Supplementary Service Data - a feature in the GSM MAP protocol that can be used to provide subscriber functions such as Balance Query.

## **VLR**

Visitor Location Register - contains all subscriber data required for call handling and mobility management for mobile subscribers currently located in the area controlled by the VLR.

## **VWS**

Oracle Voucher and Wallet Server (formerly UBE).

## **XML**

eXtensible Markup Language. It is designed to improve the functionality of the Web by providing more flexible and adaptable information identification.

It is called extensible because it is not a fixed format like HTML. XML is a 'metalanguage' — a language for describing other languages—which lets you design your own customized markup languages for limitless different types of documents. XML can do this because it's written in SGML.

## **XMS**

Three letter code used to designate some components and path locations used by the Oracle Communications Convergent Charging Controller *Messaging Manager* (on page 153) service and the Short Message Service. The published code is *MM* (on page 153) (formerly *MMX*).
