ATTACHMENT_NUMBER	The sequential number of the part, starting at number 0 for the first part of the message. Compare with PART_NUMBER, which is the MIME structured number for the part.
CONVERSION_TAG	The conversion tag(s) of the input message (only defined if the message has one or more conversion tags set).
INPUT_CHANNEL	The source channel.
INPUT_ENCODING	The encoding originally present on the body part.
INPUT_FILE	The name of the file containing the original body part. The converter should read this file.
INPUT_HEADERS	The name of the file containing the original headers for the enclosing part. The converter should read this file.
INPUT_DESCRIPTION	The content description of the input message part.

INPUT_DISPOSITION	The content disposition of the input message part.
INPUT_LANGUAGE	The content language of the input message part.
INPUT_TYPE	The content type of the input message part.
INPUT_SUBTYPE	The content subtype of the input message part.
MESSAGE_HEADERS	The name of the file containing the original headers for an enclosing message. The converter should read this file.
OUTPUT_CHANNEL	The destination channel.
OUTPUT_FILE	The name of the file where the converter should store its output. The converter should create and write this file.
OUTPUT_HEADERS	The name of the file where the converter should store MIME headers for an enclosing part. The converter should create and write this file. Note that the file should have a format of header line, header line,..., blank line; be sure to include the final blank line.
OUTPUT_OPTIONS	The name of the file from which the converter should read options (such as status values on UNIX).
PART_NUMBER	The MIME structured number for the part. Compare with ATTACHMENT_NUMBER, which is the sequential number of the part.
PART_SIZE	The size, in bytes, of the part.
content-disposition parameters	
content-type parameters	

Additional environment variables (UNIX or NT) containing Content-type: parameter information or Content-disposition: parameter information can be created as they are needed using the PARAMETER-SYMBOL-n and DPARAMETER-SYMBOL-n facilities, respectively; see Available conversion parameters, grouped by functionality.

Override options for passing information back to the conversion channel shows additional "override" options available (on UNIX) for use by the conversion channel. The converter procedure may use these to pass information back to the conversion channel. To set these options on UNIX, set OVERRIDE-OPTION-FILE=1 in the desired conversion entry and then have the converter procedure set the desired options in the OUTPUT_OPTIONS file.

Table 51.6 Override options for passing information back to the conversion channel

Override option	Description
OUTPUT_TYPE	The content type of the output message part.
OUTPUT_SUBTYPE	The content subtype of the output message part.
OUTPUT_DESCRIPTION	The content description of the output message part.
OUTPUT_DIAGNOSTIC	Text to include in the error text returned to the message sender if a message is forcibly bounced (via PMDF__FORCERETURN) by the conversion channel.
OUTPUT_DISPOSITION	The content disposition of the output message part.
OUTPUT_ENCODING	The content transfer encoding to use on the output message part.
OUTPUT_LANGUAGE	The content language of the output message part.

OUTPUT_MODE	The mode with which the conversion channel should write the output message part, hence the mode with which recipients should read the output message part.
STATUS	The MTA exit status for the converter.

51.1.3.5 Conversion entry mapping table callouts

The value for a conversion parameter may be obtained by calling out to a mapping table. The syntax for calling out to a mapping table is

```
"'mapping-table-name:mapping-input'"
```

For instance, with a mapping table

```
X-ATT-NAMES

   postscript            PS.PS$Y
   wordperfect5.1        WPC.WPC$Y
   msword                DOC.DOC$Y
```

then on UNIX, a conversion entry such as the following results in substituting generic file names in place of specific file names on attachments.

```
out-chan=tcp_local; in-type=application; in-subtype=*;
  in-parameter-name-0=name; in-parameter-value-0=/*/*;
  out-type=application; out-subtype='INPUT-SUBTYPE';
  out-parameter-name-0=name;
  out-parameter-value-0="'X-ATT-NAMES:\\'INPUT_SUBTYPE\\''";
  command="cp $INPUT_FILE $OUTPUT_FILE"
```

51.1.3.6 Conversion script header access

When performing conversions on a message part, the conversion channel has general read access (and modification access limited to specific MIME header lines) to the headers in an enclosing part, an enclosing message/rfc822 part, or to the outermost message headers if there is no enclosing message/rfc822 part. (For more general modifications of message header lines, beyond the attachment labelling modifications available to the conversion channel, see instead the Sieve editheader extension.)

For instance, the IN-A1-TYPE and IN-A1-FORMAT parameters can be used to check the A1-Type: and A1-Format: headers of an enclosing part, and the OUT-A1-TYPE and OUT-A1-FORMAT parameters can be used to set those enclosing headers. Or decisions about interior message part processing can be made based upon the message's outermost headers.

More generally, if an entry is selected that has `ORIGINAL-HEADER-FILE=1`, then the headers of that part are written to the file represented by the `INPUT_HEADERS` symbol. If an entry is selected that has `MESSAGE-HEADER-FILE=1`, then all the original headers of the enclosing message/rfc822 part are written to the file represented by the `MESSAGE_HEADERS` symbol. Or if an entry is selected that has `MESSAGE-HEADER-FILE=2`, then all the original headers of the outermost message are written to the file represented by the `MESSAGE_HEADERS` symbol.

If OVERRIDE-HEADER-FILE=1, then the conversion channel will read and use as the MIME headers on that enclosing part the contents of the file represented by the OUTPUT_HEADERS symbol. Currently, the supported MIME headers that may be set in this fashion include Content-type:, Content-disposition:, Content-transfer-encoding:, Content-mode:, Content-id:, Content-description:, Content-language:, Content-annotation:, and Content-comments:.

51.1.3.7 Conversion script exit statuses

The exit status returned by a conversion script (returned via the STATUS option in the OUTPUT_OPTIONS file on UNIX) can be used to tell the conversion channel to take one of a variety of actions. The conversion status values are defined in the file *SERVERROOT*/include/pmdf_err.h; see that file for the definitive numeric values of the status codes. Available status names, numeric values (as of this writing---but see the pmdf_err.h file for definitive values), and their meaning, are shown in Conversion exit status.

Table 51.7 Conversion exit statuses

Name	Value	Effect
PMDF__FORCERETURN	0x0A9C857A	Force return (bounce) of original message
PMDF__FORCERETURN+1	0x0A9C857B	Force return (bounce) of message, including only a sample (lines_to_return MTA option) of the original message, or a sample (lines_to_return) of whatever contents you specify in OUTPUT_FILE
PMDF__FORCEPOST	0x0A9C8612	Force message to be redirected to the postmaster (instead of going to the original recipient(s))
PMDF__FORCEASIS	0x0A9C8632	Force message to continue on unchanged
PMDF__FORCEDELETE	0x0A9C8662	Force deletion of this part (the currently being processed part) of the message
PMDF__FORCEHOLD	0xA9C86AA	Force message to be sidelined as a .HELD message file
PMDF__FORCEDISCARD	0x0A9C86B3	Force discard of entire message
PMDF__FORCEJETTISON	0x0A9C86E3	Force message to be jettisoned (non-overridable discard)

51.2 Conversion tags

The MTA has a private mechanism of *conversion tags*. Conversion tags may be set and used in a variety of ways and for a variety of purposes; besides the original use for triggering user-specific automatic documention conversion, another common use is for causing or influencing special routing of messages.

Note that conversion tags are stored in a private-to-the-MTA field in the message envelope; they are not visible in received messages. (However, message conversion tags present on messages transitting the MTA will be included in MTA message transaction log entries if the log_conversion_tag MTA option is enabled.)

Conversion tags may be added via channel options, (sourceconversiontag, destinationconversiontag, deliveryflags), via LDAP attributes (ldap_source_conversion_tag, ldap_conversion_tag, ldap_domain_attr_source_conversion_tag, ldap_domain_attr_conversion_tag), via an alias option (alias_conversion_tag) or [CONVERSION_TAG] alias file named parameter, via recipient access mapping tables

or the FROM_ACCESS mapping table, or via the Sieve conversiontag extensions. Conversion tags present on a message may influence certain mapping table operations (CONVERSIONS mapping table, CHARSET-CONVERSION mapping table, MESSAGE-SAVE-COPY mapping table when selected via message_save_copy_flags, as well as various address mapping tables as controlled by the include_conversiontag MTA option), and control matching and hence application of specific conversions entries. Complex effects due to, and manipulations of, conversion tags are also possible via Sieve conversiontag extensions.

51.3 Character set conversion and message reformatting

One very basic mapping table in the MTA is the character set conversion table. The name of this table is CHARSET-CONVERSION. It is used to specify what sorts of channel-to-channel character set conversions and message reformattings should be performed.

On many systems there is no need to do character set conversions or message reformatting and therefore this table is not needed. Situations arise, however, where character conversions must be done. For example, sites with enclaves of local users accustomed to using older charsets such as ISO-2022-JP (for Japanese) or KOI8-R (for Russian) may wish to convert messages outbound to the Internet into the general UTF-8 charset, to increase interoperability with remote Internet correspondents.

51.3.1 CHARSET-CONVERSION mapping table

The CHARSET-CONVERSION mapping table specifies what sorts of channel-to-channel character set conversions and message reformatting should be done. As suggested by the mapping name, character set conversion is its primary purpose.

The CHARSET-CONVERSION mapping can also be used to alter the format of messages. Facilities are provided to convert a number of non-MIME formats into MIME. Changes to MIME encodings and structure are also possible. These options are used when messages are being relayed to systems that only support MIME or some subset of MIME. And finally, conversion from MIME into non-MIME formats is provided in a small number of cases.

As of MS 8.0.2.1, enabling charset conversions also checks for and attempts to mitigate the various so-called MailSploit attacks. More specifically, if charset conversions are enabled for a given destination, the MTA will:

1. Check the content of and remove unnecessary encoded-words during submission. In particular, encoded-words consisting of nothing but an atom or domain will be decoded. Note that this happens only when using SUBMIT, which should always be before DKIM or similar protection mechanisms are applied.

2. Remove control characters other than those needed for MIME-compatible charsets. This includes, but is not limited to NUL, CR and LF.

3. Remove any empty encoded-words that result from (2).

4. Recognize and process encoded-words outside the contexts where they normally appear. (This behavior is appropriate for an MTA seeking to mitigate attacks that may depend on broken clients that recognize encoded-words outside the contexts where they normally occur.)

Note that the removal of NULs and similar CTLs is justified from a standards perspective since RFC 2047 requires that encoded words represent printable material in a MIME text/US-ASCII compatible charset. As such, this material should not be present in standards-compliant encoded-words.

The MTA will probe the `CHARSET-CONVERSION` mapping table in two different ways. The first probe is used to determine whether or not the MTA should reformat (or at least process) the message and if so, what formatting options should be used. (If no reformatting is specified, then the MTA does not bother to check for specific character set conversions.) The input string for this first probe has (by default) the general form:

`IN-CHAN=`*`in-channel`*`;OUT-CHAN=`*`out-channel`*`;CONVERT`

Here `in-channel` is the name of the source channel (where the message comes from) and `out-channel` is the name of the destination channel (where the message is going). New in MS 6.3, setting bit 0 (value 1) of the `include_conversiontag` MTA option will cause this first probe to instead have the form

`IN-CHAN=`*`in-channel`*`;OUT-CHAN=`*`out-channel`*`;TAG=`*`tag-list`*`;CONVERT`

where `tag-list` is a comma-separated list of any conversion tags present on the message.

If the probe matches the pattern (left hand side) of a `CHARSET-CONVERSION` mapping table entry, then the resulting string (right hand side of the mapping entry) should be a comma-separated list of keywords. The following keywords are provided:

Table 51.8 CHARSET-CONVERSION mapping keywords

Keyword	Action
`Always`	Enable conversion
`Appledouble`	Convert other MacMIME formats to Appledouble format
`Applesingle`	Convert other MacMIME formats to Applesingle format
`BASE64`	Switch MIME encodings to BASE64
`Binhex`	Convert other MacMIME formats, or parts including Macintosh type and Mac creator information, to Binhex format
`Block`	Extract just the data fork from MacMIME format parts
`Bottom`	"Flatten" any message/rfc822 body part (forwarded message) into a message content part and a header part
`Delete`	"Flatten" any message/rfc822 body part (forwarded message) into a message content part, deleting the forwarded headers
`Level`	Remove redundant multipart levels from message
`Macbinary`	Convert other MacMIME formats, or parts including Macintosh type and Macintosh creator information, to Macbinary format
`No`	Disable conversion
`Pathworks`	Convert message to Pathworks Mail format
`QUOTED-PRINTABLE`	Switch MIME encodings to QUOTED-PRINTABLE
`Record,Text`	Line wrap text/plain parts at 80 characters

`Record,Text=`*n*	Line wrap text/plain parts at *n* characters
`RFC1154`	Convert message to RFC 1154 format
`Thurman`	Convert some non-standard "attachments" to MIME format
`Top`	"Flatten" any message/rfc822 body part (forwarded message) into a header part and a message content part
`UUENCODE`	Switch MIME encodings to X-UUENCODE
`Yes`	Enable conversion

If a match is found, the MTA will perform any requested message reformatting, discussed further in Message reformatting, and for text parts, also check whether charset conversion is desired, as discussed further in Character set conversion. A `No` is assumed if no match occurs.

If the message has a conversion tag set, note that the "`T`" flag will be set, and this can be tested for (when a match on the pattern, *i.e.*, left hand side, occurred) using a `$:T` test in the template (right hand side) output string. Such tests are more commonly used in the `CONVERSIONS` mapping table, but under less common conditions may potentially be useful here in the `CHARSET-CONVERSION` mapping table.

51.3.1.1 Character set conversion

If the MTA's initial probe of the `CHARSET-CONVERSION` mapping table (to determine whether or not *any* character set conversion or message reformatting need be performed) finds that the message is to be reformatted, it will proceed to check each part of the message. Any text parts are found and their character set parameters are used to generate the second probe. Only when the MTA has checked and found that conversions may be needed does it ever perform the second probe. The input string in this second case looks like this:

`IN-CHAN=`*`in-channel`*`;OUT-CHAN=`*`out-channel`*`;IN-CHARSET=`*`in-char-set`*

The `in-channel` and `out-channel` are the same as before, and the `in-char-set` is the name of the character set associated with the particular part in question. (Note that the `include_conversiontag` MTA option, regardless of setting, has no effect on the form of this second probe of the `CHARSET-CONVERSION` mapping table.) If no match occurs for this second probe, no character set conversion is performed (although message reformatting, *e.g.*, changes to MIME structure, may be performed in accordance with the keyword matched on the first probe). If a match does occur it should typically produce a string of the form:

`OUT-CHARSET=`*`out-char-set`*

Here the `out-char-set` specifies the name of the character set to which the `in-char-set` should be converted. Note that both of these character sets must be defined in the character set definition table, `charsets.txt`, located in the MTA table directory. No conversion will be done if the character sets are not properly defined in this file. This is not usually a problem since this file defines several hundred character sets; most of the character sets in use today are defined in this file. See the description of the `imsimta chbuild` utility for further information on the `charsets.txt` file.

If all the conditions are met, the MTA will proceed to build the character set mapping and do the conversion. The converted message part will be relabelled with the name of the character

set to which it was converted. Encoded-words in message headers (text encoded according to the rules of RFC 2047) will also have the specified charset conversion applied.

In addition, the following other types of output request are supported.

When working on text parts of messages, one may also specify an encoding in which the MTA should output that part:

`OUT-ENCODING=`*`encoding-name`*

Here *`encoding-name`* must be the name of an encoding supported by the MTA, namely one of (as of this writing):

- NONE,
- 8BIT,
- 7BIT,
- ATOB,
- BASE32,
- BASE64,
- BASE85,
- BINARY,
- BINARY-8BIT,
- BINHEX,
- BTOA,
- COMPRESSED-BASE64,
- COMPRESSED-BINARY,
- COMPRESSED-UUCODE,
- COMPRESSED-UUDECODE,
- COMPRESSED-UUENCODE,
- DEFLATE-BASE64,
- DEFLATE-BINARY,
- DEFLATE-UUCODE,
- DEFLATE-UUDECODE,
- DEFLATE-UUENCODE,
- HEXADECIMAL,
- OLD-BASE64,
- PATHWORDS,
- QUOTED-PRINTABLE,
- UUCODE,
- UUDECODE,
- UUENCODE,
- X-ATOB,
- X-BASE32,
- X-BASE85,
- X-BINHEX,
- X-BTOA,
- X-C-DATA,
- X-COMPRESSED-UUCODE,
- X-COMPRESSED-UUDECODE,
- X-COMPRESSED-UUENCODE,
- X-DEFLATE-UUCODE,
- X-DEFLATE-UUDECODE,
- X-DEFLATE-UUENCODE,

- X-HEXADECIMAL,
- X-OLD-BASE64,
- X-PATHWORKS,
- X-UUCODE,
- X-UUDECODE,
- X-UUENCODE.

Both an output charset and an output encoding may be specified, by separating the clauses with a comma.

For encoded-words in message header lines (material encoded using the RFC 2047 encoding rules), the OUT-ENCODING must be one of QUOTED-PRINTABLE, HEXADECIMAL, X-HEXADECIMAL, or BASE64; attempting to set any other output encoding will result in the "unknown" encoding being used.

There are also several additional options that can be applied for conversion of the charset in message headers. Specifying

OUT-CHARSET=*out-charset*,RELABEL-ONLY=1

in the template (right hand side) of a mapping entry means that the MTA will simply use the specified charset name *out-charset* wherever the *in-charset* name had appeared. That is, this is intended to be used in cases where the original charset label was wrong, and it is desired to simply override the original labelling with correct labelling (but no actual charset conversion need be performed).

Specifying

IN-CHARSET=*

in the template (right hand side) of a mapping entry requests that the MTA attempt to sniff the data to attempt to determine what character set was truly used. Currently, the only useful such determination that can be made by the MTA is between US-ASCII, EUC-JP, SHIFT-JIS, and ISO-2022-JP.

Specifying

OUT-LANGUAGE=*lang-tag*

in the template (right hand side) of a mapping entry tells the MTA to set the specified language tag as the value of the Content-language: header line. Specifying

OUT-LANGUAGE=**lang-tag*

tells the MTA to insert the specified language tag with the charset name inside encoded-words on header lines, if no explicit language tag was already present in the encoded-words.

51.3.1.1.1 Converting ISO-2022-JP to UTF-8 and back

Suppose that ISO-2022-JP is used locally, but that a site wishes to convert to UTF-8 for use on the Internet. In particular, suppose at this site the channel used to send to the Internet is tcp_local, tcp_lmtpcs* channels are used to deliver to local users, and local users' submitted messages are submitted via tcp_submit and tcp_auth.

Example of Converting ISO-2022-JP to and from UTF-8

```
CHARSET-CONVERSION

! Entries selecting message traffic eligible for charset conversion
!
  IN-CHAN=tcp_submit;OUT-CHAN=tcp_local;CONVERT    Yes
  IN-CHAN=tcp_auth;OUT-CHAN=tcp_local;CONVERT      Yes
  IN-CHAN=tcp_local;OUT-CHAN=tcp_lmtpcs*;CONVERT   Yes
!
! Disable charset conversion for all other message traffic
!
  IN-CHAN=*;OUT-CHAN=*;CONVERT                     No
!
! Details of which charset to convert to which other charset
!
  IN-CHAN=tcp_submit;OUT-CHAN=tcp_local;IN-CHARSET=ISO-2022-JP   \
                                                   OUT-CHARSET=UTF-8
  IN-CHAN=tcp_auth;OUT-CHAN=tcp_local;IN-CHARSET=ISO-2022-JP     \
                                                   OUT-CHARSET=UTF-8
  IN-CHAN=tcp_local;OUT-CHAN=tcp_lmtpcs*;IN-CHARSET=UTF-8        \
                                                   OUT-CHARSET=ISO-2022-JP
```

51.3.2 Message reformatting

As mentioned in the discussion of the CHARSET-CONVERSION mapping table, that mapping can also be used to effect the conversion of attachments between MIME and several proprietary mail formats.

Examples of some of the other sorts of message reformatting which can be affected with the CHARSET-CONVERSION mapping are described in Non-MIME binary attachment conversion, Relabelling_MIME_header_lines, and MacMIME format conversions.

51.3.2.1 Non-MIME binary attachment conversion

Mail in certain non-standard (non-MIME) formats, *e.g.*, mail in certain proprietary Sun formats or mail from the Microsoft® Mail (MSMAIL) SMTP gateway, is automatically converted into MIME format if CHARSET-CONVERSION is enabled for any of the channels involved in handling the message. If you have a tcp_local channel, then it is normally the incoming channel for messages from a Microsoft Mail SMTP gateway, and the following will enable the conversion of messages delivered to your local users:

```
CHARSET-CONVERSION

  IN-CHAN=tcp_local;OUT-CHAN=ims-ms;CONVERT          Yes
  IN-CHAN=tcp_local;OUT-CHAN=tcp_lmtpcs*;CONVERT     Yes
```

You may also wish to add entries for channels to other local mail systems. For instance, an entry for the tcp_intranet channel:

```
CHARSET-CONVERSION

  IN-CHAN=tcp_local;OUT-CHAN=ims-ms;CONVERT          Yes
```

```
IN-CHAN=tcp_local;OUT-CHAN=tcp_lmtpcs*;CONVERT    Yes
IN-CHAN=tcp_local;OUT-CHAN=tcp_intranet;CONVERT   Yes
```

Alternatively, to cover every channel you can simply specify `OUT-CHAN=*`. However, this may bring about an increase in message processing overhead as all messages coming in the `tcp_local` channel will now be scrutinized instead of just those bound to specific channels. (More importantly, such undiscriminated conversions may place your system in the dubious and frowned upon position of converting messages --- not necessarily your own site's --- which are merely passing through your system, a situation in which you should merely be acting as a transport and not necessarily altering anything beyond the message envelope and related transport information.)

To convert MIME into the format Microsoft Mail SMTP gateway understands, use a separate channel in your MTA configuration for the Microsoft Mail SMTP gateway, *e.g.*, `tcp_msmail`, and use the following `CHARSET-CONVERSION` mapping table entry:

```
CHARSET-CONVERSION

  IN-CHAN=*;OUT-CHAN=tcp_msmail;CONVERT        RFC1154
```

51.3.2.2 MacMIME format conversions

Macintosh files have two parts, a resource fork which contains Macintosh specific information, and a data fork which contains data usable on other platforms. This introduces an additional complexity when transporting Macintosh files, as there are four different formats in common use for transporting the Macintosh file parts. (See RFC 1740 (MacMIME) and RFC 1741 (Binhex).) Three of the formats, Applesingle, Binhex, and Macbinary, consist of the Macintosh resource fork and Macintosh data fork encoded together in one piece. The fourth format, Appledouble, is a multipart format with the resource fork and data fork in separate parts. Appledouble is hence the format most likely to be useful on non-Macintosh platforms, as in this case the resource fork part may be ignored and the data fork part is available for use by non-Macintosh applications. But the other formats may be useful when sending specifically to Macintoshes.

The MTA can convert between these various Macintosh formats. The `CHARSET-CONVERSION` keywords `Appledouble`, `Applesingle`, `Binhex`, or `Macbinary` tell the MTA to convert other MacMIME structured parts to a MIME structure of `multipart/appledouble`, `application/applefile`, `application/mac-binhex40`, or `application/macbinary`, respectively. Further the `Binhex` or `Macbinary` keywords also request conversion to the specified format of non-MacMIME format parts that do nevertheless contain X-MAC-TYPE and X-MAC-CREATOR parameters on the MIME Content-type: header line. The `CHARSET-CONVERSION` keyword `Block` tells the MTA to extract just the data fork from MacMIME format parts, discarding the resource fork; (since this loses information, use of `Appledouble` instead is generally preferable).

For instance, the following `CHARSET-CONVERSION` table would tell the MTA to convert to Appledouble format when delivering to the Message Store via either an `ims-ms` channel or a `tcp_lmtpcs*` channel:

```
CHARSET-CONVERSION

  IN-CHAN=*;OUT-CHAN=ims-ms;CONVERT          Appledouble
```

```
  IN-CHAN=*;OUT-CHAN=tcp_lmtpcs*;CONVERT   Appledouble
```

The conversion to Appledouble format would only be applied to parts already in one of the MacMIME formats.

When doing conversion to Appledouble or Block format, the MAC-TO-MIME-CONTENT-TYPES mapping table may be used to indicate what specific MIME label to put on the data fork of the Appledouble part, or the Block part, depending on what the Macintosh creator and Macintosh type information in the original Macintosh file were.

51.3.2.2.1 MAC-TO-MIME-CONTENT-TYPES mapping table

When doing conversion to Appledouble or Block format, the MAC-TO-MIME-CONTENT-TYPES mapping table may be used to indicate what specific MIME label to put on the data fork of the Appledouble part, or the Block part, respectively, depending on what the Macintosh creator and Macintosh type information in the original Macintosh file were. Probes for this table have the form

format|*type*|*creator*|*filename*

where format is one of SINGLE, BINHEX or MACBINARY, where type and creator are the Macintosh type and Macintosh creator information in hex, respectively, and where filename is the file name. For instance, to convert to Appledouble when sending to the ims-ms channel and when doing so to use specific MIME labels for any MS Word or PostScript documents converted from MACBINARY or BINHEX parts, appropriate tables might be:

```
CHARSET-CONVERSION

  IN-CHAN=*;OUT-CHAN=ims-ms;CONVERT     Appledouble

MAC-TO-MIME-CONTENT-TYPES

! PostScript
   MACBINARY|45505346|76677264|*     APPLICATION/POSTSCRIPT$Y
   BINHEX|45505346|76677264|*        APPLICATION/POSTSCRIPT$Y
! Microsoft Word
   MACBINARY|5744424E|4D535744|*     APPLICATION/MSWORD$Y
   BINHEX|5744424E|4D535744|*        APPLICATION/MSWORD$Y
```

Note that the template (right hand side) of the mapping entry must have the $Y flag set in order for the specified labelling to be performed.

Sample entries for additional types of attachments may be found listed in Sample MacMIME entries.

If you wish to convert non-MacMIME format parts to Binhex or Macbinary format, such parts need to have X-MAC-TYPE and X-MAC-CREATOR MIME Content-type: parameter values provided. Note that MIME relabelling can be used to force such parameters onto parts that would not otherwise have them; see Relabelling MIME header lines for a discussion of MIME relabelling.

51.3.2.2.1.1 Sample MacMIME entries

A sample MAC-TO-MIME-CONTENT-TYPES mapping table is shown.

```
MAC-TO-MIME-CONTENT-TYPES

!
! format|type|creator|filename          type/subtype
!
! Sun Sound
   MACBINARY|554c4157|5343504c|*        AUDIO/BASIC$Y
   BINHEX|554c4157|5343504c|*           AUDIO/BASIC$Y
! Untyped Binary Data, Output File (.out file)
   MACBINARY|42494e41|68446d70|*        APPLICATION/OCTET-STREAM$Y
   BINHEX|42494e41|68446d70|*           APPLICATION/OCTET-STREAM$Y
! Computer Graphics Meta
   MACBINARY|43474d6d|474b4f4e|*        IMAGE/CGM$Y
   BINHEX|43474d6d|474b4f4e|*           IMAGE/CGM$Y
! Microsoft Word Document, Mac Microsoft Word Document
   MACBINARY|5744424e|4d535744|*        APPLICATION/MSWORD$Y
   BINHEX|5744424e|4d535744|*           APPLICATION/MSWORD$Y

51.3.3 Relabelling MIME header lines

Some user agents or gateways may emit messages with MIME header lines which are less informative than they might be, but which nevertheless contain enough information to construct more precise MIME header lines. Although the best solution is to properly configure such user agents or gateways, if they are not under your control, you can instead ask the MTA to try to reconstruct more useful MIME header lines.

If the first probe of the `CHARSET-CONVERSION` mapping table yields a "Yes" or "Always" keyword, then the MTA will check for the existence of any conversions entries. (In Unified Configuration, the MTA checks for the existence of any `conversions` entries; in legacy configuration, the MTA checks for the existence of a conversions file, `IMTA_TABLE:conversions`.) If any conversions entries exist, then the MTA will look for an

entry with RELABEL=1 and if it finds such an entry, the MTA will then perform any MIME relabellings specified in the entry. (See Conversion control for additional details on conversions entries.)

New in 7.0.5, in addition to MIME relabellings, RELABEL=1 can also perform encoding changes (OUT-ENCODING clauses will be applied); formerly, OUT-ENCODING had no effect in RELABEL=1 entries.

For instance, the combination of a `CHARSET-CONVERSION` mapping table of:

```
msconfig> show mapping:CHARSET-CONVERSION
role.mapping:CHARSET-CONVERSION.rule = IN-CHAN=tcp_*;OUT-CHAN=ims-ms;CONVERT Yes
```

and conversions entries (use `msconfig`'s `edit conversions` command to create such entries from within `msconfig`) of:

```
out-chan=ims-ms; in-type=application; in-subtype=octet-stream;
 in-parameter-name-0=name; in-parameter-value-0=*.ps;
 out-type=application; out-subtype=postscript;
 parameter-copy-0=*; relabel=1

out-chan=ims-ms; in-type=application; in-subtype=octet-stream;
 in-disposition=attachment;
 in-dparameter-name-0=filename; in-dparameter-value-0=*.ps;
 out-type=application; out-subtype=postscript;
 out-disposition=attachment; dparameter-copy-0=*; relabel=1

out-chan=ims-ms; in-type=application; in-subtype=octet-stream;
 in-parameter-name-0=name; in-parameter-value-0=*.msw;
 out-type=application; out-subtype=msword;
 parameter-copy-0=*; relabel=1

out-chan=ims-ms; in-type=application; in-subtype=octet-stream;
 in-disposition=attachment;
 in-dparameter-name-0=filename; in-dparameter-value-0=*.msw;
 out-type=application; out-subtype=msword;
 out-disposition=attachment; dparameter-copy-0=*; relabel=1
```

will result in messages that arrive on a `tcp_*` channel and are routed to the `ims-ms` channel, and that arrive originally with MIME labelling of application/octet-stream but have a filename parameter with the extension `(ps)` or `(msw)`, being relabelled as application/postscript or application/msword, respectively. (Note that this more precise labelling is what the original user agent or gateway should have performed itself.)

51.3.4 Service conversions

The MTA's conversion service facility may be used to process, with site-supplied procedures, message content so as to produce a new form of the message. Unlike either the sorts of `CHARSET-CONVERSION` operations discussed elsewhere or the `conversion` channel, which operate on the content of individual MIME message parts, conversion services operate on

entire MIME entities (MIME headers plus content). (But note that service conversions do not give access to the outermost, non-MIME header lines.) Also, unlike other CHARSET-CONVERSION operations or conversion channel operations, conversion services are expected to do their own MIME disassembly, decoding, re-encoding, and reassembly.

Service conversions may be triggered using the serviceconversion channel option. But more typically, like other CHARSET-CONVERSION operations, conversion services are enabled through the CHARSET-CONVERSION mapping table. If the first probe of the CHARSET-CONVERSION mapping table yields a "Yes" or "Always" keyword, then the MTA will check for the presence of conversions options (in Unified Configuration) or the MTA conversions file (in legacy configuration).[6] If a conversions file exists, then the MTA will look in it for an entry specifying a SERVICE-COMMAND or SERVICE-CALL, and if it finds such an entry, execute it. The conversions file entries should have the form

```
in-chan=channel-pattern;
  in-type=type-pattern; in-subtype=subtype-pattern;
  service-command=command
```

or

```
in-chan=channel-pattern;
  in-type=type-pattern; in-subtype=subtype-pattern;
  service-call=image|routine|argument
```

Of key interest is (in service-command entries) the command string. This is the command which should be executed to perform a service conversion (*e.g.,* invoke a document converter). The command must process an input file containing the message text to be serviced and produce as output a file containing the new message text. The command must exit with a 0 if successful and a non-zero value otherwise.

For instance, the combination of a CHARSET-CONVERSION table such as

```
CHARSET-CONVERSION

  IN-CHAN=bsout_*;OUT-CHAN=*;CONVERT     Yes
```

and a conversions file entry of

```
in-chan=bsout_*; in-type=*; in-subtype=*;
  service-command="/pmdf/bin/compress.sh compress $INPUT_FILE $OUTPUT_FILE"
```

will result in all messages coming from a BSOUT channel being compressed.

Environment variables (UNIX) are used to pass the names of the input and output files as well as the name of a file containing some message envelope information. The names of these environment variables are:

Table 51.9 Conversion command callout environment variables on UNIX systems

Variable	Usage
INPUT_FILE	Name of the input file to process
OUTPUT_FILE	Name of the output file to produce
INFO_FILE	Name of the file containing envelope recipient addresses

The INFO_FILE in particular contains the envelope From address, the list of the message's envelope recipient addresses, and (as of Chipotle) if present in the original message envelope the authenticated sender; this information is recorded in the form of pseudo-header lines, *e.g.*,

```
X-Author-info: authenticated-sender
X-Envelope-from: envelope-from
X-Envelope-to: recipient-list
```

The values of these three environment variables, INPUT_FILE, OUTPUT_FILE, and INFO_FILE, may be substituted into the command line by using standard command line substitution: *i.e.*, preceding the variable's name with a dollar character on UNIX. For example, when INPUT_FILE and OUTPUT_FILE have the values `a.in` and `a.out`, then the following entry on UNIX

```
in-chan=bsout_*; in-type=*; in-subtype=*;
  service-command="/pmdf/bin/convert.sh $INPUT_FILE $OUTPUT_FILE"
```

executes the command

```
/pmdf/bin/convert.sh a.in a.out
```

Note: Prior to Messaging Server 7.0, the conversions file was located via the IMTA_CONVERSION_FILE MTA Tailor file option, so usually `IMTA_TABLE:conversions`. As of Messaging Server 7.0, the conversions file is located at `config-root/conversions`.

51.4 Interactions between conversions and character set conversions

Character set conversions come into play at two points during message enqueue processing: during header processing, and during message body processing. (By header processing here we mean any actual conversions of the character set in the message header, *e.g.*, character set translation of personal names in addresses, not the MIME relabelling or other sorts of header line transformations that can also be configured via a `CHARSET-CONVERSION` mapping table.)

After the message header processing character set conversion check and before any message body character set conversion check, the MTA consults the `CONVERSIONS` mapping table (if present). If a message is to be routed to the conversion channel due to a match in the `CONVERSIONS` mapping table, then normally character set conversion for the message

body during this enqueue is disabled; it is expected instead that any relevant character set conversion of the message body will be incorporated into the conversion channel's conversion script processing of the message body parts. (The `imsimta test -translation` utility may come in useful in conversion scripts for such purposes.) Alternatively, new in MS 6.3, the "`Preprocess`" keyword may be used in channel routing entries in the `CONVERSIONS` mapping table to specify that character set conversion of the message body (including `RELABEL` operations) should be performed during the enqueue to the conversion channel (or alternate conversion channel) rather than being disabled as normal at that stage. Or yet another alternative: character set conversion of the message body for messages coming *from* the conversion channel may be configured, to convert the character set in the message body *after* the conversion channel has performed its operations; for such configuration, note that the `CHARSET-CONVERSION` probe will not normally show the conversion channel as the source channel, but rather show the "original" source channel as the source channel.

Chapter 52 MTA options

A subset of the overall Messaging Server configuration options are the MTA options.

The `mta.enable` option enables startup of the MTA upon `start-msg` startup.

The MTA uses options to provide a means of overriding the default values of various parameters that apply to the MTA as a whole. Various MTA channels also have their own channel-level options. The general MTA options have the same format as MTA channel options but are otherwise distinct --- they apply to the MTA as a whole rather than being restricted in application to any specific channel.

In older versions of the MTA, such options were stored in the so-called *MTA option file*, normally named `option.dat`. So the MTA options are also sometimes referred to as "`option.dat` options".

A variety of configuration options are controlled by MTA options. In particular, some MTA options establish sizes of the various internal, in-memory tables into which the remainder of the configuration --- the channel definitions, mapping tables, conversion entries, *etc*. --- are read.

Additional discussions of MTA options include:

- Legacy configuration MTA option file
- Getting option changes to take effect on the MTA
- Option value syntax in legacy configuration
- MTA options, listed alphabetically
- MTA options, listed by functional group

See also the `umask` Message Store option, which affects more than only Message Store files.

In contrast to MTA options, which typically modify fundamental aspects of overall MTA operation, another important category of option modifying MTA operation more specificially at the channel level is that of channel options. Note that MTA options and channel options are *mostly* distinct, as they mostly modify qualitatively different aspects of operation; however, there are some cases where an MTA option establishes a general default for all channels, which a channel option may then override on a per-channel basis.

52.1 MTA option naming in Unified Configuration

In the Unified Configuration, MTA configuration including MTA options (meaning here MTA-as-a-whole options, as opposed to channel-specific options) are set in the `config.xml` Messaging Server unified configuration file where they are XML elements. However, under normal circumstances, the Messaging Server unified configuration file `config.xml` is not--- indeed should not be--- inspected or editted manually by the MTA administrator. Instead, normally the MTA's `msconfig` utility is used to examine the MTA configuration and make configuration changes.

The `msconfig` utility presents a command line interface for viewing and editting MTA settings corresponding to the underlying XML constructs from `config.xml`; it is the

recommended interface for examining the MTA configuration and making MTA configuration changes. The `msconfig` utility represents MTA options in the general form:

instance-or-role`.mta.`*option-name*

That is, in the `msconfig` representation, MTA options are either of the form:

`instance.mta.`*option-name*

or

`role.mta.`*option-name*

However, the `instance.` and `role.` prefixes are *usually* omitted, since the `msconfig` utility is typically used in modes in which the appropriate instance or role is determined automatically by the utility, with the instance or role scope then set appropriately automatically by the utility. That is, usual usage in `msconfig` is to refer simply to:

`mta.`*option-name*

Furthermore the `mta.` prefix is often unnecessary. If the MTA option name is unambiguous (does not collide with any option name for any other component of Messaging Server), then the MTA scope (`mta.` prefix) will also be automatically supplied by the `msconfig` utility, so that often simply referring to:

option-name

will suffice. However, especially in any scripting that may be reused later, it may be best to include the `mta.` prefix to avoid the potential for future option additions to result in a name ambiguity.

Thus in typical use, MTA options (under the appropriate instance or role) would typically be shown, set, or unset using the `msconfig` commands, respectively,

```
msconfig> show mta.option-name
msconfig> set mta.option-name
msconfig> unset mta.option-name
```

The `msconfig` utility will translate between this simple `mta.option-name` representation and the (more complex form of the) underlying XML elements stored in `config.xml`.

See the `msconfig` utility for more details.

52.2 Legacy configuration MTA option file

The MTA legacy configuration option file is the file `CONFIGROOT/option.dat`.

Each time an MTA program begins running in legacy configuration mode, the MTA option file is read and loaded into memory. This overhead may be avoided by compiling your MTA configuration, in which case the contents of the option file will be incorporated into the compiled configuration. The disadvantage to this, however, is that it means that the

configuration must be recompiled and reinstalled whenever a change is made to the option file. See Compiling the MTA configuration for details on compiling your configuration.

The MTA option file is line-oriented, where each line contains the setting for one option. An option setting has the form:

option=value

where note **white space is significant**, and white space should *not* be present before the equal sign. (Indeed, for string values, even **trailing white space** is significant and -- normally -- preserved as it is meaningful and desired for some options, though as of Messaging Server 7.0, the MTA will attempt some "clean up" of certain option values, such as those for setting file names, and such "clean up" can potentially include removal of extraneous tailing spaces from the option value setting.)

value may be either a string, an integer, a floating point value, or a comma-separated list of one such type of value, depending on the option's requirements. For further details on value syntax, see Option value syntax in legacy configuration.

Long lines may be continued by ending them with a backslash, \.

Comments are allowed. Any line that begins in column one with an exclamation point, semicolon, or shart character, "!", ";", or "#", is considered to be a comment and is ignored (even if the preceding line ended with a backslash, which would normally mean that the line was a continuation). For the MTA option file, the interpretation of the characters "!", ";", and "#" as indicating a comment line is hard-coded; in particular, it is not affected by any setting of the `comment_chars` MTA option (though that option does affect the interpretation of *other* MTA configuration files, including other "option files").

Whereas white space on an option setting line is significant, note that blank lines are permitted and ignored in any option file.

Note: This same format is used for various additional MTA "option files", in addition to "the" MTA option file. That is, *some* spam/virus filter package option files, and in legacy configuration the Dispatcher option file, Job Controller option file, channel option files, *etc.*, all use this same sort of format.

52.2.1 Option value syntax in legacy configuration

Option values are typically one of string, integer, or (less commonly) floating point, or in some cases comma-separated lists of one of the above types of values, or in other cases space-separated lists of one of the above types of values. Furthermore, some option values are further constrained, as for instance an integer in a particular range, or a string that corresponds to an LDAP attribute name or to a channel name; and some option values have additional semantics as for instance a bit-encoded integer, or a boolean integer. The type of value valid for an option depends upon the option's requirements; the exact type required will be described for each option. The discussion below will touch on general syntax issues.

The length of the string specifying the option value (the length of the material to the right of the equal sign) is limited to 1024 characters; (prior to MS 6.2p8/6.3, the limit had been 256 characters). For options where the value involves substitution expansions (such as URL values using URL substitution sequences), the limit *after* such expansion is (and has been) 1024 characters.

If an option accepts an integer value, a base may be specified using notation of the form `b%v`, where `b` is the base expressed in base 10 and `v` is the actual value expressed in base `b`.

Bit-encoded integer values are used for a number of options. A bit-encoded integer value may be written as any integer would be; however, it has additional semantics. In a bit-encoded integer value, each bit of the integer controls a different feature; thus a bit-encoded integer value expresses a whole set of enable/disable choices. The least significant bit is conventionally referred to a "bit 0". The integer value of each set bit is then two raised to the bit position power; for instance, setting bit 0 means adding 1 to the value, setting bit 1 means adding 2 to the value, setting bit 2 means adding 4 to the value, *etc*.

Boolean values may be specified either as a number, 0 (false) or 1 (true), or as a string "false" or "true".

Floating point values may be written either in usual decimal notation, for instance, 3.1416, or may be written using the common scientific exponential notation, for instance, 1.045E2 meaning 104.5. The exponent indicator may be any of the characters E, e, F, or f.

For string values, note that spaces are significant in values, **including trailing spaces**, as for certain options values with trailing spaces are meaningful. (However, as of Messaging Server 7.0, the MTA will attempt some "clean up" of certain option values, such as those for setting file names, or for reading options from the Dispatcher or Job Controller configuration files -- where such "clean up" can potentially include removal of extraneous trailing spaces from the option value setting.)

52.3 Getting option changes to take effect on the MTA

Options, both MTA options and channel options, are part of the core MTA configuration. When an MTA process starts up, one of its first tasks is to get initialized with a complete view of the current "live" core MTA configuration. When a compiled configuration is in use (exists), then the current "live" core MTA configuration is the most recently compiled version of the MTA configuration; any options with values updated subsequent to the most recent compilation are not "live" (will not have an effect). When a compiled configuration is not in use, then any changes to option values are immediately "live" (though this does not mean that they will take immediate effect; see below).

Now since many MTA processes are long-running, and since they normally initialize with the MTA configuration information upon first starting up, even "live" configuration changes are not seen immediately by already running MTA processes. To update already running MTA processes with new configuration information, the `reload` utility (or one of the utilities that subsumes it) must be used. Note that since most MTA processes do automatically "cycle" --- that is, time out and expire to be replaced with new processes --- changes to the "live" configuration generally will get seen eventually, if not immediately, even if the `reload` utility is not used. (In particular, MTA server processes, such as SMTP server processes, and channel delivery job processes, do expire and get replaced regularly, if not immediately; such channel processes are usually the processes that need to "see" changes to configuration options. However, the two main control processes for the MTA, namely the Dispatcher and Job Controller, run indefinitely and do not automatically expire, so for option changes affecting them, waiting will not suffice and a `reload` will be required.)

So in particular, when a compiled configuration is being used, then options are part of the compiled configuration. And in order to get changes to options to take effect, you must: (1) re-compile the configuration (using the `cnbuild` utility or a utility that subsumes it), and furthermore for already running, long-running processes you must also (2) reload the configuration (using the `reload` utility or a utility that subsumes it).

52.4 MTA options listed alphabetically

Table of MTA options, listed alphabetically, shown below, lists the available options in alphabetic order. A brief description of each option is included, though more details can be found in the discussions of the individual options. See also MTA options, listed by functionality, which lists the options grouped together by function, and which furthermore includes links to subsections with general information about the groups of options.

Table 52.1 MTA options, listed alphabetically

Option	Usage
`access_auth`	(New in 8.0) Control whether `FROM_ACCESS` mapping table probes include the SMTP MAIL FROM AUTH parameter's value and/or the canonical username produced by authentication
`access_counts`	Control whether recipient access mapping table probes include a recipient count field
`access_errors`	Control the information issued in certain error messages
`access_orcpt`	Control whether recipient access mapping table probes include an ORCPT field
`alias_case`	Control the case sensitivity of aliases; support for this option is RESTRICTED: set it only if instructed to do so by Oracle engineering
`alias_domains`	Control the format of alias file (and hence Unified Configuration alias options) and alias database lookups
`alias_entry_cache_negative`	Whether to cache negative results (*i.e.*, failures) of alias lookups (`alias_urlN` lookups)
`alias_entry_cache_size`	Number of alias lookup (`alias_urlN`) results to keep cached
`alias_entry_cache_timeout`	How long to cache alias lookup (`alias_urlN`) results
`alias_magic`	Control the order in which alias lookups are performed; support for this option is RESTRICTED
`alias_url0`	URL for doing alias lookups
`alias_url1`	URL for doing alias lookups
`alias_url2`	URL for doing alias lookups
`alias_url3`	URL for doing alias lookups
`alias_hash_size`	Set the number of aliases allowed in the alias file
`alias_member_size`	Set the number of alias expansions allowed: in the alias file (legacy configuration), or via alias option (Unified Configuration)
`aliasdetourhost_null_optin`	(New in MS 6.2p4) Specify a value for the attribute named by the `ldap_detourhost_optin` MTA option (and new in MS 7.0.5,

	also the attribute named by the ldap_domain_attr_detourhostoptin) that means that the attribute should be ignored; the purpose is to allow a way of "turning off" message detouring (where the detouring is typically for purposes of spam/virus filtering) for sites and users whose provisioning facilities find it easier to set an attribute value rather than to remove an attribute entirely
allow_unquoted_addrs_violate_rfc2798	Look up addresses in LDAP with quotes stripped from the local part
alternate_recipient	(New in MS 8.0.1) Specify the comment string used to add an alternate recipient for an address.
alternate_recipient_mode	(New in MS 8.0.1) Control handling of multiple alternate recipients.
ap_debug	Internal MTA debugging option: enable debugging of low level address parsing; support for this option is RESTRICTED
autoreply_timeout_default	Specify a default duration between successive vacation responses to the same sender
averages_cache_size	(New in MS 6.2) Size of the cache of load average values
averages_cache_timeout	(New in MS 6.2) Timeout for the cache of load average values
block_limit	Limit the size of messages allowed through the MTA
block_size	Set the size of MTA "blocks"
blocked_mail_from_ips	Specify IP address literals whose A records should be ignored for purposes of the lookups done due to the mailfromdnsverify channel keyword (new in 6.1-0.01 release)
bounce_block_limit	Limit the amount of original message content included in bounce messages
brightmail_*	Synonyms for the corresponding spamfilter_* options; see the spamfilter_* options for definitions
buffer_size	Set the buffer size used when writing message files; default is 8192
cache_debug	Output direct LDAP lookup caching statistics
cache_magic	OBSOLETE: Control the sorting (for processing purposes) of old message files
channel_table_size	Set the number of channels allowed in the MTA configuration
circuitcheck_completed_bins	Specify the bins for the message circuit check message counters

circuitcheck_paths_size	Number of circuit check paths (entries) to allow in the circuit check configuration file
comment_chars	Set the "comment" character(s) in MTA configuration files
content_return_block_limit	Force NOTARY non-return of content flag for messages over the specified size
conversion_size	Set the number of entries allowed in the conversion file (legacy configuration) or conversions MTA option (Unified Configuration)
conversions	(Unified Configuration only) Conversion entries; replaces legacy configuration conversions file
defer_group_processing	Set a default for whether direct LDAP group (list) expansion is deferred to the reprocess channel
delimiter_char	(New in 7.0) RESTRICTED. Specify the delimiter character (normally the vertical bar character)
delivery_options	Specify interpretation of mailDeliveryOption values
dequeue_debug	Enable debugging of message dequeue operations
dequeue_map	RESTRICTED. Map files into memory when dequeuing
describe_cache_limit	Control size of message part description cache for message body processing purposes
digest_on	Specify the comment string that enables mailing list digests (in preference to regular mailing list postings); usage is **RESTRICTED**
dirsync_hack	In dirsync mode, enable "hack" of falling back to trying to do an LDAP lookup and adding the LDAP result to the alias database; usage is **DELETED**
domain_failure	Rewrite template to apply when an LDAP lookup encounters an LDAP error
domain_hash_size	Set the number of rewrite rules allowed
domain_match_cache_size	Number of domain lookup ($V rewrite template) results to keep cached
domain_match_cache_timeout	How long to cache domain lookup ($V rewrite template) results
domain_match_url	URL for an extra, special lookup for domains, *e.g.*, URL for looking up vanity domains
domain_uplevel	Control whether to search "upwards" in the DC tree for domain names, and whether to use a "canonical" domain name when searching for user entries
duplicate_tracking_url	(New in 8.0) Template for location of per-user duplicate message tracking files
enable	Enable operation of the MTA

enable_sieve_regex	Control whether Sieve filters may use the regex extension (the :regex match-type)
error_text_*	Specify alternate error text for any of various error conditions; see Table of error text options
expandable_default	Set the default for mailing lists to [NONEXPANDABLE], *i.e.*, disable use of SMTP EXPN
exproute_forward	Control whether the exproute channel option affects forward pointing headers
file_member_size	Maximum number of configuration files used by the MTA
filter_cache_size	New in 6.2. Specify the size of the per-process cache of tokenized Sieve filters
filter_cache_timeout	New in 6.2. Specify the retention time for entries in the per-process cache of tokenized Sieve filters
filter_debug	New in 6.2. Control whether detailed (stack state) debugging of Sieve evaluation is output.
filter_discard	Control whether messages discarded by a Sieve filter are immediately deleted, or instead routed to the filter_discard channel for delayed deletion
filter_jettison	New in 6.1-0.01. Control whether messages jettisoned by a Sieve filter are immediately deleted, or instead routed to the filter_discard channel for delayed deletion
forward_data_size	Hash size for the forward (database) text file
fruits_size	Number of fruits allowed in the fruit validation table
fsync	Do an fsync upon file close
general_case	Controls the case sensitivity of general database lookups
general_data_size	Hash size for the general (database) text file
group_dn_template	Template used when looking up a uniqueMember of a group
header_limit	Sets a maximum size for the primary (outermost) message header
held_sndopr	Send operator or syslog messages when messages are HELD
history_to_return	Control the amount of delivery attempt history included in bounced messages
host_hash_size	Set the number of channel host names
id_domain	Set the domain name used in constructing message IDs
idn_config_file	(New in 8.0.1) Specify the location of optional IDNKIT configuration file

improute_forward	Control the effect of the improute channel option on forward pointing headers
include_connectioninfo	New in 6.2. Include transport and application connection information in mapping table probes
include_conversiontag	New in MS 6.3. Include the conversion tag value(s) in mapping table probes
ldap_*	Specify an alternate attribute name for any of various per-user attributes; see Direct LDAP attribute name MTA options
ldap_attr_domain1_schema2	Specify an alternate attribute name for the attribute used to store the "primary" domain in Schema 2
ldap_attr_domain2_schema2	Specify an alternate attribute name for the attribute used to store the "secondary" domain in Schema 2
ldap_attr_domain_search_filter	Attribute in the configuration template area, (see the ldap_global_config_templates MTA option) that is used to store the domain search filter template
ldap_attr_name_hash_size	Internal hash size for the list of LDAP attributes relevant to the MTA
ldap_default_attr	For LDAP URLs that are supposed to return a single result, specify a single attribute to request if no attribute was specified in the original LDAP query string
ldap_default_domain	The default domain name; overrides the service.defaultdomain configutil parameter (legacy configuration) or defaultdomain base option (Unified Configuration)
ldap_domain_attr_*	Specify an alternate attribute name for any of various per-domain attributes; see Direct LDAP attribute name MTA options
ldap_domain_filter_schema1	When schema 1 is in use, specify the filter used to find domains in the DIT
ldap_domain_filter_schema2	When schema 2 is in use, specify the filter used to find domains in the DIT
ldap_domain_known_attributes	Control whether the MTA fetches all domain attributes *vs*. fetches only "known" domain attributes
ldap_domain_root	The base DN for the domain portion of the DIT; overrides the service.dcroot configutil parameter (legacy configuration) or dcroot base option (Unified Configuration)
ldap_domain_timeout	New in 6.1-0.01. Specify the retention time for entries in the domain map cache
ldap_global_config_templates	Schema 2 support: specify the DN where global configuration templates can be found
ldap_group_object_classes	The object classes required for a group

ldap_host	Host to which to connect for LDAP queries; overrides the local.ugldaphost configutil parameter (legacy configuration) or ugldaphost base option (Unified Configuration)
ldap_host_alias_list	Local host aliases; overrides (for MTA purposes) the local.imta.hostnamealiases configutil parameter (legacy configuration) or ldap_host_alias_list base option (Unified Configuration)
ldap_local_host	The local host name (official host name for the "l" channel); overrides (for MTA purposes) the local.hostname configutil parameter (legacy configuration) or hostname base option (Unified Configuration)
ldap_mail_aliases	The attributes in which aliases are stored; overrides the local.imta.mailaliases configutil parameter
ldap_mail_reverses	The attributes used for the filter generated by the $Q LDAP substitution sequence; normally used during reverse_url lookups, hence normally the attributes compared against an address to be "reversed"
ldap_max_connections	The maximum number of simultaneous LDAP connections to allow
ldap_object_class_hash_size	Internal hash size for the list of object classes relevant to the MTA
ldap_pab_host	New in 7.0. Usage: RESTRICTED. The host for PAB LDAP queries; overrides (for MTA purposes) the local.service.pab.ldaphost configutil parameter (legacy configuration) or ldaphost PAB option (Unified Configuration)
ldap_pab_password	New in 7.0. Usage: RESTRICTED. The password for PAB LDAP queries; overrides (for MTA purposes) the local.service.pab.ldappasswd configutil parameter (legacy configuration) or ldappasswd PAB option (Unified Configuration)
ldap_pab_port	New in 7.0. Usage: RESTRICTED. The port for PAB LDAP queries; overrides (for MTA purposes) the local.service.pab.ldapport configutil parameter (legacy configuration) or ldapport PAB option (Unified Configuration)
ldap_pab_username	New in 7.0. Usage: RESTRICTED. The username (bind credentials) for PAB LDAP queries; overrides (for MTA purposes) the local.service.pab.ldapbinddn configutil parameter (legacy configuration) or ldapbinddn PAB option (Unified Configuration)
ldap_password	The password to use when binding for LDAP queries; overrides (for MTA purposes) the

	`local.ugldapbindcred` configutil parameter (legacy configuration) or `ugldapbindcred` base option (Unified Configuration)
`ldap_port`	Port to which to connect for LDAP queries; overrides (for MTA purposes) the `local.ugldapport` configutil parameter (legacy configuration) or `ugldapport` base option (Unified Configuration)
`ldap_schemalevel`	The schema level in use; overrides (for MTA purposes) the `ldap_schemalevel` base option
`ldap_schematag`	The tag (name) of the schema in use; overrides the `local.imta.schematag` configutil parameter
`ldap_timeout`	Timeout value for LDAP queries
`ldap_uid_invalid_chars`	Characters that are not allowed in a `uid` or `permanent identifier`
`ldap_use_async`	Control use of asynchronous (*vs*. synchronous) LDAP lookups
`ldap_user_object_classes`	The object classes required for a user
`ldap_user_root`	The base DN for the user and group portion of the DIT; overrides (for MTA purposes) the `local.ugldapbasedn` configutil parameter (legacy configuration) or `ugldapbasedn` base option (Unified Configuration)
`ldap_username`	The DN under which to bind for LDAP queries; overrides (for MTA purposes) the `local.ugldapbinddn` configutil parameter (legacy configuration) or `ugldapbinddn` base option (Unified Configuration)
`line_limit`	Limit the size of messages allowed through the MTA
`lines_to_return`	Lines included when returning samples of message content (as in warning messages)
`log_alq`	(OpenVMS only.) Specify the default allocation quantity for the MTA message transaction log file
`log_auth`	(New in 7.0.5.) Include SMTP MAIL FROM's AUTH parameter in MTA message transaction log entries.
`log_callout_delays`	(New in 8.0) Include timers showing the time for responses from external components in MTA message transaction log entries
`log_connection`	Generate connection log entries, and/or include connection information in message transaction log entries. (New in 6.2, optionally log SMTP AUTH attempts.)
`log_connections_syslog`	Send connection log entries to syslog (UNIX) or event log (NT)

log_conversion_tag	(New in 7.0.5.) Include conversion tag(s) field in MTA message transaction log entries.
log_delay_bins	Specify the bins for delivery delay range counters
log_delivery_flags	(New in 7.0.5.) Include delivery flags field in MTA message transaction log entries.
log_diagnostics	(New in MS 7.0u1) Include diagnostics in MTA message transaction log entries
log_dkim	(New in 8.1.0.6) Include information about DKIM signing operations in message transaction log entries
log_envelope_id	New in 6.1-0.01. Include envelope ids in MTA message transaction log entries.
log_filename	Include message file names in MTA message transaction log entries
log_filter	Include Sieve filter actions applying to the message in MTA message transaction log entries.
log_format	Control the format of the MTA transaction log file(s)
log_from	(New in 8.1.0.2) Include the address found in the From: header field in message transaction log entries
log_futurerelease	(New in) Include value of FUTURERELEASE SMTP extension in MTA message transaction log entries
log_header	Include message headers in MTA message transaction log entries
log_imap_flags	(New in 7.0.5.) Include any IMAP flags set by the MTA in MTA message transaction log entries
log_intermediate	New in 6.2. Include "intermediate" and/or "original" (RCPT TO: command line) forms of destination address in MTA message transaction log entries
log_isc_status	(New in MS 8.0.2) Include Indexed Search Converter status information in LMTP server MTA message transaction log entries
log_local	Include the local domain name on "bare user name" addresses in MTA message transaction log entries
log_mailbox_uid	Include the IMAP UID and UIDVALIDITY of messages delivered by the ims-ms channel to the Message Store in MTA message transaction log entries
log_message_id	Include message IDs in MTA message transaction log entries
log_messages_syslog	Send MTA message transaction log file entries to syslog

log_mtpriority	(New in MS 8.0) Include message MT-PRIORITY in MTA message transaction log entries
log_node	OpenVMS only. Include the node name for an enqueueing process in MTA message transaction log entries
log_notary	Include a NOTARY (delivery receipt) flags indicator in MTA message transaction log entries
log_priority	Include message priority in MTA message transaction log entries
log_process	Include enqueuing process ID in MTA message transation log entries
log_queue_time	(New in MS 6.3) Include "time in queue" in MTA message transaction log entries; this also causes inclusion of "time to open or fail to open a connection" in MTA connection log entries
log_reason	Include the reason for a message rejection in MTA message transaction log entries
log_remota_mta	(New in MS 8.0.2.3) Include remote MTA name in MTA message transaction log entries
log_sensitivity	Include message's sensitivity value in MTA message transaction log entries
log_size_bins	Specify the bins for message size range counters
log_smartsend	(New in 8.1.0.1) Include additional information about smartsend plugin actions in MTA message transaction log entries
log_sndopr	Send a syslog message if the MTA's logging facilities encounter a difficulty
log_syslog_prefix	(New in MS 8.0.2.3.) Specifices the prefix used on MTA message transaction log file entries sent to syslog
log_times	(New in 8.0) Include deferred delivery time in MTA message transaction log entries
log_tracking	(New in 8.0) Include message tracking ID in MTA message transaction log entries
log_transactionlog	(New in 8.0) Include string argument from any Sieve "transactionlog" actions in MTA message transaction log entries
log_uid	(New in 8.0) Include recipient UID in MTA message transaction log entries
log_use_xtext	(New in MS 8.0) Controls xtext encoding of addresses in MTA message transaction log entries
log_username	Include user identity information in MTA message transation log entries
log_8bit_encode	Controls how non-ASCII characters are written in XMl format MTA transaction log file(s)

`logfile`	`logfile` options set at the MTA level (`mta.logfile.`*`option-name`* in Unified Configuration) affect the MTA's logging of insertion of messages into the Message Store; that is, affect logging of message insertions performed by `ims-ms` and `tcp_lmtpss_*` channels
`mail_off`	Specify the comment string that disables mail delivery for list addresses
`map_names_size`	Set the number of mapping tables
`mapping_paranoia`	(New in 7.0) Control handling of vertical bar characters in probes of mapping tables such as FROM_ACCESS, recipient access mapping tables and `AUTH_REWRITE`
`max_addheaders`	Maximum number of Sieve "`addheader`" actions that can be performed
`max_alias_levels`	Set the level of alias nesting allowed
`max_duplicates`	(New in 8.0) Maximum "`duplicate`" tests performed in a Sieve filter
`max_fileintos`	Maximum number of Sieve "`fileinto`" actions that may be performed by a Sieve script
`max_header_block_user`	Fine tune message fragmentation
`max_header_line_user`	Fine tune message fragmentation
`max_internal_blocks`	Specify size of messages beyond which to buffer to temporary files
`max_local_received_lines`	Occurrences of the local host name in Received: header lines after which a message will be HELD
`max_mime_levels`	Degree to look inside MIME messages during processing
`max_mime_parts`	Number of parts to look at when processing MIME messages
`max_mr_received_lines`	Number of MR-Received: header lines after which a message will be HELD
`max_received_lines`	Number of Received: header lines after which a message will be HELD
`max_redirects`	Maximum number of Sieve "`redirect`" actions (*i.e.*, forwards) that may be used in a Sieve filter
`max_total_received_lines`	Number of Received:, MR-Received: or X400-Received: header lines after which a message will be HELD
`max_urls`	Maximum number of URLs that may be active (nesting of references)
`max_vacations`	Maximum number of `vacation` actions that may appear in a Sieve filter
`max_variables`	Maximum number of variables that may be used in a Sieve script

max_x400_received_lines	Number of X400-Received: header lines after which a message will be HELD
memcache_expire	(New in 8.0) Time to hold idle memcached connections open
memcache_hash_algorithm	(New in 8.1.0.3) Hash function to apply to memcache keys
memcache_host	(New in 8.0) Host name of memcached server
memcache_port	(New in 8.0) memcached service port
message_hash_algorithm	(New in MS 6.3-0.15) Algorithm to use for generating message hashes for message archiving
message_hash_fields	(New in MS 6.3) Header fields to include when generating message hashes
message_save_copy_flags	(New in MS 6.3) Control the format of MESSAGE-SAVE-COPY mapping table probes
missing_recipient_group_text	Phrase to use when generating an empty group construct
missing_recipient_policy	Legalize messages that lack any recipient headers
name_table_name	OpenVMS only: Name of a logical name table storing aliases
normal_block_limit	Maximum size of message to treat as being of normal or higher priority
non_urgent_block_limit	Maximum size of message to treat as being of non-urgent priority
notary_decode	Control whether encoded-words in the original message header are decoded when performing a %H substitution during the MTA's generation of DSNs and MDNs
notary_quote	Specify the character that marks substitution sequences in return_*.txt files and disposition_*.txt files
notify_maximum_timeout	(New in MS 7.0.5) Specify the maximum timeout permitted between successive Sieve notify or enotify actions
notify_minimum_timeout	(New in MS 7.0.5) Specify the minimum timeout permitted between successive Sieve notify or enotify actions
notify_timeout_default	(New in MS 7.0.5) Specify the default timeout permitted between successive Sieve notify or enotify actions
optin_user_carryover	New in 6.2. Specify whether user spam/virus filter "opt-in" is considered to "carry over" for forwarded recipients
options_hash_size	Hash size for the internal table of MTA options (option.dat options)

or_clauses	Set default for whether to AND or OR multiple posting access control settings on mailing lists
plaintextmincipher	(New in MS 7.4-18.01; only settable at the MTA level in Unified Configuration) Disable PLAINTEXT SMTP AUTH unless SSL or TLS is active
post_off	Specify the comment string that disables posting for list addresses
projectid	(New in MS 7.3-11.01) Numeric id the MTA uses when obtaining shared memory segments
queue_cache_mode	Tells the MTA where queue cache information is being stored
received_domain	Specify the domain name (identifying the system itself) to use in constructing Received: header lines
received_version	Specify the IMTA version string to use in constructing Received: header lines; use is **NOT RECOMMENDED**
return_address	Set the return address for the local postmaster
return_debug	Enable debugging of MTA periodic return_job operations
return_delivery_history	Control whether delivery attempt history is included in returned messages
return_envelope	Control use of empty return address in notification messages, and validity checks on envelope From address
return_personal	Set the personal name for the postmaster
return_units	Control the assumed units for the notices channel option, thereby controlling the interval at which certain notification messages are generated
reverse_address_cache_size	Number of LDAP address reversal (reverse_url) results to keep cached
reverse_address_cache_timeout	How long to cache LDAP address reversal lookup (reverse_url) results
reverse_data_size	Internal hash size for the reverse (database) text file
reverse_envelope	RESTRICTED: Control application of address reversal to envelope addresses
reverse_url	URL for doing address reversal
route_to_routing_host	Forcibly route non-local hosts to the first value of mailRoutingHosts
separate_connection_log	Write connection transaction log entries to a separate file than message transaction log entries
sieve_body_needed	Specifies whether or not to retain decoded MIME body information when initial message analysis is performed.

sieve_mime_needed	Specifies whether or not to retain inner MIME structure and header information when initial message analysis is performed.
sieve_redirect_add_resent	(New in MS 6.3p1) Default for whether Sieve filter "redirect" actions cause addition of Resent-*: header lines
sieve_user_carryover	Specify whether user Sieve filters "carry over" for forwarded recipients
smtpproxypassword	(New in MS 7.0.5) Password the MMP uses to authenticate for SMTP; (supercedes the older TCP/IP-channel-specific option PROXY_PASSWORD)
sndopr_prefix	(New in MS 8.0.2.3.) Set the prefix attached to syslog notices.
sndopr_priority	Set the syslog level (facility and priority) the MTA uses when generating syslog notices
spamfilter*N*_action_*M*	URL that resolves to a Sieve filter, specifying the action to take when Spam/virus filter package *N* returns the corresponding spamfilter*N*_verdict_*M* verdict
spamfilter*N*_config_file	Location of the Spam/virus filter package configuration file
spamfilter*N*_final	Control whether the MTA passes the "intermediate" *vs*. "final" address form to the spam/virus filter package
spamfilter*N*_library	Location of the Spam/virus filter package client shared library
spamfilter*N*_name	(New in MS 7.0.5) Specify a symbolic name for the *N*th spam/virus filter package.
spamfilter*N*_null_action	URL that resolves to a Sieve filter, specifying the action to take in the case of a null verdict from Spam/virus filter package
spamfilter*N*_null_optin	New in 6.1-0.01. Specify a value for the attribute named by the ldap_domain_attr_optin*N* MTA options, the ldap_optin*N* MTA options, or the (new in MS 8.0.1.3) ldap_optout*N* MTA options that means that the attribute should be ignored; the purpose is to provide a way for these attributes to be used by provisioning facilities that find it easier to set an attribute value rather than to remove an attribute entirely
spamfilter*N*_string_action	URL that resolves to a Sieve filter, specifying the action to take in the case of verdicts from Spam/virus filter package that do not have an explicit corresponding action
spamfilter*N*_verdict_*M*	A Spam/virus filter package verdict string

sslnicknames	(New in MS 7.4-18.01; only settable at the MTA level in Unified Configuration) SSL/TLS server certificate nicknames the MTA will offer
string_pool_size_0	Set the number of strings allowed for miscellaneous MTA configuration use
string_pool_size_1	Set the number of strings allowed for MTA mapping table use
string_pool_size_2	Set the number of strings allowed for MTA alias use
string_pool_size_3	Set the number of strings allowed for MTA general (database) text file use
string_pool_size_4	Set the number of strings allowed for MTA personal conversion use
subaddress_char	Specify the character used in addresses to separate the username (mailbox) from the subaddress or foldername
token_char	Specify token character in local-part of addresses for SRS purposes
tracking_debug	(New in 8.0) Enable debugging of message tracking
tracking_hash_algorithm	(New in 8.1.0.3) Select the hash algorithm the MTA uses to generate hashes of tracking and recall secrets. The default is SHA-1.
tracking_mode	(New in 8.0) Enable message tracking data storage
tracking_retries	(New in 8.0) Number of tracking update retry attempts
tracking_retry_delay	(New in 8.0) Time delay between tracking update retry attempts
unique_id_template	(New in MS 6.3) Specify a template used to convert an address into a unique identifier; typically used in conjunction with archiving facilities
urgent_block_limit	Maximum size of message to treat as being of urgent priority
use_alias_database	Control use of the alias database
use_comment_strings	Control the format of COMMENT_STRINGS mapping table probes
use_domain_database	Control use of the domain database
use_forward_database	Control use of the forward database
use_personal_aliases	Control use of personal alias databases
use_personal_names	Control the format of PERSONAL_NAMES mapping table probes
use_permanent_error	Control whether certain error conditions are considered to be permanent errors, or temporary errors
use_reverse_database	Control use and format of the reverse mapping table and reverse database

use_temporary_error	(New in 8.0.1) Control whether certain error conditions are considered to be temporary errors, or permanent errors
use_text_databases	Control whether the general database, the reverse database, and the forward database are on-disk databases, or in-memory structures
url_result_cache_case	New in MS 8.1.0.2. Controls whether URLs are treated in a case-sensitive fashion.
url_result_cache_size	Number of rewrite rule and mapping table LDAP URL lookups ($]...[lookups) to keep cached
url_result_cache_timeout	How long to cache rewrite rule and mapping table LDAP URL lookups
user_case	Lower case postmaster; other usernames with localbehavior channel option
vacation_cleanup	Average number of times between cleanups of the per-user per-response vacation files
vacation_cleanup	(New in MS 8.1.0.3) Specifies the hash algorithm to use for creating vacation entry names
vacation_maximum_timeout	(New in MS 7.0.5) Specify a maximum value permitted for Sieve "vacation" periodicity arguments
vacation_minimum_timeout	(New in MS 7.0.5) Specify a minimum value permitted for Sieve "vacation" periodicity arguments
vacation_template	URL specifying where per-user per-response vacation information is stored
wild_pool_size	Set the total number of wildcards allowed in mappings' patterns

52.5 MTA options listed by functional group

Table of MTA options, listed by functional group, shown below, lists the available MTA options, grouped by functionality. A brief description of each option is included, though more details can be found in the discussions of each individual MTA option, and in the discussions of functional groups of MTA options. See also Table of MTA options, listed alphabetically, which lists the MTA options alphabetically.

Options that fall into more than one category (as is frequently the case) are listed under each of the groups, *except* for the LDAP attribute name (schema) options which, due to their extensive number, are listed only in the LDAP attribute name (schema) options section of the table.

Table 52.2 MTA options, listed by functionality

Option	Usage
enable	Enable operation of the MTA
Alias and address MTA options	
alias_case	RESTRICTED: Control the case sensitivity of aliases

alias_domains	Control the format of alias file, alias option, and alias database probes
alias_magic	RESTRICTED: Control the order in which alias lookups are performed
alternate_recipient	(New in MS 8.0.1) Specify the comment string used to add an alternate recipient for an address.
alternate_recipient_mode	(New in MS 8.0.1) Control handling of multiple alternate recipients.
ap_debug	Internal MTA debugging option: enable debugging of low level address parsing; support for this option is RESTRICTED
delimiter_char	(New in MS 7.0) RESTRICTED: ASCII position of delimiter character
exproute_forward	Control whether the exproute channel option affects forward pointing headers
idn_config_file	(New in MS 8.0.2) Specify the location of an optional IDNKIT configuration file
improute_forward	Control the effect of the improute channel option on forward pointing headers
local_format_restrictions	Restrict use of the vertical bar (pipe) character, |, in local mailboxes (usernames), and restrict delivery to local files (use of the +*filename* syntax)
max_alias_levels	Set the level of alias nesting allowed
missing_recipient_group_text	Phrase to use when generating an empty group construct
missing_recipient_policy	Legalize messages that lack any recipient headers
name_table_name	OpenVMS only: Name of a logical name table storing aliases
reverse_envelope	Control application of address reversal to envelope addresses
subaddress_char	Specify the character used in addresses to separate the username (mailbox) from the subaddress or foldername
token_char	Specify token character in local-part of address for SRS purposes
use_alias_database	Control use of the alias database
use_domain_database	Control use of the domain database
use_forward_database	Control use of the forward database
use_personal_aliases	Control use of personal alias databases
use_reverse_database	Control use and format of the REVERSE mapping table and reverse database
user_case	Lower case postmaster; other usernames with localbehavior channel option
Autoresponse periodicity MTA options	

autoreply_timeout_default	Specify a default duration between successive vacation responses to the same sender
notify_maximum_timeout	(New in MS 7.0.5) Specify the maximum timeout permitted between successive Sieve notify or enotify actions
notify_minimum_timeout	(New in MS 7.0.5) Specify the minimum timeout permitted between successive Sieve notify or enotify actions
notify_timeout_default	(New in MS 7.0.5) Specify the default timeout permitted between successive Sieve notify or enotify actions
vacation_cleanup	Average number of times between cleanups of the per-user per-response vacation files
vacation_cleanup	(New in MS 8.1.0.3) Specifies the hash algorithm to use for creating vacation entry names
vacation_maximum_timeout	(New in MS 7.0.5) Specify a maximum value permitted for Sieve " vacation" periodicity arguments
vacation_minimum_timeout	(New in MS 7.0.5) Specify a minimum value permitted for Sieve " vacation" periodicity arguments
vacation_template	URL specifying where per-user per-response vacation information is stored
BURL MTA options	
imap_password	(New in 7.0.) Set the password for the MTA to use when connecting to the IMAP server (for BURL purposes)
imap_username	(New in 7.0.) Set the username for the MTA to use when connecting to the IMAP server (for BURL purposes)
configutil override MTA options +	
ldap_base_dn	DELETED for MS 7.0u4; see instead ldap_user_root
ldap_default_domain	The domain name to recognize and interpret as the default domain name; overrides (for MTA purposes) the defaultdomain base option (legacy configuration service.defaultdomain configutil parameter)
ldap_domain_root	The base DN for the domain portion of the DIT; overrides the dcroot base option (legacy configuration) service.dcroot configutil parameter)
ldap_host	Host to which to connect for LDAP queries; overrides the ugldaphost base option (legacy configuration local.ugldaphost configutil parameter)

ldap_host_alias_list	Local host aliases; overrides (for MTA purposes) the ldap_host_alias_list base option (legacy configuration local.imta.hostnamealiases configutil parameter)
ldap_local_host	The local host name (official host name for the "l" channel); overrides (for MTA purposes) the hostname base option (legacy configuration local.hostname configutil parameter)
ldap_mail_aliases	The attributes in which aliases are stored; overrides the legacy configuration local.imta.mailaliases configutil parameter
ldap_pab_host	(New in MS 7.0) The host for PAB LDAP queries; overrides (for MTA purposes) the ldaphost PAB option (legacy configuration local.service.pab.ldaphost configutil parameter)
ldap_pab_max_connections	(New in MS 7.0u1) Limit on the maximum number of connections that will be made
ldap_pab_password	(New in MS 7.0) The password for PAB LDAP queries; overrides (for MTA purposes) the ldappasswd PAB option (legacy configuration local.service.pab.ldappasswd configutil parameter)
ldap_pab_port	(New in MS 7.0) The port for PAB LDAP queries; overrides the ldapport PAB option (legacy configuration local.service.pab.ldapport configutil parameter). If neither this MTA option nor the PAB option (configutil parameter) is set, then this defaults to the ldap_port value.
ldap_pab_username	(New in MS 7.0) The username (bind credentials) for PAB LDAP queries; overrides (for MTA purposes) the ldapbinddn PAB option (legacy configuration local.service.pab.ldapbinddn configutil parameter)
ldap_password	The password to use when binding for LDAP queries; overrides (for MTA purposes) the ugldapbindcred base option (legacy configuration local.ugldapbindcred configutil parameter)
ldap_port	Port to which to connect for LDAP queries; overrides (for MTA purposes) the ugldapport base option (legacy configuration local.ugldapport configutil parameter)
ldap_schematag	The tag (name) of the schema in use; overrides (for MTA purposes) the legacy configuration local.imta.schematag configutil parameter
ldap_username	The DN under which to bind for LDAP queries; overrides (for MTA purposes) the

	uglдapbinddn base option (legacy configuration local.ugldapbinddn configutil parameter)
ldap_user_root	The base DN for the user and group portion of the DIT; overrides (for MTA purposes) the ugldapbasedn base option (legacy configuration local.ugldapbasedn configutil parameter)
Conversions MTA options	
conversion_size	Set the number of entries allowed in the conversion file (legacy configuration) or conversions MTA option (Unified Configuration)
conversions	(Unified Configuration only) Conversion entries; replaces legacy configuration conversions file
include_conversiontag	(New in MS 6.3) Include the conversion tag value(s) in mapping table probes
log_conversion_tag	(New in MS 7.0.5) Include conversion tag(s) field in MTA message transaction log entries.
original_channel_probe	RESTRICTED: Determine the "input" channel for CONVERSIONS mapping table probes performed by the conversion channel and certain other, special, channels
personal_conversion_size	RESTRICTED: Maximum personal conversion entries
string_pool_size_0	Set the number of miscellaneous strings (in particular including strings in conversions entries) allowed in the MTA configuration
string_pool_size_4	Set the number of strings allowed for MTA personal conversion use
Counters MTA options	
circuitcheck_completed_bins	Specify the bins for the message circuit check message counters
enable_delay_timers	(New in MS 8.0) Enable timers measuring the total time the MTA spends waiting for responses from external components
log_delay_bins	Specify the bins for delivery delay range counters
log_frustration_limit	How many times a process will tolerate failure to be able to update the MTA counters before giving up on updating counters
log_size_bins	Specify the bins for message size range counters
log_sndopr	Send an operator or syslog message if the MTA's logging facilities encounter a difficulty
log_statistics	RESTRICTED: Normal *vs.* "string" counters creation.
Database MTA options	
alias_case	RESTRICTED: Control the case sensitivity of aliases
alias_database_url	(New in MS 8.0) memcache: URL for storing alias database data

alias_domains	Control the format of alias file, alias option, and alias database probes
alias_magic	RESTRICTED: Control the order in which alias lookups are performed
domain_database_url	(New in MS 8.0) memcache: URL for storing domain database data
forward_data_size	Hash size for the forward (database) text file
forward_database_url	(New in MS 8.0) memcache: URL for storing forward database data
general_case	Controls the case sensitivity of general database lookups
general_data_size	Hash size for the general (database) text file
general_database_url	(New in MS 8.0) memcache: URL for storing general database data
queue_cache_mode	Tells the MTA where queue cache information is being stored
queue_cache_mode_3_files	(New in MS 7.4) RESTRICTED
reverse_data_size	Internal hash size for the reverse (database) text file
reverse_database_url	(New in MS 8.0) memcache: URL for storing reverse database data
use_alias_database	Control use of the alias database
use_domain_database	Control use of the domain database
use_forward_database	Control use of the forward database
use_personal_aliases	Control use of personal alias databases
use_reverse_database	Control use and format of the REVERSE mapping table and reverse database
use_text_databases	Control whether the general database, the reverse database, and the forward database are on-disk databases, or in-memory structures
vacation_template	URL specifying where per-user per-response vacation information is stored
Debug MTA options	
ap_debug	RESTRICTED: Internal MTA debugging option; enable debugging of low level address parsing
cache_debug	Output direct LDAP lookup caching statistics
config_debug	RESTRICTED: (New in MS 8.0.1) Enable debugging of MTA configuration loading
debug_flush	(New in MS 7.1) Flush certain debug output to disk.
dequeue_debug	Enable debugging of message dequeue operations
filter_debug	(New in MS 6.2) Control whether detailed (stack state) debugging of Sieve filter evaluation is output
log_debug	RESTRICTED: Enable debugging of MTA logging operations

mm_debug	Internal MTA debugging option; enable debugging of message enqueue (MM) operation
os_debug	RESTRICTED: Internal MTA debugging option; enable debugging of low level OS interface routines, *e.g.*, file operations
return_debug	Enable debugging of MTA periodic return job operations
return_verify	(New in MS 7.0.5, replacing former imta_return_verify MTA Tailor option) Enable shell script logging within the MTA return job
tracking_debug	RESTRICTED: (New in MS 8.0) Enable debugging of the message tracking subsystem
LDAP bind and connect MTA options	
ldap_base_dn	DELETED for MS 7.0u4; see instead the ldap_user_root MTA option
ldap_host	Host to which to connect for LDAP queries; overrides (for MTA purposes) the local.ugldaphost configutil parameter (legacy configuration) or ugldaphost base option (Unified Configuration)
ldap_max_connections	The maximum number of simultaneous LDAP connections to allow
ldap_password	The password to use when binding for LDAP queries; overrides (for MTA purposes) the local.ugldapbindcred configutil parameter (legacy configuration) or ugldapbindcred base option (Unified Configuration)
ldap_port	Port to which to connect for LDAP queries; overrides (for MTA purposes) the local.ugldapport configutil parameter (legacy configuration) or ugldapport base option (Unified Configuration)
ldap_timeout	Timeout value for LDAP queries
ldap_use_async	Control use of asynchronous (*vs.* synchronous) LDAP lookups
ldap_username	The DN under which to bind for LDAP queries; overrides (for MTA purposes) the local.ugldapbinddn configutil parameter (legacy configuration) or ugldapbinddn base option (Unified Configuration)
max_urls	Maximum number of URLs that may be active (nesting of references)
Direct LDAP domain lookup MTA options	
domain_failure	Rewrite template to apply when an LDAP domain lookup encounters an LDAP error
domain_match_cache_size	Number of domain lookup ($V rewrite template) results to keep cached

domain_match_cache_timeout	How long to cache domain lookup ($V rewrite template) results
domain_match_url	URL for an extra, special lookup for domains, *e.g.*, URL for looking up vanity domains
domain_uplevel	Control whether to search "upwards" in the DC tree for domain names, and whether to use a "canonical" domain name when searching for user entries
ldap_attr_domain1_schema2	Specify an alternate attribute name for the attribute used to store the "primary" domain in Schema 2
ldap_attr_domain2_schema2	Specify an alternate attribute name for the attribute used to store the "secondary" domain in Schema 2
ldap_attr_domain_search_filter	Attribute in the configuration template area, (see the ldap_global_config_templates MTA option) that is used to store the domain search filter template
ldap_basedn_filter_schema1	(New in MS 6.3) When schema 1 is in use, specify the filter used to identify domains when performing baseDN searches
ldap_basedn_filter_schema2	(New in MS 6.3) When schema 2 is in use, specify additional filter elements used to identify domains when performing baseDN searches
ldap_default_domain	The domain name to recognize and interpret as the default domain name; overrides (for MTA purposes) the defaultdomain base option (legacy configuration service.defaultdomain configutil parameter)
ldap_domain_filter_schema1	When schema 1 is in use, specify the filter used to find domains in the DIT
ldap_domain_filter_schema2	When schema 2 is in use, specify the filter used to find domains in the DIT
ldap_domain_known_attributes	Control whether the MTA fetches all domain attributes *vs.* fetches only "known" domain attributes
ldap_domain_root	The base DN for the domain portion of the DIT; overrides (for MTA purposes) the dcroot base option (legacy configuration) service.dcroot configutil parameter)
ldap_domain_timeout	New in MS 6.1-0.01. Specify the retention time for entries in the domain map cache
ldap_host_alias_list	Local host aliases; overrides (for MTA purposes) the local.imta.hostnamealiases configutil parameter (legacy configuration) or ldap_host_alias_list base option (Unified Configuration)
ldap_local_host	The local host name (official host name for the "l" channel); overrides (for MTA purposes) the local.hostname configutil parameter (legacy configuration) or hostname base option (Unified Configuration)

Direct LDAP usergroup lookup MTA options	
alias_entry_cache_negative	Whether to cache negative results (*i.e.*, failures) of alias lookups (alias_urlN lookups)
alias_entry_cache_size	Number of alias lookup (alias_urlN) results to keep cached
alias_entry_cache_timeout	How long to cache alias lookup (alias_urlN) results
alias_url0	URL for doing alias lookups
alias_url1	URL for doing alias lookups
alias_url2	URL for doing alias lookups
alias_url3	URL for doing alias lookups
allow_unquoted_addrs_violate_rfc2798	Look up addresses in LDAP with quotes stripped from the local part
aliasdetourhost_null_optin	(New in MS 6.2p4) Specify a value for the attribute named by the ldap_detourhost_optin MTA option (and new in MS 8.0, also the attribute named by the ldap_domain_attr_detourhostoptin) that means that the attribute should be ignored; the purpose is to allow a way of "turning off" message detouring (where the detouring is typically for purposes of spam/virus filtering) for sites and users whose provisioning facilities find it easier to set an attribute value rather than to remove an attribute entirely
defer_group_processing	Set a default for whether direct LDAP group (list) expansion is deferred to the reprocess channel
group_dn_template	LDAP URL template used for fetching attributes once a user specified via a uniqueMember attribute has been located
ldap_default_attr	For URLs that are supposed to return a single result, specify a single attribute to request if no attribute was specified in the original LDAP query string
ldap_filter_reference	(New in MS 6.2.) If parental controls are enabled for a user (see the ldap_parental_controls MTA option), then the attribute named by this ldap_filter_reference MTA option specifies the DN of the entry that contains the actual head of household filter (typically, that is, the DN of the head of household user). (The attribute within that user entry containing the filter is specified by the ldap_hoh_filter MTA option, which defaults to mailSieveRuleSource. The lookup requests both the filter, contained in the attribute named by the ldap_hoh_filter MTA option, and the owner, contained in the attribute named by the ldap_hoh_owner MTA option, which defaults to mail.)

ldap_group_object_classes	The object classes required for a group
ldap_hoh_filter	(New in MS 6.2.) Specify an attribute to request when performing a head of household filter lookup.
ldap_hoh_owner	(New in MS 6.2.) Attribute in which to find the owner of the HOH Sieve
ldap_mail_aliases	The attributes in which aliases are stored; overrides the legacy configuration local.imta.mailaliases configutil parameter
ldap_mail_reverses	The attributes used for the filter generated by the $Q LDAP substitution sequence; normally used during reverse_url lookups, hence normally the attributes compared against an address to be "reversed"
ldap_parental_controls	(New in MS 6.2) Specifies the name of a user or group LDAP attribute whose value can request "head of household" (a.k.a "parental controls") Sieve filtering be applied to this user's (or group's) messages. Any of the values Yes, 1, or true is considered to be requesting parental controls.
ldap_uid_invalid_chars	Characters that are not allowed in a uid or permanent identifier
ldap_user_object_classes	The object classes required for a user
ldap_user_root	The base DN for the user and group portion of the DIT; overrides (for MTA purposes) the ugldapbasedn base option (legacy configuration local.ugldapbasedn configutil parameter)
max_alias_levels	Set the level of alias nesting allowed
max_urls	Maximum number of URLs that may be active (nesting of references)
reverse_address_cache_size	Number of LDAP address reversal (reverse_url) results to keep cached
reverse_address_cache_timeout	How long to cache LDAP address reversal lookup (reverse_url) results
reverse_url	URL for doing address reversal
Direct LDAP schema MTA options	
ldap_attr_domain_search_filter	Attribute in the global configuration template area (see the ldap_global_config_templates MTA option) that is used to store the domain search filter template; for instance, one attribute that might be used for such a purpose (hence to which this option might be set) would be inetDomainSearchFilter.
ldap_basedn_filter_schema1	(New in MS 6.3) When schema 1 is in use, specify the filter used to identify domains when performing baseDN searches
ldap_basedn_filter_schema2	(New in MS 6.3) When schema 2 is in use, specify additional filter elements used to identify domains when performing baseDN searches

ldap_domain_filter_schema1	When schema 1 is in use, specify the filter used to find domains in the DIT
ldap_domain_filter_schema2	When schema 2 is in use, specify the filter used to find domains in the DIT
ldap_domain_known_attributes	Control whether the MTA fetches all domain attributes *vs*. fetches only "known" domain attributes
ldap_domain_root	The base DN for the domain portion of the DIT; overrides (for MTA purposes) the dcroot base option (legacy configuration) service.dcroot configutil parameter)
ldap_global_config_templates	Schema 2 support: specify the DN where global configuration templates can be found
group_dn_template	LDAP URL template used for fetching attributes once a user specified via a uniqueMember attribute has been located
ldap_group_object_classes	The object classes required for a group
ldap_schemalevel	The schema level in use; overrides (for MTA purposes) the ldap_schemalevel base option
ldap_schematag	The tag (name) of the schema in use; overrides the local.imta.schematag configutil parameter
ldap_user_object_classes	The object classes required for a user
ldap_user_root	The base DN for the user and group portion of the DIT; overrides (for MTA purposes) the ugldapbasedn base option (legacy configuration local.ugldapbasedn configutil parameter)
Direct LDAP attribute interpretation MTA options	
aliasdetourhost_null_optin	(New in MS 6.2p4) Specify a value for the attribute named by the ldap_detourhost_optin MTA option (and new in MS 8.0, also the attribute named by the ldap_domain_attr_detourhostoptin) that means that the attribute should be ignored; the purpose is to allow a way of "turning off" message detouring (where the detouring is typically for purposes of spam/virus filtering) for sites and users whose provisioning facilities find it easier to set an attribute value rather than to remove an attribute entirely
allow_unquoted_addrs_violate_rfc2798	Look up addresses in LDAP with quotes stripped from the local part
capture_format_default	(New in MS 7.0u4) Specify the default "capture" format resulting from ldap_capture
delivery_options	Specify interpretation of mailDeliveryOption values
group_dn_template	LDAP URL template used for fetching attributes once a user specified via a uniqueMember attribute has been located

ldap_default_domain	The domain name to recognize and interpret as the default domain name; overrides (for MTA purposes) the defaultdomain base option (legacy configuration service.defaultdomain configutil parameter)
ldap_hoh_filter	(New in MS 6.2.) Specify an attribute to request when performing a head of household filter lookup.
ldap_hoh_owner	(New in MS 6.2.) Attribute in which to find the owner of the HOH Sieve
ldap_host_alias_list	Local host aliases; overrides (for MTA purposes) the local.imta.hostnamealiases configutil parameter (legacy configuration) or ldap_host_alias_list base option (Unified Configuration)
ldap_local_host	The local host name (official host name for the "l" channel); overrides (for MTA purposes) the local.hostname configutil parameter (legacy configuration) or hostname base option (Unified Configuration)
ldap_uid_invalid_chars	Characters that are not allowed in a uid or permanent identifier
optin_user_carryover	(New in MS 6.2.) Specify whether user spam/virus filter "optin" is considered to "carry over" for forwarded recipients
process_substitutions	(New in MS 6.3) Process substitution characters in the URL values of various LDAP attributes
route_to_routing_host	Forcibly route non-local hosts to the first value of mailRoutingHosts
sieve_user_carryover	Specify whether user Sieve filters "carry over" for forwarded recipients
spare_N_separator	(New in MS 7.0u2) Specify the handling of multiple values of the ldap_spare_N attribute for corresponding N.
vacation_maximum_timeout	(New in MS 7.0.5) Specify a maximum value permitted for Sieve "vacation" periodicity arguments
vacation_minimum_timeout	(New in 7.0.5) Specify a minimum value permitted for Sieve "vacation" periodicity arguments
Direct LDAP attribute name MTA options	
ldap_*	Specify an alternate attribute name for any of various per-user attributes; see MTA LDAP attribute name options
ldap_attr_domain_*	Specify an alternate attribute name for any of a few fundamental defining attributes of domains; see MTA LDAP attribute name options

ldap_domain_attr_*	Specify an alternate attribute name for any of various per-domain attributes; see MTA LDAP attribute name options
Direct LDAP attributes returned upon authentication MTA options	
ldap_auth_attr_hold_for	(New in MS 8.0) Specify the name of an attribute that stores authenticated hold time
ldap_auth_attr_mail_host	(New in MS 8.0) Specify an alternate attribute name for the attribute used to store the mailHost for BURL purposes
ldap_auth_attr_recall_secret	(New in MS 8.0) Specify the name of an attribute used to store the user's recall secret
ldap_auth_attr_sender	(New in MS 8.0) Specify an alternate attribute name for the attribute used to store the user's canonical address
ldap_auth_attr_submit_channel	(New in MS 8.0) Specify an alternate attribute name for the attribute used to store the authenticated submission source channel name override
LDAP and URL lookup caching and timeout options	
alias_entry_cache_negative	Whether to cache negative results (*i.e.,* failures) of alias lookups (alias_urlN lookups)
alias_entry_cache_size	Number of alias lookup (alias_urlN) results to keep cached
alias_entry_cache_timeout	How long to cache alias lookup (alias_urlN) results
cache_debug	Output direct LDAP lookup caching statistics
domain_match_cache_size	Number of domain lookup ($V rewrite template) results to keep cached
domain_match_cache_timeout	How long to cache domain lookup ($V rewrite template) results
filter_cache_size	(New in MS 6.2.) Specify the size of the per-process cache of tokenized Sieve filters
filter_cache_timeout	(New in MS 6.2.) Specify the retention time for entries in the per-process cache of tokenized Sieve filters
ldap_domain_timeout	New in MS 6.1-0.01. Specify the retention time for entries in the domain map cache
ldap_timeout	Timeout value for LDAP queries
ldap_use_async	Control use of asynchronous (*vs.* synchronous) LDAP lookups
reverse_address_cache_size	Number of LDAP address reversal (reverse_url) results to keep cached
reverse_address_cache_timeout	How long to cache LDAP address reversal lookup (reverse_url) results
url_result_cache_case	New in MS 8.1.0.2. Controls whether URLs are treated in a case-sensitive fashion.

url_result_cache_size	Number of rewrite rule LDAP URL lookups and mapping table LDAP URL lookups ($]...[lookups) to keep cached
url_result_cache_timeout	How long to cache results of rewrite rule LDAP URL lookups and mapping table LDAP URL lookups ($]...[lookups)
Directory location MTA options	
langdir	(New in MS 7.0) Specify the location of the default set of language-specific files
tmpdir	(New in MS 7.0) Specify the location of the directory for storing temporary files
DKIM MTA options	
dkim_ignore_domains	(New in MS 7.0.5) Domains to ignore in DKIM-Signature: fields
dkim_preserve_domains	(New in MS 7.0.5) Domains in DKIM-Signature: fields that trigger passthrough mode
dkim_remove_domains	(New in MS 7.0.5) Domains in DKIM-Signature: fields triggering removal of the header
DNS lookup MTA options	
blocked_mail_from_ips	(New in MS 6.1) Specify IP address literals whose A records should be ignored for purposes of the lookups done due to the mailfromdnsverify channel option
return_envelope	Control use of empty return address in notification messages, and validity checks on envelope From address
Error text and error interpretation MTA options	
access_errors	Control the information issued in certain error messages
error_text_*	Specify alternate error text for any of various error conditions; see error_text_* MTA options
missing_recipient_group_text	Phrase to use when generating an empty group construct
spamfilterN_optional	What to do if a spam/virus filter package is not responding: temporarily reject message *vs.* allow to pass unfiltered, plus whether to send syslog notice
use_permanent_error	Control whether certain error conditions are considered to be permanent errors, or temporary errors
use_temporary_error	(New in MS 8.0) Control whether certain error conditions are considered to be temporary errors, or permanent errors
External filtering context MTA options	
scan_channel	(New in MS 7.0.5) Channel to consider as source channel when initializing the MTA for spam/virus

	filter package checks performed by non-channel applications and utilities such as `imexpire`
`scan_originator`	(New in MS 7.0.5) Address to consider as the MAIL FROM/envelope From address when initializing the MTA for spam/virus filter package checks performed by non-channel applications and utilities such as `imexpire`
`scan_recipient`	(New in MS 7.0.5) Address to consider as the RCPT TO/envelope To address when initializing the MTA for spam/virus filter package checks performed by non-channel applications and utilities such as `imexpire`
File format MTA options	
`buffer_size`	Set the buffer size used when writing files; default is 8192
`cache_magic`	Obsolete PMDF option, controlling message file sorting
`cbt`	Obsolete PMDF option, to control the use of "contiguous best try" filesystem storage
`comment_chars`	Set the "comment" character(s) in MTA configuration files
`debug_flush`	(New in MS 7.1) Flush certain debug output to disk.
`dequeue_map`	RESTRICTED. Map files into memory when dequeuing
`fdirectory`	OpenVMS only.
`file_member_size`	Maximum number of configuration files used by the MTA
`fsync`	Do an fsync upon file close
`log_alq`	(OpenVMS only) Specify the default allocation quantity for the MTA message transaction log file
`log_deq`	(OpenVMS only) Specify the default extend quantity for the MTA message transaction log file
`max_internal_blocks`	Specify size of messages beyond which to buffer to temporary files
`mm_mbc`	(OpenVMS only) Set the RMS RAB MBC field; default is 4
`mm_mbf`	(OpenVMS only) Set the RMS RAB MBF field; default is 16
`notary_quote`	Specify the character that marks substitution sequences in `return_*.txt` files and `disposition_*.txt` files
`os_debug`	RESTRICTED: Internal MTA debugging option; enable debugging of low level OS interface routines, *e.g.*, file operations

osync	(New in MS 7.0.5) Specify whether or not to set the O_SYNC flag when creating message queue files on disk.
projectid	(New in MS 7.3-11.01) Numeric id MTA uses when obtaining shared memory segments
queue_cache_mode	RESTRICTED: Tells the MTA where queue cache information is being stored
queue_cache_mode_3_files	(New in MS 7.4) RESTRICTED
use_text_databases	Control whether the general database, the reverse database, and the forward database are on-disk databases, or in-memory structures
Internal size MTA options	
alias_hash_size	Set the number of aliases allowed: in the alias file (legacy configuration), or via alias option (Unified Configuration)
alias_member_size	Set the number of alias expansions allowed: in the alias file (legacy configuration), or via alias option (Unified Configuration)
channel_table_size	Set the number of channels allowed in the MTA configuration
chunk_cache_limit	Specify the size of the cache of message body chunks
circuitcheck_paths_size	Number of circuit check paths (entries) to allow in the circuit check configuration file
conversion_size	Set the number of entries allowed in the conversion file (legacy configuration) or conversions MTA option (Unified Configuration)
describe_cache_limit	Control size of message part description cache for message body processing purposes
domain_hash_size	Set the number of rewrite rules allowed
file_member_size	Maximum number of configuration files used by the MTA
forward_data_size	Hash size for the forward (database) text file
fruits_size	Number of fruits allowed in the fruit validation table
general_data_size	Hash size for the general (database) text file
host_hash_size	Set the number of channel host names
ldap_attr_name_hash_size	Internal hash size for the list of LDAP attributes relevant to the MTA
ldap_object_class_hash_size	Internal hash size for the list of object classes relevant to the MTA
map_names_size	Set the number of mapping tables
options_hash_size	Hash size for the internal table of MTA options (option.dat options in legacy configuration; mta.*option-name* options in Unified Configuration)
personal_conversion_size	RESTRICTED: Maximum personal conversion entries

reverse_data_size	Internal hash size for the reverse (database) text file
string_pool_size_0	Set the number of strings allowed for miscellaneous MTA configuration use
string_pool_size_1	Set the number of strings allowed for MTA mapping table use
string_pool_size_2	Set the number of strings allowed for MTA alias use
string_pool_size_3	Set the number of strings allowed for MTA general (database) text file use
string_pool_size_4	Set the number of strings allowed for MTA personal conversion use
wild_pool_size	Set the total number of wildcards allowed in mapping table patterns
LDAP external directory lookup MTA options	
ldap_ext_host	(New in MS 7.0u2) The host for LDAP EXT queries
ldap_ext_max_connections	(New in MS 7.0u2) Limit on the maximum number of LDAP EXT connections
ldap_ext_password	(New in MS 7.0u2) The password for LDAP EXT queries
ldap_ext_port	(New in MS 7.0u2) The port for LDAP EXT queries
ldap_ext_username	(New in MS 7.0u2) The username (bind credentials) for LDAP EXT queries
LDAP PAB lookup MTA options	
ldap_pab_host	(New in MS 7.0) The host for PAB LDAP queries; overrides (for MTA purposes) the ldaphost PAB option (Unified Configuration) or local.service.pab.ldaphost configutil parameter (legacy configuration)
ldap_pab_max_connections	(New in MS 7.0u1) Limit on the maximum number of connections that will be made
ldap_pab_password	(New in MS 7.0) The password for PAB LDAP queries; overrides (for MTA purposes) the ldappasswd PAB option (Unified Configuration) or local.service.pab.ldappasswd configutil parameter (legacy configuration)
ldap_pab_port	(New in MS 7.0) The port for PAB LDAP queries; overrides the local.service.pab.ldapport configutil parameter. If neither this option nor the configutil parameter is set, this defaults to the ldap_port value.
ldap_pab_username	(New in MS 7.0) The username (bind credentials) for PAB LDAP queries; overrides (for MTA purposes) the ldapbinddn PAB option (Unified Configuration) or local.service.pab.ldapbinddn configutil parameter (legacy configuration)
Mailing list and group MTA options	

alternate_recipient	(New in MS 8.0.1) Specify the comment string used to add an alternate recipient for an address.
alternate_recipient_mode	(New in MS 8.0.1) Control handling of multiple alternate recipients.
defer_group_processing	Set a default for whether direct LDAP group (list) expansion is deferred to the reprocess channel
digest_on	RESTRICTED. Specify the comment string that enables mailing list digests (in preference to regular mailing list postings)
expandable_default	Set the default for mailing lists to [NONEXPANDABLE] or in direct LDAP terms, to expandable: none or equivalently mgmanMemberVisibility: none; *i.e.*, disable use of SMTP EXPN
mail_off	Specify the comment string that disables mail delivery for list addresses
or_clauses	Set default for whether to AND or OR multiple posting access control settings on mailing lists
post_off	Specify the comment string that disables list postings for a list address
MAILSERV MTA options	
ldap_mlsub_*	RESTRICTED: Names of LDAP attributes for MAILSERV user list subscription entries
ldap_mluser_*	RESTRICTED: Names of LDAP attributes for MAILSERV users
mailserv_*	RESTRICTED: MAILSERV admin user settings
Access mapping table MTA options	
access_auth	(New in MS 8.0) Control whether certain FROM_ACCESS mapping table probes include the SMTP MAIL FROM AUTH parameter's value
access_counts	(New in MS 6.3.) Control whether certain *_ACCESS mapping table probes include recipient count fields
access_errors	Control the information issued in certain error messages
access_orcpt	Control whether certain *_ACCESS mapping table probes include an ORCPT field
include_connectioninfo	(New in MS 6.2) Include transport and application connection information in various (mailing list related) mapping table probes
include_conversiontag	(New in MS 6.3) Include the conversion tag value(s) in mapping table probes
include_domain	(New in MS 8.0.2.3) Include the destination domain in various mapping table probes
include_mtpriority	(New in MS 8.0) Include the value of a message's MT-PRIORITY in various mapping table probes

include_spares1	(New in MS 7u2, renamed from include_spares in 8.0.2.2) Include the values of the LDAP attributes named by the ldap_spare_N MTA options in FROM_ACCESS and/or recipient address access mapping table probes
mapping_paranoia	(New in MS 7.0) Control handling of vertical bar characters in various mapping table probes, especially *_ACCESS mapping table probes
use_auth_return	(New in MS 7.0) Control use of authenticated sender address in place of the envelope From address in various address matching contexts
use_canonical_return	(New in MS 6.3) Control address reversal of envelope From address for purposes of address matching in various contexts
use_ip_access	(New in MS 7.0) Control format of probes to the IP_ACCESS mapping table
Miscellaneous mapping table MTA options	
averages_cache_size	RESTRICTED: New in MS 6.2 but not yet fully implemented. Control caching of the load average data accessed from mapping table callouts.
averages_cache_timeout	RESTRICTED: New in MS 6.2 but not yet fully implemented. Control caching of the load average data accessed from mapping table callouts.
include_conversiontag	(New in MS 6.3) Include the conversion tag value(s) in mapping table probes
include_domain	(New in MS 8.0.2.3) Include the destination domain in various mapping table probes
include_mtpriority	(New in MS 8.0) Include the value of a message's MT-PRIORITY in various mapping table probes
include_spares2	(New in MS 8.0) Include the values of the LDAP attributes named by the ldap_spare_N MTA options in FORWARD mapping table probes
message_save_copy_flags	(New in MS 6.3) Control the format of MESSAGE-SAVE-COPY mapping table probes
original_channel_probe	RESTRICTED: Determine the "input" channel for CONVERSIONS mapping table probes performed by the conversion channel and certain other, special, channels
use_comment_strings	Control the format of COMMENT_STRINGS mapping table probes
use_personal_names	Control the format of PERSONAL_NAMES mapping table probes
url_result_cache_case	New in MS 8.1.0.2. Controls whether URLs are treated in a case-sensitive fashion.

url_result_cache_size	Number of rewrite rule LDAP URL lookups and mapping table LDAP URL lookups ($]...[lookups) to keep cached
url_result_cache_timeout	How long to cache results of rewrite rule LDAP URL lookups and mapping table LDAP URL lookups ($]...[lookups)
Memcache MTA options	
alias_database_url	(New in MS 8.0) memcache: URL for storing alias database data
domain_database_url	(New in MS 8.0) memcache: URL for storing domain database data
enable_sieve_memcache	(New in MS 8.0) Control whether Sieve filters may use the private memcache extension
enable_sieve_redis	(New in MS 8.0.2.3) Control whether Sieve filters may use the private redis extension
forward_database_url	(New in MS 8.0) memcache: URL for storing forward database data
general_case	Controls the case sensitivity of general database lookups
general_database_url	(New in MS 8.0) memcache: URL for storing general database data
reverse_database_url	(New in MS 8.0) memcache: URL for storing reverse database data
memcache_expire	(New in MS 8.0) Time to hold idle memcached connections open
memcache_hash_algorithm	(New in 8.1.0.3) Hash function to apply to memcache keys
memcache_host	(New in MS 8.0) Host name of memcached server
memcache_port	(New in MS 8.0) Memcached service port
Message archival and hashing MTA options	
journal_format	(New in MS 7.0.5) Specify whether capture message copies generated in "journal" format are generated in 2003 *vs*. 2007 "journal" style
message_hash_algorithm	(New in MS 6.3) Algorithm to use for generating message hashes for message archiving
message_hash_fields	(New in MS 6.3) Header fields to include when generating a message hash
unique_id_template	(New in MS 6.3) Specify a template used to convert an address into a unique identifier, typically used in conjunction with archiving facilities
Message size MTA options	
block_limit	Limit the size of messages allowed through the MTA
block_size	Set the size of MTA "blocks"

bounce_block_limit	Limit the amount of original message content included in bounce messages
content_return_block_limit	Force NOTARY non-return of content flag for messages over the specified size
error_text_block_over	Specify error text returned in some cases of exceeding a destination channel blocklimit
error_text_line_over	Specify error text returned in some cases of exceeding a destination channel linelimit
error_text_list_block_over	Specify error text returned in some cases of exceeding a list's [BLOCKLIMIT] or mgrpMsgMaxSize value
error_text_list_line_over	Specify error text returned in some cases of exceeding a list's [LINELIMIT] value
error_text_user_block_over	Specify error text returned in some cases of exceeding a user's mailMsgMaxBlocks value or the [BLOCKLIMIT] value for an alias
error_text_user_line_over	Specify error text returned in some cases of exceeding a user's [LINELIMIT] value
header_limit	Sets a maximum size for the primary (outermost) message header
line_limit	Limit the size of messages allowed through the MTA
max_header_block_use	Fine tune message fragmentation
max_header_blocks	Truncate message header after the specified number of MTA blocks
max_header_line_use	Fine tune message fragmentation
max_header_lines	Truncate message header after the specified number of lines
max_mime_levels	Degree to look inside MIME messages during processing
max_mime_parts	Number of parts to look at when processing MIME messages
normal_block_limit	Maximum size of message to treat as being of normal or higher priority
non_urgent_block_limit	Maximum size of message to treat as being of non-urgent priority
second_class_block_limit	Maximum size of message to treat as being of second class priority
urgent_block_limit	Maximum size of message to treat as being of urgent priority
Message Store insertion logging MTA options	
logfile	logfile options set at the MTA level (mta.logfile.*option-name* in Unified Configuration) affect the MTA's logging of insertion of messages into the Message Store; that is, affect logging of message insertions performed by ims-ms and tcp_lmtpss_* channels

Message tracking MTA options	
log_times	(New in MS 8.0) Include requested deferral time in MTA message transaction log entries
log_tracking	(New in MS 8.0) Include tracking ID in MTA message transaction log entries
tracking_hash_algorithm	(New in 8.1.0.3) Select the hash algorithm the MTA uses to generate hashes of tracking and recall secrets. The default is SHA-1.
tracking_mode	(New in MS 8.0) Enable/disable the MTA's tracking support
tracking_debug	(New in MS 8.0) Level of debug output regarding tracking
tracking_retries	(New in MS 8.0) How many times the MTA will reattempt a tracking update
tracking_retry_delay	(New in MS 8.0) The time to wait between tracking update reattempts
MeterMaid MTA options	
enable_sieve_metermaid	(New in MS 8.0) Control whether Sieve filters may use the private metermaid extension
metermaid_backoff	(New in MS 7.2)
metermaid_expire	(New in MS 7.2)
metermaid_host	(New in MS 7.2)
metermaid_port	(New in MS 7.2)
metermaid_secret	(New in MS 7.2)
metermaid_timeout	(New in MS 7.2)
MLS MTA options	
error_text_mls_access_failure	(New in MS 7.0) RESTRICTED: Not yet used
ldap_mlsrange	(New in MS 7.0) RESTRICTED: Not yet used
mls	(New in MS 7.0) RESTRICTED: Not yet fully implemented
MTQP MTA options	
mtqp_expire	(New in MS 8.0) Specify the MTQP expiration, in seconds
mtqp_port	(New in MS 8.0) Specify the MTQP port
mtqp_timeout	(New in MS 8.0) Specify the MTQP timeout, in seconds
Notification message MTA options	
bounce_block_limit	Limit the amount of original message content included in bounce messages
content_return_block_limit	Force NOTARY non-return of content flag for messages over the specified size

history_to_return	Control the amount of delivery attempt history included in bounced messages
ldap_domain_attr_report_address	Name of domain level LDAP attribute whose value specifies a domain-specific postmaster address
lines_to_return	Lines included when returning samples of message content (as in warning messages)
notary_decode	Control whether encoded-words in the original message header are decoded when performing a %H substitution during the MTA's generation of DSNs and MDNs
notary_quote	Specify the character that marks substitution sequences in return_*.txt files and disposition_*.txt files
return_address	Set the return address for the local postmaster
return_debug	Enable debugging of MTA periodic return job operations
return_delivery_history	Control whether delivery attempt history is included in returned messages
return_envelope	Control use of empty return address in notification messages, and validity checks on envelope From address
return_personal	Set the personal name for the postmaster
return_units	Control the assumed units for the notices channel option, thereby controlling the interval at which certain notification messages are generated
return_verify	(New in MS 7.0.5, replacing former imta_return_verify MTA Tailor option) Enable shell script logging within the MTA return job
use_precedence	Control whether delayed delivery notification messages are sent for list and bulk precedence messages
use_warnings_to	DELETED as of MS 7.0.5: Whether to send DSNs to Warnings-to: address
Password and TLS MTA options	
plaintextmincipher	(New in MS 7.4-18.01; available as an MTA level option in Unified Configuration only) Disable PLAINTEXT SMTP AUTH unless SSL or TLS is active
smtpproxypassword	(New in MS 7.0.5) Replaces the former TCP/IP channel option file option PROXY_PASSWORD
sslnicknames	(New in MS 7.4-18.01; available as an MTA level option in Unified Configuration only) SSL/TLS server certificate nicknames the MTA will offer
Processing priority MTA options	
defer_group_processing	Set a default for whether direct LDAP group (list) expansion is deferred to the reprocess channel

log_mtpriority	(New in MS 8.0) Include message MT-PRIORITY in MTA message transaction log entries
log_priority	Include message priority in MTA message transaction log entries
mtpriority_policy	(New in MS 8.0) MT-PRIORITY policy name to announce in SMTP EHLO response
normal_block_limit	Maximum size of message to treat as being of normal or higher priority
non_urgent_block_limit	Maximum size of message to treat as being of non-urgent priority
second_class_block_limit	Maximum size of message to treat as being of second class priority
urgent_block_limit	Maximum size of message to treat as being of urgent priority
use_precedence	Control whether delayed delivery notification messages are sent for list and bulk precedence messages
Received header line MTA options	
held_sndopr	Send operator or syslog messages when messages are HELD
id_domain	Set the domain name used in constructing message IDs
max_local_received_lines	Occurrences of the local host name in Received: headers after which a message will be HELD
max_mr_received_lines	Number of MR-Received: headers after which a message will be HELD
max_received_lines	Number of Received: headers after which a message will be HELD
max_total_received_lines	Number of Received:, MR-Received: or X400-Received: headers after which a message will be HELD
max_x400_received_lines	Number of X400-Received: headers after which a message will be HELD
received_domain	Specify the domain name (identifying the system itself) to use in constructing Received: headers
received_version	Specify the IMTA version string to use in constructing Received: header lines; use is **NOT RECOMMENDED**
Sieve filter MTA options	
systemfilter	System Sieve filter, applied to all messages at each enqueue
sieve_body_needed	Specifies whether or not to retain decoded MIME body information when initial message analysis is performed.

sieve_mime_needed	Specifies whether or not to retain inner MIME structure and header information when initial message analysis is performed.
Sieve filter interpretation MTA options	
decode_encoded_words	RESTRICTED: Decode encoded words during Sieve processing
defer_header_addition	(New in MS 7.0.5.30.0) Control whether Sieve filters see any headers added prior to Sieve processing
filter_discard	Control whether messages discarded by a Sieve filter are immediately deleted, or instead routed to the filter_discard channel for delayed deletion
filter_jettison	New in MS 6.1. Control whether messages jettisoned by a Sieve filter are immediately deleted, or instead routed to the filter_discard channel for delayed deletion
notify_ignore_errors	(New in MS 7.0.5) Control whether to abort or ignore invalid recipient in Sieve notify action
sieve_received	(New in MS 8.0) Make synthesized Received: header line visible for Sieve filter evaluation
sieve_redirect_add_resent	(New in MS 6.3p1) System default for whether Sieve "redirect" actions cause addition of Resent-* header lines
sieve_user_carryover	Specify whether user Sieve filters "carry over" for (direct LDAP mailDeliveryOption: forward) forwarded recipients
Sieve filter limit MTA options	
max_addheaders	Maximum number of Sieve "addheader" actions that can be performed
max_duplicates	(New in MS 8.0) Maximum "duplicate" tests performed in a Sieve filter
max_fileintos	Maximum number of "fileinto" actions that may be performed by a Sieve filter
max_notifys	(New in MS 6.2) Maximum number of Sieve "notify" actions that may be applied in a Sieve filter
max_redirect_addresses	(New in MS 7.0u1) Maximum number of addresses which will be used from a Sieve external list used in a redirect; *i.e.*, maximum addresses that will be used from a redirect :list Sieve action
max_redirects	Maximum number of Sieve "redirect" actions (*i.e.*, forwards) that may be performed in a Sieve filter
max_sieve_list_size	Maximum number of elements allowed in a Sieve string-list structure
max_sieve_list_size	(New in MS 8.1) Maximum number of iterations allowed in a Sieve :matches operation

max_sieve_string_size	(New in MS 7.0u3) Maximum size allowed for any string in a Sieve script
max_vacations	Maximum number of vacation actions that may appear in a Sieve filter
max_variables	(New in MS 6.2) Maximum number of variables that may be used in a Sieve script
Sieve filter caching MTA options	
filter_cache_size	(New in MS 6.2) Specify the size of the per-process cache of tokenized Sieve filters
filter_cache_timeout	(New in MS 6.2) Specify the retention time for entries in the per-process cache of tokenized Sieve filters
Sieve language extension MTA options	
enable_sieve_body	Control whether Sieve filters may use the body extension
enable_sieve_ereject	(New in MS 7.0u2) Control whether Sieve filters may use the ereject extension
enable_sieve_memcache	(New in MS 8.0) Control whether Sieve filters may use the private memcache extension
enable_sieve_metermaid	(New in MS 8.0) Control whether Sieve filters may use the private metermaid extension
enable_sieve_redis	(New in MS 8.0.2.3) Control whether Sieve filters may use the private redis extension
enable_sieve_regex	Control whether Sieve filters may use the regex extension (the :regex match-type)
strict_require	Control whether or not to strictly enforce certain rules regarding the syntax of use of "require" in Sieve filters
Sieve filter duplicate extension MTA options	
duplicate_maximum_timeout	(New in MS 8.0) Maximum period in seconds for Sieve duplicate test storage timeout
duplicate_minimum_timeout	(New in MS 8.0) Minimum period in seconds for Sieve duplicate test storage timeout
duplicate_timeout_default	(New in) Default period in seconds for Sieve duplicate test storage timeout
duplicate_tracking_url	(New in) Template for locating per-user duplicate message information
max_duplicates	(New in MS 8.0) Maximum "duplicate" tests performed in a Sieve filter
Sieve filter error text MTA options	
error_text_sieve_access	Specify the error text used when reporting on an error accessing a user's Sieve filter file (for Sieve filters stored on disk)
error_text_sieve_syntax	Specify the error text used when reporting on a syntax error in a user Sieve filter

error_text_source_sieve_access	Specify the error text used when reporting on an error accessing a source channel Sieve filter file (for Sieve filters stored on disk)
error_text_source_sieve_syntax	(New in MS 6.3) Specify the error text used when reporting on a syntax error in a source channel Sieve filter
error_text_source_sieve_authorization	(New in MS 6.3) Specify the error text used when reporting on a general error encounted attempting to use a source channel Sieve filter
Sieve filter log and debug MTA options	
filter_debug	(New in MS 6.2) Control whether detailed (stack state) debugging of Sieve filter evaluation is output
log_dkim	(New in 8.1.0.6) Include information about DKIM signing operations in message transaction log entries
log_filter	Include applicable Sieve filter actions in MTA message transaction log entries
log_from	(New in 8.1.0.2) Include the address found in the From: header field in message transaction log entries
log_smartsend	(New in 8.1.0.1) Include additional information about smartsend plugin actions in MTA message transaction log entries
log_transactionlog	(New in MS 8.0) Include Sieve "transactionlog" action strings in MTA message transaction log entries
Spamfilter MTA options	
access_errors	Control the information issued in certain error messages
brightmail_*	Aliases for corresponding spamfilter_* MTA options; see the spamfilter_* options for definitions
scan_channel	(New in MS 7.0.5) Channel to consider as source channel when initializing the MTA for spam/virus filter package checks performed by non-channel applications and utilities such as imexpire
scan_originator	(New in MS 7.0.5) Address to consider as the MAIL FROM/envelope From address when initializing the MTA for spam/virus filter package checks performed by non-channel applications and utilities such as imexpire
scan_recipient	(New in MS 7.0.5) Address to consider as the RCPT TO/envelope To address when initializing the MTA for spam/virus filter package checks performed by non-channel applications and utilities such as imexpire
error_text_spamfilter*N*_error	Specify default error text to return in cases of spam/virus filter package problems

ldap_domain_attr_optin*N*	Name of domain-level LDAP attribute selecting opt-in to spam/virus filter package *N* processing
ldap_optin*N*	Name of user-level LDAP attribute selecting opt-in to spam/virus filter package *N* processing
ldap_source_optin*N*	Name of user-level LDAP attribute selecting source opt-in to spam/virus filter package *N* processing
ldap_optoutN	Name of user-level LDAP attribute used to opt-out of spam/virus filter package N processing
optin_user_carryover	(New in MS 6.2.) Specify whether user spam/virus filter "opt-in" is considered to "carry over" for forwarded recipients
spamfilter_*	As of MS 6.3, obsoleted in favor of the new-in-MS-6.3 spamfilter1_* options with which they are (became in MS 6.3) synonymous
spamfilter*N*_action_*M*	(Values for *N* of 1--4 are new in MS 6.2; values of 5--8 are new in MS 6.3.) URL that resolves to a Sieve filter, specifying the action to take when the Nth spam/virus filter package returns the corresponding Mth verdict, that is, the action to take corresponding to the spamfilter*N*_verdict_*M* verdict
spamfilter*N*_config_file	(Values for N of 1--4 are new in MS 6.2; values of 5--8 are new in MS 6.3.) Location of the configuration file for the Nth spam/virus filter package
spamfilter*N*_final	(Values for N of 1--4 are new in MS 6.2; values of 5--8 are new in MS 6.3.) Control whether the MTA passes the "intermediate" *vs*. "final" address form to the Nth spam/virus filter package
spamfilter*N*_includeheaders	(New in MS 7.0.5) Specify whether or not to pass to the Nth (N in the range 1--8) spam/virus filter package any header lines added via the $A flag in an address *_ACCESS mapping table
spamfilter*N*_library	(Values for N of 1--4 are new in MS 6.2; values of 5--8 are new in MS 6.3.) Location of the client shared library for the Nth spam/virus filter package
spamfilter*N*_name	(New in MS 7.0.5) Specify a symbolic name for the *N*th spam/virus filter package.
spamfilter*N*_null_action	URL that resolves to a Sieve filter, specifying the action(s) to take in the case of a null verdict from the Nth spam/virus filter package
spamfilter*N*_null_optin	(Values for *N* of 1-4 are new in MS 6.2; values of 5--8 are new in MS 6.3.) Specify a value for the attribute named by the ldap_domain_attr_optin*N* MTA options, the ldap_optin*N* MTA options, the (new in MS 8.0.1.3) ldap_optout*N* MTA options, or the (new in MS 6.3) ldap_source_optin*N* MTA options that means that the attribute should be ignored; the purpose is to allow use of these attributes by provisioning facilities that find it easier

	to set an attribute value rather than to remove an attribute entirely
spamfilter*N*_optional	What to do if a spam/virus filter package is not responding: temporarily reject message *vs.* allow to pass unfiltered, plus whether to send syslog notice
spamfilter*N*_received	(New in MS 6.2) Specify whether or not to generate a pseudo-Received: header line to pass to the spam/virus filter package.
spamfilter*N*_returnpath	(New in MS 7.0 update 1) Control whether or not to add a Return-path: header line to the message passed to the spam/virus filter package
spamfilter*N*_string_action	(Values for N of 1--4 are new in MS 6.2; values of 5--8 are new in MS 6.3.) URL that resolves to a Sieve filter, specifying the action(s) to take in the case of verdicts from the Nth spam/virus filter package that do not have an explicit corresponding action
spamfilter*N*_verdict_*M*	(Values for N of 1--4 are new in MS 6.2; values of 5--8 are new in MS 6.3.) For the Nth spam/virus filter package, its Mth verdict string
SPF MTA options	
error_text_spf_*	(New in MS 6.3, but not taking effect until MS 8.0) Set the text for any of several SPF-related errors
spf_max_dns_queries	(New in MS 6.3-0.15) Maximum DNS queries per SPF check
spf_max_recursion	(New in MS 6.3-0.15) Maximum recursion during SPF checks
spf_max_time	(New in MS 6.3-0.15) Maximum time (seconds) permitted for performing an SPF check
spf_smtp_status_fail	(New in MS 6.3-0.15) How to interpret an SPF domain verification failure
spf_smtp_status_fail_all	(New in MS 6.3-0.15) How to interpret an SPF subdomain verification failure
spf_smtp_status_permerror	(New in MS 6.3-0.15) Interpretation of DNS permanent errors on SPF attempts
spf_smtp_status_softfail	(New in MS 6.3-0.15) How to interpret an SPF "soft" domain verification failure
spf_smtp_status_softfail_all	(New in MS 6.3-0.15) How to interpret an SPF subdomain "soft" verification failure
spf_smtp_status_temperror	(New in MS 6.3-0.15) How to interpret DNS temporary errors during SPF lookups
SRS MTA options	
error_text_srs_*	(New in MS 7.0u2) Set the text for any of several SRS-related errors
srs_domain	(New in 6.3p1) Domain to use in SRS addresses.

srs_hash_algoritm	(New in 8.1.0.3) Hash algorithm to use when building SRS addresses.
srs_maxage	(New in 6.3p1) Number of days before an SRS address times out
srs_secrets	(New in 6.3p1) Secret keys used for encoding and decoding SRS addresses
token_char	Specify token character in local-part of address for SRS purposes
Syslog MTA options	
held_sndopr	Send operator or syslog messages when messages are HELD
log_connections_syslog	Send MTA connection transaction log entries to syslog (UNIX)
log_messages_syslog	Send MTA message transaction log file entries to syslog
log_sndopr	Send an operator or syslog message if the MTA's logging facilities encounter a difficulty
log_syslog_prefix	(New in MS 8.0.2.3.) Specifices the prefix used on MTA message transaction log file entries sent to syslog
sndopr_prefix	(New in MS 8.0.2.3.) Set the prefix attached to syslog notices.
sndopr_priority	Set the priority of operator broadcast or the syslog level of syslog messages
spamfilter*N*_optional	What to do if a spam/virus filter package is not responding: temporarily reject message *vs.* allow to pass unfiltered, plus whether to send syslog notice
Transaction logging MTA options	
log_alq	(OpenVMS only) Specify the default allocation quantity for the MTA transaction log file(s)
log_auth	(New in MS 7.0.5) Include SMTP MAIL FROM's AUTH parameter in MTA message transaction log entries
log_callout_delays	(New in MS 8.0) Include timers showing the time for responses from external components in MTA message transaction log entries
log_connection	Include connection information in MTA transaction log entries
log_connections_syslog	Send MTA connection transaction log file entries to syslog (UNIX) in addition to, or instead of to, MTA connection transaction log file
log_conversion_tag	(New in MS 7.0.5) Include conversion tag(s) field in MTA message transaction log entries
log_debug	RESTRICTED: Enable debugging of MTA logging operations

log_deq	(OpenVMS only) Specify the default extend quantity for the MTA transaction log file(s)
log_delivery_flags	(New in MS 7.0.5) Include delivery flags field in MTA message transaction log entries
log_diagnostics	(New in MS 7.0u1) Include diagnostics in MTA message transaction log entries
log_dkim	(New in 8.1.0.6) Include information about DKIM signing operations in message transaction log entries
log_envelope_id	(New in MS 6.1) Include envelope id in MTA message transaction log entries
log_filename	Include message file names in MTA message transaction log entries
log_filter	Include applicable Sieve filter actions in MTA message transaction log entries
log_format	Control the format of the MTA transaction log file(s)
log_from	(New in 8.1.0.2) Include the address found in the From: header field in message transaction log entries
log_futurerelease	(New in) Include value of FUTURERELEASE SMTP extension in MTA message transaction log entries
log_header	Include message headers in MTA message transaction log entries
log_imap_flags	(New in MS 7.0.5) Include any IMAP flags set by the MTA in MTA message transaction log entries
log_intermediate	(New in MS 6.2) Include the "intermediate" address and/or "original" (RCPT TO: command line) forms of destination address in MTA message transaction log entries
log_isc_status	(New in MS 8.0.2) Include Indexed Search Converter status information in LMTP server MTA message transaction log entries
log_local	Include the local domain name on "bare user name" addresses in MTA message transaction log entries
log_mailbox_uid	(New in MS 7.0.5) Include the IMAP UID and UIDVALIDITY of messages delivered by ims-ms channel to the Message Store in MTA message transaction log entries
log_message_id	Include message IDs in MTA message transaction log entries
log_messages_syslog	Send MTA message transaction log file entries to syslog in addition to, or instead of to, MTA message transaction log file
log_mtpriority	(New in MS 8.0) Include message MT-PRIORITY in MTA message transaction log entries

log_node	(OpenVMS only prior to MS 6.3) Include the node name on which process runs in MTA message transaction log entries
log_notary	Include a NOTARY (delivery receipt) flags indicator in MTA message transaction log entries
log_priority	Include message priority in MTA message transaction log entries
log_process	Include process ID in MTA message transaction log entries
log_queue_time	(New in MS 6.3) Include "time in queue" in MTA message transaction log entries; this also causes inclusion of "time to open or fail to open a connection" in MTA connection log entries
log_reason	(New in MS 6.3) Include reason for message rejection in MTA message transaction log entries
log_remota_mta	(New in MS 8.0.2.3) Include remote MTA name in MTA message transaction log entries
log_sensitivity	Include message's sensitivity value in MTA message transaction log entries
log_smartsend	(New in 8.1.0.1) Include additional information about smartsend plugin actions in MTA message transaction log entries
log_sndopr	Send an operator or syslog message if the MTA's logging facilities encounter a difficulty
log_syslog_prefix	(New in MS 8.0.2.3.) Specifices the prefix used on MTA message transaction log file entries sent to syslog
log_times	(New in MS 8.0) Include requested deferral time in MTA message transaction log entries
log_tracking	(New in 8.0) Include message tracking ID in MTA message transaction log entries
log_transactionlog	(New in MS 8.0) Include Sieve "transactionlog" action strings in MTA message transaction log entries
log_uid	(New in MS 8.0) Include recipient UIDs in MTA message transaction log entries
log_use_xtext	(New in MS 8.0) Controls xtext encoding of addresses in MTA message transaction log entries
log_username	Include the username for an enqueuing process in MTA transaction log entries
log_8bit_encode	Controls how non-ASCII characters are written in XMl format MTA transaction log file(s)
return_cleanup_period	Run site's cleanup script every *N*th run of return_job
return_split_period	Start new mail.log_current file every *N*th run of return_job

separate_connection_log	Write connection transaction log entries to a separate file than message transaction log entries
OpenVMS user agent MTA options	
delivery_receipt_off	(OpenVMS only) Comment string that disables delivery receipt request
delivery_receipt_on	(OpenVMS only) Comment string that enables delivery receipt request
dis_nesting	(OpenVMS only) Nesting allowed for VMS MAIL @DIS lists
form_names	(OpenVMS only) List of the names of pop-up form images
mail_delivery_filename	(OpenVMS only) Set MAIL.DELIVERY filename
missing_address	(OpenVMS only) Address to insert of VMS MAIL From: if empty
multinet_mm_exclusive	(OpenVMS only) VMS MAIL *vs.* Multinet MM mailbox
read_receipt_off	(OpenVMS only) Comment string that disables read receipt request
read_receipt_on	(OpenVMS only) Comment string that enables read receipt request
safe_tcl_mode	(OpenVMS only) Control handling of Safe-Tcl message parts
use_mail_delivery	(OpenVMS only) Enable MAIL.DELIVERY processing
vms_mail_exclusive	(OpenVMS only) VMS MAIL *vs.* Multinet MM mailbox

+ Note that the MTA's SMTP AUTH user authentication lookups are done using general authentication library code, also used for IMAP, POP, or mshttpd user logins (authentication). The authentication library code generally does not make use of the MTA-specific options, but rather is controlled by Auth options (or in legacy configuration, configutil parameters). However, for a few specific cases of MTA options affecting authentication library operation, see the Direct LDAP attributes returned upon authentication MTA options.

52.6 enable Option Under mta

The enable MTA option, mta.enable (Unified Configuration) or local.imta.enable (legacy configuration), provides a default setting for the dispatcher.enable option and the job_controller.enable option. The mta.enable option is deprecated in favor of the two more explicit enable options.

The default if this option is not explicitly set is 0, but initial configuration may set this option to enable the MTA, as appropriate.

52.7 Alias and address MTA options

This discussion will focus on those MTA options that affect and modify certain fundamental aspects of MTA alias and address handling, and in particular those MTA options

affecting MTA alias file or alias database handling. See also the use_auth_return, use_canonial_return, and use_orig_return MTA options, which among other things can affect the form of envelope From address used in recipient-address-based *_ACCESS mapping table probes and in mailing list named parameter [*_MAPPING] mapping table probes.

For options relating more specifically to mail group or mail list handling, (as note that groups and lists are merely special forms of alias), see also Mailing list and group MTA options.

And for the (many, many) options relating more specifically to aliases stored in LDAP -- the so-called "Direct LDAP" MTA options -- see also Direct LDAP MTA options.

The ap_debug MTA option enables low-level debugging (typically meaningful only to Oracle support) relating to the parsing of aliases and addresses; (the mm_debug MTA option enables somewhat higher-level debugging of address handling, which also is typically meaningful only to Oracle support.)

52.7.1 Alias and address case sensitivity option (alias_case)

Use of settings other than those recommended by Oracle is RESTRICTED.

The alias_case option controls whether aliases (alias names) in the alias database or alias file, or in Unified Configuration alias options, are case sensitive. (It does not affect alias lookups in LDAP, that is, alias_urlN lookups: since the schema defines the mail, mailAlternateAddress, and mailEquivalentAddress LDAP attributes as case-insensitive, LDAP searches for these attributes are performed case-insensitively.) (Note that the MTA always preserves the case of the alias translation value, that is, the right hand side; the point of the alias_case option is to control whether the alias on the left hand side is case sensitive for matching purposes.) Note that even if aliases are case sensitive in general, postmaster aliases are always case insensitive. The default value is 0, meaning that aliases are not case sensitive. Bits 0 through 2 (values 0 through 7) control handling of alias file lookups (corresponding in Unified Configuration to alias options); higher bits control the handling of alias database lookups.

Table 52.3 alias_case MTA option values

Value	Usage
Lower bits (alias file and alias options)	
0	Case insensitive alias file aliases
1	Case sensitive alias file aliases
2	Alias file aliases are first searched for case-sensitively, but if not found, perform a case-sensitive search
3	Alias file aliases are first searched for case-sensitively, but if not found, perform a case-sensitive search
Higher bits (alias database)	
8	Case insensitive alias database aliases
9	Case sensitive alias database aliases and new in MS 8.0, case insensitive comparisons for memcache storage of the alias database (alias_database_url)

10	Alias database aliases are first searched for case-sensitively, but if not found, perform a case-sensitive search and new in MS 8.0, case insensitive comparisons for memcache storage of the alias database (alias_database_url)
11	Alias database aliases are first searched for case-sensitively, but if not found, perform a case-sensitive search and new in MS 8.0, case insensitive comparisons for memcache storage of the alias database (alias_database_url)

Bit 0 is the least significant bit.

52.7.2 Domains in alias lookups (alias_domains)

The alias_domains MTA option takes a bit encoded integer argument controlling the format of alias file (and hence in Unified Configuration alias option) and alias database lookups. (This option does not affect alias_urlN lookups.)

As of Messaging Server 7.0-3.01, the default value of alias_domains is 6, meaning that alias file and alias database lookups probe first with the entire address, then probe with a wildcarded localpart plus domain, and finally addresses matching the local channel probe with solely the localpart; previously, the default value had been 1, meaning that alias file and alias database lookups would probe with only the localpart (mailbox portion) of the address. Note that for addresses matching the local channel, the a localpart-only probe is made even if bit 0 (value 1) is not set. Setting bit 1 (value 2) causes a probe to be made using the entire address (including the domain name). Setting bit 2 (value 4) when bit 1 (value 2) is also set causes an additional, fall-through wildcard * probe -- effectively a "domain catchall address" probe -- to be made. Indeed, if the address included a subaddress, setting bit 2 (value 4) causes two wildcard * probes to be made, first *+*@*domain-name* and then *@*domain-name*. (For wildcarding solely the subaddress, not the localpart, see the subaddresswild channel option.) If all bits are set, *i.e.*, alias_domains=7, then the order of the probes is to first probe with the entire address (the most specific check), next probe with a wildcard * localpart plus the domain name, and finally probe with just the localpart.

Table 52.4 alias_domains MTA option bit values

Bit	Value	Usage
0	1	Look up *localpart*. Clearing this bit disables the lookup of unadorned localparts for channels other than the local channel; for the local channel, localparts are always looked up.
1	2	Look up *localpart@domainname*.
2	4	If performing entire address probes (that is, if bit 1 is also set) and if no exact match was found, try lookups with the * character for the username; more precisely, an *+*@*domainname* (if the address included a subaddress), and an *@*domainname* lookup.

Bit 0 is the least significant bit.

Note that by default only addresses rewritten to the local channel are checked against the alias file and alias database. However, via use of the aliaslocal channel option, it is possible to cause addresses matching other channels to be checked against the alias file and alias database for aliases, at which point alias_domains can affect aliasing of addresses rewriting to those other channels. Note that the effect of bit 2 (value 4), that is, the probes with the * character as the localpart, can be controlled on a per-channel basis via the aliaswild channel option.

52.7.3 Alias lookup control: alias_magic (integer)

The alias_magic MTA option controls the ordering of alias lookups. It takes a decimal-encoded integer argument, where each decimal digit represents a type of alias lookup, and the ordering of the digits controls the ordering of the lookups. The ones' place controls the first thing looked up; the tens' place controls the second thing looked up; the hundreds' place controls the third thing looked up; *etc*. A value of 1 means personal aliases; a value of 2 means logical aliases; a value of 3 means the alias database; a value of 4 means the alias file; a value of 6 means the alias_url0 LDAP lookup; a value of 7 means the alias_url1 LDAP lookup; a value of 8 means the alias_url2 LDAP lookup; a value of 9 means the alias_url3 LDAP lookup.

Prior to 7.0U3 the default value for this option was 98764321; in 7.0U3 and later the default has been changed to the recommended operating value of 8764 for direct LDAP mode. Note that that does not enable alias_url3 lookups (value 9) or alias database lookups (value 3). An alternate, sensible value for direct LDAP *plus alias database* lookups would be

```
alias_magic=987643
```

The alias_magic MTA option can be overriden for specific channels via the aliasmagic channel option.

Caution: Support for this option is **RESTRICTED**. As the alias_magic option affects MTA operation at a very fundamental level, in particular its fundamental means of doing alias lookups, which can have wide-ranging, both obvious and subtle effects, setting this option to other than a Oracle-engineering-recommended value is not supported.

52.7.4 Alias and address MTA options: alternate_recipient (string)

(New in MS 8.0.1.) The alternate_recipient MTA option specifies the comment string, including the surrounding parentheses, that is used to specify an alternate recipient address as part of a mailing list address entry. The default value for this string is (ALTERNATE-RECIPIENT).

For example, assuming the default value of this option, an entry of the form:

```
listmember@domain.com (alternate-recipient listalternate@domain.com)
```

would associated the alternate address listalternate@domain.com with the mailing list address listmember@domain.com.

52.7.5 alternate_recipient_mode Option

The alternate_recipient_mode MTA option controls the order in which additional alternate recipients are added to an existing alternate recipient list. Possible values are:

0 old recipients follow new recipient

1 new recipient follows old recipient

2 new recipient replaces any old recipients

3 new recipient is silently dropped if any old recipients are present

The default is 0, which is consistent with military messaging requirements.

52.7.6 Alias and address MTA options: delimiter_char (1-127)

RESTRICTED.

(New in 7.0.) The delimiter_char MTA option controls what character represents a delimiter. The value of this option is an integer corresponding to the ASCII character value in decimal. The default is 124, corresponding to the vertical bar or "pipe" character, |.

52.7.7 Alias and address MTA options: exproute_forward (0 or 1)

The exproute_forward MTA option controls the application of the exproute channel option to forward-pointing (To:, Cc:, and Bcc: lines) addresses in the message header. A value of 1 is the default and specifies that exproute should affect forward-pointing header addresses. A value of 0 disables the action of the exproute channel option on forward-pointing addresses.

52.7.8 idn_config_file Option

(New in MS 8.0.2.) The idn_config_file MTA option specifies the location of an optional IDNKIT configuration file. Note that this file should not be necessary in normal usage. The option has no default value.

52.7.9 Alias and address MTA options: improute_forward (0 or 1)

The improute_forward MTA option controls the application of the improute channel option to forward-pointing (To:, Cc:, and Bcc: lines) addresses in the message header. A value of 1 is the default and specifies that improute should affect forward-pointing header addresses. A value of 0 disables the action of the improute channel option on forward-pointing addresses.

52.7.10 Alias and address MTA options: local_format_restrictions (bitmask)

The local_format_restrictions MTA option affects whether the pipe character (vertical bar) may appear in local (L) channel addresses. It also affects whether filename delivery format, *+filename@local-channel-domain-name*, is permitted. Note that authenticated submissions bypass such restrictions.

In a configuration with viaaliasrequired set on the local (L) channel, such as in normal Messaging Server MTA configuration, this option is not really relevant: the viaaliasrequired effect takes precedence in requiring that every local-part correspond to an actual user -- unless the pipe character or a leading plus character were to occur in a user's e-mail address, these syntaxes would inherently not correspond to actual user e-mail

addressses and hence not be permitted. But in a different sort of configuration, such as an old PMDF configuration, this option controls whether the special syntaxes are allowed in addresses matching the local (L) channel. The default value is 1, meaning that (in the absence of viaaliasrequired), pipe characters are disallowed but filename delivery is allowed.

Table 52.5 local_format_restrictions MTA option bit values

Bit	Value	Usage
0	1	Disallow pipes in local addresses
2	4	Disallow files in local addresses

Bit 0 is the least significant bit.

The error, if such a condition is violated (and with viaaliasrequired *not* set), will be:

```
5.1.3 invalid material in localpart of address: address
```

and as an SMTP error:

```
553 5.1.3 invalid material in localpart of address: address
```

52.7.11 Alias and address MTA options: max_alias_levels (integer)

The max_alias_levels MTA option controls the degree of indirection allowed in aliases, that is, how deeply aliases may be nested, with one alias referring to another alias, etc. This applies to direct LDAP alias lookups, as well as to traditional (legacy configuration) alias database and alias file lookups. The default value is 10. See Alias recursion and nested list definitions for some additional discussion.

52.7.12 Alias and address MTA options: missing_recipient_group_text (string)

The missing_recipient_group_text MTA option specifies the phrase to use when generating an empty group construct; that is, the phrase used when missing_recipient_policy=4 (MTA-wide) or missingrecipientpolicy=4 (channel level) is being applied. The default phrase, if this option is not set, is "Recipients not specified".

52.7.13 Alias and address MTA options: missing_recipient_policy (0-6)

RFC 822 (Internet) messages are required to contain a recipient header: a To:, Cc:, or Bcc: header. A message without any such header is illegal according to RFC 822. Nevertheless, some broken user agents and mailers (*e.g.*, many older versions of sendmail) will emit such illegal (per RFC 822) messages. Note that RFC 5322, the update to RFC 822, relaxes the RFC 822 requirement and allows submitted messages to be lacking in any recipient header line. However, unless it is certain that *all* the MTAs and MUAs that may ever handle a message in fact conform to RFC 5322 (rather than the older RFC 822), it is unwise to emit a message

lacking all recipient header lines, since the behavior of an RFC 822-compliant MTA or mail user agent may be undesirable when encountering a message that is, from its point of view, illegal---results may include rejection of such a message, potentially undesired exposure of recipient information such as recipients intended as Bcc: recipients, *etc*.

The `missing_recipient_policy` MTA option takes an integer value specifying what approach to use for such messages; the default value, if the option is not explicitly present, is 0. The meaning of this default value of 0 has changed: prior to MS 6.2, it was equivalent to 2, meaning that envelope To addresses are placed in a To: header line. As of MS 6.2, it is equivalent to 1, meaning to pass such messages through unchanged, in accordance with what RFC 5322 now recommends.

Table 52.6 `missing_recipient_policy` option values

Value	Action
0	Default; in MS 6.0 and 6.1 this corresponded to a value of 2, namely place envelope To recipients in a To: header line; as of 6.2, this corresponds to a value of 1, namely pass the message through unchanged, in accordance with what RFC 5322 now recommends.
1	Pass the illegal-per-RFC 822 (though legal per RFC 5322) message through unchanged.
2	Place envelope To recipients in a To: header line.
3	Place all envelope To recipients in a single Bcc: header line.
4	Generate an empty group construct (*i.e.*, ;) To: header line. The phrase used in the group construct is controlled by the `missing_recipient_group_text` MTA option, so for instance "`To: Recipients not specified: ;`".
5	Generate a blank Bcc: header line.
6	Reject the message. The SMTP error issued with such a rejection will be: "`554 5.6.0 Error writing message - message is missing required recipient header fields`" (Note that the `acceptalladdresses` channel option, if used, modifies the timing and form of the rejection.)

Note that the `missingrecipientpolicy` channel option can be used to set per-channel controls for this sort of behavior; such per-channel controls override the setting of the MTA option `missing_recipient_policy`.

52.7.14 Alias and address MTA options: `name_table_name` (string; OpenVMS only)

OpenVMS only.

The `name_table_name` MTA option specifies the name of a logical name table to be searched for address aliases by the MTA. This table name may itself be a logical name (in the process or system directory) which specifies one or more tables to search. This option has no default; if it is not specified logical name tables are not searched for aliases.

52.7.15 Alias and address MTA options: `reverse_envelope` (0 or 1)

RESTRICTED.

The reverse_envelope option controls whether or not the MTA applies address reversal to envelope From addresses as well as header addresses. This option will have no effect unless address reversal is being performed. That is, in order for reverse_envelope to have any effect, a reverse_url must be set, a REVERSE mapping must exist, or use_reverse_database must be set to a value causing use of the reverse database.

The default for reverse_envelope is 1, which means that the MTA will attempt to apply any address reversal to envelope From addresses. A value of 0 will disable address reversal from applying to envelope From addresses; that is, disable the reverse_url MTA option setting, the address reversal database, and the REVERSE mapping from affecting envelope From addresses.

Note that at typical Oracle Messaging Server sites, reverse_envelope=0**should not** be set as disabling reverse_url lookups on envelope From addresses will disable other intended functionality; see Intended side effects of LDAP address reversal.

52.7.16 Alias and address MTA options: subaddress_char (list of integers)

The subaddress_char MTA option specifies the ASCII representation of the character to use as the subaddress indicator in the mailbox portion of an address. The default is to use the plus character, +, which has ASCII representation 43.

Note that internally the ims-ms channel always expects to see a plus character, +, and is normally always passed the plus character due to the delivery_options MTA option, regardless of what character is used "externally" as the subaddress separator character.

52.7.17 SRS MTA options: token_char (integer position of ASCII character)

RESTRICTED.

The token_char MTA option controls what character represents a token in the local-part of addresses. This is relevant for SRS address handling. The value of this option is an integer corresponding to the ASCII character value in decimal. The default is 61, corresponding to the equal sign, =.

52.7.18 Alias and address MTA options: use_alias_database (0 or 1)

The use_alias_database MTA option controls whether or not the MTA makes use of the alias database as a source of system aliases for local addresses. The default is 1, which means that the MTA will check the database if it exists. A value of 0 will disable this use of the alias database.

52.7.19 Alias and address MTA options: use_domain_database (0 or 1)

The use_domain_database MTA option controls whether or not the MTA makes use of the domain database as a source of rewrite rules. In Messaging Server 7.2 and earlier, the default

was 1, which means that the MTA would check the database if it existed; as of Messaging Server 7.3, the default is 0, which disables consultation of the domain database.

52.7.20 Alias and address MTA options: use_forward_database (bitmask)

The use_forward_database MTA option controls whether or not the MTA makes use of the forward database, and also controls the exact format of probes of the forward database and FORWARD mapping table. The value is a decimal integer representing a bit-encoded integer, the interpretation of which is given in the table below.

Table 52.7 use_forward_database MTA option bits

Bit	Value	Usage
0	1	When set, the forward database is used.
3	8	When set, channel-level granularity is used with the forward database entries. Forward database entries' left hand sides must have the form (note the vertical bars, |) *source-channel*|*from-address*|*to-address* Note that source-specific forwarding is very seldom appropriate, and in those rare cases where it is appropriate, the forward database is seldom the most suitable choice for achieving it.
4	16	When set, channel-level granularity is used with the FORWARD or any domain catchall mapping. The mapping entries' patterns (left hand sides) must have the form (note the vertical bars, |) *source-channel*|*from-address*|*to-address* Note that source-specific forwarding is very seldom appropriate, and in those rare cases where it is appropriate, the FORWARD mapping is seldom the most suitable choice for achieving it.
5	32	When set, modifies the effect of bit 3 (source-specific forward database probes) by also including the destination channel in the probe.
6	64	When set, modifies the effect of bit 4 (source-specific FORWARD or domain catchall mapping probes) by also including the destination channel in the probe.
7	128	(New in 8.0) When set, includes the initial address presented for alias processing in the FORWARD mapping probe. This address appears immediately before the intermediate address included by bit 8 below.
8	256	(New in 8.0) When set, include the current intermediate address in the FORWARD mapping probe. This address appears immediately before the final recipient address.
9	512	(New in 8.0) When set, include the authenticated sender address address in the FORWARD or any domain catchall mapping probe. This address appears immediately after the destination channel and before conversion tags.

Bit 0 is the least significant bit.

The default value for use_forward_database is 0, which means that the MTA will not use the forward database at all. Note that a FORWARD mapping table, if present, is always consulted.

52.7.21 Alias and address MTA options: use_personal_aliases (0 or 1)

The use_personal_aliases MTA option controls whether or not the MTA makes use of personal alias databases as a source of aliases for local addresses. The default is 1, which means that the MTA will check such databases, if they exist. A value of 0 will disable personal aliases and make them unavailable to all users.

52.7.22 Alias and address MTA options: use_reverse_database (bitmask)

The use_reverse_database MTA option controls whether or not the MTA makes use of the address reversal database and REVERSE mapping table as a source of substitution addresses. (Note that it cannot disable use of any reverse_url setting, although its bit 2, value 4, does affect the scope of reverse_url application.) Its value is a decimal integer representing a bit-encoded integer, the interpretation of which is given in the table below.

Table 52.8 use_reverse_database MTA option bits

Bit	Value	Usage
0	1	When set, reverse database based address reversal is applied to addresses after they have been rewritten by the MTA address rewriting process; (this does not affect reverse_url or REVERSE mapping table based address reversal subsequent to address rewriting, which is controlled merely by the existence of a reverse_url setting or existence of a REVERSE mapping table, respectively).+
1	2	When set, reverse database and/or REVERSE mapping based address reversal is applied before addresses have had MTA address rewriting applied to them; (this does not affect reverse_url based address reversal, which always occurs after rewriting has been applied; for the REVERSE mapping, setting this bit causes an additional consultation of the REVERSE mapping prior to address rewriting, in addition to the subsequent to rewriting consultation which will always be performed).+
2	4	When set, address reversal, including the reverse_url option setting if applicable, will be applied to all (except envelope To) addresses, including forward-pointing header addresses, not just to backward-pointing addresses.
3	8	When set, channel-level granularity is used with the REVERSE mapping. REVERSE mapping table (pattern) entries must have the form (note the vertical bars, |) *source-channel|destination-channel|address*
4	16	When set, channel-level granularity is used with address reversal database entries. Reversal database entries' left hand sides must have the form (note the vertical bars, |) *source-channel|destination-channel|address*
5	32	Apply REVERSE mapping even if a reverse database entry has already matched.

6	64	Apply address reversal to message ids; see Internal host names in Received: and Message-Id: header lines for an example.
7	128	When set, this modifies the effect of bit 4 (channel-level granularity of address reversal database entries); when this bit is also set, the address reversal database entries take the form (note the vertical bars, |) *destination-channel|address*
8	256	When set, this modifies the effect of bit 3 (channel-level granularity of REVERSE mapping table entries); when this bit is also set, the REVERSE mapping table entries take the form (note the vertical bars, |) *destination-channel|address*
10	1024	During subsequent-to-rewriting address reversal, (that is, that reversal due to having bit 0 (value 1) set), this disables the normal initial reverse database lookup, though a database lookup can still be caused by a $D in the REVERSE mapping table
11	2048	During prior-to-rewriting address reversal, (that is, that reversal due to having bit 1 (value 2) set), this disables the normal initial reverse database lookup, though a database lookup can still be caused by a $D in the REVERSE mapping table
12	4096	(New in 8.0.) When set, include the name of the header field the address being processed came from in the mapping probe, delimited by vertical bars, immediately after source channel, destination channel, and conversion tag information. A trailing colon is always included in the field name. A blank name appears when envelope addresses are being processed.
13	8192	(New in 8.0.) When set, do not impose source block and recipient limits and capture actions based on the envelope from (MAIL FROM) address. For background discussion, see Intended side effects of LDAP address reversal.
14	16384	(New in 8.0.) When set, do not impose source block and recipient limits and capture actions based on the authenticated sender address. For background discussion, see Intended side effects of LDAP address reversal.

+In initial iMS 5.2 and earlier versions, the 0th and 1st bits of `use_reverse_database` not only controlled when, but also *whether* a REVERSE mapping table would be consulted at all for address rewriting; now if a REVERSE mapping table exists, it definitely *will* be consulted for address reversal (at least) subsequent to address rewriting; (depending upon bit 1, it may also be consulted prior to address rewriting). So this is a change from iMS 5.2 and earlier versions.

Bit 0 is the least significant bit.

The default value for `use_reverse_database` is 5, which means that in addition to consulting any `reverse_url` setting to reverse envelope From addresses and both backwards and forwards pointing header addresses after they have passed through the normal address rewriting process, the MTA will also consult any reverse database or REVERSE mapping to reverse Envelope From addresses and both backwards and forwards pointing header addresses after they have passed through the normal address rewriting process. Simple address strings are presented to both the REVERSE mapping and the reverse database. Note that a value of 0 disables the use of the address reversal completely. (Note that the default of 5 represents a change from early versions of PMDF in which this option had a default value of 1 (reverse only backwards pointing addresses).)

Note that as of 8.0.1.3, the `usereversedatabase` source channel option can be used to override the setting of `use_reverse_database` on a channel by channel basis.

52.7.23 Alias and address MTA options: user_case (0 or 1)

The user_case MTA option causes some effects of forcing user names to lower case (on certain "local" sorts of channels), affects the forcing-to-lowercase of variants of "postmaster", and can influence the sorting of addresses. The default is 1, which has the general meaning that case sensitive user names are permitted, except that any "postmaster" variants are forced to lower case. If set to 0, and if the localbehavior channel option is set either explicitly on a channel (or implicitly forced as with the l channel), then general user names matching that channel will be forced to lower case.

The user_case MTA option also potentially, depending upon other conditions, may affect the sorting of addresses.

52.8 Autoresponse periodicity MTA options

The MTA has several options affecting its memory/tracking of previous vacation (autoreply) messages, and as of 7.0.5 its Sieve notify autoresponses, and hence its limiting of successive such messages: in other words, options controlling the periodicity of autoresponses.

For each user, the MTA maintains an autoresponse information file, the purpose of which is to record for which prior messages a vacation message has already been sent, (or as of 7.0.5, a Sieve notify action was performed), used to avoid sending additional identical autoresponse messages "too soon". The per-user, autoresponse information files are flat text files, one per local user. The files are located and named via a configurable template, specified by the vacation_template MTA option. In a user's autoresponse file, the MTA records the most recent time at which the user sent back what would be the "same" vacation message to the "same" original sender (same recipient of potential same vacation message). And as of 7.0.5, the MTA similarly records in the autoresponse file the most recent time the user had a Sieve notify action performed in response to the "same" message sender.

An explicit vacation action in a Sieve script may specify the timeout (period between sending back another "identical" vacation message to the same sender) via the standard :days parameter, or the MTA's extension :hours or :seconds parameters. Or a user's mailAutoReply* LDAP attribute values (which the MTA uses to construct on-the-fly a Sieve vacation action) may specify such a timeout via the value of the LDAP attribute named by the ldap_autoreply_timeout MTA option (default mailAutoReplyTimeout); if the user does not have their own mailAutoReplyTimeout set, then the domain value, if specified via the LDAP attribute named by the ldap_domain_attr_autoreply_timeout MTA option, will be used; or if neither the user nor the domain has such a value set, then the system wide default specified via the autoreply_timeout_default MTA option will be used.

Any such timeout settings must be greater than or equal to the minimum allowed by the vacation_minimum_timeout MTA option; values less than that will be silently (no error) adjusted upwards to the vacation_minimum_timeout value. Similarly, as of the 8.0 release, values greater than the value of the vacation_maximum_timeout MTA option will be silently adjusted downwards to that option's value.

When the MTA is deciding whether or not to generate a vacation message back to some original sender due to existence of either an explicit vacation action in a Sieve applying for the original message recipient, or mailAutoReply* LDAP attributes (more precisely, LDAP attributes named by ldap_autoreply_* MTA options) of the original message recipient,

the MTA looks in the autoresponse suppression file corresponding to the original message recipient, looking up with a key based on the original message sender and the substance of the original message recipient's vacation message to find the time (if any) of the last such vacation response. If the time is "too soon", no vacation message will be generated. Here "too soon" is as defined above: set either via an explicit `vacation` action timeout parameter, or `mailAutoReplyTimeout` if a `vacation` action is being generated for a user due to `mailAutoReply*` attribute use, as defaulted by domain and system defaults, and constrained by the system minimum permissible value.

A user's `notify` Sieve action may specify an explicit timeout via use of a `:days`, `:hours`, or `:seconds` parameter. Any such value must be at least the value of the `notify_minimum_timeout` MTA option and no greater than the value of the `notify_maximum_timeout` MTA option, or it will be silently (with no error) adjusted to conform to the permitted range. If no explicit timeout is specified, then the value of the `notify_timeout_default` MTA option is used.

Maintenance (clean up) of the per-user autoresponse files is performed automatically by the MTA, on a lazy (only when a file is already being opened), randomized (not performed every time) basis. In particular, the `vacation_cleanup` MTA option controls the probabilistic frequency of clean up of expired old entries from any such file.

For options relating to other aspects of vacation messages, see also the `max_vacations` MTA option and all the rest of the MTA options naming various LDAP attributes that specify aspects of vacation messages, `ldap_start_date`, `ldap_end_date`, `ldap_autoreply_mode`, `ldap_autoreply_subject`, `ldap_autoreply_text`, `ldap_autoreply_text_internal`, `ldap_autoreply_addresses`, as well as the already mentioned `ldap_autoreply_timeout`, and `ldap_domain_attr_autoreply_timeout`.

52.8.1 Autoresponse periodicity MTA options: `autoreply_timeout_default` (non-negative integer)

The `autoreply_timeout_default` MTA option specifies the default duration, in hours, for successive vacation (autoreply) responses to any given sender. This system-wide value specifies a default both for `vacation` actions specified explicitly in Sieve filters, and for implicit "`vacation`" effects resulting from LDAP `mailAutoReply*` attributes.

This sytem-wide default may be overridden in explicit "`vacation`" actions in Sieve filters by specifying a desired timeout via a "`:days`", "`:hours`", or "`:seconds`" parameter. Or for implicit "`vacation`" actions generated due to LDAP `mailAutoReply*` attributes, this sytem-wide default may be overridden on a per-domain basis via the domain attribute named by the `ldap_domain_attr_autoreply_timeout` MTA option, or on a per-user basis via the user attribute (normally `mailAutoReplyTimeOut`) named by the `ldap_autoreply_timeout` MTA option. The default for this option is 168 (*i.e.*, 7*24), meaning that vacation messages would only be sent back to a given sender once a week (no matter how many messages the sender sends).

52.8.2 Autoresponse periodicity MTA options: `notify_maximum_timeout` (integer)

(New in 7.0.5.) The `notify_maximum_timeout` MTA option establishes a maximum value, in seconds, for the Sieve "`notify`" action's "`:days`", "`:hours`", and "`:seconds`" parameters.

(":days" and ":hours" values are converted into seconds for the comparison.) Values higher than the maximum are silently adjusted down to the maximum; no error occurs. The default value for notify_maximum_timeout is the maximum allowed integer, 2**31-1.

52.8.3 Autoresponse periodicity MTA options: notify_minimum_timeout (integer)

(New in 7.0.5.) The notify_minimum_timeout MTA option establishes a minimum value, in seconds, for the Sieve "notify" action's ":days", ":hours", and ":seconds" parameters. (":days" and ":hours" values are converted into seconds for the comparison.) Values lower than the minimum are silently adjusted up to the minimum; no error occurs. The default value for notify_minimum_timeout is 0.

52.8.4 Autoresponse periodicity MTA options: notify_timeout_default (non-negative integer)

The notify_timeout_default MTA option specifies the default timeout, in seconds, for suppression of duplicate notifications to a given recipient. It defaults to one hour for the old form of notify actions and to two minutes for the new form.

52.8.5 Autoresponse periodicity MTA options: vacation_cleanup (non-negative integer)

The vacation_cleanup MTA option sets a modulus for the frequency at which per-user per-response vacation files are "cleaned up", (that is, scanned and expired entries removed). Each time one of the per-user per-response vacation files is opened (those files specified via the vacation_template MTA option), the value of the current time in seconds modulo the vacation_cleanup value is computed. If the result is zero, then the file is scanned and all expired entries are removed. The default value for the option is 200, which means that there is a 1 in 200 chance that a cleanup pass will be performed.

52.8.6 Autoresponse periodicity MTA options: vacation_hash_algorithm (hash algorithm name)

The vacation_hash_algorithm MTA option controls what hash algorithm the MTA uses to generate the names for vacation database entries. The value should be a hash algorithm supported by the MTA, one of MD2, MD4, MD5, SHA1, SHA256, SHA512, MD128, or MD160. The default if this option is not specified is to use MD4 for hashing the autoreply attributes and MD5 to rehash the name if it is too long. Note that the setting of this option must be the same across a deployment for successful coordination of vacation responses across hosts.

52.8.7 Autoresponse periodicity MTA options: vacation_maximum_timeout (integer)

(New in 7.0.5.) The vacation_maximum_timeout MTA option establishes a maximum value, in seconds, for the Sieve "vacation", ":days", ":hours", and ":seconds" parameters. (":days" and ":hours" values are converted into seconds for the comparison.) Values higher

than the maximum are silently adjusted down to the maximum; no error occurs. The default value for vacation_maximum_timeout is the maximum allowed integer, 2**31-1.

Since the value of the mailAutoReplyTimeOut LDAP attribute (or more precisely the value of whatever LDAP attribute is named by the ldap_autoreply_timeout MTA option) is converted into such a Sieve "vacation" parameter, the vacation_maximum_timeout MTA option value can affect the interpretation of any mailAutoReplyTimeout values also.

52.8.8 Autoresponse periodicity MTA options: vacation_minimum_timeout (integer)

(New in 7.0.5.) The vacation_minimum_timeout MTA option establishes a minimum value, in seconds, for the Sieve "vacation", ":days", ":hours", and ":seconds" parameters. (":days" and ":hours" values are converted into seconds for the comparison.) Values lower than the minimum are silently adjusted up to the minimum; no error occurs. The default value for vacation_minimum_timeout is 0.

Since the value of the mailAutoReplyTimeOut LDAP attribute (or more precisely the value of whatever LDAP attribute is named by the ldap_autoreply_timeout MTA option) is converted into such a Sieve "vacation" parameter, the vacation_minimum_timeout MTA option value can affect the interpretation of any mailAutoReplyTimeout values also.

52.8.9 Autoresponse periodicity MTA options: vacation_template (file or memcache URL)

The vacation_template MTA option specifies a template for the name and location of the per-user autoresponse information memcache entries or files. These can be flat text files, one per local user. The value should be a memcache: URL or a file URL (file:path-template).

Various substitution sequences may be used in constructing the file path template; see the MTA's LDAP URL substitution sequences. Note that the $nA and $U substitution metacharacters are likely to prove particularly useful in constructing effective vacation_template settings.

This option must be set to a sensible value in order to support user "vacation" Sieve script actions (and LDAP mailAutoReply* attributes). Prior to Messaging Server 7.4-0.01, there was no default value. As of Messaging Server 7.4-0.01, the default value is:

```
file:///DATAROOT/vacation/$3I/$1U/$2U/$U.vac
```

The machinery used to read and write these flat text files is designed in such a way that it should be able to operate correctly over NFS. This allows multiple MTAs to share a single set of files on a common filesystem. Note that when intending to use NFS to share vacation response files among multiple systems, it is important to define the same MTA user account -- same user name and uid (see the user option in restricted.cnf) -- on each system so as to avoid permission problems.

As of the 8.0 release, memcache is also supported as a back end for vacation timeout information. This is accomplished by specifying a memcache: URL. A typical setting would be:

```
memcache:///$U@$2I
```

in which case the memcache server is specified by the `memcache_host` and `memcache_port` MTA options. These options can be overidden by specifying the host and port in the URL, e.g.,

```
memcache://host:port/$U@$2I
```

The content of the URL after the host and port specifies the key used to store information in memcache. The `$U` substitution provides the necessary information for the key, but a prefix or suffix can also be included if there is a need to distinguish the keys from other information stored in the memcache instance.

As of MS 8.1.0.1, Redis URLs are also supported. These have the same semantics as memcache URLs, so a sensible setting would be:

```
redis:///$U@$2I
```

52.9 BURL MTA options

The BURL extension to SMTP SUBMIT is defined in RFC 4468 (Message Submission BURL Extension). The MTA's SMTP SUBMIT server can support this extension, if configured to do so.

Configuration of BURL support involves setting the two MTA options `imap_username` and `imap_password`, as well as configuring the `BURL_ACCESS` mapping table. The BURL MTA options `imap_username` and `imap_password` specify the credentials for the MTA to use when it connects to the IMAP server as the "submit" user, so of course these credentials (these MTA option settings) must match those configured for the IMAP server's "submit" user as configured via the `submituser` IMAP option.

52.9.1 BURL MTA options: `imap_password` (string)

In order to perform an IMAP BURL operation, the SMTP SUBMIT server has to have the ability to log in to the IMAP server as the submit user. The `imap_password` MTA option specifies the password to use for such operations (and of course must match the password value set for the `submituser` account). This option has no default.

52.9.2 BURL MTA options: `imap_username` (string)

In order to perform an IMAP BURL operation, the SMTP SUBMIT server has to have the ability to log in to the IMAP server as the submit user. The `imap_username` MTA option specifies the submit user; if not set, it defaults to the setting of the `imap.submituser` option (corresponding to the old configutil parameter `service.imap.submituser`).

52.10 Configutil override MTA options

Historically, the MTA has had a number of options available to override (specifically for MTA purposes) various general Messaging Server settings formerly set via `configutil`. In Unified

Configuration, such former `configutil` options typically are now base level options -- and MTA-specific overrides via MTA options typically still exist. (A convenient concordance of many such `base`, `configutil`, and MTA options may be found in Basic configuration settings relevant to alias LDAP lookups.)

See in particular the options:

- `ldap_default_domain`
- `ldap_domain_root`
- `ldap_host`
- `ldap_host_alias_list`
- `ldap_local_host`
- `ldap_mail_aliases`
- `ldap_pab_host`
- `ldap_pab_max_connections`
- `ldap_pab_password`
- `ldap_pab_port`
- `ldap_pab_username`
- `ldap_password`
- `ldap_port`
- `ldap_schematag`
- `ldap_username`
- `ldap_user_root`
- `projectid`

52.11 Conversions MTA options

The MTA has a number of options relating to conversion operations. The most fundamental of these in Unified Configuration is `conversions`, which replaces the legacy configuration `conversions` file, being where conversions entries are stored. Additional options relating to conversion operations include:

- `conversion_size`, `personal_conversion_size`, `string_pool_size_0`, and `string_pool_size_4`, which respectively control the maximum number of conversion entries, the maximum number of personal conversion entries, and limits the total characters in conversions entries and in personal conversions entries.

- `include_conversiontag` and `original_channel_probe`, which affect what information is used in certain mapping table probes; and

- `log_conversion_tag`, which controls whether or not message conversion tags are included in MTA message transaction log entries.

52.11.1 `conversions` Option

The `conversions` MTA option stores all conversion entries. It corresponds to the legacy configuration `conversions` file.

The `conversions` MTA option would typically be set or modified by using the `edit` command of `msconfig`, *e.g.*:

```
msconfig> edit conversions
```

52.12 Counters MTA options

The MTA has a number of options relating to its counters.

The `circuitcheck_completed_bins` MTA option relates to MTA circuit check counter binning. The `log_delay_bins` and `log_size_bins` MTA options relate to MTA counters binning. See also the `sndopr_priority` MTA option, which controls the syslog facility and severity of, among other things, syslog notices generated if and when the MTA encounters trouble with its association counters.

The `log_debug` MTA option enables low-level debugging (typically only meaningful to Oracle support) regarding the MTA's transaction logging and the incrementing of MTA channel counters.

52.12.1 Counters MTA options: `circuitcheck_completed_bins` (comma-separated list of up to eight integers)

The `circuitcheck_completed_bins` MTA option specifies the bin divisions, in seconds, for MTA circuit check counters. It takes as argument a list of up to eight integer values. The default values are 120, 300, 900, 1800, 3600, 7200, 14400, and 28800; *i.e.*, two minutes, five minutes, fifteen minutes, thirty minutes, one hour, two hours, four hours, and eight hours, respectively.

52.12.2 Counters MTA options: `enable_delay_timers` (0 or 1)

The MTA can optionally maintain timers to measure delays caused by various external processes. Setting the `enable_delay_timers` MTA option to a value of 1 enables these timers. A value of 0 (the default) disables them.

Timings are done on a per-message basis, if enabled. For details on what timers are available, see the `log_callout_delays` MTA option which discusses the details of the timers, as well as the format in which they may optionally be logged.

52.12.3 Counters MTA options: `log_delay_bins` (comma-separated list of up to five integers)

The `log_delay_bins` MTA option specifies the bin divisions for the MTA counters tracking numbers of messages delivered in the specified number of seconds. The default values are 60, 600, 6000, 60000, 600000.

52.12.4 Counters MTA options: `log_frustration_limit` (integer)

When attempting a counter update operation (whether an attempt to update channel counters or association counters), the MTA will try ten times before giving up on that particular update operation. Each MTA process keeps track of how many such update "frustrations" have occurred, that is, how many times the process has had to give up on updating the counters, and if that value exceeds the log_frustation_limit value, which by default is 100, then that process will no longer even attempt counter update operations.

52.12.5 Counters MTA options: log_size_bins (comma-separated list of up to five integers)

The log_size_bins MTA option specifies the bin divisions for the MTA counters tracking numbers of messages of the specified number of (MTA) blocks (the size of an MTA block having been defined via the block_size MTA option). The default values are 2, 10, 50, 100, 500.

52.12.6 Syslog MTA options: log_sndopr (bitmask)

The log_sndopr MTA option controls the production of syslog messages (UNIX) by the MTA message transaction and connection logging facility. If this feature is enabled by specifying a value of 1, the logging facility will produce a message if it encounters any difficulty writing to its log file. A value of 0 (the default) turns off these messages. New in MS 8.0, the option takes a bit-encoded value, with bit 0 (value 1) and bit 1 (value 2) having meaning: bit 0 enables syslog notices regarding trouble writing transaction log entries; bit 1 enables syslog notices regarding trouble creating or updating channel counters.

The sndopr_priority option controls the syslog level (facility and severity) of the syslog messages generated.

52.12.7 Counters MTA options: log_statistics (0, 1, or 2)

Usage: RESTRICTED. (In PMDF V5.1 and earlier, log_statistics=0 told PMDF not to generate and maintain its counters; but as of PMDF V5.2 and for all versions of the Messaging Server MTA, log_statistics=0 has no effect and is equivalent to log_statistics=1.) log_statistics=1 is the default and means to create counters normally. log_statistics=2 causes "strict" creation of counters; the MTA aborts if the counters cannot be created.

52.13 Database MTA options

The MTA has a number of options relating to its use of databases. These include:

- alias_magic controlling the order of consulting various sources (including databases) for aliases;
- forward_data_size, general_data_size, and reverse_data_size controlling the internal size the MTA allots for its "in-memory" versions of the forward database, general database, and reverse database, when use of such "in-memory" databases has been selected via use_text_databases;

- name_table_name (OpenVMS only) which specifies a local name table used to store aliases;
- queue_cache_mode which specifies use of an "in-memory" queue cache database by the Job Controller;
- use_alias_database, use_domain_database, use_forward_database, use_personal_aliases, and use_reverse_database which, among other effects, control the use and format of various databases; and
- vacation_template specifies the location of the "database" of per-user vacation response data;
- (new in Messaging Server 8.0) alias_database_url, domain_database_url, forward_database_url, general_database_url, and reverse_database_url, which can specify either Memcache (new in MS 8.0.2.3) Redis URLs for storing MTA database data;
- general controlling the case sensitivity of general database lookups.

See also the Direct LDAP MTA options, the Autoresponse periodicity MTA options, and the MeterMaid MTA options.

52.14 Debug MTA options

Debugging of various general MTA facilities and components may be enabled via several options. Note the distinction between debugging (verbose output especially focused on problem detection) *vs.*transaction logging (recording of processing) *vs.* event logging (call-out logging of events of particular interest).

These MTA-wide facility debug options enable certain sorts of (generally MTA low level) debugging irrespective of what MTA component is operating. For component specific debugging, including "higher level" debugging of that component's specific operation, see also component level debugging such as the channel level master_debug and slave_debug channel options, or the debug Job Controller option or debug Dispatcher option.

For a quick view of whether/what debugging you may have enabled, try:

```
msconfig> show *debug*
```

52.14.1 Debug MTA options: ap_debug (integer)

RESTRICTED. The ap_debug MTA option enables internal MTA debugging; it is intended for use by Oracle and is not intended to be used by end sites. Specifically, it enables debugging of the AP routines (low level address parsing routines). Higher settings of ap_debug cause more verbose output. The precise debug output can be expected to vary between and during releases.

When enqueuing messages, in order for ap_debug values greater than 0 to take effect, both the master_debug and slave_debug channel options must be set on the source channel except for the L channel where just master_debug or slave_debug is sufficient.

52.14.2 Debug MTA options: cache_debug (0 or 1)

The cache_debug MTA option controls debugging regarding the direct LDAP caching of lookup results (domains, aliases, address reversals). The default is 0, meaning that such debug output is disabled. Setting this option to 1 enables the debug output; the information is output just before the MTA component exits. (So for instance, imsimta test -rewrite will output information regarding what it cached at the end of its other, normal output---since imsimta test -rewrite most often is used to test just one or a couple of addresses, there is not often much it had to cache. An SMTP server process will output to its log file information regarding what it cached just before it shuts down at the end of its lifetime -- since SMTP server processes typically last for some time, there may be quite a bit of caching that occurred.)

52.14.3 Debug MTA options: config_debug (integer)

RESTRICTED. The config_debug MTA option enables internal MTA debugging; it is intended for use by Oracle and is not intended to be used by end sites.

52.14.4 Debug MTA options: debug_flush (0 or 1)

As of Messaging Server 7.1, a.k.a. Messaging Server 7.0-3.01, the debug_flush MTA option causes certain debug output to get immediately flushed to disk. This is applicable for many MTA components, including typical channel debug output, but it is especially relevant and noticeable for long-running components such as the SMTP server, and Job Controller. The flush-to-disk-log-file of the debug output may incur a bit of a performance penalty, but tends to be more convenient for debugging purposes. The default is that such debug flushing is not enabled (debug_flush = 0).

As of 7.0.5, the debug_flush MTA option can also cause flushing of Dispatcher debug output.

52.14.5 Debug MTA options: dequeue_debug (0 or 1)

The dequeue_debug MTA option specifies whether or not debugging output from the MTA's dequeue facility QU is produced; (note that master channel programs, since they are generally dequeue oriented, usually use QU routines). If enabled with a value of 1, this output will be produced on all channels that use the QU routines. The default value of 0 disables this output.

52.14.6 Debug MTA options: filter_debug (0 or 1)

New in Messaging Server 6.2. Control whether the stack state information part of Sieve filter debugging is put in debug logs. (Note that this is quite "low level" debugging, not likely to be of interest unless requested by Oracle support.)

For debugging of Sieve filters, see also the imsimta test -expression utility and the mm_debug MTA option along with the Sieve debug action.

52.14.7 Debug MTA options: log_debug (0 or 1)

RESTRICTED: The log_debug MTA option may be used to enable internal debugging of MTA logging activity, including MTA transaction logging and incrementing of the MTA channel counters; it is intended for use by Oracle, and is not intended to be used by end sites.

52.14.8 Debug MTA options: mm_debug (integer)

RESTRICTED: The mm_debug MTA option enables internal enqueue debugging; it is intended for use by Oracle, and is not intended to be used by end sites. In particular, it is not intended for, and is not supported for use for, logging purposes. Specifically, it enables debugging of the MM routines (enqueue routines handling address rewriting, mappings, conversions, *etc*.). Note that generally at least one of master_debug or slave_debug must be set on a channel in order for mm_debug settings to take effect; the OpenVMS L channel is an exception and requires setting both master_debug and slave_debug. (In PMDF V5.1 and earlier, all channels required setting both master_debug and slave_debug for mm_debug to take effect.)

Higher settings of mm_debug cause more verbose output. For instance, currently a value of 1 or more includes some message file access debugging and some alias file/database access debugging and some overview of header processing and debugging of access mapping table checks and debugging of address/subaddress variant lookups, and some commenting about spam/virus filter package verdicts, and some debugging of SPF lookups checked at MAIL FROM or RCPT TO stages; a value of 2 or more includes debugging of conversion probes and debugging of Sieve filter access and some debugging of URL lookups (LDAP and file) and debugging of auto-registration and debugging of mailing list keyword processing and debugging of constructing address/subaddress variants and debugging of domainMap/ domain-match-cache usage and debugging of whether TLS use is attempted, and further information regarding spam/virus filter package access and errors; a value of 3 or more includes debugging of mapping table use, and further debugging of the actual attribute lookups for LDAP URL lookups and domain lookups (including domain caching info), and (as of MS 6.2) debugging regarding the reason when a message for multiple recipients is "split up" into different copies, and (as of MS 6.3) debugging regarding SRS/MUL decoding; a value of 4 or more includes some file reading debug especially on OpenVMS; a value of 5 causes very verbose output, including actual contents of the incoming message body, and details regarding spam/virus filter package opt in or opt out; in particular, a value of 8 or more includes some debugging of creating message files and writing out lines of message files and reading in message lines.

The precise debug output resulting from mm_debug can be expected to vary between and during releases.

52.14.9 Debug MTA options: os_debug (0 or 1)

RESTRICTED. The os_debug MTA option enables internal MTA debugging; it is intended for use by Oracle and is not intended to be used by end sites. Specifically, it enables debugging of the OS routines (low level operating system interface routines), including some file handling and date/time operation routines. The precise debug output can be expected to vary between and during releases.

The dequeue_debug MTA option must be enabled also, in order for os_debug=1 to take effect when dequeueing messages. When enqueuing messages, in order for os_debug=1 to take effect, both master_debug and slave_debug must be on the channel. (The PORT_ACCESS mapping table $U flag may be used to selectively enable slave_debug on incoming connections.)

As of Messaging Server 7.0.5, enabling os_debug will cause the MTA to pay attention to a debugkeys Base option value of lpool, (local.debugkeys lpool in legacy configuration), and thus generate lpool debug output.

52.14.10 Debug MTA options: post_debug (0 or 1)

DEPRECATED.

Formerly, for PMDF prior to the enhanced Job Controller, the post_debug MTA option specified whether or not debugging output was produced by PMDF's periodic delivery job. (No such periodic delivery job exists for the Messaging Server MTA; instead, the Job Controller handles scheduling and initiating delivery re-try jobs as appropriate.)

52.14.11 Debug MTA options: return_debug (0 or 1)

The return_debug MTA option enables or disables debugging output in the nightly message bouncer job (the return_job). A value of 0 disables this output (the default) while a value of 1 enables it. Debugging output, if enabled, in iMS 5.2 will appear in the Job Controller's log file, usually a job_controller.log-* file, and in MS 6.1p1 and later will appear in the IMTA_LOG:return-*uniquestring*.log log file.

52.14.12 Debug MTA options: return_verify (0 or 1)

The return_verify MTA option was introduced in MS 7.0.5, in place of the former MTA Tailor option imta_return_verify. When the return_verify MTA option is set to 1, shell script logging, -x, will be enabled within the return_job shell script.

52.14.13 symbiont_debug Option

DEPRECATED.

Formerly, the symbiont_debug MTA option could be used to enable debugging of the PMDF Process Symbiont.

52.14.14 Debug MTA options: tracking_debug (0-10)

RESTRICTED: The tracking_debug MTA option is used to enable debug output from the MTA's tracking subsystem. The default value of 0 disables debug output; positive values enable it. The larger the value, the more output is produced.

52.15 Direct LDAP MTA options

In modern configurations, provisioning of mail domains, and provisioning of users, mail groups, and mail lists -- aliases from the MTA's point of view -- is typically done in LDAP. This is sometimes referred to as "Direct LDAP" provisioning or "Direct LDAP" aliases, in contrast to the older style of having MTA rewrite rules keep track of "local" domains, and storing aliases for users in those domains in the MTA alias file or MTA alias database and the MTA reverse database.

There are many MTA options for controlling the many aspects of so-called "Direct LDAP" domain and alias lookups, that range from those controlling the basics of connnecting to LDAP, to basics of the LDAP schema and DIT layout, to tweaking the interpretation of LDAP attributes, to specifying the names of the LDAP attributes of interest (re-vectoring LDAP attribute names to allow use of any semantically-compatible schema), including some attributes fetched upon successful authentication, to details of looking up domains in LDAP, then in such domains details of looking up users in LDAP, and finally caching LDAP lookup results.

52.15.1 LDAP bind and connect MTA options

MTA options exist to control the basics of its LDAP bind operations and LDAP connections: the credentials used to bind, the timeout on connection attempts, the maximum number of simultaneous connections, *etc.* Besides these MTA options controlling the MTA's "normal" LDAP connections (those LDAP connections used for lookups in the domain and user/group portions of the DIT, as well as general LDAP URL lookups sites have explicitly configured in MTA rewrite rules or mapping tables), the MTA is also capable of performing PAB (Personal Addressbook) specific LDAP lookups (see the LDAP PAB MTA options) as well as LDAP connections to some alternate, "external" LDAP directory (see the LDAP external directory lookup MTA options).

52.15.1.1 LDAP bind and connect MTA options: `ldap_host` (host)

The `ldap_host` MTA option specifies the default host to which to connect when making LDAP queries. This option, if set, overrides for MTA purposes the `ugldaphost` base-level option (in legacy configuration, the `local.ugldaphost` configutil parameter).

Prior to Messaging Server 7.0u4, the MTA's LDAP queries -- that is, `ldap:` URL uses in MTA rewrite rules, mapping tables, alias translations value, *etc.* -- in fact did not allow specifying a host in the URL itself and instead *required* that a default LDAP host had to have been specified via `ldap_host` or `ugldaphost`.

52.15.1.2 LDAP bind and connect MTA options: `ldap_max_connections` (non-negative integer)

The `ldap_max_connections` MTA option takes a non-negative integer argument specifying the maximum number of simultaneous LDAP connections that the MTA can use. The default is 1024.

52.15.1.3 LDAP bind and connect MTA options: `ldap_password` (string)

The `ldap_password` MTA option specifies the password to use when binding for LDAP queries. If set, this option overrides the `local.ugldapbindcred` configutil parameter in legacy configuration; in Unified Configuration, the equivalent option is `ugldapbindcred`.

52.15.1.4 LDAP bind and connect MTA options: `ldap_port` (integer)

The `ldap_port` MTA option specifies the port to which to connect when making LDAP queries. If set, this option overrides the `ugldapport` base option (formerly the `local.ugldapport` configutil parameter).

Prior to Messaging Server 7.0u4, the MTA's LDAP queries -- that is, `ldap:` URL uses in MTA rewrite rules, mapping tables, alias translations value, *etc.* -- in fact did not allow specifying a port in the URL itself and instead *required* that a default LDAP port had to have been specified via `ldap_port` or `ugldapport`.

52.15.1.5 LDAP bind and connect MTA options: `ldap_timeout` (integer)

The ldap_timeout MTA option controls how long to wait (in hundredths of seconds) before timing out on an LDAP query. The default value is 180000. Note that some underlying or shared code may have its own, separately controlled LDAP timeout settings. In particular, some code may instead use the general ldapsearchtimeout base option (formerly the local.ldapsearchtimeout configutil parameter setting), whilst other code uses the ADMLDAP_TIMEOUT environment variable setting (and defaults to 60 seconds if that variable is not set).

52.15.1.6 LDAP bind and connect MTA options: ldap_use_async (bitmask)

The ldap_use_async MTA option controls the use of asynchronous (as opposed to synchronous) LDAP lookups. Asynchronous lookups avoid the need to store an entire large LDAP result in memory, which seems to cause performance problems in some cases. This option takes a bit-encoded value. Each bit, if set, enables the use of asynchronous LDAP lookups in conjunction with a specific use of LDAP within the MTA. The following bits are defined:

Table 52.9 ldap_use_async MTA option bits

Bit	Value	Usage
0	1	ldap_group_url1 (mgrpDeliverTo) URLs
1	2	ldap_group_url2 (memberURL) URLs
2	4	ldap_group_dn (uniqueMember) DNs and as of Messaging Server 7.0.5, also ldap_group_dn2 DNs
3	8	[AUTH_LIST], [MODERATOR_LIST], [SASL_AUTH_LIST], [SASL_MODERATOR_LIST] list named parameter URLs (legacy configuration), or in Unified Configuration, alias_auth_list, alias_moderator_list, alias_sasl_auth_list, alias_sasl_moderator_list, alias option URLs
4	16	[CANT_LIST], [SASL_CANT_LIST] list named parameter URLs (legacy configuration), or in Unified Configuration, alias_cant_list, alias_sasl_cant_list alias option URLs
5	32	[ORIGINATOR_REPLY] list named parameter URLs (legacy configuration), or in Unified Configuration, alias_originator_reply alias option URLs
6	64	[DEFERRED_LIST], [DIRECT_LIST], [HOLD_LIST], [NOHOLD_LIST] list named parameter URLs (legacy configuration), or in Unified Configuration, alias_deferred_list, alias_direct_list, alias_hold_list, alias_nohold_list alias option URLs
7	128	[USERNAME_AUTH_LIST], [USERNAME_MODERATOR_LIST], [USERNAME_CANT_LIST] list named parameter URLs (legacy configuration), or in Unified Configuration, alias_username_auth_list, alias_username_moderator_list, alias_username_cant_list alias option URLs
8	256	alias file list URLs

9	512	alias database list URLs
10	1024	ldap_cant_url (mgrpDisallowedBroadcaster) outer level URLs
11	2048	ldap_cant_url inner level URLs
12	4096	ldap_auth_url (mgrpAllowedBroadcaster) outer level URLs
13	8192	ldap_auth_url inner level URLs
14	16384	ldap_moderator_url (mgrpModerator) URLs
15	32768	ldap_jettison_url (mgrpJettisonBroadcasters) URLs (new in 7.4-0.01)
16	65536	ldap_auth_mappingN generated outer URLs (new in 7.5-31)
17	131072	ldap_auth_mappingN generated inner URLs (new in 7.5-31)

Bit 0 is the least significant bit.

The default value of the ldap_use_async MTA option is 0, which means that asynchronous LDAP lookups are disabled by default in the MTA.

52.15.1.7 LDAP bind and connect MTA options: ldap_username (ldap-dn)

The ldap_username MTA option specifies the DN under which to bind for LDAP queries. This option, if set, overrides for MTA purposes the base-level ugldapbinddn option (in legacy configuration, the local.ugldapbinddn configutil parameter).

52.15.1.8 LDAP bind and connect MTA options: max_urls (integer)

The max_urls MTA option specifies the maximum number of URLs that may be active when reiteratively performing URL lookups; that is, this is the maximum degree of nesting of URL references. The default value as of MS 8.0 is 1024; previously, the default was 128.

52.15.2 Direct LDAP domain lookup MTA options

A number of MTA options relate to domain lookups in LDAP.

- domain_failure is a rewrite template to handle cases of LDAP errors during the MTA's fundamental domain LDAP lookup while rewriting.
- domain_match_url is available to support the *STRONGLY DISCOURAGED* use of so-called "vanity domains".
- domain_uplevel is important for domain aliasing, and in particular for implicit aliasing as in the case of supporting arbitrary subdomains of some upper domain name.
- ldap_domain_known_attributes may have performance implications with some LDAP servers. Proper setting is also important in cases of site MTA configuration with reliance upon use of additional, site-specific LDAP attributes from domain entries.
- Affecting interpretation of the results of domain lookups are ldap_default_domain, ldap_host_alias_list, and ldap_local_host.

- Controlling caching and timeouts of domain lookups are `domain_match_cache_timeout`, `domain_match_cache_size`, and `ldap_domain_timeout`.
- Schema options include `ldap_domain_filter_schema1`, `ldap_domain_filter_schema2` and `ldap_domain_root`.
- Options to rename which LDAP attributes are used/recognized in domain entries are discussed under Direct LDAP attribute name MTA options; see especially the `ldap_domain_attr_*` MTA options.

52.15.2.1 Domain lookup failures (`domain_failure`)

The `domain_failure` MTA option specifies what rewriting to apply when a rewrite rule `$V` LDAP lookup encounters an LDAP error. The default is

```
reprocess-daemon$Mtcp_local$1M$1~-error$4000000?Temporary lookup failure
```

This means that if the rewrite rule `$V` LDAP lookup encounters a (presumably temporary) LDAP error such as the LDAP server failing to allow connections, or an LDAP query timing out without a response, then the MTA will either:

- (a) for attempted submissions via `tcp_local` (attempted submisssions from the Internet) or from channels "internal" to the MTA (such as reprocess or conversion channels), reject the submission attempt with a temporary error (4*yz* error) so that the message remains where it was (on the external, Internet host, or on the internal channel) which can re-attempt submisssion later, or
- (b) for all other messages (in particular, messages submitted by "internal" user e-mail clients or "internal" hosts via channels such as `tcp_intranet`, `tcp_auth`, `tcp_submit`, *etc.*, accept the message but divert it to the reprocess channel, so that the user's message submission is completed, leaving it up to the MTA (via the reprocess channel) to later go to the work of re-trying the LDAP lookup.

In case (a), for attempted submissions from the Internet, one typically does not want to accept a message that one cannot process at the moment (and for which, in particular, one cannot even validate that the domain is one one wants to accept). Accepting such messages merely clutters one's own queues which at best cannot be processed immediately, and which at worst may need to be rejected (once domain validiation can be performed) as invalid domains. Instead, sites usually prefer to refuse such messages with a temporary rejection (so that the remote host knows to continue with additional submission attempts later). And in case (a), for attempted submissions from "internal" channels, the messages might as well stay in their current "internal" channel and await additional lookup attempts from there. In contrast, in case (b), for attempted submissions from one's own, "internal" user e-mail clients, user e-mail clients cannot usually handle making an automated resubmission attempt "later". So it is friendlier to one's own users to go ahead and accept the messages, even if the messages will end up needing to be rejected later.

In more detail, the `$M` and `$1M` rewrite rule control sequences are used here to do a preliminary check whether the `tcp_local` or any "internal" channels are doing the rewriting (attempting to enqueue). Then the `$1~` rewrite rule control sequence is used to override that initial channel match success or failure with a forced success, while truncating the rewrite rule at this point if the initial channel match failed.

So the effect is that when the `tcp_local` or an "internal" channel is attempting to enqueue, a rewrite rule template of the form

```
$U%$H@reprocess-daemon-error$4000000?Temporary lookup failure
```

is used. Because (normally) there is no channel with official host name `reprocess-daemon-error`, this rewrite rule template has the effect of forcing a channel match failure, so the $? rewrite rule control sequence comes into play, specifying that a "`4.0.0 Temporary lookup failure`" error be returned for the address. The MTA does not enqueue the message; the message remains where it was (and the remote host or internal channel can re-attempt submission later).

But if any channel other than `tcp_local` or an "internal" channel (in particular, if a channel such as `tcp_intranet`, `tcp_auth`, or `tcp_submit`) is attempting to enqueue, a rewrite rule template of the form

```
$U%$H@reprocess-daemon
```

is used. Thus in this case (messages being submitted from channels such as `tcp_intranet`, `tcp_auth`, or `tcp_submit`), the rewrite rule succeeds in directing the message to the reprocess channel; the MTA accepts the message and routes it to the reprocess channel for further processing (in particular, for further attempts to do the domain lookup in LDAP). The reprocess channel will then continue to try to process the message (in particular, reattempt the rewrite rule $V LDAP lookup) until either the LDAP lookup is completed and then the message can be processed further, or the message eventually times out (time out as controlled by the final value of the `notices` channel option applying to the reprocess channel) causing the message to be returned to the original sender. Accepting the message onto the MTA, for the MTA to later re-try the domain lookup typically makes sense in the case of messages submitted from one's own users.

52.15.2.2 Direct LDAP domain lookup URL (`domain_match_url`)

The `domain_match_url` option may be used to specify an additional, special lookup to perform when looking for domains during a $V rewrite rule template LDAP lookup; (that is, a lookup in addition to the regular lookup for normal domains triggered by $V). This additional lookup will be performed only if the check for a normal, hosted domain fails. The main use of this option is to enable use of vanity domains, vanity domain being disabled by default. To enable the use of vanity domains, in Schema 1 mode set

```
domain_match_url=ldap:///$B?msgVanityDomain?sub?(msgVanityDomain=$D)
```

Note that use of vanity domains is **NOT RECOMMENDED!**

52.15.2.3 Subdomain handling in domain lookups (`domain_uplevel`)

The `domain_uplevel` MTA option affects how domain names are searched for and used in direct LDAP mode. The option takes a bit-encoded integer argument, where each bit controls a particular aspect of domain name searching/usage; see below. The default value is 0.

Table 52.10 `domain_uplevel` option bit values

Bit	Value	Usage
0	1	When set, domain map searches, such as the `$V` search in the typical configuration's `$*` rewrite rule, iterate with successive initial portions of the domain name stripped off until a match is found (or the domain name is exhausted). That is, with this bit set then a domain entry in the DC tree implicitly causes all subdomains of that domain to also "match" for purposes of domain lookups.
1	2	When set, searches on user addresses also look for the user address with the original domain name replaced by the domain name found during the domain map process (the "canonical" domain name). In particular, this can be useful either when bit 0 (value 1) is set (subdomains implicitly present due to the presence of a domain in the DC tree), or when aliased domains are in use.
2	4	Controls whether the domain name found during the domain map process (the "canonical" domain name) is compared with the configutil parameter `service.defaultdomain` (which can be overridden by the `ldap_default_domain` MTA option) when deciding whether an entry is in a hosted domain.
3	8	New in 6.1-0.01. Check the "canonical" form of the address, that is, the address with the domain part replaced by the canonical domain, against any `mailEquivalentAddress` attributes, and disable address reversal if any match occurs. This bit and bit 5 (value 32) are useful in preventing unwanted address rewriting when canonical domains are in use.
4	16	New in 6.3-0.15. For address reversal purposes, do not reverse unless the address (original or possibly the original with domain replaced by the "canonical" domain) matches a `mailAlternateAddress` value. In particular, this allows mail domain aliases to effectively cause all users to implicitly have a `mailEquivalentAddress` value using the domain alias as the domain name.
5	32	New in 6.2-0.04. Check the "canonical" form the address, that is, the address with the domain part replaced by the canonical domain, against the `mail` attribute, and disable address reversal if it matches.

Bit 0 is the least significant bit.

See also the `ldap_domain_attr_uplevel` MTA option for specifying the name of a domain-level LDAP attribute which allows some domain-level override of the MTA-wide setting of `domain_uplevel`.

52.15.2.4 Direct LDAP attribute name MTA options: `ldap_attr_domain1_schema2` (LDAP attribute name)

The `ldap_attr_domain1_schema2` MTA option may be used to override, for MTA domain lookup purposes, the Domain Map library code's default use of the `sunPreferredDomain` LDAP attribute as the name of the Schema 2 mode domain level LDAP attribute which specifies the domain name within the domain entry. If this MTA option is not set (the default), then the Domain Map's default of `sunPreferredDomain` is used, as normal.

52.15.2.5 Direct LDAP attribute name MTA options: `ldap_attr_domain2_schema2` (LDAP attribute name)

The ldap_attr_domain2_schema2 MTA option may be used to override, for MTA domain lookup purposes, the Domain Map library code's default use of the associatedDomain LDAP attribute as the name of the Schema 2 mode domain level LDAP attribute which specifies any secondary domain names (aliases for the canonical domain name) within the domain entry. If this MTA option is not set (the default), then the Domain Map's default of associatedDomain is used, as normal.

52.15.2.6 Direct LDAP attribute name MTA options: ldap_attr_domain_search_filter (LDAP attribute name)

The ldap_attr_domain_search_filter MTA option specifies the name of the LDAP attribute in the global configuration template area (see the ldap_global_config_templates MTA option) that is used to store the domain search filter template. For instance, one attribute that might be used for such a purpose (hence to which this option might be set) would be inetDomainSearchFilter.

52.15.2.7 Direct LDAP schema MTA options: ldap_basedn_filter_schema1 (LDAP URL filter), ldap_basedn_filter_schema2 (LDAP URL filter elements)

(New in MS 6.3-0.15.) The ldap_basedn_filter_schema1 MTA option specifies the filter used to identify schema 1 domains when performing baseDN searches. The ldap_basedn_filter_schema2 MTA option specifies additional filter elements used to identify schema 2 domains when performing baseDN searches. The default is that neither the ldap_basedn_filter_schema1 MTA option nor ldap_basedn_filter_schema2 MTA option is set. When these options are not set, then the values of ldap_domain_filter_schema1 and ldap_domain_filter_schema2, respectively, are used if those options are set. But if none of these options are set, then the default for ldap_basedn_filter_schema1 is "(objectclass=inetDomain)", while the default for ldap_basedn_filter_schema2 is the empty string.

52.15.2.8 Direct LDAP attribute interpretation options: ldap_default_domain (string)

The ldap_default_domain MTA option specifies the domain name that is recognized and interpreted as the default domain *by the MTA*. In legacy configuration, this option, if set, overrides the configutil parameter service.defaultdomain. In Unified Configuration, this option, if set, overrides (for MTA purposes) the base level defaultdomain option -- but it would be more normal/preferable to only set defaultdomain so that all components of Messaging Server have a consistent choice of default domain.

In particular, in delivery_options substitutions, the canonical domain name for the domain in which a user is located is compared against the ldap_default_domain value. If they match, then substitutions such as $I will not insert a domain name; that is, ldap_default_domain is the domain name for which (in typical configurations) usernames will be left "bare" when constructing a mailbox.

The ldap_default_domain also specifies the domain name that preferentially will be returned for Sieve environment "domain" tests; if it is not set, then the MTA falls back to the received_domain if set, or otherwise the official hostname of the L channel.

52.15.2.9 Direct LDAP schema MTA options: `ldap_domain_filter_schema1` (LDAP URL filter), `ldap_domain_filter_schema2` (LDAP URL filter)

The default is that neither the `ldap_domain_filter_schema1` nor `ldap_domain_filter_schema2` option is set, neither at the MTA level nor at the base level. When these options are not set, then internal defaults in the domain map code are used, equivalent to:

```
ldap_domain_filter_schema1=(|(objectclass=inetDomain)(objectclass=inetdomainalias))
ldap_domain_filter_schema2=(objectclass=sunManagedOrganization)
```

52.15.2.10 `ldap_domain_known_attributes` Option

The `ldap_domain_known_attributes` MTA (and base) option controls whether the MTA's domain lookup LDAP queries request all domain attributes, *vs.* building and requesting a list of "known" domain attributes. The default of `0` means to request all domain attributes; setting this option to `1` causes the MTA to request its hard-coded list of "known" domain attributes.

It has been claimed that the `ldap_domain_known_attributes` setting can have a performance impact in some LDAP server environments.

The "known" attribute list consists of all attributes specified in the various `ldap_domain_attr_*` and similar MTA options, as well as any attributes specified in any LDAP domain map attribute substitutions. This should cover all the cases where the MTA requests domain attributes via its internal domain lookup facilities. However, in the unlikely event that other calls are made to the domain map facility, a site that has added additional domain attributes may be forced to use the default setting of `0` so that LDAP domain queries will return those additional, custom LDAP attribute values.

52.15.2.11 Direct LDAP schema MTA options: `ldap_domain_root` (DN)

The `ldap_domain_root` MTA option specifies, for MTA purposes, the base DN for the domain portion of the DIT. This option, if set, overrides (for MTA purposes) the base option `dcroot` (or in legacy configuration, the configutil parameter `service.dcroot`). If neither the MTA option nor the `dcroot` base option (in legacy configuration, the configutil parameter) has been explicitly set, then the default is `o=internet`.

52.15.2.12 LDAP lookup cache MTA options: `ldap_domain_timeout` (integer)

The `ldap_domain_timeout` option (available at both base and MTA levels) controls the retention time (in seconds) for entries in the domain map cache. The default is -900; as the value used is the absolute value of the `ldap_domain_timeout` setting, this corresponds to 15 minutes. If setting `ldap_domain_timeout` explicitly, set it to a positive value so that the MTA can detect that it has indeed been intentionally set.

52.15.2.13 `ldap_host_alias_list` Option Under mta

The ldap_host_alias_list MTA option specifies local host aliases for LDAP lookup result interpretation purposes. Specifying this option at MTA level overrides, for MTA purposes, the base.ldap_host_alias_list base option (local.imta.hostnamealiases configutil parameter in legacy configuration), thereby allowing the MTA to recognize a different set of such aliases than the Message Store recognizes. Neither the base nor MTA level option has a default value; if the base level option is set, it is used by the MTA unless the MTA level option has been explicitly set in which case the MTA uses the MTA level option's value.

The ldap_host_alias_list value takes a comma-separated list of up to 40 host aliases; each host alias may be at most 256 characters long; the total length of the entire list is limited to 1024 characters. (In iMS 5.2, the limits were smaller: at most 20 host aliases and each host alias at most 252 characters long.) New in Messaging Server 7.0.5.36, the MTA supports wild-carded host name values.

The ldap_host_alias_list value(s) are used by the MTA when deciding whether a domain's mailRoutingHosts value(s) or a user's mailHost value is "local" (this MTA itself). That is, once an LDAP lookup of a domain or user occurs, this option's value(s) affect the interpretation of the result of the LDAP lookup.

An important use of the ldap_host_alias_list is in email configurations spanning multiple data centers, with routing via SMTP between data centers and delivery LMTP within each data center. In such a setup the mailbox delivery_options MTA option clause is set for LMTP but is left as mailhost-dependent, rather than as in a typical configuration being marked with "#" to be mailhost-independent. Then all the LMTP hosts for the local data center are listed in the ldap_host_alias_list MTA option value on each MTA. Note that as the number of stores becomes large it's preferable to use a naming convention for stores along with a wildcard ldap_host_alias_list value, to avoid configuration churn as stores are added or deleted.

52.15.2.14 Direct LDAP attribute interpretation MTA options: ldap_local_host (string)

The ldap_local_host MTA option specifies the local hostname (official host name for the "l" channel) for LDAP lookup result interpretation purposes. If not set, it defaults to the value of the hostname Base option. If set, this option overrides the hostname Base option (in legacy configuration, the local.hostname configutil parameter). Normally ldap_local_host and channel:l.official_host_name should be set to match: the distinction is that the ldap_local_host value affects interpretation by the MTA of LDAP lookup results (as well as during initial installation/configuration controlling what hostname is generated for the "l" channel official_host_name and combined with standard channel prefixes to generate an appropriate official_host_name value for the other standard channels), whereas channel:l.official_host_name controls MTA address interpretation and processing in other contexts such as rewrite rules and SMTP server hostname defaults. But since initial installation/configuration normally sets the channel:l.official_host_name based on the hostname Base option value, they normally indeed "match".

Note that the &/IMTA_HOST/ substitution value comes from ldap_local_host (which if not set explicitly, defaults to the value of the hostname Base option, or local.hostname in legacy configuration).

52.15.3 Direct LDAP usergroup lookup MTA options

There are a number of MTA options relating to direct LDAP alias lookups (including user lookups, group lookups, and mailing list lookups) and address reversal lookups.

- The `alias_urlN`, and `reverse_url` MTA options are the major options for defining the direct LDAP alias and reverse lookups, while the (not usually modified) `alias_magic` can potentially affect the timing of when -- or even whether -- such direct LDAP lookups are performed.
- Additional options further refining/modifying the alias and reverse lookups include the `allow_unquoted_addrs_violate_rfc2798`, `ldap_default_attr`, `ldap_mail_aliases`, `ldap_mail_reverses`, `max_alias_levels`, and `max_urls` MTA options.
- The `alias_entry_cache_*` and `reverse_address_cache_*` MTA options control the caching of alias and address reversal lookup results; for further discussion see the discussion of LDAP lookup cache MTA options.
- The `defer_group_processing` MTA option affects the timing of the MTA's alias expansion of group and list entries, which has implications on operation of such aliases.
- The `ldap_user_root`, `ldap_user_object_classes`, and `ldap_group_object_classes` MTA options set the basic location in the DIT and objectClasses for the user/group entries in the DIT; see also Direct LDAP attribute name MTA options for the LDAP attributes expected/recognized in user and group entries.
- The `delivery_options`, `group_dn_template`, `ldap_uid_invalid_chars`, and `aliasdetourhost_null_optin` MTA options affect the interpretation (and validity of values) of certain LDAP attributes found during alias lookups; see Direct LDAP attribute interpretation MTA options for further discussion.
- The `ldap_filter_reference`, `ldap_hoh_filter`, and `ldap_hoh_owner` MTA options relate to "head of household controls" or "parental controls" applicability to users or aliases; further discussion of "head of household" Sieve filters can be found in Head of household Sieve filters.

52.15.3.1 Alias and address reversal MTA options: `alias_urlN` (URL)

The `alias_urlN` MTA options each specify a URL to query for alias lookups. If more than one of these options is set, then the URLs lookups specified are performed in the order specified by the `alias_magic` MTA option. The options are normally checked in numeric order, so `alias_url0`, if specified, will be the first URL queried. Note that with the usual value of `alias_magic` (8764), the `alias_url3` option is not used.

Such alias lookups will be performed any time an envelope To address matches the local ("l") channel, or any channel marked with the `aliaslocal` channel option.

The URL (that is, the `alias_urlN` option value) must be specified using standard LDAP URL syntax as per RFC 4516, with the following exception and special interpretations:

- The LDAP server and port are typically omitted, being instead specified via the `ldap_host` and `ldap_port` MTA options; (or if the MTA options are not explicitly set, the MTA will use more general options: in legacy configuration, the configutil parameters

`local.ugldaphost` and `local.ugldapport`, or in Unified Configuration the `ugldaphost` and `ugldapport` base options). (Indeed, prior to Messaging Server 7.4-18.01, the host and port had to be omitted; but as of Messaging Server 7.4-18.01, specifying the host and port in the URL itself is supported.)

- The MTA makes a distinction between a completely omitted attributes field, which as per RFC 2255 means to request the return of *all* attributes, and an attributes field consisting of the asterisk character, `*`, which the MTA instead interprets as meaning to request the return of *all known-to-the-MTA attributes*, that is, all the attributes listed in Table of MTA LDAP attribute name options. This distinction is available since for some directory setups, there may be a noticeable performance difference in LDAP directory response to one type of query (all attributes requested) *vs*. the other type of query (specific, though large, list of attributes requested).

- Various substitution sequences of the form "`$n`" are available. A literal dollar sign must be represented by "`$$`".

The LDAP URL, before any substitutions, is limited to 256 characters in length (252 in iMS 5.2 and earlier); the substitutions may insert additional material and the length after such substitutions is limited to 1024 characters. Note that the substitution of known attributes when asterisk, `*`, is specified as the attribute to return, is not considered as part of the regular substitution; this substitution is performed at a later step and the length after this "known" attributes substitution is limited to 4096 characters.

`alias_url0`, if set, is normally looked up first (unless the `alias_magic` value has been changed). Next `alias_url1`, if set, *etc*. It is permissible to have "gaps" in the `alias_urlN` list; for instance, it is permissible to set `alias_url0` and `alias_url2` without setting `alias_url1`.

Since `alias_url0` is normally looked up first, in a typical direct LDAP configuration it is used to perform the "main" user/group lookup, with `alias_url1` optionally being used by those sites that need to do an additional, secondary lookup. In particular, `alias_url1` is typically used by those sites that need to support vanity domains, or it could be used by sites that do not support vanity domains but that need to support "old-style" catch-all addresses, (that is, sites that use the deprecated approach of defining a catch-all address by means of a user `mailAlternateAddress` attribute with a wildcard, rather than using the preferred approach of defining a domain level `mailDomainCatchallAddress` attribute).

As of 7.0.5, the default value for `alias_url0` is `ldap:///$V?*?sub?$R`. Previously, there was no default and `alias_url0` had to be set explicitly. The other `alias_urlN` MTA options have no default value.

52.15.3.2 Direct LDAP usergroup lookup MTA options: `ldap_default_attr` (attribute name)

Some sites upgrading from previous software may be accustomed to using LDAP query URLs that do not specify an attribute to return (which for LDAP query URLs literally means to return *all* attributes) in places where all that they really wanted was the return of a single attribute. If the MTA sees an LDAP URL that does not specify which attribute(s) to return used in a place where the MTA knows that only a single attribute is desired, then the MTA will normally change the LDAP URL by forcibly inserting `mail` in the (omitted) *attributes* field of the LDAP URL.

The ldap_default_attr MTA option may be used to tell the MTA some other attribute to forcibly insert into the LDAP query URLs (some other attribute to request) in such cases where the *attributes* field was incorrectly omitted from the original LDAP query URL.

52.15.3.3 Direct LDAP usergroup lookup MTA options: ldap_mail_aliases (comma-separated list of attribute names)

The ldap_mail_aliases MTA option specifies in what attributes address aliases are stored. Hence in particular, this option controls what attributes are used to construct the filter that a $R LDAP substitution sequence inserts, (note that the $R substitution sequence is typically used in the settings of both the alias_url0 and reverse_url MTA options), as well as the attributes requested when doing an LDAP-based mailing list access check on an address. Up to ten comma or (in 7.0.4 or laster) space-separated attribute names may be specified.

In unifified configurations the local.imta.mailaliases configutil parameter is equivalent to ldap_mail_aliases; in legacy configurations the two are separate parameters and the ldap_mail_aliases MTA option, if specified, overrides the local.imta.mailaliases configutil option.

Of neither option is explicitly set then default values are used based upon the schema tag; (see the ldap_schematag MTA option). For a schema tag value of ims50, the default for the ldap_mail_aliases option is "mail,mailAlternateAddress,mailEquivalentAddress". For a schema tag value of nms41, the default for this option is "mail,mailAlternateAddress". For a schema tag value of sims40, the default for this option is "mail,rfc822mailalias".

52.15.3.4 Direct LDAP usergroup lookup MTA options: ldap_mail_reverses (comma-separated list of attribute names)

The ldap_mail_reverses MTA option specifies what attributes are used to build the filter referenced by the $Q LDAP substitution sequence. (In iMS 5.2p2, the reverse_url MTA option, used for address reversal, typically made use of the $Q substitution sequence. However nowadays, reverse_url typically instead makes use of the $R substitution sequence with attribute list therefore determined via the ldap_mail_aliases MTA option. So nowadays $Q, and hence ldap_mail_reverses, are of lesser interest.)

The default, if this option is not explicitly set, depends upon the schema tag. For a schema tag value of ims50 or nms41, the default for the ldap_mail_reverses option is "mail,mailAlternateAddress". For a schema tag value of sims40, the default for this option is "mail,rfc822MailAlias".

See also the ldap_mail_aliases and ldap_equivalence_addresses MTA options.

Normally, ldap_mail_reverses should be set to include, in addition to the canonical mail attribute, all attributes set for ldap_mail_aliases, but should *not* include the attribute(s) set for ldap_equivalence_addresses. In particular, if ldap_mail_aliases is changed to a non-default value, one would normally want to change ldap_mail_reverses in a corresponding fashion.

52.15.3.5 Direct LDAP schema MTA options: ldap_user_root (DN)

The ldap_user_root MTA option specifies the base DN for the user and group portion of the DIT for purposes of MTA LDAP URL lookups. (In particular, $B substitutions in LDAP

URL lookups use this value.) This option, if set, overrides the base option `ugldapbasedn` (or in legacy configuration, the configutil parameter `local.ugldapbasedn`). If neither the MTA option nor the base option (in legacy configuration, the configutil parameter) has been explicitly set, then the default is `o=isp`.

52.15.3.6 Direct LDAP usergroup lookup MTA options: `reverse_url` (URL)

The `reverse_url` MTA option specifies the URL to query for address reversal and associated side-effects. Standard LDAP URL syntax as per RFC 2255 is used, except that the LDAP server and port may be omitted (in which case they are specified by the `ldap_host` and `ldap_port` MTA options -- or in legacy configuration, alternatively specified via the configutil parameters `local.ugldaphost` and `local.ugldapport`). Also, certain substitution sequences are available. The length, before substitution, is limited to 256 characters; (the limit was 252 characters in iMS 5.2 and earlier); the length resulting from the substitutions is limited to 1024 characters.

For typical MTA configurations, the usual value to which to set the `reverse_url` MTA option is "`ldap:///$V?$N?sub?$R`". Indeed, as of 7.0.5, this is the default; (previously there was no default and a value had to be set explicitly).

Note that the `$R` substitution sequence, which is the filter for the LDAP query, uses the attributes named by the `ldap_mail_aliases` MTA option, (or if that option is not set in legacy configutation, the attributes named by the `local.imta.mailaliases` configutil parameter).

The reason that `reverse_url` normally is set to use a filter that searches on the canonical `mail` attribute, as well as the "subject to reversal" attributes such as `mailAlternateAddress`, is that `reverse_url` lookups actually do more than pure address reversal: `reverse_url` lookups also result in setting other possibly desired information for messages, including for instance use of attributes named by the `ldap_personal_name`, `ldap_capture`, and `ldap_domain_attr_report_address` MTA options. Therefore, the canonical `mail` attribute is included in the search filter (included in `ldap_mail_aliases` which controls what is included in the filter referred to via the `$R` substitution sequence) so that lookups will succeed, and find desired information, even for those users whose addresses are *already* in canonical form.

52.15.4 Direct LDAP schema MTA options

A number of MTA options relate to overall schema choice, and layout of the LDAP Directory Information Tree. In addition to these general, semantically significant such options, there are also options to "rename" the LDAP attributes normally used in the schema, see the Direct LDAP attribute name MTA options, as well as options controlling and altering the MTA's interpretation of LDAP attributes, see the Direct LDAP attribute interpretation MTA options.

52.15.4.1 Direct LDAP attribute name MTA options: `ldap_attr_domain_search_filter` (LDAP attribute name)

The `ldap_attr_domain_search_filter` MTA option specifies the name of the LDAP attribute in the global configuration template area (see the `ldap_global_config_templates` MTA option) that is used to store the domain search filter template. For instance, one attribute that might be used for such a purpose (hence to which this option might be set) would be `inetDomainSearchFilter`.

52.15.4.2 Direct LDAP schema MTA options: ldap_basedn_filter_schema1 (LDAP URL filter), ldap_basedn_filter_schema2 (LDAP URL filter elements)

(New in MS 6.3-0.15.) The ldap_basedn_filter_schema1 MTA option specifies the filter used to identify schema 1 domains when performing baseDN searches. The ldap_basedn_filter_schema2 MTA option specifies additional filter elements used to identify schema 2 domains when performing baseDN searches. The default is that neither the ldap_basedn_filter_schema1 MTA option nor ldap_basedn_filter_schema2 MTA option is set. When these options are not set, then the values of ldap_domain_filter_schema1 and ldap_domain_filter_schema2, respectively, are used if those options are set. But if none of these options are set, then the default for ldap_basedn_filter_schema1 is "(objectclass=inetDomain)", while the default for ldap_basedn_filter_schema2 is the empty string.

52.15.4.3 Direct LDAP schema MTA options: ldap_domain_filter_schema1 (LDAP URL filter), ldap_domain_filter_schema2 (LDAP URL filter)

The default is that neither the ldap_domain_filter_schema1 nor ldap_domain_filter_schema2 option is set, neither at the MTA level nor at the base level. When these options are not set, then internal defaults in the domain map code are used, equivalent to:

```
ldap_domain_filter_schema1=(|(objectclass=inetDomain)(objectclass=inetdomainalias))
ldap_domain_filter_schema2=(objectclass=sunManagedOrganization)
```

52.15.4.4 Direct LDAP schema MTA options: ldap_domain_root (DN)

The ldap_domain_root MTA option specifies, for MTA purposes, the base DN for the domain portion of the DIT. This option, if set, overrides (for MTA purposes) the base option dcroot (or in legacy configuration, the configutil parameter service.dcroot). If neither the MTA option nor the dcroot base option (in legacy configuration, the configutil parameter) has been explicitly set, then the default is o=internet.

52.15.4.5 Direct LDAP schema MTA options: ldap_global_config_templates (DN)

The ldap_global_config_templates MTA option specifies the base DN where global configuration templates can be found. It has no default. Note that this option should never be used under normal circumstances; if it is used to specify an unusual search scheme, it may result in domain inconsistencies and other problems.

52.15.4.6 Direct LDAP schema MTA options: ldap_group_object_classes (list of plus-separated list of objectclass names)

The ldap_group_object_classes MTA option specifies the object classes required to be present in a group entry. The default depends upon the schema tag (see the ldap_schematag MTA option). For a schema tag value of ims50, the default for the ldap_group_object_classes option is inetLocalMailRecipient+inetmailgroup. For a schema tag value of nms41, the default for this option is mailGroup. For a schema tag value of sims40, the default for this option is inetMailRouting+inetmailgroup.

52.15.4.7 LDAP bind and connect options: ldap_schemalevel (1 or 2)

The ldap_schemalevel base option specifies the schema level in use. This option is also available at MTA level. Supported values are 1 or 2. If this option is not set, schema level 1 is assumed to be in use.

52.15.4.8 Direct LDAP schema MTA options: ldap_schematag (list of schema tags)

The ldap_schematag MTA option specifies the tag(s) for the schema in use. Valid values are nms41, sims40, or ims50, or a comma-separated list of these values. If specified, this option overrides the value of the local.imta.schematag configutil parameter in legacy configuration; the two options are equivalent in unified configuration. If neither this option nor the local.imta.schematag configutil parameter is specified, then the default value assumed is ims50.

For purposes of authentication (*e.g.*, user IMAP or POP logins, or SMTP AUTH authentication), there is no corresponding option or configutil parameter setting an overall schema tag (hence automatically causing appropriate use of an alternate schema). Instead, see the searchfilter auth option (corresponding to the legacy configuration sasl.default.ldap.searchfilter configutil parameter), which has default value

```
(&(uid=%U)(objectclass=inetmailuser))
```

hence includes an implicit schema assumption. If using a non-default schema, that auth option (configutil parameter in legacy configuration) may need to be changed to cause user lookups (for authentication purposes) to look for objectclass(es) used in the other schema (*e.g.*, the NMS 4.1 schema).

52.15.4.9 Direct LDAP schema MTA options: ldap_user_object_classes (list of plus-separated list of objectclass names)

The ldap_user_object_classes MTA option specifies the object classes required to be present in a user entry.

The default depends upon the schema tag (see the ldap_schematag MTA option). For a schema tag value of ims50, the default for the ldap_user_object_classes option is inetLocalMailRecipient+inetmailuser. For a schema tag value of nms41, the default for this option is mailRecipient+nsMessagingServerUser. For a schema tag value of sims40, the default for this option is inetMailRouting+inetmailuser.

Note that the $K LDAP URL substitution sequence uses these object classes. For instance, when `ldap_user_object_classes=inetLocalMailRecipient+inetMailUser`, then $K results in substituting

```
(|(&(objectClass=inetLocalMailRecipient)(objectClass=inetMailUser)))
```

Or if `ldap_user_object_classes` is set to

```
inetLocalMailRecipient+inetMailUser,inetMailRouting+inetMailUser
```

then $K results in

```
(|(&(objectClass=inetLocalMailRecipient)(objectClass=inetMailUser))
       (&(objectClass=inetMailRouting)(objectClass=inetMailUser)))
```

For purposes of authentication (*e.g.*, user IMAP or POP logins, or SMTP AUTH authentication), the definition of valid user objectClass(es) is implicit in the setting of the `searchfilter` auth option (or in legacy configuration, the `sasl.default.ldap.searchfilter` configutil parameter), which has default value

```
(&(uid=%U)(objectclass=inetmailuser))
```

hence implicitly includes a schema assumption, and in particular an assumption about what are valid user objectClass(es). If using a non-default schema, this configutil parameter may need to be changed to cause user lookups (for authentication purposes) to look for objectclass(es) used in the other schema (*e.g.*, the NMS 4.1 schema).

52.15.4.10 Direct LDAP schema MTA options: `ldap_user_root` (DN)

The `ldap_user_root` MTA option specifies the base DN for the user and group portion of the DIT for purposes of MTA LDAP URL lookups. (In particular, $B substitutions in LDAP URL lookups use this value.) This option, if set, overrides the base option `ugldapbasedn` (or in legacy configuration, the configutil parameter `local.ugldapbasedn`). If neither the MTA option nor the base option (in legacy configuration, the configutil parameter) has been explicitly set, then the default is `o=isp`.

52.15.5 Direct LDAP attribute interpretation MTA options

Some MTA options control or alter the MTA's interpretation of various LDAP attributes, or specify validity restrictions on LDAP attribute values.

52.15.5.1 User/group LDAP attribute validity and interpretation options: `aliasdetourhost_null_optin` (string)

(New in MS 6.2p4.) Normally, the simple presence of a detour optin attribute (the attribute named by the `ldap_detourhost_optin` MTA option in a user entry, or new in 7.0.5,

the attribute named by the ldap_domain_attr_detourhostoptin MTA option in a domain entry) suffices to cause message detour for messages coming in a channel marked aliasoptindetourhost; the value of the attribute is irrelevant. However, some directory maintenance and provisioning tools cannot easily delete or omit an attribute; instead, they always provide the attribute but assume that some "off" or "null" value for the attribute is available. The aliasdetourhost_null_optin option allows for better interaction with such directory tools. It specifies what value the detour optin attribute (that attribute named by the ldap_detourhost_optin MTA option, or new in 7.0.5 the ldap_domain_attr_detourhostoptin MTA option) must have in order to be ignored (for the MTA to act as if the attribute was not present at all in the user or domain entry). The default value for this option is the empty string, when means that by default a present but empty detour optin attribute is ignored.

Note that message detouring of the aliasoptindetourhost type is typically a detour to some third-party host or channel performing spam/virus filtering. Thus the value of aliasdetourhost_null_optin typically means what value to be considered as the "this user hasn't asked to do spam/virus filtering" value. But note that, for instance, use of such a null value in a user entry does not necessarily disable the detouring (the spam/virus filtering); a user who is not opted-in personally may still be detoured due to a domain level setting, or a channel level (aliasdetourhost channel option) setting.

52.15.5.2 Direct LDAP usergroup lookup MTA options: allow_unquoted_addrs_violate_rfc2798 (0 or 1)

The default for the allow_unquoted_addrs_violate_rfc2798 MTA option is 0. If set to 1, then when searching for an address match the MTA also includes in the search filter a version of the address with quotes stripped off the localpart (portion to the left of the @ character) of the address.

52.15.5.3 Direct LDAP attribute interpretation MTA options: capture_format_default (0 or 1)

(New in 7.4-18.01.) The capture_format_default MTA option controls whether ldap_capture based message "capture" defaults to generating regular, report style messages (the original message encapsulated in a form of DSN), *vs*. other possible forms, such as envelope "journal" style messages. The default is 0, meaning to generate report (DSN encapsulated) messages as the "capture" copies. A value of 1 means to generate pure, unadorned (no additional strucute or header lines) messages as the "capture" copies. A value of 2 means to generate Microsoft® Exchange "journal" format messages as the "capture" copies. New in 8.0 are the values 4 and 5 which mean, respectively, to generate a DSN format message containing only the message header or an Microsoft Exchange "journal" format message containing only the message header, as the "capture" copy.

This option can be overridden on a per-capture-target-address basis by using the appropriate LDAP tag on the "capture" attribute (see ldap_capture and ldap_domain_attr_capture), where ;format-report selects the DSN encapsulated format, and ;format-journal selects the envelope "journal" format. New in 8.0, is support for the LDAP tags ;format-message, ;format-report-header, and ;format-journal-header.

52.15.5.4 Direct LDAP attribute interpretation MTA options: delivery_options (list of strings)

The delivery_options MTA option controls the effect of possible values of the LDAP attribute named by the ldap_delivery_option MTA option, (by default, the mailDeliveryOption attribute). It takes a list of up to twenty strings. Each such string specifies the effect of a particular supported value for the mailDeliveryOption attribute. The syntax for an individual string (among the list of strings) is:

ModifierValue=Effect

where *Modifier* consists of one or more of the optional modifier letters listed in the table Modifier letters for delivery_options, where *Value* is a supported value for the mailDeliveryOption attribute, and where *Effect* describes the intended effect of the corresponding mailDeliveryOption value. Note that if neither * nor & is present, then the delivery option entry is taken to apply to both users and groups.

Table 52.11 Modifier letters for delivery_options

Modifier letter	Meaning
*	Entry applies to users
&	Entry applies to groups
@	Expansion of this user or group should be deferred, by forcing to the reprocess channel
^	Inclusive time limit processing - Check for LDAP attributes specifying vacation start and end time; only apply this entry if the current time is after any specified start time and before any specified end time.
%	(New in 7.0.5) Exclusive time limit processing - Check for LDAP attributes specifying vacation start and end time; only apply this entry if the current time is before any specified start time or after any specified end time.
#	Entry is mailhost-independent; if all of a user or group's delivery options are mailhost-independent, then the MTA can act on the entry immediately rather than having to forward the message to the mailhost.
/	Force addresses produced by this delivery option to be sidelined in .HELD message files.
!	Use internal autoreply mode -- that is, generate a Sieve "vacation" scriptlet (rather than using the obsolete autoreply channel).

For instance, mailbox normally has the modifier * meaning that it applies (only) to users, whereas members normally has the modifier & meaning that it applies (only) to groups.

And while autoreply normally has the modifier * meaning that it applies (only) to users (and so normally mailing list and group entries cannot use autoreply/vacation functionality), if it is desired to allow mailing list and groups to generate their own autoreply/vacation messages, then removing the * modifier from the autoreply clause will allow this---from the MTA point of view. (Note that the Sun schema as distributed normally does not expect/permit mailAutoReply* attributes to be set on mailing list or group entries. So for purposes of placating the Directory Server side, you will likely also need to either extend the schema, or disable schema checking.) As mentioned above, each *Value* should be a supported value for the mailDeliveryOption LDAP attribute (more precisely, the attribute named by the ldap_delivery_option MTA option). And each such supported value for mailDeliveryOption must have exactly one corresponding string in delivery_options describing its intended effect.

Each *Effect* specifies what happens to an original address that has a specified mailDeliveryOption value. For instance, a mailDeliveryOption value of mailbox (which is intended to mean delivery to the message store) is implemented by forcing the address local-part onto the ims-ms or tcp_lmtpcs channel (Message Store delivery channels); a mailDeliveryOption value of native is implemented by routing the address local-part to the legacy native channel (the UNIX native mailbox delivery channel). The *Effect* definition may make use of LDAP URL substitution sequences. In addition, an *Effect* of merely * means to simply substitute back in the original address specified; an *Effect* of ** means to substitute the value of the mailForwardingAddress attribute (more precisely, the attribute named by the ldap_forwarding_address MTA option).

The current default for this option is (note that line breaks below are present merely for typographic reasons---the actual default value should be considered to appear all on one line):

```
*mailbox=$M%$\$2I$_+$2S@ims-ms-daemon,&members=*,
*native=$M@native-daemon,/hold=@hold-daemon:$1L+$2S@$D,
*unix=$M@native-daemon,&file=+$F@native-daemon,
&@members_offline=*,program=$M%$P@pipe-daemon,
#forward=**,*^!autoreply=$M+$D@bitbucket,
#*&nomail=$M+$D@bitbucket
```

This value first appeared in 8.0.1. The previous value, established in 7.0.5, differed in that it failed to preserve subaddresses in held messages:

```
*mailbox=$M%$\$2I$_+$2S@ims-ms-daemon,&members=*,
*native=$M@native-daemon,/hold=@hold-daemon:$A,
*unix=$M@native-daemon,&file=+$F@native-daemon,
&@members_offline=*,program=$M%$P@pipe-daemon,
#forward=**,*^!autoreply=$M+$D@bitbucket,
#*&nomail=$M+$D@bitbucket
```

Note the addition of the new-in-7.0.5 "nomail" clause. Setting a user to have the "nomail" delivery option causes the address to act as a valid recipient but silently delete all messages; this setting is useful for setting up an LDAP entry for a valid-but-unmonitored e-mail address. Formerly, prior to 7.0.5, the default had been:

```
*mailbox=$M%$\$2I$_+$2S@ims-ms-daemon,&members=*,
*native=$M@native-daemon,/hold=@hold-daemon:$A,
*unix=$M@native-daemon,&file=+$F@native-daemon,
&@members_offline=*,program=$M%$P@pipe-daemon,
#forward=**,*^!autoreply=$M+$D@bitbucket
```

On a system doing LMTP delivery (via LMTP client channels), this option would normally be set to (on a MS 6.1 or later system):

```
#*mailbox=@$X.LMTP:$M%$\$2I$_+$2S@lmtpcs-daemon,
&members=*,
*native=$M@native-daemon,
/hold=@hold-daemon:$1L+$2S@$D,
```

```
*unix=$M@native-daemon,
&file=+$F@native-daemon,
&@members_offline=*,
program=$M%$P@pipe-daemon,
#forward=**,
*^!autoreply=$M+$D@bitbucket,
#*&nomail=$M+$D@bitbucket
```

where that assumes the use of rewrite rules along the lines of

```
.LMTP   $E$F$U%$H.LMTP@lmtpcs-daemon
.LMTP   $B$F$U%$H@$H@lmtpcs-daemon
```

and an outbound `tcp_*` channel, (typically but not necessarily named `tcp_lmtpcs`), corresponding to the `lmtpcs-daemon`; official channel host name, and where the channel is marked with the `multigate` channel option.

For another example of an alternate setting of `delivery_options`, see Additional `ims-ms` channels.

Since up to twenty comma-separated strings may be specified for this option, note that up to twenty different possible delivery option values can be supported.

Note that the value clauses in the first two positions have special meaning as far as being the default delivery approaches for users and groups, respectively, which is why those first two value clauses are normally set to define `mailbox` and `members`. (That is, in the case of a user who has no `mailDeliveryOption` value specified in their LDAP entry, the first value clause of `delivery_options`---normally `mailbox`---will be assumed: a user with no `mailDeliveryOption` set gets messages delivered to their mailbox. Similarly, a group that has no `mailDeliveryOption` value specified will get the treatment specified by the second value clause of `delivery_options` -- normally `member`: a group with no `mailDeliveryOption` set gets messages delivered to the members of the group.) Thus if defining additional, site-specific mailbox delivery option values, be sure to add the custom values *later* in the list of option values.

Also note that when setting this option in the legacy configuration MTA option file `option.dat`, if using the backslash continuation line character to continue to additional lines, be aware of a potential confusion with "comment characters". Any line that begins in column one with one of the MTA option file's comment characters (`!`, `;`, #) will be interpreted as a comment *regardless* of whether the line above ended with a backslash. This issue can be worked around using the fact that the MTA ignores leading spaces after the comma separating individual strings within `delivery_options`; so you can use a definition such as

```
DELIVERY_OPTIONS=\
*mailbox=$M%$\$2I$_+$2S@ims-ms-daemon,&members=*,\
*native=$M@native-daemon,hold=$M?$I@hold-daemon,\
*unix=$M@native-daemon,&file=+$F@native-daemon,\
&@members_offline=*,program=$M%$P@pipe-daemon,\
 #forward=**,^*!autoreply=$M+$D@bitbucket
```

where note the critical initial space on the line that does the `forward` value definition.

New in 7.0-0.04, there is some "sanity checking" on individual clauses within `delivery_options`, with an MM initialization error issued ("`Invalid delivery option clause: clause`") if such a check fails. Previously, certain sorts of problems in clauses would instead cause the clause to be silently ignored, with no warning or error.

In particular, prior to 7.0-0.04 the overall length limit for a clause was 81 characters, with at most 40 characters allowed left of the equals sign and at most 40 characters allowed right of the equals sign. As of 7.0-0.04, the overall length limit for each clause is 256 characters (though exceeding this limit will merely cause silent truncation rather than an error), with at most 40 characters *not including leading modifier characters* to the left of the equals sign (that is, at most 40 characters in the actual "name" in the clause), and whatever remains of the 256 characters allowed on the right of the equals sign. Furthermore, as of 7.0-0.04, omission of an equals sign in a supposed clause will result in an MM initialization error.

52.15.5.5 Direct LDAP attribute interpretation MTA options: `group_dn_template` (URL template)

The `group_dn_template` MTA option affects the interpretation of the `uniqueMember` attribute (more specifically, the interpretation of the attribute named by the `ldap_group_dn` and as of 7.0.5, the `ldap_group_dn2`, MTA options). As of 7.4-18.01 , the default is:

```
ldap:///$A??sub?(mail=*)
```

The default (as of MS 6.3, but prior to 7.4-18.01) was:

```
ldap:///$A??sub?mail=*
```

And prior to MS 6.3, the default had been:

```
ldap:///$A?mail?sub?mail=*
```

Note that these earlier defaults prior to Messaging Server 7.4-18.01 were actually in error (violated LDAP search filter syntax), as they omitted the enclosing parentheses that ought to be present on the filter.

The change in the default for MS 6.3 (of no longer specifically requesting only the `mail` attribute to be returned) was to allow taking advantage, even in the case of an `mgrpAllowedBroadcaster` attribute set to a DN, of an enhancement (also implemented in MS 6.3) whereby list expansion in the context of the `mgrpAllowedBroadcaster` LDAP attribute now includes all the attributes used to store email addresses (normally `mail`, `mailAlternateAddress`, and `mailEquivalentAddress`), thereby allowing recognition of allowed broadcaster aliases. (Previously only `mail` attributes were returned, making it impossible to send to lists restricted to their own members using alternate addresses (aliases).)

52.15.5.6 Archive message format control: `journal_format` (bitmask)

The `journal_format` MTA option controls the format of Microsoft® Exchange journaling messages generated by the MTA. This is a bit-encoded option. Currently assigned bits are:

Table 52.12 `journal_format` MTA option bit values

Bit	Value	Description
0	1	If set, generate the basic 2007 journal format instead of the 2003 format.
1	2	If set, set the From:/To:/Subject: of the journal message to be the same as the message being journaled. Note that setting this may cause looping problems for setups that use header checks to determine what messages to archive.
2	4	If set, generate a X-MS-Exchange-Organization-Journal-Report: header field rather than a X-MS-Journal-Report: field.
3	8	If set, include expanded/forwarded address information in the report (if such information is available -- see the `addrtypescan` channel option). Note that bit 0 must also be set for this to work.

The default value for this option is 0. This option is intended to facilitate interoperating with Microsoft Exchange itself, in particular, so that MTA-generated journal messages can be imported into Microsoft Exchange.

52.15.5.7 Direct LDAP attribute interpretation options: `ldap_default_domain` (string)

The `ldap_default_domain` MTA option specifies the domain name that is recognized and interpreted as the default domain *by the MTA*. In legacy configuration, this option, if set, overrides the configutil parameter `service.defaultdomain`. In Unified Configuration, this option, if set, overrides (for MTA purposes) the base level `defaultdomain` option -- but it would be more normal/preferable to only set `defaultdomain` so that all components of Messaging Server have a consistent choice of default domain.

In particular, in `delivery_options` substitutions, the canonical domain name for the domain in which a user is located is compared against the `ldap_default_domain` value. If they match, then substitutions such as `$I` will not insert a domain name; that is, `ldap_default_domain` is the domain name for which (in typical configurations) usernames will be left "bare" when constructing a mailbox.

The `ldap_default_domain` also specifies the domain name that preferentially will be returned for Sieve environment `"domain"` tests; if it is not set, then the MTA falls back to the `received_domain` if set, or otherwise the official hostname of the L channel.

52.15.5.8 Head of household LDAP attribute MTA options: `ldap_hoh_filter` (LDAP attribute name), `ldap_hoh_owner` (LDAP attribute name)

The `ldap_hoh_filter` and `ldap_hoh_owner` MTA options specify the names of the LDAP attributes used to store the critical Head of Household data in users who are themselves a

Head of Household. These options default to, respectively, `mailSieveRuleSource` and `mail`. That is, `ldap_hoh_filter` specifies the name of the LDAP attribute in which a Head of Household user stores the Sieve filter used for Head of Household purposes (which may or may not be a different Sieve filter than the user's own, personal Sieve filter; the default `mailSieveRuleSource` value causes the Head of Household Sieve filter to be the same as the user's personal Sieve filter, but sites that wish a distinction may set `ldap_hoh_filter` to point to a different, site-specific LDAP attribute). Since proper evaluation of (and especially error reporting regarding) a Sieve filter requires an "owner" e-mail address associated with that Sieve filter, the `ldap_hoh_owner` MTA option specifies what LDAP attribute in the Head of Household user's entry will be the address associated with the Sieve; again, the default value of `mail` means that the Head of Household user's own, personal e-mail address will be used, but sites that wish a distinction may set `ldap_hoh_owner` to some different, site-specific LDAP attribute.

These MTA options specify the names of the LDAP attributes to return when a user entry has parental controls/head of household controls set on it (see the `ldap_parental_controls` MTA option) so that a lookup of the user's "parent" (see the `ldap_filter_reference` MTA option) is performed: in the "parent" entry, the attributes specified by `ldap_hoh_filter` and `ldap_hoh_owner` are found and their values returned.

52.15.5.9 `ldap_host_alias_list` Option Under mta

The `ldap_host_alias_list` MTA option specifies local host aliases for LDAP lookup result interpretation purposes. Specifying this option at MTA level overrides, for MTA purposes, the `base.ldap_host_alias_list` base option (`local.imta.hostnamealiases` configutil parameter in legacy configuration), thereby allowing the MTA to recognize a different set of such aliases than the Message Store recognizes. Neither the base nor MTA level option has a default value; if the base level option is set, it is used by the MTA unless the MTA level option has been explicitly set in which case the MTA uses the MTA level option's value.

The `ldap_host_alias_list` value takes a comma-separated list of up to 40 host aliases; each host alias may be at most 256 characters long; the total length of the entire list is limited to 1024 characters. (In iMS 5.2, the limits were smaller: at most 20 host aliases and each host alias at most 252 characters long.) New in Messaging Server 7.0.5.36, the MTA supports wild-carded host name values.

The `ldap_host_alias_list` value(s) are used by the MTA when deciding whether a domain's `mailRoutingHosts` value(s) or a user's `mailHost` value is "local" (this MTA itself). That is, once an LDAP lookup of a domain or user occurs, this option's value(s) affect the interpretation of the result of the LDAP lookup.

An important use of the `ldap_host_alias_list` is in email configurations spanning multiple data centers, with routing via SMTP between data centers and delivery LMTP within each data center. In such a setup the mailbox `delivery_options` MTA option clause is set for LMTP but is left as mailhost-dependent, rather than as in a typical configuration being marked with "#" to be mailhost-independent. Then all the LMTP hosts for the local data center are listed in the `ldap_host_alias_list` MTA option value on each MTA. Note that as the number of stores becomes large it's preferable to use a naming convention for stores along with a wildcard `ldap_host_alias_list` value, to avoid configuration churn as stores are added or deleted.

52.15.5.10 Direct LDAP attribute interpretation MTA options: `ldap_local_host` (string)

The ldap_local_host MTA option specifies the local hostname (official host name for the "l" channel) for LDAP lookup result interpretation purposes. If not set, it defaults to the value of the hostname Base option. If set, this option overrides the hostname Base option (in legacy configuration, the local.hostname configutil parameter). Normally ldap_local_host and channel:l.official_host_name should be set to match: the distinction is that the ldap_local_host value affects interpretation by the MTA of LDAP lookup results (as well as during initial installation/configuration controlling what hostname is generated for the "l" channel official_host_name and combined with standard channel prefixes to generate an appropriate official_host_name value for the other standard channels), whereas channel:l.official_host_name controls MTA address interpretation and processing in other contexts such as rewrite rules and SMTP server hostname defaults. But since initial installation/configuration normally sets the channel:l.official_host_name based on the hostname Base option value, they normally indeed "match".

Note that the &/IMTA_HOST/ substitution value comes from ldap_local_host (which if not set explicitly, defaults to the value of the hostname Base option, or local.hostname in legacy configuration).

52.15.5.11 Direct LDAP attribute interpretation MTA options: ldap_uid_invalid_chars (list of integers)

This option specifies the ASCII positions of those characters which are not allowed to appear in a uid or permanent identifier. (The MTA unconditionally disallows all characters below position 32, so this option specifies the list of additional characters to disallow.) The default is

```
32,33,34,35,36,37,38,40,41,42,43,44,47,58,49,60,61,62,63,65,91,92,93,96,123,125,126
```

which corresponds to the characters

```
$ ~=#*+%!@,{}()/\<>;:"`[]&?
```

(space character and dollar character have been swapped for readability). Furthermore, note that the Message Store code further enforces a restriction that the leading character of the uid may not be a hyphen, -. (This is to avoid ambiguity with IMAP ACL syntax.) Prior to Messaging Server 7.0.5, The MTA does not enforce this restriction, however.

Note that the uid (synonym for userID) LDAP attribute was defined in RFC 1274, The COSINE and Internet X.500 Schema, as a caseIgnoreString of length at most 256 characters. As of Messaging Server 7.0-0.04, the MTA checks that the uid value (more precisely, the value of the attribute named by the ldap_uid MTA option) is no more 128 octets, and a longer value will result in the user entry being considered invalid. (This check is performed because various lower layer libraries have hard buffer limits that preclude longer uids.) In general, because with Messaging Server the uid is used not only for logging in (a "computer system login name" is how RFC 1274 discussed userid), but also, in hashed form, to specify part of the file path for where user messages are stored, then Messaging Server needs additional restrictions on the uid so that the file path constructed using the uid is good and safe.

52.15.5.12 Spamfilter MTA options: optin_user_carryover (bitmask)

New in MS 6.2. The `optin_user_carryover` MTA option controls whether user spam/virus filter "opt in" requests will "carry over" when doing forwarding. That is, if the original recipient has opted-in but has then forwarded their e-mail to some other recipient, does that other recipient get the "opt in" effect?

Bit 0 (value 1): setting this bit means that "opt in" effect is disabled for all forwarded-to address(es). Bit 1 (value 2) controls the behavior for domain "opt in"; setting the bit disables the "opt in" effect for the forwarded-to address(es). Bit 2 (value 4) means that user "opt in" overrides any previous user/domain "opt in" setting. Bit 3 (value 8) controls the behavior for aliases (typically lists) marked with the `alias_optin` alias option or named parameter [OPTIN]; setting the bit disables the "opt in" effect for the forwarded-to address(es). The default is 0. Note that this option applies globally to *all* spam/virus filter packages; it does *not* come in numbered variants to apply only to one spam/virus filter package or another.

52.15.5.13 Direct LDAP attribute interpretation MTA options: `process_substitutions` (bit-encoded integer)

New in MS 6.3. The `process_substitutions` MTA option controls whether to process substitution sequences in the URL values of various LDAP attributes. See Table of LDAP URL substitution sequences for a list of substitution sequences (though only some such substitution sequences make sense and are available in the contexts discussed below). The default is 0, meaning that all such substitutions are disabled by default.

Table 52.13 `process_substitutions` MTA option bits

Bit	Value	Usage
0	1	If set, enables substitutions in `mgrpDisallowedBroadcaster` (`ldap_cant_url`)
1	2	If set, enables substitutions in `mgrpAllowedBroadcaster` (`ldap_auth_url`)
2	4	If set, enables substitutions in `mgrpModerator` (`ldap_moderator_url`)
3	8	If set, enables substitutions in `mgrpDeliverTo` (`ldap_group_url1`)
4	16	If set, enables substitutions in `memberURL` (`ldap_group_url2`)
5	32	(New in Messaging Server 7.0) If set, enables subaddress `$S` substitution in `mgrpErrorsTo` (`ldap_errors_to`)
6	64	(New in Messaging Server 7.0u3) If set, enables substitutions in `mgrpJettisonBroadcasters` (`ldap_jettison_url`)

Bit 0 is the least significant bit.

Note that the information source for substitution values varies depending on whether the attribute in question is used for authorization checks, or for actual list expansion. For authorization attributes, the whole address (`$A`), domain (`$D`), host (`$H`), and local-part (`$L`) are all derived from the authenticated sender address. In the case of list expansion attributes, all of these substitution values are derived from the envelope recipient address that specified the list. In both cases, however, the subaddress substitution (`$S`) is derived from the current envelope recipient address.

In particular, the ability to access subaddress information in list expansion URLs makes it possible and convenient to define a "meta-group"; that is, a single group entry that in effect creates an entire collection of different groups. For example, a group with attributes including:

```
mail: group@domain.com
mgrpDeliverTo: ldap:///o=usergroup?mail?sub?(department=$S)
```

would make it possible to send mail to every member of a given department with an address of the form

```
group+department@domain.com
```

Note that creation and use of such a "meta-group" does not require the use of subaddresses (though subaddresses are often a convenient syntax for such a purpose). Other mechanisms, such as other forms of "special" addresses transformed via a `FORWARD` mapping table or `ldap_url_result_mapping` attribute's value mapping table, could be used instead to provide "meta-group" functionality. Note that `process_substitutions` effects, if any, occur *after* the `ldap_url_result_mapping` table, if any, has been applied.

52.15.5.14 Direct LDAP attribute interpretation MTA options: `route_to_routing_host` (-1, 0 or 1)

When a domain entry includes the attribute named by the `ldap_domain_attr_routing_hosts` MTA option, (by default, the `mailRoutingHosts` attribute), this attribute's values are compared against the MTA's own local host name and host aliases `ldap_local_host` and `ldap_host_alias_list` values) to determine whether the domain is "owned" (or "local") to this particular MTA. "Local" addresses are of course further processed by the MTA.

The `route_to_routing_host` MTA option controls what the MTA does with addresses determined in this way to be non-local; that is, what the MTA does with addresses which, while having a local (known) domain in the directory, are marked as having some other authoritative mail host. When the `route_to_routing_host` MTA option is set to 0 (the default), such addresses are handled as specified by whatever rewrite rules apply to the address. (This was the only behavior available with iMS 5.2.) When this option is instead set to 1, then such addresses are instead routed to the first host listed in the `mailRoutingHosts` attribute.

New in 8.0.1.1, a setting of -1, in addition to disabling routing of addresses with nonlocal mailhosts to the mail routing host, acceptance of addresses without a user entry and routing them to the `mailRoutingSmartHost` defined for the corresponding domain is also disabled. The smart host for the domain will continue to be used for addresses that match user entries that fail to specify a mailhost.

52.15.5.15 Sieve filter MTA options: `sieve_user_carryover` (0 or 1)

New in MS 6.0-0.01. The default is 0. If set to 1, user Sieve filters don't "carry over" when doing `mailDeliveryOption: forward`. This option is only relevant for direct LDAP forwarding

(forwarding via `mailDeliveryOption` and `mailForwardingAddress`); it does not have any effect on other forms of forwarding.

52.15.5.16 Handling of multiple spare LDAP attributes: `spare_N_separator` (bit-encoded integer)

The `spare_N_separator` MTA options, where *N* is between 1 and 18, control how multiple user entry LDAP attributes that end up being mapping into a single spare LDAP attribute slot are handled. These options accept a nonnegative integer value. The lower 8 bits of this value are intrpreted as follows:

Table 52.14 `spare_N_separator` MTA option values

Value	Meaning
3	Multiple attribute values are not allowed - the user entry is considered invalid and ignored if multiples are present.
2	Use language tag information to decide which of the multiple attributes to use.
1	Multiple attributes are not allowed - the user entry is considered invalid if multiples are present.
0	Pick one of the values at random and use it.
32-255	Concatenate multiple attribute values together, using the character corresponding to the `spare_N_separator` value as the separator.

The remaining bits of the option are used as bit flags. Currently only bit 8 (value 256) is defined: If set, it causes the attribute name and an equals sign to be prepended to the stored value.

These options first became available in the Messaging Server 7.2-7.02 release. The default values for `spare_N_separator` are chosen to remain backwards compatible with spare attribute behavior in earlier releases, which was hardwired for a given spare slot. `spare_1_separator` and `spare_2_separator` default to 1, `spare_3_separator` defaults to 0, and `spare_4_separator`, `spare_5_separator`, and `spare_6_separator` default to 2. All of the remaining options up to `spare_18_separator` default to 0.

52.15.5.17 Autoresponse periodicity MTA options: `vacation_minimum_timeout` (integer)

(New in 7.0.5.) The `vacation_minimum_timeout` MTA option establishes a minimum value, in seconds, for the Sieve "`vacation`", "`:days`", "`:hours`", and "`:seconds`" parameters. ("`:days`" and "`:hours`" values are converted into seconds for the comparison.) Values lower than the minimum are silently adjusted up to the minimum; no error occurs. The default value for `vacation_minimum_timeout` is 0.

Since the value of the `mailAutoReplyTimeOut` LDAP attribute (or more precisely the value of whatever LDAP attribute is named by the `ldap_autoreply_timeout` MTA option) is converted into such a Sieve "`vacation`" parameter, the `vacation_minimum_timeout` MTA option value can affect the interpretation of any `mailAutoReplyTimeout` values also.

52.15.5.18 Autoresponse periodicity MTA options: `vacation_maximum_timeout` (integer)

(New in 7.0.5.) The `vacation_maximum_timeout` MTA option establishes a maximum value, in seconds, for the Sieve "`vacation`", "`:days`", "`:hours`", and "`:seconds`" parameters. ("`:days`" and "`:hours`" values are converted into seconds for the comparison.) Values higher than the maximum are silently adjusted down to the maximum; no error occurs. The default value for `vacation_maximum_timeout` is the maximum allowed integer, 2**31-1.

Since the value of the `mailAutoReplyTimeOut` LDAP attribute (or more precisely the value of whatever LDAP attribute is named by the `ldap_autoreply_timeout` MTA option) is converted into such a Sieve "`vacation`" parameter, the `vacation_maximum_timeout` MTA option value can affect the interpretation of any `mailAutoReplyTimeout` values also.

52.15.5.19 Direct LDAP MTA options: `prefix_text_attr` (HTML attribute list)

New in 8.0.1.3. A better-looking result may be produced by associating prefix text inserted into text/html message parts with a particular set of HTML attributes. The `prefix_text_attr` MTA option may be used to do this. If specified, the option causes any prefix material that is inserted into text/html parts to be enclosed in a `<div attrs">` element, where "attrs" is the value of the option.

The default for this option is the empty string, which suppresses the insertion of any additional elements.

52.15.5.20 Direct LDAP MTA options: `suffix_text_attr` (HTML attribute list)

New in 8.0.1.3. A better-looking result may be produced by associating suffix text inserted into text/html message parts with a particular set of HTML attributes. The `suffix_text_attr` MTA option may be used to do this. If specified, the option causes any suffix material that is inserted into text/html parts to be enclosed in a `<div attrs">` element, where "attrs" is the value of the option.

The default for this option is the empty string, which suppresses the insertion of any additional elements.

52.15.6 Direct LDAP attribute name MTA options

By default, the MTA assumes a particular sort of LDAP schema; that is, the MTA assumes that certain named attributes (with certain sorts of meanings) are available and used in the LDAP directory to store the user and domain information. However, the exact attribute names that the MTA looks for (recognizes) are configurable via the various `ldap_*`, `ldap_attr_domain*`, and `ldap_domain_attr_*` MTA options, listed below. Thus a different (though semantically compatible) schema may be used by setting the `ldap_*`, `ldap_attr_domain*`, and `ldap_domain_attr_*` MTA options to tell the MTA what named attributes to use (recognize).

Note that many of the attributes used (and hence the attribute name which the MTA by default expects to see used) are standardized; see for instance RFC 2798 (Definition of the inetOrgPerson LDAP Object Class). Other attributes are specific to the Sun schema; see the *Sun Schema Reference Guide*.

Note that prior to MS 6.3-0.15, each LDAP attribute could be used for only one (from the MTA's point of view) purpose. In particular, prior to MS 6.3-0.15, the MTA would not permit setting two of its LDAP attribute name options to the same underlying LDAP attribute. If a site wanted to use the "same" LDAP attribute for multiple purposes in the MTA, that previously would have to be achieved by creating a second LDAP attribute (named differently), and having its value be duplicated in LDAP. New in MS 6.3-0.15, this restriction has been relaxed, so that two MTA purposes (options) can use the same underlying LDAP attribute; for instance, one can now set, say, `ldap_optin1` and `ldap_optin2` to both point to (use/name) the same underlying LDAP attribute, *e.g.*, `mailAntiUBEService`.

Note that throughout this discussion and other MTA discussions, for convenience often LDAP attributes will be referred to merely by name. But in general, any such MTA reference to a specific attribute name really ought to be a reference to the attribute named by the corresponding MTA option. For instance, any use by the MTA of the `mailConversionTag` attribute is really a use of the attribute named by the `ldap_conversion_tag` MTA option.

However, the general authentication libraries in Messaging Server (sometimes referred to as SASL libraries, or HULA) used for authentication (both by the MTA when performing SMTP AUTH authentication, or by the Message Store when performing login to a user mailbox) do not permit the same degree of "renaming" of attributes. As the authentication infrastructure uses LDAP simple bind for traditional password authentication, if the LDAP directory itself is configured to look at an attribute other than the usual `userPassword` for LDAP simple bind, that should just work. However, in order to support CRAM-MD5/APOP, then the `userPassword` attribute must be used and it must contain the clear-text password. The authentication infrastructure also has hard dependence on various user attributes including `uid`, `inetUserStatus`, `mailUserStatus`, and `mailAllowedServiceAccess` (among others). (Note that the MMP and its proxy servers can be configured to use a different LDAP attribute in place of `mailAllowedServiceAccess` via their `tcpaccessattr` option; the IMAP, POP, and MSHTTP servers, however, always use `mailAllowedServiceAccess`.)

And of particular relevance when configuring and considering MTA operation, another attribute which is not renameable (prior to the 8.0 release) via an MTA option is the `mailSMTPSubmitChannel` user attribute. (This is because the MTA itself makes no explicit use of this attribute. Instead, authentication library code explicitly fetches the `mailSMTPSubmitChannel` attribute's value, and then uses that value to tell the MTA what source channel to set.) But as of 8.0, some renaming/specification of the attributes returned with successful authentication is possible; in particular, see the `ldap_auth_attr_submit_channel` MTA option which specifies the name of the LDAP attribute whose value the authentication library should fetch (in place of the default `mailSMTPSubmitChannel` attribute's value). Also new in 8.0, the authentication library may be directed to fetch back values of LDAP attributes other than the default `mail` and `mailHost` via the `ldap_auth_attr_sender` and `ldap_auth_attr_mail_host` MTA options, respectively. See Direct LDAP attributes returned upon authentication MTA options.

The schema sets restrictions (via an ACI) on which attributes even in his or her "own" entry an end user is allowed to modify. Reassigning the MTA's interpretation of LDAP attributes via MTA options does not, itself, affect such LDAP schema restrictions; so when reassigning end-user-modifiable LDAP attributes, be sure to also update your schema ACIs correspondingly.

Technical note: In the table below, the user/group attributes are listed in roughly the order in which they are processed by the MTA (though there have been some changes in various versions, and there are some subtleties not captured in the order shown). While this order does not matter for most purposes, on occasion it can be helpful to consider this order as an aid to understanding certain interactions and precedence between attributes.

Table 52.15 MTA LDAP attribute name options

Option	Default attribute name(s)	Valid	Meaning and notes
Per-user/group attributes			
ldap_objectclass	objectClass	UGD	
ldap_user_status	inetUserStatus	U	Prior to Messaging Server 7.0, the supported values were a strict subset of the supported mailUserStatus values, and in particular the only supported values were active, inactive, or deleted. As of Messaging Server 7.0, for the convenience of sites that may wish to "switch" the use (in effect switch the priority order in which checking occurs) of inetUserStatus and mailUserStatus, the full set of values supported for mailUserStatus are also supported for inetUserStatus. This is not intended to encourage general, direct use of such additional values for inetUserStatus, but rather, as mentioned, is intended so that the priority (order of checking) of these two status settings for users can be reordered by setting them "switched": ldap_user_status=mailUserStatus ldap_user_mail_status=inetUserStatus
ldap_user_mail_status	mailUserStatus	U	Valid values are active, inactive, disabled, deleted, overquota, hold, removed (new in MS 6.0), defer (new in MS 6.3), defer-submit (new in MS 6.3), deliver (new in 7.3-11.01), and deliver-disabled (new in 8.0.1.3/8.0.2.1). A status of removed is equivalent to deleted from the MTA's point of view; it exists as a distinct status for the benefit of the commcli user purging operation. The statuses defer and defer-submit tell the MTA to accept all messages to the user but defer them to the reprocess channel for later delivery (re)attempts; or in the case of defer-submit accept and defer to the reprocess channel those messages coming in a submit channel while giving inactive behavior, hence normally temporary errors, for attempted submissions on any other channels. A status of deliver is treated by the MTA as active active for purposes of message delivery but which other components will treat as inactive (giving the effect that messages can be delivered, but the user can not login); any other value is treated as inactive. Finally, a status of deliver-disabled is treated by the MTA as disabled by as active by other components.
ldap_group_status		G	Prior to Messaging Server 7.0, the supported values were a strict subset of the values supported for inetMailGroupStatus; in particular, the supported values were active, inactive, and deleted. New in Messaging Server 7.0, all the values supported for inetMailGroupStatus are supported for this attribute as well, for the convenience of sites that wish to "switch" the priority (order) in which they are checked by "switching" which attributes the MTA options ldap_group_status and ldap_group_mail_status point to.
ldap_group_mail_status	inetMailGroupStatus	G	Supported values are active, deleted, removed, disabled, hold, inactive, ew in Messaging Server 7.0 defer anddefer-submit, and new in MS 8.0.1.3/8.0.2.1 deliver-disabled.
ldap_permid	uid	UG	As of Messaging Server 8.0.2, the attribute specified by the ldap_permid option is used for construction of user and group identifiers rather than the attribute specified by the ldap_uid option, assuming they differ. The MTA checks that there is only one such attribute and value and that the value is no more than 128 octets long.
ldap_uid	uid	UG	As of MS 6.2, the MTA checks that there is only one such attribute; as of MS 6.3, the MTA also checks that there is only one value set for the one attribute. As of 7.0, the MTA checks that the UID value is no more than 128 octets; a longer value will result in the user entry being considered invalid. (This check is performed because various lower layer libraries have hard buffer limits that preclude longer UIDs.)
ldap_mlsrange		UG	(New in Messaging Server 7.0?) RESTRICTED
ldap_capture		UG	Specify an attribute used to trigger automatic capturing of user e-mail messages. The value of the attribute should be the address to which the "captured" messages should be sent. Typically, this attribute is set up so that it is not even visible, let alone modifiable, by the users themselves. When a user has this attribute specified on their entry, both messages sent to them, as well as from them, will also have a "capture" copy (an encapsulated copy with an entirely new message envelope) sent to the specified address. New in 7.0.5, the capture_format_default MTA option controls whether message copies generated due to use of the LDAP attribute named by ldap_capture default to being in DSN encapsulated format, or to being in envelope "journal" format. Also new in 7.4-18.01, values of the LDAP attribute may be tagged to explicitly specify the format on a per-target-address basis: the tag ;format-report selects the usual DSN encapsulated format, whereas the tag ;format-journal selects the envelope "journal" format.
ldap_recipientlimit		UG	Specify an attribute used to store a sending-user-specific maximum number of envelope recipients (additional recipients are rejected), analogous to the recipientlimit channel option. New behavior in MS 6.3 is that a per-user setting such as this will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3, a particular user can be allowed to

			send large messages as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.
ldap_recipientcutoff		UG	Specify an attribute used to store a sending-user-specific maximum number of envelope recipients (messages with more recipients are rejected entirely), analogous to the recipientcutoff channel keyword. New behavior in MS 6.3 is that a per-user setting such as this will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 63, a particular user can be allowed to send messages to a large number of recipients as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.
ldap_sourceblocklimit		UG	Specify an attribute used to store a sending-user-specific maximum message size, analogous to the sourceblocklimit channel option. New behavior in MS 6.3 is that a per-user setting such as this will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3, a particular user can be allowed to send large messages as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.
ldap_source_channel		UG	(New in 6.3) Specify a source channel to which to "switch" (if userswitchchannel is set on the current source channel)
ldap_source_optin*N*		UG	(New in 6.3) Sending user analogue of ldap_optin*N* option
ldap_preferred_language	preferredLanguage+	UG	The MTA's typical NOTIFICATION_LANGUAGE mapping table and DISPOSITION_LANGUAGE mapping table checks the value of this attribute when deciding in what language to send back notification messages. Also, as of MS 6.3, the MTA has the ability to chose between multiple LDAP attribute values with different language tags and determine the correct value to use. The language tags in effect are compared against the preferred language information associated with the envelope From address. In MS 6.3, the only attributes receiving this treatment are ldap_autoreply_subject (normally mailAutoReplySubject), ldap_autoreply_text (normally mailAutoReplyText), ldap_autoreply_text_internal (normally mailAutoReplyTextInternal), ldap_spare_4 and ldap_spare_5. As of Messaging Server 7.0-3.01, the attribute named by (new in that version) ldap_spare_6 also received such treatment; as of Messaging Server 7.2-7.01, any of the ldap_spare_N named attributes may optionally, depending upon the setting of the corresponding spare_N_separator MTA option, receive preferredLanguage treatment; and as of Messaging Server 7.3-11.01, the attribute named by ldap_add_tag also receives preferredLanguage treatment.
ldap_preferred_country		UG	(New in MS 6.3-0.15)
ldap_nosolicit		UG	New in 6.2. Specifies solicitation strings used by the SMTP NO-SOLICITING extension that this user doesn't want to receive.
ldap_routing_address	mailRoutingAddress	UG	Used to specify an address to which to route, overriding (as of MS 6.0) the usual mailHost check and mailDeliveryOption interpretation.
ldap_delivery_option	mailDeliveryOption+	UG	See the MTA option delivery_options for a discussion of the interpretation of possible values for this attribute.
ldap_personal_name		UG	Specify an attribute used to store a user's personal name. If this option is set, then the value of the specified attribute (if present in a user entry) will be inserted by the MTA as a personal name wherever the user's address appears in message headers (overriding any originally present personal name for the user that might have been present), including when generating vacation messages on behalf of the user. Note that (as of 6.2p3 for normal messages, or as of 6.2p6 for generated messages such as vacation messages) the MTA will quote the value obtained from LDAP, if required according to the quoting rules for personal names (technically "phrases") given in RFC 5322.
ldap_source_conversion_tag		UG	New in MS 6.2. Specify an attribute whose value will be applied as a conversion tag for messages coming from this user.
ldap_sender_sieve		UG	(New in MS 8.0.1)
ldap_primary_address	mail	UG	
ldap_alias_addresses	*varies with the schema tag;* mailAlternateAddress *for* ims50 *or* nms41; rfc822mailalias *for* sims40	UG	Attributes whose values (addresses) are accepted as equivalent to (aliases for) the canonical mail address on incoming messages; see also the ldap_mail_reverses MTA option which controls just which attributes (addresses) are normally converted to the canonical mail address during reverse_url application via the $Q substitution sequence.
ldap_equivalence_addresses	mailEquivalentAddress	UG	Addresses accepted as equivalent to the canonical mail address for incoming messages; such equivalent addresses are also allowed to appear on outgoing messages (are not converted during reverse_url application). Multiple, comma-separated attribute names are permitted. Note that when setting this option to a non-default value, it is also usually appropriate/necessary to modify the ldap_mail_aliases MTA option correspondingly (to include the attribute(s) named by ldap_equivalence_addresses).
ldap_optin		UG	An alias for ldap_optin1. The presence in a user entry of the attribute named by this option normally (but see the spamfilterN_null_optin MTA options) causes messages addressed to this user to be "opted-in"

			for virus/spam filter package processing (by virus/spam filter package 1), with the opt-in value specified by the value of the attribute. The *Sun Schema Reference Manual* recommends using the `mailAntiUBEService` attribute.
`ldap_optin`*`N`*		UG	(New in MS 6.2.) The presence in a user entry of the attribute named by this option normally (but see the `spamfilter`*`N`*`_null_optin` MTA option) causes messages addressed to this user to be "opted-in" for virus/spam filter package processing (by virus/spam filter package `#` *`N`*), with the opt-in value specified by the value of the attribute. The value of *`N`* can range from 1 to 8. Note that the *Sun Schema Reference Manual* recommends using the `mailAntiUBEService` attribute for optin use.
`ldap_optout`*`N`*		UG	(New in MS 8.0.1.3.) The presence in a user entry of the attribute named by this option normally (but see the `spamfilter`*`N`*`_null_optin` MTA option) causes messages addressed to this user to be "opted-out" of virus/spam filter package processing (by virus/spam filter package `#` *`N`*). The value of *`N`* can range from 1 to 8.
`ldap_presence`		UG	RESTRICTED: Not yet used.
`ldap_autosecretary`		UG	RESTRICTED: Not yet used.
`ldap_alternate_recipient`		UG	(New in MS 8.0.1) Specify an attribute whose value contains alternate recipient address(es) to whom to send the message if it cannot be delivered to this primary recipient.
`ldap_start_date`	`vacationStartDate+`	UG	The value for this attribute should have the format *`YYYYMMDDHHMMSSZ`*, which note is in the GMT timezone. The value for this attribute should have the format *`YYYYMMDDHHMMSSZ`*, which note is in the GMT timezone. An autoreply will only be generated if the current time is after the time specified by this attribute and inclusive limit processing is in effect, or before the specified limit if exclusive time limit processing is in effect. No start date limit is enforced if this attribute is missing.
`ldap_end_date`	`vacationEndDate+`	UG	The value for this attribute should have the format *`YYYYMMDDHHMMSSZ`*, which note is in the GMT timezone. An autoreply will only be generated if the current time is before the time specified by this attribute and inclusive limit processing is in effect, or after the specified limit if exclusive time limit processing is in effect. No end date limit is enforced if this attribute is missing.
`ldap_conversion_tag`	`mailConversionTag`	UG	
`ldap_detourhost_optin`		UG	Opt-in to "detour" routing, as specified by the `aliasoptindetourhost` source channel option
`ldap_blocklimit`	`mailMsgMaxBlocks`	UG	The maximum size, in MTA blocks (see the `block_size` MTA option), of message that may be sent to a user. New in MS 6.3, this attribute will also (for messages that have no return-of-content policy flag already) cause messages sent from this user that are larger than the specified size to automatically get the non-return-of-content NOTARY flag set, to make it more likely that the user will be able to receive any bounce notifications about such message.
`ldap_mailhost`	`mailHost`	UG	Normally, only the host specified by this attribute may interpret (act on) a user's delivery options; however, in the case where all such delivery options are "host-independent", as on an MTA that delivers via LMTP to "back end" message store systems, or when a user entry only contains some particular delivery options that happen to be host-independent, then processing can continue even on other hosts. This attribute is optional for groups and mailing lists. If present for a group or mailing list, it specifies that that host and *only* that host can expand the group or list; if absent, any host can expand the group or list. For a user for whom a `mailHost` is required (such as a user with `mailbox` delivery option set, when `mailbox` delivery is host-dependent per `delivery_options`, with no domain level `ldap_domain_attr_default_mailhost` attribute value set), absence of a `mailHost` attribute will cause a temporary alias expansion error: `4.0.0 temporary error returned by alias expansion: address` (or whatever text is configured via the `error_text_alias_temp` MTA option), the same sort of error that would occur if an LDAP problem had occurred during the lookup of the user entry (after an LDAP lookup of the domain had already succeeded).
`ldap_disk_quota`	`mailQuota`	U	Subsequent to the initial release of MS 6.2, support was added for `mailQuota` values specified in units other than bytes; that is, suffix characters K (kilobytes), M (megabytes), and G (gigabytes) are supported
`ldap_message_quota`	`mailMsgQuota`	U	
`ldap_program_info`	`mailProgramDeliveryInfo+`	UG	
`ldap_delivery_file`	`mailDeliveryFileURL`, `mailDeliveryFile`	UG	
`ldap_spare_1`		UGD	Specify an attribute that may be then be accessed in LDAP URL lookups via a `$E1` substitution.
`ldap_spare_2`		UGD	Specify an attribute that may be then be accessed in LDAP URL lookups via a `$E2` substitution.

ldap_spare_3		UGD	Specify an attribute that may be then be accessed in LDAP URL lookups via a $E3 substitution.
ldap_spare_4		UGD	Specify an attribute that may be then be accessed in LDAP URL lookups via a $E4 substitution as well as in Sieve extlists callouts. Note that new in MS 6.3, the MTA supports the use of multiple, language-tagged values, for this attribute. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines will use the preference noted in the envelope From user's ldap_preferred_language (normally preferredLanguage) attribute's value.
ldap_spare_5		UGD	Specify an attribute that may be then be accessed in LDAP URL lookups via a $E5 substitution, as well as in Sieve extlists callouts. As of MS 6.3, the MTA supports the use of multiple, language-tagged values, for this attribute. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines will use the value tagged as being in the language of the envelope From user's ldap_preferred_language (normally preferredLanguage) attribute's value.
ldap_spare_6		UGD	(New in 7.0-3.01) Specify an attribute that may be then be accessed in LDAP URL lookups via a $E6 substitution, as well as in Sieve extlists callouts. The MTA supports the use of multiple, language-tagged values, for this attribute. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines the MTA's next choice will be the value tagged as being in the language of the envelope From user's ldap_preferred_language (normally preferredLanguage) attribute's value.
ldap_autoreply_mode	mailAutoReplyMode+	UG+++	Supported values for this attribute are echo and reply. These modes will appear in a Sieve script as nonstandard :echo and :reply arguments to the vacation action. echo will produce a "processed" message disposition notification (MDN) that contains the original message as returned content. reply will produce a pure reply containing only the reply text. An illegal value won't manifest as any argument to the vacation action and this will produce an MDN containing only the headers of the original message.
ldap_autoreply_subject	mailAutoReplySubject+	UG+++	This attribute is used to specify the contents of the subject field to use in the vacation (autoreply) response. The value in the attribute must be a UTF-8 string. This value gets passed as the :subject argument to the vacation action. As of MS 6.2p2, the special strings $SUBJECT and $FROM are supported for use in this attribute's value, causing substitution of the original message's Subject: field value or From: field value, respectively, into the generated string. New in MS 8.0.2.2, substitutions from the vacationStartDate and vacationEndDate are also also available. These substitutions take the form $<attribute><part> where $<attribute> is "B" for the start (beginning) date or "E" for the end date, and <part> is one of the date parts defined in RFC 5260 section 4.2. Note that new in MS 6.3, the MTA supports the use of multiple, language-tagged values, for this attribute. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines the MTA's next choice will be the value tagged as being in the language of the envelope From user's ldap_preferred_language (normally preferredLanguage) attribute's value.
ldap_autoreply_text	mailAutoReplyText+	UG+++	This attribute is used to store the vacation (autoreply) text (the "reason" string) returned to all senders except users in the recipient's domain. If the recipient's LDAP entry does not have a value specified for this attribute, then external users receive no vacation message. As of MS 6.2p2, the special strings $SUBJECT and $FROM are supported for use in this attribute's value, causing substitution of the original message's Subject: field value or From: field value, respectively, into the generated string. New in MS 8.0.2.2, substitutions from the vacationStartDate and vacationEndDate are also also available. These substitutions take the form $<attribute><part> where $<attribute> is "B" for the start (beginning) date or "E" for the end date, and <part> is one of the date parts defined in RFC 5260 section 4.2. Note that new in MS 6.3, the MTA supports the use of multiple, language-tagged values, for this attribute;. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines the MTA's next choice will be the value tagged as being in the language of the envelope From user's ldap_preferred_language (normally preferredLanguage) attribute's value.
ldap_autoreply_text_internal	mailAutoReplyTextInternal+	UG+++	This attribute is used to store the vacation (autoreply) text (the "reason" string) returned to all senders in the recipient's own domain. If the recipient's LDAP entry does not have a value specified for this attribute, then internal users receive the external vacation text, stored in the

			`ldap_autoreply_text` MTA option. As of MS 6.2p2, the special strings `$SUBJECT` and `$FROM` are supported for use in this attribute's value, causing substitution of the original message's Subject: field value or From: field value, respectively, into the generated string. New in MS 8.0.2.2, substitutions from the vacationStartDate and vacationEndDate are also also available. These substitutions take the form `$<attribute><part>` where `$<attribute>` is "B" for the start (beginning) date or "E" for the end date, and `<part>` is one of the date parts defined in RFC 5260 section 4.2. Note that new in MS 6.3, the MTA supports the use of multiple, language-tagged values, for this attribute. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines the MTA's next choice will be the value tagged as being in the language of the envelope From user's `ldap_preferred_language` (normally `preferredLanguage`) attribute's value.
`ldap_autoreply_addresses`		UG+++	(New in 6.2p5.) This attribute takes multiple values specifying additional addresses to recognize as "one's own" for purposes of whether to generate a vacation message. That is, it is an analogue of the `:addresses` argument for the Sieve `vacation` action.
`ldap_autoreply_timeout`	`mailAutoReplyTimeOut+`	UG+++	This attribute stores the duration, in hours, for successive vacation (autoreply) responses to any given mail sender. Used only when `mailAutoReplyMode=reply`. If the attribute's value is 0, then a response is sent back every time a message is received. This value will be converted to the nonstandard `:hours` argument to the `vacation` action. If this attribute doesn't appear on a user entry, then a default timeout will be obtained from the user's domain (from the attribute named by the `ldap_domain_attr_autoreply_timeout` MTA option) if the domain has its own timeout, or otherwise from the `autoreply_timeout_default` MTA option.
`ldap_filter`	`mailSieveRuleSource+`	UG	This attribute stores a per-user Sieve filter.
`ldap_parental_controls`		UG	(New in 6.2.) Specifies the name of a user or group LDAP attribute whose value can request "head of household" (a.k.a "parental controls") Sieve filtering be applied to this user's (or group's) messages. Any of the values `Yes`, `1`, or `true` is considered to be requesting parental controls.
`ldap_filter_reference`		UG	(New in 6.2.) If parental controls are enabled for a user (see the `ldap_parental_controls` MTA option), then the attribute named by this `ldap_filter_reference` MTA option specifies the DN of the entry that contains the actual head of household filter (typically, that is, the DN of the head of household user). (The attribute within that user entry containing the filter is specified by the `ldap_hoh_filter` MTA option, which defaults to `mailSieveRuleSource`. The lookup requests both the filter, contained in the attribute named by the `ldap_hoh_filter` MTA option, and the owner, contained in the attribute named by the `ldap_hoh_owner` MTA option, which defaults to `mail`.)
`ldap_forwarding_address`	`mailForwardingAddress+`	UG	Address(es) used in the expansion of named delivery options with the special value "*" (normally the name "`forward`" is associated with this value).
`ldap_list_id`	`mgrpUniqueId`	G	(New in 7.3-11.01) Single valued attribute specifing a unique identifier for the group. This identifier is used to implement MAILSERV group membership; it provides the identifier on one side of the linkage between groups and entries in the mluser tree. If this attribute is present, and and the `ldap_mluser_basedn` MTA option is set, various virtual attributes are to the group automatically; the specifics vary depending on list policy settings.
`ldap_reprocess`	`mailDeferProcessing`	UG	This attribute allows per-group or per-list override of the `defer_group_processing` MTA option. Valid values are "`Yes`", "`No`", or (new in MS 6.3p1) "`AFTER_AUTH`". "`AFTER_AUTH`" causes LDAP attribute based access checks, such as `mgrpAllowedBroadcaster`, *etc.*, to get performed "in-line", while deferring membership expansion (as well as a second check of the LDAP attribute access checks) to the reprocess channel. New in Messaging Server 7.0u3, a channel name (*e.g.*, "`process_special`" or some similar, special, `reprocess_*` or `process_*` channel variant value) may be specified, and in this case the group or list expansion will be deferred to the specified channel.
`ldap_jettison_domain`	`mgrpJettisonDomain`	G	(New in 7.3-11.01) Messages from these domains are silently discarded. Glob-style wildcards may be used. Multiple attributes and multiple values are allowed.
`ldap_jettison_url`	`mgrpJettisonBroadcasters`	G	(New in 7.3-11.01) URL identifying mail addresses whose messages should be jettisoned if sent to this group. Multiple attributes and multiple values are allowed; `mailto:` URLs are acceptable. Each URL is expanded into a list of addresses and each address is checked against the current envelope from address. A match marks the message to be jettisoned and bypasses all other group checks and expansion. Substitution processing will be performed on this URL if bit 6 (value 64) of the `process_substitutions` MTA option is set.
`ldap_reject_action`	`mgrpMsgRejectAction`	G	(New in 6.0) Single valued attribute that controls what happens if any of the subsequent access checks fail. Only one value is defined: "TOMODERATOR", which if set instructs the MTA to redirect any access

			failures to the moderator specified by the mgrpModerator attribute. The default (and any other value of this attribute) causes an error to be reported and the message rejected.
ldap_reject_text	mgrpRejectText, mgrpMsgRejectText	G	The name of the attribute used to store a value specifying the error text to use when an attempted posting to the group/list encounters an access failure. Because the error text may appear in SMTP responses, it must conform to SMTP response limitations. In particular, it may consist merely of a single line of text limited to the US-ASCII charset. (If the value contains eight bit characters, the entire value will be ignored. If the value contains more than a single line of text, only the first line of text will be used.)
ldap_auth_policy	mgrpBroadcasterPolicy	G	Specifies level of authentication needed to send to the group. Possible tokens are "SMTP_AUTH_REQUIRED" or "AUTH_REQ", both of which mean that the SMTP AUTH command must be used to identify the sender in order to send to the group and any address produced by authentication will be used in subsequent authentication checks, "SMTP_AUTH_USED" or "AUTH_USED", both of which force the use of any authenticated address in authorization checks but does not actually require authentication, "PASSWORD_REQUIRED", "PASSWD_REQUIRED", or "PASSWD_REQ", all of which mean the password to the list specified by the mgrpAuthPassword attribute (see below) must appear in an Approved: header field in the message, "OR", which changes the or_clauses MTA option setting to 1 for this list, "AND", which changes the or_clauses MTA option setting to 0 for this list, and "NO_REQUIREMENTS", which is basically a no-op. "OR" and "AND" are new in 6.1. This attribute is limited to a single value prior to 6.1; in 6.1 multiple values are allowed and each value can consist of a comma-separated list of tokens. If SMTP AUTH is called for it also implies that any subsequent authorization checks will be done against the email address provided by the SASL layer rather than the MAIL FROM address. New in 7.3-11.01 are five new tokens for this attribute which specify list behavior for mailserv-maintained lists. The tokens are: "LIST_OPEN", "LIST_MEMBERS", "LIST_MODERATE_NONMEMBERS", "LIST_MODERATE_MEMBERS", and "LIST_MODERATE". Also new in 7.3-11.01, multiple attributes can now be mapping to this attribute slot.
ldap_cant_url	mgrpDisallowedBroadcaster	G	URLs identifying mail addresses not allowed to send mail to this group. Can be multivalued. Each URL is expanded into a list of addresses and each address is checked against the current envelope from address. A match means access checking has failed and all subsequent checks are bypassed. The expansion that is performed is similar to an SMTP EXPN with all access control checks disabled. Substitution processing will be performed on this URL if bit 0 (value 1) of the process_substitutions MTA option is set in 6.3 or later.
ldap_auth_url	mgrpAllowedBroadcaster	G	URL identifying mail addresses allowed to send mail to this group. Can be multivalued. Each URL is expanded into a list of addresses and each address is checked against the current envelope from address. A match failure with the or_clauses MTA option set to 0 (the default) means access checking has failed and all subsequent tests are bypassed. A match failure with the or_clauses MTA option set to 1 sets a "failure pending" flag; some other allowed access check must succeed in order for access checking to succeed. As of MS 6.0 a match also disables subsequent domain access checks. The expansion that is performed is similar to an SMTP EXPN with all access control checks disabled. Substitution processing will be performed on this URL if bit 1 (value 2) of the process_substitutions MTA option is set in MS 6.3 or later. New in MS 6.3, this now checks for address aliases (*e.g.*, mailAlternateAddress and mailEquivalentAddress) as well as for the canonical address (normally the mail attribute value).
ldap_cant_domain	mgrpDisallowedDomain	G	Domains not allowed to submit messages to this group. A match means access checking has failed and all subsequent checks are bypassed. In MS 6.0 this check is bypassed if the submitter has already matched an ldap_auth_url. Can be multivalued and as of MS 6.2 glob-style wildcards are allowed.
ldap_auth_domain	mgrpAllowedDomain	G	Domains allowed to submit messages to this group. A match failure with the or_clauses MTA option set to 0 (the default) means access checking has failed and all subsequent tests are bypassed. A match failure with the or_clauses MTA option set to 1 sets a "failure pending" flag; some other access check must succeed in order for access checking to succeed. In MS 6.0 this check is bypassed if the submitter has already matched an ldap_auth_url. As of MS 6.2, the value of the attribute supports use of the asterisk character, *, as a wildcard. For instance, *.domain.com means to allow all subdomains of domain.com, though not domain.com itself; to allow domain.com and all its subdomains, use two values for the attribute, domain.com and *.domain.com.
ldap_maximum_message_size	mgrpMsgMaxSize	G	Maximum message size in bytes that can be sent to the group. This attribute is obsolete but still supported for backwards compatibility; the new mailMsgMaxBlocks attribute should be used instead.
ldap_auth_password	mgrpAuthPassword	G	Specifies a password needed to post to the group.

			In iMS 5.2 the value of this attribute was saved if the `mgrpbroadcasterpolicy` attribute was set to require a password (see above) and checked against the Approved: field once the header is available. The Approved: field was removed from the header once the checkis complete. But this did not allow for routing to the moderator in the event of a password check failure. In the M 6.0 release and later the presence of a `mgrpauthpassword` attribute forces a reprocessing pass. As the message is enqueued to the reprocessing channel the password is taken from the header and placed in the envelope. Then while reprocessing the password is taken from the envelope and checked against this attribute. Additionally, only passwords that actually are used are removed from the header field. The `or_clauses` MTA option acts on this attribute in the same way it acts on the other access check attributes.
`ldap_moderator_url`	`mgrpModerator`	G	The list of URLs given by this attribute to be expanded into a series of addresses. The interpretation of this address list depends on the setting of the group's `mgrpMsgRejectAction` LDAP attribute (more precisely, the LDAP attribute named by the `ldap_reject_action` MTA option). If `mgrpMsgRejectAction`is set to "`TOMODERATOR`", then this attribute specifies the moderator address(es) the message is to be sent to should any of the access checks fail. If `mgrpMsgRejectAction` is missing or has any other value the address list is compared with the envelope From address. Processing continues if there is a match. If there isn't a match, the message is again sent to all of the addresses specified by this attribute. Expansion of this attribute is implemented by making the value of this attribute the list of URLs for the group. Any list of RFC 822 addresses or DNs associated with the group is cleared, and the delivery options for the group are set to "`members`". Finally, subsequent group attributes listed in this table are ignored. Substitution processing will be performed on this URL If bit 2 (value 4) of the `process_substitutions` MTA option is set in 6.3 or later.
`ldap_group_last_access_time`		G	(New in 8.0) Specify the name of an LDAP attribute used to keep track of the last access time for email groups defined in LDAP. If this attribute is present in a group's LDAP entry, then the MTA will update the attribute each time the group is successfully accessed for purposes of sending mail or expanding a mailing list. RFC 3339 format (a profile of ISO 8601 format) is used, *e.g.*, "`2013-09-29T17:38:52Z`". In order to prevent excessive LDAP writes, the attribute is read prior to writing and a write is only done if the current time exceeds the stored time by at least 30 minutes. (A write is also done if the attribute does not contain a valid RFC 3339 time, making it possible to set the initial value to something like "`<never accessed>`".)
`ldap_group_url1`	`mgrpDeliverTo`	G	List of URLs which, when expanded, provides a list of mailing list member addresses. Substitution processing will be performed on this URL If bit 3 (value 8) of the `process_substitutions` MTA option is set in 6.3 or later. See also the `ldap_url_result_mapping` MTA option; with it, a mapping table can be used to manipulate the value(s) of the `ldap_group_url1` attribute.
`ldap_group_url2`	`memberURL`	G	Another list of URLs which, when expanded, provides another list of mailing list member addresses. Substitution processing will be performed on this URL If bit 4 (value 16) of the `process_substitutions` MTA option is set in 6.3 or later. See also the `ldap_url_result_mapping` MTA option; with it, a mapping table can be used to manipulate the value(s) of the `ldap_group_url2` attribute.
`ldap_group_dn`	`uniqueMember`	G	List DNs or other identifiers for group members. Normally DNs are specified but other sorts of identifiers may be used depending on the URL template that is chosen. DNs may specify an entire subtree. These values are expanded by embedding them in an LDAP URL. The exact template to use is specified by the `group_dn_template` MTA option. The default value for this option is "`ldap:///$A?mail?sub?(mail=*)`"; `$A` specifies the point where the `uniqueMember` DN is inserted. As of 7.0.5, if a `GROUP_TEMPLATES` mapping table exists, it is used as a source for the template. The mapping probe is of the form "attribute-name|attribute-value". If the mapping sets `$Y`, then the mapping result is used as the template instead of the `group_dn_template` MTA option value. Multiple values are supported but only one attribute of this type is allowed on any given group. As of 7.0.5 any mapping specified by the attribute named by the `ldap_url_result_mapping` MTA option will also be applied to the results produced by these attributes.
`ldap_group_dn2`		G	(New in 7.0.5.) Like `ldap_group_dn`, a list of DNs or other identifiers for group members. This second slot with the same semantics was added so that a single group can be defined using multiple attribute values with different sematics.
`ldap_group_rfc822`	`mgrpRFC822MailMember`, `rfc822MailMember`	G	Mail addresses of members of this list. Multiple values are allowed. `rfc822MailMember` is also supported for backwards compatibility with NMS, but only one of these attributes can be used in any given group.

ldap_url_result_mapping		G	(New in MS 6.3.) The name of the attribute used to store the name of a mapping table to be applied to the values returned from the LDAP attributes named by the ldap_group_url1, ldap_group_url2, and as of 7.0.5, the ldap_group_dn and ldap_group_dn2 MTA options. That is, ldap_url_result_mapping specifies the name of an LDAP attribute whose value is the name of a mapping to apply to the results of expanding these attribute values. The mapping probe will be of the form: *LDAP-URL*|*LDAP-result* where LDAP-URL is the (literal string) value of the expansion attribute, and LDAP-result is the value returned from LDAP for that LDAP-URL query. If the mapping returns with $Y set, then the mapping result string will replace the LDAP result for alias processing purposes. If the mapping returns with $N set, then the result will be skipped. This mechanism can be used to define groups based on attributes that don't contain proper email address.
ldap_errors_to	mgrpErrorsTo	G	Used to set an envelope From address which will override the original message's envelope From address; that is, this address is a *mailing list*. Setting a value for this attribute implies mailing list, rather than group, semantics: in particular, this has implications for notification messages regarding the list definition (*e.g.*, syntactic errors in list member addresses, or syntactic errors in a list-specific Sieve filter) or regarding delivery of messages to list members, and for the handling of delivery receipt requests. Typically, the value will be some normal address. But two (three, as of 7.0-0.04) special syntaxes are also supported. Setting the value to an address of the form user+*@domain has a special meaning. The asterisk character will be expanded into a representation of the recipient address; thus a separate copy of the list message is generated for each recipient, with each copy including the intended recipient address as a subaddress within the return address. If delivery errors subsequently occur, the subaddress will indicate which was the failing address. In some cases, when dealing with remote MTAs that generate nonstandard, uninformative delivery error messages, this can in theory be useful as a way of determining which recipient address(es) failed, even when the bounce message's inner content is relatively uninformative. And it may make processing of such bounce messages by an automated program more convenient. However, the tradeoff is that such per-user-specific return address values require that a separate message copy be generated and sent for each recipient; for a "large" list, with many recipients in the same destination domains, this can be a large increase in overhead (a large decrease in efficiency). And with more prevalent use nowadays of standard format notification messages, the "need" for this sort of approach, with its extra (potentially large) overhead, is much less (since the intended recipient information can instead be extracted from the standard field in the contents of a standard format notification message). (New in MS 6.3, but not working until fix for 12194452 [Sun 6530591].) Setting the value to the forward slash character, /, has a special meaning. It tells the MTA to revert to using the original envelope From: address that had been present on the incoming message, yet in all other respects use mailing list semantics. This can be useful for setting up mailing lists that report all forms of list errors to the original sender. New in MS 6.3, the process_substitutions MTA option can enable use of the $S (recipient's subaddress) substitution in the value. This would tend to be of interest when defining a "meta-list".
ldap_delay_notifications	mgrpDelayNotifications	G	(New in 7.0u3.) Should NOTIFY=DELAY be set on list messages? Supported values are yes and no, with the obvious meanings.
ldap_add_header	mgrpAddHeader	G	Specify header fields to add to messages posted to the list. Such header fields might include, for instance, the List-*: header fields suggested in RFC 2369 (URLs for Mail List Commands through Message Headers).
ldap_remove_header	mgrpRemoveHeader	G	Specify header fields to remove from messages posted to the list. Only the field name should be specified.
ldap_add_tag	*No default;* mgrpListTag *recommended*	G	Prefix text to insert on the Subject: header line of messages to this recipient/list, analogous to the alias_tag alias option, the [TAG] named mailing list parameter, or the effect of the Sieve addtag action. As of MS 6.3, the vertical bar, |, character should not be used in the tag text; in previous versions, the space character should not have been used in tag text, as such use would interfere with the MTA's internal mechanisms for checking whether a tag was already present.
ldap_prefix_text	mgrpMsgPrefixText	G	Insert prefix text into messages as they undergo group expansion. Prior to Messaging Server 7.0 update 3, text could only be inserted into initial, TEXT/PLAIN parts; new in Messaging Server 7.0 update 3, text can be inserted into the first text part within a nested multipart (excluding multipart/alternative). The attribute values are given in UTF-8; this is then converted to match the charset of the part that the text is inserted into.
ldap_suffix_text	mgrpMsgSuffixText	G	Insert suffix text into messages as they undergo group expansion. Prior to Messaging Server 7.0 update 3, text could only be inserted into initial, TEXT/PLAIN parts; new in Messaging Server 7.0 update 3, text can be inserted into the first text part within a nested multipart (excluding

			multipart/alternative). The attribute values are given in UTF-8; this is then converted to match the charset of the part that the text is inserted into.
ldap_expandable	mgmanMemberVisibility, expandable	UG	Specify the attribute(s) used to define who (in addition to the group or list owner) may view the membership of a group or list; in MTA terms, who will get the group or list expanded in response to the SMTP EXPN command. Supported values for such an attribute or attributes are anyone, all or synonymously true (which means that only authenticated users -- hence users who have an account and provide their password---will be able to expand the group or list), and none; unrecognized values are interpreted as none. Note that group or list access controls (*e.g.*, use of attributes such as mgrpAllowedBroadcaster, *etc.*, or an mgrpBroadcasterPolicy setting of "SMTP_AUTH_REQUIRED"), also impose restrictions on who is allowed to view list membership. All applicable conditions must be met in order for group or list membership to be viewed (expanded).
MAILSERV attributes (new in 7.4-18.01)			
ldap_list_name	mgrpListName	G	Name associated with the list for administrative purposes. The value must be a UTF-8 string.
ldap_list_description	mgrpDescription	G	Textual description of the list. UTF-8 string. Multivalued and supports language-tagged attribute values.
ldap_list_advertised	mgrpAdvertised	G	Whether or not to advertise the list in the MAILSERV GUI. Possible values are yes or no.
ldap_list_public_roster	mgrpPublicRoster	G	Should the membership list be visible to anyone, or merely to members, or to admins_only.
ldap_list_subscribe_policy	mgrpSubscribePolicy	G	Policy for handling list subscription requests. Possible values are: • "immediate" - honor subscription requests immediately • "confirm" - send confirmation e-mail • "to_moderator" - require moderator approval • "both" - require both confirmation and moderator approval.
ldap_list_unsubscribe_policy	mgrpUnsubscribePolicy	G	Controls list unsubscribe policy. Same possible settings as for ldap_list_subscribe_policy.
ldap_list_trust_new_members	mgrpTrustNewMembers	G	
Head of household control support attributes			
ldap_hoh_filter	mailSieveRuleSource		(New in MS 6.2.) Specify an attribute to request when performing a head of household filter lookup.
ldap_hoh_owner	mail		(New in MS 6.2.) Attribute in which to find the owner of the HOH Sieve.
Schema 2 support attributes			
ldap_attr_domain1_schema2	sunPreferredDomain++	D	Attribute used to store the primary domain in Schema 2.
ldap_attr_domain2_schema2	associatedDomain++	D	Attribute used to store any secondary domains in Schema 2.
ldap_attr_domain_search_filter			Attribute in the global configuration template area (see the ldap_global_config_templates MTA option) that is used to store the domain search filter template.
Per-domain attributes			
ldap_domain_attr_basedn	inetDomainBaseDn	D	Domain entry attribute used to store the baseDN of domain entries.
ldap_domain_attr_alias	aliasedObjectName	D	Schema 1 attribute used in domain alias entries to specfify the DN of the actual domain entry.
ldap_domain_attr_uplevel		D	(New in MS 6.3) Specify a domain level attribute used to store a domain-specific uplevel value which overrides the value of the domain_uplevel MTA option for this particular domain. Currently only bits 0 and 2 (values 1 and 4) have meaning for the named attribute's value; the other bits of the domain_uplevel MTA option remain in effect. Note that this domain level attribute is only consulted if the domain is first *found*. Thus setting bit 0 (value 1) has no effect unless bit 0 (value 1) of the domain_uplevel MTA option is set. However, with bit 0 (value 1) of domain_uplevel is set, then clearing bit 0 in the domain level attribute can disable domain uplevel matching *for subdomains of this particular domain* while domain uplevel matching is still possible for other domains.
ldap_domain_attr_canonical	inetCanonicalDomainName	D	Specifies the canonical domain name for domains whose member entries overlap.
ldap_domain_attr_uid_separator	domainUidSeparator	D	The UID separator default for users in the domain.
ldap_domain_attr_subaddress		D	(New in 8.0) Specify the name of an LDAP attribute that controls use of subaddresses in lookups of addresses in this domain.
ldap_domain_attr_routing_hosts	mailRoutingHosts	D	Specify the hosts that are responsible for performing routing for this domain. If this MTA is one such host, then the user address will be looked up and attributes processed. Otherwise, the address will be routed onwards: by default, just routing based on rewriting the address, but if the MTA option route_to_routing_host is set to 1 then the first mailRoutingHosts value will be inserted into the address as a source route (hence the rewriting routing will depend upon that host name). Note that delivery options can be marked as mail host independent,

			thereby meaning that processing should occur regardless of whether this MTA is one of the `mailRoutingHosts`; see the `delivery_options` MTA option.
`ldap_domain_attr_smarthost`	`mailRoutingSmartHost`	D	If a user address is not found in the directory, then route onwards, inserting the `mailRoutingSmartHost` value into the address as a source route.
`ldap_domain_attr_status`	`inetDomainStatus`	D	The attribute containing the domain's overall status.
`ldap_domain_attr_mail_status`	`mailDomainStatus`	D	The attribute containing the domain's mail service status. Valid values for this attribute are: `active`, `inactive`, `deleted`, `hold`, `disabled`, `overquota`, and (new in MS 6.0) `unused` and `removed`; other values are interpreted as `inactive`. Note that the `imquotacheck` utility is what updates `mailDomainStatus` to set it to `overquota`.
`ldap_domain_attr_blocklimit`	`mailDomainMsgMaxBlocks`	D	Set a domain limit for how large of message users in the domain may receive. New in MS 6.3, this attribute is also checked during `reverse_url` lookups, and will be used (for messages that have no return-of-content policy already set) to decide whether the NOTARY non-return-of-content flag should be set.
`ldap_domain_attr_conversion_tag`	`mailDomainConversionTag`	D	New in MS 6.1. Specify a per-domain attribute whose value will be applied as conversion tags for messages sent to users or groups associated with this domain.
`ldap_domain_attr_source_conversion_tag`		D	New in MS 6.2. Specify a per-domain attribute whose value will be applied as conversion tags for messages coming from users associated with this domain.
`ldap_domain_attr_optin`		D	A deprecated synonym for `ldap_domain_attr_optin1`
`ldap_domain_attr_optin`*N*		D	Specifies the names of attributes used to opt in to spam filtering at the domain level. Messages sent or received from addresses associated with the domain will be opted in to the spam filter associated with the specified slot. Currently the slot value must be between 1 and 8.
`ldap_domain_attr_nosolicit`		D	New in MS 6.2.
`ldap_domain_attr_autoreply_timeout`		D	Name of an attribute that specifies a default autoreply timeout for users associated with this domain.
`ldap_domain_attr_default_mailhost`	No default; but the Admin SDK has a `preferredMailHost` attribute, used in provisioning, that would be one possibly appropriate attribute to also use for this purpose	D	(New in MS 6.3) Specify a default `mailHost` to take effect for all users in this domain who do not have their own explicit `mailHost` set.
`ldap_domain_attr_disk_quota`		D	
`ldap_domain_attr_message_quota`		D	
`ldap_domain_attr_filter`	`mailDomainSieveRuleSource`	D	Attribute used to specify domain-level Sieve filters.
`ldap_domain_attr_sender_sieve`	`mailDomainSenderSieve`	D	(New in MS 8.0.1)
`ldap_domain_attr_report_address`	`mailDomainReportAddress`	D	The domain's postmaster address. This value is used as the header From: address in DSNs reporting problems associated with recipient addresses in the domain. It is also used (in certain cases) when reporting problems to users within the domain regarding errors associated with nonlocal addresses. If this attribute is not set, then in those cases the reporting address will default to `postmaster@domain`. Note that regardless of whether or not this attribute is set, there are a number of cases where the overall host's postmaster address will be used, rather than any domain-specific postmaster address.
`ldap_domain_attr_catchall_address`	`mailDomainCatchallAddress`	D	Specifies the name of an attribute whose value is a "catch all" address for the domain: an address to which to route any messages to addresses "in" this domain but with an unrecognized local-part.
`ldap_domain_attr_catchall_mapping`	No default; `mailDomainCatchallMapping` recommended	D	(New in MS 6.3.) Specify the name of an attribute used to specify the name of a mapping table which will be consulted when an address associated with the domain fails to match any particular user entry. The format of the mapping table probe is the same as that of the `FORWARD` mapping table, and is affected by any setting of the `use_forward_database` MTA option in the same way as the `FORWARD` mapping table probe is affected. If the mapping sets the `$Y` metacharacter, then the resulting string will replace the address being processed.
`ldap_domain_attr_sourceblocklimit`		D	Specify a per-domain attribute, analogous to the per-user `ldap_sourceblocklimit`. New behavior in MS 6.3 is that a per-domain setting such as this will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3, a particular domain can be allowed to send large messages as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.
`ldap_domain_attr_source_channel`		D	(New in MS 6.3) Specify a source channel to which to "switch" (if `userswitchchannel` is specified on the current source channel)
`ldap_domain_attr_recipientlimit`		D	Specify a per-domain attribute, analogous to the per-user `ldap_recipientlimit` and the `recipientlimit` channel option. New behavior in MS 6.3 is that a per-domain setting such as this will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3, a particular domain can be allowed to send messages to many recipients as an

			exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.
ldap_domain_attr_recipientcutoff		D	Specify a per-domain attribute, analogous to the per-user ldap_recipientcutoff and the recipientcutoff channel option. New behavior in MS 6.3 is that a per-domain setting such as this will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3, a particular domain can be allowed to send messages to many recipients as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.
ldap_domain_attr_detourhostoptin		D	(New in 7.0.5) Specify a per-domain attribute, analogous to the per-user ldap_detourhost_optin. If this attribute has the special value (if any) specified by the aliasdetourhost_null_optin MTA option, that will be considered equivalent to the domain attribute being absent.

+ User-modifiable LDAP attribute.

++ Domain map code has the specified default, not the MTA proper

+++ While the MTA in principle allows this attribute on group/mailing list entries, the typical configuration of the delivery_options MTA option disables this support; plus, the Sun schema does not, as distributed, allow this attribute on group/mailing list entries. See the delivery_options MTA option for some discussion regarding enabling use of this attribute on group/mailing list entries.

52.15.6.1 Access controls on LDAP attributes

The schema sets restrictions (via an ACI) on which attributes even in his or her "own" entry an end user is allowed to modify. Reassigning the MTA's interpretation of LDAP attributes via MTA options does not, itself, affect such LDAP schema restrictions; so when reassigning end-user-modifiable LDAP attributes, be sure to also update your schema ACIs correspondingly. Also, when adding new attributes to the schema (and then making them known to the MTA via MTA options), consider in each case whether or not the new attribute should be end-user-modifiable (and in some cases consider whether the new attribute should even be end-user-visible), and when appropriate set an ACI to achieve the proper effect.

52.15.6.2 Direct LDAP attribute name MTA options: ldap_objectclass (LDAP attribute name)

The default for the ldap_objectclass MTA option is objectClass. This LDAP attribute is valid on user, group, and domain entries.

52.15.6.3 Direct LDAP attribute name MTA options: ldap_user_status (LDAP attribute name)

The ldap_user_status MTA option specifies the name of a user LDAP attribute, by default inetUserStatus, used to store user general status. (Contrast with the ldap_user_mail_status MTA option which names an LDAP attribute, by default mailUserStatus, used to store specifically a user's mail status. Also consider the analogous domain LDAP attribute, by default inetDomainStatus, named by the ldap_domain_attr_status MTA option.)

Prior to Messaging Server 7.0, the supported values for the LDAP attribute named by the ldap_user_status MTA option, by default inetUserStatus, were a strict subset of the supported mailUserStatus values, and in particular the only supported values were active, inactive, or deleted. As of Messaging Server 7.0, for the convenience of sites that may wish to "switch" the use (in effect switch the priority order in which checking occurs) of inetUserStatus and mailUserStatus, the full set of values supported

for `mailUserStatus` are also supported for `inetUserStatus`. This is not intended to encourage general, direct use of such additional values for `inetUserStatus`, but rather, as mentioned, is intended so that the priority (order of checking) of these two status settings for users can be reordered by setting them "switched":

```
msconfig> set ldap_user_status mailUserStatus
msconfig# set ldap_user_mail_status inetUserStatus
```

or in legacy configuration mode:

```
ldap_user_status=mailUserStatus
ldap_user_mail_status=inetUserStatus
```

52.15.6.4 Direct LDAP attribute name MTA options: `ldap_user_mail_status` (LDAP attribute name)

The `ldap_user_mail_status` MTA option specifies the name of a user LDAP attribute, by default `mailUserStatus`, used to store the user's status for mail purposes. (Contrast with the `ldap_user_status` MTA option which names an LDAP attribute, by default `inetUserStatus`, used to store the user's general status for services in addition to mail. And consider also the `ldap_domain_attr_mail_status` MTA option which names an analogous domain LDAP attribute.)

For the LDAP attribute named by `ldap_user_mail_status`, valid values are `active`, `inactive`, `disabled`, `deleted`, `overquota`, `hold`, `removed` (new in MS 6.0), `defer` (new in MS 6.3), `defer-submit` (new in MS 6.3), `deliver` (new in 7.3-11.01), and `deliver-disabled` (new in 8.0.1.3/8.0.2.1).

A status of `removed` is equivalent to `deleted` from the MTA's point of view; it exists as a distinct status for the benefit of the commcli user purging operation.

The statuses `defer` and `defer-submit` tell the MTA to accept all messages to the user but defer them to the reprocess channel for later delivery (re)attempts; or in the case of `defer-submit` accept and defer to the reprocess channel those messages coming in a `submit` channel while giving `inactive` behavior, hence normally temporary errors, for attempted submissions on any other channels.

A status of `deliver` is treated by the MTA as active `active` for purposes of message delivery but which other components will treat as `inactive` (giving the effect that messages can be delivered, but the user can not login); any other value is treated as `inactive`.

(Note that the `acceptalladdresses` channel option, if used, modifies the timing and form of recipient rejections due to errors such as "`overquota`" or "`disabled`" status. New in MS 8.0.1.1.0, the `accepttemporaryfailures` channel option, if used, modifies the timing and form of recipient deferrals due to temporary errors such as "`inactive`" status. Note also that the `use_temporary_error` and `use_permanent_error` MTA options, and `usetemporaryerror` and `usepermanenterror` channel options, can alter the interpretation of whether such status errors are considered temporary *vs*. permanent errors.)

52.15.6.5 Direct LDAP attribute name MTA options: `ldap_group_status` (LDAP attribute name)

The ldap_group_status MTA option specifies the name of a group LDAP attribute intended to store general group status. There is no default; (there is no such LDAP attribute pre-defined in the schema). See also the more-specific-to-email ldap_group_mail_status MTA option, normally corresponding to the inetMailGroupStatus LDAP attribute. And see the ldap_domain_attr_status MTA option, normally corresponding to the inetDomainStatus domain LDAP attribute, which sets a domain level status.

If an LDAP attribute is defined (and added to the schema) and the MTA configured to use it via the ldap_group_status MTA option, note that prior to Messaging Server 7.0-0.04, the MTA's supported values were a strict subset of the values supported for inetMailGroupStatus (more precisely, the attribute named by ldap_group_mail_status); in particular, the supported values were active, inactive, and deleted. New in Messaging Server 7.0-0.04, all the values supported for inetMailGroupStatus are supported for this attribute as well, for the convenience of sites that wish to "switch" the priority (order) in which they are checked by "switching" which attributes the MTA options ldap_group_status and ldap_group_mail_status point to.

52.15.6.6 Direct LDAP attribute name MTA options: ldap_group_mail_status (LDAP attribute name)

The ldap_group_mail_status MTA option specifies the name of a group LDAP attribute storing the group's status for e-mail purposes. The default is inetMailGroupStatus. (See also the ldap_group_status MTA option for defining a more general, not specific to e-mail, group status LDAP attribute. And see the ldap_domain_attr_mail_status MTA option, normally corresponding to the mailDomainStatus domain LDAP attribute, which sets a domain level mail status.)

In the LDAP attribute named by ldap_group_mail_status, the MTA supports values of active, deleted, removed, disabled, hold, inactive, (new in Messaging Server 7.0-0.04) defer and defer-submit, and (new in MS 8.0.1.3/8.0.2.1) deliver-disabled.

(Note that the acceptalladdresses channel option, if used, modifies the timing and form of recipient rejections due to "disabled" status.)

52.15.6.7 Direct LDAP attribute name Base options: ldap_permid (LDAP attribute name)

The ldap_permid base option names a user or group LDAP attribute that contains a permanent identifier for the user. The value of such an attribute will be used preferentially as the identifier for the user or group which is used for such purposes as:

- The unique name (or domain-qualified unique name) for the user in the message store. This includes delivery by ims_master or LMTP, as well as mailbox autocreation by popd, imapd or other store tools.
- The canonical user name for authentication purposes.
- The identifier associated with store access connections when using the imsconnutil tool.
- The identifier used when storing (but not when displaying or accessing) IMAP ACLs or shared folder user names.
- May be part of the DN of the user's entry in the LDAP directory.

The use of the permanent identifier in constructing the user's unique mailbox name in the message store means that attempting to change a user's permanent identifier tends to be quite problematic (a change breaks access to the user's old mailbox). So make every attempt to avoid changing the value of this attribute, value; use some other LDAP attribute for values subject to change (such as the user's legal name, display name or login name) and leave the permanent identifier as an arbitrary, immutable identifier.

The attribute specified by the `ldap_permid` option must be indexed in LDAP as it is used for canoncial user identity searches in LDAP.

In most cases, the value of the attribute named by the `ldap_uid` MTA option will be used as the user or group permanent identifier if the attribute named by `ldap_permid` is not present in the user or group entry. However, for canoncial identity search operations, such as those necessary for Cassandra store account auto-creation, the attribute named by `ldap_permid` must be set for the correct LDAP entry to be found so autocreation can proceed.

52.15.6.8 `ldap_extid` Option

The `ldap_extid` base option names a user LDAP attribute which contains an external display identifier for the user for use with the Cassandra Message Store. The external display identifier must be unique within the user's domain. IMAP shared folders and Access Control Lists (ACLs) are internally stored using the identifier from the ldap_permid attribute, but when shared folder owner names or ACLs are changed or sent over IMAP, the external display identifier is used. If the external display identifier does not contain '@', then the domain name will be added for domains other than the default domain.

The Cassandra Message Store caches a copy of the value of this attribute in the 'userid' column of the user table in the ms_mbox meta data keyspace. To refresh the stored value, TBD.

The default value for the `ldap_extid` base option is the value of the `ldap_uid` MTA option and that option defaults to 'uid'.

52.15.6.9 Direct LDAP attribute name MTA options: `ldap_uid` (LDAP attribute name)

The `ldap_uid` MTA option names a user or group LDAP attribute which will be used as the user or group identifier if no permanent identifier (specified by the ldap_permid option) is present in the user or group entry. This option also impacts the default login identity for authentication purposes.

Note that although the MTA option `ldap_uid` exists to rename/redirect the attribute used *for some MTA, Store and authentication purposes*, other components of Messaging Server such as some MTA and Message store utilties (including `improgram`, `imquotacheck`, and `mboxutil`) hard-code use of the 'uid' attribute and may not work correctly with an alternate attribute name.

Although this option is documented to permit a list of LDAP attribute names, that facility did not work prior to Messaging Server 8.0.2 and as of MS 8.0.2, only the first attribute name in the list will be honored for certain operations (including MTA and store authentication).

Regarding the use of the LDAP attribute named by `ldap_uid`, normally `uid`, and its valid values: As of MS 6.2, the MTA checks that there is only one such attribute; as of MS 6.3-0.15, the MTA also checks that there is only one value set for the one attribute. As of 7.0-0.04, the MTA checks that the `uid` value is no more than 128 octets; a longer value

will result in the user entry being considered invalid. (This check is performed because various lower layer libraries have hard buffer limits that preclude longer `uid`s.) See also the `ldap_uid_invalid_chars` MTA option which enforces restrictions (some required by other components such as the Message Store) on what characters are permitted in a `uid` value. See also the `ldap_domain_attr_uid_separator` MTA option which names a domain level LDAP attribute specifying, for addresses in that domain, what character separates the UID from the domain name.

52.15.6.10 Direct LDAP attribute name MTA options: `ldap_mlsrange` (LDAP attribute name)

RESTRICTED: Not yet used.

52.15.6.11 Direct LDAP attribute name MTA options: `ldap_capture` (LDAP attribute name)

The `ldap_capture` MTA option specifies the names of one or more user or group LDAP attributes that will be used to trigger automatic "capturing" of user or group e-mail messages. There is no default; (no pre-defined LDAP attribute for this purpose). Typically, the LDAP attribute defined for this purpose, and named by `ldap_capture`, should be set up with an ACI so that it is not even visible, let alone modifiable, by the users themselves.

As of the 8.0.1 release, the attribute mailCaptureAddress has been added to the Messaging Server schema for use with this attribute. However, it is still not the default.

Note that the LDAP attribute(s) specified by the `ldap_domain_attr_capture` MTA option have similar semantics except the attribute(s) are placed in the domain rather than in the user or group entry.

The value(s) of the LDAP attribute named by `ldap_capture` should be the address(es) to which the "captured" message copies should be sent. When a user has this attribute specified on their LDAP entry, both messages sent to them, as well as from them, will also have a "capture" copy (normally an encapsulated copy with an entirely new message envelope) sent to the specified address.

New in Messaging Server 7.4-18.01, the `capture_format_default` MTA option controls whether message copies generated due to use of the LDAP attribute named by `ldap_capture` default to being in DSN encapsulated format, or to being in another format such as envelope "journal" format. Also new in Messaging Server 7.4-18.01, values of the LDAP attribute may be tagged to explicitly specify the format on a per-target-address basis: for instance, the tag `;format-report` selects the usual DSN encapsulated format, whereas the tag `;format-journal` selects the envelope "journal" format. New in the 8.0 release are the attribute tags `;format-message`, `;format-report-header`, and `;format-journal-header`, which can be used to specify header-only capture addresses.

52.15.6.12 Direct LDAP attribute name MTA options: `ldap_recipientlimit` (LDAP attribute name)

The `ldap_recipientlimit` MTA option specifies the name of a user or group LDAP attribute that will be used to store a sending-user-specific maximum number of envelope recipients per message submission (additional recipients are rejected), analogous to the `recipientlimit` channel option. There is no default; (no pre-defined LDAP attribute for this purpose).

New behavior in MS 6.3-0.15 is that a per-user setting such as this will override more general settings such as a channel `recipientlimit`, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3-0.15, a particular user can be allowed to send messages to a large number of recipients as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect. (But a TCP/IP-channel-specific option setting of `ALLOW_RECIPIENTS_PER_TRANSACTION` can *not* be overridden!)

See also the `ldap_recipientcutoff` MTA option for a similar but slightly different effect. And see the `ldap_domain_attr_recipientlimit` MTA option for similar effect at the domain, rather than user, level.

52.15.6.13 Direct LDAP attribute name MTA options: `ldap_recipientcutoff` (LDAP attribute name)

The `ldap_recipientcutoff` MTA option specifies the name of a user or group LDAP attribute that will be used to store a sending-user-specific maximum number of envelope recipients per message submission (messages with more recipients are rejected entirely), analogous to the `recipientcutoff` channel option. There is no default; (no pre-defined LDAP attribute for this purpose).

New behavior in MS 6.3-0.15 is that a per-user setting such as this will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3-0.15, a particular user can be allowed to send messages to a large number of recipients as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.

See also the `ldap_recipientlimit` MTA option for a similar but slightly different effect. And see the `ldap_domain_attr_recipientcutoff` MTA option for a similar effect at the domain, rather than user, level.

52.15.6.14 Direct LDAP attribute name MTA options: `ldap_sourceblocklimit` (LDAP attribute name)

The `ldap_sourceblocklimit` MTA option specifies the name of a user or group LDAP attribute used to store a sending-user-specific maximum message size, analogous to the `sourceblocklimit` channel option. There is no default, (no pre-defined LDAP attribute for this purpose); if desiring to have the exact same sending limit as receiving limit, then the `ldap_sourceblocklimit` MTA option could be set to the same value as the `ldap_blocklimit` MTA option, which by default is `mailMsgMaxBlocks`.

New behavior in MS 6.3-0.15 is that a per-user setting such as the value of the LDAP attribute named by `ldap_sourceblocklimit` will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3-0.15, a particular user can be allowed to send large messages as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.

(Note also that the `acceptalladdresses` channel option, if used, may modify the timing and form of rejections due to exceeding message size constraints.)

52.15.6.15 Direct LDAP attribute name MTA options: `ldap_source_channel` (LDAP attribute name)

(New in MS 6.3-0.15) The ldap_source_channel MTA option specifies the name of a user or group LDAP attribute which will be used to store the source channel for messages submitted by this user. There is no default; (no pre-defined LDAP attribute for this purpose).

The value of the LDAP attribute named by ldap_source_channel sets a source channel to which to "switch" for messages submitted by the user, if userswitchchannel is set on the current source channel. If the user LDAP attribute is present, it will override any domain-level setting made via the LDAP attribute named by the ldap_domain_attr_source_channel MTA option.

52.15.6.16 Direct LDAP attribute name MTA options: ldap_source_optin*N* for *N*=1--8 (LDAP attribute name)

(New in MS 6.3-0.15) The ldap_source_optin*N* MTA options specify, respectively, the names of user/group LDAP attributes used to select "opt in" to spam/virus filter package *N*, *N*=1--8. These MTA options have no default (no pre-defined LDAP attribute for the purpose). If it is desired to have "opt in" for the messages a user sends, just the same as for the messages a user receives, then both ldap_source_optin*N* and ldap_optin*N* could be set to the same LDAP attribute.

The LDAP attributes named by ldap_source_optin*N* are the sending user analogues of ldap_optin*N*. In particular, the presence in a user entry of the LDAP attribute named by ldap_source_optin*N* normally (but see the spamfilter*N*_null_optin MTA options) causes messages sent *from* that user to be "opted-in" for spam/virus filtering via the spam/virus filter package *N*, with the "opt-in" value specified by the value of the LDAP attribute.

52.15.6.17 Direct LDAP attribute name MTA options: ldap_preferred_language (LDAP attribute name)

The ldap_preferred_language MTA option specifies the name of a user or group LDAP attribute, by default preferredLanguage, used to store the user's language preference.

The schema sets an ACI on the default attribute, preferredLanguage, to allow user modification.

The MTA's typical NOTIFICATION_LANGUAGE mapping table and DISPOSITION_LANGUAGE mapping table check the value of this attribute (for the sender of the original message) when deciding in what language to send back notification messages. Also, as of MS 6.3-0.15, the MTA has the ability to chose between multiple LDAP attribute values with different language tags and determine the preferred value to use. The language tags in effect are compared against the preferred language information associated with the envelope From address. In MS 6.3-0.15, the only attributes receiving this treatment are those named by ldap_autoreply_subject (normally mailAutoReplySubject), ldap_autoreply_text (normally mailAutoReplyText), ldap_autoreply_text_internal (normally mailAutoReplyTextInternal), ldap_autoreply_addresses, ldap_prefix_text, ldap_suffix_text, ldap_spare_4, and ldap_spare_5. As of Messaging Server 7.0-3.01, the attribute named by (new in that version) ldap_spare_6 also receives such treatment. As of Messaging Server 7.2-7.02, any of the ldap_spare_*N* named attributes may optionally, depending upon the setting of the corresponding spare_*N*_separator MTA option, receive preferredLanguage treatment; the default for the spare_*N*_separator MTA options is such that the ldap_spare_4, ldap_spare_5, ldap_spare_6 named attributes receive

preferredLanguage treatment. As of Messaging Server 7.3-11.01, the attribute named by ldap_add_tag also receives such treatment.

52.15.6.18 Direct LDAP attribute name MTA options: ldap_preferred_country (LDAP attribute name)

The ldap_preferred_language MTA option specifies the name of a user or group LDAP attribute used to store a country preference; there is no default.

52.15.6.19 Direct LDAP attribute name MTA options: ldap_nosolicit (LDAP attribute name)

The ldap_nosolicit MTA option specifies the name of a user or group level LDAP attribute intended for users or groups to specify what classes of e-mail solicitations they wish to reject. See RFC 3865 (NO-SOLICITING SMTP Extension) for a discussion of the SMTP extension utilized.

The ldap_nosolicit MTA option has no default: there is no LDAP attribute already in the schema for this purpose. If adding some LDAP attribute to the schema for this purpose, consider establishing it with an ACI allowing users to modify their own attribute's value themselves.

Note that the MTA expects the value of whatever attribute is named by ldap_solicit to consist of a comma-separated list of strings.

52.15.6.20 Direct LDAP attribute name MTA options: ldap_routing_address (LDAP attribute name)

The ldap_routing_address MTA option specifies the name of a user or group LDAP attribute, by default mailRoutingAddress, used to specify an address to which to route, overriding (as of MS 6.0) the usual mailHost and mailDeliveryOption interpretation.

52.15.6.21 Direct LDAP attribute name MTA options: ldap_delivery_option (LDAP attribute name)

The ldap_delivery_option MTA option specifies the name of a user or group LDAP attribute, by default mailDeliveryOption, used to specify the delivery choices of the user or group. See the delivery_options MTA option for discussion of the MTA's interpretation of the values stored in this named attribute. In particular, note that the MTA (with normal delivery_options configuration) interprets absence of this attribute on a user entry as meaning to perform delivery to the user mailbox, and interprets absence of this attribute on a group entry as meaning to perform delivery to the group members. (This provides sensible and useful behavior for user or group entries lacking any explicit mailDeliveryOption value. However, note that this behavior also has implications when updating a user or group entry: in particular, if deleting the one and *only* mailDeliveryOption setting from a user or group, consider what delivery behavior you may wish to *explicitly set* in its place, as in the absence of any explicit setting you will get normal delivery; explicitly setting a value of nomail, or setting the user status or group status to a value such as inactive or disabled can be done if you truly desire *no* delivery effect.)

The schema sets an ACI on the default attribute, mailDeliveryOption, to allow user modification.

52.15.6.22 Direct LDAP attribute name MTA options: `ldap_personal_name` (LDAP attribute name)

The `ldap_personal_name` MTA option specifies the name of a user or group LDAP attribute used to specify a user's (or group's) choice of personal name. This option has no default; some sites might choose to set it to `cn`.

If the `ldap_personal_name` MTA option is set, then the value of the specified attribute (if present in a user entry) will be inserted by the MTA as a personal name wherever the user's address appears in message headers (overriding any originally present personal name for the user that might have been present), including when generating vacation messages on behalf of the user. Note that (as of 6.2p3 for normal messages, or as of 6.2p6 for generated messages such as vacation messages) the MTA will quote the value obtained from LDAP, if required according to the quoting rules for personal names (technically "phrases") given in RFC 822.

For messages submitted through MSHTTP (messages submitted from web clients), see also the `fullfromheader` MSHTTP option.

52.15.6.23 Direct LDAP attribute name MTA options: `ldap_source_conversion_tag` (LDAP attribute name)

The `ldap_source_conversion_tag` MTA option specifies the name of a user or group LDAP attribute which may be used to specify a conversion tag to add to messages sent from that user or group. The option has no default; sites that wish to use exactly the same conversion tag(s) for messages *from* as well as *to* a user might set it to `mailConversionTag`, while sites wishing to distinguish directionality in conversion tags will wish to use a distinct LDAP attribute.

Note that there is a domain level analogue, `ldap_domain_attr_source_conversion_tag`.

52.15.6.24 Direct LDAP attribute name MTA options: `ldap_sender_sieve` (LDAP attribute name(s))

New in MS 8.0.1. The `ldap_sender_sieve` MTA option specifies the name of an LDAP attribute -- or a list of such names -- used to store a specific-to-that-ser Sieve filter that is applied to messages sent by that authenticated user.

This option has no default value.

52.15.6.25 Direct LDAP attribute name MTA options: `ldap_primary_address` (LDAP attribute name)

The `ldap_primary_address` MTA option specifies the name of the user or group LDAP attribute which contains the primary email address for that user or group, by default the `mail` attribute.

Compare with the MTA options that specify the names of LDAP attributes which store email aliases, `ldap_alias_addresses` which by default names the `mailAlternateAddress` attribute (or in the `sims40` schema, names the `rfc822mailalias` attribute), and `ldap_equivalence_addresses` which by default names the `mailEquivalentAddress`.

52.15.6.26 Direct LDAP attribute name options: ldap_alias_addresses (list of LDAP attribute names)

The ldap_alias_addresses MTA option specifies the name(s) of the user or group LDAP attribute(s) in which e-mail aliases will be stored. That is, this MTA option names LDAP attributes whose values (addresses) are accepted as equivalent to (aliases for) the canonical mail address on incoming messages; see also the ldap_mail_reverses MTA option which controls just which attributes (addresses) are normally converted to the canonical mail address during reverse_url application via the $Q substitution sequence. Use a comma-separated list if specifying more than one LDAP attribute name.

The default for ldap_alias_addresses depends upon the schema tag in effect, as set via the ldap_schematag MTA option. Normally, with ldap_schematag=ims50 set (or with ldap_schematag=nms41 set), the default for ldap_alias_addresses is mailAlternateAddress. But if ldap_schematag=sims40 is set, then the default is instead ldap_alias_addresses=rfc822mailalias.

The aliases stored in a ldap_alias_addresses LDAP attribute are subject to address reversal (canonicalization back to the value of the LDAP attribute named by ldap_primary_address, normally the mail attribute) by the MTA. In contrast, for an alias intended to be emitted as well as recognized, see the ldap_equivalence_addresses MTA option, normally naming the mailEquivalentAddress LDAP attribute.

52.15.6.27 Direct LDAP attribute name options: ldap_equivalence_addresses (list of LDAP attribute names)

The ldap_equivalence_addresses MTA option specifies the name(s) of the user or group LDAP attribute(s) in which e-mail aliases will be stored. That is, this MTA option names the LDAP attributes containing addresses accepted as equivalent to the canonical mail address for incoming messages; such equivalent addresses are also allowed to appear on outgoing messages (are not converted during reverse_url application). (In contrast, for aliases that will be accepted but canonicalized, see the ldap_alias_addresses MTA option.) Use a comma-separated list if specifying more than one LDAP attribute name.

Note that when setting the ldap_equivalence_addresses MTA option to a non-default value, it is also usually appropriate/necessary to modify the ldap_mail_aliases MTA option correspondingly (to include those attribute(s) named by ldap_equivalence_addresses).

52.15.6.28 Direct LDAP attribute name options: ldap_optin*N* (list of LDAP attribute names)

The ldap_optin*N*, *N*=1,...,8, MTA options may be used to name user or group LDAP attributes whose presence in an entry normally (but see the spamfilter*N*_null_optin MTA options) causes messages addressed *to* that user or group to be "opted-in" for spam/virus filter package processing (by spam/virus filter package *N*), with the opt-in value specified by the value of the attribute.

See also the ldap_source_optin*N* MTA options, which serve an analogous purpose for messages coming *from* a user or group.

These MTA options have no default, though the *Schema Reference Manual* (back in the days where it was assumed that at most one spam/virus filter package would be used) suggested

using an LDAP attribute named `mailAntiUBEService`. The `mailAntiUBEService` attribute is defined in the schema. If you will be using multiple spam/virus filter packages and wish to have distinct attributes for the different spam/virus filter packages, you may define new attributes modelled on `mailAntiUBEService`, perhaps using suggestive attribute names corresponding to their function, *e.g.*, `milterOptin`, *etc.*.

For aliases defined via an alias option, the analogous option is `alias_optin`*`N`*; or for aliases defined in the alias file, the analogous setting is the Alias file named parameter [OPTIN*n*].

52.15.6.29 Direct LDAP attribute name options: `ldap_optout`*`N`* (list of LDAP attribute names)

The `ldap_optout`*`N`*, *`N`*=1,...,8, MTA options may be used to name user or group LDAP attributes whose presence in an entry normally (but see the `spamfilter`*`N`*`_null_optin` MTA options) causes messages addressed *to* that user or group to be "opted-out" of spam/virus filter package processing (by spam/virus filter package *`N`*).

Note that the scope of opt-outs only extends to the immediate expansion values of the LDAP entry - if the entry expands to another alias that alias will not honor the outer level opt-out.

These MTA options have no default.

For aliases defined via an alias option, the analogous option is `alias_optin`*`N`*; or for aliases defined in the alias file, the analogous setting is the Alias file named parameter [OPTOUT*n*].

52.15.6.30 Direct LDAP attribute name MTA options: `ldap_presence` (LDAP attribute name)

RESTRICTED: Not yet used.

52.15.6.31 Direct LDAP attribute name MTA options: `ldap_autosecretary` (LDAP attribute name)

RESTRICTED: Not yet used.

52.15.6.32 Direct LDAP attribute name MTA options: `ldap_alternate_recipient` (list of LDAP attribute names)

(New in MS 8.0.1.) The `ldap_alternate_recipient` MTA option specifies the name(s) of one or more user-level LDAP attributes whose value(s) are alternate recipient addresses to whom to send messages that cannot be delivered to this primary recipient.

Compare with the alias option `alias_alternate_recipient`.

52.15.6.33 Direct LDAP attribute name MTA options: `ldap_start_date` (LDAP attribute name)

The `ldap_start_date` MTA option specifies the name of a user (or group) LDAP attribute, by default `vacationStartDate`, used to specify the start of the date/time range for which to apply autoreply (vacation) processing. (The MTA in principle allows this attribute on group/mailing list entries as well as on user entries, but the typical configuration of the `delivery_options` MTA option disables interpreting the attribute's value in the case of groups. Futhermore, the Sun schema does not, as distributed, allow this attribute on group/

mailing list entries. See the `delivery_options` MTA option for some discussion regarding enabling use of this attribute on group/mailing list entries.)

The value stored in the named attribute should have the format `YYYYMMDDHHMMSSZ`, which note is in the GMT timezone. An autoreply will only be generated if the current time is after the time specified by this attribute and inclusive limit processing is in effect, or before the specified limit if exclusive time limit processing is in effect. No start date limit is enforced if this attribute is missing.

The schema sets an ACI on the default attribute, `vacationStartDate`, to allow user modification.

52.15.6.34 Direct LDAP attribute name MTA options: `ldap_end_date` (LDAP attribute name)

The `ldap_end_date` MTA option specifies the name of a user (or group) LDAP attribute, by default `vacationEndDate`, used to specify the end of the date/time range for which to apply autoreply (vacation) processing. (The MTA in principle allows this attribute on group/mailing list entries as well as on user entries, but the typical configuration of the `delivery_options` MTA option disables interpreting the attribute's value in the case of groups. Futhermore, the Sun schema does not, as distributed, allow this attribute on group/mailing list entries. See the `delivery_options` MTA option for some discussion regarding enabling use of this attribute on group/mailing list entries.)

The value stored in the named attribute should have the format `YYYYMMDDHHMMSSZ`, which note is in the GMT timezone. An autoreply will only be generated if the current time is before the time specified by this attribute and inclusive limit processing is in effect, or after the specified limit if exclusive time limit processing is in effect.

The schema sets an ACI on the default attribute, `vacationEndDate`, to allow user modification.

52.15.6.35 Direct LDAP attribute name MTA options: `ldap_conversion_tag` (LDAP attribute name)

The `ldap_conversion_tag` MTA option specifies the name of a user or group LDAP attribute, by default `mailConversionTag`, which may be used to specify a conversion tag to add to messages addressed to that user or group.

Compare with `ldap_source_conversion_tag` which may be used to specify a conversion tag to add to messages sent *from*, instead of *to*, a user or group. Note that there is also a domain level analogue, `ldap_domain_attr_conversion_tag`.

52.15.6.36 Direct LDAP attribute name MTA options: `ldap_detourhost_optin` (LDAP attribute name)

The `ldap_detourhost_optin` MTA option specifies the name of a user or group LDAP attribute which may be used to specify "opt-in" to "detour" routing, as specified by the `aliasoptindetourhost` channel option. Normally the presence of the specified attribute on a user or group entry causes "opt in", however, see the `aliasdetourhost_null_optin` MTA option.

Note that there is a domain level analogue, `ldap_domain_attr_detourhostoptin`.

52.15.6.37 Direct LDAP attribute name MTA options: `ldap_blocklimit` (LDAP attribute name)

The `ldap_blocklimit` MTA option specifies the name of a user or group LDAP attribute, by default `mailMsgMaxBlocks`, which may be used to specify the maximum size, in MTA blocks (see the `block_size` MTA option), of messages that may be sent to the user or group.

New in MS 6.3, this attribute will also (for messages that have no return-of-content policy flag already) cause messages sent from this user that are larger than the specified size to automatically get the non-return-of-content NOTARY flag set, to make it more likely that the user will be able to receive any bounce notifications about such message.

Compare with the alias option `alias_blocklimit`, with the domain-level `ldap_domain_attr_blocklimit` MTA option, and with the similar limit on messages a user may *send* controlled via the `ldap_sourceblocklimit`.

(Note that the `acceptalladdresses` channel option, if used, may modify the timing and form of rejections due to exceeding message size constraints.)

52.15.6.38 Direct LDAP attribute name MTA options: `ldap_mailhost` (list of LDAP attribute names)

The `ldap_mailhost` MTA option specifies the names of user (or group) LDAP attributes, by default `mailHost`. used to specify the mail host of the user (or group). When a user (or group) has no explicitly specified `mailHost`, see also the `ldap_domain_attr_default_mailhost` MTA option which if set, specifies a domain level LDAP attribute for the MTA to use as a default `mailHost` for users without their own explicit value set.

Normally, only the host specified by `mailHost` attribute may interpret (act on) a user's delivery options; however, in the case where all such delivery options are "host-independent", as on an MTA that delivers via LMTP to "back end" message store systems, or when a user entry only contains some particular delivery options that happen to be host-independent, then processing can continue even on other hosts. This attribute is optional for groups and mailing lists. If present for a group or mailing list, it specifies that that host and only that host can expand the group or list; if absent, any host can expand the group or list. For a user for whom a `mailHost` is required (such as a user with `mailbox` delivery option set, when `mailbox` delivery is host-dependent per `delivery_options`, with no domain level `ldap_domain_attr_default_mailhost` attribute value set), absence of a `mailHost` attribute will cause a temporary alias expansion error:

```
452 4.0.0 temporary error returned by alias expansion: address
```

(or whatever text is configured via the `error_text_alias_temp` MTA option), the same sort of error that would occur if an LDAP problem had occurred during the lookup of the user entry (after an LDAP lookup of the domain had already succeeded).

For some further discussion of the use of `mailHost`, see the Overview of Direct LDAP discussion.

For the MMP, see the analogous `mailhostattrs` option; for authentication results, see the similar `ldap_auth_attr_mail_host` option.

52.15.6.39 Direct LDAP attribute name MTA options: ldap_disk_quota (LDAP attribute name)

The ldap_disk_quota MTA option names the user LDAP attribute used to set user disk quota, by default the mailQuota LDAP attribute. See also the ldap_message_quota MTA option, which names an LDAP attribute storing a per-message quota (size limit).

By default, the value stored in the LDAP attribute named by ldap_disk_quota is assumed to have units of bytes. Suffix characters on the value allow units of other than bytes: K (kilobytes), M (megabytes), or G (gigabytes) are supported.

52.15.6.40 Direct LDAP attribute name MTA options: ldap_message_quota (LDAP attribute name)

The ldap_message_quota MTA option names the user LDAP attribute, by default mailMsgQuota, used to set a user per-message quota (size limit). See also the ldap_disk_quota MTA option, which names an LDAP attribute storing user disk quota.

52.15.6.41 Direct LDAP attribute name MTA options: ldap_program_info (LDAP attribute name)

The ldap_program_info MTA option specifies the name of a user or group LDAP attribute, by default mailProgramDeliveryInfo, whose value specifies the program which the pipe channel will run to effect delivery for a mailDeliveryOption value of program. (A mailDeliveryOption value of program causes routing to the pipe channel per the program clause of the delivery_options MTA option's value; then the pipe channel interprets the value of mailProgramDeliveryInfo to determine how to perform the actual delivery.)

The schema sets an ACI on the default attribute, mailProgramDeliveryInfo, to allow user modification.

52.15.6.42 Direct LDAP attribute name MTA options: ldap_delivery_file (LDAP attribute name list)

The ldap_delivery_file MTA option specifies the name of user or group LDAP attributes, by default mailDeliveryFileURL and mailDeliveryFile, whose values specify a file to which to "deliver" messages. (This might, for instance, be a list posting archive file.)

52.15.6.43 Direct LDAP attribute name MTA options: ldap_spare_*N* (LDAP attribute name)

The ldap_spare_*N*, *N*=1,...,18, MTA options may be used to name LDAP attributes intended for site-customizable purposes, to be made known to the MTA (and hence be more easily accessible in MTA LDAP URLs and certain MTA mapping tables, *etc.*). ldap_spare_6 was new in Messaging Server 7.0-3.01; ldap_spare_*N* for N=7,...,18 were new in Messaging Server 7.2-7.02.

When a ldap_spare_*N* option has been set to the name of an LDAP attribute, then the value of the named attribute may be substituted in MTA LDAP URLs via the $*N*E substitution sequence.

For *N*=1,...,6, the value of the named attribute may optionally (see the include_spares1 MTA option) be included in various recipient access mapping table probes and FROM_ACCESS mapping table probes. And as of 8.0, such named LDAP attribute values may also be included (see the include_spares2 MTA option) in FORWARD mapping table probes.

ldap_spare_4, ldap_spare_5, and ldap_spare_6 will be included in SIEVE_EXTLISTS mapping table probes. And as of MS 6.3, the MTA supports the use of multiple, language-tagged values for these (ldap_spare_4, ldap_spare_5, and ldap_spare_6) attributes. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines will use the value tagged as being in the language of the envelope From user's ldap_preferred_language (normally preferredLanguage) attribute's value.

See the respective spare_*N*_separator MTA options for configuration of whether a ldap_spare_*N* LDAP attribute is allowed to have multiple values and if so, how to handle the multiple values.

For aliases defined in the alias file (legacy configuration), or via alias options (Unified Configuration), see the [SPARE*] alias file named parameters or alias_spare* alias options, respectively.

52.15.6.44 Direct LDAP attribute name MTA options: ldap_autoreply_mode (LDAP attribute name)

The ldap_autoreply_mode MTA option specifies the name of the user (or group) LDAP attribute which will store what "type" of autoreply/vacation message the user or group wishes to emit. The default LDAP attribute for this purpose is mailAutoReplyMode. (The MTA in principle allows this attribute on group/mailing list entries as well as on user entries, but the typical configuration of the delivery_options MTA option disables support for interpreting the attribute's value in the case of groups. Futhermore, the Sun schema does not, as distributed, allow this attribute on group/mailing list entries. See the delivery_options MTA option for some discussion regarding enabling use of this attribute on group/mailing list entries.)

The schema sets an ACI on the default attribute, mailAutoReplyMode, to allow user modification.

Supported values for the value of the LDAP attribute named by ldap_autoreply_mode, *e.g.*, mailAutoReplyMode, are echo and reply. These modes will appear in the Sieve script (constructed by the MTA on the fly, based on these LDAP values) as nonstandard :echo and :reply arguments to the vacation action. echo will produce a "processed" message disposition notification (MDN) that contains the original message as returned content. reply will produce a pure reply containing only the reply text. An illegal value won't manifest as any argument to the vacation action and this will produce an MDN containing only the headers of the original message.

52.15.6.45 Direct LDAP attribute name MTA options: ldap_autoreply_subject (LDAP attribute name)

The ldap_autoreply_subject MTA option specifies the name of the user (or group) LDAP attribute which will store the text to put on the Subject: header line of any autoreply/vacation message generated on behalf of the user. The default LDAP attribute for this purpose

is `mailAutoReplySubject`. (The MTA in principle allows this attribute on group/mailing list entries as well as on user entries, but the typical configuration of the `delivery_options` MTA option disables this support in the case of groups. Futhermore, the Sun schema does not, as distributed, allow this attribute on group/mailing list entries. See the `delivery_options` MTA option for some discussion regarding enabling use of this attribute on group/mailing list entries.)

The schema sets an ACI on the default attribute, `mailAutoReplySubject`, to allow user modification.

In whatever attribute is named by `ldap_autoreply_subject`, the value in the attribute must be a UTF-8 string. This value gets passed as the `:subject` argument to the `vacation` action.

As of MS 6.2-2.01, the special strings `$SUBJECT` and `$FROM` are supported for use in this attribute's value, causing substitution of the original message's Subject: field value or From: field value, respectively, into the generated string.

New in MS 8.0.2.2, substitutions from the vacationStartDate and vacationEndDate are also also available. These substitutions take the form `$<attribute><part>` where `$<attribute>` is "B" for the start (beginning) date or "E" for the end date, and `<part>` is one of the date parts defined in RFC 5260 section 4.2. So for example, the string `$EDATE"` would substitute in the end date in YYYY-MM-DD format. These substitution strings are treated as regular text if the corresponding attribute is not defined or is set to an invalid value.

Note that new in MS 6.3-0.15, the MTA supports the use of multiple, language-tagged values, for this attribute. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines the MTA's next choice will be the value tagged as being in the language of the envelope From user's `ldap_preferred_language` (normally `preferredLanguage`) attribute's value.

Prior to 7.0.5, the length of the value of `mailAutoReplySubject` was limited to 256 characters (though the maximum length of a `:subject` parameter in a Sieve `vacation` action has always been 1024 characters). As of 7.0.5, the length limit for `mailAutoReplySubject` has been raised so that at least 900 characters can be specified.

52.15.6.46 Direct LDAP attribute name MTA options: `ldap_autoreply_text` (LDAP attribute name)

The `ldap_autoreply_text` MTA option specifies the name of the user (or group) LDAP attribute which will store the vacation/autoreply text (the "reason" string) returned to all senders except users in the recipient's own domain. The default LDAP attribute for this purpose is `mailAutoReplyText`. (The MTA in principle allows this attribute on group/mailing list entries as well as on user entries, but the typical configuration of the `delivery_options` MTA option disables this support in the case of groups. Futhermore, the Sun schema does not, as distributed, allow this attribute on group/mailing list entries. See the `delivery_options` MTA option for some discussion regarding enabling use of this attribute on group/mailing list entries.) If the recipient's LDAP entry does not have a value specified for the attribute named by `ldap_autoreply_text` (normally the `mailAutoReplyText` attribute), then note that "external" senders will receive no vacation message. Note that when generating an autoreply/vacation message back to a fellow "internal" user, the value of the attribute named by the `ldap_autoreply_text_internal` MTA option will be used instead of the value of the attribute named by the `ldap_autoreply_text` MTA option.

The schema sets an ACI on the default attribute, `mailAutoReplyText`, to allow user modification.

As of MS 6.2-2.01, the special strings `$SUBJECT` and `$FROM` are supported for use in this attribute's value, causing substitution of the original message's Subject: field value or From: field value, respectively, into the generated body text string.

New in MS 8.0.2.2, substitutions from the vacationStartDate and vacationEndDate are also also available. These substitutions take the form `$<attribute><part>` where `$<attribute>` is "B" for the start (beginning) date or "E" for the end date, and `<part>` is one of the date parts defined in RFC 5260 section 4.2. So for example, the string `$EDATE"` would substitute in the end date in YYYY-MM-DD format. These substitution strings are treated as regular text if the corresponding attribute is not defined or is set to an invalid value.

Note that new in MS 6.3-0.15, the MTA supports the use of multiple, language-tagged values, for this attribute;. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines the MTA's next choice will be the value tagged as being in the language of the envelope From user's `ldap_preferred_language` (normally `preferredLanguage`) attribute's value.)

52.15.6.47 Direct LDAP attribute name MTA options: `ldap_autoreply_text_internal` (LDAP attribute name)

d

The `ldap_autoreply_text_internal` MTA option specifies the name of the user (or group) LDAP attribute which will store the vacation/autoreply text (the "reason" string) returned to all senders in the recipient's own domain. (The MTA in principle allows this attribute on group/mailing list entries as well as on user entries, but the typical configuration of the `delivery_options` MTA option disables this support in the case of groups. Futhermore, the Sun schema does not, as distributed, allow this attribute on group/mailing list entries. See the `delivery_options` MTA option for some discussion regarding enabling use of this attribute on group/mailing list entries.) If the recipient's LDAP entry does not have a value specified for this attribute, then internal users receive the external vacation text, stored in the `ldap_autoreply_text` MTA option.

The schema sets an ACI on the default attribute, `mailAutoReplyTextInternal`, to allow user modification.

As of MS 6.2-2.01, the special strings `$SUBJECT` and `$FROM` are supported for use in this attribute's value, causing substitution of the original message's Subject: field value or From: field value, respectively, into the generated body text string.

New in MS 8.0.2.2, substitutions from the vacationStartDate and vacationEndDate are also also available. These substitutions take the form `$<attribute><part>` where `$<attribute>` is "B" for the start (beginning) date or "E" for the end date, and `<part>` is one of the date parts defined in RFC 5260 section 4.2. So for example, the string `$EDATE"` would substitute in the end date in YYYY-MM-DD format. These substitution strings are treated as regular text if the corresponding attribute is not defined or is set to an invalid value.

Note that new in MS 6.3-0.15, the MTA supports the use of multiple, language-tagged values, for this attribute;. When multiple, language-tagged values are present, the MTA will preferentially use the value tagged as being in the language preference expressed in a header line such as Accept-Language:, or in the absence of such header lines the MTA's

next choice will be the value tagged as being in the language of the envelope From user's ldap_preferred_language (normally preferredLanguage) attribute's value.)

52.15.6.48 Direct LDAP attribute name MTA options: ldap_autoreply_addresses (LDAP attribute name)

The ldap_autoreply_addresses MTA option specifies the name of an LDAP attribute in which to store additional, recognized-for-vacation-message-purposes, versions of the recipient's address; there is no default (no pre-defined LDAP attribute for this purpose). (The MTA in principle allows this attribute on group/mailing list entries as well as on user entries, but the typical configuration of the delivery_options MTA option disables this support in the case of groups. Futhermore, the Sun schema does not, as distributed, define an attribute for this purpose. See the delivery_options MTA option for some discussion regarding enabling use of this attribute on group/mailing list entries.) If adding such an LDAP attribute to the schema, this is an attribute to consider making user self-modifiable (have an ACI set on it allowing user modification).

The attribute named by the ldap_autoreply_addresses MTA option takes multiple values specifying additional addresses to recognize as "one's own" for purposes of whether to generate a vacation message. That is, it is an analogue of the :addresses argument for the Sieve vacation action. As of MS 6.3-0.15, the MTA supports use of language-tagged values for the attribute named by ldap_autoreply_addresses.

52.15.6.49 Direct LDAP attribute name MTA options: ldap_autoreply_timeout (LDAP attribute name)

The ldap_autoreply_timeout MTA option specifies the name of the user (or group) LDAP attribute which will store the duration (the "timeout") between successive vacation/autoreply responses to any given sender. (The MTA in principle allows this attribute on group/mailing list entries as well as on user entries, but the typical configuration of the delivery_options MTA option disables this support in the case of groups. Futhermore, the Sun schema does not, as distributed, allow this attribute on group/mailing list entries. See the delivery_options MTA option for some discussion regarding enabling use of this attribute on group/mailing list entries.)

The schema sets an ACI on the default attribute, mailAutoReplyTimeOut, to allow user modification.

The value in the attribute named by ldap_autoreply_timeout should be represented in units of hours. If the attribute's value is 0, then a response is sent back every time a message is received. The attribute's value will be converted to the nonstandard argument to the vacation action. (Note that the standard Sieve vacation action is defined to only support the :days argument for this purpose and doesn't allow a value of 0; so this support for shorter intervals between responses is an extension in the MTA's Sieve support.)

If the attribute named by ldap_autoreply_timeout is not present in a user entry, then a default timeout will be obtained from the user's domain (from the attribute named by the ldap_domain_attr_autoreply_timeout MTA option) if the domain has its own timeout, or otherwise from the autoreply_timeout_default MTA option.

52.15.6.50 Direct LDAP attribute name MTA options: ldap_filter (LDAP attribute name)

The `ldap_filter` MTA option specifies the name of the LDAP attribute which will store the Sieve filter of the user or group.

The schema sets an ACI on the default attribute, `mailSieveRuleSource`, to allow user modification.

52.15.6.51 Direct LDAP attribute name MTA options: `ldap_parental_controls` (LDAP attribute name)

The `ldap_parental_controls` MTA option names a user or group LDAP attribute to use to select whether or not a user will have "parental controls" (or "head-of-household controls") applied. There is no default; (no pre-defined LDAP attribute for this purpose). Note that when adding an attribute for this purpose, this typically should *not* be an attribute modifiable by the user himself; instead, it should typically instead be modifiable by the "parent" ("head-of-household") user.

For the LDAP attribute named by `ldap_parental_controls`, any of the values `Yes`, `1`, or `true` is considered to be requesting parental controls. If such a value is present enabling parental controls, then the LDAP attribute named by the `ldap_filter_reference` MTA option will be consulted to determine who (what DN in the directory) is the "parent" of ("head-of-household" for) this user.

52.15.6.52 Direct LDAP attribute name MTA options: `ldap_filter_reference` (LDAP attribute name)

The `ldap_filter_reference` MTA option specifies the name of a user or group LDAP attribute to be used to locate the "parent" of ("head-of-household" for) the current user or group entry. There is no default; (no pre-defined LDAP attribute for this purpose). Note that when adding an attribute for this purpose, this typically should *not* be an attribute modifiable by the user himself; instead, it should typically instead be modifiable by the "parent" ("head-of-household") user.

If parental controls are enabled for a user (see the `ldap_parental_controls` MTA option), then the attribute named by this `ldap_filter_reference` MTA option specifies the DN of the entry that contains the actual parent/head of household Sieve filter (typically, that is, the DN of the head of household user). (The LDAP attribute within that head of household user entry containing the Sieve filter is specified by the `ldap_hoh_filter` MTA option, which defaults to `mailSieveRuleSource`. The lookup requests both the Sieve filter, contained in the attribute named by the `ldap_hoh_filter` MTA option, and the owner, contained in the LDAP attribute named by the `ldap_hoh_owner` MTA option, which defaults to `mail`.)

52.15.6.53 Direct LDAP attribute name MTA options: `ldap_forwarding_address` (LDAP attribute name)

The `ldap_forwarding_address` MTA option specifies the name of a user or group LDAP attribute which will store a forwarding address for the user or group, to be used if `mailDeliveryOption` attribute (or whatever attribute is named by the `ldap_delivery_option` MTA option) has a value of `forward`.

The schema sets an ACI on the default attribute, `mailForwardingAddress`, to allow user modification.

52.15.6.54 Direct LDAP attribute name MTA option: ldap_reprocess (LDAP attribute name)

The ldap_reprocess MTA option specifies the name of a user or group LDAP attribute which will control whether alias expansion of the entry is deferred to the reprocess channel *vs*. being performed immediately (in-line). The default is mailDeferProcessing. The value of the attribute overrides the MTA's general default controlled by the defer_group_processing MTA option.

Valid values for the LDAP attribute named by ldap_reprocess include: "Yes", "No", or (new in MS 6.3p1) "AFTER_AUTH". "AFTER_AUTH" causes LDAP attributed based access checks, such as mgrpAllowedBroadcaster, *etc*.., to get performed "in-line", while deferring membership expansion (as well as a second check of the LDAP attribute based access checks) to the reprocess channel. New in Messaging Server 7.0u3, it is also valid to specify as the attribute's value a channel name (*e.g.*, "process_special" or the name of some similar, special, reprocess_* or process_* channel variant), and in this case the group or list expansion will be deferred to the specified channel.

For several examples of use of the attribute named by ldap_reprocess, see the discussion of Moderated mailing lists.

For aliases defined in Unified Configuration via alias options, see alias_reprocess. Or for aliases defined in legacy configuration in the alias file, see the [REPROCESS] alias file named parameter.

52.15.6.55 Direct LDAP attribute name MTA option: ldap_jettison_domain (LDAP attribute name list)

(New in Messaging Server 7.3-11.01.) The ldap_jettison_domain MTA option specifies the name of an LDAP attribute, by default mgrpJettisonDomain, whose value(s) name domains from which to silently discard all messages. Glob-style wildcards may be used in the value(s). Multiple attributes and multiple values are allowed.

52.15.6.56 Direct LDAP attribute name MTA option: ldap_jettison_url (LDAP attribute name list)

(New in Messaging Server 7.3-11.01.) The ldap_jettison_url MTA option specifies the name of an LDAP attribute, by default mgrpJettisonBroadcasters, whose value(s) specify a URL identifying mail addresses whose messages should be jettisoned if sent to this group. Multiple attributes and multiple values are allowed; mailto: URLs are acceptable. Each URL is expanded into a list of addresses and each address is checked against the current envelope From address. A match marks the message to be jettisoned and bypasses all other group checks and expansion. Substitution processing will be performed on this URL If bit 6 (value 64) of the process_substitutions MTA option is set.

52.15.6.57 Direct LDAP attribute name MTA options: ldap_list_id (LDAP attribute name)

RESTRICTED.

The ldap_list_id MTA option specifies the name of a group LDAP attribute, by default mgrpUniqueId, used to store a unique identifier for the group/list.

The presence of the LDAP attribute named by `ldap_list_id` on group or list entries in LDAP is optional for groups/lists in general, but is required for groups to be managed by the MTA's MAILSERV. The attribute's presence and value provides the linkage between mluser entries and the group definition in the user/group tree.

52.15.6.58 Direct LDAP attribute name MTA options: `ldap_reject_action` (LDAP attribute name)

The `ldap_reject_action` MTA option specifies the name of a group LDAP attribute, by default `mgrpMsgRejectAction`, whose value will control what to do when a message "fails" a posting check.

For whatever LDAP attribute is named by `ldap_reject_action`, the MTA supports values for the attribute of `reply` and `toModerator`, meaning, respectively, to issue a message rejection, or to redirect the message to the group/list moderator address. Note that for a value of `reply` (meaning that the attempted post will be rejected), the value of a `mgrpRejectText` or `mgrpMsgRejectText` LDAP attribute (or more precisely, the value of whatever attributes are named by the `ldap_reject_text` MTA option) may be used to control the error text to send back to the attempting poster.

52.15.6.59 Direct LDAP attribute name MTA options: `ldap_reject_text` (LDAP attribute name list)

The `ldap_reject_text` MTA option specifies the names of group LDAP attributes, by default `mgrpRejectText`, `mgrpMsgRejectText`, whose value will control what error text to use when rejecting an attempted posting to a list due to the attempted posting failing an access check. Because the error text may appear in SMTP responses, it must conform to SMTP response limitations. In particular, it may consist merely of a single line of text limited to the US-ASCII charset. (If the value contains eight bit characters, the entire value will be ignored. If the value contains more than a single line of text, only the first line of text will be used.)

52.15.6.60 Direct LDAP attribute name MTA options: `ldap_auth_policy` (LDAP attribute name)

The `ldap_auth_policy` MTA option specifies the name of a group LDAP attribute, by default `mgrpBroadcasterPolicy`. The LDAP attribute named by `ldap_auth_policy` may contain multiple, comma-separated keywords. Supported keywords in the value include `SMTP_AUTH_REQUIRED` and `AUTH_REQ` (require SMTP AUTH use to post), `PASSWORD_REQUIRED` and `PASSWD_REQUIRED` and `PASSWD_REQ` (require a password to post), and `OR` and `AND` (affect combination of multiple access controls), and `NO_REQUIREMENTS`. New in Messaging Server 7.0u4 are the keywords `LIST_OPEN`, `LIST_MEMBERS`, `LIST_MODERATE_NONMEMBERS`, `LIST_MODERATE_MEMBERS`, `LIST_MODERATE`, supported only for lists with a `mgrpUniqueId` (normally MAILSERV lists).

52.15.6.61 Direct LDAP attribute name MTA options: `ldap_cant_url` (LDAP attribute name)

The `ldap_cant_url` MTA option names the group LDAP attribute, by default `mgrpDisallowedBroadcaster`, whose value specifies via an MTA URL a list of (envelope From) addresses *not* allowed to post to the group or list. Note that depending on the setting of the `process_substitutions` MTA option, certain substitution sequences may be used in the URL.

Note that the use_auth_return, use_canonical_return, and use_orig_return MTA options select which form of a message's envelope From address is compared in making the access determination.

52.15.6.62 Direct LDAP attribute name MTA options: ldap_auth_url (LDAP attribute name)

The ldap_auth_url MTA option names the group LDAP attribute, by default mgrpAllowedBroadcaster, whose value specifies via an MTA URL a list of (envelope From) addresses allowed to post to the group or list. Note that depending on the setting of the process_substitutions MTA option, certain substitution sequences may be used in the URL.

As of MS 6.3, when a URL is expanded to get back a list of those sending addresses allowed to post, the MTA will request (for local users) aliases as well as canonical addresses; this means that lists where only members are allowed to post *do* allow local members to post using their defined aliases.

Note that the use_auth_return, use_canonical_return, and use_orig_return MTA options select which form of a message's envelope From address is compared in making the access determination.

52.15.6.63 Direct LDAP attribute name MTA options: ldap_cant_domain (LDAP attribute name)

The ldap_cant_domain MTA option names the group LDAP attribute, by default mgrpDisallowedDomain, whose values specify domains not allowed to post to the group or list.

Note that the use_auth_return, use_canonical_return, and use_orig_return MTA options select which form of a message's envelope From address is compared in making the access determination.

52.15.6.64 Direct LDAP attribute name MTA options: ldap_auth_domain (LDAP attribute name)

The ldap_auth_domain MTA option names the group LDAP attribute, by default mgrpAllowedDomain, whose values specify domains allowed to post to the group or list. As of MS 6.2, the value of the attribute supports use of the asterisk character, *, as a wildcard. For instance, a value of *.domain.com means to allow all subdomains of domain.com, though not domain.com itself; to allow domain.com and all its subdomains, use two values for the attribute, domain.com and *.domain.com.

Note that the use_auth_return, use_canonical_return, and use_orig_return MTA options select which form of a message's envelope From address is compared in making the access determination.

52.15.6.65 Direct LDAP attribute name MTA options: ldap_maximum_message_size (LDAP attribute name)

The ldap_maximum_message_size MTA option specifies the name of a group LDAP attribute, by default mgrpMsgMaxSize, whose value sets an upper limit, in units of MTA

blocks (block_size), on how large of message may be posted to the group or list. (Compare with the user LDAP attribute mailMsgMaxBlocks.)

(Note that the acceptalladdresses channel option, if used, may modify the timing and form of rejections due to exceeding message size constraints.)

52.15.6.66 Direct LDAP attribute name MTA options: ldap_maximum_messages_per_day (LDAP attribute name)

RESTRICTED: Not yet fully implemented.

52.15.6.67 Direct LDAP attribute name MTA options: ldap_auth_password (LDAP attribute name list)

The ldap_auth_password MTA option specifies the name of a group level LDAP attribute, by default mgrpAuthPassword, used to store a password needed to post to the group.

In iMS 5.2 the value of this attribute was saved if the mgrpBroadcasterPolicy attribute was set to require a password, and the value was then checked against the Approved: field once the header became available. The Approved: field was removed from the header once the check was complete. But this did not allow for routing to the moderator in the event of a password check failure.

In the MS 6.0 release and later, the presence of a mgrpAuthPassword attribute forces a reprocessing pass. As the message is enqueued to the reprocessing channel, the password is taken from the header and placed in the envelope. Then while reprocessing, the password is taken from the envelope and checked against this attribute. Additionally, only passwords that actually are used are removed from the header field.

Note that the or_clauses MTA option acts on the mgrpAuthPassword attribute in the same way it acts on the other access check attributes.

52.15.6.68 Direct LDAP attribute name MTA options: ldap_moderator_url (LDAP attribute name list)

The ldap_moderator_url MTA option specifies the name of a group level LDAP attribute, by default mgrpModerator, that stores a list of URLs to be expanded into a series of addresses. The interpretation of this address list depends on the value of the LDAP attribute named (by default, mgrpMsgRejectAction) by the ldap_reject_action MTA option.

If the LDAP attribute named by ldap_reject_action has its value set to "TOMODERATOR", then the LDAP attribute named by ldap_moderator_url specifies the moderator address(es) the message is to be sent to should any of the access checks fail. If the LDAP attribute named by ldap_reject_action is missing or has any other value, then the ldap_moderator_url attribute's expanded address list is compared with the envelope From address. (Setting particular bits in any of the MTA options use_auth_return, use_canonical_return, or use_orig_return can control which "form" or version of the envelope From address is compared.) Processing continues if there is a match. If there isn't a match, then the message is again sent to all of the addresses specified by the ldap_moderator_url attribute's value(s).

Expansion of the ldap_moderator_url attribute's values is implemented by making the values of this attribute the list of URLs for the group; that is, any list of member RFC 822 addresses or DNs previously determined for the group is (temporarily) cleared, and the

delivery options for the group (the `ldap_moderator_url` expanded values) are set to "`members`". Any additional, subsequent group LDAP attributes (as listed in Table of MTA LDAP attribute name options) will be ignored at this stage of processing.

Note that as of MS 6.3, substitution processing will be performed on the URL value(s) of the LDAP attribute named by `ldap_moderator_url` if bit 2 (value 4) of the `process_substitutions` MTA option is set.

52.15.6.69 Direct LDAP attribute name MTA options: `ldap_group_last_access_time` (LDAP attribute name)

(New in 8.0.) The `ldap_group_last_access_time` MTA option specifies the name of an LDAP attribute used to keep track of the last access time for email groups defined in LDAP. If this attribute is present in a group's LDAP entry, then the MTA will update the attribute each time the group is successfully accessed for purposes of sending mail or expanding a mailing list. RFC 3339 format, an Internet profile of ISO 8601 format, is used, *e.g.*, "`2013-09-29T17:38:52Z`".

In order to prevent excessive LDAP writes, the LDAP attribute named by the `ldap_group_last_access_time` MTA option is read prior to writing and a write is only done if the current time exceeds the stored time by at least 30 minutes. (A write is also done if the attribute does not contain a valid RFC 3339 time, making it possible to set the initial value to something like "`<never accessed>`".)

52.15.6.70 Direct LDAP attribute name MTA options: `ldap_group_url1` (LDAP attribute name)

The `ldap_group_url1` MTA option names an LDAP attribute which may be placed on a group entry in LDAP as one way of identifying members of the group. The default LDAP attribute name is `mgrpDeliverTo`; its value should be a URL identifying the members of the group. See also the `ldap_group_url2` MTA option which names another LDAP attribute (by default `memberURL`) of analogous purpose.

See also the `ldap_url_result_mapping` MTA option; with it, a mapping table can be used to manipulate the value(s) and results of expanding the value(s) of the attributes named by `ldap_group_url1` and `ldap_group_url2`.

52.15.6.71 Direct LDAP attribute name MTA options: `ldap_group_url2` (LDAP attribute name)

The `ldap_group_url2` MTA option names an LDAP attribute which may be placed on a group entry in LDAP as one way of identifying members of the group. The default LDAP attribute name is `memberURL`; its value should be a URL identifying the members of the group. See also the `ldap_group_url1` MTA option which names another LDAP attribute (by default `mgrpDeliverTo`) of analogous purpose.

See also the `ldap_url_result_mapping` MTA option; with it, a mapping table can be used to manipulate the value(s) and results of expanding the value(s) of the attributes named by `ldap_group_url1` and `ldap_group_url2`.

52.15.6.72 Direct LDAP attribute name MTA options: `ldap_group_dn` (LDAP attribute name)

The ldap_group_dn MTA option names an LDAP attribute which may be placed on a group entry in LDAP as one way of identifying members of the group. The default LDAP attribute name is uniqueMember.

Typically, and in default use, the value in the LDAP attribute named by ldap_group_dn is a DN (Distinguished Name), so that the members of the group are being identified via their position (DN) in the DIT. Note that such a DN may specify an entire subtree of the DIT. Specifically, in basic use the value of the LDAP attribute named by ldap_group_dn is substituted into the URL template defined by the group_dn_template MTA option, whose default value is:

```
ldap:///$A?mail?sub?(mail=*)
```

where the uniqueMember (or whatever LDAP attribute named by ldap_group_dn) value is substituted in place of the $A.

However, the exact use/interpretation of the LDAP attribute named by ldap_group_dn is controlled not only by the group_dn_template MTA option, but optionally may be further modified via the GROUP_TEMPLATES mapping table, as well as any special mapping table specified for that group via the group LDAP attribute named by the ldap_url_result_mapping MTA option. As of Messaging Server 7.0.5, if a GROUP_TEMPLATES mapping table exists, then it is used to determine what template (what alternative to group_dn_template) to apply to the value of the LDAP attribute named by ldap_group_dn. The GROUP_TEMPLATES mapping probe is of the form

object-classes|*attribute-name*|*attribute-value*

If the mapping sets the $Y output flag, then the mapping result is used as the template instead of the group_dn_template MTA option's value.

Multiple values of the LDAP attribute named by ldap_group_dn are allowed on a group entry, *e.g.*, multiple uniqueMember values are allowed, but only one attribute name may be specified as ldap_group_dn. To use another named LDAP attribute (perhaps in a slightly different way) use ldap_group_dn2.

As of Messaging Server 7.0.5 any mapping specified by the ldap_url_result_mapping MTA option will also be applied to the results produced by the ldap_group_dn and ldap_group_dn2 attributes.

52.15.6.73 ldap_group_dn2 Option

The ldap_group_dn2 MTA option names an LDAP attribute in which to store a list of DNs, *or other identifiers*, for group members.

The ldap_group_dn2 MTA option names an LDAP attribute which may be placed on a group entry in LDAP as a way of identifying members of the group. The ldap_group_dn2 MTA option has no default. The purpose of the ldap_group_dn2 MTA option, and whatever LDAP attribute it names, is primarily to allow alternate approaches to identifying group members, beyond the identification-via-DN typically achieved via the uniqueMember LDAP attribute (more precisely, whatever LDAP attribute is named by the ldap_group_dn MTA option) being expanded via the URL template specified via the group_dn_template MTA option.

While the LDAP attribute named by ldap_group_dn2 may be used to store a DN (like the default use of the LDAP attribute named by ldap_group_dn), more typically it would be used to store some other means of identifying members of a group, with the GROUP_TEMPLATES mapping table then being configured to make "appropriate" use of the value of the LDAP attribute named by ldap_group_dn2. For instance, if

```
ldap_group_dn2=listID
```

and a GROUP_TEMPLATES mapping table is configured as

```
GROUP_TEMPLATES

! Normal use of ldap_group_dn attribute uniqueMember
  *|uniqueMember|*  $Yldap:///$A?mail?sub?(mail=*)
! Find users who have a memberOf attribute set to the value of the group's
! memberID attribute
  *|listID|*      $Yldap:///baseDN-of-users??sub?(memberOf=$$A)
```

then "traditional" groups with membership defined via values of the uniqueMember LDAP attribute will continue to work as always, while also allowing groups to have membership defined as "all users who have a memberOf attribute value matching the group's listID attribute value".

Multiple values of the LDAP attribute named by ldap_group_dn2 are allowed on a group entry, *e.g.*, continuing the example above multiple memberID values would be allowed, but only one attribute name may be specified as ldap_group_dn2. Allowing the capability to have two differently named LDAP attributes, potentially expanded via different URL templates, is the reason why ldap_group_dn2 exists in addition to ldap_group_dn.

As of Messaging Server 7.0.5 any mapping specified by the ldap_url_result_mapping MTA option will also be applied to the results produced by the ldap_group_dn and ldap_group_dn2 attributes.

52.15.6.74 Direct LDAP attribute name MTA options: ldap_group_rfc822 (LDAP attribute name list)

The ldap_group_rfc822 MTA option specifies the name of one or more group LDAP attributes, by default mgrpRFC822MailMember and RFC822MailMember, whose value(s) will be RFC 822 email addresses of members of the group.

52.15.6.75 Direct LDAP attribute name MTA options: ldap_url_result_mapping (LDAP attribute name)

The ldap_url_result_mapping MTA option names an LDAP attribute which may be placed on a group entry in LDAP for purposes of manipulating the results of lookups of the mgrpDeliverTo and memberURL attributes (or more precisely, the attributes named by the ldap_group_url1 and ldap_group_url2 MTA options), and as of Messaging Server 7.0-5, also uniqueMember (the attributes named by the ldap_group_dn and ldap_group_dn2 MTA options). Currently there is no default value (default attribute) for ldap_url_result_mapping; to use this feature, you must choose a (new) attribute and add it to the schema (or disable schema checking).

This attribute's value should name an MTA mapping table to be applied to any resulted returned by expanding either a `mgrpDeliverTo` or a `memberURL` attribute, or as of Messaging Server 7.0-5 also a `uniqueMember` attribute as well as any custom attribute named by `ldap_group_dn2`. The mapping probe will be of the form:

`LDAP-URL``|`*`LDAP-result`*

where `LDAP-URL` is the (literal string) value of the `mgrpDeliverTo`, `memberURL`, or `uniqueMember` attribute itself (or custom attribute named by `ldap_group_dn2`), and `LDAP-result` is the value returned from LDAP for that `LDAP-URL` query. If the mapping returns with `$Y` set, then the mapping result string will replace the LDAP result for alias processing purposes. If the mapping returns with `$N` set, then the result will be skipped.

In particular, this mechanism can be used to define groups based on attributes that don't contain proper email addresses.

52.15.6.76 Direct LDAP attribute name MTA options: `ldap_errors_to` (LDAP attribute name)

The `ldap_errors_to` MTA option specifies the name of a group LDAP attribute used to specify an override Envelope From address. Presence of the specified attribute on a group entry is *the*critical distinction between whether a group entry is merely a group -- an e-mail auto-forwarder (equivalent to having lots of aliases) -- *vs*. whether the entry defines a true mailing list. In particular, the presence of such an attribute on a group LDAP entry has implications for notification messages regarding the list definition (*e.g.*, syntactic errors in list member addresses, or syntactic errors in a list-specific Sieve filter) or regarding delivery of messages to list members, as well as for the handling of delivery receipt requests.

Typically, the value stored in the specified LDAP attribute will be some normal email address. But two (three, as of MS 6.3) special syntaxes are also supported.

Setting the value stored in the specified LDAP attribute to an address of the form `user+*@domain` has a special meaning. The asterisk character will be expanded into a representation of the recipient address; thus a separate copy of the list message is generated for each recipient, with each copy including the intended recipient address as a subaddress within the return address. If delivery errors subsequently occur, the subaddress will indicate which was the failing address. In some cases, when dealing with remote MTAs that generate nonstandard, uninformative delivery error messages, this can in theory be useful as a way of determining which recipient address(es) failed, even when the bounce message's inner content is relatively uninformative. And it may make processing of such bounce messages by an automated program more convenient. However, the tradeoff is that such per-user-specific return address values require that a separate message copy be generated and sent for each recipient; for a "large" list, with many recipients in the same destination domains, this can be a large increase in overhead (a large decrease in efficiency). And with more prevalent use nowadays of standard format notification messages, the "need" for this sort of approach, with its extra (potentially large) overhead, is much less (since the intended recipient information can instead be extracted from the standard field in the contents of a standard format notification message).

(New in MS 6.3, but not working until fix for CR # 6530591.) Setting the value stored in the specified LDAP attribute to the forward slash character, /, has a special meaning. It tells the MTA to revert to using the original envelope From address that had been present on the incoming message, yet in all other respects use mailing list semantics. This can be useful for setting up mailing lists that report all forms of list errors to the original sender.

New in MS 6.3, the `process_substitutions` MTA option can enable use of the *$S* (recipient's subaddress) substitution in the value. This would tend to be of interest when defining a "meta-list".

For users defined via alias options, see instead the `alias_envelope_from` alias option; or in legacy configuration alias file or alias database definitions, see the [ERRORS_TO] alias file named parameter.

52.15.6.77 Direct LDAP attribute name MTA options: `ldap_delay_notifications` (LDAP attribute name)

The `ldap_delay_notifications` MTA option specifies the name of a group LDAP attribute, by default `mgrpDelayNotifications`, whose value controls whether NOTIFY=DELAY should be set on list messages. In the specified LDAP attribute, the MTA supports values of *yes* and *no*.

52.15.6.78 Direct LDAP attribute name MTA options: `ldap_digest_interval` (LDAP attribute name)

RESTRICTED. Not yet fully implemented.

52.15.6.79 Direct LDAP attribute name MTA options: `ldap_add_header` (LDAP attribute name)

The `ldap_add_header` MTA option specifies the name of the group LDAP attribute, by default `mgrpAddHeader`, which contains header lines to add to messagtes posted to the list. Such header lines might include, for instance, the List-*: header lines suggested in RFC 2369 (URLs for Mail List Commands through Message Headers).

See also the `ldap_remove_header` MTA option, for removing header lines from postings to the group or list.

For groups or lists defined via alias file or alias database (legacy configuration) or alias options (Unified Configuration), see instead the [HEADER_ADDITION] alias file named parameter or `alias_header_addition` alias option, respectively.

Use of `mgrpAddHeader` (or whatever LDAP attribute is named by `ldap_add_header`) is a very simple approach when unconditional additional of certain header lines is desired. For more complex requirements, consider setting a Sieve filter on the group or list (see the `ldap_filter` MTA option) that makes use of the Sieve editheader extension.

52.15.6.80 Direct LDAP attribute name MTA options: `ldap_remove_header` (LDAP attribute name)

The `ldap_remove_header` MTA option specifies the name of a group LDAP attribute, by default `mgrpRemoveHeader`, whose value specifies header lines to remove from postings to the group or list.

See also the `ldap_add_header` MTA option, for adding header lines to postings to the group or list.

For groups or lists defined via alias file or alias database (legacy configuration) or alias options (Unified Configuration), see instead the [HEADER_TRIM] alias file named parameter or `alias_header_trim` alias option, respectively.

Use of mgrpRemoveHeader (or whatever LDAP attribute is named by ldap_remove_header) is a very simple approach when unconditional removal of certain header lines is desired. For more complex requirements, consider setting a Sieve filter on the group or list (see the ldap_filter MTA option) that makes use of the Sieve editheader extension.

52.15.6.81 Direct LDAP attribute name MTA options: ldap_add_tag (LDAP attribute name)

The ldap_add_tag MTA option specifies the name of a group LDAP attribute used to specify prefix text to insert on the Subject: header line of messages to this recipient/list, analogous to the alias_tag alias option, the [TAG] named mailing list parameter, or the effect of the Sieve addtag action.

As of MS 6.3, the vertical bar, |, character should not be used in the tag text; in previous versions, the space character should not have been used in tag text, as such use would interfere with the MTA's internal mechanisms for checking whether a tag was already present. As of Messaging Server 7.3, the MTA supports language-tagged values for the attribute named by ldap_add_tag, and will select amongst such according to the user's preferredLanguage value (more precisely, the value of the LDAP attribute named by the ldap_preferred_langauge MTA option).

52.15.6.82 Direct LDAP attribute name MTA options: ldap_prefix_text (LDAP attribute name)

The ldap_prefix_text MTA option specifies the name of a group LDAP attribute, by default mgrpMsgPrefixText, to be used to store text to be inserted into messages posted to the group or list.

This prefix text from the LDAP attribute named by ldap_prefix_text (by default the mgrpMsgPrefixText attribute) is inserted into messages as they undergo group expansion. Prior to Messaging Server 7.0-3.01, text could only be inserted into initial, TEXT/PLAIN parts; new in Messaging Server 7.0-3.01, text can be inserted into the first text part within a nested multipart (excluding multipart/alternative). The attribute values are stored in LDAP in UTF-8; this is then converted by the MTA to match the charset of the part that the text is inserted into.

Support for HTML prefix text, insertion of text into text/html parts, and processing multiple parts in multipart/alternative was added in MS 8.0. As of MS 8.0.1.3 control over the HTML attribuates on the inserted text is also possible; see the prefix_text_attr MTA option for details.

For users defined via alias options, see instead the alias_prefix_text alias option; or in legacy configuration alias file or alias database definitions, see the [PREFIX_TEXT] alias file named parameter. Also see the addprefix Sieve action.

52.15.6.83 Direct LDAP attribute name MTA options: ldap_suffix_text (LDAP attribute name)

The ldap_suffix_text MTA option specifies the name of a group LDAP attribute, by default mgrpMsgSuffixText, to be used to store text to be inserted into messages posted to the group or list.

This suffix text from the LDAP attribute named by `mgrpMsgSuffixText` is inserted into messages as they undergo group expansion. Prior to Messaging Server 7.0-3.01, text could only be inserted into initial, TEXT/PLAIN parts; new in Messaging Server 7.0-3.01, text can be inserted into the first text part within a nested multipart (excluding multipart/alternative). The attribute values are stored in LDAP in UTF-8; this is then converted by the MTA to match the charset of the part that the text is inserted into.

Support for HTML suffix text, insertion of text into text/html parts, and processing multiple parts in multipart/alternative was added in MS 8.0. As of MS 8.0.1.3 control over the HTML attributes on the inserted text is also possible; see the `suffix_text_attr` MTA option for details.

For users defined via alias options, see instead the `alias_suffix_text` alias option; or in legacy configuration alias file or alias database definitions, see the [SUFFIX_TEXT] alias file named parameter. Also see the `addsuffix` Sieve action.

52.15.6.84 Direct LDAP attribute name MTA options: `ldap_expandable` (LDAP attribute name)

The `ldap_expandable` MTA option specifies the names of user and group LDAP attributes, by default `mgmanMemberVisibility` and `expandable`, used to define who (in addition to the group or list owner) may view the membership or a group or list; in the context of the MTA, this means who will get the group or list expanded in response to the SMTP EXPN command.

Supported values for the attribute(s) named by the `ldap_expandable` MTA option are:

- `anyone` (which means that the group or list has no specific-to-itself restrictions and all SMTP EXPN commands are performed, unless restricted by general channel or MTA configuration restrictions: see for instance the `expndisable` channel option),
- `all` or synonymously `true`, (which means that only authenticated users -- hence users who have an account and provide their password---will be able to expand the group or list),
- and `none`.

Unrecognized values are interpreted as `none`.

Note that group or list access controls (*e.g.*, use of attributes such as `mgrpAllowedBroadcaster`, *etc.*, or an `mgrpBroadcasterPolicy` setting of `SMTP_AUTH_REQUIRED`), also impose restrictions on who is allowed to view list membership. *All* applicable conditions must be met in order for group or list membership to be viewed (expanded)!

52.15.6.85 Direct LDAP attribute name MTA options: `ldap_auth_mapping1` (LDAP attribute name), `ldap_auth_mapping2` (LDAP attribute name), `ldap_auth_mapping3` (LDAP attribute name), `ldap_auth_mapping4` (LDAP attribute name)

New in Messaging Server 7.0.5.

The ldap_auth_mappingN MTA options may be used to specify the names of group attributes to include in GROUP_AUTH mapping table probes. These MTA options have no default.

52.15.6.86 Direct LDAP attribute name MTA options: ldap_check_header (LDAP attribute name)

New in Messaging Server 7.0.5.

The ldap_check_header MTA option is used to specify the name of a group attribute used to determine whether or not the message header should be checked for duplication of list recipient addresses. The option does not have a default value.

If the specified attribute has a value of "jettison", the list copy for the recipient specified in the header will jettisoned. If the value is "discard", the system will behave as if the system Sieve had performed a discard on the list copy for that recipient.

The same capability is also available to aliases defined in the alias file or database via the (also new in Messaging Server 7.0.5) [HEADER_CHECK] named parameter, or in Unified Configuration via the alias_header_check alias option.

This capability depends on address typing being enabled - either the addrtypescan or addrtypescanbccdefault channel option needs to be set on the source channel.

Although this capability has the potential to reduce unwanted message duplicates, *extreme* care should be exercised when it is used. Headers fields are trivially forged, making it possible to send a message that claims to have been sent to someone when in fact it has not. This could potentially be used to suppress the list copy for a given recipient.

52.15.6.87 Head of household LDAP attribute MTA options: ldap_hoh_filter (LDAP attribute name), ldap_hoh_owner (LDAP attribute name)

The ldap_hoh_filter and ldap_hoh_owner MTA options specify the names of the LDAP attributes used to store the critical Head of Household data in users who are themselves a Head of Household. These options default to, respectively, mailSieveRuleSource and mail. That is, ldap_hoh_filter specifies the name of the LDAP attribute in which a Head of Household user stores the Sieve filter used for Head of Household purposes (which may or may not be a different Sieve filter than the user's own, personal Sieve filter; the default mailSieveRuleSource value causes the Head of Household Sieve filter to be the same as the user's personal Sieve filter, but sites that wish a distinction may set ldap_hoh_filter to point to a different, site-specific LDAP attribute). Since proper evaluation of (and especially error reporting regarding) a Sieve filter requires an "owner" e-mail address associated with that Sieve filter, the ldap_hoh_owner MTA option specifies what LDAP attribute in the Head of Household user's entry will be the address associated with the Sieve; again, the default value of mail means that the Head of Household user's own, personal e-mail address will be used, but sites that wish a distinction may set ldap_hoh_owner to some different, site-specific LDAP attribute.

These MTA options specify the names of the LDAP attributes to return when a user entry has parental controls/head of household controls set on it (see the ldap_parental_controls MTA option) so that a lookup of the user's "parent" (see the ldap_filter_reference MTA option) is performed: in the "parent" entry, the attributes specified by ldap_hoh_filter and ldap_hoh_owner are found and their values returned.

52.15.6.88 Direct LDAP attribute name MTA options: ldap_attr_domain1_schema2 (LDAP attribute name)

The ldap_attr_domain1_schema2 MTA option may be used to override, for MTA domain lookup purposes, the Domain Map library code's default use of the sunPreferredDomain LDAP attribute as the name of the Schema 2 mode domain level LDAP attribute which specifies the domain name within the domain entry. If this MTA option is not set (the default), then the Domain Map's default of sunPreferredDomain is used, as normal.

52.15.6.89 Direct LDAP attribute name MTA options: ldap_attr_domain2_schema2 (LDAP attribute name)

The ldap_attr_domain2_schema2 MTA option may be used to override, for MTA domain lookup purposes, the Domain Map library code's default use of the associatedDomain LDAP attribute as the name of the Schema 2 mode domain level LDAP attribute which specifies any secondary domain names (aliases for the canonical domain name) within the domain entry. If this MTA option is not set (the default), then the Domain Map's default of associatedDomain is used, as normal.

52.15.6.90 Direct LDAP attribute name MTA options: ldap_attr_domain_search_filter (LDAP attribute name)

The ldap_attr_domain_search_filter MTA option specifies the name of the LDAP attribute in the global configuration template area (see the ldap_global_config_templates MTA option) that is used to store the domain search filter template. For instance, one attribute that might be used for such a purpose (hence to which this option might be set) would be inetDomainSearchFilter.

52.15.6.91 Direct LDAP attribute name MTA options: ldap_domain_attr_basedn (LDAP attribute name)

The ldap_domain_attr_basedn MTA (and base) option names the domain LDAP attribute, by default inetDomainBaseDn, used to store the base DN for the domain's users and groups.

The presence in a domain entry of the attribute named by ldap_domain_attr_basedn is not always obligatory with Schema 2, as with Schema 2 in the domain attribute's absence user and group entries will be assumed to reside directly under the domain entry.

Note that the mapping table domain map attribute substitution $}domain,_base_dn_{ returns either the value of the LDAP attribute named by the ldap_domain_attr_basedn MTA option (so normally the value of the inetDomainBaseDN LDAP attribute), or if no such LDAP attribute is set as can be the case in Schema 2 mode, returns a constructed DN corresponding to the DN for the domain entry.

52.15.6.92 Direct LDAP attribute name MTA options: ldap_domain_attr_alias (LDAP attribute name)

The ldap_domain_attr_alias MTA (and base) option specifies the name of an LDAP attribute (by default aliasedObjectName) used to identify domain alias entries in the directory. The attribute is present only on a domain alias entry, not on the canonical domain entry; it contains the DN of the entry for which it is an alias. It is used only in Schema 1 or in Schema 2 compatibility mode (with a DC Tree), not in Schema 2 native mode (no DC Tree).

52.15.6.93 Direct LDAP attribute name MTA options: `ldap_domain_attr_uplevel` (LDAP attribute name)

The `ldap_domain_attr_uplevel` MTA option specifies the name of a domain-level LDAP attribute used to store a domain-specific analogue of the `domain_uplevel` MTA option that overrides that MTA option for this specific domain. That is, the attribute named by this option stores a bitmask value controlling certain aspects of domain name searching and usage. Currently only bits 0 and 2 (values 1 and 4) are used from this value; the other bits of the general `domain_uplevel` MTA option remain in effect.

Note that the attribute named by the `ldap_domain_attr_uplevel` MTA option is only consulted if the domain is looked up. This means that setting bit 0 of this value to 1 for a domain won't make subdomains of the domain match unless bit 0 of `domain_uplevel` is also set. As such, the way to get subdomain matching for some domains but not others is to set bit 0 of `domain_uplevel` (thus enabling subdomain matches for all domains), and then clear bit 0 of the `ldap_domain_attr_uplevel` attribute for the domains where you don't want uplevel matching to occur.

52.15.6.94 `ldap_domain_attr_mailserv` Option

The `ldap_domain_attr_mailserv` MTA option specifies the name of a domain level LDAP attribute. It has no default, but the recommended LDAP attribute name to use is `inetDomainMailserv`.

52.15.6.95 Direct LDAP attribute name MTA options: `ldap_domain_attr_canonical` (LDAP attribute name)

The `ldap_domain_attr_canonical` MTA option names the domain LDAP attribute, by default `inetCanonicalDomainName`, used to store the canonical domain name.

In Schema 1 mode, any domain alias entry needs such an attribute pointing back to the "real" (canonical) domain name. And in either Schema, any cases of multiple actual (non-alias) domain entries with "overlapping" users require use of such an attribute.

Note that the mapping table domain map attribute substitution `$}`*`domain`*`,_canonical_name_{` returns either the value of the LDAP attribute named by the `ldap_domain_attr_canonical` MTA option (so normally the value of the `inetCanonicalDomainName` LDAP attribute), or if no such LDAP attribute is set, returns the domain name.

52.15.6.96 Direct LDAP attribute name MTA options: `ldap_domain_attr_uid_separator` (LDAP attribute name)

The `ldap_domain_attr_uid_separator` MTA (and base) option names the domain LDAP attribute, by default `domainUidSeparator`, used to store what the separator character is between UIDs and domains for addresses in this domain. This option is used both by the MTA, and by the authentication code; the authentication code looks first for the option to be set at base level, but if not set there, the authentication code will use the MTA level option setting.

52.15.6.97 Direct LDAP attribute name MTA options: `ldap_domain_attr_subaddress` (LDAP attribute name)

The `ldap_domain_attr_subaddress` MTA option specifies the name of the attribute that controls whether or not the domain supports subaddressing. Subaddress handling will be disabled if the specified attribute has a value of "`No`", "`0`", or "`false`". This option has no default.

52.15.6.98 Direct LDAP attribute name MTA options: `ldap_domain_attr_routing_hosts` (LDAP attribute name)

The `ldap_domain_attr_routing_hosts` MTA option names the domain LDAP attribute, by default `mailRoutingHosts`, used to specify the hosts that are responsible for performing routing for this domain. If this MTA is one such host, then the user address will be looked up and attributes processed. Otherwise, the address will be routed onwards: by default, just routing based on rewriting the address, but if the MTA option `route_to_routing_host=1` is set, then the first `mailRoutingHosts` value will be inserted into the address as a source route (hence the rewriting routing will depend upon that host name).

Note that delivery options can be marked as mail host independent, thereby meaning that processing should occur regardless of whether this MTA is one of the `mailRoutingHosts`; see the `delivery_options` MTA option.

52.15.6.99 Direct LDAP attribute name MTA options: `ldap_domain_attr_smarthost` (LDAP attribute name)

The `ldap_domain_attr_smarthost` MTA option names the domain LDAP attribute, by default `mailRoutingSmartHost`, used for routing of addresses in the domain but without a directory entry. That is, if a user address is not found in the directory, then route onwards, inserting the `mailRoutingSmartHost` value into the address as a source route.

Since the value of the `mailRoutingSmartHost` attribute (or whatever attribute is named by `ldap_domain_attr_smarthost`) will be used as a source route, note that that means that the actual routing of the address will depend on how the MTA has been configured to route such an address. In particular, best practice is to specify a FQDN (Fully Qualified Domain Name) as the value, since comprehensive configuration for proper routing of such domain names is part of normal MTA configuration. Use of less recommended substitutes, such as short-form hostnames or IP literal addresses, will only yield desired results if the MTA has been explicitly configured to route such substitute names appropriately.

52.15.6.100 Direct LDAP attribute name MTA options: `ldap_domain_attr_status` (LDAP attribute name)

The `ldap_domain_attr_status` MTA (and base) option names the domain LDAP attribute, by default `inetDomainStatus`, whose value specifies the current status of the domain. (The analogous user level attribute is `inetUserStatus` or whatever user LDAP attribute is named by the `ldap_user_status` MTA option; an analogous group attribute can be defined via the `ldap_group_status` MTA option. Compare also with the `ldap_domain_attr_mail_status` MTA option naming the domain LDAP attribute specifying the current mail status of the domain.) Valid values for the attribute named by the `ldap_domain_attr_status` option are `active`, `inactive`, or `deleted`. If no such attribute is present, or is present but with no value, a value of `active` is assumed.

52.15.6.101 Direct LDAP attribute name MTA options: `ldap_domain_attr_mail_status` (LDAP attribute name)

The ldap_domain_attr_mail_status MTA (and base) option names the domain LDAP attribute, by default mailDomainStatus, whose value specifies the current mail status of the domain. (The analogous user level attribute is mailUserStatus or whatever user LDAP attribute is named by the ldap_user_mail_status MTA option; the analogous group attribute is inetMailGroupStatus or whatever group LDAP attribute is named by the ldap_group_mail_status MTA option. Compare also with the ldap_domain_attr_status MTA option naming the domain LDAP attribute specifying the current general status of the domain.) Valid values for the attribute named by the ldap_domain_attr_mail_status option are: active, inactive, deleted, hold, disabled, overquota, and (new in MS 6.0) unused and removed and (new in 8.0) nonlocal; other values are interpreted as inactive. Note that the imquotacheck utility is what updates mailDomainStatus to set it to overquota.

(Note that the acceptalladdresses channel option, if used, modifies the timing and form of the rejection.)

52.15.6.102 Direct LDAP attribute name MTA options: ldap_domain_attr_blocklimit (LDAP attribute name(s))

The ldap_domain_attr_blocklimit MTA option specifies the name of an LDAP attribute -- or a list of such names -- used to store a size limit on messages to users in the domain. The default LDAP attribute name is mailDomainMsgMaxBlocks.

The effect of the attribute named by ldap_domain_attr_blocklimit is a destination (recipient) analogue of the effect of whatever attribute is named by ldap_domain_attr_sourceblocklimit MTA option, which limits the size of message that may be sent by users in the domain. The attribute named by ldap_domain_attr_blocklimit may also be considered as the domain-level analogue of the user-level mailMsgMaxBlocks attribute (or whatever attribute is named by the ldap_blocklimit MTA option) and group mgrpMsgMaxSize attribute (or whatever attribute is named by the ldap_maximum_message_size MTA option).

New in MS 6.3, this attribute is also checked during reverse_url lookups, and will be used (for messages that have no return-of-content policy already set) to decide whether the NOTARY non-return-of-content flag should be set.

A new effect in MS 6.3-0.15 is that a per-domain setting such as this will override more general settings (and a per-user setting will override even a per-domain setting), rather than (as previously) the minimum of all applicable limits being applied. Thus new in MS 6.3-0.15, users in a particular domain maybe allowed to send large messages as an exception to more general, smaller limits, by setting a large value for this domain attribute while a general smaller limit (such as that set via the blocklimit channel option) remains in effect.

(Note that the acceptalladdresses channel option, if used, may modify the timing and form of rejections due to exceeding message size constraints.)

52.15.6.103 Direct LDAP attribute name MTA options: ldap_domain_attr_conversion_tag (LDAP attribute name(s))

The ldap_domain_attr_conversion_tag MTA option specifies the name of a domain LDAP attribute, by default mailDomainConversionTag; the value stored in the specified attribute will be applied as conversion tags for messages sent to users or groups associated with this domain.

52.15.6.104 Direct LDAP attribute name MTA options: ldap_domain_attr_source_conversion_tag (LDAP attribute name(s))

The ldap_domain_attr_source_conversion_tag MTA option specifies the name of a domain LDAP attribute; there is no default. The value stored in the specified attribute will be applied as conversion tags for messages sent from users or groups associated with this domain.

52.15.6.105 Direct LDAP attribute name MTA options: ldap_domain_attr_optinN (LDAP attribute name list)

For values of N=1--8 (N=1--4 new in MS 6.2, N=5--8 new in MS 6.3-0.15), the ldap_domain_attr_optinN MTA option names a domain LDAP attribute used to store the fact and specific "opt-in" value string that recipients in the domain are "opted-in" to filtering performed by spam/virus filter package package N. ldap_domain_attr_optin is a synonym for ldap_domain_attr_optin1.

The ldap_optinN MTA options provide analogous per-user (rather than per-domain) opt-in capability.

52.15.6.106 Direct LDAP attribute name MTA options: ldap_domain_attr_presence (LDAP attribute name)

RESTRICTED. Not yet used.

52.15.6.107 Direct LDAP attribute name MTA options: ldap_domain_attr_autosecretary (LDAP attribute name)

RESTRICTED. Not yet used.

52.15.6.108 Direct LDAP attribute name MTA options: ldap_domain_attr_nosolicit (LDAP attribute name)

The ldap_domain_attr_nosolicit MTA option specifies the name of a domain-level LDAP attribute used to store solicitation labels to block for recipients in the domain. The attribute named is thus a domain-level analogue of the user-level attribute named by the ldap_nosolicit MTA option; and supplements any channel-level solicitation blocking configured via destinationnosolicit and sourcenosolicit channel options.

See RFC 3865 (No Soliciting SMTP Extension) for background on the NO-SOLICITING SMTP extension.

52.15.6.109 Direct LDAP attribute name MTA options: ldap_domain_attr_autoreply_timeout (LDAP attribute name)

The ldap_domain_attr_autoreply_timeout MTA option specifies the name of an LDAP attribute which is a domain-level analogue of the user-level LDAP attribute named by the ldap_autoreply_timeout MTA option. That is, the LDAP attribute named by

`ldap_domain_attr_autoreply_timeout` stores the duration, in hours, for successive vacation (autoreply) responses to any given mail sender, to be used for vacation messages generated on behalf of users in this domain who do not have their own, user-level, specific timeout set (no `ldap_autoreply_timeout` attribute set).

`ldap_domain_attr_autoreply_timeout` attribute's value will not be used only when a user has `mailAutoReplyMode=echo`. If the attribute's value is 0, then a response is sent back every time a message is received. This value will be converted to the nonstandard "`:hours`" argument to the "`vacation`" action. If neither this domain-level attribute is set, nor the user-level attribute is set, then the timeout used will be that set via the `autoreply_timeout_default` MTA option.

52.15.6.110 Direct LDAP attribute name MTA options: `ldap_domain_attr_default_mailhost` (LDAP attribute name)

RESTRICTED: Not supported by the MMP.

The `ldap_domain_attr_default_mailhost` MTA option specifies the name for a domain LDAP attribute, (no default but the `preferredMailHost` LDAP attribute formerly used in provisioning would be one possibly appropriate attribute to also use for this purpose), used to store a default mail host to be used if a user or group entry in the domain has no explicit `mailHost` value (more precisely, no value for the LDAP attribute named by the `ldap_mailhost` MTA option).

52.15.6.111 Direct LDAP attribute name MTA options: `ldap_domain_attr_disk_quota` (LDAP attribute name(s))

RESTRICTED. Not yet fully implemented.

52.15.6.112 Direct LDAP attribute name MTA options: `ldap_domain_attr_message_quota` (LDAP attribute name(s))

RESTRICTED. Not yet fully implemented.

See the user level LDAP attribute named by the `ldap_message_quota` MTA option. Also see the Message Store option `defaultmessagequota`.

52.15.6.113 Direct LDAP attribute name MTA options: `ldap_domain_attr_filter` (LDAP attribute name(s))

The `ldap_domain_attr_filter` MTA option specifies the name of an LDAP attribute (by default `mailDomainSieveRuleSource`) -- or a list of such names -- used to store a specific-to-that-domain Sieve filter.

In operational terms, such a domain Sieve filter is applied to any recipients in that domain; it is added to any personal Sieve filter for the recipient and applied at the same time as the recipient user's personal Sieve filter.

52.15.6.114 Direct LDAP attribute name MTA options: `ldap_domain_attr_sender_sieve` (LDAP attribute name(s))

New in MS 8.0.1. The `ldap_domain_attr_sender_sieve` MTA option specifies the name of an LDAP attribute (by default `mailDomainSenderSieve`) -- or a list of such names -- used to store a specific-to-that-domain Sieve filter that is applied to messages sent by authenticated users associated with that domain.

52.15.6.115 Direct LDAP attribute name MTA options: `ldap_domain_attr_capture` (LDAP attribute name(s))

New in the 8.0 release. The `ldap_domain_attr_capture` MTA option specifies the name of a domain LDAP attribute that will be used to trigger automatic "capturing" of user or group e-mail messages for all users and groups in the domain. There is no default - no pre-defined LDAP attribute for this purpose. Typically, the LDAP attribute defined for this purpose, and named by `ldap_domain_attr_capture`, should be set up with an ACI so that it is not even visible, let alone modifiable, by users.

The value(s) of the LDAP attribute named by `ldap_domain_attr_capture` should be the address(es) to which the "captured" message copies are supposed to be sent. When a domain has this attribute specified, then both messages sent to users in the domain, as well as messages from users in the domain, will also have a "capture" copy (normally an encapsulated copy with an entirely new message envelope) sent to the specified address.

Note that the LDAP attribute(s) specified by the `ldap_capture` MTA option have similar semantics except the attribute(s) are placed in the user or group entry instead of at the domain level.

The `capture_format_default` MTA option controls whether message copies generated due to use of the LDAP attribute named by `ldap_domain_attr_capture` are generated in DSN encapsulated format, *vs*. another formats such as envelope "journal" format.

52.15.6.116 Direct LDAP attribute name MTA options: `ldap_domain_attr_report_address` (LDAP attribute name(s))

The `ldap_domain_attr_report_address` MTA option specifies the name of an LDAP attribute (by default `mailDomainReportAddress`) -- or a list of such names -- used to store the address of the domain postmaster.

The domain postmaster, if set, is used as the header From: address in DSNs reporting problems associated with recipient addresses in the domain. It is also used (in certain cases) when reporting problems to users within the domain regarding errors associated with non-local addresses. If this attribute is not set, then in those certain cases the reporting address will default to `postmaster@domain`. (This is the specific domain name, as opposed to the default or host domain.) But note that regardless of whether or not this attribute is set, there are a number of other cases where the overall host's postmaster address will be used, rather than any domain-specific postmaster address.

52.15.6.117 Direct LDAP attribute name MTA options: `ldap_domain_attr_catchall_address` (LDAP attribute name(s))

The `ldap_domain_attr_catchall_address` MTA option specifies the name of an LDAP attribute (by default `mailDomainCatchallAddress`) -- or a list of such names -- used to store a "catch all" address for the domain: an address to which to route any messages to recipients apparently in the domain but with an unrecognized local-part (*unknown-user@domain-name*).

52.15.6.118 Direct LDAP attribute name MTA options: ldap_domain_attr_catchall_mapping (LDAP attribute name(s))

The ldap_domain_attr_catchall_mapping MTA option specifies the name of an LDAP attribute (by default mailDomainCatchallMapping) -- or a list of such names -- used to store the name of an MTA mapping table.

A mapping table named in such an attribute will be consulted when an address associated with the domain fails to match any particular user entry. The format of the mapping table probe is the same as that of the FORWARD mapping table, and is affected by any setting of the use_forward_database MTA option in the same way as the FORWARD mapping table probe is affected. The effect of the mapping is that if the mapping sets the $Y metacharacter, then the resulting string will replace the address being processed. (The other output flags supported by the FORWARD mapping table are not supported by a domain catchall mapping.)

Flag comparisons supported by the FORWARD mapping table are, in general, also supported in a domain catchall mapping. This includes more recently added flag comparisons, including: New in Messaging Server 7.0-0.04, the use/non-use of POP-before-SMTP can be checked in a domain catchall mapping by checking for presence or absence of the $P input flag; that is, by checking for $:P or $;P respectively. New in MS 8.0, support for $:R or $;R, and $:U or $;U tests. (However, the FORWARD mapping table's $:V or $;V flag test is *not* supported in a domain catchall mapping.)

52.15.6.119 Direct LDAP attribute name MTA options: ldap_domain_attr_sourceblocklimit (LDAP attribute name(s))

The ldap_domain_attr_sourceblocklimit MTA option specifies the name of an LDAP attribute -- or a list of such names -- used to store a size limit on messages sent by users in the domain.

The effect of the attribute named by ldap_domain_attr_sourceblocklimit is a source (sending) analogue of the effect of the mailDomainMsgMaxBlocks attribute (or whatever attribute is named by ldap_domain_attr_blocklimit), which limits the size of message that may be received by users in the domain. The attribute named by ldap_domain_attr_sourceblocklimit may also be considered as the domain-level analogue of the user-level attribute named by ldap_sourceblocklimit.

A new effect in MS 6.3-0.15 is that a per-domain setting such as this will override more general settings (and a per-user setting will override even a per-domain setting), rather than (as previously) the minimum of all applicable limits being applied. Thus new in MS 6.3-0.15, users in a particular domain maybe allowed to send large messages as an exception to more general, smaller limits, by setting a large value for this domain attribute while a general smaller limit (such as that set via the sourceblocklimit channel option) remains in effect.

(Note that the acceptalladdresses channel option, if used, may modify the timing and form of rejections due to exceeding message size constraints.)

52.15.6.120 Direct LDAP attribute name MTA options: ldap_domain_attr_source_channel (LDAP attribute name)

The ldap_domain_attr_source_channel MTA option specifies the name of an LDAP attribute used, when the userswitchchannel channel option is in effect, to store the name of an MTA channel to consider as the source channel for messages submitted from users in

this domain. See also the `ldap_source_channel` MTA option which names an analogous user-level LDAP attribute. If both a user-level and domain-level attribute are set, the user-level value overrides the domain-level value.

52.15.6.121 Direct LDAP attribute name MTA options: `ldap_domain_attr_prefix_text` (LDAP attribute name(s))

The `ldap_domain_attr_prefix_text` MTA option specifies the name of a domain LDAP attribute which in turn is used to specify text to insert at the top of messages. The default LDAP attribute used for this purpose if this option is not specified is `mailDomainPrefixText`.

Any text specified by the attribute will be inserted into messages submitted by any authenticated user associated with the domain. Either plain text or HTML can be used. A maximum of 4096 octets from the attribute value will be processed.

HTML values are indicated in a prefix addition by enclosing the addition in <html></html> tags. (These tags are removed from the addition.)

Prefix additions to text/html parts are placed immediately after the <body> tag.

Plain text additions to text/html are preceded by
<pre> and followed by </pre>
. HTML additions to text/plain parts have all HTML tags removed and all entities are converted to corresponding characters. Character set conversions are performed as needed; the attribute value must be specified in UTF-8.

52.15.6.122 Direct LDAP attribute name MTA options: `ldap_domain_attr_suffix_text` (LDAP attribute name(s))

The `ldap_domain_attr_suffix_text` MTA option specifies the name of a domain LDAP attribute which in turn is used to specify text to insert at the bottom of messages. The default LDAP attribute used for this purpose if this option is not specified is `mailDomainSuffixText`.

Any text specified by the attribute will be inserted into messages submitted by any authenticated user associated with the domain. Either plain text or HTML can be used. A maximum of 4096 octets from the attribute value will be processed.

HTML values are indicated in a suffix addition by enclosing the addition in <html></html> tags. (These tags are removed from the addition.)

Suffix additions to text/html parts are placed immediately before the </body> tag.

Plain text additions to text/html are preceded by
<pre> and followed by </pre>
. HTML additions to text/plain parts have all HTML tags removed and all entities are converted to corresponding characters. Character set conversions are performed as needed; the attribute value must be specified in UTF-8.

52.15.6.123 Direct LDAP attribute name MTA options: `ldap_domain_attr_recipientlimit` (LDAP attribute name)

The `ldap_domain_attr_recipientlimit` MTA option specifies the name of a per-domain LDAP attribute, analogous to the per-user `ldap_recipientlimit`

MTA option, the recipientlimit channel option, and the per-SMTP-server ALLOW_RECIPIENTS_PER_TRANSACTION TCP/IP-channel-specific option.

Compare with the ldap_domain_attr_recipientcutoff MTA option which specifies the name of a per-domain LDAP attribute for controlling a related, but not identifical, effect.

New behavior in MS 6.3 is that a per-domain setting such as this will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3, a particular domain can be allowed to send messages to many recipients as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.

52.15.6.124 Direct LDAP attribute name MTA options: ldap_domain_attr_recipientcutoff (LDAP attribute name)

The ldap_domain_attr_recipientcutoff MTA option specifies the name of a per-domain LDAP attribute, analogous to the per-user LDAP attribute named by the ldap_recipientcutoff MTA option, the recipientcutoff channel option, and the per-SMTP-server REJECT_RECIPIENTS_PER_TRANSACTION TCP/IP-channel-specific option.

Compare with the ldap_domain_attr_recipientlimit MTA option which specifies the name of a per-domain LDAP attribute for controlling a related, but not identifical, effect.

New behavior in MS 6.3 is that a per-domain setting such as this will override more general settings, rather than (as previously) the minimum of all applicable limits being applied; thus new in MS 6.3, a particular domain can be allowed to send messages to many recipients as an exception to more general, smaller limits, by setting a large value for this attribute while general small limits remain in effect.

52.15.6.125 Direct LDAP attribute name MTA options: ldap_domain_attr_detourhostoptin (LDAP attribute name)

(New in Messaging Server 7.0.5.) The ldap_domain_attr_detourhostoptin MTA option specifies the name of a per-domain LDAP attribute, analogous to the per-user LDAP attribute named by the ldap_detourhost_optin MTA option. If this LDAP attribute named by ldap_domain_attr_detourhostoptin has the special value (if any) specified by the aliasdetourhost_null_optin MTA option, that will be considered equivalent to the domain attribute being absent.

52.15.6.126 Direct LDAP attribute name MTA options: ldap_creation_date (LDAP attribute name)

(New in 8.0.) The ldap_creation_date MTA option specifies the name of a user or group LDAP attribute used to store the account creation date for the user or group. The actual date value stored in such an attribute must be in RFC 3339 format (a superset of the format used for vacation start and end times).

52.15.6.127 Direct LDAP attribute name MTA options: ldap_domain_attr_creation_date (LDAP attribute name)

(New in 8.0.) The ldap_domain_attr_creation_date MTA option specifies the name of a domain LDAP attribute used to store the creation date for that domain. The actual date

value stored in such an attribute must be in RFC 3339 format (a superset of the format used for vacation start and end times).

52.15.7 Direct LDAP attributes returned upon authentication MTA options

By default, the MTA and the authentication library assume a particular sort of LDAP schema. However, as of the 8.0 release the exact attribute names that the authentication library returns (for the MTA to use) are configurable via various `ldap_auth_attr_*` MTA options.

52.15.7.1 LDAP attributes returned upon authentication MTA options: `ldap_auth_attr_mail_host` (LDAP attribute name)

The `ldap_auth_attr_mail_host` MTA option specifies the name of an LDAP attribute whose value should be returned, upon successful authentication, as the "mail host" for the user. The default such LDAP attribute, if this option is not specified, is `mailHost`.

52.15.7.2 LDAP attributes returned upon authentication MTA options: `ldap_auth_attr_sender` (LDAP attribute name)

(New in 8.0.) The `ldap_auth_attr_sender` MTA option specifies the name of the LDAP attribute whose value should be returned (upon successful authentication) as the "authenticated sender". The default such LDAP attribute, if this option is not set, is the `mail` attribute.

52.15.7.3 LDAP attributes returned upon authentication MTA options: `ldap_auth_attr_submit_channel` (LDAP attribute name)

(New in 8.0.) The `ldap_auth_attr_submit_channel` MTA option specifies the name of an LDAP attribute whose value should be returned, upon successful authentication, as the desired source channel name (the source channel to which to "switch" when `saslswitchchannel` channel option is set). The default LDAP attribute name, if this option is not set, is `mailSMTPSubmitChannel`.

52.15.7.4 LDAP attributes returned upon authentication MTA options: `ldap_auth_attr_recall_secret` (LDAP attribute name)

The `ldap_auth_attr_recall_secret` MTA option specifies the name of the LDAP attribute where a user's general recall secret is stored. This option has no default.

See the `trackinggenerate` channel option for further discussion of the purpose and use of the value stored in the specified LDAP attribute.

52.15.7.5 LDAP attributes returned upon authentication MTA options: `ldap_auth_attr_hold_for` (LDAP attribute name)

(New in MS 8.0)

52.15.8 LDAP lookup cache MTA options

There are a number of MTA options controlling the caching of LDAP and URL lookup results. See also the `ldap_timeout` MTA option, controlling how long the MTA waits for a response from LDAP before timing out a query attempt.

See also the Sieve filter caching MTA options, which control caching of parsed Sieve filters regardless of source (so including but not limited to Sieve filters fetched from LDAP).

Note that the MTA has no specific-to-itself setting for caching of authentication (SMTP AUTH) results from LDAP; that is instead controlled by the general (base level) settings for the `authcachesize` and `authcachettl` options (in legacy configuration, the `configutil` parameters `service.authcachesize` and `service.authcachettl`).

The MMP has its own cache of of the results of searching for users in LDAP; see the `ldapcachesize` and `ldapcachettl` options.

The `cache_debug` MTA option enables low-level debugging regarding the MTA's caching of LDAP lookup results.

52.15.8.1 LDAP and URL lookup cache options: `alias_entry_cache_negative` (0 or 1), `alias_entry_cache_size` (integer), `alias_entry_cache_timeout` (integer)

The `alias_entry_cache_*` MTA options control some performance tuning relevant when operating in direct LDAP mode, in particular when `alias_urlN` options are being used. When `alias_urlN` lookups are performed, the results can be cached; that is, an in memory cache is maintained of the results of "recent" such lookups. The `alias_entry_cache_size` option, which defaults to 1000, controls how many results are cached. The `alias_entry_cache_timeout` option, which defaults to 600, controls how long in seconds to maintain cache results. The `alias_entry_cache_negative` option, which takes a boolean argument and defaults to 0 (false), controls whether or not negative results (that is, failures to find an alias) are cached.

There is a trade-off between performance on the one hand, *vs*. memory usage and speed with which changes to the LDAP entries take effect on the other hand.

52.15.8.2 Domain match cache control (`domain_match_cache_size`, `domain_match_cache_timeout`)

As of MS 6.0, the `domain_match_cache_size` MTA option (as well as the `domain_match_cache_timeout` MTA option) is mostly irrelevant, since as of MS 6.0 there is an underlying domain map cache of domains. That is, the underlying domain lookup code used by the MTA as well as other Messaging Server components now maintains a (large) cache of lookup results; see the `ldap_domain_timeout` MTA option for a discussion of the timeout on the underlying domain lookup cache entries. The MTA's own private-to-the-MTA cache has thus become mostly redundant -- it's a cache in front of a cache (though its entries are smaller in the case of negative matches, so potentially if one was especially concerned about optimizing the case of caching of large numbers of negative matches, the MTA's private cache might be slightly useful).

The `domain_match_cache_*` options control some performance tuning formerly (in iMS 5.2) relevant when operating in direct LDAP mode, in particular when a rewrite rule with a `$V` in the template is being used. When such `$V` domain map lookups are performed, the results can

be cached by the MTA (apart and in addition to the caching done by the underlying domain map LDAP lookup code); that is, an in memory cache is maintained by the MTA of the results of "recent" such lookups. The `domain_match_cache_size` MTA option, which defaults to 100000, controls how many results are cached. The `domain_match_cache_timeout` MTA option, which defaults to 600, specifies how long in seconds to maintain cache results. But note that all that's being cached here by the MTA is whether or not the domain is "local", (that is, in the DIT). The actual values of attributes, such as `domainStatus`, is cached in the underlying domain map code; see the `ldap_domain_timeout` MTA option for a discussion of the timeout for that underlying cache.

There is a trade-off between performance on the one hand, *vs*. memory usage and speed with which changes to the LDAP entries take effect on the other hand.

52.15.8.3 LDAP lookup cache MTA options: `ldap_domain_timeout` (integer)

The `ldap_domain_timeout` option (available at both base and MTA levels) controls the retention time (in seconds) for entries in the domain map cache. The default is -900; as the value used is the absolute value of the `ldap_domain_timeout` setting, this corresponds to 15 minutes. If setting `ldap_domain_timeout` explicitly, set it to a positive value so that the MTA can detect that it has indeed been intentionally set.

52.15.8.4 LDAP lookup cache MTA options: `reverse_address_cache_size` (integer) and `reverse_address_cache_timeout` (integer)

The `reverse_address_cache_*` MTA options control some performance tuning relevant when operating in direct LDAP mode, in particular when the `reverse_url` MTA option is set. When such `reverse_url` address reversal LDAP lookups are performed, the results can be cached; that is, an in-memory cache is maintained of the results of "recent" such lookups. The `reverse_address_cache_size` option, which defaults to 100000, controls how many results are cached. The `reverse_address_cache_timeout` option, which defaults to 600, specifies how long in seconds to maintain cache results. There is a trade-off between performance on the one hand, vs. memory usage and speed with which changes to the LDAP entries take effect on the other hand.

52.15.8.5 URL result case sensitivity option (`url_result_cache_case`)

New in MS 8.1.0.2. The `url_result_cache_case` MTA option controls whether or not the URL result cache entry names are case sensitive. Setting the option to 1 makes them case sensitive. The default is 0, in which case the entry names are case-insensitive.

This option needs to be set to 1 if case-sensitive LDAP attributes are being used. Note that this may have an adverse effect on cache efficiency.

52.15.8.6 LDAP lookup cache MTA options: `url_result_cache_size` (integer) and `url_result_cache_timeout` (integer)

LDAP lookups done from callouts in rewrite rules or mapping tables may be cached; that is to say, `$]...[` lookups may be cached. The `url_result_cache_size` MTA option controls

the size of this cache; the default is 10000. The `url_result_cache_timeout` MTA option controls the timeout, in seconds, for entries in this cache; the default is 600.

52.16 Directory location MTA options

As of Messaging Server 7.0-0.04, many formerly configurable (via MTA Tailor option) MTA directory locations are now hard-coded. But `tmpdir` (replacing the former `imta_tmp` MTA Tailor option) and `langdir` (replacing the former `imta_lang` MTA Tailor option) are still configurable; (note that in legacy configuration, these two options are MTA option file options).

52.16.1 Directory location MTA options: `tmpdir` (directory path)

The `tmpdir` MTA option (prior to MS 7.0, this MTA option was instead called `imta_tmp` and located in the MTA Tailor file, whereas `tmpdir` in legacy configuration is an MTA option file `option.dat` option) specifies the temporary file directory; it defaults to `/tmp/` (trailing slash included).

On Linux, this option should instead be set to `/dev/shm/`.

52.16.2 Directory location MTA options: `langdir` (dir-path or list of dir-paths)

The `langdir` MTA option specifies the directory containing localized MTA return and disposition templates. (Prior to MS 7.0, this was called `imta_lang`, and located in the MTA Tailor file.)

52.17 DKIM MTA options

New in Messaging Server 7.0.5 are several MTA and channel options that affect message handing based on the presence of certain DKIM signatures. See also the `dkim*` and `destinationdkim*` channel options, which perform a similar function on a per-channel basis.

52.17.1 DKIM MTA options: `dkim_ignore_domains` (list of domain names)

(New in Messaging Server 7.0.5.) The `dkim_ignore_domains` MTA option modifies the effect of the `dkimpreserve`, `destinationdkimpreserve`, `dkimremove`, and `destinationdkimremove` channel options. `dkim_ignore_domains` specifies a list of domain names which will be *ignored* in DKIM-Signature: header lines, both for DKIM signature preservation purposes (that is, *ignored* when either the `dkimpreserve` or `destinationdkimpreserve` channel options is specified), as well as for DKIM signature removal purposes (that is, *ignored* when either the `dkimremove` or `destinationdkimremove` channel option is specified). A domain name listed in `dkim_ignore_domains` will be, for the MTA's DKIM handling purposes, invisible on DKIM-Signature: header lines---such a domain will trigger neither `passthrough` mode to preserve DKIM signatures, nor DKIM signature removal.

52.17.2 DKIM MTA options: dkim_preserve_domains (list of domain names)

(New in Messaging Server 7.0.5.) The dkim_preserve_domains MTA option modifies the effect of the dkimpreserve and destinationdkimpreserve channel options. When such a channel option is being applied, after first checking each domain on a DKIM-Signature: header line against dkim_ignore_domains for domain names to ignore, next the MTA will check the list of domain names specified by dkim_preserve_domains and if a match is found, passthrough mode will be triggered (further general message processing is terminated). Note that once such a match on the dkim_preserve_domains list is found, the MTA need not, and does not, bother to scan further in the message or list for additional matches.

52.17.3 DKIM MTA options: dkim_remove_domains (list of domain names)

(New in Messaging Server 7.0.5.) The dkim_remove_domains MTA option modifies the effect of the dkimremove and destinationdkimremove channel options. When such a channel option is being applied, after first checking each domain on a DKIM-Signature: header line against dkim_ignore_domains for domain names to ignore, next the MTA will check the list of domain names specified by dkim_remove_domains and if a match is found, then the corresponding DKIM-Signature: field is removed from the message.

52.18 DNS lookup MTA options

In addition to the blocked_mail_from_ips and return_envelope MTA options with some DNS lookup effects, see also TCP/IP channels for additional, but channel-specific, DNS-related options. And see SPF MTA options for DNS SPF lookup MTA options.

52.18.1 MAIL FROM domain blocking by IP address (blocked_mail_from_ips)

The introduction of DNS wildcard entries in the COM and ORG top level domains which occurred in September 2003 had severely limited the effectiveness of the mailfromdnsverify channel option. As of the 6.1-0.01 release of the MTA, the mailfromdnsverify channel option code was modified to address this. When the DNS returns one or more A records (which would normally be considered a "success" and the message would be allowed in), their values are compared against the domain literals specified by the blocked_mail_from_ips MTA option. If a match is found, then the domain is considered to be invalid. Thus in order to restore useful behavior to the mailfromdnsverify channel option, the current correct setting of this option is:

```
blocked_mail_from_ips=[64.94.110.11]
```

52.18.2 Notification message MTA options: return_envelope (bitmask)

The `return_envelope` MTA option takes a bitmask value.

Bit 0 (value = 1) controls whether or not return notifications generated by the MTA are written with a blank envelope address *vs.* with the address of the local postmaster. Setting the bit forces the use of the local postmaster address, while clearing the bit forces the use of a blank address. Note that the use of a blank address is mandated by RFC 1123. However, some systems do not handle blank envelope From addresses properly and may require the use of this option.

Bit 1 (value = 2) controls whether or not the MTA replaces all blank envelope addresses with the address of the local postmaster. Again, this is used to accomodate incompliant systems that don't conform to RFC 821, RFC 822, or RFC 1123.

Bit 2 (value = 4) controls whether or not the MTA checks that any (non-empty) envelope From address matches (rewrites to) an MTA channel.

Setting bit 3 (value = 8) is the global (for all channels) equivalent of setting the `mailfromdnsverify` channel option: it controls whether or not the MTA checks that the domain in the envelope From address resolves in the DNS. That is, setting the bit causes the MTA to require that a DNS entry can be found corresponding to the domain in the envelope From address; but the type of DNS entry does not matter.

Setting bit 4 (value = 16) causes the MTA to enforce that if the envelope From address claims a local domain name, the envelope From address must correspond to a user address (user alias).

New in 8.0, bit 6 (value = 64) modifies the effect of setting bit 3 (value = 8) on domain validity checks. With both these bits set, if the domain in the MAIL FROM address corresponds to a null MX domain, that address will be rejected as invalid. That is, setting bit 6 causes the bit 3 domain check to also implement support for draft-delany-nullmx-01.txt.

Note also that the `returnenvelope` channel option can be used to impose these sorts of control on a per-channel basis.

52.19 Error text and error interpretation MTA options

The MTA has a number of options affecting error interpretation, and allowing setting (customizing) of error text.

Regarding errors connecting to a spam/virus filter package, see also the `spamfilterN_optional` MTA options.

52.19.1 Error text and error interpretation MTA options: `access_errors` (0 or 1)

As of MS 6.2, if `access_errors` is set to 0 (the default), then when a recipient address encounters a recipient address `*_ACCESS` mapping table access failure (that does not supply explicit rejection text of its own), the MTA will report it as if the error were an "unknown host" error. That is, the text of the `error_text_unknown_host` MTA option will be used, so by default the error will be reported as an "unknown host or domain" error, corresponding to the SMTP error:

```
550 5.7.1 unknown host or domain: recipient-address
```

This is the same error that would be reported if the address were simply illegal. Although confusing, this usage nevertheless provides an important element of security in circumstances where information about access restrictions should not be revealed. Setting `access_errors` to 1 will override this default and provide a more descriptive default error text, as specified by the `error_text_access_failure` MTA option, defaulting to 5.7.1 you are not allowed to use this address, corresponding to the SMTP error:

```
550 5.7.1 you are not allowed to use this address: recipient-address
```

But in any case, the setting of `access_errors` merely controls the default error text issued for recipient address `*_ACCESS` mapping table rejections; entries that perform rejections may override such default rejection text by supplying their own explicit rejection text. Prior to MS 6.2, this `access_errors` option did not affect the default text used for recipient address `*_ACCESS` mapping table `$N` rejections, which was instead the `error_text_permanent_failure` text, normally "unknown host or domain".

This option also controls the default error text issued when a spam/virus filter package rejects a recipient address with an other-than-temporary rejection.

This option also, in versions prior to 7.0-0.04, affected the now obsolete-and-removed feature whereby MTA provided facilities to restrict access to channels on the basis of group ids on UNIX (the analogue of rightslist identifiers in PMDF for OpenVMS). That is, in versions prior to 7.0-0.04, the error text issued in cases of address rejections due to access failures due to non-matching group id would also be affected by this option. Indeed, prior to MS 6.2, this (control of the error text due to group id mismatch) was the only purpose and only effect of this option.

52.19.2 error_text MTA options

The `error_text_*` options specify error text describing various error conditions; see the Table of `error_text_*` MTA options for details. Not all of the error responses potentially emitted by the MTA are configurable. In general, only error conditions that can be considered more or less local, or more or less proprietary to the MTA, such as invalid address conditions, user status problems such as a user being disabled or over-quota, attempts to exceed local message size limits, Sieve filter syntax errors, *etc.*, are configurable. As a rule of thumb, error conditions that arise solely in the case of a message addressed to a "local" user have configurable error text, on the presumption that customized explanations may be useful and are likely to be comprehensible to someone who corresponds with a "local" user.

However, error conditions that are more fundamental to the SMTP protocol, that more naturally arise when the MTA is performing a function of pure SMTP relaying, generally do not have configurable error text; in such cases where an error response may well be going back to some remote user who has no connection (not even as a correspondent) with "local" users, the MTA always emits its own standard, technically precise, error response.

Keep in mind that all the `error_text_*` error text may potentially be emitted as SMTP error response text. Thus the values of all these options must conform to the requirements of SMTP error response text. In particular, they are constrained to be in the US-ASCII character set: the MTA will convert any eight bit characters in such option values into the dollar character, $. Also, SMTP responses are limited by the SMTP line length limit (998 characters, not including the final CRLF, and not including the leading numeric error code and extended error code).

Table 52.16 `error_text_*` MTA options

Option	SMTP code	Extended code	Default string used when option is not set	Meaning and notes
`error_text_unknown_host`	550 or 450*	5.1.2	unknown host or domain	Specifies the error text issued when, for instance, the domain in an address does not rewrite to any channel. (In particular, prior to Messaging Server 7.0.5, assuming that no "catch-all" or "`.`" rewrite rule had been specified, an attempt to submit a message addressed to a top-level Internet domain not specified in the `internet.rules` file would result in this error. As of Messaging Server 7.0.5, the `internet.rules` file was modified to consist of solely a "`.`" rule which consults the set of top level domain names from the `tlds.txt` file -- so in Messaging Server 7.0.5 or later, an out-of-date `tlds.txt` file or an attempt to submit a message to a top-level Internet domain not specified in the `tlds.txt` file will result in this error.)
`error_text_unknown_user`	550 or 450*	5.1.1	unknown or illegal user	This error will be returned in cases such as illegal characters (or no characters) in a uid found during an `alias_urlW` lookup, or for users set to "native" (UNIX mailbox) delivery who do not have a UNIX account.
`error_text_unknown_alias`	550 or 450*	5.1.1	unknown or illegal alias	This error will be returned if an address that matches (rewrites to) a channel marked with the `viaaliasrequired` channel option is not found as an alias. In particular, this is normally the error that will be returned in the case of non-existent "user" addresses in a domain hosted on a Messaging Server system, unless a domain is configured with special handling for "non-existent user" addresses such as a "catch-all" address or a `mailRoutingSmartHost`.
`error_text_access_failure`	550	5.7.1	you are not allowed to use this address	This error text is not normally used unless the `access_errors` MTA option has been set. In that case, this error will be returned when an address cannot be submitted due to a group identifier on the destination channel, or due to `*_ACCESS` mapping table rejections.
`error_text_alias_locked`	452	4.2.0	list is currently reserved and locked	This error is returned if an attempt to look up an alias in the alias file finds the alias file locked, or if an attempt to access a list file (such as an `[AUTH_LIST]` file) finds the list file locked.
`error_text_alias_auth`	530 or 550++	5.7.1	you are not allowed to use this list	This error is returned when, for instance, a list posting authorization check fails. (See also the discussion of access errors in the discussions of the `ldap_reject_text` MTA option and `alias_error_text` alias option.)
`error_text_alias_fileerror`	452 or 550+	4.5.0	error opening file/ URL referenced by alias	This error is returned when a file or URL referenced by an alias cannot be opened; (that is, it exists but cannot be opened---compare with `error_text_alias_fileexist`).
`error_text_alias_fileexist`	452 or 550+	4.5.0	nonexistant file referenced by alias	This error is returned when a file referenced by an alias does not exist.
`error_text_alias_temp`	452	4.0.0	temporary error returned by alias expansion	This error is returned in cases, for instance, of temporary LDAP errors attempting to lookup an alias, such as the LDAP server not responding. It is also returned if a user entry that requires a `mailHost` attribute (not all user entries do) is lacking the attribute.
`error_text_send_remote_error`	550	5.6.1	no protocol to SEND/SAML	This error is returned in cases of an attempt to submit a message for direct broadcast (SEND) or for

				direct broadcast and e-mail (SAML) to a "local" user address that includes explicit routing characters (@, %, or !).
error_text_send_unknown_error	550	5.5.5	do not know how to SEND/SAML	This error will be returned if attempting to send to a destination (channel) that does not support SEND/SAML functionality.
error_text_block_over	550	5.2.3	channel limit of %d kilobytes on message size exceeded	This error will be returned (in the case of SMTP attempted submissions, at the RCPT TO stage of the SMTP dialogue) if a message exceeds the intended destination channel's blocklimit channel keyword setting *and* the sending e-mail client used the SIZE SMTP extension on the MAIL FROM command to inform the MTA "up front" of the message size. As of 7.0.5, a %d, if present, will be replaced with the actual limit value. (Prior to 7.0.5, the default text was "channel limit on message size exceeded".) This default error text, or any configured error text, will be suffixed with a colon and the recipient address being rejected. Note that this error text is not used for cases of exceeding a channel sourceblocklimit option setting, or the block_limit MTA option setting. First off, in those cases the MTA can potentially advertise its size limit to a sending client before a message is ever even submitted, so potentially the MTA never actually rejects the message itself; instead potentially a client that supports the SMTP SIZE extension refrains from even trying to send the message (and generates some message back to the original sender itself). If a message is submitted to the MTA despite the MTA's possibly advertised size limit, then in cases of exceeding a sourceblocklimit or block_limit when the client has used the SIZE extension, then the error text "Message exceeds local size limit." is used, or if the client does not use the SIZE extension (or puts a falsely small value in SIZE) so that the MTA has to reject the message after all the DATA has been sent and the MTA has computed the message size itself, the error_text_message_too_large message is used instead.
error_text_line_over	550	5.2.3	channel limit of %d lines on message length exceeded	This error will be returned if a message exceeds the intended destination channel's linelimit channel option setting, and that fact is apparent when the recipient address(es) are being processed. As of 7.0.5, a %d, if present, will be replaced with the actual limit value. (Prior to 7.0.5, the default text was "channel limit on message length exceeded".) However, message line length is *not* normally apparent at recipient address processing time, but rather only apparent after the message body is processed; therefore this error text is not normally used. Note also that this error text is not used for cases of exceeding the line_limit MTA option setting. Thus normally the following non-configurable text is used: "a message *x* lines long exceeds the line limit of *y* lines computed for this transaction".
error_text_list_block_over	550	5.2.3	list limit of %d kilobytes on message size exceeded	This error is returned if a message exceeds a list's configured size limit (in MTA blocks---see the block_size MTA option), configured via the [BLOCKLIMIT] named mailing list parameter for a list defined in the alias file or alias database, or via the alias_blocklimit alias option (Unified Configuration), or configured via the user/group-level mgrpMsgMaxSize attribute (more precisely, the attribute named by the ldap_maximum_message_size MTA option) or domain-level mailDomainMsgMaxBlocks

				attribute (more precisely, the attribute named by the `ldap_domain_attr_blocklimit` MTA option) for groups and lists defined in LDAP. As of 7.0.5, a `%d`, if present, will be replaced with the actual limit value. (Prior to 7.0.5, the default text was "list limit on message size exceeded".)
`error_text_list_line_over`	550	5.2.3	list limit of %d lines on message length exceeded	This error is returned if a message exceeds a list's configured line limit, configured via the [LINELIMIT] named mailing list parameter for a list defined in the alias file or alias database, or via the `alias_linelimit` alias option (Unified Configuration), and that fact is apparent when recipient address(es) are being processed. But since message line length is not normally known that early during message processing. As of 7.0.5, a `%d`, if present, will be replaced with the actual limit value. (Prior to 7.0.5, the default text was "list limit on message length exceeded".)
`error_text_user_block_over`	550	5.2.3	user limit of %d kilobytes on message size exceeded	This error is returned if a message exceeds the maximum message size (in MTA blocks---see the `block_size` MTA option) that a user may receive, as configured via the [BLOCKLIMIT] named parameter for aliases in the alias file or alias database, or via the `alias_blocklimit` alias option (Unified Configuration), or via the user-level `mailMsgMaxBlocks` attribute (more precisely, the attribute named by the `ldap_blocklimit` MTA option) or domain-level `mailDomainMsgMaxBlocks` attribute (more precisely, the attribute named by the `ldap_domain_attr_blocklimit` MTA option) for users defined in LDAP. As of 7.0.5, a `%d`, if present, will be replaced with the actual limit value. (Prior to 7.0.5, the default text was "user limit on message size exceeded".)
`error_text_user_line_over`	550	5.2.3	user limit of %d lines on message length exceeded	This error is returned if a message exceeds a user's configured line limit, configured via the [LINELIMIT] named parameter for an alias defined in the alias file or alias database, or via the `alias_linelimit` alias option in Unified Configuration, and that fact is apparent when recipient address(es) are being processed. But since message line length is not normally known that early during message processing, instead normally the non-configurable general error text "a message *x* lines long exceeds the line limit of *y* lines computed for this transaction" is used. As of 7.0.5, a `%d`, if present, will be replaced with the actual limit value. (Prior to 7.0.5, the default text was "user limit on message length exceeded".)
`error_text_message_too_large`	550	5.3.4	a message size of %d kilobytes exceeds the size limit of %d kilobytes computed for this transaction	New in 7.0.5 - this error message was hard coded in previous releases. This error will be returned (in the case of SMTP attempted submissions, at the end of the data transfer stage of the SMTP dialogue) if a message exceeds computed size limit for the transaction. The first `%d`, if present, will be replaced with the estimated message size and the second with the computed limit, both in units of MTA blocks.
`error_text_message_too_long`	550	5.3.4	a message %d lines long exceeds the line limit of %d lines computed for this transaction	New in 7.0.5 - this error message was hard coded in previous releases. This error will be returned (in the case of SMTP attempted submissions, at the end of the data transfer stage of the SMTP dialogue) if a message exceeds computed line limit for the transaction. The first `%d`, if present, will be replaced with the estimated number of message lines and the second with the computed limit.

error_text_insufficient_disk	452	4.3.4	message exceeds disk space available at this time	New in 7.0.5 - this error message was hard coded in previous releases. This error will be returned (in the case of SMTP attempted submissions, at the end of the data transfer stage of the SMTP dialogue) if the storage requirements for the message exceed the amount of disk space available.
error_text_wrong_account	550	5.7.17	account information on file is older than actual user account	This error is returned if an RRVS check on the account fails; see checkrrvs.
error_text_wrong_domain	550	5.7.18	domain owner has changed	This error is returned if an RRVS check on the domain fails; see checkrrvs.
error_text_recipient_over	452 or 550+	4.2.3	too many recipients specified	This error is returned if a message exceeds any configured limit on recipients, that is, exceeding a channel recipientlimit keyword setting, a FROM_ACCESS mapping table $S recipient limit, a domain recipient limit (see the ldap_domain_attr_recipientlimit MTA option), or a user recipient limit (see the ldap_recipientlimit MTA option).
error_text_sieve_access	452	4.7.1	sieve filter access error	This error is returned when the MTA cannot open a recipient user Sieve filter file.
error_text_sieve_syntax	452	4.7.1	sieve filter syntax error	This error is returned when there is a syntax error in (or trouble in reading) a recipient user Sieve filter file.
error_text_disabled_user	550 or 450*	5.2.1	user disabled; cannot receive new mail	This error is returned when the MTA detects that a user's personal status (inetUserStatus or mailUserStatus) or the user's domain status (mailDomainStatus) is disabled during alias expansion.
error_text_disabled_alias	550 or 450*	5.2.1	alias disabled; cannot receive new mail	
error_text_over_quota	451 or 550+	4.2.2	user over quota; cannot receive new mail	This the error returned, for instance by the SMTP server, when the MTA detects that either a user's personal status (inetUserStatus or mailUserStatus) or their domain status (mailDomainStatus) is overquota during alias expansion. But note that once a message is in a final delivery channel (ims-ms or tcp_lmtpc*) well past alias expansion processing, then the handling of messages to overquota users, and the error message returned, is controlled by the Message Store's configuration of overquota message handling, including the Message Store's grace period configuration, and the Message Store uses the IMAP over quota text as its error text in reports on overquota messages.
error_text_temporary_failure	452		unknown host or domain	Note that this error text for certain generic temporary failures defaults to the same error text used also in cases of clear-cut "bad" domain names, error_text_unknown_host, as well as in cases of generic permanent failures, error_text_permanent_failure.
error_text_permanent_failure	550 or 530++		unknown host or domain	Note that this error text for generic permanent failures defaults to the same error text used also in cases of clear-cut "bad" domain names, error_text_unknown_host, as well as in cases of generic temporary failures, error_text_temporary_failure.
error_text_illegal_8bit	553	5.1.3	illegal 8bit characters in address	Incorrect eight bit data present in an address.

error_text_illegal_8bit_from	553	5.1.3	illegal 8bit characters in return address	Incorrect eight bit data present in the return address.
error_text_disallowed_8bit	553	5.1.0	8bit characters in address not allowed in this context	Eight bit data present in an address when eight bit is not allowed.
error_text_disallowed_8bit_from	553	5.1.0	8bit characters in return address not allowed in this context	Eight bit data present in the return address when eight bit is not allowed.
error_text_receipt_it	250	2.0.0	message accepted for list expansion processing	This option specifies the text used (by default "message accepted for list expansion processing") by the MTA when generating a delivery receipt (a notification message) to let a sender know that their message has gotten to the point of being expanded to a list. Note that the NOTARY specification (RFC 3461) explicitly requires that delivery receipt requests to mailing lists be responded to at the list expansion step; see Section 5.2.7.1 of RFC 3461 (which updates Section 6.2.7.1 of RFC 1891).
error_text_inactive_user	452 or 550+	4.2.1	mailbox temporarily disabled	
error_text_inactive_group	452 or 550+	4.2.1	group temporarily disabled	This error is returned when the MTA detects that a group's status (the value of the inetMailGroupStatus attribute, or more precisely, the values of whatever LDAP attributes are named by the ldap_group_status or ldap_group_mail_status MTA options) or the group's domain status (mailDomainStatus, or more precisely the attribute named by the ldap_domain_attr_mail_status MTA option) is inactive during alias expansion.
error_text_disabled_group	550	5.2.1	group disabled; cannot receive new mail	This error is returned when the MTA detects that a group's status (the value of the inetMailGroupStatus attribute, or more precisely, the values of whatever LDAP attributes are named by the ldap_group_status or ldap_group_mail_status MTA options) or the group's domain status (mailDomainStatus, or more precisely the attribute named by the ldap_domain_attr_mail_status MTA option) is disabled during alias expansion.
error_text_deleted_user	550	5.1.6	recipient no longer on server	This error will be returned when a user has an inetUserStatus or mailUserStatus attribute, (more precisely, an attribute named by the ldap_user_status or ldap_user_mail_status MTA options) with value of "deleted" or "removed"
error_text_deleted_group	550	5.1.6	group no longer on server	This error will be returned when a group has an inetMailGroupStatus attribute with value of "deleted" or "removed"; or more precisely, if either of the attributes named by the ldap_group_status or ldap_group_mail_status MTA options has such a value
error_text_duplicate_addrs	553	5.1.4	duplicate/ ambiguous directory match	The recipient address has matched multiple entries in the directory; this typically indicates that a mistake was made while provisioning users and domains in the directory.
error_text_spamfilter_error	451	4.7.1	filtering/scanning error	As of MS 6.3, a synonym for the new-in-6.3 error_text_spamfilter1_error MTA

				option; as of MS 6.3, obsolete and used only if `error_text_spamfilter1_error` is not set.
`error_text_spamfilter`*N*`_error`	451	4.7.1	filtering/scannning error	New in MS 6.3. The default error text to use when there is a problem attempting to use the *N*th spam/virus filter package, *if* no more specific error text regarding the exact spam/virus filter package problem is available; *N* can have values in the range 1--8. As of 7.0.5.37, any value specified for this option unconditionally overrides any error text returned by the filter package.
`error_text_brightmail_error`	451	4.7.1	filtering/scanning error	This obsolete option is used only if the `error_text_spamfilter1_error` MTA option is not set
`error_text_still_held`	452	4.2.1	cannot reenqueue while still held	Default error text to use when there is an attempt to reenqueue to a recipient whose status is "`hold`"; for instance, an attempt to release a message from the hold channel when a recipient still has a personal or domain status of "`hold`"
`error_text_empty_alias`	550	5.2.4	alias failed to expand to any valid addresses	New in MS 6.1.
`error_text_nosolicit`	550 or 530++	5.7.1	solicitations of this type are not allowed	New in MS 6.2. Default solicitation violation rejection text, if no more specific rejection text is available.
`error_text_srs_syntax`	553	5.1.3	Syntax error in SRS/MUL address	The error text returned when the MTA's attempt to SRS/MUL decode an address encounters a syntax error in the SRS/MUL encoding.
`error_text_srs_timeout`	550	5.7.1	SRS/MUL address has timed out	Error text returned when the MTA attempts to decode an SRS/MUL encoded address whose timestamp has expired.
`error_text_srs_badhash`	550	5.7.1	SRS/MUL address has a bad hash value	Error text returned when the MTA's attempt to decode an SRS/MUL encoded address finds an invalid hash value.
`error_text_spf_temperror_4`	451	4.7.24	temporary error in SPF verification of MAIL FROM domain	(New in MS 6.3, but not taking effect until Messaging Server 8.0) If the MTA option `spf_smtp_status_temperror` is set to 4, then this is error text to use when a temporary DNS error occurs attempting an SPF lookup on the domain from the MAIL FROM at either the MAIL FROM or RCPT TO stage; the domain name (inside parentheses) will be suffixed to the specified error text
`error_text_spf_temperror_5`	550	4.7.24	temporary error in SPF verification of MAIL FROM domain	(New in MS 6.3 but not taking effect until Messaging Server 8.0) If the MTA option `spf_smtp_status_temperror` is set to 5, then this is error text to use when a temporary DNS error occurs attempting an SPF lookup on the domain from the MAIL FROM at either the MAIL FROM or RCPT TO stage; the domain name (inside parentheses) will be suffixed to the specified error text.
`error_text_spf_permerror_4`	451	5.7.24	permanent error in SPF verification of MAIL FROM domain	(New in MS 6.3 but not taking effect until Messaging Server 8.0) If the MTA option `spf_smtp_status_permerror` is set to 4, then this is error text to use when a permanent DNS error occurs attempting an SPF lookup on the domain from the MAIL FROM at either the MAIL FROM or RCPT TO stage; the domain name (inside parentheses) will be suffixed to the specified error text.
`error_text_spf_permerror_5`	550	5.7.24	permanent error in SPF verification of MAIL FROM domain	(New in MS 6.3, but not taking effect until Messaging Server 8.0) If the MTA option `spf_smtp_status_permerror` is set to 5, then this is error text to use when a permanent DNS error occurs attempting an SPF lookup on the

				domain from the MAIL FROM at either the MAIL FROM or RCPT TO stage; the domain name (inside parentheses) will be suffixed to the specified error text.
error_text_spf_fail_4	451	5.7.23	SPF verification of MAIL FROM domain failed	(New in MS 6.3, but not taking effect until Messaging Server 8.0) If the MTA option spf_smtp_status_fail is set to 4, then this is the error text to use when an SPF lookup on the domain from the MAIL FROM at either the MAIL FROM or RCPT TO stage determines that the domain has failed to verify; the domain name (inside parentheses) will be suffixed to the specified error text. If additional explanation text is available, then it will also be suffixed (with a colon) after the domain name. So, for instance, the entire error could appear as: `451 5.7.23 SPF verification of MAIL FROM domain failed (domain): explanation` or: `451 5.7.23 error_text_spf_fail_4 (domain): explanation`
error_text_spf_fail_5	550	5.7.23	SPF verification of MAIL FROM domain failed	(New in MS 6.3, but not taking effect until Messaging Server 8.0) If the MTA option spf_smtp_status_fail=5 is set, then this is the error text to use when an SPF lookup on the domain from the MAIL FROM at either the MAIL FROM or RCPT TO stage determines that the domain has failed to verify; the domain name (inside parentheses) will be suffixed to the specified error text. If additional explanation text is available, then it will also be suffixed (with a colon) to the error text. So, for instance, the entire error could appear as: `550 5.7.23 SPF verification of MAIL FROM domain failed (domain): explanation` or: `550 5.7.23 error_text_spf_fail_5 (domain): explanation`
error_text_spf_softfail_4	451	4.7.23	SPF verification of MAIL FROM domain soft failed (*domain*)	(New in MS 6.3, but not taking effect until Messaging Server 8.0) This is the error text to use when an SPF lookup of the MAIL FROM domain, performed at MAIL FROM time (configured via use of spfmailfrom) or RCPT TO time (configured via use of spfrcptto), determines that the domain has a "soft" verification failure and the MTA is configured to treat such verification failures as temporary errors: either an SPF SoftFail was returned for the specific domain name and spf_smtp_status_softfail=4 is set, or an SPF SoftFail "all" was returned for domain names including the specific domain name and spf_smtp_status_softfail_all=4 is set. The domain name (inside parentheses) will be suffixed to the specified error text. Note that for SPF lookups performed at EHLO/HELO (spfhelo) time, the error_text_spf_ehlo_softfail_4 text is used instead.
error_text_spf_softfail_5	550	4.7.23	SPF verification of MAIL FROM domain soft failed	(New in MS 6.3, but not taking effect until Messaging Server 8.0) This is the error text to use when an SPF lookup of the MAIL FROM domain, performed at MAIL FROM time (configured via use of spfmailfrom) or at RCPT TO time (configured via use of spfrcptto), determines that the domain has a "soft" verification failure and the MTA is configured to treat such verification failures as permanent errors: either an SPF SoftFail

				was returned for the specific domain name and `spf_smtp_status_softfail=5` is set, or an SPF SoftFail "all" was returned for domain names including the specific domain name and `spf_smtp_status_softfail_all=5` is set. The domain name (inside parentheses) will be suffixed to the specified error text. Note that for SPF lookups performed at EHLO/HELO (`spfhelo`) time, the `error_text_spf_ehlo_softfail_5` text is used instead.
`error_text_spf_ehlo_temperror_4`	451	4.7.24	temporary error in SPF verification of EHLO/HELO domain	(New in 8.0) If the MTA option `spf_smtp_status_temperror` is set to 4, then this is error text to use when a temporary DNS error occurs attempting an SPF lookup on the domain from the EHLO/HELO command.
`error_text_spf_helo_temperror_5`	550	4.7.24	temporary error in SPF verification of EHLO/HELO domain	(New in 8,0) If the MTA option `spf_smtp_status_temperror` is set to 5, then this is error text to use when a temporary DNS error occurs attempting an SPF lookup on the domain from the EHLO/HELO command.
`error_text_spf_helo_permerror_4`	451	5.7.24	permanent error in SPF verification of EHLO/HELO domain	(New in 8,0) If the MTA option `spf_smtp_status_permerror` is set to 4, then this is error text to use when a permanent DNS error occurs attempting an SPF lookup on the domain from the EHLO/HELO command
`error_text_spf_ehlo_permerror_5`	550	5.7.24	permanent error in SPF verification of EHLO/HELO domain	(New in 8.0) If the MTA option `spf_smtp_status_permerror` is set to 5, then this is error text to use when a permanent DNS error occurs attempting an SPF lookup on the domain from the EHLO/HELO command.
`error_text_spf_ehlo_fail_4`	451	5.7.23	SPF verification of EHLO/HELO domain failed	(New in 8.0) If the MTA option `spf_smtp_status_fail` is set to 4, then this is the error text to use when an SPF lookup of the domain from the EHLO/HELO command determines that the domain has failed to verify. If additional explanation text is available, then it will be suffixed (with a colon) to the error text. So, for instance, the entire error could appear (at the EHLO/HELO command stage) as: `451 5.7.23 SPF verification of EHLO/ HELO domain failed: explanation` or: `451 5.7.23 error_text_spf_ehlo_fail_4: explanation`
`error_text_spf_ehlo_fail_5`	550	5.7.23	SPF verification of EHLO/HELO domain failed	(New in 8.0) If the MTA option `spf_smtp_status_fail=5` is set, then this is the error text to use when an SPF lookup of the EHLO/HELO domain determines that the domain has failed to verify. If additional explanation text is available, then it will be suffixed (with a colon) to the error text. So, for instance, the entire error could appear as: `550 5.7.23 SPF verification of EHLO/ HELO domain failed: explanation` or: `550 5.7.23 error_text_spf_ehlo_fail_5: explanation`
`error_text_spf_ehlo_softfail_4`	451	4.7.23	SPF verification of EHLO/HELO domain soft failed	(New in 8.0) This is the error text to use when an SPF lookup of the EHLO/HELO domain name (configured via use of `spfhelo`), determines that the domain has a "soft" verification failure and the MTA is configured to treat such verification failures as temporary errors: either an SPF SoftFail was returned for the specific domain name and `spf_smtp_status_softfail=4` is set, or an SPF SoftFail "all" was returned for domain names including the specific domain name and `spf_smtp_status_softfail_all=4` is set. If

				additional explanation text is available, then it will be suffixed (with a colon) to the error text.
error_text_spf_ehlo_softfail_5	550	4.7.23	SPF verification of MAIL FROM domain soft failed	(New in 8.0) This is the error text to use when an SPF lookup of the MAIL FROM domain, performed at RCPT TO time (configured via use of spfrcptto), determines that the domain has a "soft" verification failure and the MTA is configured to treat such verification failures as permanent errors: either an SPF SoftFail was returned for the specific domain name and spf_smtp_status_softfail=5 is set, or an SPF SoftFail "all" was returned for domain names including the specific domain name and spf_smtp_status_softfail_all=5 is set. If additional explanation text is available, then it will be suffixed (with a colon) to the error text.
error_text_mailfromdnsverify	550 or 450	5.1.8 or 4.1.8	invalid/host-not-in-DNS return address not allowed	(New in MS 6.3) The 450 4.1.8 error is returned for all cases of DNS verification lookup "failures" other than HOST_NOT_FOUND; hence DNS lookup difficulties such as DNS server failure to respond will result in this error. Normally, the 550 5.1.8 error is returned when a DNS verification lookup returns a definitive HOST_NOT_FOUND error. However, if bit 5/value 32 of the returnenvelope channel option is set, then HOST_NOT_FOUND will also result in a temporary 450 4.1.8 error rather than the permanent 550 5.1.8 rejection.
error_text_null_mx	521 or 550**	5.1.10 or 5.7.26**	host/domain does not accept mail	(New in 8.0) This error is returned when the domain associated with a recipient address resolves to a so-called "null MX". This error message is also returned when bit 3 (value 8) and bit 6 (value 64) of the returnenvelope channel option or the return_envelope MTA option are set and a domain with a "null MX" appears in the envelope sender (MAIL FROM) address.
error_text_invalid_return_address	550	5.1.7	invalid/unroutable return address not allowed	(New in MS 6.3) The 550 5.1.7 error is returned if bit 2 (value 4) of the returnenvelope channel option is set and rewriting of the MAIL FROM failed to match any channel.
error_text_unknown_return_address	550	5.1.8	invalid/no-such-user return address	(New in MS 6.3) The 550 5.1.8 error is returned if bit 4 (value 16) of the returnenvelope channel option is set and the MAIL FROM address is local but could not be resolved to any known user.
error_text_accepted_return_address	250	2.5.0	return address invalid/unroutable but accepted anyway	(New in MS 6.3) This is not, properly speaking, an error - this message is returned when an invalid MAIL FROM address is given but accepted by the MTA anyway.
error_text_source_sieve_access	450	4.3.0	source channel sieve filter access error	(New in MS 6.3) This error is returned when the MTA cannot open a source channel Sieve filter file.
error_text_source_sieve_syntax	450	4.3.0	source channel sieve filter syntax error:	(New in MS 6.3) This error is returned when there is a syntax error in (or trouble in reading) a source channel Sieve filter.
error_text_source_sieve_authorization	450	4.3.0	source channel sieve filter authorization error	(New in MS 6.3) Currently unused.
error_text_transaction_limit_exceeded	450	4.5.3	number of transactions exceeds allowed maximum	(New in MS 6.3) Error returned at MAIL FROM when the channel transactionlimit option, specifying the maximum number of transactions allowed in the session, is exceeded.
error_text_insufficient_queue_space	450	4.3.1	insufficient free queue space available	(New in MS 6.3) Issued in response to a MAIL FROM: command if the free disk space available to the MTA in the MTA's queue area dips below 10 MTA blocks

error_text_temporary_write_error	451	4.4.5	error writing message temporary file	(New in MS 6.3) The SMTP server prefixes this error text with the message: `451 4.4.5 Error writing message temporaries -` An internal channel such as the reprocess channel would record this error text in its delivery history, and in its "Q" record.
error_text_smtp_lines_too_long	554	5.6.0	lines longer than SMTP allows encountered; message rejected	(New in MS 6.3) Issued when rejectsmtplonglines is in effect, and a line longer than 998 characters (not including the SMTP CRLF line terminator) is seen in the message data.
error_text_unnegotiated_eightbit	554	5.6.0	message contains unnegotiated 8bit	(New in MS 6.3) Issued when a source TCP/IP channel has eightstrict or utf8strict set, and the incoming message contains unnegotiated eight bit data.
error_text_mls_access_failure	550	5.7.1	security access check failure	(New in 7.0) This restricted option is currently unused.
error_text_spare_error				Obsolete (does not exist) as of MS 6.2.
error_text_spare1_error				(New in MS 6.2) This option provides a spare slot so a new settable error message can be added to an existing release. Use of this option is restricted.
error_text_spare2_error				(New in MS 6.2) This option provides a spare slot so a new settable error message can be added to an existing release. Use of this option is restricted.

+ Whether the error code used is a temporary 4yz (the default) or a permanent 5yz error code is controlled by the use_permanent_error MTA option.

++ In place of the usual 550 error code, the 530 error code is used when the problem relates to security: as for instance failure to properly authenticate (successfully use SMTP AUTH) when authentication is required.

+++ Errors at MAIL FROM: stage use 450; errors at RCPT TO: stage use 452.

* (Added in 8.0.) Whether the error code used is a permanent 5yz (the default) or a temporary 4yz error code is controlled by the use_temporary_error MTA option.

** (Added in 8.0) Error regarding null MX for a recipient uses 521 5.1.10; error regarding null MX for a sender uses 550 5.7.26.

Also note that errors authenticating (errors attempting SMTP AUTH use) are a separate category of error type, returning hard-coded error text. (So for instance the error_text_disabled_user option discussed above is relevant to attempts by the MTA to verify that the user is a currently valid recipient; for instance, that error could be returned as an SMTP rejection of that user's address as an envelope recipient address. But an attempt by that same disabled user to submit a message using SMTP AUTH to authenticate would fail authentication and result in a different error, discussed in the table MTA AUTH errors.) Note that for security reasons, a number of different underlying error conditions cause the same error text to be returned in the SMTP rejection, while more specific details can be provided in the message-id field of MTA connection transaction logging if the MTA option log_message_id is enabled.

Table 52.17 MTA AUTH errors

SASL error or code	SMTP code	Extended code	Basic SMTP error text+	log_message_id text in "U" record	Notes
HULA_BADPARAM or HULA_NOMEM	450	4.3.0	SASL initialization failed; server unavailable		LDAP server unavailable/unresponsive for authentication; proxy authentication not properly configured or trouble performing it; server running out of memory; *etc.*

SASL_UNAVAIL	454	4.7.0	Authentication server unavailable	Authentication server unavailable	LDAP server unavailable/unresponsive for authentication.
	503	5.7.0	AUTH command already issued		SMTP AUTH already successfully performed.
	533	5.7.1	AUTH command is not enabled		No maysaslserver or mustsaslserver enabled on channel.
	501	5.7.0	Cannot decode BASE64	Cannot decode BASE64	Argument right of = fails to BASE64 decode; or, argument on new line fails to BASE64 decode.
	503	5.7.1	Mail transaction already in progress		SMTP AUTH not permitted now that message submission has begun.
	501	5.7.0	AUTH operation aborted by client	Client aborted AUTH operation	
SASL_OK	235	2.7.0	*mechanism* authentication successful	authentication successful++	
SASL_NOMECH	504	5.5.4	Unrecognized authentication type	Unrecognized authentication type	
SASL_BADPROT	501	5.5.0	Invalid input	Invalid input	
SASL_NOUSER	535	5.7.8	Bad username or password	No such user	
SASL_PWLOCK	534	5.7.8	Bad username or password	Password/account is locked	(New in MS 8.0.2)
SASL_WEAKPASS	534	5.7.9	Password is too weak	Password is too weak	(New in MS 8.0)
SASL_TOOWEAK	535	5.7.8	Bad username or password	Authentication mechanism is too weak	
SASL_BADAUTH	535	5.7.8	Bad username or password	Bad password	
SASL_NOAUTHZ	535	5.7.8	Authorization failure	Authorization failure	
SASL_ENCRYPT	538	5.7.11	Encryption needed to use mechanism	Encryption needed for mechanism	
SASL_EXPIRED	524	5.7.11	Password expired, has to be reset	Password expired; has to be reset	
SASL_DISABLED with mailUserStatus: inactive	525	5.7.13	Account disabled	Account disabled (inactive)	
SASL_DISABLED with mailUserStatus: hold	525	5.7.13	Account disabled	Account disabled (hold)	
SASL_UNAVAIL	454	4.7.0	Authentication server unavailable	Authentication server unavailable	
SASL_TRYAGAIN	454	4.7.0	Try again later	Try again later	
SASL_TRANS	422	4.7.12	Try changing your password	Transition password needed	
Default for other errors	500	5.7.0	Unknown authentication error	Unknown AUTH errors <sasl-errno> <sasl-aux-errno>	

+ Additional detail error text potentially may be suffixed within parentheses for error cases other than a client abort of the AUTH attempt, or successful authentication.

++ New in 7.3-11.01 version; previously, the log_message_id field was the empty string for this success case

52.19.3 Error text and error interpretation MTA options: use_permanent_error (bitmask)

The use_permanent_error MTA option controls whether certain error conditions normally considered to be temporary are instead interpreted as permanent errors; that is, this option controls whether certain error conditions result in immediately bouncing (returning) messages instead of retaining them for further delivery retries. The option takes a bit encoded integer argument, with the individual bits each controlling an individual error condition. The default is 0.

Table 52.18 use_permanent_error MTA option bits

Bit	Value	Usage

0	1	If set, causes a permanent rather than a temporary error to be returned for the error_text_inactive_user case; that is, if set, then in the case of users with an "inactive" status, the (permanent) error "550 4.2.1 mailbox temporarily disabled" is issued rather than the (temporary) error "450 4.2.1 mailbox temporarily disabled". Note that the actual text issued in the error (by default "mailbox temporarily disabled") may be customized using the error_text_inactive_user MTA option.
1	2	If set, causes a permanent rather than a temporary error to be returned for the error_text_inactive_group case.
2	4	If set, causes a permanent rather than a temporary error to be returned for errors corresponding to the error_text_over_quota case.
3	8	If set, causes a permanent rather than a temporary error to be returned for the error_text_alias_fileerror and error_text_alias_fileexist cases.
4	16	If set, causes a permanent rather than a temporary error to be returned for the error_text_recipient_over case.

The usepermanenterror channel option may be used on a per-source-channel basis to override the MTA level mta.use_permanent_error setting.

Prior to the 8.0.1.2 release the MTA converts the "defer" mailUserStatus value to "inactive" internally when performing a reprocessing operation. This means that use of the rehostuser utility, which makes use of "defer", in conjunction with setting bit 0 (value 1) of use_permanent_error can cause messages received during a rehostuser operation to be returned as undeliverable.

This issue has been addressed in 8.0.1.2 and later by having the MTA convert "defer" status to "hold" status instead.

IMPORTANT NOTE: More generally, various parts of Messaging Server, other Communications Suite components, and even external provisioning utilities assume that "inactive" status is used to indicate transient rather than permanent problems. As such, setting bit 0 (value 1) of use_permanent_error to cause a permanent error status to be returned is NOT RECOMMENDED.

52.19.4 Error text and error interpretation MTA options: use_temporary_error (bitmask)

(New in MS 8.0) The use_temporary_error MTA option controls whether certain error conditions normally considered to be permanent are instead interpreted as temporary errors; that is, this option controls whether certain error conditions result retaining messages for further delivery retries instead of immediately bouncing (returning) them. The option takes a bit encoded integer argument, with the individual bits each controlling an individual error condition. The default is 0.

Table 52.19 use_temporary_error MTA option bits

Bit	Value	Usage
0	1	If set, causes a temporary rather than a permanent error to be returned for the error_text_disabled_user case.

1	2	If set, causes a temporary rather than a permanent error to be returned for the `error_text_disabled_alias` case.
2	4	If set, causes a temporary rather than a permanent error to be returned for errors corresponding to the `error_text_unknown_alias` case.
3	8	If set, causes a temporary rather than a permanent error to be returned for the `error_text_unknown_host` case.
4	16	If set, causes a temporary rather than a permanent error to be returned for the `error_text_unknown_user` case.

The `usetemporaryerror` channel option may be used to override the MTA level `mta.use_temporary_error` on a per-source-channel basis.

52.20 External filtering context MTA options

The `scan_*` MTA options set context for filtering performed by external-to-the-MTA components, such as when `imexpire` makes use of Sieve rules or spam/virus filter packages to perform message expiration.

For MTA options relating to the MTA's own Sieve filter use or Spam/virus filter package integration, see respectively the Sieve filter MTA options and Spamfilter MTA options.

52.20.1 External filtering context MTA options: `scan_channel` (MTA channel name)

New in 7.0.5. The MTA's spam/virus filter package integration facility can be used in non-MTA (in particular, in non-channel) contexts, such as by applications or utilities such as `imexpire`, where certain fields inherently available for message processing in the MTA context are not necessarily naturally available. The `scan_channel` MTA option specifies the default source channel for such scanning operations. The default is the `l` (lowercase "L") channel.

52.20.2 External filtering context MTA options: `scan_originator` (address)

New in 7.0.5. The MTA's spam/virus filter package integration facility can be used in non-MTA (in particular, in non-channel) contexts, such as by applications or utilities such as `imexpire`, where certain fields inherently available for message processing in the MTA context are not necessarily naturally available. The `scan_originator` MTA option specifies the MAIL FROM address that's used for such scanning operations. (There is no envelope in this situation, but the MTA requires one, so a minimal pseudo envelope has to be constructed.) The default is the empty string.

52.20.3 External filtering context MTA options: `scan_recipient` (address)

New in 7.0.5. The MTA's spam/virus filter package integration facility can be used in non-MTA (in particular, in non-channel) contexts, such as by applications or utilities such as `imexpire`, where certain fields inherently available for message processing in the MTA context are not necessarily naturally available. The `scan_recipient` MTA option specifies the RCPT TO address that's used for such scanning operations. (There is no envelope in this situation and

thus no recipient, but the MTA requires one, so a pseudo recipient must be claimed.) The default is "postmaster".

52.21 File format MTA options

There are a number of MTA options affecting the format of various MTA files, or the handling of message files or log files. In particular, some of these MTA options can have performance implications.

See also the file_member_size MTA option, which sets a limit for the number of configuration files the MTA may use.

See also the os_debug MTA option which enables some low-level debugging of MTA file handling.

52.21.1 MTA enqueue buffering (buffer_size)

The buffer_size MTA option sets the buffer size (for PMDF in blocks, as defined via the block_size MTA option; for the Messaging Server MTA, buffer_size is literally the number of bytes) used when writing message files to the MTA's queues (as well as when writing temporary files when max_internal_blocks has been exceeded). The default value is 8192. The minimum allowed value is 512; the maximum allowed value is 512*512=262144.

Note that this MTA option is completely different from the BUFFER_SIZE TCP/IP-channel-specific option (which is instead more closely analogous to the max_internal_blocks MTA option).

52.21.2 File format MTA options: cache_magic (integer)

The **OBSOLETE** cache_magic MTA option was used in PMDF versions to control the order of sorting (for processing purposes) of old message files on disk. The default was 87654321.

This option is **OBSOLETE** and has no effect in modern MTA versions.

52.21.3 File format MTA options: cbt (0 or 1; OpenVMS only)

The **OBSOLETE** cbt MTA option was used in PMDF versions on OpenVMS to control the use of "contiguous best try" filesystem storage. Setting the option to 1 sets the corresponding bit in the file attributes block, or FAB.

This option is **OBSOLETE** and has no effect in modern MTA versions.

52.21.4 File format and file handling options (comment_chars)

The comment_chars MTA option controls what characters are taken to signal a comment when they appear in the first column of various MTA input files. The value of this option takes the form of a list of ASCII character values in decimal. In Unified Configuration, such a list is space separated:

```
msconfig> show -default mta.comment_chars
mta.comment_chars: 33 59
```

In legacy configuration, the default was the list {33, 59}. With either representation, this specifies exclamation points and semicolons as comment introduction characters.

As of 7.0.5, note that the comment_chars MTA option only truly controls which character(s) *in addition to* semicolon (ASCII value 59) represent comment introduction characters, since regardless of whether or not it is explicitly set (or shows up in the value of comment_chars), the semicolon will always be treated as being set in comment_chars.

Note that the comment_chars option does not apply when reading the legacy configuration MTA option file itself as this file is read before comment_chars has even been seen. For this file, the following comment characters are "hard-coded": "!", ";", and "#".

52.21.5 Debug MTA options: debug_flush (0 or 1)

As of Messaging Server 7.1, a.k.a. Messaging Server 7.0-3.01, the debug_flush MTA option causes certain debug output to get immediately flushed to disk. This is applicable for many MTA components, including typical channel debug output, but it is especially relevant and noticeable for long-running components such as the SMTP server, and Job Controller. The flush-to-disk-log-file of the debug output may incur a bit of a performance penalty, but tends to be more convenient for debugging purposes. The default is that such debug flushing is not enabled (debug_flush = 0).

As of 7.0.5, the debug_flush MTA option can also cause flushing of Dispatcher debug output.

52.21.6 File reading during dequeue (dequeue_map)

The dequeue_map option controls whether files are mapping into memory when dequeuing. The default is 1 (true), meaning that files are so mapped. Disabling this, by setting this option to 0 (false), can be expected to have a detrimental effect on performance (and will likely cause the ims-ms channel to abort and core).

Caution: Use of this option is **RESTRICTED**.

52.21.7 File format MTA options: fdirectory (0 or 1; OpenVMS only)

The fdirectory option is only available on OpenVMS.

52.21.8 File format MTA options: fsync (0 or 1)

RESTRICTED.

The fsync MTA option may be used to cause the MTA to use the fsync function (UNIX) to flush disk output when closing a message file. If such flushing is not performed explicitly by the MTA, it is left up to the O/S to perform on its own timetable; potentially, if a system crashes at just the wrong moment, messages not yet synched to disk could be lost. The tradeoff, however, is that performing explicit flushing for every message incurs a performance penalty. fsync=1, meaning that flushes are performed explicitly by the MTA, is the default, ensuring message safety at the expense of a performance hit.

For the Message Store, somewhat analogous is the former store option diskflushinterval (default 15), and even more so the newer *synclevel store options such as messagesynclevel (not advisable to set, other than in the special case of restoring from backup, per the iMS 5.3 Migration Guide).

52.21.9 File format MTA options: log_alq (integer)

OpenVMS only.

The log_alq MTA option specifies the default allocation quantity (in OpenVMS blocks) for the MTA message transaction log file, mail.log_current. The default value is 2000, or twice the log_deq value if log_deq has been explicitly set. On a busy system that is updating that log file frequently, increasing this value may provide increased efficiency.

52.21.10 File format MTA options: log_deq (integer)

OpenVMS only.

The log_deq option specifies the default extend quantity (in OpenVMS blocks) for the MTA message transaction log file, mail.log_current. The default value is 1000. On a busy system that is updating that log file frequently, increasing this value may provide increased efficiency.

52.21.11 File format MTA options: max_internal_blocks (integer)

The max_internal_blocks MTA option specifies how large (in MTA blocks---see the block_size MTA option) an incoming message the MTA will buffer entirely in memory; messages larger than this size will be written to temporary files (in the area specified by the tmpdir MTA option -- or the imta_tmp MTA Tailor file option, in legacy configuration). (Prior to MS 6.0, the area such files were written to was controlled by the now obsolete imta_scratch MTA Tailor file option.) The default is 30.

For systems with lots of memory, increasing this value may provide a performance improvement.

Note that max_internal_blocks does not affect incoming LMTP messages; that is, it does not affect the LMTP server's handling of incoming messages. As of circa 6.2p5/6.3, the LMTP server will buffer in memory up to a default of 1,000,000 bytes (in MS 6.2p5 this number is hard-coded and not configurable) or the value set for the LMTP server BUFFER_SIZE TCP/IP-channel-specific option of an incoming message, and after that will buffer to a temporary file (in the tmpdir or imta_tmp directory). Prior to this change, the LMTP server did not do in-memory buffering and instead always buffered to temporary files (in imta_tmp).

52.21.12 File format MTA options: mm_mbc (0-255)

OpenVMS only.

The mm_mbc MTA option sets the RMS RAB MBC field (the RMS disk block size) used when writing message files.

52.21.13 File format MTA options: mm_mbf (0-255)

OpenVMS only.

The mm_mbf MTA option sets the RMS RAB MBF field (the RMS multibuffer count) used when writing message files.

52.21.14 Notification message MTA options: notary_quote (1-127)

The notary_quote MTA option specifies the ASCII representation of the character that marks substitution sequences in return_*.txt files and disposition_*.txt files. It defaults to 25 (the ASCII position of the percent character) so substitutions are %R, %u, *etc.*, as listed in return_*.txt file substitution sequences.

52.21.15 File format MTA options: osync (0 or 1)

RESTRICTED.

The osync MTA option controls whether MTA message queue file creation sets the O_SYNC flag. If set to 1, the O_SYNC flag is set when creating message queue file entries on disk. The default is 0. Setting O_SYNC may provide an increase in performance on ZFS file systems, but will degrade performance considerably on UFS.

52.21.16 projectid Option Under mta

The projectid MTA option overrides, for MTA use, the projectid base option. Thus the projectid MTA option specifies the numeric identifier the MTA uses when obtaining shared memory segments. This identifier is used in ftok() calls to generate a shared memory segment key. By default, the MTA uses the value of the projectid base option. If the projectid base option is not set, then the MTA defaults to using a value of 7; (in MS 7.4, if the projectid base option was not set, the MTA defaulted to using a value of 1). Only the lowest eight bits of the value are significant.

52.21.17 File format MTA options: queue_cache_mode (integer)

RESTRICTED: The value 2 (the default) must be used for the Messaging Server MTA.

The queue_cache_mode MTA option tells the MTA the type of cache of message queue files to use. In particular, a value of 2, the default, means that the Job Controller is maintaining (in-memory) queue cache information. This option *must not* be set to any other value.

52.21.18 File format MTA options: queue_cache_mode_3_files (list of file paths)

RESTRICTED. Only relevant when the queue_cache_mode MTA option is set to a value of 3 (which is not currently supported).

52.21.19 File format MTA options: use_text_databases (bitmask)

The use_text_databases MTA option controls whether the reverse "database", the general "database", and the forward "database" are truly on-disk databases, or whether they are instead stored as in-memory structures. As of MS 8.0.2.3, the bits in the option default to 1 if the corresponding URL option is not set and 0 otherwise. The default value was 8 prior to MS 8.0.2.3. The default is 0 in versions of Messaging Server prior to 8.0.2.3. Setting a bit of use_text_databases, so that an in-memory structure is used, makes moot any setting of the corresponding, new in MS 8.0, *_database_url MTA option: the in-memory structure will be used in preference to consulting memcache.

If bit 0 (value 1) is set, then the IMTA_TABLE:general.txt file (configroot/general.txt) is read when the MTA configuration is initialized or reloaded, and the information from that file is stored in memory replacing all uses of the general database.

If bit 1 (value 2) is set, then the IMTA_TABLE:reverse.txt file (configroot/reverse.txt) is read when the MTA configuration is initialized or reloaded, and the information from that file is stored in memory replacing all uses of the reverse database.

If bit 2 (value 4) is set, then the IMTA_TABLE:forward.txt file (configroot/forward.txt) is read when the MTA configuration is initialized or reloaded, and the information from that file is stored in memory replacing all uses of the forward database.

In particular, note that enabling use of such in-memory "databases" means that changes to the "database" (changes to the underlying text file source) require recompiling the configuration, or reloading the configuration, in order to get the change seen in a compiled configuration; see the cnbuild utility and the reload utility. As of MS 6.3P1, text databases support including other files via the < character, and comment lines (indicated by the presence of any of the comment_chars characters in column one).

52.22 Internal size MTA options

The MTA has a number of options that control internal MTA table sizes. These options do not normally need to be adjusted manually. Although they provide "starting points" (and maximums) for the sizes of various internal memory tables, the MTA will resize its internal tables as necessary when running. In particular, use of the imsimta cnbuild command will cause resizing to accomodate the current configuration size (and then all subsequently started processes will use the compiled configuration sizes). If a compiled configuration has not been created, then each process when it initially starts will need to do the resizing itself. Thus the penalty for not having "good" values set for these options is merely a little initial overhead---either overhead only for the imsimta cnbuild command when a compiled configuration is used, or overhead for each starting process when a compiled configuration is not used. In other words, the relevance of these options is limited mostly to "fine-tuning" memory usage, and providing a modest performance benefit for the imsimta cnbuild command (or for all starting processes if a compiled configuration is not in use).

For those who do wish to ensure that these options are set to values matching the MTA's real memory needs, using the imsimta cnbuild utility, that is, using a command such as the UNIX command

```
# imsimta cnbuild -noimage_file -maximum -option_file
```

is usually the best approach (letting the MTA tell you what values it needs, rather than trying to guess values and manually set them yourself). The above command will output MTA

options (stored in the MTA option file in an legacy configuration) with sizes adequate for the current configuration, plus some growth room. (Note that the above shown command does not actually compile the configuration using these sizes; that would require an additional `imsimta cnbuild` command. Rather, the above command determines appropriate sizing, and outputs corresponding MTA option values; such values could then be used in any subsequent MTA process invocation and in particular, in a subsequent `imsimta cnbuild` command.)

Since the MTA will resize its internal table sizes as needed, errors about exceeding table sizes are normally seen only if the MTA's more-or-less "hard" limits on resizing are reached. (The limits are established by the `maximum.dat` file and/or "hard" limits in the code.) And since the MTA's "hard" limits are *very* generous, exceeding the limits is usually an indication of either a configuration error of a type that has confused the MTA about the intended meaning of certain configuration inputs (for instance, an extraneous blank line in the rewrite rules, causing the MTA to attempt to interpret all remaining material as channel definitions), or configuration choices involving poor use of MTA facilities that would be better handled in an alternate manner (such as attempting to hard code many thousands of mapping table entries, rather than using a few general entries that do general database callouts for the specific fields). In particular, reaching the limits specified in the normal `maximum.dat` file is usually an indication of poor configuration choices; you should contact Oracle if you believe you wish to exceed those limits, as you may be better served by alternate configuration tactics.

Note: Historically, the default values, maximum size achievable through automatic resizing, and "hard" limits for these options have been prone to change (particularly increase) during and especially between releases, to a rather greater extent than for most other options. So although a diligent attempt has been made to provide correct numbers as of press time, the on-going quest to improve performance and scalability may mean that these documented values become out-of-date.

52.22.1 Internal size MTA options: `alias_hash_size` (1-1000000)

The `alias_hash_size` MTA option sets the size of the alias hash table. This in turn is an upper limit on the number of aliases that can be defined in the alias file, or equivalently the number of named alias groups in Unified Configuration. The default is 256; the maximum that the MTA will allow with normal, automatic resizing is 15,000 (controlled from the `maximum.dat` file); the "hard" maximum value allowed is 1,000,000. Attempts to set this option higher than 1,000,000 will result in an mm_init error, "ALIAS_HASH_SIZE exceeds maximum". Attempts to specify more aliases in the alias file than allowed by this option's maximum (normally the automatic, resize maximum, unless a higher maximum has been explicited configured for this option) will result in an mm_init error, "no room in table for alias ...".

52.22.2 Internal size MTA options: `alias_member_size` (0-40000)

The `alias_member_size` MTA option controls the size of the index table that contains the list of alias translation value pointers. The total number of addresses on the right hand sides of all the alias definitions in the alias file, or addresses on the right hand sides of all named alias groups in Unified Configuration, cannot exceed this value. The default is 320; the maximum allowed with normal, automatic resizing is 30,000 (controlled from the `maximum.dat` file); the

"hard" maximum allowed is 40,000. Attempts to set this option higher than 40,000 will result in an mm_init error, "ALIAS_MEMBER_SIZE exceeds maximum". Attempts to specify more alias translation values than allowed by the maximum for this option (normally, the automatic, resizing maximum, unless a higher maximum has been explicitly configured) will result in an mm_init error, "no room in alias member table for alias ...".

52.22.3 Internal size MTA options: channel_table_size (1-8192)

The channel_table_size MTA option controls the size of the channel table. The total number of channels in the configuration file, or the total number of named channel groups in Unified Configuration, cannot exceed this value. The default is 256; the maximum that the MTA will allow with normal, automatic resizing is 2500 (controlled from the maximum.dat file); the "hard" maximum (only achievable via explicit manual configuration) is 8,192. Attempts to set this option higher than 8,192 will result in an mm_init error, "CHANNEL_TABLE_SIZE exceeds maximum". Attempts to define more channels in the MTA configuration than allowed by this option's maximum (normally the automatic, resize maximum, unless a higher maximum has been explicitly configured) will result in an mm_init error, "no room in channel table for ...".

52.22.4 Internal size MTA options: chunk_cache_limit (non-negative integer)

The chunk_cache_limit MTA option specifies the size of the cache of message body chunk storage buffers. This can affect the efficiency of processing large or multipart message bodies. The default is to allow up to 1024 buffers in the cache.

52.22.5 Internal size MTA options: circuitcheck_paths_size (0-256)

The circuitcheck_paths_size MTA option controls the size of the circuit check paths table, and thus the total number of circuit check configuration file entries. The default is 10; the maximum allowed with normal, automatic resizing is 128 (controlled from the maximum.dat file); the "hard" maximum is 256. Attempts to set this option higher than 256 will result in using the value 256 (with no error message).

52.22.6 Internal size MTA options: conversion_size (1-2000)

The conversion_size MTA option controls the size of the conversion entry table, and thus the total number of conversion file entries (or entries in the conversions option in Unified Configuration) cannot exceed this number. The default is 32; the maximum allowed with normal, automatic resizing is 500 (controlled from the maximum.dat file); the "hard" maximum is 2,000. Attempts to set this option higher than 2,000 will result in using the value 2,000 (with no error message).

52.22.7 File format and file handling (describe_cache_limit)

The describe_cache_limit MTA option specifies the size of the cache of message part descriptions. This can affect the efficiency of processing large or multipart message bodies. The default is 256.

52.22.8 Internal size MTA options: domain_hash_size (1-1000000)

The domain_hash_size MTA option controls the size of the domain rewrite rules hash table. Each rewrite rule in the configuration file, or set in Unified Configuration, consumes one slot in this hash table, thus the number of rewrite rules cannot exceed this option's value. The default is 512; the maximum allowed with normal, automatic resizing is 16,384 (controlled from the maximum.dat file); the "hard" maximum number of rewrite rules allowed is 1,000,000. Attempts to set this option higher than 1,000,000 will result in an mm_init error, "DOMAIN_HASH_SIZE exceeds maximum". Attempts to specify more rewrite rules than allowed by this option's maximum (normally the automatic, resizing maximum, unless a higher maximum has been explicitly configured) will result in an mm_init error, "no room in rewrite rule table for ...".

52.22.9 Internal size MTA options: file_member_size (1-8192)

The file_member_size MTA option sets a limit for the number of configuration files the MTA may use. The default is 32; the "hard" maximum is 8,192. Attempts to set this option higher than 8,192 will result in an mm_init error, "FILE_MEMBER_SIZE exceeds maximum". Attempts to use more configuration files than allowed by this option's maximum (normally the automatic, resizing maximum, unless a higher maximum has been explicitly configured) will result in an mm_init error, "no room in file member table for file string ...".

52.22.10 Internal size MTA options: forward_data_size (1-1000000)

The forward_data_size MTA option sets the internal hash size for the forward (database) text file entries. The default is 64; the "hard" maximum is 1,000,000. Attempts to set this option higher than 1,000,000 will result in an mm_init error, "FORWARD_DATA_SIZE exceeds maximum". Attempts to specify more forward database entries than allowed by this option's maximum will result in an mm_init error, "no room in table for forward data ...".

52.22.11 Internal size MTA options: fruits_size (1-20000)

The fruits_size MTA option controls the total number of fruits allowed in the fruit validation table. The default is 110; the maximum value allowed is 20,000.

52.22.12 Internal size MTA options: general_data_size (1-2000000)

The general_data_size MTA option controls the internal hash size for the general (database) text file entries. The default is 256; the "hard" as of 8.0, the maximum is 5,000,000;

the maximum changed from 1,000,000 in MS 6.2 to 2,000,000 for MS 6.3. Attempts to set this option higher than its hard maximum (1,000,000 or 2,000,000 or 5,000,000, depending upon version) will result in an mm_init error, "GENERAL_DATA_SIZE exceeds maximum". Attempts to specify more entries in the general database than this option's maximum will result in an mm_init error, "no room in table for general data ...".

52.22.13 Internal size MTA options: host_hash_size (1-1000000)

The host_hash_size MTA option controls the size of the channel hosts hash table. Each channel host specified on a channel definition in the MTA configuration file (both official hosts and aliases) consumes one slot in this hash table, so the total number of channel hosts cannot exceed the value specified. The default is 512; the maximum allowed with normal, automatic resizing is 16384 (controlled from the maximum.dat file); the "hard" maximum value allowed is 1,000,000. Attempts to set this option higher than 1,000,000 will result in an mm_init error, "HOST_HASH_SIZE exceeds maximum".

Attempts to specify more rewrite rules than allowed by this option's maximum (normally the automatic resizing maximum, unless a higher maximum has been explicitly configured) will result in an mm_init error, "no room in channel host table for ...". In particular, note the following. In its literal meaning, the "no room in channel host table for ..." error indicates that your configuration's current MTA internal table sizes are not large enough for the number of host names listed in your channel definitions. However, note that an extraneous blank line in the rewrite rules (upper portion) of your MTA configuration file causes the MTA to interpret the remainder of the configuration file as channel definitions; with just one such extraneous blank line, the MTA sees just one extra channel but with a lot of (all the rest of the rewrite rules as) host names on that channel. So check the line of the file that the error is complaining about: if it is not truly intended as a host name on a channel definition but rather is a line in the rewrite rules section of your configuration file, then check for an extraneous blank line somewhere *above* it.

52.22.14 Internal size MTA options: ldap_attr_name_hash_size (1-1000000)

The ldap_attr_name_hash_size MTA option specifies the size of the internal table of LDAP attribute names. The default is 64; the maximum value allowed is 1,000,000. Attempts to set this option's value higher than the maximum of 1,000,000 will result in an mm_init error, "LDAP_ATTR_NAME_HASH_SIZE exceeds maximum". Attempts to use more LDAP attributes than this option's maximum will result in an mm_init error, "Unable to expand LDAP attribute name hash table". If a system does not have enough memory to allocate the space required by this option's value, then an mm_init error will result, "Unable to allocate LDAP attribute name hash array.".

52.22.15 Internal size MTA options: ldap_object_class_hash_size (1-1000000)

The ldap_object_class_hash_size MTA option controls the size of the internal table of LDAP object classes known to the MTA. The default is 64; the maximum is 1,000,000. Attempts to set this option to more than its maximum value of 1,000,000 will result in an mm_init error, "LDAP_OBJECT_CLASS_HASH_SIZE exceeds maximum". Attempts to specify more LDAP

object classes than are permitted by this option's maximum will result in an mm_init error, "Unable to expand LDAP object class hash table". If a system has insufficient memory to allocate the space required by this option's value, then an mm_init error will result, "Unable to allocate LDAP object class hash array.".

52.22.16 Internal size MTA options: map_names_size (1-1000000)

The map_names_size option specifies the size of the mapping table name table, and thus the total number of mapping tables cannot exceed this number. The default is 32; the maximum allowed with normal, automatic resizing is 5000 (controlled from the maximum.dat file); the "hard" maximum is 1,000,000. Attempts to set this option higher than its maximum of 1,000,000 will result in an mm_init error, "MAP_NAMES_SIZE exceeds maximum".

Attempts to specify more mapping tables than allowed by this option's maximum (normally the automatic resizing maximum, unless a higher maximum has been explicitly configured) will result in an mm_init error, "no room in table for mapping named ...". In particular, note the following. In its literal meaning, the "no room in table for mapping named ..." error indicates that your configuration's current MTA internal table sizes are not large enough for your current number of mapping tables. However, also note that formatting errors in the MTA mapping file can cause the MTA to think that you have more mapping tables than you really have; for instance, check that mapping table entries are all properly indented.

52.22.17 Internal size MTA options: options_hash_size (1-1000000)

The options_hash_size MTA option sets the internal hash size for MTA options (Unified Configuration mta.option-name options or legacy configuration option.dat options). The default is 512; the maximum is 1,000,000. Attempts to set this option to more than its maximum 1,000,000 will result in an mm_init error, "OPTIONS_HASH_SIZE exceeds maximum".

52.22.18 Internal size MTA options: personal_conversion_size(1-2000)

RESTRICTED. The "personal" conversions feature is not expected to be used nowadays.

The personal_conversion_size MTA option sets the number of "personal" conversion entries each login user is permitted to have in their personal conversions file. The default is 32; the maximum to which this option may be set is 2000.

52.22.19 Internal size MTA options: reverse_data_size (1-1000000)

The reverse_data_size MTA option controls the internal hash size for the reverse (database) text file entries. The default is 256; the maximum is 1,000,000. Attempts to set this option's value to higher than its maximum of 1,000,000 will result in an mm_init error, "REVERSE_DATA_SIZE exceeds maximum". Attempts to specify more entries in the reverse

(database) text file than this option's maximum will result in an mm_init error, "no room in table for reverse data ...".

52.22.20 Internal size MTA options: string_pool_size_n (1-5000000)

The string_pool_size_N MTA options, string_pool_size_0,... string_pool_size_4, were introduced in MS 6.0; (formerly, the single option string_pool_size controlled the total number of strings available to the MTA for general configuration use). The string_pool_size_N options control the number of character slots allocated to the string pools used to hold rewrite rule templates, alias list members, mapping entries, *etc.* A fatal error will occur if the total number of characters consumed by these parts of the configuration files exceed these limits. The default for each of these options is 32,000; the maximum allowed value for each of these options is 50,000,000 as of MS 6.3; (10,000,000 in MS 6.2 and earlier). Attempts to set any of these options' values higher than their respective maximums (of 10,000,000 each in earlier versions, or 50,000,000 each as of MS 6.3) will result in the maximum value (of 10,000,000, or 50,000,000 as of MS 6.3) being used, with no error message.

string_pool_size_0 controls the string pool size for miscellaneous strings, including rewrite rule templates, MTA option values, channel option values, and strings in MTA conversions entries. string_pool_size_1 controls the string pool size for mapping tables. string_pool_size_2 controls the string pool size for aliases. string_pool_size_3 controls the string pool size for the templates (right hand sides) of database text files, including the general (database) text file, the reverse (database) text file, and the forward (database) text file. string_pool_size_4 controls the string pool size for personal conversions.

52.22.21 Internal size MTA options: wild_pool_size (1-20000)

The wild_pool_size MTA option controls the total number of patterns that may appear throughout mapping tables. A fatal error will occur if the total number of mapping patterns exceeds this limit. The default is 8,000; the maximum allowed with normal, automatic resizing is 100,000 (controlled from the maximum.dat file); the "hard" maximum allowed value is 200,000. Attempts to set this option's value higher than its maximum of 200,000 will result in a value of 200,000 being used, with no error message.

52.23 Latency server MTA options

New in the 8.1.0.6 release, as part of the smartsend facility the MTA supports sending information about message latency to a separate server in JSON format. latency_* MTA options control the MTA's connections to this server.

At present there are two fields in each JSON object: "ts" is a timestamp expressed in in milliseconds since the UNIX epoch, and "la" is the message processing latency in milliseconds. For example:

```
{"ts":1589476358903,"la":95109}
```

52.23.1 Latency server options: latency_host (host)

New in MS 8.1.0.6. The latency_host MTA option specifies the host name (or IP address) of the host providing a server that accepts message latency information from the MTA. The default is 127.0.0.1 since the usual configuration is to have a co-resident latency server.

52.23.2 Latency server options: latency_port (port)

New in MS 8.1.0.6. The latency_port MTA option specifies the port number for the server that accepts message latency information from the MTA. If not specified, it defaults to 7072, the usual port for latency servers.

52.23.3 Latency server options: latency_expire (integer)

New in MS 8.1.0.6. The latency_expire MTA option specifies the amount of time, in seconds, that a connection to a latency server can remain idle and still be eligible for reuse.

52.23.4 Latency server options: latency_timeout (integer)

New in MS 8.1.0.6. The latency_timeout MTA option specifies the amount of time, in seconds, to wait on a connection to a latency server.

52.23.5 Latency server options: latency_max_failures (integer)

New in MS 8.1.0.6. The latency_max_failures MTA option specifies the number of attempts the MTA will make to connect to the latency server before disabling latency server support. Note that this is a per-process limit and only counts failures attempts 5 or more seconds apart.

52.24 LDAP external directory lookup MTA options

There are options controlling the LDAP fundamentals of any extldap:url lookups the MTA any be configured to perform. Such lookups, hence such options, were added for Messaging Server 7.2-7.02.

While the feature, new in Messaging Server 7.4-18.01, to allow explicit host and port specifications in LDAP URLs configured for MTA use means that these options might not all seem quite as necessary -- in operation since an external LDAP directory will likely require different bind credentials than an internal LDAP directory, as well as potentially other different settings, it is generally still useful to specifically configure using extldap: lookups instead of ldap: lookups.

Example uses for LDAP external directory lookups -- LDAP lookups directed against some LDAP directory other than the one used for regular user/group data -- would be cases where Sieve external lists are stored in some external LDAP directory, or for cases of looking up some data in mapping tables from an LDAP directory other than the usual LDAP directory.

52.24.1 LDAP external directory lookup MTA options: ldap_ext_host (host-name)

The ldap_ext_host MTA option takes a host name argument, and specifies the host to which to connect when making external LDAP (extldap:) queries. There is no default; this option must be explicitly set in order to successfully perform extldap: queries.

52.24.2 LDAP external directory lookup MTA options: ldap_ext_max_connections (non-negative integer)

The ldap_ext_max_connections MTA option takes a non-negative integer argument specifying the maximum number of simultaneous connections to permit to the external LDAP server. The default is 1024.

52.24.3 LDAP external directory lookup MTA options: ldap_ext_password (string)

The ldap_ext_password MTA option takes a string argument as the password used to authenticate for LDAP external directory (extldap:) queries. There is no default.

52.24.4 LDAP external directory lookup MTA options: ldap_ext_port (port)

The ldap_ext_port MTA option takes a non-negative integer argument specifying the port for the LDAP external directory. If not set, this defaults to the value of the ldap_port MTA option (which itself defaults to 389, the standard LDAP server port number).

52.24.5 LDAP external directory lookup MTA options: ldap_ext_username (DN)

The ldap_ext_username MTA option takes a DN specifying the username (bind credentials) for LDAP external directory (extldap:) queries. There is no default value: if no DN is specified, then authentication will not be used.

52.25 LDAP PAB MTA options

There are MTA options controlling the LDAP fundamentals of any personal addressbook (PAB) lookups the MTA may be configured to perform; that is, options affecting the MTA's handling of pabldap:url lookups. Such lookups, hence such options, were added for Messaging Server 7.0-0.04, though not all the functionality was fully fleshed out for that version.

Note that in order for the MTA to successfully perform any such PAB lookups, typically it is necessary to add an ACI to the PAB to allow the MTA read access. Such an ACI might be along the lines of:

```
dn: o=piServerDb
changetype: modify
add: aci
aci: (targer="ldap:///o=piServerDb")
 (targetattr="*")
 (version 3.0; acl "PAB Administrator read rights"; allow (read,search)
 groupdn="ldap:///cn=Messaging End User Administrator Group, ou=groups, o=isp";)
```

52.25.1 LDAP PAB MTA options: ldap_pab_host (hostname)

(New in 7.0-0.04) The ldap_pab_host MTA option specifies the host for the MTA's PAB LDAP queries; overrides for MTA PAB lookup purposes the ldaphostPAB option (local.service.pab.ldaphost configutil parameter in legacy configuration).

52.25.2 LDAP PAB MTA options: ldap_pab_max_connections (integer)

(New in Messaging Server 7.0u1) The ldap_pab_max_connections MTA option specifies a limit on the maximum number of connections that will be made by the MTA to the PAB Directory Server. The default is 1024.

52.25.3 LDAP PAB MTA options: ldap_pab_password (string)

(New in 7.0-0.04) The ldap_pab_password MTA option specifies the password for the MTA's PAB LDAP queries; overrides for MTA PAB lookup purposes the ldappasswdPAB option (local.service.pab.ldappasswd configutil parameter in legacy configuration).

52.25.4 LDAP PAB MTA options: ldap_pab_port (integer)

(New in 7.0-0.04) The ldap_pab_port MTA option specifies the port for the MTA's PAB LDAP queries; overrides for MTA PAB lookup purposes the ldapportPAB option (local.service.pab.ldapport configutil parameter in legacy configuration).

52.25.5 LDAP PAB MTA options: ldap_pab_username (dn)

(New in 7.0-0.04) The ldap_pab_username MTA option specifies the username (bind credentials) for the MTA's PAB LDAP queries; overrides for MTA PAB lookup purposes the ldapbinddnPAB option (local.service.pab.ldapbinddn configutil parameter in legacy configuration).

52.26 Mailing list MTA options

The MTA has a number of options relating specifically to mailing lists and groups.

As mailing lists and groups are merely a special form of alias, see also the general MTA options relating to aliases. And for mailing lists or groups defined in LDAP, see also the Direct LDAP MTA options, and specifically the Direct LDAP usergroup lookup MTA options.

52.26.1 Alias and address MTA options: alternate_recipient (string)

(New in MS 8.0.1.) The alternate_recipient MTA option specifies the comment string, including the surrounding parentheses, that is used to specify an alternate recipient address as part of a mailing list address entry. The default value for this string is (ALTERNATE-RECIPIENT).

For example, assuming the default value of this option, an entry of the form:

```
listmember@domain.com (alternate-recipient listalternate@domain.com)
```

would associated the alternate address listalternate@domain.com with the mailing list address listmember@domain.com.

52.26.2 alternate_recipient_mode Option

The alternate_recipient_mode MTA option controls the order in which additional alternate recipients are added to an existing alternate recipient list. Possible values are:

0 old recipients follow new recipient

1 new recipient follows old recipient

2 new recipient replaces any old recipients

3 new recipient is silently dropped if any old recipients are present

The default is 0, which is consistent with military messaging requirements.

52.26.3 Mailing list controls (defer_group_processing)

The defer_group_processing MTA mailing list option sets a default for whether direct LDAP group (list) expansion is performed "in-line", or whether it is deferred (performed via the reprocess channel). The default is 1 (true); that is, by default group expansion is deferred to the reprocess channel.

Note that when an address is deferred, the usual incoming recipient access mapping table (specifically, ORIG_SEND_ACCESS, SEND_ACCESS, ORIG_MAIL_ACCESS, and MAIL_ACCESS) checks are not performed; such checks don't take place until the reprocess channel runs and expands the address. Also, the originator address checking (via attributes such as *mgrpAllowedBroadcaster*, *etc*.) is deferred. (If the [dis]allowed broadcasters are a large dynamic group themselves, deferring this expansion is very desirable so that that lookup doesn't slow down the SMTP dialogue.) The reprocess channel when it runs will then perform all the normal access checks as if it were the original channel. In particular, the original transport and application fields (used in ORIG_MAIL_ACCESS and MAIL_ACCESS mapping tables) are available to the reprocess channel, and hence checks such as dns_verify callouts can still be performed at this later time.

If defer_group_processing=0 is set, so that the default is that groups are expanded "in-line" (for instance, during an SMTP dialogue), then deferred expansion may still be set for particular groups either by setting the mailDeferProcessing attribute (or more precisely whatever attribute is named by the ldap_reprocess MTA option) to Yes, or (deprecated) by setting the (multi-valued) mailDeliveryOption attribute (or more precisely, whatever attribute is named by the ldap_delivery_option MTA option) to have a value members_offline.

52.26.4 Mailing list and group MTA options: digest_on (string)

The digest_on MTA mailing list option specifies the comment string that enables mailing list digests (in preference to regular mailing list postings). The default is "(DIGEST)".

Caution: Usage of this option is **RESTRICTED**. It has not yet been fully implemented. Do not use this option unless and until instructed to do so by Oracle.

See also: Mailing lists.

52.26.5 Mailing list and group MTA options: expandable_default (0 or 1)

The expandable_default MTA option establishes a default for whether lists are expandable; in particular, it establishes a default for whether the EXPN SMTP command may be used to expand lists (display list membership).

The default value for this option is 1, meaning that by default lists are expandable. Note that this default may be overridden on a per list basis. For aliases in Unified Configuration, the alias_expandable and alias_nonexpandable alias options override whatever default is set via the expandable_default MTA option For lists defined in the aliases file or alias database, the [EXPANDABLE] or [NONEXPANDABLE] named parameters override whatever default is set via the expandable_default MTA option. For lists defined purely in LDAP, the mgmanMemberVisibility and expandable attributes (more precisely, those attributes named by the ldap_expandable MTA option) override the default set via expandable_default. See also the expn* channel options.

Also note that for mailing lists with posting access controls, such posting access controls affect when expansion via the SMTP EXPN command is allowed; the SMTP server will only permit an EXPN if the SMTP client passes the posting access control (*e.g.*, has issued a prior MAIL FROM: command that passes the access control). Note also that the TCP/IP-channel-specific option DISABLE_EXPAND may be used to disable the EXPN SMTP command entirely for those incoming TCP/IP channels corresponding to that default TCP/IP channel's SMTP server; see TCPIP-channel-specific options.

52.26.6 Mailing list and group MTA options: mail_off (string)

The mail_off MTA option specifies the comment string, including the surrounding parentheses, that disables mail delivery for list addresses specified in the alias file or alias database, or set via an alias setting in Unified Configuration. The default value for this string is (NOMAIL).

52.26.7 Mailing list and group MTA options: or_clauses (0 or 1)

The or_clauses MTA option sets the default for whether multiple mailing list access control settings (e.g., alias_auth_list, alias_cant_list, *etc*., or [AUTH_LIST], [CANT_LIST], *etc*. in legacy configuration) are ANDed (the default, or_clauses=0) or ORed (or_clauses=1). See Mailing list multiple access control interpretation for additional discussion.

This general MTA option setting can be overridden on a per list or group basis via the alias options alias_or or alias_and (in legacy configuration, the mailing list named parameters [OR] or [AND]), or in direct LDAP mode via use of an "OR" or "AND" value as one of the values of the LDAP attribute named by the ldap_auth_policy MTA option (by default, mgrpBroadcasterPolicy).

52.26.8 Mailing list and group MTA options: post_off (string)

The post_off MTA option specifies the comment string, including the surrounding parentheses, that disables mail posting for list addresses specified in the alias file or alias database, or set via an alias setting in Unified Configuration. The default is (NOPOST).

52.27 MAILSERV MTA options

RESTRICTED. MAILSERV is not yet fully implemented.

52.27.1 MAILSERV moderator MTA options

RESTRICTED. MAILSERV is not yet fully implemented.

When using MAILSERV, a special MAILSERV moderator user must be set up, that will handle certain MAILSERV functions. MTA options exist to specify this moderator user.

52.27.1.1 MAILSERV moderator user MTA options: mailserv_moderator_mail (RFC 822 address)

RESTRICTED. Not yet fully implemented.

The mailserv_moderator_mail MTA option specifies the e-mail address of the MAILSERV "user": the account whose Message Store mailbox is used by MAILSERV for list moderation functions.

52.27.1.2 MAILSERV moderator user MTA options: mailserv_moderator_uid (uid)

RESTRICTED. Not yet fully implemented.

The mailserv_moderator_uid MTA option specifies the uid of the MAILSERV "user": the account whose Message Store mailbox is used by MAILSERV for list moderation functions.

Note that the value must be a valid `uid` value; in particular, only a subset of ASCII characters are permitted; see the `ldap_uid_invalid_chars` MTA option.

52.27.1.3 MAILSERV moderator MTA options: `mailserv_secret` (string)

RESTRICTED. Not yet fully implemented.

The `mailserv_secret` MTA option is used internally to generate passwords used internally for lists managed by MAILSERV. It has no default.

52.27.2 MAILSERV LDAP schema MTA options

RESTRICTED. MAILSERV is not yet fully implemented.

There are a couple of MTA options specifying basics of the LDAP schema for MAILSERV.

52.27.3 MAILSERV user LDAP attribute name MTA options

RESTRICTED. MAILSERV is not yet fully implemented.

By default, the MTA assumes a particular sort of LDAP schema will be used with MAILSERV; in particular, the MTA assumes that certain named attributes (with certain sorts of meanings) are available and used in the LDAP directory to store MAILSERV user data, and MAILSERV list subscription data. However, the exact attribute names that the MTA looks for (recognizes) are configurable via the various `ldap_mluser_*` and `ldap_mlsub_*` MTA options. Thus a different (though semantically compatible) schema may be used by setting the `ldap_mluser_*` and `ldap_mlsub_*` MTA options to tell the MTA what named attributes to use (recognize). In addition to the MTA options listed here, see also the `ldap_mluser_object_class` MTA option which specifies the object class(es) for MAILSERV users.

Note that throughout MAILSERV discussions, for convenience often LDAP attributes will be referred to merely by name. But in general, any such MAILSERV reference to a specific LDAP attribute name really ought to be a reference to the attribute named by the corresponding MTA option. For instance, any use by MAILSERV of the `mail` LDAP attribute is really a use of the attribute named by the `ldap_mluser_mail` MTA option.

52.27.4 MAILSERV list subscription LDAP attribute name MTA options

RESTRICTED. MAILSERV is not yet fully implemented.

By default, the MTA assumes a particular sort of LDAP schema will be used with MAILSERV; in particular, the MTA assumes that certain named attributes (with certain sorts of meanings) are available and used in the LDAP directory to store MAILSERV user data, and MAILSERV list subscription data. However, the exact attribute names that the MTA looks for (recognizes) are configurable via the various `ldap_mluser_*` and `ldap_mlsub_*` MTA options. Thus a different (though semantically compatible) schema may be used by setting the `ldap_mluser_*` and `ldap_mlsub_*` MTA options to tell the MTA what

named attributes to use (recognize). In addition to the MTA options listed here, see also the ldap_mlsub_object_class MTA option which specifies the object class for MAILSERV list subscriptions.

Note that throughout MAILSERV discussions, for convenience often LDAP attributes will be referred to merely by name. But in general, any such MAILSERV reference to a specific LDAP attribute name really ought to be a reference to the attribute named by the corresponding MTA option. For instance, any use by MAILSERV of the mlsubListIdentifier LDAP attribute is really a use of the attribute named by the ldap_mlsub_list_id MTA option.

52.27.5 MAILSERV list LDAP attribute name MTA options

RESTRICTED. MAILSERV is not yet fully implemented.

By default, the MTA assumes a particular sort of LDAP schema will be used with MAILSERV; in particular, the MTA assumes that certain named attributes (with certain sorts of meanings) are available and used in the LDAP directory to store mailing list data. However, the exact attribute names that the MTA looks for (recognizes) on list entries managed by MAILSERV are configurable via the various ldap_list_* MTA options. Thus a different (though semantically compatible) schema may be used by setting the ldap_list_* MTA options to tell the MTA what named attributes to use (recognize).

Note that throughout MAILSERV discussions, for convenience often LDAP attributes will be referred to merely by name. But in general, any such MAILSERV reference to a specific LDAP attribute name really ought to be a reference to the attribute named by the corresponding MTA option. For instance, any use by MAILSERV of the mgrpListName LDAP attribute is really a use of the attribute named by the ldap_list_name MTA option.

52.28 Mapping table MTA options

A number of MTA options affect the syntax or operation of MTA mapping tables. For such options affecting in particular the access mapping tables, see Access mapping table MTA options; for options affecting MTA mapping table syntax in general, or the use of other (non-access) MTA mapping tables, see Miscellaneous mapping table MTA options.

52.28.1 Access mapping table MTA options

This discussion will focus on those MTA options that specifically or primarily affect the *_ACCESS mapping tables as well as mailing list access mapping tables. In particular, many of these options alter the format of *_ACCESS mapping table probes by causing inclusion of additional fields, thus additional information, in the *_ACCESS mapping table probes. The use_auth_return, use_canonical_return, and use_orig_return options can, among other things, affect the form of envelope From address used in recipient-address-based *_ACCESS mapping table probes and in mailing list named parameter [*_MAPPING] mapping table probes. See also the access_errors MTA option for control of the default error text resulting from recipient address *_ACCESS mapping table rejections. And see also Miscellaneous mapping table MTA options for a discussion of additional options with more miscellaneous (less specifically focused on access mapping table) effects.

52.28.1.1 Access mapping table MTA options: access_auth (bitmask)

(New in MS 8.0) The access_auth MTA option is used to cause inclusion of additional authentication information in mapping probes. This is a bit-encoded field; currently two bits are defined. If bit 0 (value 1) is set, the value of the SMTP MAIL FROM command's AUTH parameter is included in the FROM_ACCESS mapping probe immediately following the authenticated sender address. If bit 1 (value 2) is set, the canonical username result produced by authentication is included in the FROM_ACCESS mapping probe immediately following the SMTP AUTH parameter. The default value for this option is 0.

52.28.1.2 Access mapping table MTA options: access_counts (bitmask)

(New in MS 6.3.) The access_counts MTA option provides a way to get at various types of recipient count information in the various recipient-based *_ACCESS mappings. access_counts is bit-encoded in the same way as access_orcpt is, and if set, enables the addition of a set of counts after the (optional) access_orcpt field and before the (optional) include_conversiontag field in the access mapping probe string. Currently the format of the count addition is:

RCPT-TO-count/total-recipient-count/expansion-count/

Note the trailing slash. It is expected that additional counter information will be added to this field in the future; all mappings making use of this information should be coded to ignore anything following the (current) last slash or they may break without warning. The *total-recipient-count* is the count of valid recipients resulting from previous RCPT TO commands (*not* including the RCPT TO command corresponding to this probe).

New in 8.0.1.2 is *expansion-count*, a count of the number of actual recipient addresses produced by the current RCPT TO command, including the current one.

Table 52.20 access_counts MTA option bit values

Bit	Value	Usage
0	1	If set, include recipient counts in each [ORIG_]SEND_ACCESS and [ORIG_]MAIL_ACCESS mapping table probe
1	2	If set, include recipient counts in each ORIG_SEND_ACCESS probe
2	4	If set, include recipient counts in each SEND_ACCESS probe
3	8	If set, include recipient counts in each ORIG_MAIL_ACCESS probe
4	16	If set, include recipient counts in each MAIL_ACCESS probe

Bit 0 is the least significant bit.

52.28.1.3 Access mapping table MTA options: access_orcpt (bitmask)

The access_orcpt option's default value is 0. Setting access_orcpt to 1 adds an additional vertical bar delimited field to the probe value passed to the recipient access mapping tables (that is, the SEND_ACCESS, ORIG_SEND_ACCESS, MAIL_ACCESS, and ORIG_MAIL_ACCESS mapping tables) that contains the original recipient (ORCPT) address (or if the message doesn't have an ORCPT address, then the original unmodified RCPT TO: address is used instead). A new feature added for MS 6.3 are separate bits to separately control

inclusion of the ORCPT value in these various mapping table probes. Note that such values take the form of an address type string, followed by a semicolon, followed by the address. For instance, `rfc822;user@domain.com`.

Table 52.21 `access_orcpt` MTA option bit values

Bit	Value	Usage
0	1	If set, include ORCPT value in each `[ORIG_]SEND_ACCESS` and `[ORIG_]MAIL_ACCESS` mapping table probe
1	2	(New in 6.3) If set, include ORCPT value in each `ORIG_SEND_ACCESS` probe
2	4	(New in 6.3) If set, include ORCPT value in each `SEND_ACCESS` probe
3	8	(New in 6.3) If set, include ORCPT value in each `ORIG_MAIL_ACCESS` probe
4	16	(New in 6.3) If set, include ORCPT value in each `MAIL_ACCESS` probe

Bit 0 is the least significant bit.

52.28.1.4 Access mapping table MTA options: `include_connectioninfo` (bitmask)

(New in MS 6.2.) This option selectively enables the inclusion of the transport and application connection information in various mapping table probes that otherwise would not include this material. The relevant mapping tables correspond to certain alias options in Unified Configuration, or in legacy configuration to certain named (that is, nonpositional) alias parameters in the alias file, most often used on mailing lists defined via the alias file. If included, the connection information appears at the beginning of the mapping probe in the same format used in the `FROM_ACCESS`, `MAIL_ACCESS`, and `ORIG_MAIL_ACCESS` mappings. The option takes a bit-encoded value that defaults to 0. The following bits are defined:

Table 52.22 `include_connectioninfo` MTA option bit values

Bit	Value	Usage
0	1	AUTH_MAPPING or `alias_auth_mapping`
1	2	MODERATOR_MAPPING or `alias_moderator_mapping`
2	4	CANT_MAPPING or `alias_cant_mapping`
3	8	DEFERRED_MAPPING or `alias_deferred_mapping`
4	16	DIRECT_MAPPING or `alias_direct_mapping`
5	32	HOLD_MAPPING or `alias_hold_mapping`
6	64	NOHOLD_MAPPING or `alias_nohold_mapping`
7	128	SASL_AUTH_MAPPING or `alias_sasl_auth_mapping`
8	256	SASL_MODERATOR_MAPPING or `alias_sasl_moderator_mapping`
9	512	SASL_CANT_MAPPING or `alias_sasl_cant_mapping`

Bit 0 is the least significant bit.

52.28.1.5 Access mapping table MTA options: `include_conversiontag` (bitmask)

New in MS 6.3. This option selectively enables the inclusion of conversion tag information in various mapping table probes. When enabled, the current set of conversion tags will appear in the relevant mapping table probe as a comma separated list. The option takes a bit-encoded integer value. The following bits are defined:

Table 52.23 `include_conversiontag` MTA option bit values

Bit	Value	Usage
0	1	CHARSET-CONVERSION : include as a `;TAG=`*`comma-separated-values`* field before `;CONVERT`
1	2	CONVERSIONS : include as a `;TAG=comma-separated-values` field before `;CONVERT`
2	4	FORWARD : include just after any authenticated sender and to any `ldap_spare_*` fields (with a vertical bar, `|`, delimiter)
3	8	ORIG_SEND_ACCESS : include as a final (barring any `ldap_spare_*` fields) field; that is, include after the optional access count field and prior to any `ldap_spare_*` fields (with a vertical bar, `|`, delimiter)
4	16	SEND_ACCESS : include as a final (barring any `ldap_spare_*` fields) field; that is, include as a field after the optional access count field and prior to any `ldap_spare_*` fields (with a vertical bar, `|`, delimiter)
5	32	ORIG_MAIL_ACCESS : include as a final (barring any `ldap_spare_*` fields) field; that is, include as a field after the optional access count field and prior to any `ldap_spare_*` fields (with a vertical bar, `|`, delimiter)
6	64	MAIL_ACCESS : include as a final (barring any `ldap_spare_*` fields) field; that is, include as a field after the optional access count field and prior to any `ldap_spare_*` fields (with a vertical bar, `|`, delimiter)
7	128	FROM_ACCESS : (New in 7.0-3.01? post MS 6.3) include as a final (barring any `ldap_spare_*` fields) field; that is, include as a field after the optional access count field and prior to any `ldap_spare_*` fields (with a vertical bar, `|`, delimiter)
8	256	REVERSE : (New in 7.0.5) include as a field after any source or destination channel fields, but before the actual address in the probe (with a vertical bar, `|`, delimiter). Note that only the "final" REVERSE mapping table probe, used to (possibly) modify addresses as a message is being enqueued, includes the conversion tags; earlier probes, such as for (possibly) modifying the envelope From for *_ACCESS mapping table probe purposes, or for (possibly) setting an "override" postmaster address do not include conversion tags regardless of the setting of this bit of `include_conversiontag`.
9	512	PERSONAL_NAMES : (New in 8.0) include as a field after any source or destination channel fields, but before any addresses in the probe (with a vertical bar, `|`, delimiter).
10	1024	Domain catchall mappings: (New in 8.0) include as a field after any authenticated sender address, but before any MT-PRIORITY and recipient address in the probe (with a vertical bar, `|`, delimiter).
11	2048	AUTH_ACCESS mapping: (New in 8.0.2.2) include as a field after the username, but before the destination system in the probe (with a vertical bar, `|`, delimiter).

12	4096	DEQUEUE_ACCESS mapping: (New in 8.0.2.3) include as a field after the auth-sender, but before the priority in the probe (with a vertical bar, `|`, delimiter).
13	8192	AUTH_REWRITE mapping: (New in 8.1.0.1) include as a field after the auth-param, but before any extra header fields in the probe (with a vertical bar, `|`, delimiter).
14	16384	(New in 8.1.0.1) Include the global conversion tag list as an X-Tags: field in the first section of the second part of any DSNs that are generated. Note that this may expose internal information and is only intended for use when all DSNs are processed internally.
15	32768	(New in 8.1.0.1) Include the global conversion tag list in any SMTP_ACTIONS mapping probe.
16	65536	(New in 8.1.0.1) Include the global conversion tag list in any MX_ACCESS mapping probe.

Bit 0 is the least significant bit.

The default is 0, meaning that conversion tag values are not included in any mapping table probes.

52.28.1.6 Mapping table MTA options: `include_mtpriority` (bitmask)

(New in 8.0.) The current MT-PRIORITY value (an integer in the range -9 to 9) and the current message size estimate may be includeed in various mapping probes. This is all controlled by the `include_mtpriority` MTA option. When these values are included in a probe they appear as separate fields. This option is bit-encoded, with the bits defined as follows:

Table 52.24 `include_mtpriority` MTA option values

Bit	Value	Meaning
0	1	Include MT-PRIORITY and size estimate in `FROM_ACCESS` probes immediately after any `include_spares1` values
1	2	Include MT-PRIORITY and message size estimate in `FORWARD` probes immediately after any conversion tag field (resulting from setting the `include_conversiontag` MTA option)
2	4	Include MT-PRIORITY and message size estimate in `ORIG_SEND_ACCESS` probes immediately after any `include_spares1` values
3	8	Include MT-PRIORITY and message size estimate in `SEND_ACCESS` probes immediately after any `include_spares1` values
4	16	Include MT-PRIORITY and message size estimate in `ORIG_MAIL_ACCESS` probes immediately after any `include_spares1` values
5	32	Include MT-PRIORITY and message size estimate in `MAIL_ACCESS` probes immediately after any `include_spares1` values
6	64	Append the MT-PRIORITY and message size estimate values in the form "`;MT-PRIORITY=<value>;BLOCKS=<value>`" to the `CONVERSIONS` mapping probe immediately after any "`TAG=`" clause.
7	128	Append the MT-PRIORITY and message size estimate values in the form "`;MT-PRIORITY=<value>;BLOCKS=<value>`" to any domain catchall

		mapping probe immediately after any conversion tag clause and before the recipient address.

Bit 0 is the least significant bit.

The default is 0, meaning that no MT-PRIORITY or message size estimates are includes in the various mapping table probes. With the exception of the `CONVERSIONS` mapping, the MT-PRIORITY and message size estimate are added in that order, delimited by vertical bars.

The message size estimate is the size of the queued message entry for internal channels; it's the value given by the SMTP SIZE extension for incoming SMTP channels. The size is given in MTA blocks and will be 0 if no size information is available. Note that message sizes can change as a result of channel processing, encoding, decoding, and conversion operations.

52.28.1.7 Access mapping table MTA options: `include_retries` (bitmask)

New in MS 8.0.2.3. This option selectively enables the inclusion of message retry count information in various mapping table probes. When enabled, the number of previous retry attempts as well as a "skip count" will be included as a field in the probe, separated by a comma. A -1 will appear if the retry count or skip count, respectively, cannot be determined.

The skip count is an integer value encoded as part of the queue entry filename that is intended for use in keeping track of round-robin positioning in IP address lists.

FORWARD COMPATIBILITY NOTE: Additional comma-separated values may be added to this field in the future. Implementations should be aware of this and take appropriate steps to handle the field valye properly.

This option takes a bit-encoded integer value. The currently defined bits are shown in the following table:

Table 52.25 `include_retries` MTA option bit values

Bit	Value	Usage
0	1	AUTH_ACCESS : include after the filename and before the queue time
1	2	DEQUEUE_ACCESS : include after the filename and before the queue time
2	4	MESSAGE-SAVE-COPY : include after the filename

52.28.1.8 Access mapping table MTA options: `include_spares1` (bitmask)

(New in Messaging Server 7u2, renamed from `include_spares` to `include_spares1` in MS 8.0.2.2.) LDAP attribute values associated with originator or recipient address processing may be included in `FROM_ACCESS` or the various recipient address access mapping probes, respectively. This is all controlled by the `include_spares1` MTA option. This option is bit-encoded, with the bits defined as follows:

Table 52.26 `include_spares1` MTA option values

Bit	Value	Meaning
0	1	Include sender `ldap_spare_1` attribute in FROM_ACCESS probes
1	2	Include sender `ldap_spare_2` attribute in FROM_ACCESS probes

2	4	Include sender ldap_spare_3 attribute in FROM_ACCESS probes
3	8	Include sender ldap_spare_4 attribute in FROM_ACCESS probes
4	16	Include sender ldap_spare_5 attribute in FROM_ACCESS probes
5	32	Include sender ldap_spare_6 attribute in FROM_ACCESS probes
6	64	Include recipient ldap_spare_1 attribute in ORIG_SEND_ACCESS probes
7	128	Include recipient ldap_spare_2 attribute in ORIG_SEND_ACCESS probes
8	256	Include recipient ldap_spare_3 attribute in ORIG_SEND_ACCESS probes
9	512	Include recipient ldap_spare_4 attribute in ORIG_SEND_ACCESS probes
10	1024	Include recipient ldap_spare_5" attribute in ORIG_SEND_ACCESS probes
11	2048	Include recipient ldap_spare_6 attribute in ORIG_SEND_ACCESS probes
12	4096	Include recipient ldap_spare_1 attribute in SEND_ACCESS probes
13	8192	Include recipient ldap_spare_2 attribute in SEND_ACCESS probes
14	16384	Include recipient ldap_spare_3 attribute in SEND_ACCESS probes
15	32768	Include recipient ldap_spare_4 attribute in SEND_ACCESS probes
16	65536	Include recipient ldap_spare_5 attribute in SEND_ACCESS probes
17	131072	Include recipient ldap_spare_6 attribute in SEND_ACCESS probes
18	262144	Include recipient ldap_spare_1 attribute in ORIG_MAIL_ACCESS probes
19	524288	Include recipient ldap_spare_2 attribute in ORIG_MAIL_ACCESS probes
20	1048576	Include recipient ldap_spare_3 attribute in ORIG_MAIL_ACCESS probes
21	2097152	Include recipient ldap_spare_4 attribute in ORIG_MAIL_ACCESS probes
22	4194304	Include recipient ldap_spare_5 attribute in ORIG_MAIL_ACCESS probes
23	8388608	Include recipient ldap_spare_6 attribute in ORIG_MAIL_ACCESS probes
24	16777216	Include recipient ldap_spare_1 attribute in MAIL_ACCESS probes
25	33554432	Include recipient ldap_spare_2 attribute in MAIL_ACCESS probes
26	67108864	Include recipient ldap_spare_3 attribute in MAIL_ACCESS probes
27	134217728	Include recipient ldap_spare_4 attribute in MAIL_ACCESS probes
28	268435456	Include recipient ldap_spare_5 attribute in MAIL_ACCESS probes
29	536870912	Include recipient ldap_spare_6 attribute in MAIL_ACCESS probes

Bit 0 is the least significant bit.

The default is 0, meaning that no LDAP spare attribute values are included in the *_ACCESS mapping table probes. If inclusion of any spare attribute values is enabled, those spare attribute values are suffixed to the probe after the optional (see include_conversiontag) conversion tag value(s). Any spare attribute values enabled are suffixed in order (first a vertical bar and ldap_spare_1 if enabled, then a vertical bar and ldap_spare_2 if enabled, *etc.*).

Note that spare attribute slots can be assigned to point to attributes already used for other purposes by the MTA. That is, via this mechanism, the *_ACCESS mapping tables can in fact be sensitive to the value of any attribute available to the MTA during the relevant mapping table probe: just about any recipient or sender attribute likely to be of interest could be made available to the mapping probe.

52.28.1.9 Miscellaneous mapping table MTA options: include_spares (bitmask)

Replaced in 8.0.2.2 by the include_spares1 MTA option.

52.28.1.10 Access mapping table MTA options: mapping_paranoia (integer)

(New in Messaging Server 7.0) Since access-check mappings such as the recipient address *_ACCESS mappings, the FROM_ACCESS mapping, the AUTH_REWRITE mapping, the BURL_ACCESS mapping, the SIEVE_EXTLISTS mapping, and new in Messaging Server 7.3-11.01 the MILTER_MACROS mapping table, and new in 7.0.5 the GROUP_AUTH mapping table and AUTH_ACCESS mapping table, use vertical bars as delimiters, issues can arise when externally provided material such as envelope From or To addresses themselves contain vertical bars. The mapping_paranoia MTA option is intended to provide various tools to handle such issues.

Giving the mapping_paranoia MTA option a nonnegative value will cause any vertical bars in the externally supplied portions of various mapping input strings to be replaced in the mapping probe with the character whose ASCII value is given by this option. (Attempting to set mapping_paranoia to a positive value greater than 127 will result in the value 124, the default, being used.) That is, the "regular", field-separating, vertical bars will still be present, but a vertical bar within an external field (such as within an address) will be replaced by the specified character. A negative value will cause the vertical bar to simply be dropped entirely from the probe. The default value for this option is 124, the ASCII value for vertical bar, which causes vertical bars to be left untouched.

Note that many mapping tables where mappings_paranoia is relevant also have a feature for testing whether a vertical bar was originally present in externally supplied probe fields; use of mapping_paranoia to replace the original vertical bar characters does not affect such testing: the test flag is set based on the original presence of a vertical bar character, regardless of whether it is later replaced due to mapping_paranoia.

52.28.1.11 Access mapping table MTA options: use_ip_access (bitmask)

(New in Messaging Server 7.0.) If bit 0 (value 1) of the use_ip_access MTA option is set, then a delivery attempt count field will be suffixed to the end of the IP_ACCESS mapping table probes. The default is 0.

52.28.1.12 Return address type used in checks MTA options: use_auth_return, use_canonical_return, use_orig_return

The MTA maintains three different forms of the envelope From address: the original from the MAIL FROM SMTP command (or its equivalent in other protocols), one that has had address reversal applied, and one that has been fully canonicalized, which includes mapping of mailEquivalentAddress attribute matches to the corresponding mail attribute value. Additionally, there may be an address produced as a result of an authentication operation that has similar semantics.

There are many places where the MTA performs comparisons against or constructs mapping probes containing the "return" address. But since there are multiple "return" addresses, there needs to be a way to select the one that is used. This is controlled by the use_auth_return,

use_canonical_return, and use_orig_return MTA options. Each of these options accepts a bit-encoded integer argument, with each bit controlling a particular place where a "return" address is used.

If the bit in use_auth_return is set and an authenticated address is available, it is used and the corresponding bits in the other options become no-ops. If the bit in use_canonical_return is set (and the one in use_auth_return is clear), then the canonicalized envelope From address is used and the corresponding bit in use_orig_return becomes a no-op. if the bit in use_orig_return is set (and the ones in the other two options are clear) then the original envelope from address is used. Finally, if none of the bits are set, the envelope From address that has had address reversal applied is used.

The use_auth_return MTA option was added in 7.0; use_canonical_return is first available in 6.3.

The uses of the return address the various bits control are described in the following table:

Table 52.27 use_auth_return MTA option bits

Bit	Value	Usage
0	1	ORIG_SEND_ACCESS mapping table probes
1	2	SEND_ACCESS mapping table probes
2	4	ORIG_MAIL_ACCESS mapping table probes
3	8	MAIL_ACCESS mapping table probes
4	16	Mailing list [AUTH_LIST], [MODERATOR_LIST], [SASL_AUTH_LIST], and [SASL_MODERATOR_LIST] checks, and in Unified Configuration alias_auth_list, alias_moderator_list, alias_sasl_auth_list, alias_sasl_moderator_list alias option checks
5	32	Mailing list [CANT_LIST] and [SASL_CANT_LIST] checks, and in Unified Configuration, alias_cant_list and alias_sasl_cant_list alias option checks
6	64	Mailing list [AUTH_MAPPING], [MODERATOR_MAPPING], [SASL_AUTH_MAPPING], and [SASL_MODERATOR_MAPPING] checks, and in Unified Configuration, alias_auth_mapping, alias_moderator_mapping, alias_sasl_auth_mapping, and alias_sasl_moderator_mapping alias option checks
7	128	Mailing list [CANT_MAPPING] and [SASL_CANT_MAPPING] checks, and in Unified Configuration, alias_cant_mapping and alias_sasl_cant_mapping alias option checks
8	256	Mailing list [ORIGINATOR_REPLY] comparisons, and in Unified Configuration, alias_originator_reply alias option comparisons
9	512	Mailing list [DEFERRED_LIST], [DIRECT_LIST], [HOLD_LIST], and [NOHOLD_LIST] checks, and in Unified Configuration, alias_deferred_list, alias_direct_list, alias_hold_list, and alias_nohold_list alias option checks
10	1024	Mailing list [DEFERRED_MAPPING], [DIRECT_MAPPING], [HOLD_MAPPING], and [NOHOLD_MAPPING] checks,

		and in Unified Configuration, `alias_deferred_mapping`, `alias_direct_mapping`, `alias_hold_mapping`, and `alias_nohold_mapping` alias option checks
11	2048	Mailing list checks for whether the sender is the list moderator
12	4096	Mailing list `ldap_auth_domain` LDAP attribute (*e.g.*, `mgrpAllowedDomain`) checks
13	8192	Mailing list `ldap_cant_domain` LDAP attribute (*e.g.*, `mgrpDisallowedDomain`) checks
14	16384	Mailing list `ldap_auth_url` LDAP attribute (*e.g.*, `mgrpAllowedBroadcaster`) checks
15	32768	Mailing list `ldap_cant_url` LDAP attribute (*e.g.*, `mgrpDisallowedBroadcaster`) checks
16	65536	**OBSOLETE**. In iMS 5.0 and 5.1 this controlled mailing list `ldap_moderator_rfc822` comparisons; since as of iMS 5.2 there is no longer any such MTA option nor need for such an attribute (since the `ldap_moderator_url` attribute value can, in fact, specify a mailto: URL pointing to an RFC 822 address), this bit no longer has any meaning.
17	131072	Mailing list `ldap_moderator_url` LDAP attribute (*e.g.*, `mgrpModerator`) comparisons
18	262144	Source-specific `FORWARD` mapping table probes
19	524288	Source-specific forward database probes
20	1048576	(New in 6.3) Source-specific domain catchall mappings
21	2097152	(New in 7.2-7.02) `FROM_ACCESS` mapping

The default for `use_auth_return` and `use_canonical_return` is 0. The default for `use_orig_return` is 0 prior to 7.2-7.02; in 7.2-7.02 and later it is 2097152, which preserves the existing default of using the original envelope From access in the `FROM_ACCESS` mapping. Also note that setting bit 21 in `use_auth_return` makes no sense as the authenticated sender address is available as a separate field in the probe.

52.28.2 Miscellaneous mapping table MTA options

This discussion lists MTA options affecting miscellaneous mapping tables. See also Access mapping table MTA options which lists those MTA options primarily affecting `*_ACCESS` and mailing list access mapping tables. See also the `string_pool_size_1` option. And if performing explicit LDAP callouts in mapping tables, see also the `url_result_cache_*` MTA options controlling the per-process caching of results of such LDAP lookups.

52.28.2.1 `averages_cache_size` Option

Not currently implemented. The MeterMaid facility provides an alternate, more general, facility.

52.28.2.2 `averages_cache_timeout` Option

Not currently implemented. The MeterMaid facility provides an alternate, more general, facility.

52.28.2.3 Miscellaneous mapping table MTA options: include_spares2 (bitmask)

(New in 8.0.) LDAP attribute values associated with originator or recipient address processing may be included in FORWARD mapping probes. This is controlled by the include_spares2 MTA option. This option is bit-encoded, with the bits defined as follows:

Table 52.28 include_spares2 MTA option values

Bit	Value	Meaning
0	1	Include sender ldap_spare_1 attribute in FORWARD probes
1	2	Include sender ldap_spare_2 attribute in FORWARD probes
2	4	Include sender ldap_spare_3 attribute in FORWARD probes
3	8	Include sender ldap_spare_4 attribute in FORWARD probes
4	16	Include sender ldap_spare_5 attribute in FORWARD probes
5	32	Include sender ldap_spare_6 attribute in FORWARD probes
6	64	(New in MS 8.0.2.2) Include recipient ldap_spare_1 attribute in FORWARD probes
7	128	(New in MS 8.0.2.2) Include recipient ldap_spare_2 attribute in FORWARD probes
8	256	(New in MS 8.0.2.2) Include recipient ldap_spare_3 attribute in FORWARD probes
9	512	(New in MS 8.0.2.2) Include recipient ldap_spare_4 attribute in FORWARD probes
10	1024	(New in MS 8.0.2.2) Include recipient ldap_spare_5 attribute in FORWARD probes
11	2048	(New in MS 8.0.2.2) Include recipient ldap_spare_6 attribute in FORWARD probes

Bit 0 is the least significant bit.

The default is 0, meaning that no LDAP spare attribute values are included in FORWARD mapping probes. If inclusion of any spare attribute values is enabled, those spare attribute values are suffixed to the probe after the optional (see include_conversiontag) conversion tag value(s). Any spare attribute values enabled are suffixed in order (first a vertical bar and ldap_spare_1 if enabled, then a vertical bar and ldap_spare_2 if enabled, *etc.*).

Note that spare attribute slots can be assigned to point to attributes already used for other purposes by the MTA. That is, via this mechanism, the FORWARD mapping table can in fact be sensitive to the value of any attribute available to the MTA during the relevant mapping table probe: just about any recipient or sender attribute likely to be of interest could be made available to the mapping probe.

For a similar feature of adding LDAP attribute values to FROM_ACCESS or recipient address-based access mapping tables, see the include_spares1 MTA option.

52.28.2.4 Internal size MTA options: map_names_size (1-1000000)

The map_names_size option specifies the size of the mapping table name table, and thus the total number of mapping tables cannot exceed this number. The default is 32; the maximum

allowed with normal, automatic resizing is 5000 (controlled from the `maximum.dat` file); the "hard" maximum is 1,000,000. Attempts to set this option higher than its maximum of 1,000,000 will result in an mm_init error, "`MAP_NAMES_SIZE exceeds maximum`".

Attempts to specify more mapping tables than allowed by this option's maximum (normally the automatic resizing maximum, unless a higher maximum has been explicitly configured) will result in an mm_init error, "`no room in table for mapping named ...`". In particular, note the following. In its literal meaning, the "`no room in table for mapping named ...`" error indicates that your configuration's current MTA internal table sizes are not large enough for your current number of mapping tables. However, also note that formatting errors in the MTA mapping file can cause the MTA to think that you have more mapping tables than you really have; for instance, check that mapping table entries are all properly indented.

52.28.2.5 Miscellaneous mapping table MTA options: `message_save_copy_flags` (bitmask)

(New in MS 6.3) The `message_save_copy_flags` MTA option controls whether certain additional, optional fields are included in `MESSAGE-SAVE-COPY` mapping table probes. The option takes a bit-encoded integer value. The following bits are defined:

Table 52.29 `message_save_copy_flags` option bit values

Bit	Value	Usage
0	1	Include transport and application information fields as the first and second, respectively, fields of the mapping table probe
1	2	Include the source channel as an additional field in the mapping table probe, between the application information field and conversion tag field (if those fields are enabled)
2	4	Include conversion tag(s) as an additional field in the mapping table probe, immediately after the source channel field
3	8	Include the MT-PRIORITY value for this message (an integer between -9 and 9) in the mapping table probe, immediately after the conversion tag field (if the field is enabled).
4	16	(New in 8.0.1.3) Include the transaction log action code value for the first recipient in the mapping table probe, immediately after the MT-PRIORITY field (if the field is enabled). This single character will normally be a "D" when delivery was successful.
5	32	(New in 8.0.2.1) Include the destination host for the first recipient in the mapping table probe, immediately after the transaction action code value (if the field is enabled).

Bit 0 is the least significant bit.

The default is 0.

52.28.2.6 Miscellaneous mapping table MTA options: `original_channel_probe` (0 or 1)

RESTRICTED.

The original_channel_probe MTA option controls whether things like CONVERSIONS mapping table probes, when performed by the conversion channel and any additional conversion_* channels, or the process channel or hold channel, use the original channel as the input channel name, or use the current source channel as the input channel name. For instance, this distinction can make a difference when applying both conversion and character set conversions to the same message. Conversions happen before character set conversion. So this option affects which channel name should appear in the IN-CHAN=*channel-name* clause of the CHARSET-CONVERSION mapping probe, the original channel, or the current source channel (which will be the conversion channel at that point). The default is 0, meaning to use the current input channel name.

52.28.2.7 Miscellaneous mapping table MTA options: use_comment_strings (bitmask)

(New in MS 6.1.) The use_comment_strings MTA option takes a bit encoded integer argument. If bit 0 (value 1) of this option is set, then the familiar

source-channel|*destination-channel*|

prefix will be included in COMMENT_STRINGS mapping table probes. See the commentmap and sourcecommentmap channel options, and RFC 822 comments strings and personal name modification for more discussion of the COMMENT_STRINGS mapping table.

52.28.2.8 Alias and address MTA options: use_forward_database (bitmask)

The use_forward_database MTA option controls whether or not the MTA makes use of the forward database, and also controls the exact format of probes of the forward database and FORWARD mapping table. The value is a decimal integer representing a bit-encoded integer, the interpretation of which is given in the table below.

Table 52.30 use_forward_database MTA option bits

Bit	Value	Usage
0	1	When set, the forward database is used.
3	8	When set, channel-level granularity is used with the forward database entries. Forward database entries' left hand sides must have the form (note the vertical bars, |) *source-channel*|*from-address*|*to-address* Note that source-specific forwarding is very seldom appropriate, and in those rare cases where it is appropriate, the forward database is seldom the most suitable choice for achieving it.
4	16	When set, channel-level granularity is used with the FORWARD or any domain catchall mapping. The mapping entries' patterns (left hand sides) must have the form (note the vertical bars, |) *source-channel*|*from-address*|*to-address* Note that source-specific forwarding is very seldom appropriate, and in those rare cases where it is appropriate, the FORWARD mapping is seldom the most suitable choice for achieving it.

5	32	When set, modifies the effect of bit 3 (source-specific forward database probes) by also including the destination channel in the probe.
6	64	When set, modifies the effect of bit 4 (source-specific FORWARD or domain catchall mapping probes) by also including the destination channel in the probe.
7	128	(New in 8.0) When set, includes the initial address presented for alias processing in the FORWARD mapping probe. This address appears immediately before the intermediate address included by bit 8 below.
8	256	(New in 8.0) When set, include the current intermediate address in the FORWARD mapping probe. This address appears immediately before the final recipient address.
9	512	(New in 8.0) When set, include the authenticated sender address address in the FORWARD or any domain catchall mapping probe. This address appears immediately after the destination channel and before conversion tags.

Bit 0 is the least significant bit.

The default value for use_forward_database is 0, which means that the MTA will not use the forward database at all. Note that a FORWARD mapping table, if present, is always consulted.

52.28.2.9 Alias and address MTA options: use_reverse_database (bitmask)

The use_reverse_database MTA option controls whether or not the MTA makes use of the address reversal database and REVERSE mapping table as a source of substitution addresses. (Note that it cannot disable use of any reverse_url setting, although its bit 2, value 4, does affect the scope of reverse_url application.) Its value is a decimal integer representing a bit-encoded integer, the interpretation of which is given in the table below.

Table 52.31 use_reverse_database MTA option bits

Bit	Value	Usage
0	1	When set, reverse database based address reversal is applied to addresses after they have been rewritten by the MTA address rewriting process; (this does not affect reverse_url or REVERSE mapping table based address reversal subsequent to address rewriting, which is controlled merely by the existence of a reverse_url setting or existence of a REVERSE mapping table, respectively).+
1	2	When set, reverse database and/or REVERSE mapping based address reversal is applied before addresses have had MTA address rewriting applied to them; (this does not affect reverse_url based address reversal, which always occurs after rewriting has been applied; for the REVERSE mapping, setting this bit causes an additional consultation of the REVERSE mapping prior to address rewriting, in addition to the subsequent to rewriting consultation which will always be performed).+
2	4	When set, address reversal, including the reverse_url option setting if applicable, will be applied to all (except envelope To) addresses, including forward-pointing header addresses, not just to backward-pointing addresses.

3	8	When set, channel-level granularity is used with the REVERSE mapping. REVERSE mapping table (pattern) entries must have the form (note the vertical bars, |) *source-channel|destination-channel|address*
4	16	When set, channel-level granularity is used with address reversal database entries. Reversal database entries' left hand sides must have the form (note the vertical bars, |) *source-channel|destination-channel|address*
5	32	Apply REVERSE mapping even if a reverse database entry has already matched.
6	64	Apply address reversal to message ids; see Internal host names in Received: and Message-Id: header lines for an example.
7	128	When set, this modifies the effect of bit 4 (channel-level granularity of address reversal database entries); when this bit is also set, the address reversal database entries take the form (note the vertical bars, |) *destination-channel|address*
8	256	When set, this modifies the effect of bit 3 (channel-level granularity of REVERSE mapping table entries); when this bit is also set, the REVERSE mapping table entries take the form (note the vertical bars, |) *destination-channel|address*
10	1024	During subsequent-to-rewriting address reversal, (that is, that reversal due to having bit 0 (value 1) set), this disables the normal initial reverse database lookup, though a database lookup can still be caused by a $D in the REVERSE mapping table
11	2048	During prior-to-rewriting address reversal, (that is, that reversal due to having bit 1 (value 2) set), this disables the normal initial reverse database lookup, though a database lookup can still be caused by a $D in the REVERSE mapping table
12	4096	(New in 8.0.) When set, include the name of the header field the address being processed came from in the mapping probe, delimited by vertical bars, immediately after source channel, destination channel, and conversion tag information. A trailing colon is always included in the field name. A blank name appears when envelope addresses are being processed.
13	8192	(New in 8.0.) When set, do not impose source block and recipient limits and capture actions based on the envelope from (MAIL FROM) address. For background discussion, see Intended side effects of LDAP address reversal.
14	16384	(New in 8.0.) When set, do not impose source block and recipient limits and capture actions based on the authenticated sender address. For background discussion, see Intended side effects of LDAP address reversal.

+In initial iMS 5.2 and earlier versions, the 0th and 1st bits of `use_reverse_database` not only controlled when, but also *whether* a REVERSE mapping table would be consulted at all for address rewriting; now if a REVERSE mapping table exists, it definitely *will* be consulted for address reversal (at least) subsequent to address rewriting; (depending upon bit 1, it may also be consulted prior to address rewriting). So this is a change from iMS 5.2 and earlier versions.

Bit 0 is the least significant bit.

The default value for use_reverse_database is 5, which means that in addition to consulting any reverse_url setting to reverse envelope From addresses and both backwards and forwards pointing header addresses after they have passed through the normal address rewriting process, the MTA will also consult any reverse database or REVERSE mapping to reverse Envelope From addresses and both backwards and forwards pointing header addresses after they have passed through the normal address rewriting process. Simple address strings are presented to both the REVERSE mapping and the reverse database. Note that a value of 0 disables the use of the address reversal completely. (Note that the default of 5 represents a change from early versions of PMDF in which this option had a default value of 1 (reverse only backwards pointing addresses).)

Note that as of 8.0.1.3, the usereversedatabase source channel option can be used to override the setting of use_reverse_database on a channel by channel basis.

52.28.2.10 Miscellaneous mapping table MTA options: use_personal_names (bitmask)

(New in MS 6.1.) The use_personal_names MTA option takes a bit encoded integer argument. If bit 0 (value 1) of this option is set, then the familiar

source-channel|*destination-channel*|

prefix will be included in PERSONAL_NAMES mapping table probes. See the personalmap and sourcepersonalmap channel options, and RFC 822 comments strings and personal name modification for more discussion of the PERSONAL_NAMES mapping table.

Setting bit 1 (value 2) causes the inclusion of the name of the header field the address being processed came from in the mapping probe, immediately after source channel, destination channel, and conversion flag information. A trailing colon is always included in the field name.

If bit 2 (value 4) is set any personal name generated during address reverse will not be used by default. Instead the revised name will be added to the PERSONAL_NAMES mapping probe immediately following the original personal name associated with the address. If the mapping wishes to use the revised name all it needs to do is return that name and set $Y.

52.29 Memcache MTA options

New in the 8.0 release, the MTA supports use of memcache for certain database/storage uses. memcache_* MTA options control the MTA's connections to memcache. The *_database_url MTA options, when set to memcache: URL values, configure use of Memcache to store MTA databases. See also the enable_sieve_memcache MTA option, which enables Sieve filter use of a memcache operator in Sieve scripts.

52.29.1 Memcache MTA/channel options: memcache_host (host)

The memcache_host MTA/channel option specifies the host name (or IP address) of the host providing a server supporting the memcache protocol. (The server software is often, but not always, memcached.) There is no default.

Use of the memcache_host channel option is only supported in cases where a channel-specific memcache server makes sense semantically. Currently the only channels that support this usage are those associated with the MTA-STS server.

52.29.2 Memcache MTA/channel options: memcache_port (port)

The memcache_port MTA/channel option specifies the port number for the server providing support for the memcache protocol. If not specified, it defaults to 11211, the usual port for memcache servers.

Use of the memcache_port channel option is only supported in cases where a channel-specific memcache server makes sense semantically. Currently the only channels that support this usage are those associated with the MTA-STS server.

52.29.3 Memcache MTA options: memcache_expire (integer)

The memcache_expire MTA option specifies the amount of time, in seconds, that a connection to a memcache server can remain idle and still be eligible for reuse.

52.29.4 Memcache MTA options: memcache_timeout (integer)

The memcache_timeout MTA option specifies the amount of time, in seconds, to wait for a connection to a memcache server.

52.29.5 Hashing memcache keys: memcache_hash_algorithm (hash algorithm name)

New in MS 8.1.0.3. The memcache_hash_algorithm MTA option controls what hash algorithm the MTA uses to optionally hash memcache keys. The value should be a hash algorithm supported by the MTA, one of MD2, MD4, MD5, SHA1, SHA256, SHA512, MD128, or MD160. SHA1 is the default. Note that the setting of this option must be the same across a deployment for successful coordination of memcache access.

52.29.6 Memcache/Redis MTA options: alias_database_url (memcache:/redis: URL)

The value of the alias_database_url MTA option should be a either a memcache: URL or (as of MS 8.1) a redis: URL for storing alias database data.

52.29.7 Memcache/Redis MTA options: domain_database_url (memcache:/redis: URL)

The value of the domain_database_url MTA option should be either a memcache: URL or (as of MS 8.1) a redis: URL for storing domain database data (that is, supplementary rewrite rules).

52.29.8 Memcache/Redis MTA options: forward_database_url (memcache:/redis: URL)

The value of the forward_database_url MTA option should be either a memcache: or (as of MS 8.1) a redis:URL for storing forward database data. Note that forward_database_url will only be consulted if bit 2 (value 4) of the use_text_databases MTA option is clear (*not* set); setting use_text_databases to a value subsuming 4 causes any setting of forward_database_url to be ignored.

52.29.9 Memcache/Redis MTA options: general_database_url (memcache:/redis: URL)

The value of the general_database_url MTA option should be either a fully specified memcache: or (as of MS 8.1) a fully specified redis:URL for storing general database data. For example, the URL "memcache://memcache.exmaple.com/" specifies that memcache protocol should be used to connect to memcache.exmaple.com on the default memcache port. Note that in the case of Redis the host to connect to is always given by the redis.hostlist option, so the URL is always "redis:///".

Note that the general_database_url option will only be consulted if bit 0 (value 1) of the use_text_databases MTA option is clear (*not* set); setting use_text_databases to a value subsuming 1 causes any setting of general_database_url to be ignored.

52.29.10 Memcache/Redis MTA options: reverse_database_url (memcache:/redis: URL)

The value of the reverse_database_url MTA option should be either a memcache: or (as of MS 8.1) a redis:URL for storing reverse database data. Note that reverse_database_url will only be consulted if bit 1 (value 2) of the use_text_databases MTA option is clear (*not* set); setting use_text_databases to a value subsuming 2 causes any setting of reverse_database_url to be ignored.

52.30 Message archival and hashing MTA options

The MTA options discussed in this section relate to the envelope "journal" format captured messages that the MTA can optionally generate, as well as to the message hashes optionally generated by the MTA in order to facilitate integration with alternative message archiving software -- with regards to which, see also the Message Store archive options and Archiving messages. The journal_format MTA option would be used when "journal" style message capture is in use (due to Sieve "capture :journal actions, or due to LDAP attribute based message capture with optional "journal" format configured). The message hashing options would be used in conjunction with the message hash channel options.

52.30.1 Archive message format control: journal_format (bitmask)

The journal_format MTA option controls the format of Microsoft® Exchange journaling messages generated by the MTA. This is a bit-encoded option. Currently assigned bits are:

Table 52.32 journal_format MTA option bit values

Bit	Value	Description
0	1	If set, generate the basic 2007 journal format instead of the 2003 format.
1	2	If set, set the From:/To:/Subject: of the journal message to be the same as the message being journaled. Note that setting this may cause looping problems for setups that use header checks to determine what messages to archive.
2	4	If set, generate a X-MS-Exchange-Organization-Journal-Report: header field rather than a X-MS-Journal-Report: field.
3	8	If set, include expanded/forwarded address information in the report (if such information is available -- see the addrtypescan channel option). Note that bit 0 must also be set for this to work.

The default value for this option is 0. This option is intended to facilitate interoperating with Microsoft Exchange itself, in particular, so that MTA-generated journal messages can be imported into Microsoft Exchange.

52.30.2 Direct LDAP MTA options: capture_domain_replace (0-2)

Normally the effects of domain-level capture LDAP attributes (as specified by the ldap_domain_attr_capture MTA option) and user-level capture LDAP attributies (as specified by the ldap_capture MTA option) are cumulative, that is, message copies are sent to all such capture/journal recipients.

The new-in 8.0.1.3 capture_domain_replace MTA option changes this behavior. If set to a positive value N, it will change the behavior of the first N attributes so that domain-level capture addresses are replaced rather than being combined with user-level attributes.

The default value of 0 disables replacement.

Note that the special attribute value "*" can be used as a "null" capture address. This makes it possible to disable domain-level capture on a per-user basis.

52.30.3 Message archiving and hashing options: message_hash_algorithm (hash algorithm name)

The message_hash_algorithm MTA option controls what hash algorithm the MTA uses to generate a hash over the message. The value should be a hash algorithm supported by the MTA, one of MD2, MD4, MD5, SHA1, SHA256, SHA512, MD128, or MD160. The default is MD5.

52.30.4 Message archiving and hashing MTA options: message_hash_fields (list of header names)

This option takes either a comma-separated list or space-separated list of up to thirty-two known (to the MTA) header field names, each with or without a trailing colon (and intervening spaces are okay too). The default is:

```
Message-id:,From:,To:,Cc:,Bcc:,Resent-message-id:,Resent-From:,Resent-To:,
Resent-Cc:,Resent-Bcc:,Subject:,Content-id:,Content-type:,Content-description:
```

(The Content-type: and Content-description: here are those from the top or outer MIME level of the message.)

See Message identifier generation for a discussion of use of this option in the content of message archiving.

52.30.5 Message archiving and hashing MTA options: unique_id_template (string)

The unique_id_template MTA option specifies a template used to convert an address for a "local" user into a unique identifier. The template's substitution vocabulary is the same as that for delivery options; (see the delivery_options MTA option, and especially the permitted LDAP URL substitution sequences). The resulting unique identifier is intended for use by message archiving tools. So for instance a site could set

```
unique_id_template=$M@$D
```

to use each user's *uid@domain* as that user's unique identifier.

52.31 Message size MTA options

The MTA has a number of options relating to message size, such as limits on the size of messages allowed in by the MTA, message size affecting message processing priority, limits on the extent to which the MTA looks into (processes) messages of complex MIME structure, and fine tuning of message fragmentation. There are also MTA options relating specifically to the size of notification messages. And there are MTA options controlling the error text returned when messages are "too large" in one sense or another.

See also the maxprocchars channel option.

52.31.1 Message size MTA options: block_limit (integer)

The block_limit MTA option places an absolute limit on the size, in MTA blocks, of any message which may be sent by or received with the MTA. Any message exceeding this size will be rejected. By default, the MTA imposes essentially no size limits; (more precisely, the default is the maximum allowed integer, 2**31-1). Note also that the blocklimit and

sourceblocklimit channel options can be used to impose limits on a per-channel basis. The size in bytes of an MTA block is specified with the block_size MTA option.

The line_limit MTA option allows for a similar limit, expressed in terms of lines in a message.

Note that domain LDAP attributes can be used to impose per-domain limits; see the ldap_domain_attr_blocklimit MTA option (normally specifying the use of the mailDomainMsgMaxBlocks LDAP attribute) and ldap_domain_attr_sourceblocklimit MTA option. Or user LDAP attributes can be used to impose per-user limits; see the ldap_maximum_message_size MTA option (normally specifying the use of the mgrpMsgMaxSize LDAP attribute) and the ldap_sourceblocklimit MTA option.

Or for aliases stored outside of LDAP, the alias_blocklimit alias option (or [BLOCKLIMIT] alias file named parameter in legacy configuration) can be used to impose limits on a per-alias basis.

(Note also that the acceptalladdresses channel option, if used, may modify the timing and form of rejections due to exceeding message size constraints.)

52.31.2 Message size MTA options: block_size (integer > 0)

The MTA measures message size in units of MTA "blocks". For instance, the MTA message transaction log file (resulting from placing the logging option on a channel) records message sizes in terms of blocks. MTA blocks are also the unit of measurement for various message size limit and message size based effects, as specified via channel options including blocklimit, sourceblocklimit, alternateblocklimit, holdlimit, nonurgentblocklimit, normalblocklimit, urgentblocklimit, and maxblocks, and via MTA options including block_limit, bounce_block_limit, content_return_block_limit, header_limit, log_size_bins, non_urgent_block_limit, normal_block_limit, urgent_block_limit, max_header_block_use, and max_internal_blocks, and via LDAP attributes named by MTA options including mailMsgMaxBlocks (ldap_blocklimit), ldap_sourceblocklimit, mgrpMsgMaxSize (ldap_maximum_message_size), mailDomainMsgMaxBlocks (ldap_domain_attr_blocklimit), and ldap_domain_attr_sourceblocklimit, and the alias option alias_blocklimit. Normally an MTA block is equivalent to 1024 octets. This option can be used to modify this sense of what a block is.

NOTE: The MTA stores message sizes internally as an integer number of blocks. If the size of a block in bytes is set to a very small value it is possible for a very large message to cause an integer overflow. A message size of greater than 2**31 blocks would be needed, but this value is not inconceivable if the block size is small enough.

Given the extensive list (above) of values measured in units of "blocks", it may be useful here to also list values that are *not* measured in "blocks". In particular, measurements that do *not* use the block_size, but which instead are always measured in units of bytes, include the conversion channel environment variable PART_SIZE, the Content-length: MIME header line value, the SMTP protocol extension SIZE value (see RFC 1870), and the user-level mailQuota LDAP attribute (more properly from the MTA's point of view, the attribute pointed to by the ldap_disk_quota MTA option) and the domain-level mailDomainDiskQuota LDAP attribute (which note is not used by the MTA proper). Furthermore, the user-level mailQuota

LDAP attribute (more properly from the MTA's point of view, the attribute pointed to by the ldap_disk_quota MTA option) and the Sieve filter size test's value are also normally interpreted as bytes, (though Sieve size values can optionally use a K, M, or G unit indicator to indicator measuring in units of 2**10, 2**20, or 2**30, and similarly the mailQuota attribute's value can use K, M, or G unit indicators).

52.31.3 Notification message and return job options (bounce_block_limit)

The bounce_block_limit MTA option may be used to force bounces of messages over the specified size (number of blocks, as defined via the block_size MTA option) to return only the message headers, rather than the full message content. This overrides any NOTARY (RFC 1891) setting originally present on original messages.

By default, there is essentially no limit; (more precisely, the default is the maximum allowed integer, 2**31-1).

52.31.4 Notification message MTA options: content_return_block_limit (non-negative integer)

The content_return_block_limit MTA option may be used to force on the NOTARY (RFC 1891) non-return of content flag for messages over the specified size (in units of MTA blocks); if such a message is subsequently bounced by a system that supports NOTARY, then the original message contents will not be included in the bounce message. By default, this option is not set and hence entire original messages of arbitrary size potentially may be included in bounce messages; however, even when this option is not set, the MTA will automatically truncate original message content when generating a notification message if a message size limit (*e.g.*, the blocklimit channel option) has been imposed on the relevant destination channel.

This option only applies to messages that do not have their own explicit NOTARY (RFC 1891) setting controlling return of content; when NOTARY has been used, it takes precedence over this option.

52.31.5 Message size MTA options: header_limit (integer)

The header_limit option sets a limit, in MTA blocks (see the block_size MTA option), on how big a message's primary (outermost) header can be. Headers over the specified size will be (silently) truncated. The default is 2000 blocks.

Source channels may have their own, more restrictive, headerlimit set; each channel will minimize its own setting with this general, MTA-wide header_limit setting.

Compare with the max_header_blocks and max_header_lines MTA options, which instead of silent truncation in the form of deletion of the header lines, cause silent "truncation" by forcing the excess header material into the message body. And see also the maxprocchars channel option, limiting how much of the header the MTA will process. And for yet more approaches to header limits and header truncation, see the maxheaderaddrs and maxheaderchars channel options, and the MAXCHARS, MAXIMUM, and MAXLINES header trimming options.

52.31.6 Message size MTA options: line_limit (integer)

The line_limit MTA option places an absolute limit on the overall number of lines in any message which may be sent or received by the MTA. Any message exceeding this limit will be rejected. By default, the MTA imposes essentially no line count limits; (more precisely, the default limit is the maximum allowed integer, 2**31-1).

Note that the linelimit channel option can be used to impose line limits on a per-channel basis. The alias_linelimit alias option (or [LINELIMIT] alias file named parameter in legacy configuration) may be used to impose line limits on a per-alias basis. Analogously, the block_limit MTA option may be used to set a limit based on number of blocks in a message.

(Note that the acceptalladdresses channel option, if used, may modify the timing and form of rejections due to exceeding message size constraints.)

52.31.7 Message size MTA options: local_quota_checks (integer)

RESTRICTED: The local_quota_checks MTA option is not fully implemented.

52.31.8 Message fragmentation size limit MTA options: max_header_block_use (real number strictlybetween 0 and 1), max_header_line_use (real number strictly between 0 and 1)

52.31.8.1 max_header_block_use

The max_header_block_use MTA option controls what fraction of the available message blocks can be used by message headers. The default is 0.5.

This MTA option is used to fine-tune the message fragmentation effect of the maxblocks channel option.

52.31.8.2 max_header_line_use

The max_header_line_use MTA option controls what fraction of the available message lines can be used by message headers. The default is 0.5.

This MTA option is used to fine-tune the message fragmentation effect of the maxlines channel option.

52.31.9 Message size MTA options: max_header_blocks (integer)

The max_header_blocks MTA option causes truncation of the original, incoming message header after the specified number of blocks (by forcing additional, supposedly header material, into the message body). The default is no limit, but see also the max_header_lines

and header_limit MTA options. The max_header_blocks, max_header_lines, and header_limit MTA options provide some protection against denial-of-service attacks in the form of messages with extravagantly large/long headers.

See also the maxprocchars channel option, limiting how much of the header the MTA will process.

52.31.10 Message size MTA options: max_header_lines (integer)

The max_header_lines MTA option causes truncatation a of message's original, incoming message header after the specified number of lines (by forcing additional, supposedly header material, into the message body). The default is 10,000. The max_header_blocks, header_limit, and max_header_lines MTA options provide some protection against denial-of-service attacks in the form of messages with extravagantly large/long headers.

See also the maxprocchars channel option, limiting how much of the header the MTA will process.

52.31.11 Maximum message levels/parts to process MTA options: max_mime_levels (integer), max_mime_parts (integer)

52.31.11.1 max_mime_levels

Specify the maximum depth to which the MTA should process MIME messages. The default is 100, meaning that the MTA will process up to one hundred levels of message nesting. Higher values may require additional amounts of memory and, for the Dispatcher, additional per-thread storage space. If max_mime_levels>0, then levels of nesting higher than specified will not be processed. As of 8.0, if max_mime_levels<0, then in addition such messages will be sidelined as .HELD files. See the held_sndopr MTA option for discussion of optionally logging (to syslog) when such events occur.

52.31.11.2 max_mime_parts

Specify the maximum number of MIME parts which the MTA should process in a MIME message. The default value is the maximum allowed integer, 2147483647: essentially no limit is imposed. If max_mime_parts>0, then message parts greater than specified will not be processed. As of 8.0, if max_mime_parts<0, then in addition such messages will be sidelined as .HELD files. See the held_sndopr MTA option for discussion of optionally logging (to syslog) when such events occur.

52.31.12 Size effects of message priority MTA options: non_urgent_block_limit (integer), normal_block_limit (integer), second_class_block_limit (integer), urgent_block_limit (integer)

Note that as of the 8.0 release, these size-based priority override MTA option effects are nullified if the MT-PRIORITY SMTP extension has been used to set an explicit priority value.

52.31.12.1 non_urgent_block_limit

The non_urgent_block_limit MTA option may be used to instruct the MTA to downgrade the priority of messages based on size: messages above the specified size will be downgraded to lower than non-urgent priority, meaning that they will not be processed immediately and will wait for processing until the next periodic delivery run. The value is interpreted in terms of MTA blocks, as specified by the block_size MTA option. Note also that the nonurgentblocklimit channel option may be used to impose such downgrade thresholds on a per-channel basis.

52.31.12.2 normal_block_limit

The normal_block_limit MTA option may be used to instruct the MTA to downgrade the priority of messages based on size: messages above the specified size will be downgraded to non-urgent priority. The Job Controller automatically pays attention to message effective processing priority when scheduling delivery attempts. The value is interpreted in terms of MTA blocks, as specified by the block_size MTA option. Note also that the normalblocklimit channel option may be used to impose such downgrade thresholds on a per-channel basis.

52.31.12.3 second_class_block_limit

The second_class_block_limit MTA option may be used to instruct the MTA to downgrade the priority of messages based on size: messages above the specified size will be downgraded to third class priority. The value is interpreted in terms of MTA blocks, as specified by the block_size MTA option. Note also that the secondclassblocklimit channel option may be used to impose such downgrade thresholds on a per-channel basis.

52.31.12.4 urgent_block_limit

The urgent_block_limit MTA option may be used to instruct the MTA to downgrade the priority of messages based on size: messages above the specified size will be downgraded to normal priority. The Job Controller automatically pays attention to message effective processing priority when scheduling delivery attempts. The value is interpreted in terms of MTA blocks, as specified by the block_size MTA option. Note also that the urgentblocklimit channel option may be used to impose such downgrade thresholds on a per-channel basis.

52.32 Message tracking MTA options

New in 8.0 is support for Message Tracking. There are several MTA options relating to Message Tracking.

The log_tracking MTA option enables inclusion of tracking/recall information in MTA message transaction log entries.

The tracking_debug MTA option enables low-level debugging (typically only meaningful to Oracle support) regarding the MTA's message tracking operation.

The ldap_auth_attr_recall_secret MTA option specifies the name of the LDAP attributes where a user's general recall secret is stored.

52.32.1 Tracking hash function usage: tracking_hash_algorithm (hash algorithm name)

The tracking_hash_algorithm MTA option controls what hash algorithm the MTA uses to generate hashes of tracking and recall secrets for use with the MTQP protocol. The value should be a hash algorithm supported by the MTA, one of MD2, MD4, MD5, SHA1, SHA256, SHA512, MD128, or MD160. The default if this option is not specified is SHA1, as required by the MTQP protocol standard.

Important note: As of this writing (February 2020) there is no practical preimage attack on SHA-1, which is what would be required to attack its usage in MQTP. (All known practical attacks are collision attacks, which generate a collision for a known preimage.) As such, the only justification for switching to SHA-2 hash function is to meet compliance requirements, and the benefits of meeting such requirements in the absence of any technical justification must be carefully weighed against the costs of standards incompliance and being incompatible with other MTQP implementations.

52.32.2 Tracking Information Storage (tracking_mode)

The tracking_mode MTA option controls how message tracking information is stored by the MTA. The default value of 0 disables storage of tracking information, while setting tracking_mode to 1 enables storage using a memcached server shared across the deployment. The use of other values is currently restricted.

52.32.3 Tracking Update Retry Control (tracking_retries, tracking_retry_delay)

Tracking information updates can fail because of simultaneous access attempts to the underlying database. If this happens the update can be retried. The tracking_retries MTA option specifies how many times to retry the update. The default is 5 retries.

The tracking_retry_delay MTA option specifies the amount of time to delay between retry attempts in units of centiseconds. The default is 10 centiseconds.

52.33 MeterMaid MTA options

MTA options for setting general MeterMaid configuration parameters were introduced in Messaging Server 7.2-7.02; previously (from MS 6.3-0.15 onwards), only configutil parameters had been available for such settings.

The general MeterMaid configuration metermaid_* MTA options exist to control fundamentals of MeterMaid operation such as the host and port on which MeterMaid is running, *etc*. See also the enable_sieve_metermaid MTA option which permits Sieve filters to use a "metermaid" operator directly.

52.33.1 MeterMaid MTA options: metermaid_backoff (integer)

The metermaid_backoff MTA option specifies the frequency, in seconds, with which the MTA connects to MeterMaid; for MTA purposes, this MTA option if set will override the legacy configuration metermaid.mtaclient.connectfrequency configutil parameter, or its Unified Configuration equivalent, the connectfrequency MeterMaid MTA client option. If neither the MTA option, nor the (legacy configuration) configutil parameter or (Unified Configuration) MeterMaid MTA client option is set, then the default is 15.

52.33.2 MeterMaid MTA options: metermaid_expire (integer)

The metermaid_expire MTA option specifies the idle time, in seconds, that the MTA permits for a connection to MeterMaid; after this time period, the MTA will expire the connection.

52.33.3 MeterMaid MTA options: metermaid_host (hostname)

The metermaid_host MTA option specifies the MeterMaid host for the Sieve metermaid operator. This MTA option if set will override the legacy configuration metermaid.config.serverhost configutil parameter, or its Unified Configuration equivalent, the server_host MeterMaid client option. There is no default.

52.33.4 MeterMaid MTA options: metermaid_port (port)

The metermaid_port MTA option specifies the MeterMaid port for the Sieve metermaid operator. This MTA option is set overrides the legacy configuration metermaid.config.port configutil parameter, or its Unified Configuration equivalent, the port MeterMaid option. If neither the MeterMaid option nor configutil parameter/MeterMaid option is set, then the default is 63837.

52.33.5 MeterMaid MTA options: metermaid_secret (string)

The metermaid_secret MTA option specifies the secret string or strings used to verify MeterMaid communications; for the Sieve metermaid operator, this MTA option if set overrides the legacy configuration metermaid.config.secret configutil parameter, or its Unified Configuration equivalent, the secret MeterMaid option. There is no default.

This option can either contain a single secret or a series of host-secret pairs. In the latter case, the general format is:

```
host1:secret1,host2:secret2,...,hostN:secretN
```

The secret to use is selected by comparing the current Metermaid host with each host pattern on the list until a match is found. Glob-style wildcards can be used in the host patterns.

52.33.6 MeterMaid MTA options: metermaid_timeout (integer)

The `metermaid_timeout` MTA option specifies the timeout, in seconds, for receiving data from MeterMaid; for MTA purposes, this MTA option if set overrides the legacy configuration `metermaid.mtaclient.readwait` configutil parameter, or its Unified Configuration equivalent, the `timeout` MeterMaid MTA client option. If neither the MTA option nor the configutil parameter/MeterMaid MTA client option is set, then the default is 10.

52.34 MLS MTA options

RESTRICTED. Not yet fully implemented.

A couple of MTA options affect MLS (Multi Level Security) processing by the MTA. The main one is `mls`; see also the `ldap_mlsrange` MTA option which specifies the name of the user-level LDAP attribute that stores a user's MLS range, and the `error_text_mls_access_failure` MTA option, which controls the exact error text returned when an MLS access failure occurs.

See also the `mlslabel` and `mlsrange` channel options.

52.34.1 `mls` Option

RESTRICTED. Not yet fully implemented.

52.35 MTQP MTA options

New in the 8.0 release is MTQP (Message Tracking and Query Protocol) support.

52.35.1 MTQP MTA options: `mtqp_port` (port)

New in MS 8.0.

52.35.2 MTQP MTA options: `mtqp_timeout` (integer)

New in MS 8.0.

52.35.3 MTQP MTA options: `mtqp_expire` (integer)

New in MS 8.0.

52.36 Notification message MTA options

The MTA has a number of options relating to notification messages: the timing of their generation, the size of notification messages, the content of notification messages, the postmaster address visible in notification messages, *etc*.

For hosted-domain-specific postmaster addresses, see the `ldap_domain_attr_report_address` MTA option.

For the channel-specific timing of generation of notification messages, see especially the `notices` channel option, as well as the `backoff` channel option.

For detailed discussion of the format of notification messages, see the general discussion under Notification messages.

The return_split_period and return_cleanup_period MTA options control the frequency at which the MTA performs certain tasks related to the MTA return_job. The return_debug and return_verify MTA options enable, respectively, low-level debugging and shell script logging regarding the MTA's return_job.

52.36.1 Notification message and return job options (bounce_block_limit)

The bounce_block_limit MTA option may be used to force bounces of messages over the specified size (number of blocks, as defined via the block_size MTA option) to return only the message headers, rather than the full message content. This overrides any NOTARY (RFC 1891) setting originally present on original messages.

By default, there is essentially no limit; (more precisely, the default is the maximum allowed integer, 2**31-1).

52.36.2 Notification message MTA options: content_return_block_limit (non-negative integer)

The content_return_block_limit MTA option may be used to force on the NOTARY (RFC 1891) non-return of content flag for messages over the specified size (in units of MTA blocks); if such a message is subsequently bounced by a system that supports NOTARY, then the original message contents will not be included in the bounce message. By default, this option is not set and hence entire original messages of arbitrary size potentially may be included in bounce messages; however, even when this option is not set, the MTA will automatically truncate original message content when generating a notification message if a message size limit (*e.g.*, the blocklimit channel option) has been imposed on the relevant destination channel.

This option only applies to messages that do not have their own explicit NOTARY (RFC 1891) setting controlling return of content; when NOTARY has been used, it takes precedence over this option.

52.36.3 Notification message MTA options: history_to_return (1-200)

The history_to_return MTA option controls exactly how many delivery attempt history records are included in returned messages, when return_delivery_history is set to enable such inclusion. The delivery history provides some indication of how many delivery attempts were made and in some cases indicates the reason the delivery attempts failed. The default value for this option is 20.

52.36.4 Notification message MTA options: lines_to_return (integer)

The lines_to_return MTA option controls how many lines of message content the MTA includes when generating a notification message for which it is appropriate to return only a sample of the contents. The default is 20. Note that this option is irrelevant when generating a NOTARY bounce message, where either the full content or merely headers are included, according to the choice specified during the initial submission of the message. So in practice,

this option is mostly only relevant to the warning messages the MTA's return_job sends about messages awaiting further delivery retries in the MTA's message queue area.

Note that setting lines_to_return=0 will cause the warning messages generated by the MTA regarding not-yet-delivered messages to contain only message headers (none of the body of the original message).

52.36.5 Notification message MTA options: notary_decode (-1, 0, or 1)

When the MTA is generating a DSN or MDN and using a %H substitution sequence to insert original message headers into that DSN or MDN, this option controls whether encoded-words (*i.e.*, material in character sets other than US-ASCII) present in the original message header being inserted due to %H are left alone, decoded if already in the character set specified in the return_prefix.txt file or disposition_prefix.txt file being used, or forcibly converted to the return_prefix.txt character set or disposition_prefix.txt character set and *then* decoded. (Note that the character set specified in the return_prefix.txt file is the character set used for the first, human readable portion of the DSN; the character set specified in the disposition_prefix.txt file is the character set used for the first, human readable portion of the MDN.)

The default value is 0, meaning that encoded-words that match the character set specified in the return_prefix.txt file or disposition_prefix.txt file will be decoded; encoded-words in other character sets will be left in literal encoded form. A value of 1 causes encoded-words present in the original message header to be first converted to the character set specified in the return_prefix.txt or disposition_prefix.txt file and *then* decoded; that is, assuming that the character sets are all compatible, all material will be converted and decoded and no encoded-words will be left. A value of -1 disables decoding (and conversion) unconditionally; the original message headers are substituted literally, including the encoded-words in their literal (MIME encoded) form.

Caution should be exercised in setting this option to a value of 1, as information loss can occur, with resultant confusion, when a rich character set such as UTF-8 is converted to a more limited character set (a character set lacking many characters present in the original character set) such as ISO-8859-1 or US-ASCII.

52.36.6 Notification message MTA options: notary_quote (1-127)

The notary_quote MTA option specifies the ASCII representation of the character that marks substitution sequences in return_*.txt files and disposition_*.txt files. It defaults to 25 (the ASCII position of the percent character) so substitutions are %R, %u, *etc.*, as listed in return_*.txt file substitution sequences.

52.36.7 Notification message MTA options: return_address (address)

The return_address option sets the return address for the local Postmaster. By default, the local Postmaster's address is postmaster@localhost, where the localhost corresponds to the msconfig setting of channel:l.official_host_name (which itself typically references the instance.base.hostname setting via a macro substitution). The

return_address MTA option provides a way to override this default with the address of your choice.

Care should be taken in the selection of this postmaster address, as an illegal selection may cause rapid message looping and pile-ups of huge numbers of spurious error messages. See the returnaddress channel option for discussion of overriding this address on a per-channel level, or the ldap_domain_attr_report_address MTA option specifying a domain-level LDAP attribute which can be used to override this address on a per-domain basis. See also the return_personal MTA option, which sets the Postmaster's personal name (as opposed to their actual mailbox address).

52.36.8 Notification message MTA options: return_delivery_history (0 or 1)

The return_delivery_history MTA option controls whether or not a history of delivery attempts is included in returned messages. The delivery history provides some indication of how many delivery attempts were made and in some cases indicates the reason the delivery attempts failed. A value of 1 enables the inclusion of this information and is the default. A value of 0 disables return of delivery history information. The history_to_return MTA option controls how much history information is actually returned.

52.36.9 Notification message MTA options: return_envelope (bitmask)

The return_envelope MTA option takes a bitmask value.

Bit 0 (value = 1) controls whether or not return notifications generated by the MTA are written with a blank envelope address *vs.* with the address of the local postmaster. Setting the bit forces the use of the local postmaster address, while clearing the bit forces the use of a blank address. Note that the use of a blank address is mandated by RFC 1123. However, some systems do not handle blank envelope From addresses properly and may require the use of this option.

Bit 1 (value = 2) controls whether or not the MTA replaces all blank envelope addresses with the address of the local postmaster. Again, this is used to accomodate incompliant systems that don't conform to RFC 821, RFC 822, or RFC 1123.

Bit 2 (value = 4) controls whether or not the MTA checks that any (non-empty) envelope From address matches (rewrites to) an MTA channel.

Setting bit 3 (value = 8) is the global (for all channels) equivalent of setting the mailfromdnsverify channel option: it controls whether or not the MTA checks that the domain in the envelope From address resolves in the DNS. That is, setting the bit causes the MTA to require that a DNS entry can be found corresponding to the domain in the envelope From address; but the type of DNS entry does not matter.

Setting bit 4 (value = 16) causes the MTA to enforce that if the envelope From address claims a local domain name, the envelope From address must correspond to a user address (user alias).

New in 8.0, bit 6 (value = 64) modifies the effect of setting bit 3 (value = 8) on domain validity checks. With both these bits set, if the domain in the MAIL FROM address corresponds to a null MX domain, that address will be rejected as invalid. That is, setting bit 6 causes the bit 3 domain check to also implement support for draft-delany-nullmx-01.txt.

Note also that the returnenvelope channel option can be used to impose these sorts of control on a per-channel basis.

52.36.10 Notification message MTA options: return_personal (RFC 2047 encoded string)

The return_personal option specifies the personal name to use when the MTA generates postmaster messages, *e.g.*, bounce messages. By default, the MTA uses the string "Internet Mail Delivery". The global return_personal value can be overridden on a per-channel basis via the returnpersonal channel option, which itself in turn can be overridden on a language-specific basis, via a language-specific return_option.opt file RETURN_PERSONAL option setting.

52.36.11 Notification message MTA options: return_units (0 or 1)

The time unit used by the message return system is controlled with the return_units MTA option; that is, this option controls the interpretation of the values specified for the notices channel option. A value of 0 selects units of days; a value of 1 selects units of hours. By default, units of days are used.

On UNIX systems, the scheduling of the execution of the message return_job is controlled by the Scheduler. In particular, with a Unified Configuration it is the schedule.task:return_job.crontab option that controls how frequently the return_job runs: this defaults to:

```
30 0 * * * lib/return_job
```

The argument is in UNIX crontab format,

minutes hour day-of-month month-of-year day-of-week script

so the default is to run the return_job every day at 30 minutes after midnight.

In legacy configuration mode (so in versions prior to 7.0.5), the scheduling of the return_job was controlled via the configutil parameter local.schedule.return_job, which had a default of

```
30 0 * * * SERVERROOT/lib/return_job
```

with the same sort of UNIX crontab format argument.

Note: Prior to MS 6.0, the scheduling of the execution of the message return job was controlled by the Job Controller configuration, an approach that is now deprecated. With that approach, the scheduling was controlled by the Job Controller's time option in the [periodic_job=return] section of the job_controller.cnf file. For instance, to have the return job run hourly at thirty minutes past the hour, it would be set

```
[periodic_job=return]
command=IMTA_EXE:return.sh
time=00:30/1:00
```

Note that if you choose to set the return_units MTA option to a value of 1, then you will likely also need (or want) to adjust other options such as those controlling MTA transaction log file rollover.

52.36.12 Notification message MTA options: use_precedence (0 or 1)

The use_precedence MTA option controls whether or not the MTA makes use of the information contained in Precedence: header lines when deciding whether to send a delayed delivery notification message. With use_precedence set to 1, the default, such warning messages are not sent for messages with precedence "bulk" or "list". To instead have the MTA return_job ignore the Precedence: header line, set use_precedence to 0.

52.36.13 Notification message MTA options: use_warnings_to (0 or 1)

DELETED. With the advent of standardized notification handling, this option was deprecated and is now deleted.

The use_warnings_to MTA option controls whether or not the MTA makes use of the information contained in Warnings-to: header lines when returning messages. Setting this option to 1 directs the MTA to make use of these header lines. The default is 0, which disables use of this header line. Note that this default represents a changes from the default in early versions of PMDF.

52.37 Password and TLS MTA options

There are a few options affecting the MTA's overall handling of authentication, and TLS.

For channel-level configuration, see also TLS and SASL channel options.

And for general Messaging Server configuration of authentication, SSL/TLS use, and certificate handling, see the Auth options, various base.auth*, base.ssl*, and base.tls* options (and for LDAP connections, the ugldapusessl and ldaprequiretls base options), the Base certmap options, and the sectoken options.

52.37.1 plaintextmincipher Option Under mta

If the plaintextmincipher MTA option is > 0, then disable use of plaintext passwords unless a security layer (SSL or TLS) is activated. This forces users to enable SSL or TLS on their client to login, which prevents exposure of their passwords on the network. This option in the mta group presently also applies to the MTQP and ManageSieve servers.

52.37.2 smtpproxypassword Option

The submit proxy and this option have been removed from the Messaging Server 8.1 (tezpur) release.

The smtpproxypassword option specifies the password the MMP uses to authorize source channel changes on the SMTP relay servers. This option is available under mta,

submitproxy, and vdomain. To use this functionality, that is, to use the MMP's SMTP SUBMIT Proxy, the option must be set under mta on the MTA back end, and must be set for the MMP's SMTP SUBMIT Proxy (thus under either submitproxy if being set in general, or under vdomain if it is only to be applied for a particular virtual domain) on a front end MMP system, and **these values must match** between front and back ends! The option has no default.

If the mta.smtpproxypassword option is not set, client attempts to use the XPEHLO command will receive an error (issued by the MTA SMTP server):

```
503 5.5.0 Proxy support is not enabled.
```

If mta.smtpproxypassword is set but its value does not match the MMP's value, client attempts to use the XPEHLO command will receive an error (issued by the MTA's SMTP server):

```
535 5.7.8 SMTP proxy authentication check failed.
```

Note that the legacy configuration equivalent of the Unified Configuration mta.smtpproxypassword option was the PROXY_PASSWORD TCP/IP-channel-specific option (which in legacy configuration, was set in the SMTP server's TCP/IP channel option file). (The MTA option smtpproxypassword was introduced in MS 7.0u5.) And the legacy configuration equivalent of the Unified Configuration submitproxy.smtpproxypassword option (as well as the vdomain.smtpproxypassword option) was set as SmtpProxyPassword in the SmtpProxyAService.cfg file.

52.37.3 sslnicknames Option Under mta

The sslnicknames MTA option specifies a list of SSL/TLS server certificate nicknames (only one per certificate type) for MTA to offer clients if TLS is enabled. Overrides for the MTA the base level sslnicknames option (corresponding to the legacy configuration encryption.rsa.nssslpersonalityssl configutil parameter). This option in the mta group presently also applies to the MTQP and ManageSieve servers.

52.38 Processing priority MTA options

A few general MTA options affect message processing priority.

See also the log_mtpriority and log_priority MTA option which control, respectively, whether MTPRIORITY and effective processing priority are included in MTA message transaction log file entries. See also the use_precedence MTA option which controls whether Precedence: header lines affect generation of delivery delay notifications. See also the defer_group_processing MTA option which influences whether group expansion is performed "in-line" or "off-line" (by the Reprocess channel).

For additional influences on processing priority, see also the holdlimit channel option, and Job Controller priority-based processing, and the Sieve setpriority and setmtpriority extensions.

52.38.1 Message Transfer Priority Policy: mtpriority_policy (string)

New in 8.0. The mtpriority_policy MTA option is used to specify a policy name for the handling of message transfer priorities the MTA has been configured to support. This name is announced in the SMTP EHLO response on any channel where the MT-PRIORITY extension is enabled. The default is that this option is not set, which means that no policy is announced.

Note that the MTA's Priority Assignment Policy is as follows: MT-PRIORITY values of -9,..,-4 are mapped to "non-urgent" priority; MT-PRIORITY values of -3,..,3 are mapped to "normal" priority; MT-PRIORITY values of 4,..,9 are mapped to "urgent" priority. An explicit MT-PRIORITY value specified on a submitted message will override the MTA's older priority (*e.g.*, Priority: header line based) handling, as well as any of the MTA's older size-based priority override adjustments (*e.g.*, non_urgent_block_limit, *etc.*). (However, a Sieve filter setmtpriority action can override even an explicit MT-PRIORITY value.) Messages that come in without an explicitly specified MT-PRIORITY are subject to the MTA's older priority handling, and for MT-PRIORITY purposes (such as mapping table probes including MT-PRIORITY value) will be considered to have an MT-PRIORITY value of 0.

Note that the MTA's Priority Assignment Policy, described above, is essentially that of the "MIXER" Priority Assignment Policy defined in Appendix B of RFC 6710 -- this is a natural mapping for the MTA as its older Priority: header support was similarly based on RFC 2156 (MIXER: Mapping between X.400 and RFC 822/MIME).

52.38.2 Size effects of message priority MTA options: non_urgent_block_limit (integer), normal_block_limit (integer), second_class_block_limit (integer), urgent_block_limit (integer)

Note that as of the 8.0 release, these size-based priority override MTA option effects are nullified if the MT-PRIORITY SMTP extension has been used to set an explicit priority value.

52.38.2.1 non_urgent_block_limit

The non_urgent_block_limit MTA option may be used to instruct the MTA to downgrade the priority of messages based on size: messages above the specified size will be downgraded to lower than non-urgent priority, meaning that they will not be processed immediately and will wait for processing until the next periodic delivery run. The value is interpreted in terms of MTA blocks, as specified by the block_size MTA option. Note also that the nonurgentblocklimit channel option may be used to impose such downgrade thresholds on a per-channel basis.

52.38.2.2 normal_block_limit

The normal_block_limit MTA option may be used to instruct the MTA to downgrade the priority of messages based on size: messages above the specified size will be downgraded to non-urgent priority. The Job Controller automatically pays attention to message effective processing priority when scheduling delivery attempts. The value is interpreted in terms of MTA blocks, as specified by the block_size MTA option. Note also that the normalblocklimit channel option may be used to impose such downgrade thresholds on a per-channel basis.

52.38.2.3 second_class_block_limit

The second_class_block_limit MTA option may be used to instruct the MTA to downgrade the priority of messages based on size: messages above the specified size will be downgraded to third class priority. The value is interpreted in terms of MTA blocks, as specified by the block_size MTA option. Note also that the secondclassblocklimit channel option may be used to impose such downgrade thresholds on a per-channel basis.

52.38.2.4 urgent_block_limit

The urgent_block_limit MTA option may be used to instruct the MTA to downgrade the priority of messages based on size: messages above the specified size will be downgraded to normal priority. The Job Controller automatically pays attention to message effective processing priority when scheduling delivery attempts. The value is interpreted in terms of MTA blocks, as specified by the block_size MTA option. Note also that the urgentblocklimit channel option may be used to impose such downgrade thresholds on a per-channel basis.

52.39 Received header line MTA options

The MTA has a number of options related to Received: header lines and message-ids, and relating to the MTA's facility to sideline as .HELD files those messages that appear to be looping.

52.39.1 Syslog MTA options: held_sndopr (0 or 1)

The held_sndopr MTA option controls the production of syslog messages (on UNIX) when a message is forced into a held state due to certain suspicion thresholds. (Note that there are other potential causes of messages becoming .HELD, which are *not* covered by held_sndopr -- cases corresponding to explicit MTA administrator action such as execution of a imsimta qclean command, or cases where the held state can be logged as part of normal logging, such as execution of a Sieve filter hold action, either in an explicit Sieve filter or as a Sieve scriptlet executed due to a spam/virus filter package verdict, or application of an address-based *_ACCESS mapping table $H flag where syslog message generation can be performed via $< flag, or routing to the hold channel due to a user status or domain status of hold. held_sndopr is meant to warn of cases that might otherwise be easier to miss noticing, especially for unanticipated incoming problem messages.)

Suspicious cases where held_sendopr causes a syslog message include:

- A message may be forced into a held state because it has too many Received: header lines (see the various max_*received_lines MTA options for additional information):

```
HELDMSG, Header count exceeded; message has been marked .HELD automatically.
```

- Or a message may be forced into a held state because it has too many recipients (see the holdlimit channel option for more details):

```
HELDMSG, Max recipient count exceeded; message has been marked .HELD automatically.
```

- Or a message may be forced into a held state because it has too many MIME parts or levels (see the max_mime_levels and max_mime_parts MTA options):

```
HELDMSG, Max MIME part/level limit exceeded; message has been marked .HELD automatically.
```

A value of 1 for held_sndopr instructs the MTA to issue such messages when such cases occur. A value of 0 (the default) turns off these messages. The syslog messages will be issued using the configured sndopr_priority facility and severity.

52.39.2 Message-id: domain name MTA option: id_domain (string)

The id_domain MTA option specifies the domain name to use when constructing message IDs. If this option is not explicitly set (which is the default), then the official host name of the local channel is used.

52.39.3 Received header line MTA options: max_local_received_lines (integer)

As the MTA processes a message, it scans any Received: header lines attached to the message looking for references to the official local host name. (Any Received: line that the MTA inserts will contain this name). If the number of Received: lines containing this name exceeds the max_local_received_lines value, the message is entered into the MTA destination channel queue area in a held state. This check blocks certain kinds of message forwarding loops. The message must be manually moved from the held state for processing to continue. The default for max_local_received_lines is 10.

52.39.4 Received header line MTA options: max_mr_received_lines (integer)

As the MTA processes a message, it counts the number of MR-Received: header lines in the message's header. (MR-Received: header lines are added to messages processed by a PMDF-MR gateway.) If the number of MR-Received: lines exceeds the max_mr_received_lines value, the message is entered into the MTA destination channel queue area in a held state. This check blocks certain kinds of message forwarding loops. The message must be manually moved from the held state for processing to continue. The default for max_mr_received_lines is 20.

52.39.5 Received header line MTA options: max_received_lines (integer)

As the MTA processes a message, it counts the number of Received: header lines in the message's header. If the number of Received: lines exceeds the max_received_lines value, the message is entered into the MTA destination channel queue area in a held state. This check blocks certain kinds of message forwarding loops. The message must be manually moved from the held state for processing to continue. The default for max_received_lines is 50.

52.39.6 Received header line MTA options: max_total_received_lines (integer)

As the MTA processes a message, it counts the number of Received:, MR-Received:, X400-Received: header lines in the message's header. If the number of all such header lines exceeds the max_total_received_lines value, the message is entered into the MTA destination channel queue area in a held state. This check blocks certain kinds of message forwarding loops. The message must be manually moved from the held state for processing to continue. The default for max_total_received_lines is 100.

52.39.7 Received header line MTA options: max_x400_received_lines (integer)

As the MTA processes a message, it counts the number of X400-Received: header lines in the message's header. (X400-Received: header lines are added to messages processed by a PMDF-X400, PMDF-MB400, or other X.400-to-Internet e-mail gateway.) If the number of Received: lines exceeds the max_x400_received_lines value, the message is entered into the MTA destination channel queue area in a held state. This check blocks certain kinds of message forwarding loops. The message must be manually moved from the held state for processing to continue. The default for max_x400_received_lines is 50.

52.39.8 Received header line MTA options: received_domain (string)

The received_domain MTA option sets the domain name for the SMTP server to use when constructing Received: header lines (and Date-Warning: header lines). By default, the offical host name of the local channel is used, channel:l.official_host_name. Note that this MTA option does not apply to the Received: header lines generated by other channels; in particular, it does not apply to Received: header lines resulting from a pass through an intermediate channel (such as a process, reprocess, or conversion channel). In such cases, the channel official host name---suffixed with the official host name for the local channel, in the case of short form names---will be used.

If there is no ldap_default_domain set, then received_domain is also the value that a Sieve environment "domain" will return. (If neither ldap_default_domain nor received_domain is set, then the MTA falls back to the L channel's official host name.)

52.39.9 Received header line MTA options: received_version (string)

RESTRICTED: Use of this option is not recommended.

The received_version MTA option sets the MTA version string to use when the MTA constructs Received: header lines. By default, if this option is not set, an internally constructed string is used that incorporates correct, current MTA version data.

Thus this option is the complement of the (also not recommended) custom_version_string TCP/IP channel option.

52.40 Redis MTA options

New in the 8.0.2.3 release, the MTA supports use of the Redis protocol for certain database/storage uses. redis.* options control the MTA's connections to Redis. The *_database_url

MTA options, when set to redis: URL values, configure use of Redis to store MTA databases. See also the enable_sieve_redis MTA option, which enables Sieve filter use of a redis operator in Sieve scripts.

New in the 8.1.0.1 release, support has been added for Redis Sentinel. The redis.servicename option must be specified in addition to configuring Redise Sentinel to enable Sentinel support; when this is done the redis.hostlist and port options should not be specified.

52.40.1 hostlist Option Under redis_client

The hostlist redis option specifies a space separated list of Redis server hosts. The host format is *host*[:*port*]. If *port* is not specified, the port number is determined based on the setting of the redis.port option.

52.40.2 port Option Under redis_client

The portredis option specifies the Redis server default port. If the *port* is not specified in redis.hostlist, the port defaults to this value.

52.40.3 authpassword Option Under redis_client

The authpassword Redis option sets the password that will be used for authentication when communicating with Redis servers.

52.40.4 hostlist Option Under sentinel_client

The hostlist sentinel option specifies a space separated list of Redis Sentinel server hosts. The host format is *host*[:*port*]. If *port* is not specified, the port number is determined based on the setting of the sentinel.port option.

52.40.5 port Option Under sentinel_client

The portsentinel option specifies Redis Sentinel server default port. If the *port* is not specified in sentinel.hostlist, the port number defaults to this value.

52.40.6 authpassword Option Under sentinel_client

The authpassword Redis Sentinel option sets the password that will be used for authentication when communicating with Redis Sentinel servers.

52.40.7 hostlist Option Under redis

The hostlist redis option specifies a space separated list of Redis server hosts. The host format is *host*[:*port*]. If *port* is not specified, the port number is determined based on the setting of the redis.port option.

52.40.8 port Option Under redis

The portredis option specifies the Redis server default port. If the *port* is not specified in redis.hostlist, the port defaults to this value.

52.40.9 authpassword Option Under redis

The authpassword Redis option sets the password that will be used for authentication when communicating with Redis servers.

52.40.10 hostlist Option Under sentinel

The hostlist sentinel option specifies a space separated list of Redis Sentinel server hosts. The host format is *host*[:*port*]. If *port* is not specified, the port number is determined based on the setting of the sentinel.port option.

52.40.11 port Option Under sentinel

The portsentinel option specifies Redis Sentinel server default port. If the *port* is not specified in sentinel.hostlist, the port number defaults to this value.

52.40.12 authpassword Option Under sentinel

The authpassword Redis Sentinel option sets the password that will be used for authentication when communicating with Redis Sentinel servers.

52.41 Sieve filter MTA options

A number of MTA options affect the interpretation of Sieve filters and Sieve filter actions, enable or disable optional Sieve extensions or impose limits on Sieve features or structures, control the availability and operation of the Sieve duplicate extension, or affect the period between repeating autoresponse messages, tune caching of parsed Sieve filters, enable or disable Sieve filter result logging, modify error text issued in cases of Sieve filter access or processing errors, or enable Sieve filter processing debugging.

For Sieve filter processing by external (external-to-the-MTA) components such as imexpire, whether using Sieve rules for normally scheduled message expiration (see the expiresieve Message Store option), or subsequent-to-delivery spam/virus filtering using imexpire, see also the External filtering context MTA options.

52.41.1 systemfilter Option

The systemfilter MTA option takes a Sieve filter as its value, referred to as the MTA system Sieve filter. (In legacy configuration, this Sieve was stored in the IMTA_TABLE:imta.filter file.) Normally, this Sieve filter will be applied to every message processed by the MTA, at every enqueue; but see the disabledestinationfilter and disablesourcefilter channel options which can disable application of selected Sieve filters on a per-channel basis.

Because the MTA system Sieve filter, like channel filters, is controlled by the MTA administrator rather than by users, certain Sieve features are available to it not normally available to users.

Note that because the MTA system Sieve filter is applied so frequently (normally to every message, at every enqueue), it is particularly important that it be a well-written, efficient Sieve filter.

Note that a summary of the Sieve actions performed upon a message, whether from the `systemfilter` MTA system Sieve filter or any other Sieve applying to a message, may be recorded in the MTA message transaction log file by enabling the `log_filter` MTA option. This is truly a summary of what was *performed*; it will not show actions that were superceded or considered but not performed.

Since the MTA system filter typically consists of more than one line of text, its value cannot be easily set using the msconfig set command. The `edit filter` command can be used for manual editing of the system filter and the recipe language `set_option` function should be used for automating filter updates.

52.41.2 Sieve filter interpretation MTA options

The MTA has several options that modify the "meaning" or "effect" (that is, the interpretation) of Sieve filters:

- `decode_encoded_words` -- Decode encoded words during Sieve processing
- `defer_header_addition` -- (New in Messaging Server 7.0.5.31.0) Defer addition of headers upon `redirect` action
- `filter_discard` -- Delete discarded messages immediately *vs.* delayed
- `filter_jettison` -- Delete jettisoned messages immediately *vs.* delayed
- `notify_ignore_errors` -- Whether Sieve `notify` action invalid recipients cause an abort with an error, or are silently ignored
- `sieve_received` -- Sieve filters can see (an approximation of) the Received: header line that the MTA is about to add
- `sieve_redirect_add_resent` -- Whether Sieve `redirect` actions add Resent-* header lines
- `sieve_user_carryover` -- Whether user Sieve filters carry over when forwarding

52.41.2.1 Sieve filter interpretation MTA options: `decode_encoded_words` (integer)

RESTRICTED.

Control some decoding of encoded words during Sieve processing. The default value is `7`.

52.41.2.2 Sieve filter interpretation MTA options: `defer_header_addition` (0 or 1)

The `defer_header_addition` MTA option controls whether Sieve filters see headers added to messages prior to Sieve processing. This includes, but is not limited to, headers added by list expansion processing. In older versions, such added headers would not be visible to Sieve filters. This option was added for Messaging Server 7.0u5p31 with a default of `0`, meaning that added headers *are* seen by Sieve filters; setting the option to `1` restores the older behavior (where such added headers are not visible to Sieve filters on redirected messages).

Prior to the 8.0 release, Sieve "redirect" used deferred reprocessing and thus any headers added to a redirected message were affected by this option. As of 8.0 Sieve "redirect" queues to the process channel and this option no longer has any effect on header visibility in redirected messages.

52.41.2.3 Sieve filter interpretation MTA options: filter_discard (1 or 2)

The filter_discard MTA option controls whether Sieve filter "discard" actions cause such discarded messages to go to the bitbucket channel ((*i.e.*, be immediately discarded), or cause such messages to go to the filter_discard channel (which will leave them around for a short period before discarding them). The default is 1, meaning that messages discarded by a Sieve filter are immediately discarded. Setting this option to 2 causes discarded messages to instead be routed to the filter_discard channel.

52.41.2.4 Sieve filter interpretation MTA options: filter_jettison (1 or 2)

New in MS 6.1-0.01. The filter_jettison MTA option controls whether Sieve filter "jettison" actions cause such discarded messages to go to the bitbucket channel (*i.e.*, be immediately deleted), or cause such messages to go to the filter_discard channel (which will leave them around for a short period before deleting them). If this option is not explicitly set, it defaults to the value of the filter_discard MTA option. Since the default is filter_discard=1, then the default for jettisoned messages is also that such messages are immediately discarded. Setting filter_jettison=2 (or if filter_jettison is not set at all, setting filter_discard=2) causes jettisoned messages to instead be routed to the filter_discard channel.

52.41.2.5 Sieve filter interpretation MTA options: notify_ignore_errors (0 or 1)

The notify_ignore_errors MTA option specifies whether specifying an invalid notification recipient address in a Sieve "notify" action will cause Sieve filter evaluation to abort with an error (0) or cause the notify action to be silently ignored (1). 0 is the default.

52.41.2.6 Sieve access to local Received: field sieve_received

Sieve scripts are necessarily evaluated after messages are received but before messages are enqueued to specific recipients. The MTA tries to include as much information in Received: fields as possible, which means deferring Received: field generation until the actual enqueue operation is performed. This means that Sieve scripts are not able to "see" the outermost Received: field that appears on the message.

Although most of the information in the outermost Received: field is available through other means, not all of it is, and even if it is available it may not be convenient to access it through other mechanisms. So the MTA normally adds reasonable approximation to the final Received: field to the message header prior to Sieve script evaluation. This addition is controlled by the sieve_received MTA option. A value of 1 (the default) enables the addition of this Received: field while a value of 0 disables it.

52.41.2.7 Sieve filter interpretation MTA options: sieve_redirect_add_resent (0 or 1)

New in 6.3P1. The `sieve_redirect_add_resent` MTA option sets the MTA system default for whether Sieve "`redirect`" actions cause addition of Resent-* header lines. The default for this option is 1, meaning to add Resent-Date:, Resent-To:, and Resent-From: header lines when performing a "`redirect`". This MTA system default may be overridden on a per-action basis using the "`:resent`" and "`:noresent`" arguments to "`redirect`". That is, setting `sieve_redirect_add_resent=1` causes these fields to be generated unless "`:noresent`" is used; whereas setting `sieve_redirect_add_resent=0` causes the fields to be generated only if "`:resent`" is used.

52.41.2.8 Sieve filter MTA options: `reject_disables_capture` (0-2)

As of Messaging Server 8.0.1.2, if `reject_disables_capture` is set to 0 (the default), then capture and journal actions will be honored even when a message has been rejected at the sieve level by all recipients. Note that this will prevent promotion of the reject action(s) to an SMTP-level error, causing DSNs to be sent.

Setting this option to 1 will cause capture and journal actions to be canceled in this case, allowing promotion of the error to an SMTP-level response.

As of 8.0.1.3, setting this option to 2 will cause cancellation of any capture and journal actions associated with a rejected recipient address. Each recipient address is considered separately in determining whether or not to cancel these actions. Note that this only applies to capture and journal actions triggered by LDAP attributes; sieve capture and journal actions are not cancelled.

52.41.2.9 Sieve filter MTA options: `discard_disables_capture` (0-2)

As of Messaging Server 8.0.1.3, if `discard_disables_capture` is set to 0 (the default), then capture and journal actions will be honored for recipients for whom the message has been discaded and thus never actually received the mail.

Setting this option to 1 will cause capture and journal associated with such recipients to be canceled.

52.41.2.10 Sieve filter MTA options: `sieve_user_carryover` (0 or 1)

New in MS 6.0-0.01. The default is 0. If set to 1, user Sieve filters don't "carry over" when doing `mailDeliveryOption: forward`. This option is only relevant for direct LDAP forwarding (forwarding via `mailDeliveryOption` and `mailForwardingAddress`); it does not have any effect on other forms of forwarding.

52.41.2.11 Sieve filter MTA options: `sieve_mime_needed` (0 or 1)

MIME message analysis is only performed when necessary and only retains necessary information. However, the serial nature of MTA operations means that subsequent operations may require additional information, forcing the MTA to analyze the message multiple times.

The `sieve_mime_needed` MTA option controls whether or not MIME structure and header information is retained on the first message analysis pass, even if the information is not needed

immediately. A setting of 1 causes the information to be retained, 0 causes it to be discarded. The default is 1.

Saving this information may avoid having to perform another analysis pass. On the other hand, saving the information consumes memory and is wasteful when the information is not likely to be needed.

52.41.2.12 Sieve filter MTA options: `sieve_body_needed` (0 or 1)

MIME message analysis is only performed when necessary and only retains necessary information. However, the serial nature of MTA operations means that subsequent operations may require additional information, forcing the MTA to analyze the message multiple times.

The `sieve_body_needed` MTA option controls whether or not MIME body content information is retained on the first message analysis pass, even if the information is not needed immediately. Note that this information is only used by Sieve body tests. A setting of 1 causes the information to be retained, 0 causes it to be discarded. The default is 0.

Saving this information may avoid having to perform another analysis pass. On the other hand, saving the information consumes considerable memory and is wasteful when no sieve body tests are being performed.

52.41.3 Sieve filter limit MTA options

The MTA has configurable limits on how many of various Sieve actions can be applied in a Sieve filter, and on the size of certain Sieve constructs.

52.41.3.1 Sieve filter limit MTA options: `max_addheaders` (integer >= 0)

The `max_addheaders` MTA option sets the maximum number of Sieve "`addheader`" actions that can be performed in a single Sieve script. The default is 10. As of the 8.0 release, this limit only applies to user-level Sieves.

52.41.3.2 Sieve filter limit MTA options: `max_duplicates` (integer >= 0)

The `max_duplicates` MTA option specifies the maximum number of Sieve "`duplicate`" tests that may be performed by a Sieve script. The default is 2.

52.41.3.3 Sieve filter limit MTA options: `max_fileintos` (integer >= 0)

The `max_fileintos` MTA option specifies the maximum number of Sieve "`fileinto`" actions that may be performed by a Sieve script. The default is 10. As of the 8.0 release, this limit only applies to user-level Sieves.

52.41.3.4 Sieve filter limit MTA options: `max_notifys` (integer >= 0)

The `max_notifys` MTA option specifies the maximum number of "`notify`" actions that may be performed by a Sieve script. The default is 0, meaning that "`notify`" actions cannot be used.

New in 7.0.5, `max_notifys` is checked when processing Sieve "`require`" and "`ihave`" clauses; if such a clause is being applied on "`notify`", the clause will fail if `max_notifys=0` is set.

52.41.3.5 Sieve filter limit MTA options: `max_redirect_addresses` (non-negative integer)

The `max_redirect_addresses` MTA option specifies how many addresses to read in from an external list used in a Sieve"`redirect`" action; additional addresses will be ignored, without an error. (See Sieve external lists for a discussion of external list use in "`redirect`" actions.) The default for `max_redirect_addresses` is 128.

52.41.3.6 Sieve filter limit MTA options: `max_redirects` (integer >= 0)

The `max_redirects` MTA option specifies the maximum number of "`redirect`" actions that may be performed by a Sieve script; *i.e.*, the maximum number of (Sieve script caused) forwards that may be performed. The default is 32. As of the 8.0 release, this limit only applies to user-level Sieves.

52.41.3.7 Sieve filter limit MTA options: `max_sieve_list_size` (0 < integer <= 16,384)

The `max_sieve_list_size` MTA option specifies the maximum number of elements that may appear in a Sieve string-list structure (that is, strings listed within square brackets, `[`*(string)*`]`) inside a Sieve script.

The default is 64; allowed values are integers greater than 0 and less than or equal to 16384; (in MS 7.0.5 and earlier, the upper limit was 10000).

If a Sieve filter attempts to use more elements in a string list than this option allows, Sieve filtering will be aborted (the message being processed will be delivered normally though without Sieve filtering being applied), and the MTA will also generate a notification message to the Sieve owner -- the postmaster for system Sieve filters (`systemfilter` and channel filters), as well as for Sieve filters specified on groups or lists in the aliases file or via alias options, or the user whose Sieve has the error for a user's own Sieve filter. The notification message will be constructed using the `return_error.txt` file, and will include as reason/status text "`Error in sieve filter: List too large`".

52.41.3.8 Sieve filter limit MTA options: `max_sieve_match_iterations` (0 < integer <= 2147483647)

The `max_sieve_match_iterations` MTA option specifies the maximum number of iterations the internal code handling the :matches construct will attempt.

The default is 1,000,000,000; allowed values are integers greater than 0 and less than or equal to 2147483647.

If a :matches operation attempts to perform more than the allowed number of iterations, Sieve filtering will be aborted (the message being processed will be delivered normally though without Sieve filtering being applied), and the MTA will also generate a notification message to the Sieve owner -- the postmaster for system Sieve filters (`systemfilter` and channel

filters), as well as for Sieve filters specified on groups or lists in the aliases file or via alias options, or the user whose Sieve has the error for a user's own Sieve filter. The notification message will be constructed using the `return_error.txt` file, and will include as reason/status text "`Error in sieve filter: Too many iterations in :matches`".

52.41.3.9 Sieve filter limit MTA options: `max_sieve_string_size` (0 < integer <= 10,000,000)

The `max_sieve_string_size` MTA option specifies the maximum number of characters that may appear in a Sieve string. This includes both string constants, variables, and internally computed string values. The default is 65536; allowed values are integers greater than 0 and less than or equal to 10,000,000.

If a Sieve filter attempts to use more characters in a string than this option allows, Sieve filtering will be aborted (the message being processed will be delivered normally though without Sieve filtering being applied), and the MTA will also generate a notification message to the Sieve owner -- the postmaster for system Sieve filters (`systemfilter` and channel filters), as well as for Sieve filters specified on groups or lists in the aliases file or via alias options, or the user whose Sieve has the error for a user's own Sieve filter. The notification message will be constructed using the `return_error.txt` file.

Note that prior to the 8.0 release if a Sieve script enables variables, then Sieve Strings are further limited, with hard-coded truncation (with no error message) being performed at 8192 characters. As of 8.0, the `max_sieve_string_size` option's value is used as intended, even when variables are enabled.

52.41.3.10 Sieve filter limit MTA options: `max_vacations` (integer >= 0)

The `max_vacations` MTA option specifies the maximum number of Sieve "`vacation`" actions that may be performed by a Sieve script. The default is 2.

Exceeding the allowed number of `vacation` actions will result in an error "Too many vacations specified" during Sieve filter evaluation.

New in 7.0.5, `max_vacations`is checked when processing Sieve "`require`" and "`ihave`" clauses; if such a clause is being applied on "`vacation`", the clause will fail if `max_vacations=0` is set.

52.41.3.11 Sieve filter limit MTA options: `max_variables` (integer >= 0)

The `max_variables` MTA option specifies the maximum number of variables that may be used in a Sieve script. The default is 128.

Attempting to use more variables than allowed will result in an error during Sieve evaluation, "No room in table for variable: *variable-name*".

52.41.4 Sieve filter caching MTA options

At the intersection between Sieve filter processing and MTA caching of fetched data, are a couple of MTA options.

52.41.4.1 LDAP lookup cache MTA options: `filter_cache_size` (integer) and `filter_cache_timeout` (integer)

The MTA maintains a per-process cache of tokenized (*i.e.*, parsed but not yet evaluated) Sieve filters. This cache applies both to Sieve filters fetched from LDAP (*e.g.*, from `mailSieveRuleSource` and `mailDomainSieveRulesource` LDAP attributes, or more precisely from whatever LDAP attributes are named by the `ldap_filter` and `ldap_domain_attr_filter`\ MTA options), and to Sieve filters directly configured into the MTA such as channel filters. The `filter_cache_size` MTA option specifies the size of this cache; the default is 500. The `filter_cache_timeout` option specifies the retention time, in seconds, for entries in this cache; the default is 600.

52.41.5 Sieve language extension MTA options

Normally, Sieve extensions are enabled in individual Sieve scripts via use of the standard Sieve `require` action; and for convenience in combining Sieve scripts, the MTA by default is lenient in permitting use of multiple `require` clauses (but see the `strict_require` MTA option). However, for a few special cases of potentially computationally "expensive" actions, the MTA permits the mail system administrator to restrict enabling these extensions. Also see the Sieve filter limit MTA options, as setting the maximum allowed number of some types of action to 0 effectively disables use of that action. And see the Sieve filter interpretation MTA options which can modify how certain Sieve operations are interpreted or performed.

52.41.5.1 Sieve language extension MTA options: `enable_sieve_body` (0-2)

(New in Messaging Server 7.0u2) This option controls whether Sieve filters may use the body extension. The default value is 0, meaning that body is not available. A value of 1 allows body to be used in any Sieve script. A value of 2 allows body to be used in system-level Sieves only.

52.41.5.2 Sieve language extension MTA options: `enable_sieve_ereject` (0-2)

(New in 7.2-7.02.) The Sieve "`ereject`" extension defined in RFC 5429 is designed to be used to reject spam. Because of this it is only supposed to be available on ingress MTAs capable of returning an SMTP level error directly to a remote systems in other administrative domains. Ereject is not supposed to be available on internal MTAs incapable of sending a direct SMTP response because it's use on such systems can produce blowback spam.

The `enable_sieve_ereject` option provides the means to disable "`ereject`" on internal systems. A value of 1, the default, enables the use of "`ereject`" in all scripts. A value of 0 disables it; when `enable_sieve_ereject=0` is set, a Sieve script statement of '`require "ereject";`' will be ignored.

52.41.5.3 Sieve language extension MTA options: `enable_sieve_memcache` (0-2)

New in the 8.0 release. The `enable_sieve_memcache` MTA option controls whether Sieve filters may use the `memcache` operator to access and manipulate stored data using the memcache protocol. A value of `0` disables the use of `memcache` in all Sieve scripts. The default

value is 1, meaning that memcache may be used in any Sieve script. A value of 2 allows memcache to be used in system-level Sieves only.

When enable_sieve_memcache is set to 0, then any attempt to use memcache will result in a Sieve error "Memcache access has been disabled".

When enable_sieve_memcache is set to 2, then user-level attempts to use memcache will result in a Sieve error "Memcache only allowed in system-level sieves".

52.41.5.4 Sieve language extension MTA options: enable_sieve_metermaid (0-2)

New in the 8.0 release. The enable_sieve_metermaid MTA option controls whether Sieve filters may use the metermaid operator to access and manipulate data stored in MeterMaid. A value of 0 disables the use of the metermaid operator in all Sieve scripts. The default value is 1, meaning that metermaid may be used in any Sieve script. A value of 2 allows metermaid to be used in system-level Sieves only.

When enable_sieve_metermaid is set to 0, then any attempt to use metermaid will result in a Sieve error "MeterMaid access has been disabled".

When enable_sieve_metermaid is set to 2, then user-level attempts to use metermaid will result in a Sieve error "MeterMaid only allowed in system-level sieves".

52.41.5.5 Sieve language extension MTA options: enable_sieve_redis (0-2)

New in the 8.0.2.3 release. The enable_sieve_redis MTA option controls whether Sieve filters may use the redis operator to access and manipulate stored data using the redis protocol. A value of 0 disables the use of redis in all Sieve scripts. The default value is 1, meaning that redis may be used in any Sieve script. A value of 2 allows redis to be used in system-level Sieves only.

When enable_sieve_redis is set to 0, then any attempt to use redis will result in a Sieve error "Redis access has been disabled".

When enable_sieve_redis is set to 2, then user-level attempts to use redis will result in a Sieve error "Redis only allowed in system-level sieves".

52.41.5.6 Sieve language extension MTA options: enable_sieve_regex (0-2)

The enable_sieve_regex MTA option controls whether Sieve filters may use the Sieve regex extension (the ":regex" match-type). A value of 0 disables the use of regex in all Sieve scripts. The default value is 1, meaning that regex may be used in any Sieve script. As of the 7 Update 2 release, a value of 2 allows regex to be used in system-level Sieves only.

When enable_sieve_regex is set to 2, then user-level attempts to use :regex will result in a Sieve error ":regex only allowed in system-level sieves".

52.41.5.7 Sieve language extension MTA options: strict_require (0 or 1)

The `strict_require` MTA option controls whether or not the MTA enforces "strict" syntax rules on the location of any `require` clauses in Sieve filter scripts. The default is 0 (false), meaning that `require` clauses may appear anywhere in the Sieve script, not only at the very top of the Sieve script.

52.41.6 Sieve filter duplicate extension MTA options

As of 8.0, the MTA supports the Sieve duplicate extension specified in RFC 7352.

Several MTA options relate to this support. In particular, the `duplicate_tracking_url` MTA option specifies where duplicate tracking information should be stored. At present, the value *must* be a `memcache:` URL of the form:

`memcache://host:port/key-prefix`

If the host isn't specified, it defaults to the value of the `memcache_host` MTA option. It is an error for `memcache_host` not to be set in this case. If the port isn't specified, it defaults to the value of the `memcache_port` MTA option; if that option in turn isn't specified, the default is 11211, the usual port for memcache servers. `key-prefix`, if specified, is prepended to the keys the duplicate extension sends to the memcache server.

Note that duplicate tests are performed during Sieve evaluation but no memcache updates are performed. It is only after the message has been successfully processed that updates are done.

Also note that duplicate information is implicitly qualified by the owner of the Sieve. In the case of system-level Sieves, this will be the applicable postmaster address, so system-level Sieves operate in shared namespace(s). Note that the `:handle` argument can be used to force system-level Sieves to operate in their own namespace.

52.41.6.1 Duplicate test storage timeout minimum: `duplicate_minimum_timeout` (integer)

(New in 8.0.) The `duplicate_minimum_timeout` MTA option establishes a minimum value, in seconds, for the Sieve "`duplicate`" "`:seconds`" parameter that controls how long test information is retained. Values lower than the minimum are silently adjusted up to the minimum; no error occurs. The default value for `duplicate_minimum_timeout` is 0.

52.41.6.2 Duplicate test storage timeout maximum: `duplicate_maximum_timeout` (integer)

(New in 8.0.) The `duplicate_maximum_timeout` MTA option establishes a maximum value, in seconds, for the Sieve "`duplicate`" "`:seconds`" parameter that controls how long test information is retained. Values higher than the maximum are silently adjusted down to the maximum; no error occurs. The default value for `duplicate_maximum_timeout` is 604800 seconds (7 days).

52.41.6.3 Duplicate test storage timeout default: `duplicate_timeout_default` (non-negative integer)

The duplicate_timeout_default MTA option specifies the default timeout, in seconds, for storage of information provided to the Sieve "duplicate" test. The default is 604800 seconds (seven days).

52.41.6.4 Sieve duplicate detection: duplicate_tracking_url (memcache URL)

The duplicate_tracking_url MTA option specifies where duplicate tracking information produced by the Sieve duplicate extension should be stored. At present the value must be a memcache: URL of the form:

memcache://*host*:*port*/*key-prefix*

If the host isn't specified, it defaults to the value of the memcache_host MTA option. It is an error for memcache_host not to be set in this case.

If the port isn't specified it defaults to the value of the memcache_port MTA option; if that option in turn isn't specified the default is 11211, the usual port for memcache servers.

key-prefix, if specified, is prepended to the keys the duplicate extension sends to the memcache server.

52.41.6.5 Sieve filter limit MTA options: max_duplicates (integer >= 0)

The max_duplicates MTA option specifies the maximum number of Sieve "duplicate" tests that may be performed by a Sieve script. The default is 2.

52.41.7 Sieve filter error text MTA options

A few of the error_text_* MTA options discussed in error_text MTA options relate specifically to Sieve filter error messages; see the error_text_sieve_access, error_text_sieve_syntax, error_text_source_sieve_access, error_text_source_sieve_syntax, and error_text_sieve_authorization MTA options.

52.41.8 Sieve filter log and debug MTA options

A few MTA options relate to logging of Sieve filter applied actions, and debugging of MTA Sieve filter processing.

For debugging of Sieve filters, see also the mm_debug MTA option, the test -expression utility, and the Sieve debug action.

52.41.8.1 Debug MTA options: filter_debug (0 or 1)

New in Messaging Server 6.2. Control whether the stack state information part of Sieve filter debugging is put in debug logs. (Note that this is quite "low level" debugging, not likely to be of interest unless requested by Oracle support.)

For debugging of Sieve filters, see also the `imsimta test -expression` utility and the `mm_debug` MTA option along with the Sieve `debug` action.

52.41.8.2 Transaction logging MTA options: `log_filter` (0-7)

The `log_filter` option controls whether or not any mailbox filter actions (Sieve filter actions) applicable to the message are logged in enqueue "E" records or included in `LOG_ACTION` mapping probes. Bit 0 (value 1), if set, causes filter information to appear in log entries. New in 7.0-3.01, bit 1 (value 2), if set, causes filter information to be included in `LOG_ACTION` mapping probes. This information appears after the optional "intermediate" and "original" forms of the destination address (see the `log_intermediate` MTA option), before the SMTP diagnostic field (which itself only appears for SMTP messages). In XML or JSON format (`log_format` set to 4 or 5, respectively), Sieve filter action(s) logging, if enabled, appears as the `fl` attribute. The filter action(s) will be enclosed within single quote characters.

Normally the `fl` attribute only appears in XML or JSON format logs if there is an AUTH parameter value to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

As of MS 6.3p1, enabling XML or JSON format (`log_format` set to 4 or 5) causes the default for `log_filter` to be 1 (Sieve filter action logging enabled); with any other format, the default is 0, (Sieve filter actions are not logged), as in previous versions. With `log_filter` set to 1, one might see, for instance

```
'fileinto "SPAM"'
```

or

```
'redirect "user@domain.com"'
```

As of 8.0, a "`warn`" clause may also be present; see the discussion in Sieve warn extension.

Note that the case of a "`reject`" action is special, due to the inherent nature of the "`reject`" action. In this case, what occurs is the enqueue of a new message (a Message Disposition Notification) by the original enqueuing channel to the process channel, and that new message has an implicit `keep` occurring. As there is no enqueue of the rejected message, the "`reject`" does not show up in the filter action field of any transaction log record.

As of MS 8.0, the maximum size of the `log_filter` field (the maximum length of the string recording what Sieve actions were applied) has been increased from 256 to 1024 characters.

52.41.8.3 Transaction logging MTA options: `log_transactionlog` (0-3)

(New in MS 8.0.) The `log_transactionlog` MTA option controls whether Sieve `transactionlog` action strings are included in MTA message transaction log records. The option defaults to 0, meaning that such Sieve actions are not logged. Setting bit 0 (value 1) causes the `transactionlog` string to be logged at the very end of enqueue ("E") records. The XML/JSON attribute name in XML/JSON format logs (`log_format` set to 4 or 5, respectively) is "`tl`". Setting bit 1 (value 2) causes the `transactionlog` string to be included in the `LOG_ACTION` mapping table probe, again at the very end.

Normally the `tl` attribute only appears in XML or JSON format logs if there is transaction log information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

For instance, with MTA message transaction logging enabled (the `logging` channel option set for all channels) and with `log_transactionlog` also set:

```
msconfig> show logging
role.channel:defaults.logging
msconfig> set log_transactionlog 1
```

then an MTA system filter (see for instance the `msconfig` command `edit filter`) including:

```
require "variables";
if header :matches "subject" "*" {transactionlog "${0}";}
```

will cause MTA message transaction log records to include the contents of the Subject: header line. (Note that merely logging the Subject: header line of messages passing through the MTA could instead be achieved via use of `log_header` or `logheader`. But the Sieve script approach allows more fine-tuning, as a Sieve script can be coded with complex logic dependent upon other message details, such as message sender or recipient, presence of specific strings in the header, *etc.*)

52.42 Spamfilter MTA options

The MTA has a number of options affecting Brightmail, ClamAV, Cloudmark, ICAP, Milter (as of MS 6.3), SpamAssassin, Symantec SAVSE or similar virus/spam filtering plug-in facilities. These options are also used to integrate with AXS:One archiving. Most of these options affect the operation of the spam/virus filter package or archive package itself; however, there are also options that affect which user(s) and domains(s) get such filtering or archiving applied, such as the `ldap_optin`*`N`*, `ldap_source_optin`*`N`*, and `ldap_domain_attr_optin`*`N`* MTA options.

For each virus/spam filtering package used, typically at a minimum a pair of options `spamfilter`*`N`*`_library` and `spamfilter`*`N`*`_config_file` must be specified, telling the MTA the location of a library of callable routines for that virus/spam filter package and providing the location of a configuration file containing some configuration information specific to that virus/spam filter package. Additional `spamfilter*` MTA options may be used to further fine-tune the MTA's utilization of the virus/spam filter package.

Prior to MS 6.2, the MTA supported use of one spam/virus filter package callout (of the site's choice). In MS 6.2, use of up to four spam/virus filter packages callouts was supported (via `spamfilter1_*` through `spamfilter4_*` options). New in MS 6.3, up to eight spam/virus filter package callouts are supported (via `spamfilter1_*` through `spamfilter8_*` options).

The spam/virus filter packages get called asynchronously, being passed the original[1] (not yet processed by the MTA) message; thus multiple spam/filter packages may be working on the same message in parallel. The spam/filter packages report their verdicts back to the MTA on their own timelines, as they respectively finish their work. The verdicts from the

spam/virus filter packages are converted by the MTA into Sieve scriptlets, per the MTA's spamfilterN_verdict_M, spamfilterN_action_M option pairs as well as the default cases controlled via the spamfilterN_null_action and spamfilterN_string_action MTA options. The MTA then evaluates these Sieve scriptlets in order from spam/filter package 1 to spam/filter package 8; this in particular means that higher numbered, "later" spam/filter packages can see the results, such as added headers, from lower numbered, "earlier" spam/filter packages and potentially override them, if desired, although in regards to combining/weighting/overriding the verdicts-and-effects of multiple spam/virus filter packages, a flexible and perhaps more straightforward approach is to convert the spam/virus filter package verdicts into various added header lines via configuration of the above mentioned spamfilter*_action MTA options and then have the MTA's systemfilter see, consider, and make decisions based upon all the results (all the added header lines).

For spam/virus filter package invocation by external (external-to-the-MTA) components such as imexpire, see also the External filtering context MTA options.

See also the access_errors MTA option which affects the error text used when a spam/virus filter package rejects a recipient address, and the error_text_spamfilterN_error MTA options.

[1] Regarding the passing of the "original" (as received) message to the spam/virus filter packages, a few modifications are configurable via the spamfilterN_final, spamfilterN_includeheaders, spamfilterN_received, and spamfilterN_returnpath MTA options.

52.42.1 Spamfilter MTA options: optin_user_carryover (bitmask)

New in MS 6.2. The optin_user_carryover MTA option controls whether user spam/virus filter "opt in" requests will "carry over" when doing forwarding. That is, if the original recipient has opted-in but has then forwarded their e-mail to some other recipient, does that other recipient get the "opt in" effect?

Bit 0 (value 1): setting this bit means that "opt in" effect is disabled for all forwarded-to address(es). Bit 1 (value 2) controls the behavior for domain "opt in"; setting the bit disables the "opt in" effect for the forwarded-to address(es). Bit 2 (value 4) means that user "opt in" overrides any previous user/domain "opt in" setting. Bit 3 (value 8) controls the behavior for aliases (typically lists) marked with the alias_optin alias option or named parameter [OPTIN]; setting the bit disables the "opt in" effect for the forwarded-to address(es). The default is 0. Note that this option applies globally to *all* spam/virus filter packages; it does *not* come in numbered variants to apply only to one spam/virus filter package or another.

52.42.2 Spamfilter MTA options: spamfilterN_library (filepath)

The spamfilterN_library MTA options specify where a spam/virus filter package library image is located. The default is to set no library.

For instance, when using Brightmail, one of these options would be set to point to the path to the libbmiclient.so library image, *e.g.*,

```
msconfig> set mta.spamfilter1_library /opt/mailwall/lib/libbmiclient.so
```

Or for instance, when using SpamAssassin, one of these options would be set to point to the path to the `libspamass.so` library image, *e.g.*,

```
msconfig> set mta.spamfilter2_library SERVERROOT/lib/libspamass.so
```

or if using an MTA "logical name" for the directory specification:

```
msconfig> set mta.spamfilter2_library IMTA_TABLE:libspamass.so
```

Or for instance, when using a Milter, one of these options would be set to point to the path to the `libmilter.so` library image (or if making use of Oracle's per-recipient modification Milter extension the new-in-MS-7.0.5.33 `libmilters.so` library image), *e.g.*,

```
msconfig> set mta.spamfilter3_library SERVERROOT/lib/libmilter.so
```

Or for instance, when using ICAP, one of these options would be set to point to the path to the `libicap.so` library image, *e.g.*,

```
msconfig> set mta.spamfilter4_library SERVERROOT/lib/libicap.so
```

Or for instance, when using the file-drop message archiving plug-in, one of these options would be set to point to the path to the `libarch.so` library image, *e.g.*,

```
msconfig> set mta.spamfilter5_library SERVERROOT/lib/libarch.so
```

52.42.3 Spamfilter MTA options: `spamfilter`*N*`_config_file` (filepath)

The `spamfilter`*N*`_config_file` MTA options are used specify the location of the configuration file for a spam/virus filter package. The value of this option is passed to the spam/virus filter package for it to use to locate its configuration file; thus note that MTA special symbolic names (*e.g.*, `IMTA_TABLE`) should not be used; and whether the spam/virus filter package prefers absolute file paths (including full directory path), or prefers a bare filename (presumably located in some fixed/default directory) can vary with the specific spam/virus filter package in use.

This option is specifying the location of a configuration file *for the spam/virus filter plug-in itself*; the MTA passes this option value (the location of this configuration file) to the spam/virus filter package and it is then up to the spam/virus filter package to open and read that specified configuration file. Thus in particular the actual options available and supported within the specified file are dependent upon which spam/virus filter package is accessing its (own) configuration file. For details on what options may be specified within a spam/virus filter package's own configuration file, see, respectively:

- Brightmail spamfilterN_config_file
- ClamAV spamfilterN_config_file
- ICAP spamfilterN_config_file
- Milter spamfilterN_config_file
- SpamAssassin spamfilterN_config_file
- Archive spamfilterN_config_file
- Sieve spamfilterN_config_file

52.42.4 Spamfilter MTA options: spamfilter*N*_name (string)

The spamfilterN_name MTA options are new in 7.0.5.

If spamfilter*N*_library has been specified, but spamfilter*N*_name has not been explicitly set, then the string *N* will be used as the name.

Note that error messages referencing a spamfilter will show this name; that is, error messages that by default include text such as "[slot *N* name *N*]" with a name set will instead include text of the form "[slot *N* name *spamfilterN_name*]".

52.42.5 Spamfilter MTA options: spamfilter*N*_null_optin (string)

Normally, the simple presence of a spam filter opt-in attribute (the attribute named by the ldap_optin*N* MTA option or the attribute named by the ldap_source_optin*N* MTA option in a user entry, or the attribute named by the ldap_domain_attr_optin*N* MTA option in a domain entry) turns on filtering; all the value determines is what sort of filtering will be done. This isn't compatible with some directory maintenance and provisioning tools that cannot easily delete an attribute, that always provide the attribute but assume some sort of "off" or "null" value for the attribute is available that doesn't enable filtering. The spamfilter*N*_null_optin MTA options allow for better interaction with such directory tools. A spamfilter*N*_null_optin MTA option specifies what value a spam filter optin attribute must have to be ignored (by spam/virus filter package *N*). The default value for these options is the empty string, which means that by default a present but empty opt-in attribute is ignored.

52.42.6 Spamfilter MTA options: spamfilter*N*_action_*M* (URL) spamfilter*N*_verdict_*M* (string)

Each pair of options spamfilter*N*_verdict_*M* and spamfilter*N*_action_*M* for particular values of *N* and *M* specifies the action that the MTA should take upon receiving the corresponding (*M*) verdict from the virus/spam filter package number *N*. *N* can range between 1 and 4 as of MS 6.2 and range between 1 and 8 as of MS 6.3; that is, up to four (as of MS 6.2) or eight (as of MS 6.3) virus/spam filter packages may be in use simultaneously. *M* can range between 0 and 7; that is, up to eight such pairs may be specified per virus/spam filter package.

In legacy configuration, the spamfilter_action_*M* and spamfilter_verdict_*M* MTA options were synonyms, respectively, for spamfilter1_action_*M* and

spamfilter1_verdict_*M* MTA options; Unified Configuration does not support those old aliases other than for upgrade purposes.

Each spamfilter*N*_verdict_*M* MTA option specifies a possible verdict string from a virus/spam filter package such as Brightmail, with *N* corresponding to the *N* in spamfilter*N*_library and spamfilter*N*_config_file; that is, *N* specifies the (arbitrary) "number" identifying the particular virus/spam filter package. New in MS 6.2p1, the *_verdict_* MTA option value may contain wildcards and glob matches; the MTA will do pattern matching on the verdict string returned by a spam/virus filter package. See the table of Mapping pattern wildcards for the sorts of wildcards and globs that may be used in the *_verdict_* MTA option settings; (note that "saving" of wildcards or globs is disabled in this context, so in particular one may use more than ten wildcards or globs in such a value). New in MS 6.3, the length of string argument to each such option has been increased to 1024 characters (where previously the limit was 256 characters).

For each such option (verdict), a corresponding spamfilter*N*_action_*M* MTA option should also be set, specifying what action to take when the corresponding verdict is returned. The value of a spamfilter*N*_action_*M* MTA option should be a URL that resolves to a Sieve filter (where the Sieve filter specifies the action to take). The URLs can use MTA URL substitution sequences, as in Table of LDAP URL substitution sequences, though most such substitutions have no meaning or are irrelevant in this particular context, and in a few cases the meanings are different in this context. In particular:

Table 52.33 spamfilter*N*_action_*M* MTA option values

Substitution sequence	Description
$U	The verdict name string
$A	The address that this verdict is associated with
$M	(New in MS 6.0) The detailed verdict string (if the spam/virus filter package provided one - not all do)

In MS 6.2, *N* can range between 1 and 4; that is, up to four virus/spam filter packages may be in use simultaneously. As of MS 6.3, *N* can range between 1 and 8; that is, up to eight virus/spam filter packages may be in use simultaneously. *M* can range between 0 and 9; that is, up to ten such pairs may be specified per virus/spam filter package.

For instance, if the spam/virus filter package configured in the MTA as package 1 might return as its "verdict" a string of either the form

spam*...arbitrary-text...*X-HEADER: SPAM*...more-text...*

or

spam*...arbitrary-text...*discard*...more-text...*

then one might configure MTA options as follows in legacy configuration:

```
SPAMFILTER1_VERDICT_1=spam*X-Header: SPAM*
SPAMFILTER1_ACTION_1=data:, addheader "X-Header" "SPAM";
SPAMFILTER1_VERDICT_2=spam*discard*
SPAMFILTER1_ACTION_2=data:, discard;
```

or in Unified Configuration:

```
msconfig> set mta.spamfilter1_verdict_1 "spam*X-Header: SPAM*"
msconfig# set mta.spamfilter1_action_1 'data:, addheader "X-Header" "SPAM";'
msconfig# set mta.spamfilter1_verdict_2 spam*discard*
msconfig# set mta.spamfilter1_action_2" "data:, discard;"
msconfig# show spamfilter1*
role.mta.spamfilter1_action_1 = data:, addheader "X-Header" "SPAM";
role.mta.spamfilter1_verdict_1 = spam*X-Header: SPAM*
role.mta.spamfilter1_verdict_2 = spam*discard*
role.mta.spamfilter1_action_2 = data:, discard;
```

Note The special value "`data:,$M`" for a `spamfilter`*`N`*`_action_`*`M`* MTA option has some special, short-circuited handling, in that it causes the verdict to be used literally as a Sieve scriptlet itself, omitting the usual URL expansion processing. For "short" verdicts, this is a difference that makes no difference, but it avoids the length limitations imposed during URL expansion that could potentially become relevant for longer verdicts---such as those that milter likes to return. Note that other uses of `$M` in a setting still result in substitution of the original verdict string but *with* normal URL expansion (thus subject to length limits); it is only the special, literal setting "`data:,$M`" that gets the special, short-circuited handling.

Note: Brightmail has a concept of a "default" verdict, intended to mean merely "deliver normally". Brightmail is typically configured so that a Brightmail "clear of any virus or spam" result is set to a Brightmail "destination" (a "verdict" in the MTA's terminology) of "inbox", with "inbox" also being set to be the "default destination". In older Brightmail configuration, this Brightmail configuration of "default destination" would be something like:

```
blSWCClientDestinationdefault: inbox
```

The MTA has support for Brightmail's default destination concept, implemented by the MTA checking whether a verdict that it has received from Brightmail is Brightmail's default destination and if so, the MTA forcibly performs a plain "`keep`" Sieve action (forces delivery to the Inbox) and *does not apply* any `spamfilter`*`N`*`_verdict`/`spamfilter`*`N`*`_action` processing. Thus to achieve some other result for Brightmail clear messages, that is, to get `spamfilter`*`N`*`_verdict`/`spamfilter`*`N`*`_action` processing to occur for "clear" messages (such as perhaps, adding a header line saying that the message was cleared by Brightmail as well as delivering to the Inbox), Brightmail must be configured differently: either configure Brightmail so that "inbox" is *not* Brightmail's "default destination", or configure Brightmail to return some destination (some verdict, in MTA terminology) of other than "inbox". Either way, the MTA must see a non-default (in Brightmail's opinion) destination/verdict in order for it to apply "normal" `spamfilter`*`N`*`_verdict`/`spamfilter`*`N`*`_action` processing.

In addition to the explicitly-specified-verdict/corresponding-action pairs discussed above, there are also two additional types of MTA option that specify the behavior of the MTA when other verdicts are returned: the `spamfilter`*`N`*`_null_action` options controlling behavior when a so-called "null" verdict is returned, and the `spamfilter`*`N`*`_string_action` options controlling behavior when an unrecognized verdict (a verdict without a matching `spamfilter`*`N`*`verdict_`*`M`* value) is returned.

52.42.7 Spamfilter MTA options: `spamfilter`*`N`*`_final` (bitmask)

Some filtering libraries have the ability to perform a set of actions based on recipient addresses. What sort of recipient address is passed to the filtering library depends on the setting of the respective spamfilter*N*_final (*N*=1-8) MTA option. The default value of 0 results in a so-called intermediate address being passed to the filtering library. This address is suitable for use in delivery status notifications and for directory lookups of local users. If bit 0 (value 1) of spamfilter*N*_final is set, however, the final form of the recipient address is passed. This form may not be suitable for presentation, but is more appropriate for use in subsequent forwarding operations. The spamfilter*N*_final MTA options are only available in MS 6.0 and later; iMS 5.2 behaves as if the option had the default value of 0.

In MS 6.2 and later, bit 1 (value 2) of spamfilter*N*_final controls whether or not source routes are stripped from the address that's passed to the filtering interface. Setting the bit enables source route stripping.

In 7.3-11.01 and later bit 2 (value 4) of spamfilter*N*_final, if set, causes the "initial" address to be passed to the spam filter. This is the address that was initially passed to the alias expansion process. Bit 1 can be used to strip source routes from such addresses if desired.

52.42.8 Spamfilter MTA options: spamfilter*N*_includeheaders (0 or 1)

(New in 7.0.5) Each spamfilter*N*_includeheaders MTA option specifies whether or not any header lines added to a message due to a $A flag in either a FROM_ACCESS mapping table or a recipient address *_ACCESS mapping table will be passed over to the respective *N*th spam/virus filter package as part of the regular message header. A value of 1 causes such header lines to be passed over; a value of 0, the default, disables this capability.

52.42.9 Spamfilter MTA options: spamfilter*N*_null_action (URL)

The spamfilter*N*_null_action MTA options specify, respectively, the Sieve action to take when a "null" verdict is returned by the *N*th spam/virus filter package. The default value for these options is:

```
data:,discard;
```

meaning that a null verdict is interpreted as a request to discard the message.

52.42.10 Spamfilter MTA options: spamfilter*N*_optional (-2, -1, 0, 1, 2, 3, 4)

The spamfilter*N*_optional MTA options control the MTA's reaction when spam/virus filter package N does not respond.

By default (spamfilter*_optional=0), when use of a spam/virus filter package such as Brightmail is configured, a failure to initially connect to the spam/virus filter package, or a failure to get a response from the spam/virus filter package once the filter package has begun processing the envelope addresses or the message itself, will normally result in a temporary

error of "4.7.1 filtering/scanning error". (The exact SMTP errors are "452 4.3.0 filtering/scanning error" if the package cannot even be contacted initially, "450 4.7.1 filtering/scanning error" if the package error occurs attempting to process the MAIL FROM: (envelope From:) argument; "452 4.7.1 filtering/scanning error" if the package error occurs attempting to process a RCPT TO: (envelope To:) argument, or "451 4.7.1 filtering/scanning error" if the package error occurs attempting to process the DATA (the message itself). Alternate text in this error message may be configured via the correspondingly numbered error_text_spamfilterN_error MTA options.) Note that for an incoming SMTP message, such a temporary error means that the message is (temporarily) rejected with that error, while for a message that is already on the system and being processed by a reprocess/process/conversion sort of channel, such a temporary error means that the message is reenqueued to the reprocess channel (for the reprocess channel to subsequently reattempt the virus/spam filter package processing).

But when spamfilter*_optional=1 is set, the MTA's message processing will continue even if the spam/virus filter package cannot be accessed or does not complete its processing; that is, messages will be passed through without spam/virus filter package scanning (omitting spam/virus filter package scanning) if the spam/virus filter package scanning is not functioning.

New in MS 6.2 is support for values -2 and 2. Setting a value of 2 is similar to the effect of 1, except that a syslog notice will be generated in case of spam/virus filter package errors. A value of -1 is (currently) equivalent in effect to a value of 0. A value of -2 is similar to a value of 0, except that a syslog notice will be generated in case of spam/virus filter package errors. (See the sndopr_priority MTA option for control of the facility and priority of such syslog notices.)

New in MS 6.3 is support for values 3 and 4. A value of 3 tells the MTA that in case of a virus/spam filter package failure during attempted processing of an incoming message, to accept the message and queue it to the reprocess channel (for subsequent reattempted processing through the virus/spam filter package by the reprocess channel). A value of 4 does the same thing, but also logs the virus/spam filter temporary failure to syslog.

For most site's purposes, either a setting of -2 (meaning to temporarily reject the message, and generate a syslog notice logging the trouble occurrence), or (new in MS 6.3) a setting of 4 (meaning to defer the message to the reprocess channel, and generate a syslog notice logging the trouble occurrence) will be desirable.

52.42.11 Spamfilter MTA options: spamfilterN_received (0-7)

Some spam/virus filter packages operate best if provided with the "current" Received: header line -- the sort that the MTA will be generating for actual prefixing of the message, but subsequent to the spam/virus filter package scanning. A spamfilterN_received MTA option controls whether the MTA generates a most recent Received: header line to pass to the *N*th spam/virus filter package. This is a bit-encoded value, but any nonzero value specifies that the MTA *does* pass a pseudo-Received: header line to the spam/virus filter package. Note that this pseudo-Received: header line is not necessarily *exactly* what the MTA will truly end up inserting, but it does contain the same routing information (in particular client source IP address) which tends to be the item of especial interest to spam/virus filter packages. SpamAssassin in particular tends to operate better when provided with such a Received: header line. Bit 1 (value 0) in the option is used to cause the header to be generated without any additional options. New in Messaging Server 7.0.5 is support for the bit 1 (value 2), which

means to pass the spam/virus filter package a synthesized Received: header line that includes an additional clause:

```
(envelope-sender mail-from-address)
```

Some SpamAssassin configurations use such a clause in the Received: header line as the source of MAIL FROM addresses instead of using the standards-compliant Return-path: field.

As of the 8.0.1 release, bit 2 (value 4) is used to specify that the header *not* be generated during reprocessing operations. (This is useful since the enqueue to the reprocess channel already added a Received: header field.)

52.42.12 Spamfilter MTA options: spamfilter*N*_returnpath (0 or 1)

The spamfilter*N*_returnpath (*N*=1-8) MTA options control whether or not a synthesized Return-path: field is prepended to the message passed to the associated spam filter. (Return-path: fields are normally only added during final delivery; however, some spam filters may only be able to process envelope From address information if it is provided in a Return-path: field.) A nonzero value causes the field to be inserted. The default value is 0.

These options are new in 7.0-3.01 and aren't available in previous versions, which never insert the field.

52.42.13 Spamfilter MTA options: spamfilter*N*_string_action (URL)

The spamfilter*N*_string_action MTA options specify the default Sieve filter actions to apply whenever the correspondingly numbered spam/virus filter plugin returns a verdict string that does not have an explicit corresponding action set. That is, specify the Sieve filter actions to apply whenever a verdict string is returned by plugin *N* that does not have a spamfilter*N*_verdict_*M* match for any *M*.

The default for the spamfilter*N*_string_action MTA options is:

```
data:, require "fileinto"; fileinto "$U";
```

Prior to MS 6.2p8, the (unexpanded) string specified as the value for such an option was limited to 256 characters (with truncation occurring if it was longer); as of MS 6.2p8, the limit is 1024 characters. The length of the string *after* any expansions are performed has been 1024 characters since at least MS 6.1.

When using a Milter, the spamfilter*N*_string_action option *must* be set to:

```
data:,$M
```

So for instance:

```
msconfig> show spamfilter3_*
role.mta.spamfilter3_config_file = /opt/sun/comms/messaging64/config/miltertest.dat
role.mta.spamfilter3_library = /opt/sun/comms/messaging64/lib/libmilter.so
msconfig> set spamfilter3_string_action "data:,$M"
```

This setting is using the `$M` substitution (see the discussion of such substitutions in the discussion of the `spamfilterN_action_M` MTA options) which means to use the detailed verdict string provided by the milter.

52.43 SPF MTA options

A number of MTA options exist affecting SPF lookups. Note that SPF lookups are enabled via channel options such as `spfhelo`; the MTA options affect the interpretation of SPF results and errors. See also the `SPF_LOCAL` mapping table, which may be used to avoid performing actual DNS lookups for selected (typically local) domains. See also the SRS MTA options, as many sites using SPF will also want to enable SRS address encoding.

Sender Policy Framework, or SPF, formerly referred to as Sender Permitted From, is a mechanism that attempts to prevent email forgery. It works by looking up special TXT records associated with the domain in the MAIL FROM (envelope from) address. This operation (which can actually involve several DNS lookups) eventually produces a list of IP addresses that are authorized to send mail from the domain. The IP address of the SMTP client is checked against this list and if it isn't found the message may be considered to be fraudulent. MTA support for SPF was implemented in MS 6.3-0.15.

See also the `error_text_spf_*` MTA options which configure the error text issued in cases of SPF errors.

52.43.1 SPF MTA options: `spf_smtp_status_fail` (2, 4, or 5)

The `spf_smtp_status_fail` MTA option controls whether SPF Fail results are ignored (considered as successes), interpreted as temporary failures, or (the default) interpreted as permanent failures, with values of 2, 4, or (the default) 5, respectively, controlling this. (To emphasize, this option is controlling the interpretation of SPF lookups that succeeded in finding a relevant SPF record in the DNS and where the SPF record specified an explicit Fail for the *exact* domain name being checked; for interpretation of SPF lookups that succeed in finding an explicit Fail all SPF record applying to subdomains including the domain name being checked, see instead the `spf_smtp_status_fail_all` MTA option; and for interpretation of DNS-level errors in the SPF lookup attempt, see instead the `spf_smtp_status_permerror` MTA option.)

52.43.2 SPF MTA options: `spf_smtp_status_fail_all` (2, 4, or 5)

The `spf_smtp_status_fail_all` MTA option controls whether SPF Fail "all" results are ignored (considered as successes), interpreted as temporary failures, or (the default) interpreted as permanent failures, with values of 2, 4, or (the default) 5, respectively, controlling this. (To emphasize, this option is controlling the interpretation of SPF lookups that succeeded in finding a relevant SPF record in the DNS and where the SPF record specified an explicit Fail for all subdomains of some domain name where the domain name

being checked matched; for interpretation of SPF lookups that find a relevant SPF record for the *exact* domain name being checked, see instead the spf_smtp_status_fail MTA option; and for interpretation of DNS-level errors in the SPF lookup attempt, see instead the spf_smtp_status_permerror MTA option.)

52.43.3 SPF MTA options: spf_smtp_status_permerror (2, 4, or 5)

The spf_smtp_status_permerror MTA option controls whether DNS permanent errors attempting SPF lookups are ignored (considered as successes), interpreted as temporary failures, or (the default) interpreted as permanent failures, with values of 2, 4, or (the default) 5, respectively, controlling this. (To emphasize, this option is controlling the interpretation of DNS level errors in the attempted SPF lookups, not the interpretation of "failed to verify" results from an SPF lookup; for that, instead see the spf_smtp_status_fail and spf_smtp_status_fail_all MTA options.) The default value is 5, meaning that such DNS level errors are considered to correspond to permanent SPF failures and result in rejection of the message.

The point in the SMTP dialogue at which the SPF lookup is attempted, hence at which the DNS error is encountered, will influence what error is returned; see the spfhelo, spfmailfrom, and spfrcptto channel options. So with spfhelo set on an incoming channel, if the SPF lookup of the domain specified on the client's HELO or EHLO command encounters a permanent DNS error, then with spf_smtp_status_permerror=5 set, the SMTP server would issue a permanent rejection:

```
500 5.5.2 Permanent error in SPF verification of HELO domain
```

whereas with spf_smtp_status_permerror=4 set, the SMTP server would instead issue a temporary rejection:

```
451 4.4.3 Permanent error in SPF verification of HELO domain
```

At the MAIL FROM: and RCPT TO: stages of the SMTP dialogue, the error text also is configurable via the error_text_spf_permerror_5 and error_text_spf_permerror_4 MTA options. So with spfmailfrom or spfrcptto set on an incoming channel, if the SPF lookup of the domain from the MAIL FROM: command encounters a permanent DNS error, then with spf_smtp_status_permerror=5 set the SMTP server would issue a permanent rejection (default text):

```
550 5.5.0 permanent error in SPF verification of MAIL FROM domain (domain-name)
```

or using whatever text is configured via the error_text_spf_permerror_5 MTA option:

```
550 5.5.0 error_text_spf_permerror_5
```

whereas with spf_smtp_status_permerror=4 set, such an error would result in merely a temporary rejection at the MAIL FROM: stage (spfmailfrom) such as (default text):

```
450 4.5.1 permanent error in SPF verification of MAIL FROM domain (domain-name)
```

or at the RCPT TO: stage (`spfrcptto`) such as:

```
452 4.5.1 permanent error in SPF verification of MAIL FROM domain (domain-name)
```

or using whatever error text is explicitly configured via the `error_text_spf_permerror_4` MTA option, hence at the MAIL FROM: stage:

```
450 4.5.1 error_text_spf_permerror_4
```

or at the RCPT TO: stage:

```
452 4.5.1 error_text_spf_permerror_4
```

52.43.4 SPF MTA options: spf_smtp_status_softfail (2, 4, or 5)

The `spf_smtp_status_softfail` MTA option controls whether SPF SoftFail results are ignored (considered as successes), interpreted as temporary failures, or interpreted as permanent failures, with values of 2 (the default), 4, or 5, respectively, controlling this. (To emphasize, this option is controlling the interpretation of SPF lookups that succeeded in finding a relevant SPF record in the DNS and where the SPF record specified an explicit SoftFail for the exact domain name being checked. For the case of a SoftFail "all" SPF record that matched the domain name in a more wildcarded way, see instead the `spf_smtp_status_softfail_all` MTA option. Or for the interpretation of DNS-level temporary errors in the SPF lookup attempt, see instead the `spf_smtp_status_temperror` MTA option.)

52.43.5 SPF MTA options: spf_smtp_status_softfail_all (2, 4, or 5)

The `spf_smtp_status_softfail_all` MTA option controls whether SPF SoftFail "all" results are ignored (considered as successes), interpreted as temporary failures, or interpreted as permanent failures, with values of 2 (the default), 4, or 5, respectively, controlling this. (To emphasize, this option is controlling the interpretation of SPF lookups that succeeded in finding a relevant SPF record in the DNS and where the SPF record specified an explicit SoftFail all subdomains of some domain name where the domain name being checked matched; for interpretation of SPF lookups that find a relevant SPF record for the *exact* domain name being checked, see instead the `spf_smtp_status_softfail` MTA option. And for interpretation of DNS-level temporary errors in the SPF lookup attempt, see instead the `spf_smtp_status_temperror` MTA option.)

52.43.6 SPF MTA options: spf_smtp_status_temperror (2, 4, or 5)

The `spf_smtp_status_temperror` MTA option controls whether DNS temporary errors attempting SPF lookups are ignored (considered as successes), interpreted as temporary

failures (the default), or interpreted as permanent failures, with values of 2, 4 (the default), or 5, respectively, controlling this. (To emphasize, this option is controlling the interpretation of DNS level temporary errors during the attempted SPF lookups, *not* the interpretation of "soft failure" results from an SPF lookup; for that, instead see the spf_smtp_status_softfail and spf_smtp_status_softfail_all MTA options.)

The default value is 4, meaning that such DNS level temporary errors are considered to correspond to temporary SPF failures and result in temporary rejections (deferrals) of the message. The point in the SMTP dialogue at which the SPF lookup is attempted, hence at which the DNS error is encountered, will influence what error is returned. See the spfhelo, spfmailfrom, and spfrcptto channel options. So with spfhelo set on an incoming channel, if the SPF lookup of the domain specified on the client's HELO or EHLO command encounters a temporary DNS error, then with spf_smtp_status_temperror=5 set the SMTP server would issue a permanent rejection:

```
500 5.5.2 Temporary error in SPF verification of HELO domain
```

whereas with spf_smtp_status_temperror=4 set (the default), the SMTP server would instead issue a temporary rejection:

```
451 4.4.3 Temporary error in SPF verification of HELO domain
```

At the MAIL FROM: and RCPT TO: stages of the SMTP dialogue, the error text also is configurable via the error_text_spf_temperror_5 and error_text_spf_temperror_4 MTA options. So with spfmailfrom or spfrcptto set on an incoming channel, if the SPF lookup of the domain in the MAIL FROM: command encounters a temporary DNS error, then with spf_smtp_status_temperror=5 set the SMTP server would issue a permanent rejection (default text):

```
550 5.5.0 temporary error in SPF verification of MAIL FROM domain (domain)
```

or using whatever text is configured via the error_text_spf_temperror_5 MTA option:

```
550 5.5.0 error_text_spf_temperror_5
```

whereas with spf_smtp_status_temperror=4 set (that is, the default) such an error would result in merely a temporary rejection at the MAIL FROM: stage (spfmailfrom) such as (default text):

```
450 4.5.1 temporary error in SPF verification of MAIL FROM domain (domain)
```

or at the RCPT TO: stage (spfrcptto) such as:

```
452 4.5.1 temporary error in SPF verification of MAIL FROM domain (domain)
```

or using whatever error text is explicitly configured via the error_text_spf_temperror_4 MTA option, hence at the MAIL FROM: stage:

```
450 4.5.1 error_text_spf_temperror_4
```

or at the RCPT TO: stage:

```
452 4.5.1 error_text_spf_temperror_4
```

52.43.7 SPF MTA options: spf_max_dns_queries (integer)

The spf_max_dns_queries MTA option specifies the maximum number of DNS queries per SPF check. The default is 10, which accords with the requirement in Section 10.1 of RFC 4408 (SPF). (Setting this option to a value above 10 thus violates the RFC 4408 requirement.)

52.43.8 SPF MTA options: spf_max_recursion (integer)

The spf_max_recursion MTA option's default is 10.

52.43.9 SPF MTA options: spf_max_time (integer)

The spf_max_time MTA option specifies the maximum amount of time, in seconds, permitted when performing an SPF check. If an SPF check does not complete in this amount of time, an SPF TempError will be returned. The default is 45. (RFC 4408 (SPF) in Section 10.1 recommends allowing at least 20 seconds.)

52.44 SRS MTA options

The MTA has a number of options relating to SRS (Sender Rewriting Scheme). SRS is a mechanism that can solve certain forwarding problems inherent in SPF (Sender Policy Framework, formerly referred to as Sender Permitted From). For a discussion of SPF itself, see SPF MTA options and the spf* channel options.

SPF presents serious problems for sites that provide mail forwarding services such as universities (for their alumni) or professional organizations (for their members). A forwarder ends up sending out mail from essentially arbitrary senders, which of course can include senders who have implemented SPF policies and which of course don't list the IP addresses of the forwarding system or systems as being permitted to use addresses from their domain.

The Sender Rewriting Scheme, or SRS, provides a solution to this problem. SRS works by encapsulating the original sender's address inside a new address using the forwarder's own domain. Only the forwarder's own domain is exposed for purposes of SPF checks. When the address is used, it routes the mail (usually a notification) to the forwarder, which removes the address encapsulation and sends the message on to the real destination.

Of course address encapsulation isn't exactly new. Source routes were defined in RFC 822 and provide exactly this sort of functionality, as does percent hack routing and bang paths. However, these mechanisms are all problematic on today's Internet since allowing their use effectively turns one's system into an open relay.

SRS deals with this problem by adding a keyed hash and a timestamp to the encapsulation format. The address is only valid for some period of time, after which it cannot be used. The hash prevents modification of either the timestamp or the encapsulated address.

SRS also provides a mechanism for handling multi-hop forwarding without undue growth in address length. For this to work certain aspects of SRS address formatting have to be done in the same way across all systems implementing SRS.

SRS support is new in MS 6.3P1. SRS address decoding is enabled by setting the `srs_domain` and `srs_secrets` MTA options; setting the `srs_maxage` MTA option is optional as it has a reasonable default value. See the discussions of the specific options for more details.

Note: Every system that handles email for the selected SRS domain must be configured for SRS processing and must have all three SRS options set identically.

Enabling SRS address encoding must be more precisely configured. In particular, it should only be done to envelope From addresses that you *know* are associated with forwarding activity. In addition to requiring that the SRS domain be configured via `srs_domain` and that the decoding keys be set via the `srs_secrets` MTA option already mentioned, additional configuration is required via the `*srs` channel options, controlling exactly which addresses, on exactly which messages, have SRS encoding applied.

Prior to the 8.0 release, note that SRS decoding of addresses, as for notification messages routing back through the SRS MTA, could run afoul of the MTA's normal "relay blocking" configuration. In particular, for a "typical" configuration where all three `*srs` channel options are set on the `tcp_local` channel, this would be an issue. See SRS and Relay Blocking for a work around approach.

The basic steps to set up SRS are as follows:

1. The `srs_domain` MTA option must be set to the domain to use in SRS addresses. Email sent to this domain must always be routed to a system capable SRS operations for the domain. SRS processing is handled as an overlay on top of normal address processing so nothing pervents a site from using their primary domain as the SRS domain.

2. The `srs_secrets` MTA option must be set to contain at least one SRS secret.

3. The `srs_maxage` can optionally be set to the number of days before an generated SRS address times out and becomes unusable. The default if the option isn't specified is 14 days.

4. Configured SRS usage on the appropriate mail flows. (See below.)

Note that every system that handles email for the selected SRS domain must be configured for SRS processing and must have all three SRS options set identically.

Setting the three options described above is sufficient to enable SRS address decoding. Encoding is another matter - it should only be done to envelope from addresses yoy know are associated with forwarding activity. SRS encoding is controlled by six channel keywords: `addresssrs`, `noaddresssrs`, `destinationsrs`, `nodestinationsrs`, `sourcesrs`, and `nosourcesrs`.

Three conditions have to be met for SRS encoding to occur:

1. The current source channel has to be marked with `sourcesrs`. (`nosourcesrs` is the default).

2. The current destination channel has to be marked with `destinationsrs` (`nodestinationsrs` is the default).

3. The current address, when rewritten, has to match a channel marked `addresssrs` (`noaddresssrs` is the default).

Encoding only occurs when all of these conditions are true. About the simplest setup is a pure forwarding one where all messages enter and exit on the `tcp_local` channel and all nonlocal addresses need SRS handling. In such a setup the `tcp_local` would be marked with the three keywords `sourcesrs`, `destinationsrs`, and `addresssrs`.

See also the `error_text_srs_*` MTA options, which control the exact error text issued when SRS errors occur.

52.44.1 Sender Rewriting Scheme (SRS) controls (`srs_domain`, `srs_hash_algorithmsrs_maxage`, `srs_secrets`)

52.44.1.1 `srs_domain` (domain-name)

(New in MS 6.3P1.) The `srs_domain` MTA option must be set to the domain to use in SRS addresses. Email sent to this domain must always be routed to a system capable of SRS operations for the domain. SRS processing is handled as an overlay on top of normal address processing so nothing prevents a site from using their primary domain as the SRS domain.

52.44.1.2 `srs_maxage` (integer)

(New in MS 6.3P1.) The `srs_maxage` MTA option optionally specifies the number of days before an SRS address times out. The default if the option isn't specified is 14 days.

52.44.1.3 `srs_secrets` (comma-separated list of strings)

(New in MS 6.3P1.) The `srs_secrets` MTA option takes as argument a comma separated list of secret keys used to encode and decode SRS addresses. The first key on the list is used unconditionally for encoding. For decoding, each key is tried in order to generate a different hash value. The decoding operation proceeds if any of the hashes match. The ability to use multiple keys makes it possible to change secrets without service disruption: Add a second key, wait for all previously issued addresses to time out, and then remove the first key.

52.44.1.4 `srs_hash_algorithm` (hash-algorithm)

New in MS 8.1.0.3. The `srs_hash_algorithm` MTA option controls what hash algorithm the MTA uses to generate the hash included in SRS addresses. The value should be a hash algorithm supported by the MTA, one of MD2, MD4, MD5, SHA1, SHA256, SHA512, MD128, or MD160. SHA1 is the default. Note that the setting of this option must be the same across a deployment for successful coordination of SRS addresses.

52.44.2 SRS MTA options: `token_char` (integer position of ASCII character)

RESTRICTED.

The `token_char` MTA option controls what character represents a token in the local-part of addresses. This is relevant for SRS address handling. The value of this option is an integer corresponding to the ASCII character value in decimal. The default is 61, corresponding to the equal sign, `=`.

52.45 Syslog MTA options

The MTA has a number of options relating to generating syslog notices when certain events occur---forms of event notices. The MTA can also optionally be configured to direct its normal transaction logging to syslog. For options relating specifically to the format of transaction logging, see Transaction logging MTA options.

52.45.1 Syslog MTA options: held_sndopr (0 or 1)

The held_sndopr MTA option controls the production of syslog messages (on UNIX) when a message is forced into a held state due to certain suspicion thresholds. (Note that there are other potential causes of messages becoming .HELD, which are *not* covered by held_sndopr -- cases corresponding to explicit MTA administrator action such as execution of a imsimta qclean command, or cases where the held state can be logged as part of normal logging, such as execution of a Sieve filter hold action, either in an explicit Sieve filter or as a Sieve scriptlet executed due to a spam/virus filter package verdict, or application of an address-based *_ACCESS mapping table $H flag where syslog message generation can be performed via $< flag, or routing to the hold channel due to a user status or domain status of hold. held_sndopr is meant to warn of cases that might otherwise be easier to miss noticing, especially for unanticipated incoming problem messages.)

Suspicious cases where held_sendopr causes a syslog message include:

- A message may be forced into a held state because it has too many Received: header lines (see the various max_*received_lines MTA options for additional information):

```
HELDMSG, Header count exceeded; message has been marked .HELD automatically.
```

- Or a message may be forced into a held state because it has too many recipients (see the holdlimit channel option for more details):

```
HELDMSG, Max recipient count exceeded; message has been marked .HELD automatically.
```

- Or a message may be forced into a held state because it has too many MIME parts or levels (see the max_mime_levels and max_mime_parts MTA options):

```
HELDMSG, Max MIME part/level limit exceeded; message has been marked .HELD automatically.
```

A value of 1 for held_sndopr instructs the MTA to issue such messages when such cases occur. A value of 0 (the default) turns off these messages. The syslog messages will be issued using the configured sndopr_priority facility and severity.

52.45.2 Syslog MTA options: log_connections_syslog (integer)

The log_connections_syslog MTA option causes sending MTA connection transaction log file entries to syslog (UNIX). 0 is the default and means no syslog logging is performed. Setting the option to a non-zero value causes syslog logging. The absolute value sets the

syslog facility/severity mask. Negative values disable the generation of the regular MTA connection transaction log file entries (which would otherwise be written to `mail.log*` or to `connection.log*`, if `separate_connection_log` is enabled).

Note that in MS 6.2 and earlier, the length of the MTA output line sent to syslog is limited to 256 characters. For MS 6.3 and later, the limit is 4096 characters.

The `log_messages_syslog` MTA option operates analogously for MTA message transaction log entries.

52.45.3 Syslog MTA options: log_messages_syslog (integer)

The `log_messages_syslog` MTA option enables sending MTA message transaction log file entries to syslog (UNIX). 0 is the default and means no syslog logging is performed; setting the option to a non-zero value causes MTA message transaction log file entries to be written to syslog. The absolute value of any non-zero value sets the syslog priority and facility mask. The relation is as follows:

```
value = facility * 8 + priority
```

The syslog priority levels and their normal meanings are:

Table 52.34 syslog priority values and their meanings

Value	Severity	syslog Keyword	Description	Action
0	Emergency	emergency	Urgent action required	System is unusable.
1	Alert	alert	Immediate action required	Should be corrected immediately, therefore notify staff who can fix the problem.
2	Critical	crit	Critical conditions	Should be corrected immediately, but indicates failure in a secondary system.
3	Error	err (error)	Error conditions	Non-urgent failures, these should be relayed to developers or admins; each item must be resolved within a given time.
4	Warning	warning (warn)	Warning conditions	Warning messages, not an error, but indication that an error will occur if action is not taken.
5	Notice	notice	Normal but significant condition	Events that are unusual but not error conditions - might be summarized in an email to developers or admins to spot potential problems - no immediate action required.

6	Informational	info	Informational messages	Normal operational messages - may be harvested for reporting, measuring throughput, etc. - no action required.
7	Debug	debug	Debug-level messages	Info useful to developers for debugging the application, not useful during operations.

The predefined syslog facility codes include:

Table 52.35 syslog facility codes and their meanings

Value	Facility
0	kernel messages
1	user-level messages
2	mail system
3	system daemons
4	security/authorization messages
5	messages generated internally by syslogd
6	line printer subsystem
7	network news subsystem
8	UUCP subsystem
9	clock daemon
10	security/authorization messages
11	FTP daemon
12	NTP subsystem
13	log audit
14	log alert
15	clock daemon
16	local use 0 (local0)
17	local use 1 (local1)
18	local use 2 (local2)
19	local use 3 (local3)
20	local use 4 (local4)
21	local use 5 (local5)
22	local use 6 (local6)
23	local use 7 (local7)

For example, if informational level logging is desired under the mail facility, the value would be 2*8+6=22.

See RFC 5424 (The Syslog Protocol) for additional information about syslog semantics and the syslog protocol.

Negative values will disable the generation of the regular mail.log entries; positive values mean that the syslog entries are generated in addition to the regular mail.log* entries.

The log_connections_syslog MTA option operates analogously for MTA connection transaction log entries.

Prior to Messaging Server 7.5, positive values of log_messages_syslog would not affect header logging (would not cause the entries due to enabling log_header to be copied to syslog). (The log_header entries, if enabled, would only be sent to syslog if the generation of regular mail.log* entries were disabled via negative values of log_messages_syslog.) As of Messaging Server 7.0.5, enabling log_messages_syslog normally also applies to any entries due to setting log_header. But setting bit 16 (value 65536) of log_messages_syslog will disable the sending of the header entries to syslog, thus restoring the older behavior (of not including the header lines) if desired. That is, the lowest 16 bits of log_messages_syslog specify the priority and facility mask as always, while bit 16 (value 65536) will, if set, suppress header logging to syslog.

Note that in MS 6.2 and earlier, the length of the MTA output line sent to syslog was limited to 256 characters. For MS 6.3 and later, the limit is 4096 characters.

Note that in MS 6.2, but not in MS 6.3 and later, it was necessary to have the configutil parameter logfile.imta.syslogfacility (corresponding to the Unified Configuration mta.logfile.syslogfacility option) set (*e.g.*, to mail) to have the log_messages_syslog MTA option take effect.

52.45.4 Syslog MTA options: log_sndopr (bitmask)

The log_sndopr MTA option controls the production of syslog messages (UNIX) by the MTA message transaction and connection logging facility. If this feature is enabled by specifying a value of 1, the logging facility will produce a message if it encounters any difficulty writing to its log file. A value of 0 (the default) turns off these messages. New in MS 8.0, the option takes a bit-encoded value, with bit 0 (value 1) and bit 1 (value 2) having meaning: bit 0 enables syslog notices regarding trouble writing transaction log entries; bit 1 enables syslog notices regarding trouble creating or updating channel counters.

The sndopr_priority option controls the syslog level (facility and severity) of the syslog messages generated.

52.45.5 Syslog MTA options: log_syslog_prefix (bitmask)

New in MS 8.0.2.3. The log_syslog_prefix controls what prefix, if any, is attached to syslog messages generated by the log_connections_syslog and log_messages_syslog MTA options. The default is not to apply a prefix. Note that this behavior differs from previous releases, where the prefix was hard-coded to be "IMTA-W-".

52.45.6 Syslog MTA options: sndopr_prefix (string)

New in MS 8.0.2.3. The sndopr_prefix MTA option sets the prefix attached to MTA messages send to syslog. The default prefix is "IMTA-W-".

52.45.7 Syslog MTA options: sndopr_priority (0-127)

The sndopr_priority MTA option sets the syslog level (facility and severity) of syslog messages generated by the MTA under certain circumstances, including most cases where the MTA would generate a syslog message for an "event notice" type purpose. In particular, MTA syslog messages affected by sndopr_priority include:

- problems creating or deleting message files
- problems creating temporary files while buffering incoming SMTP messages
- (new in 8.0) MESSAGE-SAVE-COPY mapping table problems renaming or copying a message file
- an empty or otherwise invalid format message file is found in the MTA disk queue area
- problems updating MTA message or association counters
- problems executing the imsimta reload utility
- if log_sndopr is set, problems writing to the MTA transaction log files
- if held_sndopr is set, certain cases of sidelining of messages as .HELD files
- if spamfilter*N*_optional if set to -2 or 2, and trouble occurs getting a result back from the Nth spam/virus filter package
- notices configured in the LOG_ACTION mapping table or various access mapping tables that happen to support generating syslog notices via the $< and $> flags

The default is 5 (that is, LOG_NOTICE on UNIX). (If the facility has not been explicitly specified in a sndopr_priority setting, as is the case with a value of 5, then the system's default facility is used: usually but not always LOG_USER.)

Note that sndopr_priority does *not* affect the optional copying of MTA transaction entries to syslog, which would more typically be serving a normal logging purpose rather than an "event notice" type warning purpose; the syslog level of MTA transaction entries are instead separately controlled by the exact values of log_messages_syslog or log_connections_syslog, as relevant.

52.45.8 Spamfilter MTA options: spamfilter*N*_optional (-2, -1, 0, 1, 2, 3, 4)

The spamfilter*N*_optional MTA options control the MTA's reaction when spam/virus filter package N does not respond.

By default (spamfilter*_optional=0), when use of a spam/virus filter package such as Brightmail is configured, a failure to initially connect to the spam/virus filter package, or a failure to get a response from the spam/virus filter package once the filter package has begun processing the envelope addresses or the message itself, will normally result in a temporary error of "4.7.1 filtering/scanning error". (The exact SMTP errors are "452 4.3.0 filtering/scanning error" if the package cannot even be contacted initially, "450 4.7.1 filtering/scanning error" if the package error occurs attempting to process the MAIL FROM: (envelope From:) argument; "452 4.7.1 filtering/scanning error"

if the package error occurs attempting to process a RCPT TO: (envelope To:) argument, or "`451 4.7.1 filtering/scanning error`" if the package error occurs attempting to process the DATA (the message itself). Alternate text in this error message may be configured via the correspondingly numbered `error_text_spamfilterN_error` MTA options.) Note that for an incoming SMTP message, such a temporary error means that the message is (temporarily) rejected with that error, while for a message that is already on the system and being processed by a reprocess/process/conversion sort of channel, such a temporary error means that the message is reenqueued to the `reprocess` channel (for the `reprocess` channel to subsequently reattempt the virus/spam filter package processing).

But when `spamfilter*_optional=1` is set, the MTA's message processing will continue even if the spam/virus filter package cannot be accessed or does not complete its processing; that is, messages will be passed through without spam/virus filter package scanning (omitting spam/virus filter package scanning) if the spam/virus filter package scanning is not functioning.

New in MS 6.2 is support for values -2 and 2. Setting a value of 2 is similar to the effect of 1, except that a syslog notice will be generated in case of spam/virus filter package errors. A value of -1 is (currently) equivalent in effect to a value of 0. A value of -2 is similar to a value of 0, except that a syslog notice will be generated in case of spam/virus filter package errors. (See the `sndopr_priority` MTA option for control of the facility and priority of such syslog notices.)

New in MS 6.3 is support for values 3 and 4. A value of 3 tells the MTA that in case of a virus/spam filter package failure during attempted processing of an incoming message, to accept the message and queue it to the reprocess channel (for subsequent reattempted processing through the virus/spam filter package by the reprocess channel). A value of 4 does the same thing, but also logs the virus/spam filter temporary failure to syslog.

For most site's purposes, either a setting of -2 (meaning to temporarily reject the message, and generate a syslog notice logging the trouble occurrence), or (new in MS 6.3) a setting of 4 (meaning to defer the message to the reprocess channel, and generate a syslog notice logging the trouble occurrence) will be desirable.

52.46 Transaction logging MTA options

The MTA has a number of options affecting MTA transaction logging (and thus to some extent MTA monitoring). In particular, there are a number of MTA options that affect the format and information recorded to the MTA message transaction log file and MTA connection transaction log file, and the information included in `LOG_ACTION` mapping table probes.

Additional MTA options relating in somewhat different ways to MTA logging may be found elsewhere:

- Various `logfile` options may be set at the MTA level (`mta.logfile.`*`option-name`* in Unified Configuration) to control logging of insertions into the Message Store performed by `ims-ms` channels and LMTP servers;

- TCP/IP-channel-specific options: among these options are several specifically relating to MTA transaction logging including `MAX_B_ENTRIES`, `MAX_J_ENTRIES`, `MAX_H_ENTRIES`, `LOG_BANNER`, and `LOG_TRANSPORTINFO`, plus a discussion of the TCP/IP channel level version of the `LOG_CONNECTION` option (which overrides on a per-channel basis the general, MTA-level `mta.log_connection` MTA option);

- File format MTA options: the log_alq and log_deq MTA options on OpenVMS affect the efficiency of MTA transaction log file handling;
- Syslog MTA options: these options affect syslog messages the MTA can generate as a form of *event notice*, including such a syslog message in case of a difficulty performing MTA logging (log_sndopr), certain cases of sidelining a message as .HELD (held_sndopr), problems with spam/virus filter package responsiveness (spamfilterN_optional), or even redirection or duplication of MTA transaction log entries to syslog (log_messages_syslog and log_connections_syslog);
- Counters MTA options: these options affect the MTA counters, which are intended for purposes of monitoring the *trend and health* of the e-mail system, rather than for precise message tracking;
- Debug MTA options: the log_debug MTA option to cause debugging of MTA transaction logging and channel counters update operations.

See also MTA transaction logging for additional discussion of MTA log management and transaction log format.

The (new in MS 6.3-0.15) XML format for MTA message transaction and MTA connection transaction logging is much more tolerant of extensions; plus it is a new format in any case. In the past, as new logging options were added, the default was that such options were disabled, so that upgrades would not unilaterally change the MTA's transaction logging format and thereby "break" existing transaction log parsers used by sites. However, with XML format which is a new format, and where parsers should to be written to ignore non-understood attributes, this is not a concern. Therefore, as of MS 6.3P1, whenever XML format is enabled (log_format=4), many of the optional logging options default to being enabled, rather than defaulting to being disabled (as with any format other than XML format). Such options include log_filename, log_filter, log_message_id, log_notary, log_priority, log_process, log_queue_time, log_reason, and log_username. As of the 7.0.5 release, this also includes log_auth, log_delivery_flags, and log_imap_flags.

52.46.1 Transaction logging MTA options: log_alternate_recipient (0-3)

(New in MS 8.0.1.) The log_alternate_recipient MTA option controls whether or not any alternate recipient is included in MTA message transaction log entries and/or LOG_ACTION mapping table probes. Setting bit 0 (value 1) causes the alternate recipient ABY and ARCPT values to be logged immediately after the SMTP DELIVERBY value is logged, before the intermediate address. "ab" and "al" attributes are used in the XML log format. If bit 1 (value 2) is set in the log_alternate_recipient MTA option, then this information appears as a pair of values in the LOG_ACTION mapping table probe immediately after the DELIVERBY, before the intermediate address.

52.46.2 Transaction logging MTA options: log_auth (0-7)

The log_auth MTA option has the same basic semantics as log_username, except that if set log_auth will cause logging of the value of the SMTP MAIL FROM's AUTH parameter on enqueue, assuming one was specified and retained. (Note that this is the AUTH parameter from the MAIL FROM command, whjich potentially differs from whatever might be the

authenticated identity specified via an SMTP AUTH command.) On dequeue the AUTH parameter is only logged if it is passed on to the remote SMTP server. The SMTP AUTH parameter field resulting from setting log_auth appears immediately after the username field in the old style MTA message transaction log format. An "au" attribute is used in XML or JSON format (log_format set to 4 or 5, respectively).

Normally the au attribute only appears in XML or JSON format logs if there is an AUTH parameter value to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

Enabling XML or JSON format transaction logging, log_format set to 4 or 5, causes the default for log_auth to be 1 (SMTP AUTH parameter field logged); with any other format, the default is 0 (SMTP AUTH parameter field not logged). If bit 1 (value 2) is set in the log_auth MTA option, then the SMTP AUTH parameter field appears in the LOG_ACTION mapping table probe immediately after the username field.

52.46.3 Transaction logging MTA options: log_callout_delays (0-3)

The MTA can optionally use timers to measure the total time the MTA spends waiting for various external components to return a response. The log_callout_delays MTA option controls the logging of this timer information. Bit 0 (value 1), if set, causes the callout logging information to be logged immediately after delivery flags in "E" (enqueue) log records. The XML attribute name in XML format logs is "cd". Bit 1 (value 1), if set, causes callout logging information to be included in the LOG_ACTION mapping probe, again immediately after delivery flags. In both cases the information is formatted as described below.

Timings are done on a per-message basis.

The following callout timers have been implemented:

- Time spent waiting for spam filters 1-8. (S1 - S8)
- Time spent waiting for mapping routine callouts. (MC)
- Time spent in the following specific mappings waiting for routine callouts:
  - PORT_ACCESS (PA)
  - FROM_ACCESS (FA)
  - ORIG_SEND_ACCESS (OSA)
  - SEND_ACCESS (SA)
  - ORIG_MAIL_ACCESS (OMA)
  - MAIL_ACCESS (MA)
  - AUTH_REWRITE (AW)
  - REVERSE (RV)
  - All Sieve mappings (S)

- Rewrite rule routine callouts. (RR)
- Time spent creating an SMTP transaction for the MTA to process; (note that this necessarily includes MTA processing time). (STT)
- Time spent writing the message file(s) to the MTA queue area. (QW)
- Time used by the Indexed Search Converter (ISC) when operating as part of the LMTP server. (RD)
- Time spent creating an LMTP transaction for the store to process; (note that this necessarily includes MTA processing time). (STT)
- Time spent writing the message file(s) to the store. (QW)

When logging this information, it is formatted in the order and with delimiters as follows (note that the field names are specified in the preceding list):

```
S1,S2,S3,S4,S5,S6,S7,S8:MC,PA,FA,OSA,SA,OMA,MA,AW,RV,S:RR:STT,QW,RD
```

Each value appears an an integer time in centiseconds followed by a semicolon and an integer use count:

T;*U*

Any value consisting of a zero-time;zero-use-count pair will be omitted entirely. Use counts of 1 are also omitted. Finally, zero elements of the comma-separated sublists may be truncated from the right.

In the specific case of spam filter wait timers, an outright spam filter failure is indicated by presence of an "F" suffix followed by an integer code which indicates the phase where the failure occurred. The code values are:

Table 52.36 Spamfilter phase failure codes

Code	Failure	Spamfilter routine	Milter command
1	SYSTEM_FAILURE	bmiInitSystem	n/a
2	MESSAGE_FAILURE	bmiInitMessage	(milter connect)
3	CONNECT_FAILURE	bmiProcessConnection	SMFIC_CONNECT/ SMFIC_HELO
4	MAILFROM_FAILURE	bmiProcessFROM	SMFIC_MAIL
5	AUTHADDR_FAILURE	bmiProcessAUTH	n/a
6	RCPTTO_FAILURE	bmiAccumulateTO/ bmiRejectTO	SMFIC_RCPT
7	ENDRCPTTO_FAILURE	bmiEndTO	SMFIC_DATA
8	HEADER_FAILURE	bmiAccumulateHeaders	SMFIC_HEADER
9	ENDHEADER_FAILURE	bmiEndHeaders	SMFIC_EOH
10	BODY_FAILURE	bmiAccumulateBody	SMFIC_BODY
11	ENDBODY_FAILURE	bmiEndBody	SMFIC_BODYEOB command

12	SUBMIT_FAILURE	bmiEndMessage	SMFIC_BODYEOB response
13	UNKNOWN_FAILURE	n/a	n/a

Parsers should be aware that additional, colon-delimited elements may be added to the list as a whole, comma-separated elements may be added to sublists, and even semicolon-separated elements may be added to individual timer values.

Some samples of the timers field in XML format:

```
cd="1410,,,15:::123,25"
cd="1243,,,21:::127,33"
cd="172:1855;5,,107,248,400,500,600::4836,14"
cd=":::1222,11"
```

52.46.4 Transaction logging MTA options: log_connection (0-1023)

The log_connection MTA option controls whether or not connection information, *e.g.*, the domain name of the SMTP client sending the message, is saved in the mail.log file (or the connection.log file if separate_connection_log is set to 1). This value is a decimal integer representing a bit-encoded integer, the interpretation of which is given in the table below.

Table 52.37 log_connection MTA option bit values

Bit	Value	Usage
0	1	When set, connection information is included in E, D and R log records. In XML-compatible format (log_format is 4), this information appears in the ss attribute within en elements.
1	2	When set, connection open/close/fail records are logged by message enqueue and dequeue agents such as the SMTP and X.400 clients and servers. This bit also enables use of the $T flag (for causing logging) in PORT_ACCESS rejection entries. In XML-compatible format (log_format set to 4), this information is logged in co elements.
2	4	When set, I records are logged recording ETRN events.
3	8	When set, include transport information in E, D and R log records for SMTP messages even if other connection information logging is not enabled. In XML-compatible format (log_format is 4), this is the tr attribute.
4	16	When set, C entries may include site-supplied text from a PORT_ACCESS mapping table entry; the text is added to the application information field. (Prior to Messaging Server 7.0, when SMTP server processes began unconditionally probing PORT_ACCESS, this bit had a meaningful side-effect of causing SMTP server processes to always query PORT_ACCESS regardless of channel *sasl* option setting; prior to Messaging Server 7.0, SMTP server processes only queried PORT_ACCESS when the relevant channel was marked maysasl, maysaslserver, mustsasl, or mustsaslserver -- or when this bit was set.)

5	32	When set, include transport information: TCP|*MTA-IP*|*MTA-port*|*remote-IP*|*remote-port* in message log enqueue entries (E* entries): . This information appears after the SMTP delivery-status/diagnostic information. In XML-compatible format (log_format set to 4), this is the tr attribute.
6	64	When set, include application information in message log enqueue entries (E* entries). (For instance, that the SMTP protocol is in use.) This information appears after the optional (see bit 5) transport information. In XML-compatible format (log_format set to 4), this is the ap attribute.
7	128	(New in 6.2.) When set, write "U" records for SMTP AUTH attempts (successes and failures). The SASL error will be recorded in the message-id field of the connection record (immediately after the optional---see bit 6---application information); the username used in the authentication will be recorded in the username field of the connection record (which is the following field of the record); the actual SMTP response sent back to the client will be recorded in the diagnostic (final) field of the connection record.
8	256	(New in 7.0-3.01.) Include source system field in LOG_ACTION mapping table probes.
9	512	(New in 7.0-3.01.) Include both application field and transport field in LOG_ACTION mapping table probes.

Thus for instance setting log_connection to 3 will result both in additional sorts of log file entries---entries showing when an SMTP connection is opened or closed---and also additional information in regular log file entries showing the name of the system connecting (or being connected to), or the channel hostname of the enqueuing channel when the enqueuing channel is not an SMTP channel. (This is a change from PMDF V5.1 and earlier, where the value was simply 0 or 1, with 1 enabling all the then-available connection logging.) TCP/IP channels have a channel-specific option that can override this setting for particular channels.

52.46.5 Logging Conversion Tags: log_conversion_tag (bitmask)

New in 7.0.5. The log_conversion_tag MTA option causes a field recording any conversion tags to be included in MTA message transaction log file entries (both "E" and "D") and/or LOG_ACTION mapping table probes.

Bit 0 (value 1) enables including the field in MTA message transaction log file entries; bit 1 (value 2) enables including the field in LOG_ACTION mapping table probes. If enabled, this field appears after the "time in queue" field (log_queue_time option) and before the IMAP flags field (log_imap_flags option). The XML or JSON format tag for this field is "tg". The default is 0 (even in XML or JSON format logging operation).

Normally the tg attribute only appears in XML or JSON format logs if there is conversion tag information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

As of MS 8.0.2.3, bit 3 (value 8) will cause the first conversion tag associated with each message recipient, if present, to be treated as an additional "virtual channel" by the MTA counter

subsystem. This "channel" will then appear in counter output along with all the other channels. Note that no attempt is made to distinguish these virtual channels from normal channels; use of unique names must be dealt with by appropriate configuration.

As of MS 8.1.0.3, bit 4 (value 16) will cause the conversion tags associated with the current message being dequeued to be logged in the extra field of any connection log records.

52.46.6 Transaction logging MTA options: log_deliver_by (0-3)

(New in MS 8.0.1.) The log_deliver_by MTA option controls whether or not any SMTP DELIVERBY value (see RFC 2852) is included in MTA message transaction log entries and/or LOG_ACTION mapping table probes. Setting bit 0 (value 1) causes the DELIVERBY time value, expressed as an offset in seconds from the current time, a semicolon, the DELIVERBY mode, and (if trace information is present) the trace value, to be logged immediately after the priority is logged, before the alternate recipient. A "db" attribute is used in the XML log format. If bit 1 (value 2) is set in the log_deliver_by MTA option, then this information appears in the LOG_ACTION mapping table probe immediately after the priority, before the alternate recipient.

52.46.7 Transaction logging MTA options: log_diagnostics (0-3)

(New in 7.0-3.01.) Bit 0 (value 1), if set in log_diagnostics, causes diagnostics information to appear in certain log entries. Bit 1 (value 2), if set, causes diagnostics information to be included in LOG_ACTION mapping probes. For instance, in the case of "B" records (bad commands received by the SMTP server), the diagnostic field will show the SMTP server error response. In the case of connection close "C" records, the diagnostic file will show the reason why the connection was closed, *e.g.*, reaching some session disconnect limit. In the case of authentication "U" entries (which note are generated as connection transaction entries, rather than message transaction entries), the result of an authentication attempt is shown in the diagnostic field. Appears just after the reason field (see the log_reason MTA option) and before the time-in-queue field (see the log_queue_time MTA option). In XML or JSON format (log_format set to 4 or 5, respectively), diagnostic information, if enabled, appears as the di attribute.

Normally the di attribute only appears in XML or JSON format logs if there is diagnostic information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

This option defaults to 1 in order to maintain compatibility with previous releases, where diagnostics information was always logged.

52.46.8 Transaction logging MTA options: log_dkim (0-7)

(New in MS 8.1.0.6.) The log_dkim MTA option controls whether or not the results of any DKIM signing operations are included in transaction log entries and mapping probles. A value of 0 means no DKIM information is extracted. Setting bit 0 (value 1) causes DKIM results to be logged just prior to any smartsend string. The results value consists of a comma-separated list

of entries, one for each active DKIM signing slot. Each entry in turn consists of the slot number and a status string separated by a colon. Status strings beginning with a question mark are error messages, other strings consist of the DKIM identity and selector that were used.

The default for this option is 0 in all log formats except flat JSON (log_format value 6), where it is 1.

The XML/JSON attribute name in XML/JSON format logs (log_format set to 4 or 5-6, respectively) is "fm". Setting bit 1 (value 2) causes from address to be included in the LOG_ACTION mapping table probe, again just prior to the smartsend string.

Normally the dk attribute only appears in XML or JSON format logs if there is DKIM activity to log. However, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

52.46.9 Transaction logging MTA options: log_envelope_id (0-7)

(New in MS 6.1.) The log_envelope_id MTA option controls whether or not the envelope ID (ENVID parameter of the MAIL FROM ESMTP command) is included in mail.log records and LOG_ACTION mapping probes. This information may be useful when tracking a message across multiple systems. The default is 0, meaning that the field is not logged. Setting bit 0 (value 1) causes the envelope ID to be logged, immediately after the message filename field and immediately before the message-id field. In XML or JSON format (log_format set to 4 or 5, respectively), envelope ID logging, if enabled, appears as the ei attribute. New in 7.0-3.01, bit 1 (value 2), if set, causes the information to be included in LOG_ACTION mapping probes.

Normally the ei attribute only appears in XML or JSON format logs if there is envelope id information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

52.46.10 Transaction logging MTA options: log_filename (0-7)

The log_filename MTA option controls whether or not the names of the files in which messages are stored are saved in the mail.log file or included in LOG_ACTION mapping probes. Setting bit 0 (value 1) enables file name logging. When file name logging is enabled, the file name will appear as the first field after the final form envelope To: address. In XML or JSON format (log_format set to 4 or 5, respectively), file name logging, if enabled, appears as the fi attribute. As of MS 6.3p1, enabling XML or JSON format (log_format set to 4 or 5) causes the default for log_filename to be 1 (filename logging enabled); with any other format, the default is 0 (file name logging disabled), as in earlier versions. New in 7.0-3.01, bit 1 (value 2), if set, causes filename information to be included in LOG_ACTION mapping probes.

Normally the fi attribute only appears in XML or JSON format logs if there is filename information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

52.46.11 Transaction logging MTA options: log_filter (0-7)

The log_filter option controls whether or not any mailbox filter actions (Sieve filter actions) applicable to the message are logged in enqueue "E" records or included in LOG_ACTION mapping probes. Bit 0 (value 1), if set, causes filter information to appear in log entries. New in 7.0-3.01, bit 1 (value 2), if set, causes filter information to be included in LOG_ACTION mapping probes. This information appears after the optional "intermediate" and "original" forms of the destination address (see the log_intermediate MTA option), before the SMTP diagnostic field (which itself only appears for SMTP messages). In XML or JSON format (log_format set to 4 or 5, respectively), Sieve filter action(s) logging, if enabled, appears as the fl attribute. The filter action(s) will be enclosed within single quote characters.

Normally the fl attribute only appears in XML or JSON format logs if there is an AUTH parameter value to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

As of MS 6.3p1, enabling XML or JSON format (log_format set to 4 or 5) causes the default for log_filter to be 1 (Sieve filter action logging enabled); with any other format, the default is 0, (Sieve filter actions are not logged), as in previous versions. With log_filter set to 1, one might see, for instance

```
'fileinto "SPAM"'
```

or

```
'redirect "user@domain.com"'
```

As of 8.0, a "warn" clause may also be present; see the discussion in Sieve warn extension.

Note that the case of a "reject" action is special, due to the inherent nature of the "reject" action. In this case, what occurs is the enqueue of a new message (a Message Disposition Notification) by the original enqueuing channel to the process channel, and that new message has an implicit keep occurring. As there is no enqueue of the rejected message, the "reject" does not show up in the filter action field of any transaction log record.

As of MS 8.0, the maximum size of the log_filter field (the maximum length of the string recording what Sieve actions were applied) has been increased from 256 to 1024 characters.

52.46.12 Transaction logging MTA options: log_format (1-6)

The log_format option controls formatting options for the MTA message transaction log file, mail.log, (as well as the MTA connection transaction log file, connection.log, if separate_connection_log=1 has been set so that connection entries are being recorded separately rather than in mail.log).

A value of 1 (the default) is the standard format. A value of 2 requests non-null formatting: empty address fields are converted to the string "<>". A value of 3 requests counted formatting: all variable length fields are preceded by "N:", where "N" is a count of the number of characters in the field. That is, log_format set to 3 causes length-count tagging of the following fields: The envelope-from address, the original-recipient address, the current-recipient address, the filename, the envelope-message-id, the message-id, the username, the connection information, the intermediate address(es), the Sieve filter action(s), the rejection reason text, the SMTP

diagnostic, the transport information, the application information. A value of 4 (new in MS 6.3) requests XML-compatible format.

A value of 5 (new in MS 8.0.2.3) requests JSON-compatiable format. And finally, a value of 6 (new in MS 8.1.0.2) specifies "flat" JSON format.

As of MS 6.3p1, note that setting log_format to a value greater than 3 (XML or JSON format) also changes the defaults for a number of other log_* options. In general, it enables much of the useful (but in other formats disabled by default) optional logging options, including: log_filename, log_filter, log_message_id, log_notary, log_priority, log_process, log_queue_time, log_reason, log_username, and (new options in 7.0.5) log_auth, log_delivery_flags, and log_imap_flags.

In the (new in MS 6.3) XML-compatible format (log_format set to 4), each message log entry appears as a single XML element containing multiple attributes and no subelements. Three elements are currently defined: en for message transaction (*e.g.*, enqueue/dequeue entries), co for connection transaction entries, and he for header entries (the optional additional records in the message transaction log file resulting from setting log_header to 1).

In the (new in MS 8.0.2.3) JSON-compatible format (log_format set to 5), each message log entry appears as a single JSON object containing multiple name-value pairs. All values are strings or integers; at present there are no arrays or nested objects. The first name-value pair always has a name of "ty" and its value specifies the object type. Three object types are currently defined: "en" for message transaction (*e.g.*, enqueue/dequeue entries), "co" for connection transaction entries, and "he" for header entries (the optional additional records in the message transaction log file resulting from setting log_header to 1).

The (new in MS 8.1.0.2) value of 6 also creates a JSON-compatible format, but one which attempts to avoid both JSON structure and structured field content, as well as making the format compatible for consumption by Lumberjack. Specifically, the following changes are made:

- The ts timestamp attribute is encoded as integer number of milliseconds since the epoch.
- The tl transactionlog attribute is renamed to msg and is included in every log entry.
- The tg conversion tag attribute is broken up into as many as 10 separate tag attributes t0, t1, t2, ..., each containing a separate tag. The eleventh and subsequent tags, if they exist, are not logged.
- The he array of header field values is broken up into as many as 10 separate header attributes h0, h1, h2, ..., each containing a separate header field value. The eleventh and subsequent header fields, if they exist, are not logged.
- The so attribute contains the envelope from address. The domain from this address is broken out and appears in an additional sd attribute.
- The various protocol modifiers to the ac action attribute are moved to a separate sp attribute.
- When the tr transport information attribute contains TCP address information it is replaced by li and ri attributes containing the local and remote IP addresses, respectively. Port information is not logged.
- The ap application information attribute is replaced by a po attribute containing the protocol and, if SSL/TLS is being used, a cs attribute containing the TLS/SSL information string. Other parts of the application information string are not logged.

Note that the maximum length of MTA transaction record, both for message transaction records and connection transaction records and regardless of format, is 4096 characters.

52.46.12.1 Transaction entries

Message transaction (en) elements/objects can have the following attributes (in XML) or name-value pairs (in JSON):

- ts - time stamp (always present) Note: The format changes from ISO 8601 format to a UNIX epoch value in milliseconds if log_format is set to 6
- no - node name (present if log_node is 1)
- pi - process id (present if log_process is 1)
- sc - source channel (always present)
- dc - destination channel (field always present, though it will be empty for types of entries other than an enqueue "E" entry)
- ac - entry type or action (always present)
- sp - protocol modifier values from action field (Separated out from the action field if log_format is set to 6)
- sz - message size, reported in units of MTA blocks (field always present, though potentially empty for types of entries such as J or V entries)
- so - source address (always present)
- sd - domain from source address (present if log_format is set to 6)
- od - original destination address (field always present, though potentially empty for types of entries such as J entries)
- de - destination address (field always present, though potentially empty)
- rf - recipient flags (present if bit 0/value 1 of log_notary is set)
- fi - filename (present if bit 0/value 1 of log_filename is set)
- ei - envelope ID (present if bit 0/value 1 of log_envelope_id is set)
- mt - (new in 8.0) message tracking id and timeout, in the format tracking-id:timeout (present if bit 0/value 1 of log_tracking is set and the message has a tracking ID and/or timeout)
- dd - (new in 8.0) deferred delivery time (present if bit 0/value 1 of log_timesis set and the message has a deferred delivery time request)
- ex - (new in 8.0) expiry time (present if bit 2/value 4 of log_times is set and the message has an expiry time)
- mi - message ID and optionally the message IDs of related messages, separated by commas (present if bit 0/value 1 of log_message_id is set)

- us - username (present if bit 0/value 1 of log_username is set and a username is available)
- as - (new in 8.0) Authenticated user's primary mail address, *i.e.*, normally the value of the user's mail attribute (present if bit 2/value 4 of log_username is set and a primary address is available)
- au - (new in 7.0.5) SMTP AUTH parameter (present if bit 0/value 1 of log_auth is set and an AUTH parameter was present)
- ss - source system (present if bit 0/value 1 of log_connection is set and source system information is available)
- se - sensitivity (present if bit 0/value 1 of log_sensitivity is set)
- mp - (new in 8.0) MT-PRIORITY (present if bit 0/value 1 of log_mtpriority is set)
- pr - priority (present if bit 0/value 1 of log_priority is set)
- in - intermediate address (present if bit 0/value 1 of log_intermediate is set and intermediate address information is available)
- ia - initial (RCPT TO) address (present if bit 1/value 2 of log_intermediate is set and initial address information is available)
- ui - (new in 8.0) recipient UID (present if bit 0/value 1 of log_uid is set and a recipient UID is available; in particular, will never be present in dequeue "D" records)
- mu - (new in 7.0.5) IMAP UID and UIDVALIDITY for messages delivered via an ims-ms channel (present if bit 0/value 1 of log_mailbox_uid is set and UID and/or UIDVALIDITY data is available)
- fr - SMTP extension FUTURERELEASE value (present if bit 0/value 1 of log_futurerelease is set and future release value is present)
- fl - Sieve filter actions applied (present if bit 0/value 1 of log_filter is set and Sieve filter information is available; in particular, will never be present in dequeue "D" records since there is no Sieve filtering performed (hence no filter information) at that point)
- re - reason (present if bit 0/value 1 of log_reason is set and a reason string is available)
- di - diagnostic (present if bit 0/value 1 of log_diagnostics is set (the default) and diagnostic information is available)
- tr - transport information (present if bit 5/value 32 of log_connection is set, transport information is available, and log_format is not set to 6)
- li - local IP address (present if bit 5/value 32 of log_connection is set, transport information is available, and log_format is set to 6)
- ri - remote IP address (present if bit 5/value 32 of log_connection is set, transport information is available, and log_format is set to 6)
- ap - application information (present if bit 6/value 64 of log_connection is set, application information is available, and log_format is not set to 6)
- po - application protocol (present if bit 6/value 64 of log_connection is set, application information is available, and log_format is set to 6)

- po - SSL/TLS information string (present if bit 6/value 64 of log_connection is set, application information is available, SSL/TLS is being used, and log_format is set to 6)
- qt - time in queue (present if bit 0/value 1 of log_queue_time is set)
- tg - (new in 7.0.5) conversion tags (present if bit 0/value 1 of log_conversion_tag is set and any conversion tags are present) Note: This changes from a single tg attribute to per-tag t0, t1, ... attributes if log_format is set to 6
- if - (new in 7.0.5) IMAP flags (present if bit 0/value 1 of log_imap_flags is set and any IMAP flags are present)
- df - (new in 7.0.5) delivery flags (present if bit 0/value 1 of log_delivery_flags is set)
- cd - (new in 8.0) time spent waiting on external service callouts (present if bit 0/value 1 of log_callout_delays is set)
- sm - smartsend information(present if bit 0/value 1 of log_smartsend is set and smartsend information is available)
- dk - (new in 8.1.0.6) DKIM signing information (present if bit 0/value 1 of log_dkim is set and DKIM signing was enabled)
- fm - (new in 8.1.0.2) Address from header From: field (present if bit 0/value 1 of log_from is set and a parsable From: field address is present)
- tl - (new in 8.0) String produced by "transactionlog" Sieve actions Note: The attribute name changes from tl to msg if log_format is set to 6
- he - (new in 8.1.0.1) Selected header fields (present if bit 2/value 4 of log_header is set and any of the selected headers are present) Note: This changes from a single he attribute to per-field h0, h1, ... attributes if log_format is set to 6

Here are two sample en entries in XML format showing various different fields being logged (wrapped for printing clarity; the actual log file entries always appear in reality on a single line):

```
<en ts="2004-12-08T00:40:26.70" pi="0d3730.10.43" sc="tcp_local"
dc="l" ac="E" sz="12" so="info-E8944AE8D033CB92C2241E@whittlesong.com"
od="rfc822;ned+2Bcharsets@mauve.sun.com"
de="ned+charsets@mauve.sun.com" rf="22"
fi="/path/ZZ01LI4XPX0DTM00IKA8.00" ei="01LI4XPQR2EU00IKA8@mauve.sun.com"
mi="&lt;11a3b401c4dd01$7c1c1ee0$1906fad0@elara&gt;" us=""
ss="elara.whittlesong.com ([208.250.6.25])"
in="ned+charsets@mauve.sun.com" ia="ietf-charsets@innosoft.com"
fl="spamfilter1:rvLiXh158xWdQKa9iJ0d7Q==, addheader, keep"/>

<en ts="2016-08-30T06:28:59.93" pi="28e3d.4.233" sc="tcp_local"
dc="process" ac="E" sz="5" so="" od="rfc822;user+2Berrors@example.com"

"df":68,"cd":":0,,,0,,,::1567,0"}
```

52.46.12.2 Connection entries

Connection transaction (`co`) entries can have the following attributes/name-value pairs:

- `ts` - time stamp (always present; also appears in `en` entries)
- `no` - node name (present if `log_node` is 1; also appears in `en` entries)
- `pi` - process id (present if `log_process` is 1; also appears in `en` entries)
- `sc` - source channel (always present; also appears in `en` entries)
- `dr` - direction (always present; specific to connection entries): a "`+`" for inbound connections, or a "`-`" for outbound connections
- `ac` - entry type or action (always present; also appears in `en` entries)
- `tr` - transport information (always present; may also appear in `en` entries when bit 5 of `log_connection` is set);
- `ap` - application information (always present; may also appear in `en` entries when bit 6 of `log_connection` is set)
- `mi` - the name presented on the ETRN command line (present only if bit 0/value 1 of `log_message_id` is set, and ETRN was used with an argument; note that setting bit 0/value 1 of `log_message_id` also causes the logging of message ID information, if available, in message transaction (`en`) log records)
- `us` - username (present only if bit 0/value 1 of `log_username` is set and username information is available; also appears in `en` entries)
- `ex` - (new in 8.0) in "U" records, additional authentication information such as the authentication mechanism (present only if bit 4/value 16 of `log_username` is set and such extra information is available) (new in MS 8.1.0.3) in connection open/close records, conversion tags associated with the current message being dequeued (present only if bit 4 (value 16) is set and there are conversion tags to log)
- `di` - diagnostic (present only if bit 0/value 1 of `log_diagnostic` is set and diagnostic information is available; also appears in `en` entries)
- `ct` - time to connect/fail to connect/connection was open (present only if bit 0/value 1 of `log_queue_time` is set; specific to connection entries)

Here is a sample `co` entry in XML format (wrapped purely for printing clarity; in reality, such entries always appear on a single line):

```
<co ts="2004-12-08T00:38:28.41" pi="1074b3.61.281" sc="tcp_local" dr="+"
ac="O" tr="TCP|209.55.107.55|25|209.55.107.104|33469" ap="SMTP"/>
```

And here is a similar entry in JSON format: (also wrapped for clarity):

```
{"ty":"co","ts":"2018-10-16T07:14:09.27","pi":"547a.3.0","sc":"tcp_local",
"dr":"+","ac":"O","tr":"TCP|127.0.0.1|25|127.0.0.1|48023","ap":"SMTP"}
```

52.46.12.3 Header entries

Header (he) entries have the following attributes/name-value pairs:

- ts - time stamp (always present; also used in en entries)
- no - node name (present if log_node is 1; also used in en entries)
- pi - process id (present if log_process is 1; also used in en entries)
- va - header line value (always present)

Here is a sample he entry in XML:

```
<he ts="2004-12-08T00:38:31.41" pi="1074b3.61.281" va="Subject: foo"/>
```

And one in JSON:

```
{"ty":"he","ts":"2018-10-16T07:14:35.35","pi":"547a.3.3",
 "va":"Subject: This is a test"}
```

52.46.13 Transaction logging MTA options: log_from (0-7)

(New in MS 8.1.0.2.) The log_from MTA option controls whether or not the address in the header From: field is extracted and used in transaction log entries and mapping probles. A value of 0 means the From: field is not extracted. Setting bit 0 (value 1) causes from address to be logged just prior to any DKIM string. The XML/JSON attribute name in XML/JSON format logs (log_format set to 4 or 5-6, respectively) is "fm". Setting bit 1 (value 2) causes from address to be included in the LOG_ACTION mapping table probe, again just prior to the DKIM string.

The default for this option is 0 in all log formats except flat JSON (log_format value 6), where it is 1.

Normally the fm attribute only appears in XML or JSON format logs if there is a from address to log. However, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

52.46.14 Transaction logging MTA options: log_futurerelease (0-3)

(New in 8.0.) The log_futurerelease MTA option controls whether or not any SMTP FUTURERELEASE value is included in MTA message transaction log entries and/or LOG_ACTION mapping table probes. Setting bit 0 (value 1) causes the future release value, expressed as an offset in seconds from the current time, to be logged immediately after the mailbox UID is logged, before the Sieve filter information. A "fr" attribute is used in the XML log format. If bit 1 (value 2) is set in the log_futurerelease MTA option, then this information appears in the LOG_ACTION mapping table probe immediately after the mailbox UID, before the Sieve filter information.

52.46.15 Transaction logging MTA options: log_header (0-7)

The log_header MTA option controls whether the MTA writes message headers to the message transaction log file, mail.log. Or, as of MS 6.0, see also the channel option logheader, which may be used to enable this facility on a per-channel basis, as well as to override log_header on a per-channel basis.

Originally, the permitted values for log_header were merely 0 or 1. As of at least MS 6.1, the option takes a bit-encoded integer value instead, with the lowest two bits defined as a group. A value of 1 for these bits enables message header logging for both enqueue and dequeue directions; a value of 2 enables message header logging for message enqueues, without enabling logging for message dequeues. A value of 0, the default, disables message header logging. As of MS 8.0.2, a value of 3 for the lowest two bits is also supported, which enables header logging during dequeues but not enqueues.

As of MS 8.1.0.1, bit 2, value 4, is also defined. If set it causes header logging to be included in the transaction log entry itself. A value of 0 logs header information in separate records.

Note that only outermost message headers are available for logging purposes; the "inner" headers on inner MIME parts, if any, are not available. The specific headers written to the log file are controlled by a site-supplied log_header.opt file in legacy configuration or unified configuration prior to MS 8.1.0.1. As of MS 8.1.0.1, the log_header_options MTA option should be used to control which headers are written. The format of this file/option is that of other MTA header option files. For instance, a log_header.opt file containing

```
To: MAXIMUM=1
From: MAXIMUM=1
Defaults: MAXIMUM=-1
```

would result in writing the first To: and the first From: header per message to the log file.

When header field logging is enabled and log_format is 1, 2, or 3, the header fields are logged in the format:

dd-mmm-yyyy hh:mm:ss.ss > header-line

or up to two additional fields may be present (if log_node is 1 and log_process is 1 -- the header line logging makes no display of any other fields):

dd-mmm-yyyy hh:mm:ss.ss node process-field > header-line

with one such line per header line to be logged. In XML-compatible format (log_format set to 4), the header fields are he elements.

When enabling log_header, consider also enabling log_process, as it is helpful for correlating header entries with corresponding regular message entries.

If the goal is to record subsets of information from one or more header lines, rather than necessarily logging full header lines, see as an alternative to log_header the (both new-in-MS-8.0) log_transactionlog MTA option and Sieve "transactionlog" action.

52.46.16 log_header_options Option

The log_header_options MTA option contains the entire header options file controlling the logging of header fields. It corresponds to the legacy configuration log_header.opt file.

The log_header_options MTA option would typically be set or modified by using the edit command of msconfig, *e.g.*:

```
msconfig> edit log_header_options
```

52.46.17 log_headers_maxchars Option

New in MS 8.1.0.1, the log_headers_maxchars MTA options places a limit on the size of the header lines included in primary transaction log entries as a result of the actions of the AUTH_REWRITE or AUTH_ACCESS mapping. THe default is 200 bytes.

52.46.18 Logging IMAP flags: log_imap_flags (bitmask)

New in 7.0.5. The log_imap_flags MTA option causes a field recording IMAP flags (those set by the MTA) to be included in MTA message transaction log file entries and/or LOG_ACTION mapping table probes.

Bit 0 (value 1) enables including the field in MTA message transaction log file entries; bit 1 (value 2) enables including the field in LOG_ACTION mapping table probes. If enabled, this field appears after the conversion tag field (log_conversion_tag option). The XML format tag for this field is "if". The default in non-XML format logging is 0; the default when XML format (log_format=4) is enabled is 1.

52.46.19 Transaction logging MTA options: log_delivery_flags (bitmask)

New in 7.0.5. The log_delivery_flags MTA option causes a field recording delivery flag bits (recorded as an integer) in MTA message transaction log file entries and/or LOG_ACTION mapping table probes. Bit 0 (value 1) enables including the field in MTA message transaction log file entries; bit 1 (value 2) enables including the field in LOG_ACTION mapping table probes.

If enabled, this field appears after the IMAP flags field (log_imap_flags MTA option). The XML format tag for this field is "df". The default in non-XML format logging is 0; the default when XML format (log_format=4) is enabled is 1.

Bits 0 (value 1) and 1 (value 2) of the logged field roughly correspond to those in the deliveryflags channel option. The other bits in this value are intentionally undocumented.

52.46.20 Transaction logging MTA options: log_intermediate (0-63)

(New in MS 6.2.) The log_intermediate MTA option controls the inclusion of the "intermediate" form of the destination address, and the inclusion of the "original" (RCPT TO) form of the destination address, in MTA message transaction log (mail.log) records. The option takes a bit-encoded integer value.

Table 52.38 log_intermediate MTA option bit values

Bit	Value	Usage
0	1	When set, the "intermediate" address form is logged, after the optional (see the log_priority MTA option) priority field. In XML or JSON format (log_format set to 4 or 5, respectively), the intermediate address is the in attribute.
1	2	When set, the "original" (RCPT TO) address form is logged. This information appears after the optional (see bit 0) "intermediate" address form and before the optional (see the log_filter MTA option) Sieve filter field. In XML or JSON format (log_format set to 4 or 5, respectively), the initial address is the ia attribute.
2	4	When set, the "intermediate" address form is included in LOG_ACTION mapping probes.
3	8	When set, the "original" (RCPT TO) address form is included in LOG_ACTION mapping probes.
3	8	New in 8.0.2.3. When set, the in attributes appears in XML and JSON logs unconditionally, even when there is no intermediate address information to log.
3	8	New in 8.0.2.3. When set, the ia attributes appears in XML and JSON logs unconditionally, even when there is no initial address information to log.

52.46.21 Transaction logging MTA options: log_local (0 or 1)

The log_local MTA option controls whether or not the domain name for the local host is appended to logged addresses that don't already contain a domain name. A value of 1 enables this feature, which is useful when logs from multiple systems are concatenated and processed. A value of 0, the default, disables this feature.

52.46.22 Logging Indexed Search Converter status: log_isc_status (bitmask)

New in MS 8.0.2. The log_isc_status MTA option causes a field recording information sent to or reported by the Indexed Search Converter (ISC) to be included in log file entries (both "S" and "J" entries on LMTP server systems, "E" entries on front end systems) and/or LOG_ACTION mapping table probes.

Bit 0 (value 1) enables including the field in MTA message transaction log file entries; bit 1 (value 2) enables including the field in LOG_ACTION mapping table probes. If enabled, this field appears after the "diagnostics" field (log_diagnostics option) and before the transport

information filed (log_transportinfo option). The XML format tag for this field is "is". The default is 1 in XML and JSON format logs and 0 in other formats.

Normally the is attribute only appears in XML or JSON format logs if there is ISC status information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

The content of the "is" field differs depending on the type of system performing the logging. On LMTP server systems the field will begin with an indication of whether or not immediate conversion was requested - "IMMEDIATE" if it was, "DEFERRED" if it wasn't. This will be optionally followed by any status information returned by the converter.

On all other types of systems the "is" will contain when the indexing operaton is supposed to be performed if a preference was selected by the system doing the logging. A value of "DEFERRED" is recorded if deferred indexing was requested. A value of "IMMEDIATE-*r*-*t*, where *r* is the retry limit and *t* is the timeout, is recorded when immediate indexing is requested.

52.46.23 Transaction logging MTA options: log_mailbox_uid (0-3)

Messages delivered to an IMAP store are tagged with a UID and the folder's UIDVALIDITY value upon insertion. The log_mailbox_uid MTA option provides the means to log this type of information, which can be useful when there is a need to correlate a message in the store with MTA actions. Prior to MS 8.0 the field consisted of these two values delimited by a colon. in MS 8.0 and later release two additional fields have been added: One for the message digest and another for the name of the folder the message is actually delivered to. Note that the message digest is only included when one is calculated for other reasons.

The log_mailbox_uid MTA option defaults to 0. Setting bit 0 (value 1) logs the UID and UIDVALIDITY of messages delivered by the ims-ms channel to the store. The UID and UIDVALIDITY appears immediately after the LDAP uid. A "mu" attribute is used in the XML or JSON log format (log_format set to 4 or 5, respectively). If bit 1 (value 2) is set in the log_uid MTA option, then the uid appears in the LOG_ACTION mapping table probe immediately after the LDAP uid.

Normally the mu attribute only appears in XML or JSON format logs if there is mailbox uid information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

It's a simple matter to log this information in the case of ims-ms channel. But in the case of LMTP things are not so simple - the information naturally exists in the LMTP server but not the client. An LMTP extension is needed to pass the information to the client for logging purposes.

Consequently, as of MS 8.0.1.2, the LMTP client and server have been enhanced to support a new UID extension. This extension, if present, provides a single UID parameter on the MAIL FROM command that accepts the values "NO" or "RET". If the latter is specified the final LMTP responses to DATA/BDAT will include the UID, UIDVALIDITY, digest value (if available), and optionally the folder if different from INBOX, separated by colons and enclosed in angle brackets. For example:

```
S: 220 multke.mrochek.com -- Server LMTP (Oracle Communications Messaging Server 8.0.1.2 64bit (built Sep 19 2015))
C: LHLO multke.mrochek.com
S: 250-multke.mrochek.com
S: 250-8BITMIME
S: 250-UID
S: 250-PIPELINING
S: 250-CHUNKING
S: 250-XDFLG
S: 250-XQUOTA
S: 250-XAFLG
S: 250-ENHANCEDSTATUSCODES
S: 250-HELP
S: 250 SIZE 0
C: MAIL FROM:<> UID=RET
S: 250 2.5.0 Address Ok.
C: RCPT TO:<test1+folder@ims-ms-daemon> XDFLGS=5
S: 250 2.1.5 test1@ims-ms-daemon OK.
C: RCPT TO:<test2@ims-ms-daemon>
S: 250 2.1.5 test2@ims-ms-daemon OK.
C: DATA
S: 354 Enter mail, end with a single ".".
C: Subject: Test message
C:
C: This is a test.
C: .
S: 250 2.5.0 <1445028362:2::folder> Delivery to user OK
S: 250 2.5.0 <1440097745:2:> Delivery to user OK
```

This extension is enabled by default and cannot be disabled. The LMTP client will use if it present to obtain UID information to use in conjunction with the `log_mailbox_uid` MTA option as well as the recall facility.

Additionally, as of MS 8.0.1.2 the `log_mailbox_uid` MTA option now enables logging of UID information in the S records logged by the LMTP server. Note that this logging does not depend on use of the LMTP extension.

Compatibility note: Additional information will be added to this field in the future. When that happens it will appear as additional colon-separated values. Any code written to process this field needs to take this into account.

52.46.24 Transaction logging MTA options: `log_message_id` (0-7)

The `log_message_id` MTA option primarily controls whether or not message IDs are saved in the `mail.log` file or included in `LOG_ACTION` mapping probes. Bit 0 (value 1), if set, enables message ID logging in MTA transaction logging. When message ID logging is enabled, the message ID will be logged after the final form envelope To address entry---and after the message file name, if `log_filename` is also enabled. In XML or JSON format (`log_format` set to 4 or 5, respectively), message ID logging, if enabled, appears as the `mi` attribute. As of MS 6.3p1, enabling XML or JSON format (`log_format` set to 4 or 5) causes the default for `log_message_id` to be 1 (message ID logging enabled); with any other format, the default is 0 (message ID logging disabled), as in previous versions.

Multiple message IDs can appear, separated by commas. When mutiple IDs are present, the first is the ID of the message being logged and subsequent IDs are the IDs of related messages, e.g., when a DSN or MDN is generated and enqueued by the MTA, the second message ID will be that of the message the DSN or MDN is in regards to.

Normally the `mi` attribute only appears in XML or JSON format logs if there is message id information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

Note that the log_message_id option's transaction log field is also used in authentication "U" records to record the SASL error, and in SMTP ETRN "I" records to record the host name from the client ETRN command.

New in 7.0-3.01, bit 1 (value 2), if set, causes message ID information to be included in LOG_ACTION mapping probes.

52.46.25 Logging message transfer priorities: log_mtpriority (bitmask)

New in 8.0. The Message Transfer Priority SMTP extension MT-PRIORITY, defined in RFC 6710, provides the means to associate a message transfer priority with a given message. Logging of these priority values, ranging from -9 to 9, with a default value of 0, is controlled by the log_mtpriority MTA option.

Note that there is a Priority: header-based priority mechanism and associated logging option log_priority. These are separate mechanisms. An explicit MT-PRIORITY overrides the older Priority: header handling.

The log_mtpriority option defaults to 0. Setting bit 0 (value 1) enables logging of the message transfer priority associated with each transaction. The message transfer priority appears immediately after the message sensitivity and before the header-based priority in each log entry. A "mp" element is used in the new XML log format (log_format=4). If bit 1 (value 2) is set in the log_mtpriority MTA option, then the message transfer priority appears in the LOG_ACTION mapping table probe, again immediately after the sensitivity field and before the header-based priority field.

52.46.26 Transaction logging MTA options: log_node (0 or 1; OpenVMS only until MS 6.3)

The log_node MTA option controls whether or not the node associated with the process generating an entry is saved in the mail.log file (and connection.log file, if a separate connection log file is used). This may be useful information when the MTA is running in a multi-node cluster.

A value of 1 enables node name logging. When the node name is logged, it will appear as the first field following the date and time stamps in log entries. In XML-compatible format (log_format set to 4), node logging, if enabled, appears as the no attribute. A value of 0 (the default) disables node name logging. (Note that on UNIX and Windows, prior to MS 6.3, the node name was always considered to be null, so on UNIX and Windows, attempting to set log_node to 1 merely resulted in an empty node field; *i.e.*, an extra space after the time stamp in formats other than XML format. As of MS 6.3, if log_node is 1, then the MTA on UNIX will log the result of a gethostname call when that call found a value, or the "L" channel official host name, otherwise.)

52.46.27 Transaction logging MTA options: log_notary (0-3)

The log_notary MTA option controls whether the MTA includes an indicator of NOTARY (delivery receipt) flags in the mail.log file entries or in LOG_ACTION mapping probes.

Bit 0/value 1, if set, enables NOTARY flag logging. As of MS 6.3P1, enabling XML format (log_format set to 4) causes the default for log_notary to be 1; with any other format, the default is 0, as in previous versions. The NOTARY flags will be logged as a bit encoded integer after the current form of the envelope To: address. In XML-compatible format (log_format set to 4), notification flag logging, if enabled, appears in the rf attribute.

Table 52.39 log_notary MTA option bit value

Bit	Value	Usage
0	1	Use header-style delivery receipt requests, corresponding to the use of the reportheader channel option or reportboth channel option.
1	2	Suppress header-style delivery receipt requests.
2	4	NDN failure notification requested: Generate an NDN if the message fails delivery, *i.e.*, NOTARY parameter NOTIFY=FAILURE.
3	8	DSN delivery receipt requested: Send a DSN (delivery receipt) if message delivery succeeds, *i.e.*, NOTARY parameter NOTIFY=SUCCESS.
4	16	DSN delay warning requested: Send a "delivery of your message has been delayed" DSN if message delivery is delayed, *i.e.*, NOTARY parameter NOTIFY=DELAY.
5	32	Internal flag keeping track of notification handling for mailing lists.
6	64	Suppress all notifications, *i.e.*, NOTARY parameter NOTIFY=NEVER.
7	128	Generate a delay DSN if the first delivery attempt fails.
8	256	NOTARY was used; set whenever any NOTIFY parameter was used during envelope From submission.

New in 7.0-3.01, bit 1 (value 2), if set, causes NOTARY information to be included in LOG_ACTION mapping probes.

52.46.28 Transaction logging MTA options: log_priority (0-3)

The log_priority MTA option controls whether or not the effective processing priority for the message is included in the mail.log file entries or LOG_ACTION mapping probes. Bit 0/value 1, if set, enables priority logging. As of MS 6.3P1, enabling XML format (log_format set to 4) causes the default for log_priority to be 1; with any other format, the default is 0, as in previous versions. If logging is enabled, the priority will be logged after the message sensitivity value, before the transport information. In XML-compatible format (log_format set to 4), priority logging, if enabled, appears as the pr attribute.

New in 7.0-3.01, bit 1 (value 2), if set, causes priority information to be included in LOG_ACTION mapping probes.

As of 8.0, the MTA also supports the SMTP MT-PRIORITY extension, which provides a different, non-header-based, priority facility. The logging of MT-PRIORITY is controlled separately, via the log_mtpriority MTA option.

52.46.29 Transaction logging MTA options: log_process (0 or 1)

The log_process MTA option controls whether or not the ID of the process is saved in the mail.log file (and the connection.log file, if a separate connection log is used).

A value of 1 enables process ID logging. A value of 0 disables it. As of MS 6.3p1, enabling XML format (log_format set to 4) causes the default for log_process to be 1; with any other format, the default is 0, as in previous versions.

The process ID will be logged after the date and time stamps in log entries---and after the node name, if log_node is also enabled. In XML-compatible format (log_format set to 4), process ID logging, if enabled, appears is the pi attribute. The process ID field itself will consist of the process ID in a hexadecimal representation followed by a period, next in the case of a multithreaded channel the thread ID followed by a period, followed by a (per process) sequence number that uniquely identifies the logging operation as a whole. That is, in the case of a single threaded channel

process-id.sequence

or in the case of a multithreaded channel

process-id.thread-id.sequence

Note in particular that via the process id and thread id, TCP/IP channel message enqueue/dequeue (E/D) records may be correlated with SMTP connection open/close (O/C) records. The sequence number provides the ability to identify all the entries associated with the processing a a specific queue entry.

log_process is one of the most useful MTA logging options for correlating between multiple transaction records relating to the same message, observing the timing between entries, *etc.*

52.46.30 Transaction logging MTA options: log_queue_time (0-3)

(New in MS 6.3.) The log_queue_time MTA option controls whether "time in queue" information, measured in seconds, is included in MTA message transaction log records or LOG_ACTION mapping probes.

Bit 0/value 1, if set, enables such logging; having the bit clear disables such logging. As of MS 6.3P1, enabling XML format (log_format set to 4) causes the default for log_queue_time to be 1; with any other format, the default is 0, as in previous versions.

If logging is enabled, then the time that the message has been in this channel queue (the current system time minus the creation time at which this message file was generated as stored in the envelope information in the message file) will be logged after the optional log_connection bit 6 (value 64) application information. (In versions prior to 7.0.5, this made queue time the very last field logged. But some optional new fields added in 7.0.5 can appear after queue time.) Note that the final ordering is: log_filter field, log_reason field, log_diagnostics diagnostic field, log_remote_mta remote-MTA field, transport field (log_connection bit 5/value 32), application field (log_connection bit 6/value 64), queue time field. (Note that queue time is not a counted-length field; log_format set to 3 has no effect upon this field.) When log_format is set to 4 so that XML format is output, queue time logging, if enabled, appears in the qt attribute.

As of 6.3P1, setting bit 0/value 1 of log_queue_time also enables logging of connection time information in "O" (time to open conection), "Y" (time spent before open failure), and

"C" (time connection was open) connection log records. If XML format logging is enabled this information appears in the ct attribute.

New in 7.0, the queue time field also contains meaningful (though slightly different in meaning) information on LMTP server back end hosts: there it represents how long the message transaction took (the time from start of the message transaction until message deposit into the store and acknowledgement back to the LMTP client). Also new in 7.0, setting log_queue_time to 1 will cause inclusion of a final field in MTA connection log O and Y records showing the time it took to open the connection, or fail to open a connection, respectively. (This is the time that it took from just before the MTA begins attempting any appropriate DNS lookups, until writing its connection log entry.)

New in 7.0-3.01, bit 1 (value 2), if set, causes queue time and/or connection time information to be included in LOG_ACTION mapping probes for both transaction and connection log records.

52.46.31 Transaction logging MTA options: log_reason (0-3)

(New in MS 6.3.) The log_reason MTA option controls whether message rejection reason text is included in MTA message transaction log entries and LOG_ACTION mapping probes that correspond to a message rejection ("R" or "K" records).

Setting bit 0/value 1 enables such logging; clearing the bit disables such logging. As of MS 6.3P1, enabling XML format (log_format set to 4) causes the default for log_reason to be 1; with any other format, the default is 0, as in previous versions.

If logging is enabled, the reason text string will be logged just after the filter field (log_filter set to 1) and just before the SMTP delivery status (log_diagnostics SMTP diagnostic) field. In XML or JSON format (log_format set to 4 or 5, respectively), the reason logging, if enabled, appears as the re attribute.

Normally the re attribute only appears in XML or JSON format logs if there is reason information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

New in 7.0-3.01, bit 1 (value 2), if set, causes reason information to be included in LOG_ACTION mapping probes.

52.46.32 Transaction logging MTA options: log_remote_mta (0-3)

(New in MS 8.0.2.3.) The log_remote_mta MTA option controls whether the remote MTA name is included in MTA message transaction log entries as a separate field and LOG_ACTION mapping probes that correspond to an operation involving a remote SMTP or LMTP server.

Setting bit 0/value 1 enables the generation of the remote MTA and also disables the inclusion of this information in the diagnostics field; clearing the bit disables the use of a separate field. The default is 0.

If logging is enabled, the remote MTA name will be logged just after the SMTP delivery status (log_diagnostics SMTP diagnostic) field and just before the ISC status field. In XML or JSON format (log_format set to 4 or 5, respectively), the reason logging, if enabled, appears as the rm attribute.

Normally the rm attribute only appears in XML or JSON format logs if there is remote MTA information to log. Setting bit 2 (value 4) will cause the attribute to appear unconditionally.

Bit 1 (value 2), if set, causes remote MTA information to be included in LOG_ACTION mapping probes.

52.46.33 Transaction logging MTA options: log_sensitivity (0-3)

The log_sensitivity MTA option controls whether message Sensitivity: header values are included in MTA message transaction log entries or LOG_ACTION mapping probes.

Bit 0/value 1, if set, enables such logging; clearing the bit disables such logging. If logging is enabled, the sensitivity value will be logged in an integer representation after the connection information, before the priority field. In XML-compatible format (log_format set to 4), sensitivity logging, if enabled, appears in the se attribute. The values are (with "Normal" being the default, intended for less sensitive material, and "Company-Confidential" corresponding to the most sensitive material):

Table 52.40 log_sensitivity MTA option values

Value	Meaning
0	Normal
1	Personal
2	Private
3	Company-Confidential

New in 7.0-3.01, bit 1 (value 2), if set, causes sensitivity information to be included in LOG_ACTION mapping probes.

52.46.34 Transaction logging MTA options: log_smartsend (0-7)

(New in MS 8.1.0.1.) The log_smartsend MTA option controls whether information about the actions of smartsend callouts are included in MTA message transaction log records. The option defaults to 0, meaning that this information isnot logged. Setting bit 0 (value 1) causes smartsend information to be logged just prior to any header from string. The XML/JSON attribute name in XML/JSON format logs (log_format set to 4 or 5, respectively) is "sm". Setting bit 1 (value 2) causes smartsend information to be included in the LOG_ACTION mapping table probe, again just prior to the header from string.

Normally the sm attribute only appears in XML or JSON format logs if there is transaction log information to log. However, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

As of MS 8.1.0.6 the DEQUEUE_ACCESS mapping and the AUTH_ACCESS mapping provide the means to append strings to the smartsend log value.

52.46.35 Transaction logging MTA options: log_times (0-63)

The log_times MTA option controls whether deferred delivery time request values -- and optionally message expiry time values -- are included in MTA message transaction log entries or LOG_ACTION mapping probes.

Bit 0 (value 1), if set, enables logging any deferred delivery request time, as for instance requested via the FUTURERELEASE SMTP extension or Deferred-delivery: header line. Clearing bit 0 disables such logging. In XML or JSON format (log_format set to 4 or 5, respectively), the deferred delivery time logging, if enabled, appears in the dd attribute. Bit 1 (value 2), if set, causes a deferred delivery request time field to be included in LOG_ACTION mapping probes.

Normally the dd attribute only appears in XML or JSON format logs if there is deferred delivery time information to log. As of MS 8.0.2.3, setting bit 4 (value 16) will cause the attribute to appear unconditionally.

Bit 2 (value 4), if set, enables logging any message expiry time. In XML or JSON format (log_format set to 4 or 5, respectively), the message expiry logging, if enabled, appears in the ex attribute. Setting bit 3 (value 8) causes a message expiry field to be included in LOG_ACTION mapping probes.

Normally the dd attribute only appears in XML or JSON format logs if there is expiry date information to log. As of MS 8.0.2.3, setting bit 5 (value 32) will cause the attribute to appear unconditionally.

If enabled, the deferred delivery time and message expiry time fields appear immediately after the tracking ID field and immediately prior to the message ID field.

52.46.36 Log Tracking Information (log_tracking)

The log_tracking MTA option controls logging of message tracking/recall information. Bit 0 (value 0), if set, includes the tracking id and the current tracking in transaction log entries. The two appear as a single field; the id appears first and is separated from the timeout value by a colon. Tracking information appears immediately after the envelope id and before the deferred delivery time. An "mt" attribute is used in XML or JSON format (log_format set to 4 or 5, respectively).

Normally the mt attribute only appears in XML or JSON format logs if there is tracking information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

If bit 1 (value 2) is set in the log_tracking MTA option, then the tracking id and timeout, again separated by a colon, appear in the LOG_ACTION mapping table probe, again immediately after the envelope id and before the deferred delivery time.

52.46.37 Transaction logging MTA options: log_transactionlog (0-3)

(New in MS 8.0.) The log_transactionlog MTA option controls whether Sieve transactionlog action strings are included in MTA message transaction log records. The option defaults to 0, meaning that such Sieve actions are not logged. Setting bit 0 (value 1) causes the transactionlog string to be logged at the very end of enqueue ("E") records. The XML/JSON attribute name in XML/JSON format logs (log_format set to 4 or 5, respectively)

is "tl". Setting bit 1 (value 2) causes the transactionlog string to be included in the LOG_ACTION mapping table probe, again at the very end.

Normally the tl attribute only appears in XML or JSON format logs if there is transaction log information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

For instance, with MTA message transaction logging enabled (the logging channel option set for all channels) and with log_transactionlog also set:

```
msconfig> show logging
role.channel:defaults.logging
msconfig> set log_transactionlog 1
```

then an MTA system filter (see for instance the msconfig command edit filter) including:

```
require "variables";
if header :matches "subject" "*" {transactionlog "${0}";}
```

will cause MTA message transaction log records to include the contents of the Subject: header line. (Note that merely logging the Subject: header line of messages passing through the MTA could instead be achieved via use of log_header or logheader. But the Sieve script approach allows more fine-tuning, as a Sieve script can be coded with complex logic dependent upon other message details, such as message sender or recipient, presence of specific strings in the header, *etc.*)

52.46.38 Transaction logging MTA options: log_uid (0-7)

Certain alias operations, particularly alias expansion of user addresses, involve looking up LDAP entries with uid attributes. When such entries are encountered, the uid is carried through the uid expansion process and, in the case of delivering to the Message Store, the uid is typically incorporated into the resulting address. The log_uid MTA option provides the means to log such uids. This can be useful when there is a need to identify the last LDAP entry involved in the alias expansion. Note that uids are only logged on message enqueue operations; there is no uid available to log on message dequeues.

The log_uid MTA option defaults to 0. Setting bit 0 (value 1) logs any available uid. The uid appears immediately after the initial recipient address. A "ui" attribute is used in the XML or JSON log format (log_format set to 4 or 5, respectively). If bit 1 (value 2) is set in the log_uid MTA option, then the uid appears in the LOG_ACTION mapping table probe immediately after the initial destination address field.

Normally the ui attribute only appears in XML or JSON format logs if there is uid information to log. As of MS 8.0.2.3, setting bit 2 (value 4) will cause the attribute to appear unconditionally.

52.46.39 Transaction logging MTA options: log_use_xtext (bitmask)

The log_use_xtext MTA option controls the use of xtext encoding of addresses in MTA transaction log file entries and LOG_ACTION mapping probes.

52.46.40 Transaction logging MTA options: log_username (0-511)

The log_username MTA option is a bit-encoded value which controls whether or not user information associated with a process that enqueues mail is saved in the mail.log file (and optional connection.log file) or included in LOG_ACTION mapping probes.

Note that messages submitted via SMTP with authentication (SMTP AUTH) will be considered to be owned by the username that authenticated, prefixed with the asterisk, *, character. (Note also that messages enqueued to the filter_discard channel always get the enqueueing username set to literally FILTER_DISCARD; this is for access control purposes.)

The bits in the log_username option are described in the following table:

Table 52.41 log_username option bit values

Bit	Value	Usage
0	1	Enables authenticated username logging in transaction log entries. (Username logging in connection log "U" records is always enabled.) In the MTA message transaction log entries the username will be logged after the final form envelope To address field - and after the message ID, if log_message_id is enabled also, before the connection information, if bit 0/value 1 of log_connection is enabled also. In the MTA connection transaction log entries, the username will be logged after the application information (and after the optional field present if log_message_id is enabled). In XML-compatible format (log_format set to 4), the username appears in the us attribute.
1	2	(New in 7.0-3.01) Causes username information to be included in LOG_ACTION mapping probes.
2	4	(New in MS 8.0) Enables inclusion of the primary mail address associated with the authenticated username in the transaction log. This information appears immediately after the username and under the XML attribute "as".
3	8	(New in MS 8.0) Enables inclusion of the primary mail address associated with the authenticated username in LOG_ACTION mapping table probes. This address appears immediately after the username in the mapping table probe.
4	16	(New in MS 8.0) Causes additional information associated with an authentication operation to be logged (currently just the name of the authentication mechanism), XML tag "ex"; additional information may be added in the future) to be included in connection log "U" records;
5	32	(New in MS 8.0) Causes the same additional information described under the the previous bit to be included in LOG_ACTION mapping table probes immediately after the authenticated username.

6	64	(New in MS 8.0.2.1) Causes the administrator's username, in the case of administrative proxy authentication to be logged in "U" connection log records immediately after the additional authentication information field and using the XML tag "ua".
7	128	(New in MS 8.0.2.1) Causes the administrator's username, in the case of administrative proxy authentication to be included in LOG_ACTION mapping table associated with "U" connection log records. The field appears immediately after the additional authentication information field.
8	256	(New in MS 8.0.2.3) Include the "us" attribute in XML or JSON format transaction entries, regardless of whether or not there's user name information to log.
9	512	(New in MS 8.0.2.3) Include the "as" attribute in XML or JSON format transaction entries, regardless of whether or not there's user name information to log.

Bit 0 is the least significant bit.

As of MS 6.3p1, enabling XML or JSON format (log_format set to 4 or 5, respectively) causes the default for log_username to be 1; with any other format, the default is 0, as was always the case in previous versions.

52.46.41 Transaction logging MTA options: log_8bit_encode 0 or 1)

The log_8bit_encode MTA option controls how non-ASCII material is written to XML format MTA transaction log files. A value of 0 causes such material to be written as-is. Any nonzero value will cause all valid UTF-8 characters to be written as XML numeric character references.

How non-ASCII octets that does not begin a valid UTF-8 sequence is controlled by specific values of the log_8bit_encode MTA option. Currently defined values are:

1. Write the octet as a XML numeric character reference. Note that this is tantamount to interpreting the octet as a character in the ISO-8859-1 charset.
2. Write the octet as an XML entity reference of the form &raw-xx, where xx is the lower-case hexadecimal representation of the octet.
3. Write out a space in place of the octet.

Note that this setting only applies to XML format logs (log_format = 4); non-ASCII characters are always written as-is when other formats are used.

52.46.42 Transaction logging MTA options: separate_connection_log (0 or 1)

The separate_connection_log MTA option controls whether the connection log information generated by setting log_connection to 1 is stored in the usual MTA message transaction logging files, mail.log*, or stored separately in connection.log* files. A separate_connection_log value of 0, the default, causes connection transaction logging

to be stored in the regular message transaction log files; a value of 1 causes the connection transaction logging to be stored separately.

52.46.43 Transaction logging MTA options: return_split_period (integer)

The return_split_period MTA option affects the frequency of MTA transaction log file roll over. The MTA will start new mail.log_current and connection.log_current files every return_split_period runs of the return_job. That is, if return_split_period has the value *N*, then new log files will be started on every *N*th run of the return_job.

For normal operation, a value of 1 is recommended for this option. That causes new log files to be started every time the return_job is run. If, however, the return_job is being run hourly via the schedule.task:return_job.crontab option, then changing return_split_period to the value 24 is recommended. That causes new log files to only be started once per day despite the return_job running once per hour.

52.46.44 Transaction logging MTA options: return_cleanup_period (integer)

Sites may supply a cleanup script, DATAROOT/site-programs/bin/daily_cleanup, which will then be run every time the return_job runs. Such a script might, for instance, move or rename MTA transaction log files. To only run this site-supplied script on every *N*th run of the return job, set the value of the return_cleanup_period MTA option to *N*.

52.47 OpenVMS user agent MTA options

A number of long-standing MTA options exist that, relevant only on OpenVMS, affect the MTA's interaction with OpenVMS user agents such as VMS MAIL, PMDF MAIL, and DECwindows MAIL. These MTA options are not relevant on other platforms.

52.47.1 delivery_receipt_off Option

OpenVMS only.

This option is used to specify a special RFC 822 comment string used in IN% addresses in VMS MAIL to disable any requests for a delivery receipt. The default if this option is not specified is:

```
(NO-DELIVERY-RECEIPT)
```

The enclosing parentheses are required and must be specified in the option value.

52.47.2 delivery_receipt_on Option

OpenVMS only.

This option is used to specify a special RFC 822 comment string used in IN% addresses in VMS MAIL to request a delivery receipt. The default if this option is not specified is:

```
(DELIVERY-RECEIPT)
```

The enclosing parentheses are required and must be specified in the option value.

52.47.3 OpenVMS user agent MTA options: dis_nesting (non-negative integer)

OpenVMS only.

The dis_nesting MTA option controls how many nesting levels the MTA allows in the expansion of VMS MAIL distribution lists. A value of 0 disables the ability to use VMS MAIL distribution lists. Currently this option only affects the PMDF MAIL utility. The default value for this option is 20.

52.47.4 OpenVMS user agent MTA options: form_names (string; OpenVMS only)

OpenVMS only.

The form_names option specifies the names of pop-up form images. Multiple values should be separated with commas but *not* with spaces. The default is "FAX-FORM,PH-FORM,X500-FORM".

52.47.5 mail_delivery_filename Option

OpenVMS only.

52.47.6 missing_address Option

OpenVMS only.

52.47.7 multinet_mm_exclusive Option

OpenVMS only.

52.47.8 OpenVMS user agent MTA options: read_receipt_off (string)

OpenVMS only.

The read_receipt_offMTA option is used to specify a special RFC 822 comment string used in IN% addresses in VMS MAIL to disable any requests for a read receipt. The default if this option is not specified is:

```
(NO-READ-RECEIPT)
```

The enclosing parentheses are required and must be specified in the option value.

52.47.9 OpenVMS user agent MTA options: read_receipt_on (string)

OpenVMS only.

The read_receipt_on MTA option is used to specify a special RFC 822 comment string used in IN% addresses in VMS MAIL to request a read receipt. The default if this option is not specified is:

```
(READ-RECEIPT)
```

The enclosing parentheses are required and must be specified in the option value.

52.47.10 OpenVMS user agent MTA options: safe_tcl_mode (bitmask)

OpenVMS only.

The safe_tcl_mode MTA option takes a bitmask argument. The lowest bit, when set, allows components of PMDF to interpret message parts of type application/safe-tcl upon user confirmation. (At present, PMDF MAIL is the only component of PMDF which supports Safe-Tcl.) The second lowest bit, when set, puts PMDF's Safe-Tcl interpreter into a very paranoid mode in which it will not allow information from sensitive message header lines to be disclosed to Safe-Tcl scripts.

The default value for this option is 3 which allows Safe-Tcl scripts to be executed upon user confirmation, but does so in "paranoid" mode.

52.47.11 use_mail_delivery Option

OpenVMS only.

52.47.12 vms_mail_exclusive Option

OpenVMS only.

Chapter 53 MTA Tailor options

In legacy configuration, various MTA installation and operational parameters would be set in the MTA Tailor file (`imta_tailor`) of option settings. But with Unified Configuration, the MTA Tailor file is obsolete and no longer used.

Old MTA Tailor options that specified locations of MTA directories or names of MTA configuration files have typically been replaced by rationalized, consistent locations based off the installation main location and located via the SERVERROOT environment variable.

The SERVERROOT value in turn is used to construct the DATAROOT value (either `/var`/SERVERROOT or SERVERROOT/`data`) and CONFIGROOT value (either `/var`/SERVERROOT/`config` or SERVERROOT/`config`).

New in 8.0, the recipe language has a "`get_path`" function that takes as argument "`server`", "`data`", or "`config`", and returns a file path to the current server instance; *e.g.*:

```
msconfig> exec get_path "server"
> "/opt/sun/comms/messaging64"
msconfig> exec get_path "config"
> "/opt/sun/comms/messaging64/config"
msconfig> exec get_path "data"
> "/opt/sun/comms/messaging64/data"
```

As of Messaging Server 7.0.5, MTA Tailor options that determined the username and group of the MTA user and unprivileged user have been moved to the file `restricted.cnf`.

MTA Tailor options controlling some aspects of scheduling of MTA tasks have either been incorporated into values in Scheduler tasks, or replaced by various `mta.`*`option-name`* Unified Configuration options.

53.1 Directory location MTA Tailor options

As of Messaging Server 7.0-0.04, many formerly configurable (via MTA Tailor option) MTA directory locations are now hard-coded. `tmpdir` (formerly called `imta_tmp`) and `langdir` (formerly called `imta_lang`) are still configurable.

53.1.1 MTA Tailor options: `imta_root` (directory path)

DELETED. Root of the MTA installation is now determined via the SERVERROOT environment variable.

Note that for MTA purposes, a special symbolic name IMTA_ROOT is still available for use in certain contexts (such as when the MTA is interpreting msconfig option values, or file path specifications).

53.1.2 MTA Tailor options: imta_lib (MTA directory path)

DELETED.

The directory containing MTA run-time libraries is no longer configurable and instead is now determined via the SERVERROOT, namely *SERVERROOT*/lib/.

Note that for MTA purposes, a special symbolic name IMTA_LIB is still available for use in certain contexts, such as when specifying the location of an Oracle-supplied shared library being used in a mapping callout or rewrite rule callout.

53.1.3 MTA Tailor options: imta_bin (MTA directory path)

DELETED.

The directory containing MTA executable binaries is no longer configurable, instead now being determined via the SERVERROOT, namely *SERVERROOT*/lib/.

Note that the special symbol name IMTA_BIN is still available for use in some MTA contexts.

53.1.4 MTA Tailor options: imta_table (MTA directory path)

DELETED.

The location of the MTA configuration directory is now determined using the CONFIGROOT. Note that with Unified Configuration, many fewer files comprise the MTA configuration than formerly, with legacy configuration, so this *CONFIGROOT*/ directory contains fewer files.

Note that the special symbol name IMTA_TABLE is still available for use in some MTA contexts.

53.1.5 MTA Tailor options: imta_dl (MTA directory path)

DELETED.

Obsolete directory used by iMS 5.x for directory synchronization. No longer used.

53.1.6 MTA Tailor options: imta_log (MTA directory path)

DELETED.

Formerly, the imta_log MTA Tailor option specified the directory where the MTA log files are stored. This location is now determined from the SERVERROOT environment variable, as SERVERROOT/log/. Sites may change it through the use of a symbolic link.

53.1.7 imta_tmp Option

The legacy configuration imta_tmp MTA Tailor option has been replaced in Unified Configuration by tmpdir.

(Note that in MS 7.0, the imta_tmp MTA Tailor option was replaced by the tmpdir option in the MTA option file.)

53.1.8 imta_db_tmp Option

The former imta_db_tmp MTA Tailor option used to be used to specify the MTA database temporary file location. The subdirectory name stopped being configurable as of Messaging Server 7.0-0.04 when the former IMTA_DB_TMP MTA Tailor option (available in MS 6.x versions, and typically set during installation of such versions to /tmp/.mtadb/) was removed, and instead as of Messaging Server 7.0 the MTA began using a hard-coded subdirectory of .imtadb underneath the (still-configurable) imta_tmp location. In Unified Configuration, the legacy configuration MTA Tailor option imta_tmp has been replaced by the tmpdir MTA (or base) option.

In other words: In MS 6.x, the MTA database temp file directory was fully configurable via the former IMTA_DB_TMP MTA Tailor option, and was typically set via that option to /tmp/.mtadb/. As of Messaging Server 7.0, the MTA database temp file directory was hard-coded as the .imtadb subdirectory underneath imta_tmp -- so typically /tmp/.imtadb/. As of Unified Configuration, imta_tmp has been replaced by the tmpdir MTA (or base) option, so the MTA database temp file directory location is tmpdir-value/.imtadb/.

53.1.9 imta_queue Option

The obsolete imta_queue MTA Tailor option located the directory for the MTA's store-and-forward message queues. This directory is now determined from the SERVERROOT environment variable. Sites may change it using either a symbolic link or using it as a file system mount point.

Note that for MTA purposes, a special symbolic name IMTA_QUEUE is still available for use in certain contexts (such as when the MTA is interpreting msconfig option values, or file path specification input to MTA command line utilities).

53.1.10 imta_help Option

Formerly, the location of the MTA help files was controllable by an MTA Tailor option, imta_help. That Tailor option (indeed, the Tailor file as a whole) is now obsolete; in particular, the location of MTA help files is no longer configurable.

53.1.11 imta_lang Option

The legacy configuration imta_lang MTA Tailor option has been replaced in Unified Configuration by the langdir MTA option, mta.langdir.

53.1.12 MTA Tailor options: imta_program (MTA directory path)

DELETED.

Formerly, the imta_program MTA Tailor option specified the location of the directory containing site-supplied executables for the pipe channel. This directory location is no longer configurable, and is now always located as *DATAROOT*/site-programs/. If location customization is desired, use symbolic links.

Note that the special symbol name IMTA_PROGRAM is still available for use in some MTA contexts.

53.2 File name MTA Tailor options

A number of MTA Tailor file options existed in legacy configuration to specify the name (and location) of various MTA configuration files. Such Tailor options are, by and large, obsolete as of Unified Configuration, when "rationalized", consistent names and locations are used unconditionally.

53.2.1 MTA Tailor options: imta_option_file (MTA file path)

DELETED.

Location of the (legacy configuration mode) option.dat file. No longer configurable; when legacy configuration is used, the option.dat file is located as *CONFIGROOT*/option.dat.

With a Unified Configuration, the option.dat file is obsolete and no longer used; instead MTA options are stored in the Unified Configuration file, config.xml, and inspected or modified using the msconfig utility. Generally, the options formerly stored in option.dat correspond to mta.*option-name* options in Unified Configuration -- though with occasional exceptions for options instead at base level or which have been consolidated with other, general, Messaging Server options.

53.2.2 MTA Tailor options: imta_system_filter_file (MTA file path)

DELETED.

Location of the MTA-wide Sieve filter file. No longer configurable, it is now located in legacy configuration as *CONFIGROOT*/imta.filter; in Unified Configuration, see instead the systemfilter MTA option.

53.2.3 MTA Tailor options: imta_config_file (MTA file path)

DELETED.

Name and location of the primary MTA configuration file, imta.cnf. The name and location of this file are no longer configurable.

In legacy configuration mode, it is CONFIGROOT/imta.cnf. But in Unified Configuration, the contents of the legacy imta.cnf file have been incorporated into the Unified Configuration file config.xml file, located at *CONFIGROOT*/config.xml.

53.2.4 MTA Tailor options: imta_xml_config_file (MTA file path)

DELETED.

The location of the Unified Configuration file, config.xml, is automatically determined using the SERVERROOT environment variable, namely *CONFIGROOT*/config.xml

53.2.5 MTA Tailor options: imta_command_data (MTA file path)

DELETED.

The location and name of compiled command line data built by the clbuild from the pmdf.cld file. This location and name are no longer configurable, instead being located via the SERVERROOT environment variable, namely *CONFIGROOT*/advanced/command_data.

53.2.6 MTA Tailor options: imta_config_data (MTA file path)

DELETED.

The location and name of the compiled configuration built by the cnbuild utility. The location and name are no longer configurable, instead being located via the SERVERROOT environment variable, namely *CONFIGROOT*/advanced/config_data.

53.2.7 MTA Tailor options: imta_charset_data (MTA file path)

DELETED.

The location and name of compiled character set data built by the chbuild utility. This information is no longer configurable, instead being located via the SERVERROOT environment variable, namely *CONFIGROOT*/advanced/charset_data.

53.2.8 MTA Tailor options: imta_alias_file (MTA file path)

DELETED.

Name and location of the MTA alias file. In legacy configuration, the name and location became no longer configurable as of Messaging Server 7.0, being instead located via the CONFIGROOT value, namely *CONFIGROOT*/aliases

In Unified Configuration, the MTA alias file is obsolete and instead the contents of the MTA alias file have been incorporated into the Unified Configuration file, config.xml, as alias settings.

53.2.9 MTA Tailor options: imta_primary_log (MTA file path)

DELETED.

In legacy configuration, the MTA Tailor option imta_primary_log specified the name and location of today's MTA message transaction log file. This is no longer configurable, and instead located via the SERVERROOT environment variable as *DATAROOT*/log/mail.log_current.

53.2.10 MTA Tailor options: imta_secondary_log (MTA file path)

DELETED.

Name and location of yesterday's MTA message transaction log file. No longer configurable, and instead located via the SERVERROOT environment variable as *DATAROOT*/log/mail.log_yesterday.

53.2.11 MTA Tailor options: imta_tertiary_log (MTA file path)

DELETED.

Name and location of the MTA's cumulative message transaction log file. No longer configurable, and instead located via the SERVERROOT environment variable as *DATAROOT*/log/mail.log.

53.2.12 imta_primary_connection_log Option

DELETED.

Name and location of today's MTA connection transaction log file. No longer configurable, and instead located via the SERVERROOT environment variable as *DATAROOT*/log/connection.log_current.

53.2.13 imta_secondary_connection_log Option

DELETED.

Name and location of yesterday's MTA connection transaction log file. No longer configurable, and instead located via the SERVERROOT environment variable as *DATAROOT*/log/connection.log_yesterday.

53.2.14 imta_tertiary_connection_log Option

Name and location of the MTA's cumulative connection transaction log file. No longer configurable, and instead located via the SERVERROOT environment variable as *DATAROOT*/log/connection.log.

53.2.15 imta_name_content_file Option

Table of conversion channel part reading defaults by media type and file extensions. The name and location of this file is no longer configurable, and instead located via the SERVERROOT environment variable as *SERVERROOT*/lib/name_content.dat.

53.2.16 imta_forward_data Option

The DELETED imta_forward_data MTA Tailor option had been used to specify the name and location of the forward address translation text database file which replaces the deprecated crdb form of forward database. The name and location of this file is no longer configurable; the text form source file is now unconditionally IMTA_TABLE:forward.txt (where note that IMTA_ROOT is a special symbolic name interpreted by the MTA).

53.2.17 imta_reverse_data Option

The DELETED imta_reverse_database MTA Tailor option had been used to specify the name and location of the reverse address translation text database file which replaces the deprecated crdb form of the reverse database. The name and location of this file are no longer configurable; the text form source file is now unconditionally IMTA_TABLE:reverse.txt (where note that IMTA_ROOT is a special symbolic name interpreted by the MTA).

53.2.18 imta_general_data Option

DELETED: Location no longer configurable. (The imta_general_data MTA Tailor option had been used to specify the location and name of the text file source for the MTA general database, used when the use_text_database MTA option specifies use of such "text" form, replacing the deprecated crdb form of the general database.) The text form source file is now unconditionally IMTA_TABLE:general.txt (where note that IMTA_ROOT is a special symbolic name interpreted by the MTA).

53.2.19 imta_alias_database Option

DELETED: Location no longer configurable. (The imta_alias_database MTA Tailor option had been used to specify the location and name of the deprecated crdb form of MTA alias database.)

Various ways of storing aliases are supported, not necessarily in a "database".

53.2.20 imta_reverse_database Option

DELETED: Location no longer configurable. (The imta_reverse_database MTA Tailor option had been used to specify the location and name of the deprecated crdb form of MTA reverse database.)

For continued use of a so-called "reverse database" in modern configurations, see the use_text_databases MTA option.

53.2.21 imta_forward_database Option

DELETED: Location no longer configurable. (The imta_forward_database MTA Tailor option had been used to specify the location and name of the deprecated crdb form of MTA forward database.)

For continued use of a so-called "forward database" in modern configurations, see the use_text_databases MTA option.

53.2.22 imta_general_database Option

DELETED: Location no longer configurable. (The imta_general_database MTA Tailor option had been used to specify the location and name of the deprecated crdb form of MTA general database.)

For continued use of a so-called "general database" in modern configurations, see the use_text_databases MTA option.

53.2.23 imta_domain_database Option

DELETED: Location no longer configurable. (The imta_domain_database MTA Tailor option had been used to specify the location and name of the deprecated domain database.)

53.2.24 imta_ssr_database Option

DELETED: Location no longer configurable. (The imta_ssr_database MTA Tailor option had been used to specify the location and name of the deprecated Server Side Rules database -- the database accessed when evaluating no longer supported ssr: URLs.)

53.2.25 imta_dn_to_id_database Option

DELETED: the imta_dn_to_id_database MTA Tailor option had specified the name and location of the legacy dirsync DN to ID database.

53.2.26 imta_user_profile_database Option

DELETED: Location no longer configurable. (The imta_user_profile_database MTA Tailor option had been used to specify the location and name of the deprecated profile database -- a database optionally used by pipe channels.)

53.2.27 imta_charset_option_file Option

DELETED: Location no longer configurable. (The imta_charset_option_file MTA Tailor option had been used to specify the name and location of chbuild's charset options file. This name and location are no longer configurable.)

53.2.28 imta_mapping_file Option

DELETED: This location is not longer configurable. (The imta_mapping_file MTA Tailor option had been used to specify the name and location of the file containing MTA mapping tables.)

In legacy configuration, the mappings file is now always *CONFIGROOT*/mappings. In Unified Configuration, the content of the mappings file has been incorporated into the XML configuration file, config.xml, as named mapping groups.

53.2.29 imta_conversion_file Option

DELETED: This location is no longer configurable. (The imta_conversion_file MTA Tailor option had been used to specify the name and location of the conversions file storing message conversion commands. This name and location are no longer configurable; in Unified Configuration, see instead the conversions MTA option.)

53.2.30 imta_hold Option

Formerly, the name and location of the file storing the list of stopped MTA channels (see the qm utility's stop command) was controllable by an MTA Tailor option, imta_hold. That Tailor option (indeed, the Tailor file as a whole) is now obsolete; in particular, the name and location of the file listing stopped MTA channels is no longer configurable.

53.2.31 imta_jbc_config_file Option

Formerly, the location of the Job Controller's configuration file was controlled by an MTA Tailor option, imta_jbc_config_file. That Tailor option (indeed, the Tailor file as a whole) is now obsolete, as the contents of the Job Controller configuration file have been incorporated into the XML configuration file; see instead Job Controller options.

53.2.32 imta_dispatcher_config Option

Formerly, the location of the Dispatcher's configuration file was controlled by an MTA Tailor option, imta_dispatcher_config. That Tailor option (indeed, the Tailor file as a whole) is now obsolete, as the contents of the Dispatcher configuration file have been incorporated into the XML configuration file; see instead Dispatcher options.

53.2.33 imta_libutil Option

Formerly, the name and location of the imtautil shared library was controllable by an MTA Tailor option, imta_libutil. That Tailor option (indeed, the Tailor file as a whole) is now obsolete; in particular, the name and location of the imtautil shared library is no longer configurable.

53.2.34 imta_libmap Option

Formerly, the name and location of the imtamap shared library was controllable by an MTA Tailor option, imta_libmap. That Tailor option (indeed, the Tailor file as a whole) is now obsolete; in particular, the name and location of the imtamap shared library is no longer configurable.

53.2.35 imta_security_config_file Option

Formerly, the name and location of the MTA security configuration file was controllable by an MTA Tailor option, imta_security_config_file. That MTA Tailor option has been deleted; the contents of the MTA security configuration file have been incorporated into the XML configuration file instead.

53.3 User MTA Tailor options

As of Messaging Server 7.0.5, the former imta_user, imta_user_username, and imta_world_group MTA Tailor options have been moved to the restricted.cnf file under the names user, noprivuser, and group, respectively.

53.3.1 Tailor file options: imta_user (string)

DELETED as of MS 7.0.5.

In earlier versions, the (now deleted) imta_user MTA Tailor option specified the user name for MTA operations. As of MS 7.0.5, it was moved to the restricted.cnf file as the "user" option (which also subsumes the former Message Store serveruid option).

53.3.2 Tailor file options: imta_user_username (string)

DELETED.

User name for untrusted operations such as MTA sequence number file access, or untrusted pipe channel operations. Moved to the restricted.cnf file as the "noprivuser" option.

53.3.3 Tailor file options: imta_world_group (string)

DELETED.

Prior to MS 7.0.5, the imta_world_group MTA Tailor file option specified the group name for messaging server operations. As of MS 7.0.5, it has instead been moved to the restricted.cnf file as the "group" option.

53.4 Scheduling MTA Tailor options

Various former MTA Tailor options relating to scheduling of MTA operations have been moved (sometimes renamed) or obsoleted as of Messaging Server 7.0.5.

The former imta_version_limit, imta_version_limit_period, imta_return_period, imta_return_synch_period, and imta_synch_cache_period MTA Tailor options are obsolete. The effects they were used to achieve should instead nowadays be configured via the appropriate settings on relevant Scheduler tasks, in particular, settings on the purge and return_job tasks, and by using the synch_time Job Controller option.

The former imta_return_split_period has become mta.return_split_period; imta_verify_return has become (note the change in name!) mta.return_verify; imta_return_split_period has become mta.return_split_period; imta_return_cleanup_period has become mta.return_cleanup_period.

53.4.1 imta_version_limit Option

The imta_version_limit option is obsolete as of Messaging Server 7.0.5. (Formerly controlled the number of MTA log file versions retained when imsimta purge was run periodically.) In Unified Configuration, see instead the schedule.task:purge.crontab option.

53.4.2 imta_version_limit_period Option

Obsolete option. In Unified Configuration, see instead the schedule.task:purge.crontab option.

53.4.3 imta_return_period Option

Obsolete option. In Unified Configuration, see instead the schedule.task:return_job.crontab option.

53.4.4 imta_return_synch_period Option

Obsolete option. See the synch_time Job Controller option instead.

53.4.5 imta_return_split_period Option

The legacy configuration imta_return_split_period MTA Tailor option has been replaced in Unified Configuration by the return_split_period MTA option, mta.return_split_period.

53.4.6 imta_return_cleanup_period Option

The legacy configuration imta_return_cleanup_period MTA Tailor option has been replaced in Unified Configuration by return_cleanup_period MTA option, mta.return_cleanup_period.

53.4.7 imta_verify_return Option

The legacy configuration imta_verify_return MTA Tailor option has been replaced in Unified Configuration by the return_verify MTA option, mta.return_verify.

53.4.8 imta_synch_cache_period Option

Obsolete option. See the synch_time Job Controller option instead.

Chapter 54 Dispatcher

The Dispatcher is one of the two major, "control" processes of the MTA (the other major such process being the Job Controller).

The MTA's Dispatcher is a multithreaded connection dispatching agent that permits multiple multithreaded server processes to share responsibility for a given service. When using the MTA's service Dispatcher, it is possible in particular to have several multithreaded SMTP server processes and several SMTP SUBMIT server processes running concurrently. In addition to having multiple server processes for a single service, each server process may have one or more active connections.

54.1 Dispatcher operation

The Dispatcher works by acting as a central receiver for the TCP ports listed in its configuration. For each defined service, the Dispatcher may create one or more Worker Processes that will actually handle the connections after they've been established.

The Dispatcher can selectively accept or reject incoming connections to the services it manages. See the `PORT_ACCESS` mapping table.

In general, when the Dispatcher receives a connection for a defined TCP port, it checks its pool of available Worker Processes and chooses the best candidate for the new connection. If no suitable candidate is available and the configuration permits it, the Dispatcher may create a new Worker Process to handle this and subsequent connections. The Dispatcher may also proactively create a new Worker Process in expectation of future incoming connections. There are several configuration options which may be used to tune the Dispatcher's control of its various services, and in particular, to control the number of Worker Processes and the number of connections each Worker Process handles; see Creation and expiration of Dispatcher Worker Processes and Dispatcher options.

54.1.1 Creation and expiration of Dispatcher Worker Processes

There are automatic housekeeping facilities within the Dispatcher to control the creation of new and expiration of old or idle Worker Processes. The basic options that control the Dispatcher's behavior in this respect are `min_procs` and `max_procs`. `min_procs` provides a guaranteed level of service by having a number of Worker Processes ready and waiting for incoming connections. `max_procs`, on the other hand, sets an upper limit on how many Worker Processes may be concurrently active for the given service.

Since it is possible that a currently running Worker Process might not be able to accept any connections either because it is already handling the maximum number of connections of which it is capable or because the process has been scheduled for termination, the Dispatcher may create additional processes to assist with future connections.

The `min_conns` and `max_conns` options provide a mechanism to help you distribute the connections among your Worker Processes. `min_conns` specifies the number of connections that flags a Worker Process as "busy enough" while `max_conns` specifies the "busiest" that a Worker Process can be.

In general, the Dispatcher will create a new Worker Process when the current number of Worker Processes is less than `min_procs` or when all existing Worker Processes are "busy enough" (the number of currently active connections each has is at least `min_conns`).

The `max_life_conns`, `max_life_time`, and `max_idle_time` Dispatcher options all affect when the Dispatcher will expire "old" or idle Worker Processes.

Note that if a Worker Process is killed unexpectedly, *e.g.*, by the UNIX `kill` command, the Dispatcher will still create new Worker Processes as new connections come in. Only shutting down the specific Dispatcher service, disabling the specific Dispatcher service followed by restarting the Dispatcher, or shutting down the Dispatcher itself, will stop the Dispatcher's creation of new, as-needed, Worker Processes, (up to the Dispatcher's configured maximum number of such processes). (See the shutdown utility, or after disabling a service the restart utility, for how to shut down a service entirely.)

54.2 Dispatcher options

The Dispatcher has a number of options, settable either at the Dispatcher top level (hence affecting overall Dispatcher operation or becoming a default for Dispatcher services), or settable under specific Dispatcher services (hence applying only to that service). *E.g.*,

```
msconfig> set dispatcher.debug 7
msconfig# set dispatcher.min_procs 2
msconfig# set dispatcher.service:SMTP.min_procs 3
```

In legacy configuration mode, Dispatcher options are set in the `dispatcher.cnf` file.

Generally, the Dispatcher must be restarted in order for its option changes to take effect.

When the `dispatcher.use_nslog` option has been enabled, see also the logfile options set as `dispatcher.logfile.*`.

In addition to the substantial number of Dispatcher options relevant to modern configurations, the Dispatcher also has a very large number of older options of only historical interest nowadays (such as those for setting various OpenVMS process quotas), listed under Old Dispatcher options.

54.2.1 `enable` Option Under dispatcher

The `enable` Dispatcher option is used to enable the dispatcher daemon. This defaults to the value of the `mta.enable` (Unified Configuration) or `local.imta.enable` (legacy configuration) option. When the Dispatcher is enabled, the default for `schedule.task:purge.enable` (Unified Configuration) or `local.schedule.purge.enable` (legacy configuration) is 1.

54.2.2 `enable` Option Under service

(New in 7.0.5) The `enable` Dispatcher `service` option controls whether the service is enabled. It defaults to `1`, but may be set to `0` to disable a service.

54.2.3 `backlog` Option Under service

The `backlog` Dispatcher `service` option controls the depth of the TCP backlog queue for the socket. The default value for each Dispatcher service is `max_conns`*`max_procs` for that service (with a minimum value of 128). Prior to the 7.0.5 release, the minimum value was 5.

54.2.4 debug Option Under dispatcher

The `debug` Dispatcher option (available under `dispatcher` and `service`) enables debug output from the Dispatcher. It may be set either directly at the `dispatcher` level, or may be enabled or disabled more selectively for a specific Dispatcher service by setting it under a named `service`.

The `IMTA_DISPATCHER_DEBUG` environment variable can also be used to control dispatcher debugging.

Table 54.1 Dispatcher Debug Bit Mask Values

Bit	Value	Description
0-31	-1	Extremely verbose output
0	1	Startup, initialization, shutdown message
1	2	Thread increment/decrement messages
2	4	Configuration loading messages
3	8	Process creation messages
4	16	Process activity messages
5	32	PORT_ACCESS mapping, connection messages
6	64	Process calculation messages
7	128	Process shutdown messages
8	256	Socket listen, cookie messages
9	512	Dispatcher internal I/O messages
10	1024	Dispatcher internal read messages
11	2048	Currently unused
12	4096	Process management messages
13	8192	Process handoff messages
14	16384	Dispatcher message processing messages
15	32768	Currently unused
16	65536	Successful connection message
17	131072	Connection accept, TLS messages
18	262144	Currently unused
19	524288	Commands
20	1048576	Statistics messages
21	2097152	Currently unused
22	4194304	Currently unused
23	8388608	Currently unused
24	16777216	Connection rejection message (subset of bits 4 and 5)

54.2.5 dns_verify_domain Option

Various groups maintain information about spam sources or open relay sites and some sites like to check incoming IP connections against the lists maintained by such groups. The dns_verify_domain Dispatcher service option specifies the host name or IP address of source against which to check incoming connections.

Note that an alternative to use of the dns_verify_domain Dispatcher service option is use of a dns_verify routine callout from a mapping table such as PORT_ACCESS. The dns_verify_domain Dispatcher service option is simple to set -- but use of dns_verify

callouts (which come in several flavors) from a mapping table allows for more precise control of checks.

Note that PORT_ACCESS mapping table probes (which may optionally be configured to perform their own DNS verification checks using a dns_verify routine callout) are made before any dns_verify_domain Dispatcher service option lookups are consulted. If a PORT_ACCESS probe rejects a connection, then the dns_verify_domain Dispatcher service option lookup does not need to be (and is not) performed. And as of MS 6.0, an explicit match in the PORT_ACCESS mapping table that accepts a connection will cause any dns_verify_domain lookups to be omitted for that connection; thus the PORT_ACCESS mapping table can be used to "white list" source IP addresses (such as internal IP addresses) which should not receive the DNS verification lookup.

In legacy configuration, up to five dns_verify_domain options are permitted for each service. In Unified Configuration, the dns_verify_domain Dispatcher service option takes a host-list of up to five hosts. (Note that SMTP is typically the only service for which such checks make sense.) For example, in Unified Configuration:

```
msconfig> set dispatcher.service:SMTP.dns_verify_domain "rbl.maps.vis.com dul.maps.vis.com"
```

Or analogously in legacy configuration:

```
[SERVICE=SMTP]
PORT=25
DNS_VERIFY_DOMAIN=rbl.maps.vix.com
DNS_VERIFY_DOMAIN=dul.maps.vix.com
```

If this option is enabled on a well-known port (25, 110, or 143), then a standard message such as the one below will be sent before the connection is closed:

```
500 5.7.1 access_control: host 192.168.51.32 found on DNS list and rejected
```

If you wish the MTA to log such rejections, you may set the 24th bit (starting at bit 0) of the Dispatcher debugging debug option, in Unified Configuration:

```
msconfig> set dispatcher.debug 16777216
```

or in legacy configuration debug=16%1000000, to cause logging of the rejections to the dispatcher.log file; see Dispatcher debugging and log files. Such dispatcher.log entries will take the form:

```
access_control: host a.b.c.d found on DNS list and rejected
```

54.2.6 historical_time Option

The historical_time Dispatcher option controls how long (in seconds) expired connections (those that have been closed) and processes (those that have exited) remain listed for statistical purposes. Note that the setting of this option affects the amount of virtual

memory that the Dispatcher requires. This option is available both directly at dispatcher level, or may be set under named Dispatcher services to override for that service the general Dispatcher value.

Prior to 7.0.5, the default value had been 120 (2 minutes) but initial configuration set this value to 0 (no history retained). As of 7.0.5, the default value is 0.

54.2.7 image Option

The image Dispatcher service option specifies the binary executable file that will be run by Worker Processes when such processes are created by the Dispatcher. Note that the specified executable file should be one designed to be controlled by the Dispatcher. Service names beginning with "SMTP", "LMTP" or "MSADMIN" have default paths built-in as of the 7.0.5 release.

54.2.8 interface_address Option

The legacy option interface_address (Job Controller option and Dispatcher option) is an alias for the job_controller.listenaddr and dispatcher.listenaddr options in Unified Configuration.

54.2.9 listenaddr Option Under dispatcher

The listenaddr Dispatcher option (formerly INTERFACE_ADDRESS in legacy configuration) can be used to specify the IPv4 address interface to which the Dispatcher service should bind. By default, the Dispatcher binds to all IP addresses. But for systems having multiple network interfaces each with its own IP address, it may be useful to bind different services to the different interfaces. listenaddr may be set either directly under dispatcher as dispatcher.listenaddr, in which case it sets the global default for all services, or may be set under a specific service, dispatcher.service:*service-name*.listenaddr, in which case it is setting the interface address to which that particular service should bind.

Note that if listenaddr is specified for a service, then that is the only interface IP address to which that Dispatcher service will bind. Only one such explicit interface IP address may be specified for a particular service (though other similar Dispatcher services may be defined for other interface IP addresses). Note that the interfaceaddress channel option provides the complementary capability for specifying which interface address a TCP/IP channel uses for outgoing connections and messages.

The allowed values for this option include an IPv4 address in dotted decimal form (e.g., 127.0.0.1), or a short form or fully-qualified DNS host name which will be resolved to an IPv4 address by obtaining the DNS A record for the name. To explicitly specify the default value of binding to all available interfaces, the string "INADDR_ANY" may be used. To bind to the loopback device, 127.0.0.1, the string "localhost" may be specified.

54.2.10 listenaddr Option Under service

The listenaddr Dispatcher service option (formerly INTERFACE_ADDRESS in legacy configuration) can be used to specify the IPv4 address interface to which the Dispatcher service should bind. By default, the Dispatcher binds to all IP addresses. But for systems having multiple network interfaces each with its own IP address, it may be useful to bind

different services to the different interfaces. listenaddr may be set either directly under dispatcher as dispatcher.listenaddr, in which case it sets the global default for all services, or may be set under a specific service, dispatcher.service:*service-name*.listenaddr, in which case it is setting the interface address to which that particular service should bind.

Note that if listenaddr is specified for a service, then that is the only interface IP address to which that Dispatcher service will bind. Only one such explicit interface IP address may be specified for a particular service (though other similar Dispatcher services may be defined for other interface IP addresses). Note that the interfaceaddress channel option provides the complementary capability for specifying which interface address a TCP/IP channel uses for outgoing connections and messages.

The allowed values for this option include an IPv4 address in dotted decimal form (e.g., 127.0.0.1), or a short form or fully-qualified DNS host name which will be resolved to an IPv4 address by obtaining the DNS A record for the name. To explicitly specify the default value of binding to all available interfaces, the string "INADDR_ANY" may be used. To bind to the loopback device, 127.0.0.1, the string "localhost" may be specified.

54.2.11 logfilename Option

Specifying the logfilename option for a named service causes the Dispatcher to direct output for corresponding Worker Processes to the specified file. The log file may include the system's name by including the %s token. (The value may also make use of special symbolic names known to the MTA, such as IMTA_LOG.) The default log file name is the service name with a ".log" suffix, except for "SMTP_SUBMIT" which defaults to "IMTA_LOG:tcp_submit_server.log" and "SMTP" which defaults to "IMTA_LOG:tcp_smtp_server.log".

54.2.12 max_conns Option Under dispatcher

The max_conns Dispatcher option specifies the maximum number of concurrent connections handled by a single server process (Worker Process). When the maximum number of concurrent sessions is reached, the server process stops listening for new connections. When all currently open connections are closed, the process will exit. Setting dispatcher.max_conns sets a global default, which may be overridden for specific services by setting max_conns under that service, *e.g.*, dispatcher.service:*service-name*.max_conns.

Prior to Messaging Server 7.0.5, the default value was 10, but initial configuration set the option explicitly to 50. As of 7.0.5, the default value is now 50. In Messaging Server 7.2 and earlier, the maximum possible value for this option was unconditionally 50, with attempts to set a value higher than 50 resulting in the value of 50 being used. As of Messaging Server 7.3, the maximum of 50 is only enforced on 32 bit platforms; 64 bit platforms allow any value.

Setting max_conns to higher values allows more connections, but at the potential cost of decreased performance for each individual connection. If it is set to 1, then for every incoming client connection, only one server process will be used. When the client shuts down, the server process will also exit. Note that the max_conns value times the max_procs value controls the maximum number of simultaneous connections that can be accepted.

54.2.13 max_conns Option Under service

The max_conns Dispatcher service option, dispatcher.service:*service-name*.max_conns, specifies the maximum number of concurrent connections handled by a single server process (Worker Process) for this service. When the maximum number of concurrent sessions is reached, the server process stops listening for new connections. When all currently open connections are closed, the process will exit.

Such a per-service setting overrides any global Dispatcher setting (dispatcher.max_conns).

The default value for this option is 50. In Messaging Server 7.0.2 and earlier as well as legacy 32 bit platforms, the maximum possible value for this option was unconditionally 50, with attempts to set a value higher than 50 resulting in the value of 50 being used.

In principle, for services running under the Dispatcher where the server image is not multithreaded, this option must be set to 1. However, the main Dispatcher services of interest, including the MTA's SMTP server and LMTP server, are multi-threaded and therefore capable of handling multiple clients. For such multithreaded servers, the choice of setting for this option is mainly a performance issue relating to the number of processes and the size of the process virtual address space. Setting max_conns to higher values allows more connections, but at the potential cost of decreased performance for each individual connection. If it is set to 1, then for every incoming client connection, only one server process will be used. When the client shuts down, the server process will also exit. Note that the max_conns value times the max_procs value controls the maximum number of simultaneous connections that can be accepted.

54.2.14 min_conns Option

The Dispatcher attempts to distribute connections evenly across its pool of currently available Worker Processes. The Dispatcher uses the min_conns value to determine the minimum number of connections that each Worker Process must have before there will be any consideration of adding new Worker Processes to the pool. Prior to 7.0.5, the default value was 3 while initial configuration set this to 30. As of 7.0.5, the default value is 30.

min_conns may be set either under dispatcher (to establish a general default for Dispatcher services), or under a specific named service (to apply only to that named service).

54.2.15 max_handoffs Option

The max_handoffs Dispatcher option (available under dispatcher and service) specifies the maximum number of concurrent asynchronous handoffs in progress that the Dispatcher will allow for newly established TCP/IP connections to a service port. The option may be set either directly at the dispatcher level to establish a default value for all Dispatcher servioces, or may be set for specific named services. The default value is 5.

54.2.16 max_idle_time Option

When a Worker Process has had no active connections for the period of the max_idle_time Dispatcher option, the process will be eligible for being shut down. max_idle_time may be set either directly under dispatcher, to set a default for all Dispatcher servies, or may be set for a particular service under the Dispatcher, *e.g.*,

dispatcher.service:SMTP.max_idle_time. Note that the max_idle_time option is only effective if there are more than the value of min_procs Worker Processes currently in the Dispatcher's pool for this service.

Prior to 7.0.5, the default value had been 0 while initial configuration set this to 600. As of 7.0.5, the default value is 600 seconds (10 minutes).

54.2.17 max_life_conns Option Under dispatcher

As part of the Dispatcher's ability to perform Worker Process housekeeping, the max_life_conns Dispatcher option (available under dispatcher and service) requests that Worker Processes only be kept around for the specified number of connections. After a Worker Process has handled the specified number of connections, it is subject to being shut down. For instance, when specified in an SMTP service section, this is the number of total connections an SMTP server process is able to accept before being retired so a new SMTP server process can take its place. This is different from the max_conns Dispatcher option, which limits the number of concurrent connections.

The default value has been 300, while initial configuration set the option value to 10000. As of 7.0.5, the default value is 10000.

54.2.18 max_life_time Option Under dispatcher

When the Dispatcher creates a server Worker Process, a countdown timer is set to the number of seconds specified by the max_life_time Dispatcher option. When this countdown time has expired, the Worker Process is subject to being shut down. The max_life_time option may be set either directly under dispatcher, as a default for services, or may be set at the named service level to affect solely that named service. The Dispatcher's default is 1 day (86400).

54.2.19 max_procs Option

The max_procs Dispatcher option (available under dispatcher and service) controls the maximum number of Worker Processes that will be created for a service. Thus this value times max_conns specifies the maximum number of simultaneous connections that can be handled. The max_procs option may be set either directly under dispatcher, as a default for all services, or may be set for a named service to affect solely that named service. Prior to 7.0.5, the default value was 5 while initial configuration set this to 10. As of 7.0.5, the default value is 10.

54.2.20 max_shutdown Option

The max_shutdown Dispatcher option (available under dispatcher and service) specifies a maximum number of processes that may be shutting down. In order to provide a minimum availability for the service, the Dispatcher will not shut down Worker Processes that might otherwise be eligible to be shut down if shutting them down would result in having more than max_shutdown Worker Processes for the service in the shutting down state. This means that processes that may be eligible to be shut down may continue running until a shutdown "slot" is available. Having this option set to about half of the value of the max_procs option is usually appropriate. The max_shutdown option may be set either directly under dispatcher, as a default for all services, or may be set for a named service to affect solely that named service. As of 7.0.5, the default value is 5.

54.2.21 min_procs Option

The min_procs Dispatcher option (available under dispatcher and service) determines the minimum number of Worker Processes that will be created by the Dispatcher for the current service. The min_procs option may be set either directly under dispatcher, as a default for all services, or may be set for a named service to affect solely that named service. Upon startup, the Dispatcher will create this many detached processes to start its pool. When an old such process expires, the Dispatcher will ensure that there are at least this many available processes (by creating a new process, if necessary) in the pool for this service.

As of 7.0.5, the default is 1; in prior versions, the default had been 0.

54.2.22 parameter Option

The interpretation and allowed values for the parameter Dispatcher service option are service specific. In the case of an SMTP service, the parameter option may be set to CHANNEL=*channelname*, to associate a default TCP/IP channel with the port for that SMTP service. (Note that the presence of the equal sign within the value means that when using msconfig, the value will need to be quoted.) For example, the SMTP_SUBMIT service sets parameter to "CHANNEL=tcp_submit" so that incoming mail submissions are handled on that channel.

```
msconfig> show service:SMTP_SUBMIT.parameter
role.dispatcher.service:SMTP_SUBMIT.parameter = CHANNEL=tcp_submit
```

Note that using parameter to set a channel name can be useful if you wish to run SMTP servers on multiple ports---perhaps because your internal POP and IMAP clients have been configured to use a port such as the submission port 587 rather than port 25, thus separating their message traffic from incoming SMTP messages from external SMTP hosts---and if you wish to associate different TCP/IP channels with the different port numbers.

54.2.23 port Option Under dispatcher

In Unified Configuration, the tcp_ports Dispatcher service option is the preferred name for the Dispatcher PORT option used in legacy configuration.

54.2.24 Service group

Besides a few options affecting Dispatcher operation as a whole, or set directly at the dispatcher level to establish defaults for Dispatcher services lacking their own specific settings, the primary way that Dispatcher options are set is within named service groups, to define specific Dispatcher services. Each such named service has associated ports (established via the tcp_ports and/or ssl_ports options); the Dispatcher listens for TCP connections on those ports, and then hands off the connections to Worker Processes for the named service, where the Worker Process will then execute the image specified for that service.

For instance, at its most basic, in principle the SMTP service *could* be defined as:

```
msconfig> set dispatcher.service:SMTP.tcp_ports 25
msconfig# set dispatcher.service:SMTP.image IMTA_BIN:tcp_smtp_server
msconfig# set dispatcher.service:SMTP.enable 1
```

More typically, however, additional options, such as a logfilename and perhaps parameter as well as various options tuning performance would be set also; while since the enable Dispatcher service option defaults to 1, and as of MS 7.0.5 the named SMTP service defaults to the image shown, in reality neither of those options needs to be *explicitly* set.

Within a named Dispatcher service group, besides the port tcp_ports and/or ssl_ports) and image option settings establishing the correspondence between port(s) and service, many other Dispatcher option settings are available to specify and further control operation of that service: thresholds at which to create new or additional server processes, age at which to expire "old" server processes, *etc*.

Thus in particular note that in MTA terminology and operation, a Dispatcher *service* such as the SMTP service encompasses potentially multiple (transient) SMTP *server processes*: the SMTP server processes come and go, created and expired as needed by the Dispatcher, within the parameters established in the Dispatcher's SMTP service definition.

Note that special symbolic names known to the MTA -- such as IMTA_BIN and IMTA_LOG -- are supported (and convenient) for values of service group options.

54.2.25 stacksize Option

The stacksize Dispatcher service option specifies a minimum per-thread stack size. Various components may have their own minimum values; the larger of an explicitly specified stacksize option value and the component's own internal minimum will be used. The default value is 2048000 as of the 7.0.5 release.

54.2.26 ssl_ports Option Under service

The ssl_ports Dispatcher service option specifies the TCP port(s) on which the Dispatcher will listen for incoming TLS connections for the current service. Connections made to this port or these ports will automatically (without use of commands such as STARTTLS in the case of SMTP) negotiate TLS use and be transferred to one of the Worker Processes created for this service. The SMTP client analogue of this option is the (new in 7.0.5) SSL_CLIENT TCP/IP-channel-specific option.

Note that channels for servers using ssl_ports need to set maytlsserver or musttlsserver to properly initialize as an SSL server.

See also the tcp_ports Dispatcher service option.

54.2.27 tcp_ports Option Under service

The tcp_ports Dispatcher service option (which is the new, Unified Configuration name for the legacy configuration PORT Dispatcher option) specifies the TCP port(s) on which the Dispatcher will listen for incoming connections for the current service. Connections made to this port or these ports will be transferred to one of the Worker Processes created for this service.

For instance, in a typical configuration:

```
msconfig> show dispatcher.service:SMTP.tcp_ports
role.dispatcher.service:SMTP.tcp_ports = 25
```

```
msconfig> show dispatcher.service:SMTP_SUBMIT.tcp_ports
role.dispatcher.service:SMTP_SUBMIT.tcp_ports = 587
```

meaning that the Dispatcher runs the SMTP service on port 25, and the SMTP SUBMIT service on port 587.

See also the ssl_ports Dispatcher service option.

54.2.28 tls_min_bits Option

The tls_min_bits Dispatcher service option specifies the minimum number of bits of encryption strength that must be in use in order for the connection to be permitted. Connections that are established with fewer bits of encryption, including no encryption, will be sent the error text defined by tls_bits_reject_msg, and then closed.

54.2.29 tls_bits_reject_msg Option

The tls_bits_reject_msg Dispatcher service option specifies some optional error text to send before the connection is closed when a connection fails to meet the minimum encryption strength required by tls_min_bits.

54.2.30 user Option Under dispatcher

The user Dispatcher option used to specify the Unix user id to run the Dispatcher worker processes as. This option is now ignored.

54.2.31 user Option Under service

The user Dispatcher service option used to specify the Unix user id to run the Dispatcher worker processes as. This option is now ignored.

54.2.32 use_nslog Option Under dispatcher

The use_nslog Dispatcher option may be set to 1 to enable use of nslog() for Dispatcher debug log files. The default is 0. When use_nslog has been enabled, see also the logfile options that may be set as dispatcher.logfile.*. Note that the loglevel option is *not* supported for the Dispatcher as its debug level is controlled instead by use of the debug Dispatcher option, dispatcher.debug.

54.2.33 loglevel Option Under mta

The mta.logfile.loglevel option is ignored by the Dispatcher and Job Controller unless the dispatcher.use_nslog and job_controller.use_nslog options are set for them, respectively.

Note that this MTA-wide setting of mta.logfile.loglevel (by default affecting both ims-ms channels and the LMTP server) can be overridden for the LMTP server via a tcp_lmtp_server.loglevel setting.

Also note that the mta.loglevel option is defined and can be set to the same set of values, but as of MS 8.0.1.2 it is a no-op. It's behavior in previous version is erratic - in some cases it works and mta.logfile.loglevel does not, in other cases the value is ignored.

54.2.34 Old Dispatcher options

Many Dispatcher options are no longer relevant for the modern MTA. See older printed documentation for details on these Dispatcher options.

Such historical Dispatcher options include:

- `astlm`
- `biolm`
- `bytlm`
- `cpulm`
- `diolm`
- `enqlm`
- `fillm`
- `group`
- `jtquota`
- `pgflquota`
- `prcmlm`
- `tqelm`
- `wsdefault`
- `wsextent`
- `wsquota`
- `trace_total_buffer_size`
- `trace_per_conn_buffer_size`
- `enable_rbl`
- `ident`
- `vms_group`
- `ucx_hold`
- `process_priority`
- `needs_dcl`
- `set_network`
- `new_features`
- `wp_timeout`
- `unix_domain`
- `unix_domain_dir`

54.3 Dispatcher debugging and log files

Dispatcher error and debugging output (if enabled) are by default written to the file `dispatcher.log` in the MTA log directory. (But see the `use_nslog` Dispatcher option if you prefer to direct Dispatcher error and debugging output to an nslog file.)

Debugging output may be enabled using the `debug` Dispatcher option in Unified Configuration (or the option DEBUG in the Dispatcher configuration file in legacy configuration), or on a per-process level, via the PMDF_DISPATCHER_DEBUG environment variable (UNIX). (In legacy configuration, when enabling the DEBUG option in the Dispatcher configuration file, note that it may be set either globally, or (by setting it within specific SERVICE sections) only for one or more services; in particular, to enable debugging for the Dispatcher but *not* for its worker processes (such as SMTP server processes), it may be set within a [SERVICE=DISPATCHER] section.)

Note that as of MS 7.0.5, enabling the MTA option `debug_flush` will cause Dispatcher debugging to get flushed to disk immediately.

The format of records in the Dispatcher log file is:

hh.mm.ss.ss (four-digit-thread-id): debug-message

Physical lines in the Dispatcher log file are limited to 79 characters. If a record has to be continued to a second line (due to the *debug-message* getting "too long"), then the rest of the *debug-message* will be indented with white space for the *time-stamp* and *four-digit-thread-id* fields, to line up with the initial part of *debug-message*.

Note that the Dispatcher itself always has *thread-id* number 1; that is, records for the main Dispatcher process itself begin

hh.mm.ss.ss (1):

The debug Dispatcher option (DEBUG option in dispatcher.cnf in legacy configuration) or PMDF_DISPATCHER_DEBUG environment variable (UNIX) defines a 32-bit debug mask in hexadecimal. Enabling all debugging is done by setting the option to -1, or by defining the environment variable system-wide to the value FFFFFFFF. The actual meaning of each bit is described in Dispatcher debugging bits.

Table 54.2 Dispatcher debugging bits

Bit	Hexadecimal value	Decimal value	Usage
0	x00001	1	Basic Dispatcher main module debugging
1	x00002	2	Extra Dispatcher main module debugging
2	x00004	4	Dispatcher option (Unified Configuration) or configuration file (legacy configuration) logging
3	x00008	8	Basic Dispatcher miscellaneous debugging
4	x00010	16	Basic service debugging
5	x00020	32	Extra service debugging, including PORT_ACCESS mapping table probes
6	x00040	64	Process related service debugging
7	x00080	128	Shutdown queue debugging
8	x00100	256	Basic Dispatcher and process communication debugging
9	x00200	512	Extra Dispatcher and process communication debugging
10	x00400	1024	Packet level communication debugging
11	x00800	2048	Not used
12	x01000	4096	Basic Worker Process debugging
13	x02000	8192	Extra Worker Process debugging
14	x04000	16384	Additional Worker Process debugging, particularly connection handoffs
15	x08000	32768	Not used
16	x10000	65536	Basic Worker Process to Dispatcher I/O debugging
17	x20000	131072	Extra Worker Process to Dispatcher I/O debugging, including some TLS initialization debugging

20	x100000	1048576	Basic statistics debugging
21	x200000	2097152	Extra statistics debugging
24	x1000000	16777216	Log PORT_ACCESS, dns_verify_domain, and enable_rbl denials to the dispatcher.log file

Chapter 55 Job Controller

The Job Controller is one of the two major, "control" processes of the MTA (the other major such process being the Dispatcher).

The Job Controller has two main responsibilities: (1) maintaining an in-memory "queue cache database" containing information about what message files are on disk awaiting delivery; and (2) scheduling and executing channel jobs to perform message processing (attempt message delivery). (The Job Controller is capable also of running additional, non-channel, periodically scheduled jobs. But that capability is not normally used in modern versions of the MTA.)

In contrast to the Dispatcher, which is responsible for accepting incoming TCP/IP connections and creating and managing server processes, the Job Controller is responsible for creating and managing MTA channel jobs (in particular SMTP client outbound processes and Message Store delivery channel processes) to attempt message delivery. Notable examples are that the Dispatcher oversees SMTP server processes for accepting messages incoming to the MTA, whereas the Job Controller oversees Message Store delivery channels and SMTP channel client

processes for delivering outbound messages. (Though note that there can be exceptions to the overly simplistic "inbound equals Dispatcher, delivery equals Job Controller" separation, as in the case of channels that "pull" messages as well as deliver messages, or in the case of delivery channels that also enqueue new messages such as notification messages.) The topic Job Controller operation will go further into Job Controller operation.

As the Job Controller is so fundamental to MTA operation, in normal operation is should always be present; see the topic Checking that the Job Controller is running. Indeed, normally the Watcher and msprobe are configured to monitor and perform automatic checks on the Job Controller, with the Watcher restarting the Job Controller if it appears to be absent or malfunctioning.

Furthermore, as operational advice, note that other than in cases of drastic configuration changes to the MTA or to site deployment, when a Job Controller restart often is necessary in order for changes to take effect, normally the Job Controller should be left running, without gratuitous restarting, as shutting down the delivery "half" of the MTA even briefly tends to be disruptive to optimal performance of outbound message delivery. (In particular, message delivery problems or delivery throughput concerns are not good reasons to restart the Job Controller! Message delivery problems should be attacked at the channel level where the delivery problem actually occurs, not at the Job Controller level; and overall delivery throughput generally suffers a temporary dip when the Job Controller must be restarted.) Certain operationally interesting Job Controller options can instead have values adjusted "on the fly" (without requiring a Job Controller restart) using the `imsimta cache -change` utility.

55.1 Job Controller operation

The Job Controller does not process or deliver messages itself, but rather keeps track of message files, and creates and manages channel jobs to process those messages.

Upon receipt of an incoming message from any source, the MTA channel that is handling the receipt of the message determines the destination, enqueues the message, and sends a request to the Job Controller to execute the next channel. The Job Controller will then initiate a channel job, if one is needed (that is, if there is not such a channel job already running, or if there are not "enough" jobs for that channel). Channel jobs, in turn, ask for and receive from the Job Controller the name of which message they should process next. When there are multiple messages to process, a channel process may end up running for "awhile", in a cycle of asking the Job Controller for a message and then processing (delivering) it, and then asking for another, *etc.*. And if the number of messages eligible for immediate delivery attempts is sufficiently "high", the Job Controller will initiate more than one channel job to work in parallel, each delivering a subset of the messages.

Internally, the Job Controller maintains a data structure of a set of queues of messages awaiting delivery attempts. This data structure is referred to as the *queue cache database*. New messages are inserted into this data structure sorted onto queues according to their destination channel, in some cases also sorted by their destination domain name, and further sorted according to message processing priority. Additional queues are maintained (one for each destination channel) of those messages that have already had at least one unsuccessful delivery attempt, and which are waiting for another delivery attempt.

The Job Controller configuration establishes processing *pools*; each such pool has a limit (`job_limit`) on how many processes may execute in it simultaneously (and a pool may optionally be configured with restrictions on times of day or days of the week in which it may execute processes). Each channel is constrained (via the `pool` channel option) to run in

one such pool, and may optionally be further constrained on how many processes it may run simultaneously within the pool (maxjobs). Multiple channels may be configured to run in the same pool, if it is desired for those channels to share (contend for) the same pool of process slots.

The Job Controller tracks how many processes each channel has running (and in the case of multithreaded channels specifically written to operate with the Job Controller by letting the Job Controller initiate delivery threads, the Job Controller tracks how many threads are running). When there are "enough" messages eligible for an immediate delivery attempt, the Job Controller will initiate a new delivery thread, or whole new delivery process, as needed (if the configured limits on such jobs have not yet been reached).

The Job Controller will also "cycle" channel jobs, aging out (expiring) sufficiently old channel jobs and then creating new channel jobs (as needed) to take their place. Thus channel jobs, even for busy channels, have a limited life-span. That this is a built-in aspect of the Job Controller both increases robustness in the face of unexpected problems, and ensures that updates to the MTA configuration, and changes to user and domain data in LDAP, will propagate through to affect channel jobs automatically, with bounded delay.

As part of the Job Controller's housekeeping and self-maintenance of its internal message queueing data structures, the Job Controller will periodically do a disk scan of the MTA queue area, to detect any message files omitted from its in-memory queues and reconcile its in-memory lists with what is physically present on disk.

So to summarize: the Job Controller's primary responsibilities are to maintain internal queues of which messages need delivery attempts and when, to initiate channel jobs to attempt those deliveries as needed, and to hand over to channel jobs the name of which message the job should attempt to process next.

55.1.1 Job Controller operation under stress

The Job Controller has several self-managing features that work together to aid in managing work load in general, and in particular to continue to operate successfully even under exceptionally heavy load. Beyond the Job Controller's general queueing strategy and creation (and expiration) of Worker Process threads discussed under Job Controller operation, the Job Controller's max_cache_messages and stress* options particularly relate to operation under load.

Under typical circumstances, the Job Controller keeps track in memory of all the active messages (non-.HELD message files) in the MTA queues. However, to limit its maximum memory requirement, the Job Controller has a configurable limit, max_cache_messages, on how many messages to track *in memory*. When the Job Controller's max_cache_messages capacity is exceeded, the Job Controller will not bother to retain *in memory* information about additional messages. But in such a case, the affected (excess) message files themselves had already been safely deposited in the MTA's store and forward message queues, where they will be detected later (at which time normal message processing will resume). At such times of "excess" messages, any enqueuing channel requests to the Job Controller for *immediate* insertion of messages into the Job Controller's "queue cache database" list of messages due for processing are ignored; but it is merely the *immediate* message processing that is suspended at such times for the affected messages. The Job Controller will detect any such "excess" message files later, during one of its housekeeping operations, and then begin delivery attempts for such messages. So max_cache_messages is a limit on how many messages will get normal/optimal processing (as in more-or-less immediate processing, in a "first in, first out" order); but messages that exceed max_cache_messages will be processed also, eventually.

New in Messaging Server 7.0 is a "stress" feature in the Job Controller, whereby the Job Controller can be informed that channels are "stressed" and then in response temporarily reduce delivery jobs on that channel to give the destination some respite. This is primarily relevant for Message Store delivery channels. Besides accepting new messages, the Message Store is also responsible for responding to end user e-mail client message access requests. So when the Message Store is extraordinarily busy, temporarily reducing the rate of new message deliveries to the Message Store may allow the Message Store to instead focus its resources on maintaining responsiveness to end users; that is, slowing down insertion of new messages into the Message Store may free up the Message Store to respond more quickly to e-mail client access to existing mailboxes and messages.

Message Store delivery channels (`ims-ms` or `tcp_lmtpcs*` channels) will automatically inform the Job Controller of stress, when the Message Store detects that it is stressed. In the case of `ims-ms` channels, when an `ims-ms` channel job is about to shut down, it will query the Message Store as to whether the store is stressed, and if it is then that `ims-ms` channel job will inform the Job Controller. In the case of LMTP delivery, after each successful delivery into the Message Store the LMTP server will query as to whether the store is stressed and if so, the LMTP server will report that back to the LMTP client via a special

```
250 2.3.99 Delivery OK but store under stress
```

success status; the MTA's LMTP client recognizes that special status and will then inform the MTA Job Controller of the back end Message Store stress.

An MTA administrator may also, using the new `imsimta qm stress` command, manually direct the Job Controller to consider any arbitrary channel to be "stressed".

When the Job Controller is informed that a channel is under "stress", it checks to see if it has already been told this recently: the Job Controller ignores "stress" alerts that are received within `stressblackout` seconds of a previous stress alert for the same channel. But if the stress alert is "new" information, then the Job Controller will multiply the effective `threaddepth` parameter for the channel by `stressfactor`, and subtract `stressjobs` from the effective job limit for the channel. (In the absence of stress, the effective job limit would be simply the minimum of the channel's `maxjobs` and the `job_limit` for the pool in which that channel runs.[1]) In addition, the Job Controller will ask all current master program processes for the channel to exit, and will, if the message queue for that channel is not empty, start an appropriate number of new processes: that is, any old processes are shut down and an appropriate, reduced number of new processes are started in their place.

But the Job Controller's cut back on jobs for "stressed" channels is intended to be temporary, on the presumption/hope that such a channel should/may "recover" after a time and be able to return to normal processing levels. The Job Controller attempts to gradually return to the originally configured settings, at step times and step sizes controlled by `stresstime` and `unstressfactor` and `unstressjobs`, as follows, (assuming that no further "stress" alerts or manual `imsimta qm` stress changes are received to further modify the settings and schedule). Automatically, `stresstime` seconds after the last stress change (or alternately upon receipt of an `imsimta qm unstress` command), the Job Controller divides the effective `threaddepth` by `unstressfactor` (never allowing the effective `threaddepth` to drop below the original configured `threaddepth`), and adds `unstressjobs` to the effective job limit (never allowing the effective job limit to rise above the original configured limit). A "stress change" is either an increase in stress or a decrease in stress.

[1] The effective `threaddepth` never goes over 134,217,727, and the effective job limit never goes below 1.

55.1.2 Job Controller priority-based processing

New in 8.0, the MTA supports the MT-PRIORITY SMTP extension defined in RFC 6710 (SMTP Extension for Message Transfer Priorities). An explicit MT-PRIORITY value overrides any of the older Priority: header line base priority settings, or the MTA's old size-based priority adjustment effects. See the discussion of the `mtpriority_policy` MTA option for a description of how MT-PRIORITY values are mapped to the older Priority: values. So a message with an explicit MT-PRIORITY value will get priority handling based on the mapping of that MT-PRIORITY value to the older Priority: value. Only a Sieve filter `setmtpriority` action can override a message's explicitly specified MT-PRIORITY value.

The standardized Priority: header field, defined in RFC 2156 (MIXER: Mapping between X.400 and RFC 822/MIME), is respected by the MTA. Note that this MTA message processing priority, as indicated in a Priority: value, affects MTA processing priority: that is, it affects when the MTA processes that message especially in contention with other messages of differing priority, and potentially how long the MTA continues to reattempt delivery of messages experiencing temporary delivery failures. Note that this Priority: effect is completely different from the sort of user e-mail client display feature requested via a Precedence: or Importance: header field (though users sometimes confuse and conflate these different sorts of effects). Keep in mind that time-criticality (processing priority) is not necessarily the same thing as importance: a relatively insignificant message may be time-critical due to time-limited relevance, or conversely a message of significant importance may concern an event far removed in time.

Priority: is an MTA-level feature, not typically appropriate for arbitrary users to set themselves (though specially privileged users such as administrators may desire and be entitled to access to priority adjustment). Priority handling may come at a "cost", whether that cost is simply additional work by the MTA, additional charges to the user, or an effect that delivery attempts abort sooner (thus causing messages to potentially be *less* likely to get through, being bounced sooner rather than getting additional delivery attempts if the message can't be delivered "quickly"). Importance: or Precedence: on the other hand, are user-level features, appropriate for users to set on the messages they send to request special handling by recipients or special display features when recipients' e-mail clients display the messages.

By default Priority: values are honored and make a "difference" in the MTA's message handling, affecting handling by the Job Controller, though that "difference" is generally small and hardly noticeable.

The Job Controller sorts messages, by priority, into separate internal processing queues. With just default configuration, the Job Controller will preferentially process "`urgent`" messages before "`normal`" messages before "`non-urgent`" messages among those messages all eligible for delivery at the same time. However, under normal circumstances there are so many messages flowing through the MTA so quickly, with so many messages being handled in parallel, that this sort of difference in handling based on priority tends to be pretty much moot. Unless there's a big enough backlog of newly submitted messages that the usually fairly "immediate" delivery attempts are a bit delayed, the Job Controller's automatic sorting of messages by priority doesn't much matter; instead, with no backlog, each freshly submitted message can get an essentially "immediate" delivery attempt, regardless of the message's priority.

When it comes to delivery retries on messages that didn't get through on first attempt, there the default MTA configuration (with only the `backoff` channel option set) is to retry urgent messages at shorter periods than normal messages, and retry nonurgent messages at longer periods. This may be precisely controlled further via the *`priority`*`backoff` channel option

settings. So by default, priority does have an (in principle) noticeable effect on the delivery retries scheduled by the Job Controller -- but once you're in the regime of having to retry to deliver, the messages are by definition "delayed", and the exact length of retry interval may matter little compared to the time scale of whatever is causing the delivery attempts to fail. So again, this is a difference, but perhaps not a difference that "matters" much.

As for how long messages are retained if they continue to fail to be deliverable, there the MTA default (the default handling by the `return_job`) is that priority doesn't have an effect -- though you can change that via the *`priority`*`notices` channel option settings. But note that even if your own MTA hasn't been configured to make a distinction, other MTAs that your messages pass through in principle might care and bounce "`urgent`" messages sooner if they fail delivery---this is one of the potential "costs" of higher priority processing mentioned above.

Now, if you choose to configure different Job Controller delivery execution windows, you can potentially have very different handling of different priorities of messages, even for freshly submitted new messages. With that (non-default) configuration, then you could see very noticeably different handling of different priorities of messages. See the `nonurgent_delivery`, `normal_delivery`, and `urgent_delivery` Job Controller options.

In particular, one type of use of priority delivery execution windows is to defer the processing of "`non-urgent`" messages to "off hours"; *e.g.*, in legacy configuration set in the `job_controller.cnf` file:

```
! Add to a pool definition to postpone delivery attempts of non-urgent
! messages to the hours between 11:00 PM and 4:00 AM any day, or any time
! Sunday.
!
NONURGENT_DELIVERY=23:00 - 04:00, Sun 00:00 - 23:59
```

Or in Unified Configuration, set via:

```
msconfig> set option job_controller.job_pool:SMTP_POOL.nonurgent_delivery "23:00 - 04:00, Sun 00:00 - 23:59"
```

When priority "matters", note that the MTA has ways of overriding the priority specified on a Priority: header line. The priority that the MTA actually uses is the *effective priority*---normally what is specified on a Priority: header line, unless overridden in some way. The *`priority`*`blocklimit` channel options, for instance, and the new in Messaging Server 7.4-0.01 system Sieve action `setpriority` can be used to override the original processing priority, setting a new effective processing priority. As of the 8.0 release, an explicitly specified MT-PRIORITY value on a message will override any Priority: header based setting, or MTA size-based priority adjustment. Only the Sieve filter `setmtpriority` action can override an explicitly specified MT-PRIORITY value.

55.2 Job Controller default configuration

The MTA is distributed with an initial Job Controller configuration that is a suitable starting point for most sites. The default configuration defines three pools: (1) one named `DEFAULT` with a job limit of ten, to be used for miscellaneous channels, (2) one named `IMS_POOL` with a job limit of two, to be used for running `ims-ms` channel jobs, and (3) one named `SMTP_POOL` with a job limit of ten, to be used for outbound TCP/IP SMTP/LMTP channel jobs.

The following figure shows a default configuration in Unified Configuration.

Sample Job Controller option settings in Unified Configuration

```
msconfig> show job_controller
role.job_controller.tcp_ports = 27442                                          (3)
role.job_controller.job_pool:DEFAULT.job_limit = 10                            (5),(6)
role.job_controller.job_pool:IMS_POOL.job_limit = 2
role.job_controller.job_pool:SMTP_POOL.job_limit = 10
role.job_controller.channel_class:bitbucket.master_command = IMTA_BIN:bitbucket  (7)
role.job_controller.channel_class:bsmtp*.master_command = IMTA_BIN:bsout_master  (8)
role.job_controller.channel_class:bsmtp*.slave_command = IMTA_BIN:bsin_master    (8)
role.job_controller.channel_class:conversion*.master_command = IMTA_BIN:conversion
role.job_controller.channel_class:defragment.master_command = IMTA_BIN:defragment
role.job_controller.channel_class:filter_discard (novalue)                     (11)
role.job_controller.channel_class:hold.master_command = IMTA_BIN:reprocess
role.job_controller.channel_class:ims-ms*.master_command = IMTA_BIN:ims_master   (9)
role.job_controller.channel_class:ims-ms*.max_life_askwork = 20000               (9)
role.job_controller.channel_class:ims-ms*.max_life_time = 14400                  (9)
role.job_controller.channel_class:native.master_command = IMTA_BIN:l_master
role.job_controller.channel_class:pipe*.master_command = IMTA_BIN:pipe_master
role.job_controller.channel_class:process*.master_command = IMTA_BIN:reprocess
role.job_controller.channel_class:reprocess*.master_command = IMTA_BIN:reprocess
role.job_controller.channel_class:sms*.master_command = IMTA_BIN:sms_master
role.job_controller.channel_class:tcp_*.master_command = IMTA_BIN:smtp_client    (10)
role.job_controller.channel_class:uucp_*.master_command = IMTA_BIN:uucp_master
role.job_controller.channel_class:uucp_*.slave_command = IMTA_BIN:uucp_slave
instance.job_controller.secret (suppressed)                                    (1)
```

In legacy configuration, the Job Controller configuration is stored in a file, `job_controller.cnf`. And in legacy configuration, this Job Controller configuration file is required. If it is not present or its contents are incorrect the Job Controller will not start.

There is no need to modify the Job Controller configuration settings (the Job Controller configuration file in legacy configuration), unless you choose to add pools, modify pool parameters, modify global Job Controller settings (such as debugging), or add processing information for locally developed channels.

In legacy configuration, if you do wish to make such modifications, you should not alter the Job Controller configuration file itself (since it will be replaced when you upgrade the MTA and in legacy configuration you will lose your modifications), but rather should create a `job_controller.site` file in the MTA table directory containing your own definitions. The Job Controller configuration file will read in this site supplied file, if it exists.

A sample Job Controller configuration file is shown below.

```
!
! Global defaults
!
SECRET=abc123      (1)
SLAVE_COMMAND=NULL (2)
TCP_PORT=27442     (3)
!
! Site specific pools and channnels are read
! indirectly if this include file exists.
!
<IMTA_TABLE:job_controller.site  (4)
```

```
!
! Pool definitions
!
[POOL=DEFAULT]  (5)
JOB_LIMIT=10    (6)
!
[POOL=IMS_POOL]
JOB_LIMIT=2
!
[POOL=SMTP_POOL]
JOB_LIMIT=10
!
! Channel definitions
!
[CHANNEL=bitbucket]     (7)
MASTER_COMMAND=IMTA_BIN:bitbucket
!
[CHANNEL=bsmtp*]        (8)
MASTER_COMMAND=IMTA_BIN:bsout_master
SLAVE_COMMAND=IMTA_BIN:bsin_master
!
[CHANNEL=conversion*]
MASTER_COMMAND=IMTA_BIN:conversion
!
[CHANNEL=defragment]
MASTER_COMMAND=IMTA_BIN:defragment
!
[CHANNEL=ims-ms*]       (9)
MAX_LIFE_AGE=14400
MAX_LIFE_CONNS=20000
MASTER_COMMAND=IMTA_BIN:ims_master
!
[CHANNEL=native]
MASTER_COMMAND=IMTA_BIN:l_master
!
[CHANNEL=pipe*]
MASTER_COMMAND=IMTA_BIN:pipe_master
!
[CHANNEL=process*]
MASTER_COMMAND=IMTA_BIN:reprocess
!
[CHANNEL=sms*]
MASTER_COMMAND=IMTA_BIN:sms_master
!
[CHANNEL=tcp_*]         (10)
MASTER_COMMAND=IMTA_BIN:smtp_client
!
[CHANNEL=reprocess*]
MASTER_COMMAND=IMTA_BIN:reprocess
!
[CHANNEL=uucp_*]
MASTER_COMMAND=IMTA_BIN:uucp_master
SLAVE_COMMAND=IMTA_BIN:uucp_slave
```

```
!
[CHANNEL=hold]
MASTER_COMMAND=IMTA_BIN:reprocess
!
[CHANNEL=filter_discard]  (11)
```

The key items in the above examples are:

1. This global option sets a "secret" used on this host by the Job Controller to verify its internal communications.

2. Set a default SLAVE_COMMAND for subsequent [CHANNEL] sections.

3. This global option defines the TCP port number on which the Job Controller listens for requests.

4. Attempt to include the optional, site-supplied `job_controller.site` file (in which sites may place their site-specific customizations, so as to retain such customizations after upgrading).

5. This [POOL] section defines a queue named "DEFAULT". This pool will be used by all channels which do not specify a pool name using the `pool` channel option.

6. Set the JOB_LIMIT for this pool to 10.

7. This [CHANNEL] section applies to a channel named bitbucket. The only definition required in this section is the MASTER_COMMAND which the Job Controller issues to run this channel. (Note that the `bitbucket` channel normally never needs to run, so normally this image is never executed, since in normal use messages supposedly "enqueued" to the `bitbucket` channel are instead merely deleted---however, a `bitbucket` channel image does exist to delete messages, and if a message does exist in the `bitbucket` channel queue, perhaps due to being manually placed there by the MTA administrator, then this channel image can "process" it ---that is, delete it.) Since no wildcard appears in the channel name, the channel name must match exactly.

8. This [CHANNEL] section applies to any channel whose name begins with `bsmtp_*`. For this channel, both a MASTER_COMMAND and a SLAVE_COMMAND are necessary. Since this channel name includes a wildcard, it will match any channel whose name begins with "`bsmtp_`".

9. This [CHANNEL] section applies to any channel whose name begins with `ims-ms*`. For this channel, used to deliver to the Messaging Server Message Store, it is a good idea to set the `max_life_time` (formerly MAX_LIFE_AGE) and `max_life_askwork` (formerly MAX_LIFE_CONNS) Job Controller (channel class) options to let the channel jobs "persist" (rather than being "recycled" in favor of a new channel job) for relatively extended periods.

10. This [CHANNEL] section applies to any channel whose name begins with `tcp_*`; this includes SMTP over TCP/IP and LMTP over TCP/IP channels. This section only defines (the Job Controller only knows/cares about) a MASTER_COMMAND defining the SMTP/LMTP client "half" of any such channel; the slave "half" of any such channel (SMTP servers or LMTP servers) is handled by the Dispatcher.

11. This [CHANNEL] section applies to the filter_discard channel. The absence of any MASTER_COMMAND in this section is intentional.

55.3 Job Controller options

A number of options affect Job Controller operation.

In Unified Configuration, Job Controller options are set using the `msconfig` utility. The option names are set and inspected under `job_controller` for options affecting overall/global Job Controller operation, or under `job_controller.job_pool:`*`pool-name`* for options affecting a specific, named pool, or under `job_controller.channel_class:`*`channel-name-prefix`* for options affecting a certain channel or type of channel; *e.g.*,

```
msconfig> show job_controller.tcp_ports
role.job_controller.tcp_ports = 27442
msconfig> show job_pool:DEFAULT.*
role.job_controller.job_pool:DEFAULT.job_limit = 10
msconfig> show channel_class:tcp*
role.job_controller.channel_class:tcp_*.master_command = IMTA_BIN:smtp_client
```

In legacy configuration mode, Job Controller options are set in the `job_controller.cnf` file.

Generally, the Job Controller must be restarted in order for its option changes to take effect. But as restarting the Job Controller is undesirable, tends to degrade performance, and should be avoided in operation except when *truly* necessary, the `imsimta cache -change` utility provides a means to change the effective values for certain, especially operationally relevant, Job Controller options "on the fly", without requiring a Job Controller restart.

When the `job_controller.use_nslog` option has been enabled, see also the logfile options set as `job_controller.logfile.*`.

55.3.1 `enable` Option Under job controller

The `enable` Job Controller option is used to enable the Job Controller daemon. This defaults to the value of the `mta.enable` (Unified Configuration) or `local.imta.enable` (legacy configuration) option. When the job_controller is enabled, the default for `schedule.task:purge.enable` (Unified Configuration) or `local.schedule.purge.enable` (legacy configuration) is 1. In addition, the default for `schedule.task:return_job.enable` (Unified Configuration) or `local.schedule.return_job.enable` (legacy configuration) is also 1 in this case.

55.3.2 `debug` Option Under job controller

The `debug` Job Controller option sets a bit mask for various types of debugging. When debugging is enabled, it is written to the Job Controller log file. That file is located in the MTA log directory, *SERVERROOT*`/log/`, and named `job_controller.log-`*`uniqueid`* where *`uniqueid`* is a unique string disambiguifying the file name. (Note that the `imsimta purge` utility understand the *`uniqueid`*s and can be used to purge back older log files.)

55.3.3 `listenaddr` Option Under job controller

The `listenaddr` Job Controller option (formerly INTERFACE_ADDRESS in legacy configuration) can be used to specify the IPv4 address interface to which the Job Controller

should bind for listening for its own communications; (see the tcp_ports Job Controller option in Unified Configuration, which replaced the legacy configuration TCP_PORT Job Controller option). By default, the Job Controller binds to the tcp_ports (legacy configuration TCP_PORT) on all IP addresses. But for systems having multiple network interfaces each with its own IP address, it may be useful to listen only on a particular interface. Note that if listenaddr is specified, then that is the only interface IP address to which the Job Controller will bind for its internal use.

Note that the interfaceaddress channel option provides a capability for specifying which interface address a TCP/IP channel uses for outgoing connections and messages; this is quite separate from the Job Controller's internal use of interface address(es). Also note that the Dispatcher has its own setting for listenaddr, controlling which IP address a particular Dispatcher service listens on.

55.3.4 job_limit Option

The job_limit Job Controller job_pool option relates to pool configuration, rather than channel configuration: it is set either for a specific Job Controller job_pool, or if set directly under job_controller it becomes the default for all pools which don't explicitly specify a job_limit. The option's (unsigned integer) value specifies the maximum number of jobs that a pool can execute in parallel. Execution of a request will use a UNIX process, so this corresponds to the maximum number of UNIX processes you allow a pool to use. The job_limit applies to each pool individually; the maximum total number of jobs is the sum of the job_limit parameters for all pools.

Note that multithreaded processes, *e.g.*, the TCP/IP client program (tcp_smtp_client) and the Message Store delivery channel program (ims-ms_master), may run multiple threads within a single process, hence in that sense multiple "delivery jobs" within a process. The discussion of jobs here refers to job *processes*.

Setting job_limit to 0 effectively stops a pool: it can't process any requests.

See Job Controller default configuration for examples of job_limit values.

Channel configuration normally specifies a pool for each channel to run in via the channel pool option (or in legacy configuration via the pool keyword on each channel defined in the MTA configuration file, imta.cnf). By having different channels run in different pools, they can be kept from competing with each other. By grouping "related" channels to run in the same pool, they can share (compete) for resources (processing slots) amongst each other, while not being allowed to compete for processing slots with those channel(s) running in other pools. Use of the maxjobs keyword on a channel can limit how much of the job_limit of the pool that the channel runs in the channel is allowed to use; this is normally only of interest when multiple channels are running in the same pool, being used to limit how much of the pool's job_limit a particular channel is allowed to use.

In legacy configuration, job_limit is set either within a [POOL] section, or globally at the top of the job_controller.cnf file. If set outside of a section, it will be used as the default by any [POOL] section which doesn't specify job_limit. This option is ignored inside of a [CHANNEL] section.

Note that the imsimta cache -change utility may be used to change a channel's effective job_limit "on the fly".

55.3.5 master_command Option

The master_command Job Controller channel_class option relates to channel configuration, rather than pool configuration: it is set for a specific channel or type of channel under a job_controller.channel_class:*channel-name-prefix*. The option's value specifies the full path to the command to be executed by the UNIX process created by the Job Controller in order to run the channel and dequeue messages outbound on that channel. This option is not available for a job_pool.

Prior to Messaging Server 7.0.5, there were no defaults in the MTA code for master_command value(s); however, MTA initial configuration created a job_controller.cnf file which set an appropriate master_command value for each type of normally installed channel. As of Messaging Server 7.0.5, each normally installed channel class has an appropriate default master_command value. (These defaults are different for each sort of channel class.)

Note that in legacy configuration, the master_command option is specified inside [CHANNEL=...] sections of the Job Controller configuration file, or if specified at the top in the global section becomes a default for all channels which don't explicitly specify a master_command. This option is ignored inside of a [POOL] section.

55.3.6 max_cache_messages Option

The max_cache_messages option is available only as a global Job Controller option, job_controller.max_cache_messages.

The Job Controller keeps information about messages in an in-memory structure (the "queue cache database"). This is essentially a cached-in-memory index to the message files currently on disk. In the event that a large backlog of messages builds up on disk, the Job Controller may need to limit the size of this in-memory structure so as not to allow memory usage to grow excessively. If the number of messages in the backlog exceeds the Job Controller's currently computed maximum messages value (see below -- the Job Controller uses the specified max_cache_messages value as a starting point, but during operation may adjust that value up or down according to circumstances), then information about subsequent messages is not kept in the in-memory queue cache database. Mail messages are not lost because they are always written to disk, (and the disk queue area will get scanned by the Job Controller eventually, and remaining messages will then be detected and processed) but such messages are not considered for delivery until the number of messages known by the Job Controller drops to half this number. At this point, the Job Controller scans the queue directory mimicking an imsimta cache -sync command. The initial default for max_cache_messages is 100,000. But the Job Controller, while running, may adjust this size either up or down, depending on circumstances.

To manually adjust the effective max_cache_messages size "on the fly" (without having to restart the Job Controller to get a change to the max_cache_messages option to take effect), you may use the imsimta cache -change utility:

```
# imsimta cache -change global -max_messages=value
```

Note that exceeding the current maximum messages value means that subsequent messages can be expected to be processed "out-of-order". max_cache_messages is not truly a performance-related option -- increasing it will not improve message throughput nor will decreasing it (unless decreased to an absurdly low number) have much effect on message processing speed. Rather, its purpose is to place a limit on the Job Controller's memory usage, and its operational effect is to limit on how many messages the Job Controller will attempt to schedule in "first in, first out" order. The Job Controller's scheduling is normally roughly "first

in, first out", as modified by message processing priority, response speed of destination being delivered to, and effects of "bunching up" messages to the "same" host onto the same process and even process thread. But once the current maximum messages value is exceeded, the Job Controller is only attempting "first in, first out" scheduling on the messages it has in its in-memory queue cache database; the remaining messages don't get a shot at being processed until later (once the Job Controller initiated channel jobs have managed to deliver a lot of the original backlog of message). And scanned messages picked up via a disk scan (whether manually executed `imsimta cache -sync` or the Job Controller's automatic rescans such as due to dropping sufficiently below the current maximum messages value), are all considered to be of lower processing priority than newly submitted, normal priority messages.

In legacy configuration mode, `maxmessages` was a deprecated synonym for `max_cache_messages`; that old `maxmessages` name is not a synonym in Unified Configuration, where it refers instead to a different option for the Message Store.

55.3.7 `max_life_askwork` Option

The `max_life_askwork` Job Controller option (available both at global `job_controller` level to set a default for all `channel_class`es, or at `channel_class` level to specify the limit for that specific type of channel) imposes another limit on channel master job life expectancy, in addition to the limit set for each channel type by the `max_life_time` Job Controller option setting. The `max_life_askwork` option sets a limit on the number of times a channel master job can ask the Job Controller if there are any messages for the job to process. If this option is not specified for a channel, then the global default value is used. If no default value is specified, 300 is used.

55.3.8 `max_life_conns` Option Use With max_life_conns Under job controller

For the Job Controller, the legacy configuration `max_life_conns` option has been renamed to `max_life_askwork`. (The preferred name `max_life_askwork` is supported in legacy configuration as of MS 7.0.5.)

55.3.9 `max_life_time` Option Under job controller

The `max_life_time` Job Controller option (available both at global `job_controller` level to set a default for all `channel_class`es, or at `channel_class` level to specify the limit for that specific type of channel) requests that Job Controller channel master jobs only be kept around for the specified number of seconds. (See also the `max_life_askwork` Job Controller option which imposes another limit on channel master job persistence.) When the Job Controller creates a channel master job process, a countdown timer is set to the specified number of seconds. When the countdown time has expired, the channel job is subject to being shut down. The `max_life_time` option may be set either directly under the `job_controller` group, as a default for all channel types, or may be set at the `channel_class` level to affect solely that type of channel. The Job Controller's default is 4 hours (14400).

The Job Controller's `max_life_time` option had the synonyms `max_life_age` and `max_age`, which are now deprecated.

55.3.10 `notice_time` Option

RESTRICTED: This option affects Job Controller internal processing, intended for future use.

The Job Controller occasionally performs some housekeeping intended for future use in generating notification messages; (for current operation, see instead the notices channel option). The notice_time option controls when the Job Controller performs such housekeeping. It is of the form HH:MM/hh:mm, or /hh:mm. hh:mm is the interval in hours and minutes between operations, and HH:MM is a notional clock time at which the operation starts. If HH:MM is not specified, the first scan will be hh:mm after the Job Controller starts. If HH:MM is specified, the first scan will be the first time that HH:MM + n * hh:mm is greater than the Job Controller start time. The default is /00:30.

55.3.11 port Option Under job controller

The port Job Controller option specifies the TCP port that the Job Controller uses for inter-process communication.

55.3.12 rebuild_parallel_channels Option

On startup the Job Controller scans the queues for messages left over from a previous invocation. It reads from several channel queues at the same time to somewhat "balanced" (across queues) its initial message delivery attempts. The rebuild_parallel_channels Job Controller option limits the number of channel queues to be scanned simultaneously. The default is 12.

Note that an imsimta cache -change -global -parallel_rebuild=*n* command may be used to change the parallelism "on the fly".

55.3.13 secret Option Under job controller

The secret Job Controller option specifies a string secret used on this host by the Job Controller to verify its internal communications.

Note that the Job Controller secret option's value is normally set to a randomly generated string during initial configuration. It is safe to change this value; *however*, do note that the value normally is (and *should be*) set as an instance option, rather than a role option, using a different value on each host (a different value set for each instance).

55.3.14 slave_command Option

The slave_command Job Controller channel_class option relates to channel configuration, rather than pool configuration; it is set either for a specific channel or type of channel under a job_controller.channel_class:*channel-name-prefix*. The option's value specifies the full path to the command to be executed by the UNIX process created by the Job Controller in order to run the channel and poll for any messages inbound on the channel. Note that many MTA channels do not have a slave_command.

```
msconfig> set role.job_controller.channel_class:bsmtp*.slave_command "IMTA_BIN:bsin_master"
```

Prior to Messaging Server 7.0.5, the default value of slave_command for all channel classes was the special value NULL. As of Messaging Server 7.0.5, the bsmtp channel class has a

default value for slave_command (see above), while all other normally installed channels have as default the special value NULL.

Note that in legacy configuration, the slave_command option is specified inside [CHANNEL=...] sections of the Job Controller configuration file, or if specified at the top in the global section becomes a default for all channels which don't explicitly specify a slave_command. If a channel does not have a slave_command (has no sensible slave direction), the reserved value NULL should be specified. This option is not available under job_pool (or in legacy configuration, is ignored inside of a [POOL] section).

55.3.15 stressblackout Option

The Job Controller ignores repeated indications from channels saying they are stressed for a short time after a stressed indicator is received. The stressblackout Job Controller option specifies for how long (in seconds) to ignore repeated such indications. The default is 60 seconds, *i.e.*, one minute.

55.3.16 stresstime Option

The stresstime Job Controller option specifies for how long, in seconds, a channel remains at an elevated stress level after a stress notification is received before the stress level starts being lowered. The default is 120 seconds, *i.e.*, two minutes.

Note that the stress level actually lowered when a new job controller job is initiated. As of the 8.0.2 release, the stress level is also lowered when unstresscount messages have been processed by the channel and stresstime time has elapsed without any indication of stress. unstresscount defaults to 10000.

55.3.17 stressfactor Option

When a channel's stress level is raised, the threaddepth for the channel is multiplied by the stressfactor Job Controller option value to obtain a temporarily increased effective threaddepth, thereby reducing the Job Controller's aggressiveness in spawning new threads and jobs for the channel. The default is 5.

55.3.18 unstressfactor Option

When a channel's stress level is lowered, the effective threaddepth for the channel is divided by the unstressfactor Job Controller option value, thereby increasing the Job Controller's aggressiveness in spawning new threads and jobs for the channel. If not explicitly set, the stressfactor value is taken as the default.

55.3.19 stressjobs Option

When a channel's stress level is raised, the effective job limit for the channel is decreased by the stressjobs Job Controller option value. The default is 2.

55.3.20 unstressjobs Option

When a channel's stress level is lowered, the effective job limit for the channel is increased by the unstressjobs Job Controller option value. The default is the same value set for stressjobs.

55.3.21 synch_time Option

The Job Controller occasionally scans the channel queue directories for message files it does not know about, to insert corresponding entries into its in-memory queue cache database The synch_time option controls when. The value is of the form HH:MM/hh:mm, or /hh:mm. hh:mm is the interval in hours and minutes between scans, and HH:MM is a notional clock time at which this starts. If HH:MM is not specified, the fist scan will be hh:mm after the Job Controller starts. if HH:MM is specified, the first scan will be the first time the HH:MM + n * hh:mm is greater than the Job Controller start time. The default is /04:00.

This automatic disk scan is akin to performing a manual imsimta cache -sync operation.

55.3.22 tcp_ports Option Under job controller

The tcp_ports Job Controller option, job_controller.tcp_ports, specifies the TCP port on which the Job Controller should listen for request packets; that is, it is the port on which the Job Controller listens for its internal protocol communications. You generally do not want to change this option unless the default conflicts with another TCP application on your system. This is a global Job Controller option, set directly under job_controller; it is not available under channel_class or job_pool groups. The default is 27442.

55.3.23 Job Controller job pool options: nonurgent_delivery (execution-window string), normal_delivery (execution-window-string), urgent_delivery (execution-window-string)

The nonurgent_delivery, normal_delivery, and urgent_delivery Job Controller job_pool options each set an "execution window" for messages of the respective effective processing priority. The default is that all messages are eligible for processing at all times.

An execution window consists of up to five, comma-separated time windows. Each time window is either a daily window (a window of time allowed every day) of the form:

hh:*mm* - *hh*:*mm*

or a weekly window (a window of time allowed per week) of either of the forms

ddd hh:*mm* - *ddd hh*:*mm*

or (with the ending day assumed to be the same as the beginning day)

ddd hh:*mm* - *hh*:*mm*

For instance, a time window

```
18:00 - 22:00
```

means between 6:00 PM and 10:00 PM each day.

```
20:00 - 06:30
```

means between 8:00 PM and 6:30 AM each night.

```
Sat 06:15 - 15:30
```

means each Saturday between 6:15 AM and 3:30 PM.

```
Wed 12:00 - Fri 00:00
```

means between noon Wednesday and midnight Thursday/Friday (the midnight dividing Thursday from Friday). And thus an execution window specifying that processing is allowed any night or all day on weekends could be

```
22:00 - 05:30, Sat 00:00 - Sun 23:59
```

Note that the MTA can be configured to modify messages' effective processing priority based on certain criteria such as message size, see the `*blocklimit` channel options, or via the MTA's non-standard Sieve extension "`setpriority`". As of the 8.0 release, an explicitly specified MT-PRIORITY value for a message will override the older Priority: header value or the MTA's size-based effective processing priority adjustments, and in particular take precedence for Job Controller delivery execution window purposes. Only the MTA's non-standard Sieve extension "`setmtpriority`" can override an explicitly specified MT-PRIORITY value.

55.3.24 use_nslog Option Under job controller

The `use_nslog` Job Controller option may be set to `1` to enable use of `nslog()` for Job Controller debug log files. The default is 0. When `use_nslog` has been enabled, see also the logfile options that may be set as `job_controller.logfile.*`. Note that the `loglevel` option is *not* supported for the Job Controller as its debug level is controlled instead by use of the `debug` Job Controller option, `job_controller.debug`.

55.3.25 loglevel Option Under mta

The `mta.logfile.loglevel` option is ignored by the Dispatcher and Job Controller unless the `dispatcher.use_nslog` and `job_controller.use_nslog` options are set for them, respectively.

Note that this MTA-wide setting of `mta.logfile.loglevel` (by default affecting both `ims-ms` channels and the LMTP server) can be overridden for the LMTP server via a `tcp_lmtp_server.loglevel` setting.

Also note that the `mta.loglevel` option is defined and can be set to the same set of values, but as of MS 8.0.1.2 it is a no-op. It's behavior in previous version is erratic - in some cases it works and `mta.logfile.loglevel` does not, in other cases the value is ignored.

55.3.26 job_pool

The `job_pool` group (under `job_controller`) is not a Job Controller option itself, but rather a grouping of Job Controller options defining a particular named Job Controller processing pool. For instance:

```
msconfig> set job_controller.job_pool:OFFHOURS_POOL.job_limit 3
msconfig# set job_pool:OFFHOURS_POOL.normal_delivery "14:00 - 12:00, Sat 00:00 - Sun 23:59"
msconfig# set job_pool:OFFHOURS_POOL.nonurgent_delivery "17:00 - 9:00, Sat 00:00 - Sun 23:59"
```

This defines a pool named OFFHOURS_POOL which: allows at most three simultaneous jobs, limits delivery attempts of "normal" priority messages to occur outside the hours of noon until 2:00 PM on weekdays, and limits delivery attempts of "non-urgent" priority messages to occur outside business hours Monday through Friday. That is, if any channels are assigned via the pool channel option to run in this new OFFHOURS_POOL Job Controller pool, any messages enqueued to such channels will get delivery attempts only at times as follows: "urgent" priority messages can get delivery attempts at any time, as usual; "normal" priority messages will not get delivery attempts around lunch time on weekdays, but can get delivery attempts at any other times; "non-urgent" priority messages can only get delivery attempts outside business hours, *i.e.*, on weekends, or after 5:00 PM or before 9:00 AM on weekdays.

See Job Controller operation for further discussion of how the Job Controller utilizes such processing pools, see Job Controller default configuration for several examples of processing pool definition, and see the pool channel option for further details on how each channel is assigned to some such processing pool.

The other type of grouping of Job Controller options is under the channel_class group, used to set parameters on Job Controller channel job initiation and execution.

55.3.27 channel_class

The channel_class group (under job_controller) is not a Job Controller option itself, but rather a grouping of Job Controller options defining a particular named Job Controller channel, or class of channels having a certain name pattern. For instance:

```
msconfig> show channel_class:ims-ms*
role.job_controller.channel_class:ims-ms*.master_command = IMTA_BIN:ims_master
role.job_controller.channel_class:ims-ms*.max_life_askwork = 20000
role.job_controller.channel_class:ims-ms*.max_life_time = 14400
```

This defines the class of channels whose names begin ims-ms. Such channels have a master program (named ims_master), and have max_life_askwork and max_life_time options set to force delivery jobs for such channels to "time out" after certain work and time limits, so that a new, fresh delivery job will be created (as necessary) by the Job Controller.

See Job Controller operation for further discussion of how the Job Controller tracks messages and initiates channel jobs that run channel programs, see Job Controller default configuration for several examples of channel definitions, see Available channels for a list of the normal channels supplied with the MTA, and see the imsimta cache -change utility for how to inform an already running Job Controller process of a new channel_class "on the fly".

The other type of grouping of Job Controller options is under the job_pool group, used to set parameters on Job Controller processing pools.

55.4 Checking that the Job Controller is running

You may check that the Job Controller is running with the command `imsimta process`. You should see output similar to that shown below, perhaps with additional jobs present if your system is currently processing messages.

```
# imsimta process
    USER   PID S  VSZ  RSS    STIME        TIME COMMAND
 mailsrv 12435 S 32936 9672 13:54:01        0:00 /opt/SUNWmsgsr/lib/job_controller
 mailsrv 12433 S 32480 8936 13:54:01        0:00 /opt/SUNWmsgsr/lib/dispatcher
```

Normally, the Watcher is configured to check periodically that the Job Controller is running (and start a new Job Controller, if there is none present).

The Job Controller log file, `job_controller.log-`*`uniqueid`*, may be inspected to check for any Job Controller error messages. Note that, unless Job Controller debugging has been enabled, the Job Controller only writes to its log file if it encounters an error condition; that is, the Job Controller log file will be empty under normal, no-errors, no-debugging-enabled, conditions.

Chapter 56 Compiling the MTA configuration

When using a compiled configuration, whenever you make a change to the MTA configuration, such as to mappings, rewrite rules, channels, aliases, conversions, dispatcher configuration (8.0 or later), job controller configuration (8.0 or later), or channel-specific options (8.0 or later), you must recompile your configuration for the changes to take effect. Compilation reads the entire configuration and writes it out as a single binary file.

Whenever a component of the MTA (such as a channel program) must read the configuration file, it first checks to see if a compiled configuration file exists. If it does, the image is loaded instead of reading the various configuration files.

The command to compile the MTA configuration is:

```
imsimta cnbuild
```

Prior to MS 7.0.5, two MTA Tailor options were relevant for `imsimta cnbuild`: `imta_config_data` specified the default output image file, and `imta_option_file` specified an option file adjusting configuration internal table sizes. As of MS 7.0.5, these MTA Tailor options have been deleted, and hard-coded file paths are used instead, *config-root*`/advanced/config_data` and *server-root*`/lib/option_config.dat`, where *server-root* is the install directory or the value of the `SERVERROOT` environment variable.

Compiled configurations have a static part and a dynamic reloadable part. If the dynamic part is changed, and you run the `imsimta reload` command, all running MTA processes will reload the dynamic data. The dynamic parts are presently the mapping tables and text databases. Everything else is static.

Using a compiled configuration makes it easy to test configuration changes because the configuration files themselves do not "go live" until they are compiled. Most MTA test utilities provide a `-noimage` switch which tells them to ignore the compiled configuration and instead read the configuration from the original files. This lets you test things to make sure they are working before affecting the running system.

If you make changes to your mappings or reverse, forward, or general text databases, then after recompiling issue the command `imsimta reload` to get the changes to take effect. Note that a compiled configuration is a prerequisite to using `imsimta reload`.

Note that `imsimta reload` also reloads authentication, SSL/TLS, and as of Messaging Server 8.0.2, affinity group options. This is done even if the MTA's configuration is not compiled.

If you make changes to other parts of the configuration you must restart the components whose configuration was changed. Some of the dependencies are:

imsimta restart smtp	Changes to mappings, aliases, channels, rewrite rules, channel-specific options for SMTP channels, or text databases.
imsimta restart dispatcher	Changes to the dispatcher configuration, mappings, aliases, channels, rewrite rules, channel-specific options for SMTP channels, text databases

imsimta restart job_controller	Changing the job controller configuration, adding or deleting channels, or changing the values of any of the channel options `pool`, `maxjobs`, `master`, `slave`, `single`, `single_sys`, or `multiple`. Note that adding or changing a `threaddepth` channel option value can be dealt with instead by using the `imsimta cache -change -thread_depth=...` command. You must also restart the job controller if you want changes to master channel jobs to take effect immediately (rather than waiting for the controller to time-out existing channel jobs).

Try to avoid restarting the Job Controller, especially at times when large numbers of messages are in the queues, unless one of the preceding conditions necessitates a restart.

The following changes for compiled MTA configurations were introduced in Messaging Server 8.0:

- The dispatcher configuration, job controller configuration, and channel-specific options are now part of the compiled configuration.
- The `configure` command no longer generates a compiled configuration by default, for both legacy and Unified Configuration.
- Unified Configuration provides the `-xmlfile=xml-config-file` switch in various test utilities like `imsimta test -rewrite`. When combined with the `-noimage`, this allows testing of configuration files in non-default locations.
- The `imsimta version` command now shows if a compiled configuration is used or not.

Chapter 57 Mail filtering and access control

A common goal is to outright reject messages from (or to) certain users at the system level, or to limit the number of throttle the rate at which messages are accepted, or to institute more complex restrictions of message traffic between certain users, or to allow users to set up filters on their own incoming messages (including rejecting messages based on contents of the message headers). The MTA has a number of facilities in such areas, including:

- system level mapping tables such as SEND_ACCESS, FROM_ACCESS, and MAIL_ACCESS that permit both simple and sophisticated restrictions of message traffic based on source and destination and envelope From and To addresses---see Access mapping tables;
- the PORT_ACCESS mapping table that permits restriction of SMTP and LMTP connection attempts based on source IP address; if using the MMP as an SMTP proxy, see also the MMP's access filters;
- user level (and system level) message filtering using Sieve filters, including sophisticated filtering based on message headers---see Sieve filters.
- the general MeterMaid facility that can be used to count or track numbers of messages (or other "events" of interest) across processes and either perform "throttling" itself, or be queried from system level mapping tables or Sieve filters that then make access decisions based upon the MeterMaid counts.

Use of the PORT_ACCESS mapping table for connections to the MTA Dispatcher (*e.g.*, connections to the SMTP server) or TCP wrappers for client connections to the Message Store servers is a very efficient approach when rejection decisions can be taken based purely upon source IP address. Use of mapping tables such as SEND_ACCESS, MAIL_ACCESS, FROM_ACCESS, *etc.*, is an efficient approach when "envelope level" controls are desired---see Access mapping tables. When users wish to implement their own personalized controls, or when message header and body content-based filtering is desired, the more general mail filtering approach using Sieve is likely appropriate---see Sieve filters.

The MTA also uses mapping tables to check other sorts of access, including:

- Deciding which IP addresses are "internal": INTERNAL_IP
- Permitting use of specific SMTP commands:
  - ETRN commands: ETRN_ACCESS
  - BURL commands: BURL_ACCESS
  - STARTTLS commands: TLS_ACCESS
- Controlling mailing list posting access:
  - GROUP_AUTH

  - Many alias options (or in legacy configuration, alias file named parameters) that name site-specific mapping tables, including alias options `alias_auth_mapping`, `alias_cant_mapping`, `alias_hold_mapping`, `alias_nohold_mapping`, `alias_moderator_mapping`, `alias_sasl_auth_mapping`, `alias_sasl_cant_mapping`, and `alias_sasl_moderator_mapping`

- Controlling outbound SMTP connections and authentication:
  - `AUTH_ACCESS`
  - `AUTH_DEACCESS`
  - `MX_ACCESS`
  - `IP_ACCESS`

57.1 Access mapping tables

There are several MTA mapping tables that may be used to control who may or may not connect to the SMTP/SMTP SUBMIT/LMTP servers, what destination hosts and IP addresses may be sent to, what connections may use certain SMTP commands, who may send mail, who may receive mail, or control who may post to mailing lists. For general information on the format and usage of MTA mapping tables, see Mapping table format.

The `PORT_ACCESS` mapping table is used by the Dispatcher to control blocking of connections from particular IP addresses or IP address ranges, and to control use of different authentication mechanisms for different sorts of connections. The `PORT_ACCESS` mapping table in particular is relevant for certain techniques falling under the general category of see defending against denial of service attacks. Although the `PORT_ACCESS` mapping table does not have access to message address information and hence does not permit the fine level granularity of, for instance, the `ORIG_MAIL_ACCESS` mapping table, and although it only applies to incoming SMTP/SMTP SUBMIT/LMTP over TCP/IP messages, note that for what it does do it is a very efficient approach (more efficient than using one of the later, address-based access mapping tables) since it rejects a disallowed host's connection attempt at the TCP level, before the channel dialogue (the SMTP/SMTP SUBMIT/LMTP transaction) has even begun.

The `FROM_ACCESS` mapping table is probed at the point of attempted message submission where the envelope From address has been provided; in SMTP terms, at the stage of the MAIL FROM: command. In particular, this is after the `PORT_ACCESS` probe (that decides whether to allow an SMTP/SMTP SUBMIT/LMTP connection) but before the recipient address mapping tables probes (that decide whether to allow particular recipient addresses). Another feature of the `FROM_ACCESS` mapping table is that it also has access to the authenticated sender information (SMTP AUTH information in particular).

The four recipient access mapping tables, `ORIG_SEND_ACCESS`, `SEND_ACCESS`, `ORIG_MAIL_ACCESS`, and `MAIL_ACCESS`, can make use of envelope address information (as well as, in some cases, all the IP information available to the `PORT_ACCESS` mapping table). The nature of these mapping tables is very general, and allows per channel granularity, that is, channel-specific controls.

Of the recipient access control mapping tables applied at the SMTP RCPT TO command stage, the `MAIL_ACCESS` and `ORIG_MAIL_ACCESS` mapping tables are the most general, having available not only the address and channel information available to `SEND_ACCESS` and `ORIG_SEND_ACCESS`, but also any information that would be available via the `PORT_ACCESS` mapping table, including IP address and port number information. But when IP address information is not relevant to the desired controls, then use of `SEND_ACCESS` or `ORIG_SEND_ACCESS` may be simpler. And for some purposes, combining use of two or more

of these tables may be convenient; see When access mapping table controls are applied for a discussion of the timing and ordering of when access mapping table controls are applied.

The AUTH_REWRITE mapping table is checked after the SMTP DATA is received, so that it has access not only to SMTP envelope fields but also to the header fields in the message itself. Thus while it is not usually the primary tool for checking sender access, as its check occurs later and thus is less efficient for outright blocking certain undesired senders, it can be very useful for enforcing site policy requirements regarding use of proper (perhaps authenticated) From: addresses, by rejecting messages that do not conform to policy.

57.1.1 PORT_ACCESS mapping table

The MTA Dispatcher is able to selectively accept or reject incoming connections to the services it manages such as SMTP, SMTP SUBMIT, or LMTP, based on IP address and port number. At Dispatcher startup time, the Dispatcher will look for a mapping table named PORT_ACCESS. If the mapping was present when the Dispatcher was started, then Dispatcher operation will include checking the mapping for each incoming connection. For each incoming connection the Dispatcher will format connection transport information in the form:

```
TCP|server-address|server-port|client-address|client-port
```

and try to match against all PORT_ACCESS mapping entries. If the result of the mapping contains $N or $F, the connection will be immediately closed. Any other result of the mapping indicates that the connection is to be accepted. $N or $F may optionally be followed by a rejection message. If present, the message will be sent back down the connection just prior to closure.

As of MS 8.0.1.3, tildes (~) may be used as delimiters between multiplie lines in order to create a multiline response. Also note that a CRLF terminator will be appended to the string before it is sent back down the connection.

If no entry matched, then and only then will any dns_verify_domain lookups, as specified via a Dispatcher option (in particular in legacy configuration mode, in the Dispatcher configuration file), be performed, and the result of such a lookup is another way a connection may be refused. In particular, note that either an explicit rejection in PORT_ACCESS, or (as MS 6.0) a match without a rejection hence an "accept" effect will prevent dns_verify_domain lookups from occurring; this allows PORT_ACCESS to do initial filtering on connections, either "black listing" or "white listing" them, with dns_verify_domain taking effect only on any other source IP addresses.

The flag $< followed by an optional string causes the MTA to send the string to syslog (UNIX) if the mapping probe matches; the flag $> followed by an optional string causes the MTA to send the string to syslog (UNIX) if access is rejected.

If bit 1 (value 2) of the log_connection MTA option is set and the $N flag is set so that the connection is rejected, then also specifying the $T flag will cause a "T" entry to be written to the MTA connection log. Note that running processes do not notice the periodic "roll-over" of the mail.log_current file into the mail.log_yesterday file, and the creation of a new mail.log_current file; such changes are normally noticed merely because new processes come into existence and see the "new" file. But in the case of the Dispatcher, which is normally a very long running process (normally not restarted except at times of certain configuration changes), this means that the Dispatcher, which is writing the "T" records, will continue writing to the "old" log file. For instance, after a mail.log_current file has been renamed to mail.log_yesterday, the Dispatcher will keep writing its "T" records

to the file it "knew" about, now named `mail.log_yesterday`; it will not know to start writing to `mail.log_current` unless and until the Dispatcher is restarted. (As of MS 6.2, the Dispatcher periodically (namely once an hour) forces a close and re-open of the connection log file.) So, if you are using "`T`" records, you may wish to restart your Dispatcher daily (at the time of log file rollover)---especially if you are running a version prior to MS 6.2.

The `PORT_ACCESS` mapping table, in addition to its normal use by the Dispatcher, is also optionally probed again by the SMTP server and LMTP server for the purpose of determining the appropriate SASL rule set (when SMTP AUTH has been used during message submission); as of 7.0, the SMTP server probe of the `PORT_ACCESS` mapping table is unconditional (always performed). (However, the LMTP server probe of `PORT_ACCESS` is still conditional.) Or enabling bit 4 of the `log_connection` MTA option also causes the SMTP server and LMTP server to probe the `PORT_ACCESS` mapping table; in this case site-supplied text may be provided in the `PORT_ACCESS` entry to include in the SMTP server's and LMTP server's *`application-info`* field---a field which is used in certain types of log entries (such as "C" connection log entries entries). To specify such text, include two vertical bar characters in the right hand side of the entry, followed by the desired text. New in MS 6.3-0.15, such SMTP server probes of `PORT_ACCESS` will respect the `$N` (in the case of SMTP AUTH usage), `$>`, and `$<` flags, whereas in prior versions the SMTP server probe results were only relevant for setting the SASL ruleset and the optional logging text; as of the fix for 12208860 (Sun 6590888) (MS 6.3-5.02), `$N` rejections will be respected in all cases. Thus new in MS 6.3-0.15 for the special case of SMTP AUTH use, and true in general subsequently, the SMTP server probes of `PORT_ACCESS` can be used to achieve connection rejections (in this case performed by the SMTP server processes, rather than by the main Dispatcher process); for "simple" rejections it is more efficient to perform such rejections from the main Dispatcher process, but for potentially complex or "slow" rejections (such as rejections determined by the results of DNS verification lookups), deferring the rejection until the individual SMTP server process stage can avoid "bottlenecking" the main Dispatcher process waiting for a result of a probe. (LMTP server probes of `PORT_ACCESS` remain, as previously, relevant only for setting the SASL ruleset and the optional logging text.)

Table 57.1 `PORT_ACCESS` mapping flags

Flag	Description
`$U`	(New in 6.3-0.15) Enable channel debugging. As of 7.3-11.01, this includes consulting the `mm_debug` and `os_debug` MTA options and enabling any debugging they specify. This is only supported for SMTP server probes of the `PORT_ACCESS` mapping table; it is not supported for Dispatcher probes of the `PORT_ACCESS` mapping table.
`$G`	(New in MS 7.0u5 for SMTP server; new in MS 8.1 for LMTP server) Enable `TRACE_LEVEL=2` channel debug output. Only supported for SMTP or LMTP server probes; not supported for Dispatcher probes.
`$V`	(New in MS 7.0) Enable the MTA's private SMTP extensions XADR, XCIR, XGEN, and XSTA, overriding any SMTP server `DISABLE_*` TCP/IP-channel-specific options. Only supported for SMTP server probes; not supported for LMTP server or Dispatcher probes.
`$/`	(New in 7.0-0.04) Set the "fast disconnect" flag for sessions that have not yet succeeded in starting a transaction; for such sessions, any subsequent disconnect is done with SO_LINGER enabled and a timeout of 0, which may clear slots quicker on intermediate firewalls and proxies. Only supported for SMTP server and Dispatcher probes; not supported for LMTP probes.

$V	(New in 7.0-0.04) Enable the MTA's private SMTP extensions XADR, XCIR, XGEN, and XSTA, overriding any SMTP server DISABLE_* TCP/IP-channel-specific options. This is only supported for SMTP server probes of the PORT_ACCESS mapping table; it is not supported for Dispatcher probes of the PORT_ACCESS mapping table.
$Y	Allow access.
$T	If bit 1 of the log_connection MTA option is set, and if a connection is rejected ($N is also specified), then write a connection log file "T" record, including any of the optional text specified with $N. This is only supported for Dispatcher probes of the PORT_ACCESS mapping table; it is not supported for SMTP server or LMTP server probes of the PORT_ACCESS table.
	Flags with arguments, in argument reading order[1]
$A*string*	(New in Messaging Server 7.4-18.01; for LMTP server, new in MS 8.0.1.) Set the HULA debug flags specified by the argument string; comma-separated flags can be "perf", "connect", "authserv", and "hula"; see the AUTH_DEBUG TCP/IP-channel-specific option. This is only supported for SMTP server and LMTP server probes of the PORT_ACCESS mapping table; it is not supported for Dispatcher probes of the PORT_ACCESS mapping table.
$<*string*	Send *string* to syslog (UNIX) if probe matches.
$>*string*	Send *string* to syslog (UNIX) if access is rejected.
$N*string*	Reject access with the optional error text *string*.
$F*string*	Synonym for $N*string*, *i.e.*, reject access with the optional error text *string*.
$D*delay*	(New in 6.3-0.15) Delay the banner flush by the specified number of centiseconds, overriding the BANNER_PURGE_DELAY value. This is only supported for SMTP server probes of the PORT_ACCESS mapping table; not supported for LMTP server or Dispatcher probes of the PORT_ACCESS mapping table.
$S*channel-name*	(New in Messaging Server 7.0-0.04) Set the specified channel as the source channel for this SMTP session. This is only supported for SMTP server probes of the PORT_ACCESS mapping table; not supported for LMTP server or Dispatcher probes of the PORT_ACCESS mapping table.
Additional non-flagged fields	Description
TLS-certificate-nicknames	(New in Messaging Server 7.0-0.04) Comma-separated list of TLS certificate nicknames (which must appear subsequent to a vertical bar character). This is only supported for SMTP server probes of the PORT_ACCESS mapping table; not supported for LMTP server or Dispatcher probes of the PORT_ACCESS mapping table.
text	If bit 4 of the log_connection MTA option is set, then the optional text *text* (which must appear subsequent to two vertical bar characters) may be included in the connection log "C" entry [tm]. This is only supported for SMTP server and LMTP server probes of the PORT_ACCESS mapping table; it is not supported for Dispatcher probes of the PORT_ACCESS mapping table.

Flag comparisons	Description
$:A	Match only when the probe is performed by the Dispatcher
$;A	Match only when the Dispatcher is not performing the probe
$:S	Match only when the probe is performed by an SMTP server or LMTP server
$;S	Match only when neither an SMTP server nor an LMTP server is performing the probe

[1] To use multiple flags with arguments, or the non-flagged fields, separate the arguments with the vertical bar character, |, placing the arguments in the order listed in this table.

Note that prior to MS 6.3-0.15, Dispatcher probes of the PORT_ACCESS mapping table could not make use of LDAP callouts ($]...[callouts).

The following example PORT_ACCESS mapping will only accept SMTP connections (to port 25, the normal SMTP port) from a single network, except for a particular host singled out for rejection without explanatory text:

```
PORT_ACCESS

  TCP|*|25|192.123.10.70|*      $N500
  TCP|*|25|192.123.10.*|*       $Y
  TCP|*|25|*|*                  $N500$ Bzzzzzzzzt$ thank$ you$ for$ playing.
```

Note that you will need to restart the Dispatche - or as of MS 6.3-0.15 use the imsimta reload utility to reload the changed mappings file into running processes such as the Dispatcher - after making any changes to the PORT_ACCESS mapping table so that the Dispatcher will see the changes. (Note that this requires a compiled MTA configuration and you'll first need to recompile before reloading.)

The PORT_ACCESS mapping table is specifically intended for performing IP number based rejections; for more general control at the email address level, the e-mail address access mappings such as SEND_ACCESS or MAIL_ACCESS may be more appropriate.

57.1.1.1 Initial PORT_ACCESS mapping table

Initial configuration will generate a basic PORT_ACCESS mapping table that makes use of a subsidiary INTERNAL_IP mapping table to recognize "internal" *vs*. "external" IP sources:

```
PORT_ACCESS

  *|*|*|*|*  $C$|INTERNAL_IP;$3|$Y$E
  *  $YEXTERNAL
```

57.1.2 INTERNAL_IP mapping table

Modern MTA configurations typically make use of an INTERNAL_IP mapping table as a convenient, single location for storing a site's list of "internal" IP addresses. MTA components that need to check whether or not a source IP address is "internal" then can make use of the INTERNAL_IP mapping table for this determination, rather than each component having its own separate list. So while knowledge and use of the INTERNAL_IP mapping table is not hard-coded into the MTA, it is a common configuration feature.

Typical component users of an INTERNAL_IP mapping table include: the PORT_ACCESS mapping table (to determine SASL ruleset), and a backwards-pointing IP literal rewrite rule (for the purpose of switchchannel "switching" to the tcp_intranet channel).

A typical INTERNAL_IP mapping table might appear something like the following, shown from within msconfig:

```
msconfig> show mapping:INTERNAL_IP.*
role.mapping:INTERNAL_IP.rule = host's-public-IP-address $Y
role.mapping:INTERNAL_IP.rule = $<192.168.0.0/16> $Y
role.mapping:INTERNAL_IP.rule = ${::1} $Y
role.mapping:INTERNAL_IP.rule = 127.0.0.1 $Y
role.mapping:INTERNAL_IP.rule = * $N
```

or in legacy configuration:

```
INTERNAL_IP

  host's-public-IP-address    $Y
  $<192.168.0.0/16>           $Y
  ${::1}                      $Y
  127.0.0.1                   $Y
  *                           $N
```

This sample INTERNAL_IP mapping table's rules explicitly match the host's public IP address, use a subnet match to match private IP addresses, and match IPv6 and IPv4 forms of loopback address. A final, fall-through wildcard $N rule ensures that any IP addresses not listed/matched earlier in the INTERNAL_IP table will fail the mapping check (not be considered "internal").

57.1.3 Recipient access mapping tables

The ORIG_SEND_ACCESS, SEND_ACCESS, ORIG_MAIL_ACCESS, and MAIL_ACCESS mapping tables may be used to control who may or may not send mail, receive mail, or both. The access checks have available a message's envelope from address and envelope to addresses, and knowledge of what channel the message came in, and what channel it would attempt to go out; in additional, the ORIG_MAIL_ACCESS and MAIL_ACCESS mapping tables also have access to all the information available to the PORT_ACCESS mapping table. Note that when the envelope To addresses are irrelevant and only the envelope From address matters, then use of the FROM_ACCESS mapping table, described in FROM_ACCESS mapping table, may be more convenient and efficient.

If an ORIG_SEND_ACCESS or SEND_ACCESS mapping table exists, then by default for each recipient of every message passing through the MTA, the MTA will probe the ORIG_SEND_ACCESS and/or SEND_ACCESS mapping tables with a probe string of the form (note the use of the vertical bar character, |)

src-channel|*from-address*|*dst-channel*|*to-address*

where *src-channel* is the channel originating the message (*i.e.*, enqueueing/submitting the message); *from-address* is the address of the message's originator; *dst-channel* is the channel to which the message will be enqueued/submitted; and *to-address* is the address to which the message is addressed. Use of an asterisk in any of these fields causes that field

to match any channel or address, as appropriate; see Mapping table format for additional matching characters and sequences.

Note that the addresses here are envelope addresses, that is, envelope From address and envelope To address. The *from-address* used is by default the so-called *mapped return address*: the envelope From address after simple address reversal has been applied to it (but not including, for instance, destination-specific address reversal). However, the MTA options use_orig_return, and (new in MS 6.3) use_canonical_return, and (new in MS 7.0) use_auth_return, can be used to probe with a different form of the envelope From address. In the case of SEND_ACCESS, the envelope To address is checked after rewriting, alias expansion, *etc.*, have been performed; in the case of ORIG_SEND_ACCESS the originally specified envelope to address is checked after rewriting, but before alias expansion.

The MTA options access_orcpt, access_counts, include_conversiontag, and include_spares1 (which in 8.0.2.2 replaced the previous include_spares MTA option) can cause inclusion of additional fields in the probes. If the relevant bits of all these options are set (the options take bit-encoded integer arguments with distinct bits controlling the inclusion of the fields in the distinct mapping tables), then the format of probes with all optional fields enabled becomes

src-chan|*from-addr*|*dst-chan*|*to-addr*|*orcpt*|*access-counts*|*list-of-tags*|*s1*|*s2*|*s3*|*s4*|*s5*|*s6*

The optional *orcpt* field is the SMTP ORCPT field; that is, it will contain the address type (typically "rfc822") followed by a semicolon, followed by the "original" to address, *e.g.*, "rfc822;user@domain.com". The optional *access-counts* field contains a count of which recipient address (RCPT TO) this probe is for, followed by a forward slash, following by a count of the number of valid recipient addresses resulting from previous recipient address submissions (addresses resulting from previous RCPT TO commands), followed by a forward slash, potentially followed by additional counts expected to be added in future versions; so note that good practice is to always use an asterisk here, so that future additions will not cause old entries to stop working. The optional *list-of-tags* field contains a comma-separated list of conversion tags already present on this message. (Note that conversion tags apply to entire message copies, different recipient conversion tags causing message copy "split up". But these recipient address probes occur before final recipient determination and hence before application of recipient conversion tags occurs.) The optional *s** fields contain the values of the LDAP attributes named by the ldap_spare_* MTA options.

The MAIL_ACCESS mapping table is a superset of the SEND_ACCESS and PORT_ACCESS mapping tables; that is, it combines both the channel and address information of SEND_ACCESS, with the IP address and port number information of PORT_ACCESS. (See PORT_ACCESS mapping table for discussion of the PORT_ACCESS mapping table.) Similarly, the ORIG_MAIL_ACCESS mapping table is a superset of the ORIG_SEND_ACCESS and PORT_ACCESS mapping tables. The format for the default probe string for MAIL_ACCESS is

port_access-probe-info|*app-info*|*submit-type*|*send_access-probe-info*

and similarly the format for the default probe string for ORIG_MAIL_ACCESS is

port_access-probe-info|*app-info*|*submit-type*|*orig_send_access-probe-info*

Here *port_access-probe-info* consists of all the information usually included in a PORT_ACCESS mapping table probe (see PORT_ACCESS mapping table) in the case of incoming SMTP messages (including originally-incoming-SMTP messages that have been deferred to the reprocess channel), or will be blank otherwise, and *app-info* will usually be SMTP/*claimed-HELO-name* in the case of messages submitted via SMTP or SMTP/TLS-*crypto-info*/*claimed-HELO-name* in the case of messages submitted via SMTP

over TLS (including the case of originally-incoming-SMTP messages that have been deferred to the reprocess channel), and blank otherwise. *submit-type* may be one of MAIL, SEND, SAML, or SOML, corresponding to how the message was submitted into the MTA. Normally the value is MAIL, meaning it was submitted as a message; SEND, SAML, or SOML can occur in the case of broadcast requests (or combined broadcast/message requests) submitted to the SMTP server. And for the MAIL_ACCESS mapping table, *send_access-probe-info* consists of all the information usually included in a SEND_ACCESS mapping table probe (including, if the MTA options access_orcpt, access_counts, include_conversiontag, and/or include_spares1 are enabled, their respective additional fields). Similarly for the ORIG_MAIL_ACCESS mapping, *orig_send_access-probe-info* consists of all the information usually included in an ORIG_SEND_ACCESS mapping table probe (including, if the MTA options access_orcpt, access_counts, include_conversiontag, and/or include_spares1 are enabled, their respective additional fields). (See above for additional discussion of SEND_ACCESS and ORIG_SEND_ACCESS probes, as well as the access_orcpt, access_counts, include_conversiontag, include_spares1 MTA options.)

New in MS 7.0, the MTA option mapping_paranoia can cause vertical bars present within a field to be replaced by a different character, thereby ensuring that the only vertical bar characters in a probe are the field delimiter occurrences.

Now, if the probe string matches a pattern (*i.e.,* the left hand side of an entry in the table), then the resulting output of the mapping is checked. If the output contains the flags $Y or $y, then the enqueue for that particular recipient (envelope To) address is permitted.

If the mapping output contains any of the flags $N, $n, $F, or $f, then the enqueue to that particular address is rejected. In the case of a rejection, optional rejection text may be supplied in the mapping output. This string will be included in the rejection error the MTA issues.+ (Unless an at-sign character, @, is part of the explicit rejection text, the MTA will append a colon and the recipient address to the end of the explicitly specified rejection text.) The specific enhanced status code, which in turn determines whether the error is temporary or permanent, can be specified through the use of $X; see the access mapping flags table below for details.

If no string is output (other than the $N, $n, $F, or $f flag), then some default rejection text will be used. As of 6.2, the exact default text depends upon the value of the access_errors option; by default, if that option is 0, then the full SMTP error, including text, is:

```
550 5.7.1 unknown host or domain: recipient-address
```

This default rejection text is rather intentionally misleading for reasons of security, as under some circumstances it may be desirable to avoid revealing the real reason for a rejection. When no such security concerns apply, it is often more user-friendly to take the option of specifing some explanatory rejection text, either your own choice of text, or set access_errors=1. If access_errors is 1, then the full SMTP error, including text, is: but if that option is 1, then the text is:

```
550 5.7.1 you are not allowed to use this address
```

Technical note: When the MTA generates a probe, it may also set various input flags specific to certain probe conditions: *e.g.*, the A input flag is set if SMTP AUTH has been used. Though these input flags are not part of the string part of the probe, they may be detected (tested) in a mapping entry via flag comparison tests in the entry template (right hand side). See the "Input flag comparisons" section of Address access mapping table flags for a full list. Input flags are separate from output flags: even in an iterative mapping, a flag set as output on one line will

not become an input flag for possible subsequent probes, as it is the original input flags which are the input flags for all the probes. Sophisticated uses of the *_ACCESS mapping tables may make use of such input flag tests to more precisely specify under which circumstances to apply mapping effects.

See Address access mapping table flags for descriptions of additional flags. Note that input flags (set by the MTA prior to probing) are the only flags that may be tested using the input flag comparisons. Output flags, those set in the template (right hand side) of a mapping entry, are separate and not subject to such testing.

Table 57.2 Address access mapping table flags[1]

Output flag	Description
$/	(New in MS 7.0) Set the "fast disconnect" flag for sessions that have not yet succeeded in starting a transaction; for such sessions, any subsequent disconnect is done with SO_LINGER enabled and a timeout of 0, which may clear slots quicker on intermediate firewalls and proxies.[3]
$!	Disable (Sieve requested) vacation messages regarding this message[3]
$*	(New in MS 7.0 for FROM_ACCESS; new in MS 7.0u2 for the other address *_ACCESS mappings) If used with $N, force disconnect of the SMTP session.
$+L	(New in MS 7.0.5) If used with $M in FROM_ACCESS, cause the captured message copy to be in journal format
$B	Redirect the message to the bitbucket
$H	Hold the message as a .HELD file
$J	(New in MS 7.0u4) If used with $M, cause generation of envelope "journal" format rather than the default DSN encapsulated format for the "capture" message copy [5]
$O	Forces single-copy-per-recipient message copy "split up", as if the single channel option were set on the relevant destination channel(s).
$P	Force to enqueue to the reprocess channel. (For instance, this might be useful as part of $.text. handling when attempting an LDAP lookup that encountered an LDAP directory temporary problem; that is, in case of an LDAP lookup problem, defer to the reprocess channel.)
$V	Force Sieve filter discard behavior for *all* recipients of this message copy.
$v	(New in MS 7.0u3) Force Sieve filter discard behavior for solely this recipient[5]. For FROM_ACCESS, $v remains equivalent to $V as meaning force Sieve filter discard for all recipients.
$Y	Allow access.
$Z	Force Sieve filter jettison behavior (non-overridable discard) for *all* recipients of this message copy.
$z	(New in MS 7.0u3) Force Sieve filter jettison behavior (non-overridable discard) for solely this recipient[5]. For FROM_ACCESS,

	$z remains synonymous with $Z as meaning force Sieve filter jettison for all recipients.
Output flags with arguments, in argument reading order[2]	
$U*n*	Enable channel (slave) debugging; if the optional *n* argument is specified, it also sets the specified value for enqueue debugging.
$~*channel-name*	(New in MS 7.0, as well as MS 6.3p1) Change source channel to *channel-name* -- this may be of especial interest for the case of incoming notification messages (incoming messages with empty envelope From). Note that when this feature is used and it actually *changes* the source channel, then the FROM_ACCESS check process is restarted; also, $~ can only be applied once.[3]
$J*address*	Replace original envelope From address with specified address[3]
$K*address*	Replace original Sender: address with specified *address*[3] (Note that while $K sets the MTA's internal value for the sender, hence will affect various access checks, whether or not a new Sender: header line should be added to the message displaying the newly specified sender address is controlled by the authrewrite channel option; that is, use of $K does not, *on its own*, cause addition of a Sender: header line showing the new sender address.)
$I*user|identifier*	Check specified user for specified groupid (UNIX) and if not in the group, reject access (effectively sets the $N output flag).
$<*string*	Send *string* to syslog (UNIX) if probe matches; see also the sndopr_priority MTA options[4]
$>*string*	Send *string* to syslog (UNIX) if access is rejected; see also the sndopr_priority MTA option[4]
$D*delay*	Delay response for an interval of *delay* hundredths of seconds; a positive value causes the delay to be imposed on each command in the transaction; a negative value causes the delay to be imposed only on the address handover (SMTP MAIL FROM: command for the FROM_ACCESS table; SMTP RCPT TO: command for the recipient address access mapping tables).
$T*probe-tag*	Prefix subsequent address *_ACCESS mapping table probes with the tag *probe-tag*. New in MS 7.0.5, the last such tag set may optionally be prepended to the AUTH_REWRITE mapping table probe.
$A*header*	Add the header line *header* to the message; (see the spamfilter*_includeheaders MTA options if it is desired to have this added header line be visible to spam/virus filter packages).
$G*conv-tag*	(New in MS 6.0) Add the conversion tag (or comma-separated tags) *conv-tag* to the message.
$M*address*	Capture a copy of the message, sending the captured and encapsulated copy to address. By default, this captured copy is DSN-encapsulated -- but see the no-argument, non-FROM_ACCESS $J output flag above.
$S*x* $S*x*,*y* $S*x*,*y*,*z*	FROM_ACCESS[6]: Set an effective blocklimit, and optionally recipientlimit, and optionally recipientcutoff for the transaction. Prior to MS 6.3, these values were minimized with whatever

	other such limits were already in effect; as of MS 6.3 these values override any global MTA option or source-based such limits that may already be effect (but destination-based limits will still be applied, later).[3]
`$,`*x*	(New in 6.1) Set a spam level value *x* (between -10000 and 10000). If the message already had a spam level, this is a `"spamadjust"` effect (adds or subtracts the specified amount *x* from the prior spam level). Note that such a spam level/spamadjust effect applies to all recipients (even for the recipient-specific mapping tables such as `SEND_ACCESS`) in order for tests to see if one of the recipients is a "honeypot" address.
`$Q`*language* `$Q`*language*`|`*country*	(New in MS 6.3) Set a preferred language and optionally a preferred country[3]
`$(`*postmaster-address*	`FROM_ACCESS`[6]: (New in MS 6.3) Set an override postmaster address[3]
`$)`*postmaster-address*	(New in MS 6.3) Set an override postmaster address if none was previously set[3]
`$+E`*name*`|`*value*	(New in MS 7.0u2) Set the Sieve environment item *name* to *value*
`$+R`*n*`|`*string*	(New in MS 7.0u2) `FROM_ACCESS`[6]: Opt-in to spam/virus filtering.[7] *n* specifies which spam/virus filter package; *string* is the opt-in string to pass to that spam/virus filter package.[3] The string may be blank but the preceding vertical bar may not be omitted.
`$+R`*n1*`,`*s1*`,`*n2*`,`*s2*`,...`	(New in MS 8.0.2.3) `FROM_ACCESS`[6]: Opt-in to spam/virus filtering.[7] *n1, n2 ...* specifies the spam/virus filter packagew; *s1, s2, ...* specify the opt-in strings to pass to the associated spam/virus filter package.[3] The opt-in strings may be blank but the commas may not be omitted.
`$+^`*n1*`,`*n2*`,...`	(New in MS 8.0.1.3) `FROM_ACCESS`: Disable selected filters, overriding any source channel optins. The argument is a comma-separated list of integer values *n1, n2, n3 ...* specifying which spam filters to disable.
`$+&`*n1*`,`*s1*`,`*n2*`,`*s2*`...`	(New in MS 8.0.2.2) `FROM_ACCESS`: Load sender spare attribute with specified value The argument is a comma-separated list of integer-string value pairs *n1, s1, n2, s2 ...* specifying the index of the attribute to load and the value to load into it.
`$W`*n*	(New in MS 8.0) `FROM_ACCESS`: Set the MT-PRIORITY level to *n*.
`$X`*error-code*	Issue the specified *error-code* extended SMTP error code if rejecting the message; if the first digit of the extended SMTP error code *x.y.z* is a 4, then the rejection will be issued as a temporary rejection, `452 4.`*y.z*, instead of the usual `550 5.`*y.z* sort of permanent rejection
`$N`*string*	Reject access with the optional error text *string*
`$F`*string*	Synonym for `$N`*string*, *i.e.*, reject access with the optional error text *string*
`$(`*file-spec*	`[ORIG_][SEND|MAIL]_ACCESS`[6]: If rejecting a message to a mailing list (or other envelope-From-overridden sort of message) with other than a 4xx (temporary) error, override the usual

	`error_text_*` error text option values with values from the file *`file-spec`*; the values should be specified one per line in the file, in the order of the `error_text_*` options as shown in `error_text_*` MTA options.[5]
`$S`*`url`*	`[ORIG_][SEND|MAIL]_ACCESS`[6]: Apply the Sieve filter obtained from resolving *`url`*[5]
`$+R`*`n`*`|`*`string`*	(New in 7.0u2) `[ORIG_][SEND|MAIL]_ACCESS`[6]: Opt-in to spam filtering.[7] Only applied if neither `$N` nor `$F` is set. *`n`* is which spam/virus filter package; *`string`* is the opt-in string to pass to that spam/virus filter package.[5] The string may be blank but the preceding vertical bar may not be omitted.
`$+R`*`n1,s1,n2,s2,...`*	(New in MS 8.0.2.3) `[ORIG_][SEND|MAIL]_ACCESS`[6]: Opt-in to spam filtering.[7] Only applied if neither `$N` nor `$F` is set. *n1, n2, ...* specify which the spam/virus filter packages to activate; *s1, s2, ...* specify the the opt-in strings to pass to the associated spam/virus filter package.[5] The opt-in strings may be blank but the commas may not be omitted.
`$+^`*`n1,n2...`*	(New in MS 8.0.1.3) `[ORIG_][SEND|MAIL]_ACCESS`[6]: Disable selected filters, overriding any active optins. The argument is a comma-separated list of integer values *n1, n2 ...* specifying which spam filters to disable. Note that this effect only extends to the current level of alias expansion - optins at inner levels will be honored.
Input flag comparisons	Description
`$:|`	(New in MS 7.0) Match only if external material (*e.g.*, an envelope address) in the probe contained a vertical bar
`$;|`	(New in MS 7.0) Match only if no vertical bars were present in any external material in the probe
`$:A`	Match only if SMTP AUTH (authenticated submission) has been used
`$;A`	Match only if SMTP AUTH (authenticated submission) has *not* been used
`$:D`	Match only if DELAY delivery receipts have been requested (*e.g.*, NOTIFY=DELAY)[5]
`$;D`	Match only if DELAY delivery receipts have *not* been requested[5]
`$:E`	(New in MS 6.3) Match only if ESMTP has been used
`$;E`	(New in MS 6.3) Match only if ESMTP has not been used
`$:F`	Match only if FAILURE delivery receipts have been requested (*e.g.*, NOTIFY=FAILURE)[5]
`$;F`	Match only if FAILURE delivery receipts have *not* been requested[5]
`$:L`	(New in MS 6.3) Match only if LMTP has been used
`$;L`	(New in MS 6.3) Match only if LMTP has not been used
`$:P`	(New in MS 7.0) Match only if POP-before-SMTP was used
`$;P`	(New in MS 7.0) Match only if POP-before-SMTP was not used

$:R	(New in MS 8.0) Match if the current, enqueueing channel is an "internal" channel such as the reprocess channel
$;R	(New in MS 8.0) Match if the current, enqueueing channel is something other than an "internal" channel
$:S	Match only if SUCCESS delivery receipts have been requested (*e.g.*, NOTIFY=SUCCESS)[5]
$;S	Match only if SUCCESS delivery receipts have *not* been requested[5]
$:T	Match only if TLS has been used
$;T	Match only if TLS has *not* been used
$:V	(New in MS 7.0u1) Match only if recipient address expanded via an alias[5]
$;V	(New in MS 7.0u1) Match only if recipient address did not expand via an alias[5]
$:C	(New in MS 8.0.1.3) Match only if message is the result of a capture/journal action.
$;C	(New in MS 8.0.1.3) Match only if message is not the result of a capture/journal action.

[1] These flags are relevant for the SEND_ACCESS, ORIG_SEND_ACCESS, MAIL_ACCESS, ORIG_MAIL_ACCESS, and FROM_ACCESS mapping table, except where footnotes indicate special restrictions. Note that the PORT_ACCESS mapping table supports a somewhat different set of flags.

[2] To use multiple flags with arguments, separate the arguments with the vertical bar character, |, placing the arguments in the order listed in this table.

[3] Available for the FROM_ACCESS mapping table only.

[4] It is a good idea to use the $D flag when dealing with problem senders, to prevent a denial of service attack. In particular, it is a good idea to use $D in any $> entry or $< entry rejecting access.

[5] Not available for the FROM_ACCESS mapping table.

[6] This output flag has a different meaning and/or occurs in a different position, relative to other output flags, for FROM_ACCESS *vs.* the other address *_ACCESS mapping tables. See the rest of this table for the other occurrence of this flag, describing its operation for the other type of mapping table.

[7] Only one $+R and corresponding value can be used in a single mapping result.

+ Note that it is up to whatever is attempting to send the message whether the MTA rejection error text is actually presented to the user who attempted to send the message. In particular, in the case when SEND_ACCESS is used to reject an incoming SMTP message, the MTA merely issues an SMTP rejection code including the optional rejection text; it is up to the sending SMTP client to use that information to construct a bounce message to send back to the original sender.

An example of an important use of the ORIG_SEND_ACCESS mapping table is discussed in Blocking SMTP relaying.

57.1.3.1 Initial SEND_ACCESS mapping table

Initial configuration will generate a basic SEND_ACCESS mapping table to immediately issue errors in cases of attempts to submit messages to certain invalid domain names:

SEND_ACCESS

```
tcp_*|*|*|*@[127.*]  $X5.1.2|$NBad$ destination$ system
tcp_*|*|*|*@localhost.*  $X5.1.2|$NBad$ destination$ system
tcp_*|*|*|*@example.com  $X5.1.2|$NBad$ destination$ system
tcp_*|*|*|*@example.net  $X5.1.2|$NBad$ destination$ system
tcp_*|*|*|*@example.org  $X5.1.2|$NBad$ destination$ system
tcp_*|*|*|*@*.test  $X5.1.2|$NBad$ destination$ system
tcp_*|*|*|*@*.example  $X5.1.2|$NBad$ destination$ system
tcp_*|*|*|*@*.invalid  $X5.1.2|$NBad$ destination$ system
tcp_*|*|*|*@*.localhost  $X5.1.2|$NBad$ destination$ system
```

57.1.4 FROM_ACCESS mapping table

The FROM_ACCESS mapping table may be used to control who can send mail, or to override purported From: addresses with authenticated addresses, or both.

The input probe string to the FROM_ACCESS mapping table is similar to that for a MAIL_ACCESS mapping table, minus the destination channel and address, and with the addition of authenticated sender information, if available. Thus if a FROM_ACCESS mapping table exists, then for each attempted message submission the MTA will probe the table with a probe string of the form (note the use of the vertical bar character, |)

port_access-probe-info|*app-info*|*submit-type*|*src-channel*|*from-address*|*auth-from*

Here *port_access-probe-info* consists of all the information usually included in a PORT_ACCESS mapping table probe in the case of incoming SMTP messages (including originally-incoming-SMTP messages that have been deferred to the reprocess channel), or will be blank otherwise, and *app-info* will usually be SMTP/*claimed-HELO-name* in the case of messages submitted via SMTP, or SMTP/TLS-*crypto-info*/*claimed-HELO-name* in the case of messages submitted via SMTP over TLS (including the case of originally-incoming-SMTP messages that have been deferred to the reprocess channel), and blank otherwise. *submit-type* may be one of MAIL, SEND, SAML, or SOML, corresponding to how the message was submitted into the MTA. Normally the value is MAIL, meaning it was submitted as a message; SEND, SAML, or SOML can occur in the case of broadcast requests (or combined broadcast/message requests) submitted to the SMTP server. *src-channel* is the channel originating the message (*i.e.*, queueing the message); *from-address* is the address of the message's purported originator (that is, the envelope From address); note that as of Messaging Server 7.0u2, the MTA options use_orig_return , and (new in 6.3) use_canonical_return, and (new in Messaging Server 7.0) use_auth_return , can be used to probe with a different form of the envelope From address. *auth-from* is the authenticated originator address, if such information is available (*e.g.*, from an SMTP AUTH command, in which case it is the user's mail attribute value which is returned from the SASL library code and substituted in this field of the probe), or blank if no authenticated information is available.

The include_conversiontag and include_spares1 (renamed from include_spares as of MS 8.0.2.2) and access_auth MTA options can cause inclusion of additional fields in the FROM_ACCESS probes. If the relevant bits of these options are set, then the format of the probes with all optional fields enabled becomes

port_access-probe|app-info|submit-type|src-chan|from-addr|auth-from|source-auth|username|list-of-tags|s1|s2|s3|s4|s5|s6

The *source-auth* field contains the value of the SMTP MAIL FROM command's AUTH parameter; the *username* field contains the canonical username result produced by authentication. The optional *list-of-tags* field contains a comma-separated list of conversion tags already present on this message. (Note that conversion tags apply to entire message copies, different recipient conversion tags causing message copy "split up". But these recipient address probes occur before final recipient determination and hence before application of recipient conversion tags occurs.) The optional *s** fields contain the values of the LDAP attributes named by the ldap_spare_* MTA options.

Now, if the probe string matches a pattern (*i.e.,* the left hand side of an entry in the table), then the resulting output of the mapping is checked. If the output contains the flags $Y or $y, then the enqueue from that particular From: address is permitted. If the mapping output contains any of the flags $N, $n, $F, or $f, then the enqueue from that particular address is rejected. In the case of a rejection, optional rejection text may be supplied in the mapping output. This string will be included in the rejection error the MTA issues.[1] If no string is output (other than the $N, $n, $F, or $f flag), then default rejection text will be used,

```
550 5.7.1 Initial access check failure
```

See Address access mapping table flags for descriptions of additional flags.

As of MS 6.2p4, the initial configuration of the MTA generates a minimal FROM_ACCESS mapping table that disables generation of vacation messages back to typical list "owner" addresses.

This configuration can easily be extended to block submission entirely based on various criteria. For example, suppose that in addition to not being allowed to receive mail, is is also desirable to prevent over quota users from sending mail. The following settings would expose the mailUserStatus attribute in the sixth spare slot:

```
msconfig> set ldap_spare_6 mailUserStatus
msconfig# set include_spares1 32
```

And the following addition at the end of the FROM_ACCESS mapping would check the attributes value:

```
FROM_ACCESS

  TCP|*|SMTP*|MAIL|tcp_*|*|*|overquota $X4.2.3|$NOver$ quota$ users$ cannot$ send$ mail
```

Besides determining whether to allow a message to be submitted based on the originator, FROM_ACCESS can also be used to alter the envelope From address via the $J flag, or to set a different "sender" address via the $K flag. Although the envelope From and sender address are not always seen in message headers, they can be quite significant for various functional operations (such as access checks). And depending upon other configuration, they may potentially end up visible in header lines (envelope From in the Return-path: header line added during final delivery, and sender address in a Sender: header line if added due to use of the authrewrite channel option). For instance, this mapping table can be used to cause the original envelope From address to simply be replaced by the authenticated address, when an authenticated address is present:

```
FROM_ACCESS

  *|SMTP*|*|tcp_local|*|     $Y
  *|SMTP*|*|tcp_local|*|*    $Y$J$4
```

[1]Note that it is up to whatever is attempting to send the message whether the MTA rejection error text is actually presented to the user who attempted to send the message. In particular, in the case when FROM_ACCESS is used to reject an incoming SMTP message at the MAIL FROM: stage of the SMTP dialogue, the MTA merely issues an SMTP rejection code including the optional rejection text; it is up to the sending SMTP client to use that information to construct a bounce message to send back to the original sender.

57.1.4.1 Initial FROM_ACCESS mapping table

Initial configuration of the MTA normally generates a basic FROM_ACCESS mapping table that uses the $! flag to disable generation of vacation messages back to envelope From addresses that typically correspond to list owner addresses.

```
msconfig> show mapping:FROM_ACCESS.*
role.mapping:FROM_ACCESS.rule = *|SMTP*|*|*|MAILER-DAEMON@*|* $!$Y
role.mapping:FROM_ACCESS.rule = *|SMTP*|*|*|LISTSERVE*@|* $!$Y
role.mapping:FROM_ACCESS.rule = *|SMTP*|*|*|majordomo@*|* $!$Y
role.mapping:FROM_ACCESS.rule = *|SMTP*|*|*|*-request@*|* $!$Y
role.mapping:FROM_ACCESS.rule = *|SMTP*|*|*|*-owner@*|* $!$Y
role.mapping:FROM_ACCESS.rule = *|SMTP*|*|*|owner-*@*|* $!$Y
```

This corresponds to legacy configuration of:

```
FROM_ACCESS

! Entries to block certain submissions normally would be inserted here,
! above the intended-to-be-final entries that while permitting submission,
! merely disable any potential "vacation" effect.
!
! The following entries disable Sieve "vacation" action on lists sorts
! of addresses, as recommended by the Sieve "vacation" extension draft.
!
   *|SMTP*|*|*|MAILER-DAEMON@*|*    $!$Y
   *|SMTP*|*|*|LISTSERVE*@|*        $!$Y
   *|SMTP*|*|*|majordomo@*|*        $!$Y
   *|SMTP*|*|*|*-request@*|*        $!$Y
   *|SMTP*|*|*|*-owner@*|*          $!$Y
   *|SMTP*|*|*|owner-*@*|*          $!$Y
```

57.1.5 When access mapping table controls are applied

The MTA checks access control mapping tables as early as possible. Exactly when this happens depends upon the e-mail protocol in use---when the information that must be checked becomes available.

For incoming SMTP messages, the Dispatcher consults the PORT_ACCESS mapping table to decide whether or not to accept the SMTP connection -- before even accepting a connection. In the case of an accepted SMTP connection handed over to an SMTP server process thread, then (as of Messaging Server 7.0) each SMTP server process thread makes its own additional probe of PORT_ACCESS after the hand off of a connection from the Dispatcher, prior to issuing the server's SMTP banner line. (If the "client" is the MMP and it sends an XPEHLO command, that resets the effective source IP address and so the SMTP server process thread will then do yet another PORT_ACCESS probe.) There are trade-offs in performance between the Dispatcher check and the server process check of PORT_ACCESS; see the PORT_ACCESS mapping table discussion for additional details.

Continuing with the (incoming) SMTP protocol, where addresses are presented in the initial part of the attempted message handover, well before the message data itself would be handed over, note that a FROM_ACCESS rejection will occur in response to the MAIL FROM: command, *before* the sending side ever gets to send the recipient information let alone the message data, while a recipient access mapping table (ORIG_SEND_ACCESS, SEND_ACCESS, ORIG_MAIL_ACCESS, or MAIL_ACCESS) sort of rejection will occur in response to the RCPT TO: command, *before* the sending side ever gets to send the message data. Thus if an SMTP message is rejected due to such a *_ACCESS mapping table rejection, the MTA never even accepts or sees the message data, thereby minimizing the overhead of performing such rejections.

In contrast, note that an AUTH_REWRITE mapping table which (as of MS 6.2) may reject messages, or a Sieve script "refuse" message rejection, since they in principle may make use of information from the message as a whole (message header lines and body content), cannot be applied until after the message data has been received by the MTA. In particular, in the case of an SMTP message, these forms of rejection cannot occur until after the end of the DATA phase of processing, thus they involve more overhead (both network traffic, and MTA processing overhead) than rejections performed via a *_ACCESS mapping table.

So the order in which access mapping tables are checked for incoming messages is:

- PORT_ACCESS (by Dispatcher),
- PORT_ACCESS (by SMTP server as of Messaging Server 7.0),
- TLS_ACCESS (by SMTP server after successful STARTTLS negotiation), or ETRN_ACCESS (by SMTP server when an ETRN command is received),
- SASL_ACCESS (after SMTP AUTH),
- FROM_ACCESS (after SMTP MAIL FROM),
- ORIG_SEND_ACCESS, SEND_ACCESS, ORIG_MAIL_ACCESS, and MAIL_ACCESS (after SMTP RCPT TO, after the MTA's address rewriting and alias processing has been applied, all four are checked in the order listed),
- BURL_ACCESS (by SMTP SUBMIT server when a BURL command is received instead of regular message DATA),
- AUTH_REWRITE (after SMTP DATA).

In the list above, failing a check at one stage normally aborts message acceptance and processing and hence no further checks need be performed. But as regards the recipient address based mapping tables ORIG_SEND_ACCESS, SEND_ACCESS, ORIG_MAIL_ACCESS, and MAIL_ACCESS, note that they are all checked at the same stage of processing (which is

after address rewriting and alias processing); if multiple of these recipient address access control mapping tables exist, then the MTA will check them all (and any side-effects they cause will take place) in the order just listed (which is a point to keep in mind when using such mapping tables to obtain side-effects such as addition of header lines, logging to `syslog`, *etc.*).

The MTA is designed to do most processing upon message enqueue. So outgoing SMTP messages receive relatively little processing. However, there are a few possible access checks for outgoing SMTP messages. See the `AUTH_ACCESS`, `IP_ACCESS`, and `TLS_ACCESS` mapping tables.

57.2 Defending against denial of service attacks

A denial of service attack is where an attacker tries (intentionally or inadvertently) to overwhelm your system by flooding you with e-mail.

The MTA is designed to continue operating even when impacted by an attempted denial of service attack. The design of the Dispatcher includes limits, which are configurable, on how many simultaneous inbound connections to accept, how many processes to generate to handle inbound connections, and how to apportion such inbound connections to those Worker Processes. Similarly, the Job Controller has various self-managing features; see the discussion of Job Controller operation under stress. However, sites subject to malicious attacks, or sites that communicate with particularly ill-behaved correspondents, may want to take further explicit steps for protection.

In some cases, adding a simple static mapping entry to unconditionally reject messages from the problem address or site is a sufficient defense, particularly if you know ahead of time (or can quickly detect) that the attack is occurring; see Access mapping tables and Client access to Message Store servers. In other cases, however, you may either wish to automate dynamic detection of message volume upswings sufficient to be considered an attack. Or you may not wish to reject *all* messages from the problem address or site and instead wish merely to "turn down the volume", *i.e.*, slow down the flow to a level more easily managed by your users or system. For instance, you may be under a practical or legal mandate to accept certain messages, or good messages may be mixed in with the bad message flow; in such a case turning down the volume to a manageable level allows the good messages a chance to get into your system while preventing the bad messages from overloading your resources.

The `PORT_ACCESS` and `SEND_ACCESS` mapping tables ---as well as related mapping tables discussed in Access mapping tables---can be used in more sophisticated ways than simple unconditional entries to achieve such goals, and can indeed be hooked into dynamic, heuristic routines to decide "Yea" or "Nay" on accepting messages, such as MeterMaid, or `dns_verify` routines, or calling out to PureMessage IP Blocker via the `pmxbl` routine, or calling out to a third-party anti-spam/anti-virus package that supports so-called "early verdicts" via the `mm_check_reputation` routine, or callouts to site-provided routines.

First, on the most simple level, the `PORT_ACCESS`, `SEND_ACCESS` or related mapping tables can take a random argument, effectively having the MTA "flip a coin" each time it needs to decide whether to accept a connection or message, respectively, or in the case of `SEND_ACCESS` and related mapping tables whether to sideline a message; see the $? substitution (under Mapping tables) for details.

For more sophisticated needs, the `PORT_ACCESS`, `SEND_ACCESS`, or related mapping tables can call out to facilities such as MeterMaid, or the `dns_verify` routines, or call out to site-

supplied shareable image routines; see Site-supplied routine substitutions (under Mapping tables) for details. Such routines can, if you wish, use PMDF API calls to access MTA counters information; this can allow for heuristic decisions based on recent message load, comparing MTA counters levels at one sampled time with MTA counters levels when checked a little later; *e.g.*, "lots of messages came in to the tcp_local channel in the last few minutes, so let us reject additional connection attempts for the moment" or whatever decision basis you decide to implement.

As of Messaging Server 7.0u2, use of a `LOG_ACTION` mapping table calling out to MeterMaid may be an even better approach for making dynamic decisions.

If you have a site approach for monitoring syslog notices, note that the `log_messages_syslog` and `log_connections_syslog` MTA options can be enabled to cause message and connection entries, respectively, to also be sent to syslog.

As of the 8.0 release, the Sieve "`memcache`" operator and Sieve "`metermaid`" operator are available to query and update memcache or MeterMaid, respectively, from within a Sieve script. Sieve script powerful logic can thereby allow for especially flexible or "targetted" updates of memcache or MeterMaid tables, if desired, when such tables are to be queried for connection blocking or throttling type purposes.

The heuristics for making dynamic decisions about accepting or rejecting messages tend to be very site specific, and involve a variety of critical issues. Note also that sites may wish to keep the details of their own heuristic algorithms secure. Sites interested in implementing their own denial of service prevention techniques may wish to obtain specialized consulting assistance.

Particularly when implementing dynamic rejection mechanisms, the following TCP/IP-channel-specific options may be of interest:

- `ALLOW_TRANSACTIONS_PER_SESSION`, `ALLOW_RECIPIENTS_PER_TRANSACTION`, and `TRANSACTION_LIMIT_RCPT_TO`. The `ALLOW_TRANSACTIONS_PER_SESSION` option can be used to limit the number of messages accepted during a particular connection. After refusing a number of connection attempts from a particular site, once you do let them connect, they are liable to have a backlog of messages for your site which they will try to deliver during that connection. If you are attempting to "slow down" how much mail you accept from that site, you likely will want to use this option to say, in effect, "enough for now" after some point in the connection. Similarly, the `ALLOW_RECIPIENTS_PER_TRANSACTION` option can be used to limit the number of recipients allowed for a particular message submission (additional recipients during that submission attempt being rejected with a temporary error, so that they may be tried again later); this can be useful in slowing down the number of recipients handed over during a single message transaction. Thus both these options may be useful protecting against a denial of service attack in the form of a rapid flood of messages blanketing large numbers of your users. The `TRANSACTION_LIMIT_RCPT_TO` option modifies the effect of `ALLOW_RECIPIENTS_PER_TRANSACTION`, in that it controls at which SMTP command (RCPT TO: or MAIL FROM:) the "extra" recipient addresses are rejected.

- `REJECT_RECIPIENTS_PER_TRANSACTION`. The `REJECT_RECIPIENTS_PER_TRANSACTION` option can be considered a more aggressive version of `ALLOW_RECIPIENTS_PER_TRANSACTION`; whereas `ALLOW_RECIPIENTS_PER_TRANSACTION` allows up to the specified number of recipients to be accepted (while additional recipients get a temporary rejection) thereby merely "slowing down" the incoming messages, `REJECT_RECIPIENTS_PER_TRANSACTION` causes the MTA to issue a temporary rejection (after the DATA command) for *all* recipients of a message if too many recipients are attempted. That is, with

REJECT_RECIPIENTS_PER_TRANSACTION, a message will not be allowed in at all until the sending side decreases the number of recipients it is trying to submit during a single transaction. So for a sufficiently flexible sender, REJECT_RECIPIENTS_PER_TRANSACTION is simply a somewhat more forceful way of slowing down the message flow. But for a sender that is not so flexible about retrying sending a message with fewer recipients per transaction, REJECT_RECIPENTS_PER_TRANSACTION may result in the message not getting through at all.

- ALLOW_REJECTIONS_BEFORE_DEFERRAL. The ALLOW_REJECTIONS_BEFORE_DEFERRAL option causes the MTA, after the specified number of recipients have failed (been determined to be invalid addresses), to reject (with a temporary error) all further recipients in that transaction, good or bad. That is, this option penalizes message submissions that include a lot of bad recipient addresses (on the theory that such message submissions may be cases of dictionary-based or automatically-generated lists of recipients).

- SIZE_DELAY_THRESHHOLDS, SIZE_DELAY_AMOUNTS, RECIPIENT_DELAY_THRESHHOLDS, RECIPIENT_DELAY_AMOUNTS, TRANSACTION_DELAY_THRESHHOLDS, TRANSACTION_DELAY_AMOUNTS. These options are specifically available to progressively "slow down" the acceptance of incoming messages once specified threshholds have been exceeded.

The above items focus on MTA features. However, many sites will also have a spam/virus filter package that may be capable of maintaining heuristic data concerning connections; if such a spam/virus filter package has useful such abilities and is configured to report or make available relevant such data to the MTA, as for instance via a mm_check_reputation routine call from the PORT_ACCESS mapping table, that can be yet another useful tool in the arsenal for defending against denial of service attacks.

Chapter 58 Spam and virus filtering

The MTA supports calling out to up to eight spam/virus filter packages while processing incoming messages. The configuration of how the MTA should locate and communicate with such spam/virus filter packages is controlled via spamfilter MTA options; the configuration of which routes of messages traffic receive which spam/virus filtering may be controlled via spamfilter channel options; in addition to, or instead of, channel-level control, the MTA also supports per address (either sender or receiver) opt-in to spam/virus filtering via various user-level or domain-level LDAP attributes, and via `alias_optinN` alias options.

When use of multiple spam/virus filter package "slots" is configured, the MTA calls all the configured spam/virus filter packages as messages are being received (enqueued). Thus the spam/virus filter package processing of messages is essentially in parallel with each other (and with the MTA's own inherent processing). The MTA then uses (applies) the spam/virus filter package results -- their respective verdicts -- in the order of the configured spam/virus filter package "slots": `spamfilter1*`, before `spamfilter2*`, before `spamfilter3*`, *etc.*

Generally, spam/virus filter package verdicts regarding specific messages are interpreted by the MTA as requesting correspondingly configured Sieve filter actions. Via the interaction of various types and levels of Sieve filters in the MTA's Sieve hierarchy, complex logic weighting or comparing verdicts from multiple spam/virus filter packages can be achieved. The Sieve `spamtest` and `virustest` extensions can be particularly useful in the context of consulting multiple spam/virus filter packages.

With those spam/virus filter packages that support connection-based "early verdicts", the MTA can also make use of such information as a special application of its general Mail filtering and access control functionality. See also the topics of Defending against denial of service attacks and Triggering effects from transaction logging with LOG_ACTION.

Note that many spam/virus filter packages do not themselves support returning different verdicts for different recipients of a single message. However, Brightmail does; and as of Messaging Server 7.0.5.33, Oracle's milter implementation supports a single recipient extension to effect different milter actions for different recipients. Furthermore, note that even with a spam/virus filter package that does not itself support returning different verdicts for different recipients, different per-recipient eventual effects can be achieved (at the cost of some additional configuration complexity) in a couple of ways. One way to achieve different

effects for different users even with a spam/virus filter package that does not support per-recipient verdicts is to have the spam/virus filter package result "mark up" a message in one way or another (*e.g.*, by adding a header line, or setting a spam level) and then make use of the MTA's Sieve hierarchy to take individualized actions in user-level Sieve filters. Another way to achieve individualized effects even with a spam/virus filter package that has no such inbuilt support is to assign different MTA spamfilter "slots" (that is, different *N* in the `spamfilterN_*` MTA options) to different configurations of a single spam/virus filter package, and then "opt in" users to the appropriate "package" configurations, either at the domain level or at the individual user level; see the `ldap_domain_attr_optinN` and `ldap_optinN` MTA options.

Integrating spam/virus filter package use as a "call-out" via spamfilter MTA options is generally much preferable in functionality to use of an "in front" or "on the side" separate, dedicated spam/virus filter SMTP host, or even site or third-party written filtering MTA channel, for reasons including:

- the call-out approach permits "up front" address validation by the MTA, thus avoiding wasting time on invalid (perhaps dictionary attack generated) recipient addresses;
- the call-out approach preserves SMTP responsibility and full SMTP features (*e.g.*, message size limits, message notification handling requests, message authentication data, *etc.*) for incoming messages with the MTA whose primary function that is;
- the call-out approach tends to maximize performance and throughput of messages; in particular, it avoids the overhead of additional full transfers of the messages and avoids SMTP performance bottlenecks or message buildups on third-party SMTP implementations;
- the call-out approach permits the use of multiple spam/virus filter packages "in parallel", which for sites that like to use (or compare) different spam/virus packages has benefits including:

  1. higher throughput due to the parallelization of the MTA calling all the spam/virus filter packages in parallel while messages are being enqueued,
  2. convenient comparison of and swapping between different spam/virus filter packages at site convenience,
  3. the potential for complex combining and weighting of verdicts from different spam/virus filter packages,
  4. provisioning of user use of email spam/virus services that is integrated with the provisioning of user email addresses, routing, and other email services.

However, the MTA does also support hooking in site or third-party written MTA channels via the alternate conversion channel approach.

The Message Store's `imexpire` utility also supports operating in a mode where it calls out to spam/virus filter packages "as if" it were an MTA channel, applying a subset of Sieve filter actions corresponding to the spam/virus filter package verdicts again "as if" it were an MTA channel. This feature thus permits post-delivery scanning of messages for spam/virus, and removal from the Message Store of such messages determined (post-delivery) to be spam or virus-contaminated.

58.1 Brightmail spamfilterN_config_file

When using Brightmail (and running it on a separate, remote system), a `spamfilterN_config_file` MTA option might be set as

```
msconfig> set mta.spamfilter1_config_file /opt/mailwail/config.remote
```

For Brightmail, the file that this option names may contain an extensive list of option settings. Listed below in Some Brightmail configuration file options are some especially relevant valid options, but for a full list of valid options, consult Brightmail documentation. Brightmail configuration file option names are not case-sensitive. However, the values (right hand sides) are potentially case-sensitive. The Brightmail configuration file uses LDIF format; in particular, options are specified as

option-name: *option-value*

Table 58.1 Some Brightmail configuration file options

Option name	Meaning	Typical setting for MTA use
blSWPrecedence	A message may receive multiple forms of processing hence multiple verdicts; for instance, receive verdicts of both `spam` and `virus`. This option specifies the order in which verdicts are processed for messages with multiple verdicts. Verdicts should be separated with the hyphen character, `-`. A verdict appearing first (left-most) in the hyphen-separated list will be processed before a verdict appearing next (to the right), *etc.*. Supported verdicts are `virus` and `spam`. Brightmail recommends that virus verdicts be processed first.	`blSWPrecedence: virus-spam`
blSWClientDestinationDefault	This option specifies how to handle messages that have no verdict (for instance, that are not gray or virus and hence do not require additional filtering). Usually such messages should simply be delivered normally, that is, to the user's usual inbox. The value `inbox` has this meaning, and hence is usually the recommended setting.	`blSWClientDestinationDefault: inbox`

blSWLocalDomain	Occurrences of this option specify which domain(s) are considered local, hence which domains get the handling specified by blSWClientDestinationLocal options (as opposed to handling specified by blSWClientDestinationForeign options).	`blSWLocalDomain:`
		`  *your-domain-1*.com`
		`blSWLocalDomain:`
		`  *your-domain-2*.com`
		`...`
		`blSWLocalDomain:`
		`  *your-domain-n*.com`

blSWClientDestinationLocal	This option specifies *verdict-name*|*destination-data* pairs for recipients in a local domain (a domain specified by a `blSWLocalDomain` option). (`blSWClientDestinationForeign` options control the handling for recipients in any other domains). That is, a setting of this option controls what verdict string (destination-data) is passed to the MTA corresponding to a particular Brightmail verdict. The MTA is normally configured (via a `spamfilterN_null_action=data,discard;` MTA option setting) to consider a null *destination-data* value to be a request to discard the message. And since the MTA's default action, given a non-null verdict (non-null destination-data), is to file to a folder of the same name as the verdict (destination-data), due to the default:	The default settings are:
		
		`blSWClientDestinationLocal:`
		`  spam|junkmail`
		`blSWClientDestinationLocal:`
		`  virus|`
		
		which by default has the effect that messages that Brightmail considers to be virus will be discarded while messages that Brightmail considers to be spam will be filed to a recipient's "`junkmail`" folder.

	spamfilter*N*_string_action=data:,require "fileinto"; fileinto "$U"; This typically but not necessarily amounts to *verdict-name*|*folder-name* pairs, with a null (empty) folder-name meaning to discard the message. But more precisely, it truly consists of *Brightmail-verdict-name*|*MTA-verdict-string* pairs, where the *MTA-verdict-string* can be specified in an MTA option of the form spamfilter*N*_verdict_M=*MTA-verdict-string* to correspond to an action specified in a spamfilter*N*_action_m option, and with a null *MTA-verdict-string* being handled in accordance with the MTA's corresponding spamfilter*N*_null_action option. Supported *verdict-name* values include spam and virus.	
blSWClientDestinationForeign	Analogous in syntax and meaning to blSWClientDestinationLocal settings above, but applying to recipients who are not in one of the blSWLocalDomain domains.	
blSWClientOptin	This option specifies the handling of opt-in decisions by the Brightmail Client, and for use with the MTA must be set to TRUE.	blSWClientOptin: TRUE
blswcServerAddress	This option specifies the IP address(es) and port(s) of one or more Brightmail servers. The syntax is *ip*:*port*[,*ip*:*port*,...]	blswcServerAddress: *ip*:*port* or blswcServerAddress: *ip-1*:*port-1*, *ip-2*:*port-2*,..., *ip-n*:*port-n*
blCommonDebugFilename	This option specifies the location of Brightmail's own debug log file. It can be set to any of syslog or syslog|syslog-facility (the default when logging to syslog if the facility is not set is mail), stderr, or a *path-to-filename*.	blswcCommonDebugFileName: /opt/mailwall/logs/common_log
blCommonDebugLevel	This option enables Brightmail's own debugging. The value is a comma-separated list of pairs of values. The first subvalue in each pair is either a positive integer (specifying a section of Brightmail code - use reserved for Brightmail) or the keyword ALL, meaning that all Brightmail code is debugged. The second value in each pair is an integer between 0 and 7, specifying the severity of the error as defined in syslog. Brightmail recommends that for problem situations, this option be set to ALL,6. And Brightmail recommends that after solving the difficulty, that the option be set back to ALL,4.	blCommonDebugLevel: ALL,4
blswcDebugFileName		blswcDebugFileName: /opt/mailwall/logs/bmclient_log
blswcDebugLevel		
blswsDebugFileName		blswsDebugFileName: /opt/mailwall/logs/bmserver_log
blswsDebugLevel		

Material in this table is taken from the *Brightmail Solution Suite 4.0 for iPlanet Messaging Server* manual. While presented again here for convenience, that manual should be considered the definitive source for Brightmail documentation.

58.2 ClamAV spamfilterN_config_file

When using ClamAV, a `spamfilterN_config_file` MTA option might be set as

```
msconfig> set mta.spamfilter3_config_file IMTA_TABLE:clamav.dat
```

With ClamAV, the file that a `spamfilterN_config_file` MTA option names may contain the following options:

- DEBUG (integer; default is 0).
- USE_INSTREAM (0 or 1; default is 0). New in Messaging Server 7.0u3. The default 0 selects that ClamAV "STREAM" request is sent; setting 1 selects that ClamAV "INSTREAM" request is sent.
- MESSAGE_BUFFER_SIZE (integer; default is 1048576).
- HOST (hostname or IP address). A value must be specified for this option; (its presence is required).
- PORT (integer). A value must be specified for this option; (its presence is required).
- SOCKS_HOST (string).
- SOCKS_PORT (integer; default is 1080).
- SOCKS_USERNAME (string).
- SOCKS_PASSWORD (string).
- TIMEOUT (integer; default is 3600).
- MODE (integer; default is 0).
- FIELD (string; default is "`Virus-Test`").
- VERDICT (string).

58.3 ICAP spamfilterN_config_file

When using ICAP, a `spamfilterN_config_file` MTA option might be set as

```
msconfig> set mta.spamfilter4_config_file IMTA_TABLE:icap.dat
```

With ICAP, the file that a `spamfilterN_config_file` MTA option names may contain the following options:

- DEBUG (integer; default 0)
- TIMEOUT (integer; default 3600)
- SOCKS_HOST (string)
- SOCKS_PORT (integer; default 1800)
- SOCKS_USERNAME (string)
- HOST (string or IP address); this option is required (a value must be set)

- PORT (integer; default 1344)
- MODE (integer; default 0)
- FIELD (string; default "`Virus-Test`")
- VERDICT (string)

58.4 Milter spamfilterN_config_file

When using Milter, a `spamfilterN_config_file` MTA option might be set as

```
msconfig> set mta.spamfilter4_config_file IMTA_TABLE:milter.dat
```

With milter (supported as of MS 6.3), the file that a `spamfilterN_config_file` MTA option names may contain the following options:

- `CONNECT_TIMEOUT` (integer). (New in 8.0) This option provides a separate timeout for the initial milter connection separate from the timeout waiting for milter responses. If this option is not set, it defaults to the value set for the `TIMEOUT` option. A non-positive setting for `CONNECT_TIMEOUT`, whether explicitly set or inherited from `TIMEOUT`, will result in using a `CONNECT_TIMEOUT` value of `60`.
- `CONTEXT_EDITS` (integer; default is 1). (New in 8.0.1) The milter interface expresses header modification actions in terms of offsets, e.g., "delete the third occurrence of the Authentication-results: header field" or "replace the value of the first occurrence of the DKIM-Signature: field with ...". For the most part these actions have obvious analogues in Sieve using the index extension. However, when multiple milters acting in parallel modify the same header field it's possible for the changes to overlap and produce anomalous results. This can be ameliorated by converting offsets into references to the header field's value, something the Sieve editheader extension also supports. The `CONTEXT_EDITS` option controls whether or not milter header modification actions are translated from offsets into value references. A non-zero value (the default) enables this translation; a zero value disables it.
- `DEBUG` (integer; default is 0). Non-zero values enable increasingly higher levels of debug output: a value of 1 enables basic debugging; a value of 2 enables, for instance, hex dumps of the milter responses; a value of 3 is also meaningful, enabling output of the octets of the milter responseand as of the 8.0 release, additional other debug output such as debugging of use of the `MILTER_MACROS` mapping table.
- `DEFER_MESSAGE_TRANSFER` (integer; default is 0). (New in MS 8.0.1) Normally messages are transferred to the milter server as they are presented to the MTA. Setting `DEFER_MESSAGE_TRANSFER` to a non-zero value defers the transfer until after the preceding spamfilter plugin has completed its actions, at which point the message header and body are transferred to the milter server from the MTA's internal storage areas. Normally this option is used in conjunction with setting the `IMMEDIATE_HEADER_MODIFICATIONS` option on a previous milter spamfilter plugin, which results in the modifications made by the previous milter being visible to the current milter.
- `HOST` (hostname or IP address). Specify a host running a Milter server. A value must be specified for this option; (its presence is required).

- DATA_IN_BODYEOB (0 or 1; default is 0). (New in 8.0.2, and for libmilters.so new in a patch to MS 7.0.5) When set to 0 (the default), message body material is not sent as part of the milter BODYEOB (body end of body) command. Setting this option to 1 allows message body material to be sent with the BODYEOB command, which while legal per the milter specifications and more efficient, may cause trouble with milters such as Proofpoint's milter.

- IGNORE_BAD_CERT (0 or 1; default is 0). (New in 8.0.1.3.) Setting this option to 1 disables SSL/TLS certificate checking. This option is only meaningful if the USE_SSL option is set to 1.

- IMMEDIATE_HEADER_MODIFICATIONS (integer, default 0). (New in MS 8.0.1) By default the milter interface converts milter header modification actions to Sieve actions. Setting this option to a non-zero value will cause the plugin to modify the MTA's internal copy of the message header directly; no Sieve actions will be generated. IMPORTANT NOTE: This option should ONLY be used with plugins enabled on the basis of the source channel; use with plugins enabled via destination channels will cause inconsistent results. Additionally, the 8.0.1 release of this capability implements different semantics for multiple deletes with different indices than would be obtained otherwise. These semantics have been brought in line with normal milter operation as of MS 8.0.2.2.

- MAX_PREPEND_INDEX (integer; default is 1) (New in 8.0) Specifies the smallest index value that can be passed to SMFI_INSHEADER by the milter server and cause the resulting header field to be inserted at the top of the header block rather than the bottom.

- PER_RECIPIENT_ACTIONS (0 or 1; default is 0). (New in 7.0.5.33) Setting this option to 1 enables availability of Oracle's milter extension SMFIF_SPECRCPT for per-recipient modification actions.

- PRESERVE_BREAKS (0 or 1; default is 1) (New in Messaging Server 7.0.5) Preserve line breaks (line folding) in header lines during processing.

- PORT (integer). Specify the port on which the Milter server is listening. A value must be specified for this option; (its presence is required).

- QUARANTINE_ACTION (string; default is "hold;"). (New in 8.0.1.) This option specifies the Sieve action to use when a milter quarantine message modifier (SMFIF_QUARANTINE) is engaged. For example: `QUARANTINE_ACTION=require "fileinto"; fileinto "spam";` Milter quarantine actions always have an associated "reason" string. A $R can be used to substitute this string into the Sieve action. For example: `QUARANTINE_ACTION=require "reject"; reject "Message rejected, reason: $R";` A literal dollar sign in the Sieve action string must be doubled, *e.g.*, $$. The default action that is performed if QUARANTINE_ACTION is not set is "hold;".

- REPROCESS_CONNECT_TIMEOUT (integer). (New in 8.0.2.3) This option's value is used instead of the CONNECT_TIMEOUT value when a message is undergoing reprocessing. This allows a longer timeout to be used in the case where there's no protocol session and thus no need for quick completion. If this option is not set, it defaults to the value set for the REPROCESS_TIMEOUT option. A non-positive setting for REPROCESS_CONNECT_TIMEOUT, whether explicitly set or inherited from TIMEOUT, will result in using a REPROCES_CONNECT_TIMEOUT value of 60.

- REPROCESS_TIMEOUT (integer). (New in 8.0.2.3) This option's value is used instead of the TIMEOUT value when a message is undergoing reprocessing. This allows a longer timeout to be used in the case where there's no protocol session and thus no need for quick completion. If this option is not set, it defaults to the value set for the TIMEOUT option. A non-positive

setting for REPROCESS_TIMEOUT, whether explicitly set or inherited from TIMEOUT, will result in using a REPROCES_TIMEOUT value of 240.

- RESETDEBUG (integer; default is 0). Setting RESETDEBUG enables milter debugging conditionally: only if channel debugging enabled. (Such channel debugging might be enabled via slave_debug on the channel, or via the $U flag in a FROM_ACCESS and recipient *_ACCESS mapping table.)
- TIMEOUT (integer; default is 3600). Attempting to set a non-positive value will result in a value of 120 being used.
- SESSION_INACTIVITY_TIMEOUT (integer; default is 180). (New in 8.0) Time in session that a session is allowed to remain idle and still be a candidate for reuse.
- SESSION_TIME (integer; default is 3600). (New in 8.0) Maximum time, in seconds, that a single session can be used.
- TRANSACTIONS_PER_SESSION (integer; default is 100). (New in 8.0) Number of transactions allowed in a single session.
- TCP_NODELAY (0 or 1; default 0). (New in 8.0.1.3.) Setting this option to 1 causes the NODELAY flag to be set at the TCP level on all milter connections. Note that the behavior of the milter protocol is highly dependent on what options are negotiated: One milter may require many round trips per message while another may only need one. As such, it isn't clear that there's an optimal setting for the NODELAY flag.
- USE_JETTISON (0 or 1; default is 0). (New in Messaging Server 7.0 update 2.) If this option is set to 1, then the Sieve "jettison" action will be used instead of "discard" if the milter calls for the message to be discarded. The default value of 0 causes "discard" to be used.
- USE_QUIT_NC (0 or 1; default is 0). (New in 8.0) Setting this option to 1 enables use of the QUIT_NC milter command so that sessions can be reused. This should only be set when the version of libmilter is recent enough to support the feature (Sendmail 8.14 or later).
- USE_SSL (0 or 1; default is 0). (New in 8.0.1.3.) Setting this option to 1 enables use of SSL/TLS on the milter connection. Note that libmilter.so does not provide support for SSL/TLS so a proxy/tunnel server such as stunnel must be placed in front of most milters before this option can be used.

As of 8.0, support for milter connections via Socks has been removed, so the SOCKS_HOST, SOCKS_PORT, SOCKS_USERNAME, and SOCKS_PASSWORD milter options are no longer supported.

Some complex modifications of the milter spam filter plugin's behavior may be achieved using the MILTER_MACROS mapping table.

Note that when using a Milter, the only relevant spamfilter*N*_*_action options are spamfilter*N*_null_action (which has a proper default value) and spamfilter*N*_string_action; the spamfilter*N*_action_*M* and spamfilter*N*_verdict_*M* MTA options used with other sorts of spam/virus filter packages are *not* relevant with a Milter. And it is essential with Milter to also explicitly set the spamfilter*N*_string_action MTA option (to its special-for-Milters value of data:,$M) as the default value for spamfilter*N*_string_action is not appropriate for Milter use.

58.5 SpamAssassin spamfilterN_config_file

When using SpamAssassin, a `spamfilterN_config_file` MTA option might be set as

```
msconfig> set mta.spamfilter1_config_file IMTA_TABLE:spamassassin.dat
```

With SpamAssassin (supported as of MS 6.1), the file that this option names may contain the following options:

- DEBUG (0 or 1 up through MS 6.2; in MS 6.3, value is an integer and currently values of 0, 1, or 2 have meaning), default 0.
- MESSAGE_BUFFER_SIZE (integer), default 100000. New in MS 6.2. Specifies the maximum message size; larger messages will be truncated.
- HOST (hostname or IP address). A value must be specified for this option (its presence is required).
- PORT (integer), default 783.
- USE_CHECK (integer), default 1. If set to 1, use the spamd CHECK command rather than SYMBOLS command
- (New in 8.0) CONNECT_TIMEOUT (integer), defaults to the TIMEOUT option's value if TIMEOUT is greater than 0; if TIMEOUT is 0, then CONNECT_TIMEOUT defaults to 120. Attempting to set CONNECT_TIMEOUT to a non-positive value will result in a value of 60 being used. This option specifies the time, in seconds, that the MTA will wait to connect to SpamAssassin.
- (New in 6.2p5 and 6.3.) TIMEOUT (integer), default 3600 (seconds). This option controls how long the MTA will wait for a response from SpamAssassin. (Prior to MS 6.3 the timeout was hard-coded as 3600 seconds.) Note that the timeout for an initial connection to SpamAssassin is not controlled by this option, but rather is a setting for the TCP stack; this option instead controls the timeout for the MTA in getting back responses after the initial connection is established.
- SOCKS_HOST
- SOCKS_PORT (integer), default 1080.
- SOCKS_USERNAME
- SOCKS_PASSWORD
- MODE default 0. (Values 0, 1, 2, and (new in MS 6.2p1) 3 are supported.)
- FIELD default "Spam-Test".
- VERDICT
- USE_CHECK (0 or 1), default 1.
- USERNAME
- (New in MS 6.3p1.) USERNAME_MAPPING. This option is used to specify the name of a mapping table to probe with address information as the plugin receives recipient addresses from the MTA, to potentially override the USERNAME option's value. The probe format is:

current-username|*current-recipient-address*|*current-optin-string*

- Both the *current-optin-string* and the preceeding vertical bar are omitted if no optin value was specified. If the mapping sets the $Y flag, then the output string is taken to be the updated username (overriding the USERNAME SpamAssassin option value) to pass to spamd.

For instance, with SpamAssassin configured as spam/virus filter package number 2, and SpamAssassin option file settings that include

```
MODE=2
FIELD=
```

and a setting that does an "addheader" action, such as

```
msconfig> set spamfilter2_string_action 'data:,addheader "Spam-test: $U";'
msconfig# show spamfilter2_string_action
role.mta.spamfilter2_string_action = data:,addheader "Spam-test: $U";
```

or in legacy configuration:

```
SPAMFILTER2_STRING_ACTION1=data:,addheader "Spam-test: $U"
```

could result in the addition of header lines such as:

```
Spam-test: False ; 0.1 / 4.5 ; FORGED_RCVD_HELO
Spam-test: True ; 12.9 / 4.5 ; RCVD_HELO_IP_MISMATCH,RCVD_IN_BL_SPAMCOP_NET,
 RCVD_IN_XBL,RCVD_NUMERIC_HELO,URIBL_OB_SURBL,URIBL_SC_SURBL,URIBL_WS_SURBL
```

58.6 Archive spamfilterN_config_file

As of MS 6.3, the MTA supports archiving as a plug-in, similar to spam/virus filter package plug-ins. When using AXS:one, it.com, or Microsoft® Exchange Journal archiving, a spamfilter*N*_config_file MTA option might be set as

```
msconfig> set mta.spamfilter7_config_file IMTA_TABLE:archive.dat
```

With AXS:One, it.com or Microsoft Exchange Journal format use, the following options are available; see MTA configuration for AXS:One archiving for further discussion.

- DEBUG (integer; default 0)
- RESETDEBUG (integer; default 0). (New in 8.0.) Enables or disables debug output on a per-transaction basis. If RESETDEBUG is nonzero, then channel debugging controls archiving debugging: If channel debugging is enabled, then the RESETDEBUG value becomes the debug level for the archiver; if channel debugging is disabled, then archiving debugging is disabled.
- STYLE (1-3; required). (Value 2 new in Messaging Server 7.0u1, value 3 new in 8.0.1.) The default value, 1, specifies AXS:One archiving. A value of 2 specifies it.com archiving and a value of 3 specified Microsoft Exchange Journal format archiving.

- DIRECTORY (string; no default). This option is required for AXS:One and it.com archives and is not used for Microsoft Exchange Journal format archiving. It specifies the directory where archive files are supposed to be written. In the case of it.com archives, `strftime` substitutions can be used to insert date and time information into the directory name.
- DESTINATION (string; no default; Microsoft Exchange Journal format only). If set, this option specifies the address where Exchange Journal format archive messages are to be sent. If the option is not set archive messages are sent to the various capture attributes associated with the message's authorized sender, envelope from, and envelope recipient addresses.
- SOURCE_CHANNEL (channel name; no default; required for Microsoft Exchange Journal format only). The SOURCE_CHANNEL option specifies the name of the channel used to submit Microsoft Exchange Journal format messages. It is recommended that a separate channel be created for this purpose so that such submissions are clearly identifiable in the logs.
- MODE (integer; default 8%660). Sets the file creation mode used on all archive files that are created for AXS:One or it.com archives. Note that mode values can be written in the customary octal form by prefixing the value with "8%".
- SUBDIRS (integer; default 0). Specify how many subdirectories to use for AXS:One or it.com archives. Only values between 0 and 1000 will be used; attempting to set a value outside that range will result in 0 (no subdirectories) being used.
- REVERSE (0 or 1; default 1; AXS:One only).
- USEHEADERRECIPIENTS (0 or 1; default 0; AXS:One only). (New in MS 7.0.5).
- TRUSTEXISTINGHASH (0 or 1; default 0; AXS:One only).
- IDSUFFIX (string; default ""; AXS:One only). This option specifies a suffix to all MessageID fields generated in the AXS:One format. The default is the empty string. This option should be set to "-0100MD500" when running in operational mode and to "-0000MD500" when running in compliance mode.
- POSTEDDATEMODE (integer; default 100; AXS:One only). (New in Messaging Server 7.0u4). A value of 0 means to use the date/time from the Date: header field. The default value of 100 means to use an appropriate time, depending upon whether this is compliance *vs.* operational archiving: for compliance mode, use the start time of the archiving operation, whereas for operational mode, use the message's internal date. Any other value for POSTEDDATEMODE means to use a Received: header date/time.

58.7 Sieve spamfilterN_config_file

As of MS 8.0.2, the MTA provides a simple spamfilter plugin, libsieve.so, that can be used to execute a fixed Sieve script at a particular point in the spam filter evaluation/interpretation process. The primary purpose of this plugin is for testing, but it can be used in production environments to execute a "fixup" script between two other spam filters.

The configuration file for this plugin consists of zero or more options, zero or more blank lines, and then the actual Sieve script. The following options are available:

- DEBUG (integer; default 0)
- RESETDEBUG (integer; default 0). Enables or disables debug output on a per-transaction basis. If RESETDEBUG is nonzero, then channel debugging controls archiving debugging:

If channel debugging is enabled, then the RESETDEBUG value becomes the debug level for the Sieve plugin; if channel debugging is disabled, then debugging is disabled.

58.8 Spamfilter early verdicts

Most spam/virus filter plugins base their decisions on message content. (SpamAssassin in particular acts solely based upon the message content it receives---though it attempts to make some assumptions about the message envelope based on material in the message itself.) However, as of Messaging Server 7.0 the MTA supports allowing spam/virus filters packages to return a so-called "early verdict", based upon the source IP address alone (as for instance in cases where the incoming connection is from a source IP that the spam/virus filter package considers to be a known spam source). Currently only the Brightmail and milter plugins are capable of returning such an early verdict. Early verdicts must be explicitly enabled in Brightmail; in milter, an early verdict corresponds to a message reject action taken at the SMFIC_CONNECT phase.

If the spam filter plugin is activated based on the source channel or the envelope from address, any early verdict checks are done at the start (MAIL FROM) of the SMTP transaction. However, if the spam filter plugin is activated based on destination channel or the recipient address, the check won't happen until that recipient address is communicated (RCPT TO). But in either case the rejection only occurs after the SMTP connection has been accepted by the Dispatcher and passed to the SMTP server.

In some cases it is preferable to have such checks done from the Dispatcher so that the connection itself can be refused. A mapping callout routine, `mm_check_reputation`, is therefore provided so this can be done from the `PORT_ACCESS` mapping. The callout accepts two arguments separated by a vertical bar: (1) the slot number of the spam filter plugin to use, and (2) the IP address to check. The callout succeeds if an early verdict is returned.

An example of directly using Brightmail's "early verdict string" (without any additional MTA text, as would normally be added) is:

```
PORT_ACCESS

   *|*|*|*      $:A$[IMTA_LIB:libimta.so,mm_check_reputation,1|$1]$N
```

The `$:A` is used in this example to make sure this check is only done from the Dispatcher, and not the SMTP server. (In contrast, `$:S` would be used to ensure that the check would be done only from the SMTP server and not from the Dispatcher.)

58.9 Milter implementation

The milter interface negotiates supports for various capabilities and actions. A given milter has the option of requiring a capability or action, optionally using a capability or action, or ignoring it entirely. This section documents what capabilities and actions are supported by Messaging Server as well as when support was first introduced.

The status of support for milter capabilities is:

Table 58.2 Milter capabilities

Capability	Description	Support Added

SMFIP_NOCONNECT	Skip SMFIC_CONNECT	6.3
SMFIP_NOHELO	Skip SMFIC_HELO	6.3
SMFIP_NOMAIL	Skip SMFIC_MAIL	6.3
SMFIP_NORCPT	Skip SMFIC_RCPT	6.3
SMFIP_NOBODY	Skip SMFIC_BODY	6.3
SMFIP_NOHDRS	Skip SMFIC_HEADER	6.3
SMFIP_NOEOH	Skip SMFIC_EOH	6.3
SMFIP_NR_HDR	Skip SMFIC_HEADER responses	7u4
SMFIP_NOUNKNOWN	Skip unknown commands	8.0
SMFIP_NODATA	Skip SMFIC_DATA	8.0
SMFIP_SKIP	MTA understands SMFIS_SKIP	7u4
SMFIP_RCPT_REJ	MTA should also send rejected RCPTs	8.0
SMFIP_NR_CONN	No reply for connect	8.0
SMFIP_NR_HELO	No reply for HELO	8.0
SMFIP_NR_MAIL	No reply for MAIL	8.0
SMFIP_NR_RCPT	No reply for RCPT	8.0
SMFIP_NR_DATA	No reply for DATA	8.0
SMFIP_NR_UNKN	No reply for UNKN	8.0
SMFIP_NR_EOH	No reply for end of header	8.0
SMFIP_NR_BODY	No reply for body chunk	8.0
SMFIP_HDR_LEADSPC	Header value leading space	8.0

The status of support for milter actions is:

Table 58.3 Milter actions

Action	Description	Support Added
SMFIF_ADDHDRS	Add headers	6.3
SMFIF_CHGBODY	Change body chunks	6.3
SMFIF_ADDRCPT	Add recipients	6.3
SMFIF_DELRCPT	Remove recipients	6.3
SMFIF_CHGHDRS	Change or delete headers	6.3
SMFIF_QUARANTINE	Quarantine message	6.3
SMFIF_CHGFROM	Filter may change from	8.0
SMFIF_ADDRCPT_PAR	Add recipients including args	unsupported
SMFIF_SETSYMLIST	Can send set of wanted macros	unsupported
SMFIF_SPECRCPT	Support per-recipient modification actions	7.0.5.33

The macros provided by the milter interface are:

Table 58.4 Available milter macros

Name	Protocol Phase	Content
${auth_authen}	MAIL FROM	Authenticated sender address.
${auth_author}	MAIL FROM	The value of the AUTH parameter to MAIL FROM. Added in 8.0.
${client_addr}	CONNECT	The IP address of the SMTP client, expressed as a dotted quad value. Only set when SMTP over TCP is being used.
${destination_channel}	RCPT TO	MTA destination channel for the current recipient.
$i	MAIL FROM	Queue id for the current message. The MTA generates a unique id for each session; this id is what appears in the $i macro.
$j	CONNECT	Text placed in the "by" clause of Received: header fields. This is controlled by the `received_domain` MTA option. If the option is not set, the official host on the local channel is used instead.
${mail_addr}	MAIL FROM	The MAIL FROM address for the current transaction.
${mail_host}	MAIL FROM	The host part of the MAIL FROM address for the current transaction.
${optin}	RCPT TO	Spamfilter optin value for the current RCPT TO adress.
${rcpt_addr}	RCPT TO	Current RCPT TO address.
${rcpt_host}	RCPT TO	The host part of the current RCPT TO address.
${rcpt_mailer}	RCPT TO	Set to "local" for valid recipient addresses, "error" for invalid addresses. New in 8.0.
${source_channel}	MAIL FROM	MTA source channel.

The MTA's milter macros support can be extended/modified using the `MILTER_MACROS` mapping table.

The smfi_insheader modification action associated with the SMFIF_ADDHDRS action flag specifies an index into the header where the field is to be inserted. Such semantics are not provided by Sieve; indeed, the smfi_insheader documentation itself notes that indices are not reliable. Prior to the 8.0 release, smfi_insheader was implemented by using a plain Sieve "`addheader`" for an index of 0 and "`addheader :last`" for a nonzero index. However, some milters, notably OpenDKIM, have been observed using an index value of 1 in an attempt to insert a field above the Received: field added by sendmail. Accordingly, a new milter spamfilter option, `MAX_PREPEND_INDEX`, has been added to deal with this and similar situations. `MAX_PREPEND_INDEX` specifies the smallest index value that can be passed to smfi_insheader by the milter server and cause the resulting header field to be inserted at the top of the header block rather than the bottom. The default value is 1.

The libmilter provided by sendmail 8.14 now supports milter session reuse for multiple SMTP sessions or transactions. Unfortunately this support does not appear to be negotiated, making

it necessary to have an option to enable it in addition to various options to control its use. Accordingly, several new options have been added to the milter spamfilter option file:

- `USE_QUIT_NC` (boolean, default 0) - Enable use of the QUIT_NC milter command so sessions can be reused. This should only be set when the version of libmilter is recent enough to support the feature. (Sendmail 8.14 or later.)
- `SESSION_INACTIVITY_TIMEOUT` (integer, default 180) - Time in session a session is allowed to remain idle and still be a candidate for reuse.
- `TRANSACTIONS_PER_SESSION` (integer, default 100) - Number of transactions allowed in a single session.
- `SESSION_TIME` (integer, default 3600) - Maximum time, in seconds, that a single session can be used.

As of the 8.0 release, proper remote port information is transferred through the smfi_connect callback.

Finally, support for milter connections via Socks has been removed, so the `SOCKS_HOST`, `SOCKS_PORT`, `SOCKS_USERNAME`, and `SOCKS_PASSWORD` milter options are no longer supported in 8.0 and later versions.

Most spam/virus filter packages return package-specific so-called "verdict strings", which the MTA is configured to interpret as desired (Sieve actions), with the correspondence controlled via pairs of MTA options `spamfilter`*`N`*`_verdict_`*`M`* and `spamfilter`*`N`*`_action_`*`M`*. However, milter normally returns an actual Sieve scriptlet, which should be used verbatim. So the usual pairs of verdict/action MTA options are *not* used in the MTA's configuration for milter integration; instead, only the `spamfilter`*`N`*`_null_action` and `spamfilter`*`N`*`_string_action` MTA options are relevant for the MTA's milter configuration.

The default value for `spamfilter`*`N`*`_null_action`, namely `data:,discard;`, is proper for use with milter, as if milter returns no verdict then the meaning is that the message should be discarded. To have milter's Sieve scriptlets used when milter *does* return a verdict, the `spamfilter`*`N`*`_string_action` option *must* be set to *exactly*:

```
data:,$M
```

So for instance:

```
msconfig> show spamfilter3_*
role.mta.spamfilter3_config_file = /opt/sun/comms/messaging64/config/miltertest.dat
role.mta.spamfilter3_library = /opt/sun/comms/messaging64/lib/libmilter.so
msconfig> show -default spamfilter3_null_action
role.mta.spamfilter3: data:,discard
msconfig> set spamfilter3_string_action "data:,$M"
```

This setting of `spamfilter3_string_action` above is using the `$M` substitution (see the discussion of such substitutions in the discussion of the `spamfilter1_action_0` MTA option) which means to use the detailed verdict string provided by the milter directly as a Sieve scriptlet (and triggers special handling to allow proper handling of extra "long" returned verdicts, such as a milter-returned entire Sieve scriptlet).

58.9.1 MILTER_ACTIONS mapping table

As of MS 8.0.2, the MILTER_ACTIONS can be used to augment or modify the behavior various milter actions. The basic probe format for this mapping is:

tag|number|action

which may then be followed by zero or more additional arguments depending on the action. The basic arguments are:

tag — A tag value which is passed between successive calls to the MILTER_ACTION mapping. The tag value is initially empty.

number — The number of the spam filter slot of the milter issuing the action.

action — The milter action that invoked the mapping.

At present the following milter actions call the MILTER_ACTIONS mapping:

Table 58.5 MILTER_ACTIONS mapping actions and arguments

Action	Additional Argument #1
ACCEPT	
DISCARD	
REJECT	
TEMPFAIL	
REPLYCODE	Milter supplied error message
INSHEADER	Header index, Header name, Header value
ADDHEADER	Header name, Header value

ADDHEADER and INSHEADER support was added in MS 8.0.2.3.

The mapping result consists of metacharacters as well as a series of result strings separated by vertical bars. These strings are consumed by the various metacharacters in the order given below.

$A	Force the action action to ACCEPT.
$T	Set the milter tag to the specified string.
$+^	Disable processing of subsequent spam filters. The specified string consists of a comma-separated list of spam filter index numbers. The specified filters with index values greater than the current filter are shut down and any results they have produced are discarded.
$M (REJECT, TEMPFAIL, and REPLYCODE actions)	Override the error message with the specified string.
$M (ADDHEADER action)	Override header name and/or value. One or two arguments may be supplied separated by a vertical bar. If a single argument is specified it replaces the header value. If two

	arguments are specified the first replaces the header name and the second the header value. If the name is left blank it remain unchanged.
$M (INSHEADER action)	Override header index, name and/or value. One to three arguments may be supplied separated by vertical bars. If a single argument is specified it replaces the header value. If two arguments are specified the first replaces the header name and the second the header value. If three arguments are specified the first specifies a new index, the second a new header name, and the third a new header value. If the name is left blank it remain unchanged.

58.9.2 MILTER_MACROS mapping table

Support for the `MILTER_MACROS` mapping table was added for Messaging Server 7.3-11.01. `MILTER_MACROS` is called by the milter spam filter plugin each time a macro is passed to the milter server. The probe format is:

`spamfilter-index``|`*`command`*`|`*`macro-name`*`|`*`macro-value`*

Here *`spamfilter-index`* is an integer between 1 and 8 specifying the spam filter slot this milter is in, *`command`* is the command this macro precedes, so one of:

- `CONNECT`
- `MAIL`
- `RCPT`

The *`macro-name`* is simply the name of the macro being defined and *`macro-value`* is its value. Note that the `mapping_paranoia` MTA option, if set, will cause any vertical bar characters that would have been in the *`macro-value`* field to be replaced by the specified character.

When the mapping returns, if $N or $F are set then the macro is dropped and never sent to the milter server. (This is also the behavior if $Y or $T is set, but with no additional string returned by the mapping template.)

If none of $N, $F, $Y or $T is set, then the original macro name and value are used, as if the `MILTER_MACROS` mapping table had not applied.

If, however, $Y or $T is set and a string is returned also, then the mapping's string result is processed as a series of macro name/value pairs, each name or value separated by vertical bars. Finally, if $| is set in the mapping template in addition to $Y or $T, then only a single name-value pair is read from the result and the second and subsequent vertical bars are treated as part of the value.

Note that if either the original *`macro-value`*, or a replacement macro value returned as a string along with $Y or $T, includes a vertical bar character, `|`, then regardless of whether `mapping_paranoia` is used, the vertical bar test flag will be set (so that a mapping template may check for the original presence of a vertical bar in the macro name via a `$:|` *vs.* `$;|` test).

58.9.3 Milter single recipient extension

New in 7.0.5.33. Oracle has implemented a milter extension for per-recipient modification actions. This extension can be implemented in libmilter with the following changes:

- Add the following constant and routine declaration to `include/libmilter/mfapi.h`:

```
/* Oracle extension for recipient-specific modification actions */
#define SMFIF_SPECRCPT    0x1000000   // Recipient-specific modification actions

/*
**  Specify a recipient for whom subsequent modification actions
**  apply. Modification actions specified prior to this point will
**  no longer apply to this recipient.
**
**      SMFICTX *ctx; Opaque context structure
**      char *rcpt; Null terminated list of null terminated envelope
**              recipient addresses subsequent actions apply to. These should
**              be in exactly the form passed to xxfi_envrcpt or the address
**              may not be selected for subsequent modification actions.
*/

LIBMILTER_API int smfi_specrcpt __P((SMFICTX *, char *));
```

- Add the following constant to include/libmilter/mfdef.h:

```
/* Oracle extension for recipient-specific modification actions */
#define SMFIR_SPECRCPT          'v'     /* Per-recipient modification actions */
```

- Add the following routine to libmilter/smfi.c:

```
/*
**  SMFI_SPECRCPT -- Recipient-specific result (Oracle extension)
**
**      Parameters:
**              ctx -- Opaque context structure
**              rcpt -- null terminated list of null terminated
**                      recipient addresses
**
**      Returns:
**              MI_SUCCESS/MI_FAILURE
*/

int
smfi_specrcpt(ctx, rcpt)
        SMFICTX *ctx;
        char *rcpt;
{
        size_t len, l;
        struct timeval timeout;
        char *ptr;

        if (rcpt == NULL || *rcpt == '\0')
                return MI_FAILURE;
        if (!mi_sendok(ctx, SMFIF_SPECRCPT))
                return MI_FAILURE;
        timeout.tv_sec = ctx->ctx_timeout;
        timeout.tv_usec = 0;
        len = 0;
        ptr = rcpt;
        do
        {
                len += (l = strlen(ptr) + 1);
```

```
                ptr += l;
        } while (*ptr != '\0');
        return mi_wr_cmd(ctx->ctx_sd, &timeout, SMFIR_SPECRCPT, rcpt, len);
}
```

In terms of the milter protocol, this extension consists of a single additional milter response:

```
**

'v' SMFIR_SPECRCPT Specify recipient subsequent modification actions
   apply to.

char rcpt[][] List of NUL terminated recipients
```

The semantics are straightforward: SMFIR_SPECRCPT specifies a list of message recipients, and subsequent modification actions (SMFIR_ADDHEADER, SMFIR_INSHEADER, SMFIR_CHGHEADER, and SMFIR_QUARANTINE). The modification actions SMFIR_ADDRCPT and SMFIR_DELRCPT may be specified subsequent to an SMFIR_SPECRCPT, but are by nature not recipient-specific. SMFIR_REPLBODY is too expensive to implement on a per-recipient basis; its behavior subsequent to a SMFIR_SPECRCPT is undefined.

Because it's possible this extension may conflict with someone else's private extension, it must be explicitly enabled by setting the `PER_RECIPIENT_ACTIONS` option to 1 in the milter plugin options file.

Since extensive code changes were required to implement this extension, it has not been incorporated into the normal `libmilter.so` library. A new `libmilters.so` library containing the extension has been provided instead.

58.9.4 Milter errors

A number of milter error conditions can get reported to the MTA, which in turn will generate an SMTP error during the SMTP transaction.

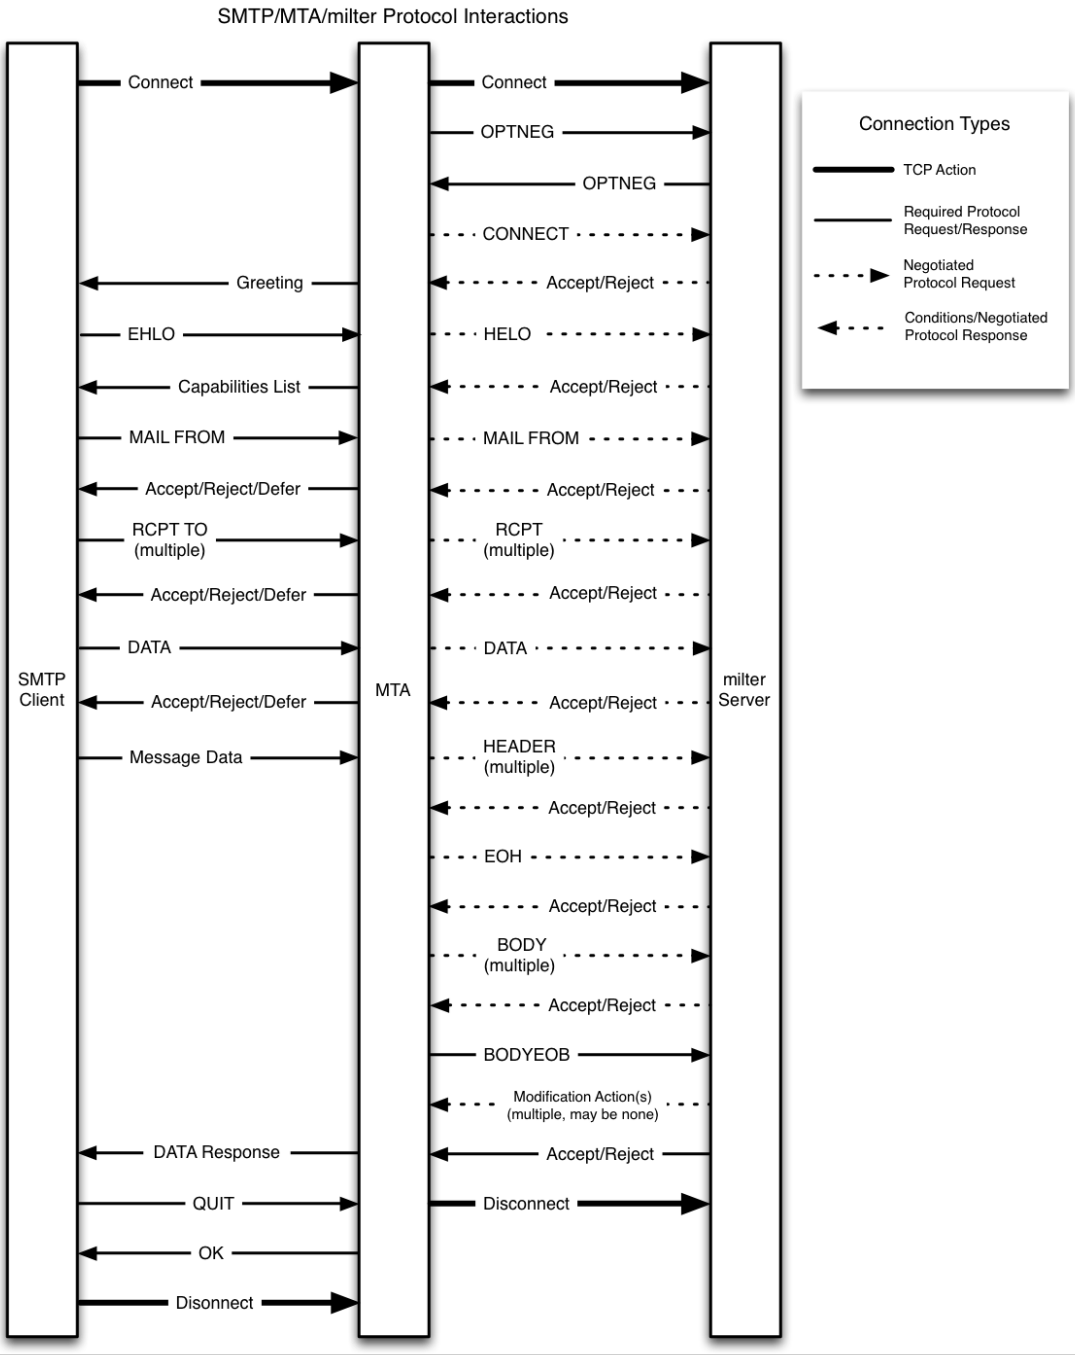
58.10 Milter operation

Milter is implemented as a client-server protocol, with Messaging Server in client role and any of a wide variety of software packages in the server role. Most, but not all, milter servers are written on top of the libmilter library that is provided as part of sendmail.

Unfortunately, the milter protocol provides no authentication, privacy, or integrity protection facilities. As such, it is essential that milter protocol connections be restricted to protected networks, and under no circumstances should they be operated over the open Internet.

The libmilter library is multithreaded and supports a limited amount of threading configuration. Even so, multiple milter servers are often required in large configurations. The Messaging Server milter client does not provide any load balancing capabilities beyond those provided by the DNS (i.e., multiple A/AAAA records), so the use of a load balancer may be required in large, high performance milter configurations.

The milter protocol allows for interaction at every stage of the SMTP protocol. The following diagram illustrates the relationship between a typical SMTP/SUBMIT dialogue and milter protocol commands:



Note that this simplified diagram omits:

- Negotiation of SMTP transport security,
- SUBMIT authentication,
- optional milter macro commands (Macros can precede CONNECT, HELO, MAIL, and RCPT),
- multiple message transfers in the same SMTP/milter session (not used by the MS MTA),

- use of the QUIT_NC command to process multiple connections in the same milter session,
- interactions between multiple milters operating in parallel,
- due to the ability to activate milters based on source or destination channel, milter connect may be deferred to as late as the RCPT TO step in the SMTP diaglogue, and
- if enabled, unknown commands sent by the SMTP will cause the MTA to send UNKNOWN milter commands to the milter server independent of protocol state, and
- PROGRESS responses may be sent by the milter server at any time. These are ignored by the MTA.

The milter Accept/Reject actions are:

- SMFIR_ACCEPT - Accept message unconditionally. No further milter commands or responses will be exchanged.
- SMFIR_CONTINUE - Accept command and continue processing
- SMFIR_DISCARD - Tells the MTA to discard the message. No further milter commands or responses will be exchanged.
- SMFIR_REJECT - In response to a RCPT command, indicates that the recipient should be rejected with a permanent error. In any other context this indicates that the entire message should be rejected with a permanent error and that no further milter commands or responses will be exchanged.
- SMFIR_TEMPFAIL - In response to a RCPT command, indicates that the recipient should be rejected with a temporary error. In any other context this indicates that the entire message should be rejected with a temporary error and that no further milter commands or responses will be exchanged.
- SMFIR_REPLYCODE - In response to a RCPT command, indicates that the recipient should be rejected with the specified error. In any other context this indicates that the entire message should be rejected with the specified error and that no further milter commands or responses will be exchanged.

58.11 imexpire invoking spamfilter packages

New in Messaging Server 7.0.5, the `imexpire` utility has a new `channel` attribute to specify the name of an MTA channel. When this attribute is used, any source channel spam/virus filter package configured on that channel will be applied to each message that is scanned by `imexpire`, and any `spamadjust`, `spamtest`, `virusset`, `virustest`, or added headers will then be visible to the Sieve expression used to expire messages. (Of course, use of Sieve expressions to expire messages must also be enabled via the `expiresieve` Message Store option.)

The MTA options `scan_channel`, `scan_originator`, and `scan_recipient` may be used to establish context (Sieve values) for non-channel evaluations of Sieve filters, such as `imexpire` invocations of spam/virus filter packages, though note that `scan_channel` is not needed for `imexpire`'s spamfilter package invocation case (since in such a case `imexpire`'s `channel` attribute is used to set the MTA channel).

For example, suppose that MTA channel invokes SpamAssassin, which is then configured to perform a `spamadjust` to communicate its results. In this scenario, an expression of the form

```
require ["comparator-i;ascii-numeric", "relational", "spamtest"];
spamtest :value "ge" :comparator "i;ascii-numeric" "5";
```

should expire any message that received a spam score of 5 or more.

The new-in-7.0.5 `rescanhours` attribute is also especially relevant when using `imexpire` to perform post-delivery spam/virus filtering. `rescanhours` tells `imexpire` to rescan those messages that have not been scanned for the specified number of hours.

See the Scheduler's `expire` task for configuration of automatic scheduling of executions of `imexpire`.

Chapter 59 MeterMaid

MeterMaid is a facility that comprises a server, which maintains "tables" of data, and a client side (in particular, the MTA's callouts to MeterMaid via mapping table MeterMaid routine callouts, `metermaid:` URLs encoded into MTA configuration, and (new in Messaging Server 7.2) Sieve "`metermaid`" tests or actions). The MeterMaid server maintains its data in-memory; this offers high performance, but note that it does imply that the MeterMaid data is *not* preserved across MeterMaid (or Messaging Server as a whole) restarts. As multiple processes can communicate with the MeterMaid server over protocol, MeterMaid permits across-process tracking of data. MeterMaid is thus particularly suited for configuring "throttle" effects.

MeterMaid requires configuration of itself -- the MeterMaid server, and some basics of MeterMaid client operation -- configured in Unified Configuration via MeterMaid options and MeterMaid client options, or in legacy configuration via configutil parameters. Once MeterMaid's own operation is established, then configuring the MTA on how to find/communicate with MeterMaid is configured via MeterMaid MTA options. And then any specific MeterMaid uses may be configured into the MTA via mapping table routine callouts, `metermaid:` URLs in appropriate MTA configuration options, or use of Sieve "`metermaid`" tests or actions.

For a number of examples of MeterMaid use in the form of MTA mapping table callouts to MeterMaid routines, see the discussion of Triggering effects from transaction logging with LOG_ACTION.

To find all options potentially relevant to MeterMaid, try doing

```
msconfig> apropos metermaid
```

Note that there are the options relevant for the MeterMaid server, settable under the metermaid group, and there are options relevant for any MeterMaid clients, settable under metermaid_client group; respectively, these correspond to the legacy configuration metermaid.* and metermaid.mtaclient.* configutil parameters. Some options are settable either generally for a named metermaid or metermaid_client group, or settable specifically for a named table under a local_table or remote_table group. (Note that a named remote_table group may only be set under metermaid_client; a named local_table group may only be set under metermaid.)

Then there are also a number of MTA options that override, for MTA purposes, some of the normal metermaid or metermaid_client options. There are also the viametermaid and metermaidtable IMAP options (under the pwexpirealert group), to specify whether to use MeterMaid, and what MeterMaid table to use, for password expiration alerts.

See also the logfile options, as they are settable under metermaid.

59.1 metermaid options

A MeterMaid server is configured via options under the metermaid group. (Named metermaid groups may be used if desired, but usually are not needed, with options relating to general operation of this MeterMaid server being set directly under metermaid.) Then specific MeterMaid tables maintained by this MeterMaid server are configured under named local_table groups under metermaid (metermaid.table.* configutil parameters in legacy configuration). For instance, on a host running a MeterMaid server with default values for most operational settings, and with one table defined, (bad_password_attempts, perhaps similar to the example Syslog notices after SMTP AUTH attempts with bad password discussed under Triggering effects from transaction logging with LOG_ACTION), one might see:

```
msconfig> show metermaid.*
role.metermaid.enable = 1
role.metermaid.local_table:bad_password_attempts.data_type = string
role.metermaid.local_table:bad_password_attempts.max_entries = 1000
role.metermaid.local_table:bad_password_attempts.quota = 2
role.metermaid.local_table:bad_password_attempts.quota_time = 3600
role.metermaid.secret (suppressed)
```

(Note that use of MeterMaid tables by MeterMaid clients, possibly clients on other hosts, would be configured via settings under metermaid_client on the client host, and especially, settings under a named metermaid_client.remote_table group, or in legacy configuration, metermaid.mtaclient.* configutil parameters on the client host.)

logfile options may also be set under metermaid.

59.1.1 enable Option Under metermaid

The enable MeterMaid option enables the MeterMaid service on start-msg startup.

59.1.2 async Option

The async MeterMaid option sets whether MeterMaid should use asynchronous thread scheduling (default) or the new, experimental linear thread scheduling.

59.1.3 backlog Option Under metermaid

The backlog MeterMaid option specifies the number of connections to permit to be established in the TCP listen queue.

59.1.4 listenaddr Option Under metermaid

The listenaddr metermaid option specifies the IPv4 address on which MeterMaid should listen. If unset specifically for MeterMaid, MeterMaid defaults to the base value of listenaddr (service.listenaddr in legacy configuration).

The allowed values for this option include an IPv4 address in dotted decimal form (e.g., 127.0.0.1), or a short form or fully-qualified DNS host name which will be resolved to an IPv4 address by obtaining the DNS A record for the name. To explicitly specify the default value of binding to all available interfaces, the string "INADDR_ANY" may be used. To bind to the loopback device, 127.0.0.1, the string "localhost" may be specified.

59.1.5 local_table

Under a MeterMaid named local_table group, there are a number of options that may be set. *E.g.*,

```
msconfig> show -default metermaid.local_table:table-name.quota
role.metermaid.local_table:table-name.quota: 100
```

59.1.5.1 data_type Option

The data_type MeterMaid local_table option specifies the type of data to be stored in this table: one of ipv4, ipv6, or string.

59.1.5.2 block_time Option

The block_time MeterMaid local_table option specifies an initial period for greylisting during which requests will be blocked. It takes an argument in either the standard ISO 8601 P format, specifying the duration of the period, or a plain integer argument which will be interpreted as a number of seconds for the period.

59.1.5.3 resubmit_time Option

The resubmit_time MeterMaid local_table option specifies the period for greylisting during which a request must be received again in order to be permitted in the future. It takes an argument in either the standard ISO 8601 P format, specifying the duration of the period, or a plain integer argument which will be interpreted as a number of seconds for the period.

59.1.5.4 inactivity_time Option

The inactivity_time MeterMaid local_table option specifies a period for greylisting during which a resubmitted entry will remain 'known' to MeterMaid. It takes an argument in either the standard ISO 8601 P format, specifying the duration of the period, or a plain integer argument which will be interpreted as a number of seconds for the period.

59.1.5.5 max_entries Option

The max_entries MeterMaid local_table option specifies the maximum number of entries to maintain in this table.

59.1.5.6 table_options Option

The table_options MeterMaid local_table option specifies a space-separated list of options for this table. The currently available options are nocase and penalize.

nocase — When working with data, all comparisons are done using a case-insensitive comparison function. (This option is valid only for string data.)

penalize — After quota_time seconds, the throttle will normally reset the connection count to 0, but if the penalize option is enabled, the throttle will decrement the connection count by quota (but not so the value ends up less than 0) so that additional connection attempts will penalize future quota_time periods. For example, if quota were 5 with a quota_time of 60, and the system received 12 connection attempts during the first minute, the first 5 connections would be accepted and the remaining 7 would be declined. After 60 seconds has passed, the number of connections counted against the particular address would be reduced to 7, still keeping it above quota and declining connection attempts. Assuming no additional connection attempts were made, after another 60 second period, the number of connections would be further reduced down to 2, and MeterMaid would permit connection attempts again.

59.1.5.7 quota Option

The quota MeterMaid local_table option specifies the number of connections to permit per quota_time time period.

59.1.5.8 quota_time Option

The quota_time MeterMaid local_table option specifies the period of time to allow quota number of connections. It takes an argument in either the standard ISO 8601 P format, specifying the duration of the period, or a plain integer argument which will be interpreted as a number of seconds for the period.

59.1.5.9 storage Option

The storage MeterMaid local_table option specifies the method of data storage for this table: one of hash or splay.

59.1.5.10 table_type Option

The table_type MeterMaid local_table option specifies the type of table; valid selections include throttle, simple, or greylisting.

59.1.5.11 value_type Option

When using a "simple" table, the value_type MeterMaid local_table option specifies the kind of data used for the values in this table. Currently one may choose between integer or string. For instance:

```
msconfig> show metermaid.local_table.table-name.*
metermaid.local_table.table-name.table_type = simple
metermaid.local_table.table-name.value_type = string
```

59.1.6 maxthreads Option Under metermaid

The maxthreads MeterMaid option specifies the maximum number of work threads.

59.1.7 port Option Under metermaid

The port MeterMaid option specifies the TCP port number on which MeterMaid listens for connections. The default is 63837.

59.1.8 secret Option Under metermaid

The secret MeterMaid option specifies the secret used to authenticate MeterMaid clients with the server.

59.1.9 sslcachesize Option Under metermaid

The sslcachesize MeterMaid option specifies the number of SSL sessions to be cached by the MeterMaid server. If this is set to 0 or not set, this will use a default provided by the Mozilla NSS library which was 10000 last time this was checked (March 2016).

59.1.10 sslusessl Option Under metermaid

Setting the sslusessl MeterMaid option to 1 directs MeterMaid to expect that incoming connections will be SSL-enabled. Enabling this option requires that you also set the corresponding MeterMaid client sslusessl option.

59.2 metermaid_client options

A MeterMaid client can be run on any Messaging Server system to talk to (connect to) a MeterMaid server (which may be running on a different system) maintaining various tables of information. That is, a MeterMaid client is a consumer/updater of information maintained by a MeterMaid server.

In Unified Configuration, any desired options for MeterMaid client operation are set under metermaid_client:

```
msconfig> set metermaid_client.connectfrequency 10
```

Under metermaid_client, two types of named groups are also supported, remote_server and remote_table.

See the MeterMaid topic for further discussion of general MeterMaid operation. And see metermaid options for discussion of MeterMaid server options set under metermaid.

59.2.1 debug Option Under metermaid_client

The debug MeterMaid Client option enables debug output from the MTA client into SMTP log files.

59.2.2 connectfrequency Option Under metermaid_client

The connectfrequency MeterMaid client option, metermaid_client.connectfrequency, specifies that the client should attempt a connection to the MeterMaid server every connectfrequency seconds.

59.2.3 connecttimeout Option Under metermaid_client

The connecttimeout MeterMaid Client option, (metermaid_client.connecttimeout in Unified Configuration or metermaid.mtaclient.connectwait in legacy configuration), specifies how long a thread should wait for a connection to be established to MeterMaid (seconds).

59.2.4 max_conns Option Under metermaid_client

The max_conns MeterMaid client option, metermaid_client.max_conns, specifies how many concurrent connections can be established to MeterMaid from a single process.

59.2.5 server_host Option Under metermaid_client

The server_host MeterMaid Client option, (metermaid_client.server_host in Unified Configuration or metermaid.config.serverhost in legacy configuration), specifies the host or IP address of the MeterMaid server to use.

59.2.6 server_port Option Under metermaid_client

The server_port MeterMaid client option specifies the TCP port to connect to when contacting the MeterMaid server. If this option is not specified but a local MeterMaid server is enabled, then the TCP port listened on by the local MeterMaid will be assumed. If no local MeterMaid server is running, then the default value of 63837 is used.

59.2.7 sslusessl Option Under metermaid_client

Setting the MeterMaid client option sslusessl to 1 directs the metermaid_client to connect to the MeterMaid server using SSL. This option also sets the default for the remote_server's sslusessl option.

Note that if configuring a MeterMaid client to use SSL to connect to a MeterMaid server, that MeterMaid server should also be configured to support SSL use; on the host where that MeterMaid server runs, see its metermaid.sslusessl option.

59.2.8 timeout Option Under metermaid_client

The timeout MeterMaid Client option, (metermaid_client.timeout in Unified Configuration, or metermaid.mtaclient.readwait in legacy configuration), specifies how long in seconds a MeterMaid client will wait for communication with MeterMaid.

59.2.9 remote_server

A `remote_server` named group may be set under `metermaid_client`.

59.2.9.1 `max_conns` Option Under remote_server

The `max_conns` MeterMaid client `remote_server` option, `metermaid_client.remote_server:`*`server-name`*`.max_conns`, specifies how many concurrent connections can be established to the specified remote server from a single process.

59.2.9.2 `server_host` Option Under remote_server

The `server_host` option for a `remote_server` specifies the host or IP address of the remote MeterMaid server to use.

59.2.9.3 `server_port` Option Under remote_server

The `server_port` MeterMaid client `remote_server` option specifies the TCP port to which the `metermaid_client` should connect for this `remote_server`.

59.2.9.4 `sslusessl` Option Under remote_server

Setting `sslusessl` to `1` in a MeterMaid client named `remote_server` group directs the `metermaid_client` to connect to the specified MeterMaid `remote_server` using SSL. Note that the default value for this option is the same as the value specified for the global `metermaid_client.sslusessl` option. If that value is set to `1`, this option will default to `1`.

59.2.10 remote_table

A `remote_table` named group may be set under `metermaid_client`, to name a table maintained by that name on a remote MeterMaid server. New in MS 8.0, the `server_nickname` option may be set under a named `remote_table` group. No further options are currently settable under `remote_table`; table options would instead be set under the `local_table` definition on the remote MeterMaid server.

59.2.10.1 `server_nickname` Option

The `server_nickname` `metermaid_client.remote_table` option specifies the name of the group of `remote_server` entries that define a remote MeterMaid server.

Chapter 60 Notification messages

The defining characteristic of notification messages is that they have an empty envelope From address. Notification message types gives an overview of the different types of notification messages, those generated by the MTA itself, as well as those notification messages generated externally and sent to the MTA.

Since notification messages (mostly) are generated automatically, there are some special aspects to them. Notification message generation timing discusses the timing of generation, and for some types of notification messages the delivery scheduling, for notification messages generated by the MTA. The special case of notification messages generated by the Message Store is briefly discussed in Message Store notifications that a user himself is overquota; see Message Store documentation for further details. The format, and potential language selection and customization options, of those notification messages generated by the MTA are discussed in Notification message format. Special handling of notification messages may sometimes be desirable; Notification message routing discusses the routing of notification messages, and Bounces of spam messages in particular discusses the case of of spam "blow back" notification messages. Notification message logging discusses special features and factors in MTA message transaction log entries relating to notification messages, and Message size limits and notification messages discusses message size limits in relation to notification messages.

60.1 Notification message types

The MTA may generate notification messages itself automatically. These may be Delivery Status Notifications (see RFCs 3461-3464, which are updates to RFCs 1891-1894), such as a notification of a successful message delivery (a so-called "delivery receipt"), or a warning to the original message sender that the delivery of their message has been delayed or has failed. The MTA can also optionally (see the `*warnpost` and `*sendpost` channel options) generate notifications to the postmaster regarding failed and/or delayed message delivery; such a notification to the postmaster is more-or-less a copy of the notification going back to the original message sender. (In particular, note that the postmaster gets a copy in the same language chosen based upon the original sender's language selection.)

Or MTA-generated notification messages may be Message Disposition Notifications (see RFC 3798, which updated RFC 2298) generated due to Sieve filter actions such as `vacation`.

Note that a common case of Message Disposition Notifications is the case of so-called "read receipts", which in Message Disposition Notifications correspond to a disposition of "displayed" (since whether or not a user actually *read* a message is a subjective question for the user, whereas the *display* of a message is something mail user agent software can detect); in any case, such "read receipt" notifications are generated by end user mail clients, *not* by the MTA (which merely relays them as with any other message).

The MTA will also automatically generate notification messages (DSN format messages of "error" type) to report certain sorts of syntax errors. Syntax errors in Sieve filters will be reported to the "responsible" address via a notification message: syntax errors in channel level Sieve filters or the system Sieve filter `systemfilter` (or in legacy configuration, the *CONFIGROOT*`/imta.filter` file, located prior to MS 7.0.5 via the `imta_system_filter_file` MTA Tailor option) will be reported to the postmaster; syntax errors in user Sieve filters will be reported to the individual user to whom the Sieve filter belongs; syntax errors in "head of household" (also called "parental control") Sieve filters will be reported to the head of household filter "owner" (see the `ldap_hoh_owner` MTA option).

Similarly, (as of MS 6.1) the MTA will report syntax errors in alias or group definitions (that is, errors of non-existent putatively "local" users in the alias/group membership, or clearly syntactically invalid addresses in the alias/group membership) to the entire alias/group membership. These error reports are in DSN format. Note:

1. There is a critical, fundamental distinction between a mailing list (where errors in list definition as well as problems with list message deliveries get reported *only* to the list "owner" as specified via an `mgrpErrorsTo` attribute overriding the original message envelope From address) *vs.* a group (which has no `mgrpErrorsTo` attribute and hence retains the original message envelope From address). From the MTA point of view, a group is merely a---possibly large -- alias---an "auto-forwarder" in Internet e-mail terms.

2. The group definition syntax errors reported to the entire group membership are not message delivery failures---which in the case of a group would be reported merely to the original message sender---but rather are those syntactic errors in the group definition which are apparent to the MTA at group alias expansion time. (Because a group, when properly used, is a set of aliases for a single person or small, closely related set of people, problems with the group membership definition are considered problems with the alias setup that the rest of the group members should be informed about so that they can fix the definition.)

The MTA will also generate messages that have the form of notification messages (they have an empty envelope From and contain the original message as an encapsulated part, usually perceived as an "attachment") in response to typical forms of *capture* configuration: that is, when a "capture" attribute (see the `ldap_capture` and `ldap_domain_attr_capture` MTA options) is set on a user or domain, or when an explicit Sieve "`capture`" action applies to a message, or when "capture" is triggered via another mechanism such as an address-based `*_ACCESS` mapping table "capture" flag (`$M`). The capture message, having the superficial form of a notification message, will be sent to the address specified to receive the capture copies. Though the form of such capture copies is similar to other sorts of notification messages, the intended purpose is usually quite different, as capture of messages is usually intended either for monitoring (of a user's e-mail) or archiving purposes.

The MTA may also issue SMTP level rejections of attempted message submissions. In such cases, the MTA is not generating the notification *message* itself; in such cases generation of a notification *message* is the responsibility of the SMTP client attempting to send the message. (And the SMTP client may or may not include the MTA's actual SMTP rejection text in the message text that it generates to display or send to the original message sender.)

The Message Store can generate "notifications" that a user is over quota; such quota "notifications" are deposited directly into the Message Store (without passing through the MTA at all); see Message Store notifications that a user himself is overquota.

Also, other non-MTA components of Messaging Server (such as msprobe) may have capabilities for generating alarm messages "from" some form of postmaster address and "to" some form of postmaster address; see the `noticesender` and `noticercpt` Alarm options.

Furthermore, the MTA also processes numerous notification messages generated by systems other than the MTA -- notification messages that arrive in to the MTA just like any other messages.

All of these cases involve different issues, and different configuration choices. Whenever a question about a notification message arises, it is critical to first determine what type of notification message is involved. Note that looking at the **outermost header of the notification message** is the **most important first step** in determining what type of notification message one is dealing with.

60.1.1 Message Store notifications that a user himself is overquota

Notifications to a user that that user himself or herself is overquota are generated by the Message Store (if the `quotanotification` Message Store option is enabled), or generated due to the system administrator using the `imquotacheck` utility to manually generate such notifications; they are not generated by the MTA, and, since such warnings are deposited directly into the store bypassing the MTA, they do not even go through the MTA. (Thus note that the warnings to a local user of that selfsame user being overquota, or near to overquota, are a separate and *very* different case than an MTA-generated notification telling a message sender that his/her message could not be delivered to its intended recipient with the reason for nondelivery happening to be that that intended local recipient was overquota.)

Such warnings to a user that he/she himself/herself has gone overquota, or is near going overquota, are configurable via a number of Message Store `quota*` options (`store.quota*` options in Unified Configuration, corresponding to legacy configuration `store.*quota*` and `local.store.*quota*` configutil parameters), as well as `imquotacheck` features. The handling of quota is a complex subject in itself; please see the *Administration Guide* for much more complete discussion, as the discussion here is simplified and merely attempts to give an (over-simplified) orientation.

The `quotanotification` Message Store option controls whether the Message Store generates quota-related notifications to the user. The reporting of user overquota status normally is triggered by a user's mailbox reaching the threshold specified by the `quotawarn` option (legacy configuration `store.quotawarn` configutil parameter). However, if `quotaoverdraft` is set, (legacy configuration `local.store.quotaoverdraft=on`), then notifications are not generated until the user's mailbox actually exceeds their specified quota. Besides depositing a warning message into a user's mailbox when that user first goes over the quota notification threshold, for users of IMAP clients that support the IMAP ALERT functionality, the warning message will be displayed on the user's client each time the user selects a mailbox. Also, the `quotaexceededmsginterval` Message Store option (in legacy configuration, the configutil parameter `store.quotaexceededmsginterval`) controls the periodic sending of additional overquota warnings if a user remains overquota.

A Messaging Server administrator may also manually trigger generation of a different form of quota warning message via the `imquotacheck` utility.

60.2 Notification message generation timing

Many sorts of notification message the MTA generates immediately whenever the relevant type of event occurs. For instance, if a message suffers a permanent rejection upon a delivery attempt, then the MTA will immediately generate a non-delivery report (often referred to as a "bounce message") to send back to the original message sender. If the MTA is expanding a mailing list (looking up the mailing list name to determine the members of the list) and discovers a clearly invalid member address (*i.e.*, a syntactically invalid address, or an address claiming to be in a local domain that does not in actuality correspond to any configured user/mailbox), then the MTA will immediately generate a non-delivery report regarding that address back to the list owner (list report address). Notifications generated due to a Sieve "`vacation`" or "`capture`" action are generated when such a Sieve filter is evaluated (when an original message that triggers the Sieve "`vacation`" or "`capture`" action is processed). Similarly, notifications warning of a Sieve syntax error are generated whenever the relevant Sieve filter is processed in an attempt to apply it to an incoming original message.

Another trigger for MTA generation of notification messages is postmaster use of the `imsimta return` utility or `imsimta qm` utility's `return` command to explicitly, immediately bounce specified messages.

But notification messages regarding temporary delivery problems, or those reporting a message delivery failure due to finally "timing out" after repeated delivery attempts, are instead generated upon a periodic (configurable) schedule; see the `*notices` channel options for configuration of eligibility for such notifications, and the MTA `return_job`'s scheduling for actual generation of such notifications. Similarly, Message-Store-generated user overquota warnings may be issued periodically; see the `quotaexceededmsginterval` Message Store option (legacy configuration `store.quotaexceededmsginterval` configutil parameter).

The reporting of delayed (or eventually timed-out-and-given-up-on) messages is triggered by the MTA `return_job`, which checks the settings of any `*notices` channel options in order to decide whether it is time to generate a notification message regarding the delayed (or eventually failed due to timing out) message. The MTA `return_job` must thus be scheduled as appropriate for a site's needs in relation to the generation of such notification messages. As of MS 6.0, the Messaging Server Scheduler, `imsched`, is normally used to schedule the running of the MTA's `return_job`. (In previous versions, such scheduling was normally performed by the Job Controller via a PERIODIC_JOB definition---an approach that is now deprecated.) In Unified Configuration, the Scheduler configuration, besides its `enable` option, consists primarily of a `crontab` option setting for each scheduled job. In particular, in Unified Configuration the MTA `return_job` schedule is set via the `schedule.task:return_job.crontab` option setting:

```
msconfig> show task:return_job.crontab
role.schedule.task:return_job.crontab = 30 0 * * * lib/return_job
```

In legacy configuration, the Scheduler configuration is controlled by `configutil` parameters; for the MTA's `return_job`, see in particular the `local.schedule.return_job` parameter, whose default value is

```
30 0 * * * /opt/SUMWmsgsr/lib/return_job
```

This is UNIX crontab format, *i.e.*,

minutes-after-hour hour day-of-month month-of-year day-of-week script

So the normal setting corresponds to the `return_job` being set to run at 30 minutes after midnight every day, (with the asterisks indicating, respectively, every day of the month, every month of the year, every day of the week).

60.3 Notification message format

The MTA generates standard notification messages (DSNs and MDNs) in the formats defined by the respective Internet standards, in particular RFC 3462 and RFC 3464 in the case of DSNs, and RFC 3798 in the case of MDNs. Shown in Example non-delivery DSN is a sample non-delivery DSN with annotations.

Example non-delivery DSN

```
Return-Path: <>                                                    (1)

--Boundary_(ID_7qPwt/LotX5gy1oVEHL7SQ)--
```

1. As with all standard notification messages, the envelope From is empty, as shown/recorded here in the Return-path: header line.

2. By default, notification messages are enqueued to the process channel; but see the `notificationchannel` channel option. Note that the Received: header line below this one---the very "first" (in time) Received: header line---corresponds to the initial enqueue of the notification message from the channel that determined that a notification message was needed to the process channel. (If the initial channel that determined that a notification message was needed had a `notificationchannel` specified other than the process channel, the initial enqueue would instead have been to that alternate `notificationchannel`.) Thus by default (no `notificationchannel` used) this second-from-the-bottom Received: header line, this second-from-oldest Received: header line, on any notification message generated by the Messaging Server MTA, will show the notification message coming from the process channel.

3. Note the "`for` *`recipient`*" clause present in this Received: header line. That such a clause is present shows that at this point in time, the message had only one recipient, and that the (default) `receivedfor` channel option was in effect. Note that the fact that there was only one recipient for the message at that point (initial enqueue to the process channel), indicates that the postmaster was not being copied on this notification: that one of `nosendpost` or `errsendpost` was in effect.

4. By default, the MTA-wide postmaster address is used in the From: header line for notifications; see the `return_address` and `return_personal` MTA options.

But override postmaster addresses may be set on a per-channel basis (see the returnaddress and returnpersonal channel options), or on a per-domain basis (see the mailDomainReportAddress attribute, or more precisely, the attribute named by the ldap_domain_attr_report_address MTA option), or on a per-message basis via the FROM_ACCESS mapping table's $(or $) flags.

5. The Subject: field for DSNs has the default text shown in Table of DSN types and their default Subject: field text. The default may be overridden for all types of DSNs using the SUBJECT option in the return_option.opt file, or may be overridden on a per-type-of-DSN basis using the $T flag of the NOTIFICATION_LANGUAGE mapping table.

6. DSNs at the outermost MIME level have type:

```
Content-type: multipart/report; ... report-type=delivery-status
```

7. The MIME header lines for the first message part (the human-readable part) are controlled by the return_prefix.txt file . Which language-specific return_prefix.txt file is used may be controlled by the NOTIFICATION_LANGUAGE mapping table .

8. This line (or optionally multiple lines) of introductory text is also set in the return_prefix.txt file. Normally, return_prefix.txt also includes a %H substitution to cause insertion of (a sample of) the original message headers.

9. The return_header.opt file controls exactly which header lines a %H substitution inserts. The %H substitution itself is located in the language-specific return_prefix.txt file.

10. This line of text is set in the appropriate return_*.txt file , corresponding to the type of DSN being generated: failed, bounced, timedout, delayed, deferred, delivered, read, relayed, expanded, capture, or error. In the case of this sample DSN, this is a "failed" DSN (the original message could not be delivered), so the return_failed.txt file sets the line of text, as well as causing insertion of a list of the message's recipients via a %R substitution.

11. If the relevant return_*.txt file requested it via a %R substitution, then a description of the recipients of the original message (and what happened for each such recipient) will be included. (Note tht the exact form of recipient address reported as "Recipient address:" may be affected by the setting on the source channel -- the channel generating the notification -- of includefinal, suppressfinal, or useintermediate.) Overall, this is intended as a more human-readable version of the information also presented (in standard, machine-readable form) in the second part of the DSN, at (17). In particular, the text labels for each of these fields (*e.g.*, " Recipient address: "---note the two leading spaces as well as the terminal colon and trailing space are considered part of the label) are configurable via the language-specific return_option.opt file (selected via the NOTIFICATION_LANGUAGE mapping table).

12. Optionally, additional, alternate text can be configured per SMTP enhanced status code (*e.g.*, in this example 5.1.1); if such alternate text has been configured in the return_option.opt file corresponding to the enhanced status code being reported, then it would be presented after the "Original address: " (ORIGINAL_ADDRESS) line and before the "Reason: " (REASON) line.

13. If the return_delivery_history MTA option is enabled (the default) and the original message has a history of delivery attempts, then some delivery history, up to the

limit specified by `history_to_return`, will be included here (after the `%R` recipient information), having the format:

```
Delivery attempt history for your mail:

time-stampdelivery-detailtime-stampdelivery-detail

...
```

14. Note that the `return_delayed.txt` file used when generating a delayed delivery warning often includes additional text *after* the `%R` recipient substitution, (and hence *after* any delivery history detail, as discussed in (13)), detailing how much longer the MTA will continue to attempt delivery. For instance, the distributed English language version of `return_delayed.txt` causes inclusion of text:

```
The mail system will continue to try to delivery your message
for an additional N time-units .
```

where `N` is derived from the `notices` final value, and `time-units` is derived from the `return_units` setting.

15. This second part of a DSN is a machine-readable part. Note that unlike the first, human-readable part of a DSN, see (7), the machine-readable part is *not* subject to customization/localization/alternate language selection. This part uses the format and fields specified in RFC 3464 (An Extensible Message Format for Delivery Status Notifications). Because this part is in a precisely specified, machine-readable format, clients or gateways that choose to do so can in principle make choices of their own on how and whether to present this part to users, potentially including performing their own (client or gateway level) translation of the (precisely defined) content of this part.

16. The reporting MTA (the MTA that is generating the notification message) is reported here. Note that this is not necessarily the MTA that rejected the message: as in the case of this example, where the rejection occurred at the SMTP protocol level, with the message being rejected by a remote host, but where the "local" MTA then had responsibility for generating the notification message. Note also that the Received: header lines on the DSN itself---in particular the first (in time, so lowest in the header) Received: header line---also show you what MTA generated the DSN. But whichever place you gather this piece of information from, note that it is a *critical* piece of information: you can only customize the DSNs that *your* system generates!

17. Some additional fields can potentially appear here, including X400-Content-identifier:, Content-identifier:, and UA-content-id:. As of MS 7.0, Arrival-date: and Future-release-request: also may potentially appear.

18. A set of information fields is output for each of the recipients of the original message, describing what happened for that recipient.

19. The exact form of recipient address reported as the "Final-recipient:" may be affected by the setting on the source channel (the channel generating the notification) of `includefinal`, `suppressfinal`, or `useintermediate`.

20. The Return-path: records the envelope From of the original message.

21. The third and final part of the DSN contains the original message (or merely the headers of the original message, if the sender originally set the NOTARY non-return-of-content flag, or if the MTA was obliged to set or perform non-return-of-content due to message size restrictions). The entire header of the original message is included.

The MTA generates "autoreply" or "vacation" messages, whether requested due to the use of `mailAutoReply*` attributes in a user's LDAP entry, or requested due to explicit use of the "`vacation`" action in a user's Sieve filter, as a form of notification message also. Such "vacation" messages may optionally be generated either in standard MDN format, or (for the benefit of recipients whose user agents lack good handling for standard MDN messages) as more "simple" messages consisting of a single text part. (Standard MDN format for a "vacation" message is requested by use of `mailAutoReplyMode: echo` in the user's LDAP entry, or use of the `:echo` argument to a `vacation` action in the user's Sieve script. The "simple" form of "vacation" message is requested by use of `mailAutoReplyMode: reply` in the user's LDAP entry, or use of the `:reply` argument to a `vacation` action in the user's Sieve script.)

Selective choice of language used in, and customization of the contents of, notification messages is possible, as discussed in DSN language and customization and MDN language and customization below. But keep in mind that any such language usage and customization must be within the guidelines of the overall notification message format, which in many cases is prescribed by the above-mentioned Internet standards.

60.3.1 DSN language and customization

As mentioned in the discussion of the sample DSN of Example non-delivery DSN, there are a number of localizable, customizable files consulted when constructing DSNs; these files will be discussed further in Customizing DSNs via the return files. By default, if no `NOTIFICATION_LANGUAGE` mapping table is configured, the `return_*.*` files located in the IMTA_LANG: directory will be used to generate all DSNs. However, separate sets of `return_*.*` files can be created and located in separate directories---for localization or site customization purposes. Indeed, the MTA is distributed with several sets of language-specific `return_*.*` files, and a basic `NOTIFICATION_LANGUAGE` mapping table (referenced in the mappings file via file inclusion of the `mappings.locale` file) which selects among the language-specific directories based on language preference of original message senders. That is, the `NOTIFICATION_LANGUAGE` mapping table selects, based on any language preference of the original message sender, a directory in which to find an appropriate set of `return_*.*` files for generating a DSN back to that sender.

Probes to the `NOTIFICATION_LANGUAGE` mapping table have the form:

`dsn-type|source-channel|accept-language|return-address|1st-recipient`

In the probe, `dsn-type` can be a comma-separated list including any of `failed`, `bounced`, `timedout`, `delayed`, `deferred`, `delivered`, `read`, `relayed`, `expanded`, `capture`, `error`, or (as of MS 7.0u2) `journal`. The `accept-language` field will have any values (possibly a comma-separated list) found on (preferentially) an Accept-Language: header line in the original message (the message that the DSN will be reporting on), or if that header line is not present then from a Preferred-language: header line if present, or failing that an X-Accept-Language: header line. Note that valid language tag values are discussed in RFC 3066 (Tags for the Identification of Languages).

The pattern (right hand side) of a `NOTIFICATION_LANGUAGE` entry may set the `$I` flag to specify the directory (or as of MS 7.0 update 3, a list of comma-separated directories) from which the MTA should use `return_*.*` files when constructing a DSN. It may also

optionally set the $T flag to set an override Subject: header field value to use in the DSN. Note that the default Subject: field values for the various types of DSNs are shown in Table of DSN types and their default Subject: field text. When both flags are set, the directory argument should be first (left-most), separated by a vertical bar character from the Subject: header field.

Note: If using NOTIFICATION_LANGUAGE to select an alternate directory of return_*.txt regardless of DSN type, then it is important to have a *complete* set of return_*.txt files present in the specified directory. If the MTA cannot locate a return_*.txt file of the appropriate type in the directory in which the MTA has been told to find such files, then the DSN will be constructed omitting that part of the usual structure and the resulting DSN will therefore look "odd" or "incomplete".

Note: When the MTA has been configured to send copies of notifications to the postmaster (see for instance the sendpost and warnpost channel options), those postmaster copies of the notification message back to the original sender are copies of the text sent back to the original sender, and in particular are in the language selected for the original sender. The postmaster's own personal language preferences, if any, are not relevant to these copies; the purpose of these copies being to be a *copy* of what the original sender was sent.

60.3.1.1 Customizing DSNs via the return_*.* files

When the MTA needs to construct a notification message, the MTA will consult the NOTIFICATION_LANGUAGE mapping table to find a language-appropriate set of return_*.* files. The MTA will then use that set of return_*.* files to construct the notification message. The return_header.opt file and (optional) return_option.opt file are modifier files, potentially affecting the spectrum of notification messages. The return_*.txt files, in contrast, are template files for the different types of notification messages. Each such return_*.txt file is used nearly verbatim for its particular type(s) of notification messages, with possible substitutions as specified via % substitutions. (The notary_quote MTA option controls this meaning of the percent character, %, in notification message template files.) Note that in order to specify inserting a literal percent character in a return_*.txt file, the percent character must itself be quoted with another percent character, %%.

60.3.1.1.1 The sample header lines in DSNs: the return_header.opt file

The purpose of the return_header.opt file is to specify which message header lines to include to identify a message in the human-readable first part of DSNs. Typically it is desired to return only a few of the possible header lines a message might contain, only those most significant to the original message sender.

Prior to MS 7.0 update 2, the return_header.opt file was not language-specific: it always resided and was found in the IMTA_LANG: directory. All the other return_*.* files may be language-specific, as the directory in which to locate them may be varied using the NOTIFICATION_LANGUAGE mapping table. As of MS 7.0 update 2, the MTA will first look for a language-specific return_header.opt in the directory (or as of MS 7.0 update 3, list of directories) selected via $I in the NOTIFICATION_LANGUAGE or DISPOSITION_LANGUAGE mapping table, as relevant; but if the MTA does not find a language-specific such file, then it will fall back to looking in the LANGDIR directory instead. (As of MS 7.0, the former IMTA_LANG Tailor file option is deprecated and replaced by the langdir MTA option as far as locating on disk where files are located. But IMTA_LANG may still be used in, for instance, mapping tables: the MTA will translate occurrences of IMTA_LANG to the location specified by the langdir MTA option.)

As a concrete example, the return_header.opt file installed in the IMTA_LANG: directory is shown here. The settings shown here mean that the %H substitution typically used in the

return_prefix.txt file will cause insertion of solely the Message-Id:, Date:, From:, To:, and Subject: header lines of the original message into the first, human-readable portion of the DSN messages constructed by the MTA; all other header lines from the original message will be omitted. See the imsimta test -header utility for an example of application of this header trimming to a set of headers. (Note that the notary_decode MTA option controls any decoding and/or character set conversion of any MIME encoded non-US-ASCII material in such substituted header lines.)

Sample distributed return_header.opt file

```
Message-Id: PRECEDENCE=3
Date: PRECEDENCE=4
From: PRECEDENCE=5
To: PRECEDENCE=6
Subject: PRECEDENCE=7
Others: MAXIMUM=-1
Defaults: MAXIMUM=-1
```

60.3.1.1.2 The required full set of DSN type-specific return_*.txt files

Within a language-specific directory as selected via the NOTIFICATION_LANGUAGE mapping table, each type of DSN should have its own return_dsn-type.txt file, to be used in constructing the text in the human-readable first part of the DSN, where the dsn-type in the file name is also the value in the NOTIFICATION_LANGUAGE probe. Each type of DSN also has a default Subject: header field value, shown in Table of DSN types and their default Subject: field text, though these values may be overridden either via the NOTIFICATION_LANGUAGE mapping table as described in DSN language and customization or via the SUBJECT option in the return_option.opt file. Table of DSN types and their default Subject: field text lists the usage of each of these return_dsn-type.txt files.

Table 60.1 DSN types and their default Subject: field text

Type of DSN	Subject: field default text[2]	Usage
capture	Message Capture Copy	Used for the "capture" copy of a message captured due to Sieve script or LDAP attribute capture
bounced (security)	Delivery Notification: Potential security problem found	
bounced (manual)	Delivery Notification: Delivery has been manually aborted	The message was manually returned due to the postmaster using a utility such as imsimta return or the imsimta qm utility's return command to bounce the message; this is one case of "R" MTA message transaction log entries
timedout	Delivery Notification: Delivery has timed out and failed	Used when generating a bounce message due to a message exceeding the final notices value; this is one case of "R" MTA message transaction log entries
failed	Delivery Notification: Delivery has failed	Recipient encountered a permanent delivery failure (a rejection); this is one case of "R" MTA message transaction log entries

deferred	Delivery Notification: Delivery has been deferred	Used when a notification is generated that a message that had a "Deliver on first try" notification request set encountered a temporary failure on that first attempt
delayed	Delivery Notification: Delivery has been delayed	Used when a warning notification is generated for a message that remains in the MTA's queues as yet undelivered: that is, this is the text used for warning messages generated at the non-final `notices` values, so corresponding to "W" MTA message transaction log entries
delivered	Delivery Notification: Delivery has been successful	Used when generating a delivery receipt for a message that had a NOTARY delivery receipt request
relayed	Delivery Notification: Message successfully relayed	Used when a message that had a NOTARY delivery receipt request is relayed onward to a host that does not support NOTARY
expanded	Delivery Notification: Mailing list successfully expanded	Used when an address that had a delivery receipt notification request is expanded into a mailing list; per NOTARY rules, such expansion is considered to be a successful "delivery" of the message (and the delivery receipt request does not get propagated/ carried through to the message copies addressed to actual list members)
error	Problem during delivery processing	Used, for instance, for error reports to a Sieve "owner" regarding Sieve syntax problems
journal[1]	Message Journal Copy	Used in messages captured with the Sieve `capture` action's `:journal` parameter

[1] New in MS 7.0u2.

[2] The Subject: field value can be overridden by setting a single value to be used for *all* DSNs via the SUBJECT option of `return_option.opt`. Alternatively, a more complex approach is to use the `$T` flag in the `NOTIFICATION_LANGUAGE` mapping table to set Subject: field values.

As a concrete example, the distributed English language set of `return_*.txt` files will be presented here. The prefix, bounced, capture, deferred, delayed, delivered, error, failed, forwarded, timedout, and suffix files are the ones normally found in the directory located via the `langdir` MTA option, typically `IMTA_TABLE:locale/C`. The MTA is also distributed with sets of `return_*.txt` files in other, language-specific directories under `IMTA_ROOT:lib/locale`. Note that regardless of what language is a site's own "preferred" language, notifications may be generated by the MTA in other languages, using the `return_*.txt` files from other language-specific directories, according to any expressed language preference of the *original* message sender (who will receive the DSN). That is, it is not a site's own language preference, but rather the language preference of the DSN recipient -- who is possibly a remote user---that matters most when it comes to DSN language!

Sample English language `return_prefix.txt` file

```
Content-type: text/plain; charset=us-ascii
Content-language: en-US

This report relates to a message you sent with the following header fields:
%H
```

Sample English language `return_bounced.txt` file

```
Your message is being returned.  It was forced to return by the postmaster.

The recipient list for this message was:
%R
```

Sample English language `return_capture.txt` file

```
Attached message captured in accordance with site policy.
```

Sample English language `return_deferred.txt` file

```
This system has been unable to deliver your message to the
following recipients:
%R
```

Sample English language `return_delayed.txt` file

```
Your message has been enqueued and undeliverable for %C %u%s
to the following recipients:
%R

The mail system will continue to try to deliver your message
for an additional %L %u%s.
```

Sample English language `return_delivered.txt` file

```
Your message has been successfully delivered to the following recipients:
%R
```

Sample English language `return_error.txt` file

```
Processing errors occurred during delivery:
%R

Delivery processing continued in spite of these errors.
```

Sample English language `return_failed.txt` file

```
Your message cannot be delivered to the following recipients:
%R
```

Sample English language `return_forwarded.txt` file

```
Your message has been successfully relayed to the recipients
%R

on a remote system that does not support the generation of successful
delivery receipts.  This does NOT mean that your message has actually been
placed in the recipients' mailboxes; merely that it has passed through a
part of the message transport infrastructure. In the event of a nondelivery
you should expect to receive a nondelivery notification; in the event of
successful delivery, however, you are unlikely to receive a positive
confirmation of delivery.
```

Sample English language `return_timedout.txt` file

```
Your message is being returned; it has been enqueued and undeliverable for
%C %u%s to the following recipients:
%R
```

Sample English language `return_suffix.txt` file - normally empty

```

```

(Note: the `return_suffix.txt` file is typically empty.)

60.3.1.1.3 The optional `return_option.opt` file

The `return_option.opt` file is the one optional file among the `return_*.*` files; it need not exist, as in its absence, a reasonable set of (English language) default values will be used. (Indeed, the English language defaulting for the text controlled by this file is actually a bit more sophisticated than the handling available via the options in the file.) However, while (unlike the other `return_*.*` files) its existence is not *required*, it is normally desirable to have such a file in non-English, language-specific directories. The options available for `return_option.opt` are listed below. Note that it is critical that any charset parameter setting in the `return_prefix.txt` file be coordinated with the values used (the representation of text used) in `return_option.opt` option values: the charset must match (except for SUBJECT which, if non-US-ASCII characters are to be presented, must be specified as an already RFC 2047 encoded value).

60.3.1.1.3.1 DAY (string), HOUR (string)

Specify the text string to use for %U and %u substitutions. When the MTA option `return_units=0` (units of days) is set, the string specified for DAY will be used; when the

MTA option `return_units=1` (units of hours) is set, the string specified for HOUR will be used. So for instance, in a French language version of `return_option.opt`:

```
DAY=jour
HOUR=heure
```

Note that the English language default handling, if no DAY and HOUR options are set, is slightly more sophisticated than available with the option, in that the default English language handling includes a case distinction: it will substitute Day or Hour in place of `%U`, while substituting "day" or "hour" in place of `%u`. It is important that the actual values be specified in the charset matching the charset parameter configured for the Content-type: header line in the `return_prefix.txt` file.

60.3.1.1.3.2 DIAGNOSTIC_CODE (string)

The English language default is:

```
DIAGNOSTIC_CODE=  Diagnostic code:
```

or for example a French language setting could be:

```
DIAGNOSTIC_CODE=  Code de diagnostic :
```

60.3.1.1.3.3 ORIGINAL_ADDRESS (string)

The English language default is:

```
ORIGINAL_ADDRESS=  Original address:
```

Or for example a French language setting could be:

```
ORIGINAL_ADDRESS=  Adresse d'origine :
```

60.3.1.1.3.4 RETURN_PERSONAL (RFC 2047-encoded string)

Specify the personal name (RFC 822 phrase) to use with the postmaster address. If specified, this will override the Postmaster personal name specified for the source channel via `returnpersonal` as well as the global default specified via the `return_personal` MTA option.

60.3.1.1.3.5 SUBJECT (RFC 2047-encoded string)

Specify the value to use on the Subject: header line of DSNs, in RFC 2047 encoded form. So for instance in a French language version of `return_option.opt`:

```
SUBJECT==?iso-8859-1?Q?Notification_de_l=27=E9tat_de_remise?=
```

Note that the English language handling, if SUBJECT is not specified, is slightly more sophisticated than available via this option as different values will be used for different types of DSNs; see DSN types and their default Subject: field text. It is also possible to specify use of different Subject: values via the `$T` flag of the `NOTIFICATION_LANGUAGE` mapping table.

60.3.1.1.3.6 REASON (string)

The English language default is:

```
REASON=  Reason:
```

or for example a French language setting could be:

```
REASON=  Raison :
```

60.3.1.1.3.7 RECIPIENT_ADDRESS (string)

The English language default is effectively:

```
RECIPIENT_ADDRESS=  Recipient address:
```

or for example a French language setting could be:

```
RECIPIENT_ADDRESS=  Adresse du destinataire :
```

60.3.1.1.3.8 REMOTE_SYSTEM (string)

The English language default is:

```
REMOTE_SYSTEM=  Remote system:
```

or for example a French language setting could be:

```
REMOTE_SYSTEM=  Système distant :
```

60.3.1.1.3.9 *x.y.z* (string)

For any possible SMTP enhanced status code that might be reported in a notification, it is possible to configure additional, alternate text to include in the human-readable portion of the notification. Such text might be chosen to perhaps "better explain" (or at least provide a description in an alternate language) the corresponding enhanced status code. For instance:

```
5.1.0=Il y avait un erreur indefini avec l'adresse du destinaire.
5.1.1=La boite aux lettres a l'adresse specifiee n'existe pas.
5.1.2=Le systeme du destination specifiee dan l'adresse n'existe ou est incapable d'accepter la poste.
```

etc. See RFC 1893 for definitions of the standard meanings of enhanced status codes. Such explanation text, if specified, will be output after the ORIGINAL_ADDRESS information and before the REASON information as part of the %R recipient information substitution.

60.3.1.1.3.10 Option usage

So in particular, note that `return_option.opt` can re-define the meanings of some of the various % substitutions available in the `return_*.txt` files. The available substitution

sequences, along with any `return_option.opt` options controlling their text effect, are shown in return_*.txt file substitution sequences.

Table 60.2 return_*.txt file substitution sequences

Sequence	`return_option.opt` option	Default value	Meaning
%%		%	Substitute a literal % character.
%B			Substitute a boundary marker.
%C			Substitute the length of time (in days or hours---see the `return_units` MTA option and the %u and %U substitutions) the message has been queued; that is, the length of time during which the MTA has been trying to deliver a not-yet-delivered message.
%F			Substitute the length of the time the message may remain in the queue prior to the MTA bouncing it; that is, the final `backoff` keyword value minus the %C time-queued-so-far.
%H			Substitute those header lines specified in the `return_header.opt` file. See the `notary_decode` MTA option for discussion of decoding of material encoded due to use of non-US-ASCII characters.
%I			Substitute the length of time until the next notice; the next `notices` value minus the current %C time-queued-so-far.
%L			Substitute the length of time remaining until the MTA will bounce (return) a not-yet-delivered message; the length of time until the final `backoff` keyword value. See the `return_units` MTA option for whether this length of time is in units of days or hours; and see the %u and %U unit name substitutions.
%N			Substitute the length of time corresponding to the next `notices` value; this is the total amount of time between enqueue and that notice being due for generation, not the remaining time (for which see instead %I).
%O			(New in MS 6.2) Treat the % character as having no special meaning in the remainder of this `return_*.txt` file. That is, disable all % substitution sequence interpretation in the remainder of this template file.
%R	*see below*	`Recipient address:` *`address`* `Original address:` *`orcpt-value`* `Reason:` *`reason`* `Diagnostic code:` *`SMTP-error`* `Remote system:` *`name-and-details`*	The %R substitution causes output of a whole set of recipient-specific information, for each relevant envelope recipient, as a set of lines in *customizable-field-name field-value* format. These are intended as human-readable analogues (and in particular customizable and localizable versions for use in the human-readable portion of the DSN) of some of the standardized fields that RFC 3464 defined for use in the machine-readable portion of the DSN. The *customizable-field-name* text may be customized using a number of `return_option.opt` options.
%R	RECIPIENT_ADDRESS	`Recipient address:`	The setting of `includefinal`, `suppressfinal`, or `useintermediate` on the current source channel (the channel generating the notification) can affect what form of the recipient address is presented
%R	ORIGINAL_ADDRESS	`Original address:`	
%R	`x.y.z`	*MTA-error-text-for-x.y.z-status*	Substitute text explaining the "meaning" of the extended SMTP status *x.y.z*---typically this would be alternate language text intended to be more comprehensible than the English language SMTP error text.
%R	REASON	`Reason:`	
%R	DIAGNOSTIC_CODE	`Diagnostic code:`	

%R	REMOTE_SYSTEM	Remote system:	
%s		s	Substitute a literal " s" character if the previously substituted numeric value was not equal to one; typically used after a %u or %U substitution.
%S		S	Substitute a literal " S" character if the previously substituted numeric value was not equal to one; typically used after a %u or %U substitution.
%u	DAY	day	
%u	HOUR	hour	
%U	DAY	Day	
%U	HOUR	Hour	

60.3.2 MDN language and customization

There are a number of localizable, customizable files the MTA consults when constructing MDNs; these files will be discussed further in Customizing MDNs via the disposition files. By default, if no DISPOSITION_LANGUAGE mapping table is configured, the disposition_*.* files located in the langdir directory will be used to generate all MDNs. However, separate sets of disposition_*.* files can be created and located in separate directories---for localization or site customization purposes. Indeed, the MTA is distributed with several sets of langauge-specific disposition_*.* files, and a basic DISPOSITION_LANGUAGE mapping table (referenced in the mappings file via file inclusion of the mappings.locale file) which selects among the language-specific directories based on language preference of original message senders. That is, the DISPOSITION_LANGUAGE mapping table selects, based on any language preference of the original message sender, a directory in which to find an appropriate set of disposition_*.* files for generating an MDN back to that sender.

Probes to the DISPOSITION_LANGUAGE mapping table have the form:

mdn-type|*modifier*|*source-channel*|*accept-language*|*return-address*|*recipient*

where *mdn-type* can be any of displayed, dispatched, processed, deleted, denied, or failed, and where *modifier* can be a comma-separated list including any of error, warning, superseded, or expired. The accept-language field will have any values (possibly a comma-separated list) found on (preferentially) an Accept-Language: header line, or if that header line is not present then from a Preferred-language: header line if present, or failing that an X-Accept-Language: header line. Note that valid language tag values are discussed in RFC 3066 (Tags for the Identification of Languages).

The pattern (right hand side) of a DISPOSITION_LANGUAGE entry may set the $I flag to specify the directory from which the MTA should use disposition_*.* files when constructing an MDN, and optionally following a vertical bar character a destination charset. The pattern may also optionally use the $T flag to set the Subject: field value to use when constructing this MDN; the Subject: field follows yet another vertical bar character. (Note that the $T Subject: will only be used if there is neither a specific Subject: field for this type of MDN (such as a Sieve "vacation :subject" might specify), nor a SUBJECT option set in the disposition_option.opt file. That is, the $T specified Subject: field value is of low precedence compared to the other ways of setting the Subject: field value.) The pattern may also optionally set the names of the files to use when constructing this MDN instead of the normal disposition_prefix.txt, disposition_*mdn-type*.txt, and disposition_suffix.txt files; these are specified following the directory specification but prior to the first vertical bar character, with comma separators. All together, the syntax of the pattern is:

`$I$T`*`langdir`*`,`*`option`*`,`*`prefix`*`,`*`mdn-type-file`*`,`*`suffix`*`|`*`dest-charset`*`|`*`subject`*

See Sample NOTIFICATION_LANGUAGE and DISPOSITION_LANGUAGE mapping tables for an example `DISPOSITION_LANGUAGE` mapping table.

Note that as of MS 7.0.5, all MDNs generated by the MTA include an Auto-Submitted: header line, per the recommendation of RFC 3834 (Recommendations for Automatic Responses to Electronic Mail) -- in prior versions only certain forms of MDNs contained such a header line -- and the value placed on the Auto-submitted: header line has been updated to include the additional information suggested in RFC 5436 (Sieve Notification Mechanism: mailto) including additional values (such as `auto-notified`) and the `owner-email` parameter.

60.3.2.1 Customizing MDNs via the `disposition_*.*` files

When the MTA needs to construct an MDN, the MTA will consult the `DISPOSITION_LANGUAGE` mapping table to find a language-appropriate set of `disposition_*.*` files, and optionally some override files and values. The MTA will then use that set of `disposition_*.*` files, plus as relevant the `return_option.opt` and `return_header.opt` files discussed in Customizing DSNs via the return files, to construct the MDN.

The `return_option.opt` file, `return_header.opt` file, and (optional) `disposition_option.opt` files are modifier files, potentially affecting the spectrum of MDN messages. The `disposition_*.txt` files, in contrast, are template files for the different types of MDNs. The `disposition_prefix.txt` and `disposition_suffix.txt` template files are used to "wrap" the MDN-type-specific text; each such `disposition_`*`mdn-type`*`.txt` file is used nearly verbatim for its particular type(s) of MDN, with possible substitutions as specified via % substitutions (defined from `return_option.opt`). (The `notary_quote` MTA option controls this meaning of the percent character, %, in MDN template files.) Note that in order to specify inserting a literal percent character in a `disposition_*.txt` file, the percent character must itself be quoted with another percent character, %%. For the %H substitution typically used in the `disposition_prefix.txt` file (to insert header lines from the original message into the generated MDN), note that any decoding and/or character set conversion of any MIME-encoded, non-US-ASCII material in those original header lines is controlled by the `notary_decode` MTA option.

60.3.2.1.1 The `disposition_*.txt` files

The set of MDN `disposition_*.txt` template files is:

```
disposition_prefix.txt
disposition_deleted.txt
disposition_denied.txt
disposition_dispatched.txt
disposition_displayed.txt
disposition_failed.txt
disposition_processed.txt
disposition_suffix.txt
```

But note that currently, of these MDN-type files, only `disposition_deleted.txt` (an old-style Sieve "`reject`" action), and `disposition_dispatched.txt` (Sieve "`notify`" action), are routinely used by the MTA as those (and some forms of vacation messages) are

the types of MDNs that the MTA routinely generates---and vacation messages have their own distinct mechanisms for generating their text. The `disposition_prefix.txt` and `disposition_suffix.txt` files are also used, to prefix and suffix, respectively, the context placed in an MDN.

Each type of MDN has a default Subject: header field value, shown in MDN types and their default Subject: field text, though these values may be overridden either via the `DISPOSITION_LANGUAGE` mapping table or via the SUBJECT option in the `disposition_option.opt` file. Furthermore, some types of MDNs have their own, higher-precedence way, of specifying the Subject: header field value---as for instance the "`vacation :subject`" parameter. MDN types and their default Subject: field text lists the usage of each of these `disposition_`*`mdn-type`*`.txt` files.

Table 60.3 MDN types and their default Subject: field text

Type of MDN	Subject: field default text[1]	Usage
`deleted`	`Message has been deleted`	Old-style Sieve "`reject`" action
`denied`	`Message has been denied`	
`displayed`	`Message has been displayed`	Would be used for read receipts, if the MTA generated read receipts (which it doesn't--- read receipts are up to user agents to generate)
`dispatched`	`Message has been dispatched`	Sieve "`notify`" action
`failed`	`Message has failed`	
`processed`	`Message has been processed`	"`vacation :echo`" messages (or `mailAutoReplyMode: echo` messages); note that vacation messages may set their own Subject: field value

[1] The Subject: field value can be overridden by setting a single value to be used for *all* MDNs via the SUBJECT option of `disposition_option.opt`. Alternatively, a more complex approach is to use the `$T` flag in the `DISPOSITION_LANGUAGE` mapping table to set Subject: field values. Certain types of MDNs have their own, more explicit, methods for setting the Subject: field value.

As a concrete example, a few of the distributed English language set of `disposition_*.txt` files will be presented here. Shown in Sample English language `disposition_prefix.txt` file, Sample English languge `disposition_deleted.txt` file, Sample English language `disposition_dispatched.txt` file, and Sample English language `disposition_suffix.txt` file these are some of the files typically found in the directory located via the `langdir` MTA option, `IMTA_TABLE:locale/C/`. The MTA is also distributed with sets of `disposition_*.txt` files in other, language-specific directories under `IMTA_ROOT:lib/locale`.

Note that regardless of what language is a site's own"preferred" language, notifications such as MDNs may be generated by the MTA in other languages, using the `disposition_*.txt` files from other language-specific directories, according to any expressed language preference of the *original* message sender (who will receive the MDN). That is, it is not a site's own language preference, but rather the language preference of the MDN recipient -- who is possibly a remote user -- that matters most when it comes to MDN language!

Sample English language `disposition_prefix.txt` file

```
Content-type: text/plain; charset=us-ascii
Content-language: EN-US

This disposition report relates to a message you sent with the following header
fields:
%H
```

Sample English language `disposition_deleted.txt` file

```
Your message was refused by %R and has been deleted.
The reason given for the deletion was the following:
```

Sample English language `disposition_dispatched.txt` file

```
Your message has been sent somewhere in some manner (e.g., printed,
faxed, forwarded) without necessarily having been read by the recipient
%R.
```

Sample English language `disposition_suffix.txt` file - normally empty

```
```

(Note: the `disposition_suffix.txt` file is typically empty.)

60.3.2.1.2 The disposition_option.opt file

The `disposition_option.opt` file is optional; in its absence, a reasonable set of (English language) default values will be used. (Indeed, the English language defaulting for the text controlled by this file is actually a bit more sophisticated than the handling available via the options in the file.) However, while its existence is not *required*, it is normally desirable to have such a file in non-English, language-specific directories. The `disposition_option.opt` file supports the following options:

60.3.2.1.2.1 SUBJECT

The SUBJECT option sets a default field value for the Subject: header line. The precedence is that any Subject: field value specific to the type of MDN -- for instance, a subject specified via a Sieve "`vacation`" action---takes precedence over the setting of the SUBJECT option. But the SUBJECT option in turn, when set, takes precedence over any Subject: field value set via the `$T` flag in the `DISPOSITION_LANGUAGE` mapping table, which in turn takes precedence over the default text shown in MDN types and their default Subject: field text.

60.3.2.1.2.2 RETURN_PERSONAL

When an MDN with a From: header address of the postmaster address is being generated, (which note is not the case for all types of MDNs), then the RETURN_PERSONAL option sets the so-called "personal name" (technically, the RFC 822 "phrase") to use with the postmaster address.

60.3.2.1.2.3 TEXT_CHARSET

When generating a vacation MDN in `:reply` format, and not using `:mime` (so not supplying all MIME header lines and any necessary MIME encoding), the vacation reason text may need to have charset conversion performed. The TEXT_CHARSET option specifies the output charset.

60.3.3 NOTIFICATION_LANGUAGE and DISPOSITION_LANGUAGE sample mapping tables

The normal configuration of the MTA, established by initial configuration, includes basic `NOTIFICATION_LANGUAGE` and `DISPOSITION_LANGUAGE` mapping tables, as well as subsidiary mapping tables. (In legacy configuration, these mappings were included into the main MTA mappings file via a reference to the distributed file `mappings.locale`; these language-related mappings were stored in `mappings.locale` for MTA administrator convenience, as they are rather large mappings, complicated to read, and seldom changed by MTA administrators.)

In Unified Configuration, these mappings appear as:

```
msconfig> show mapping:NOTIFICATION_LANGUAGE
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|en*|*|* $IIMTA_TABLE:locale/C/,IMTA_LIB:locale/C/
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|de*|*|* $IIMTA_TABLE:locale/de/,IMTA_LIB:locale/de/
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|es*|*|* $IIMTA_TABLE:locale/es/,IMTA_LIB:locale/es/
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|fr*|*|* $IIMTA_TABLE:locale/fr/,IMTA_LIB:locale/fr/
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|ja*|*|* $IIMTA_TABLE:locale/ja/,IMTA_LIB:locale/ja/
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|zh-TW|*|* $IIMTA_TABLE:locale/zh_TW/,IMTA_LIB:locale/zh_TW/
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|zh*|*|* $IIMTA_TABLE:locale/zh/,IMTA_LIB:locale/zh/
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|ko*|*|* $IIMTA_TABLE:locale/ko/,IMTA_LIB:locale/ko/
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|$_*,$T**|*|* $R$0|$1|$4|$5|$6
role.mapping:NOTIFICATION_LANGUAGE.rule = *|*|*|*@*|* $C$|LDAP_USERS_LANGUAGE;$3@$4|$E
msconfig> show mapping:LDAP_USERS_LANGUAGE
role.mapping:LDAP_USERS_LANGUAGE.rule = *@* $C|DC|$0@$1|$|DOMAIN_DC;$1|
role.mapping:LDAP_USERS_LANGUAGE.rule = |DC|*@*|* $C|BDN|$0@$1|$2|$]ldap:///$2,o=internet?inetDomainBaseDN?sub?(objectClass=inetDomain)[
role.mapping:LDAP_USERS_LANGUAGE.rule = |DC|*@*|* $C|BDN|$0@$1|$2|$]ldap:///$2,o=internet?aliasedObjectName?sub?(objectClass=inetDomainAlias)[
role.mapping:LDAP_USERS_LANGUAGE.rule =
  |BDN|*|*|* $C|LANG|$]ldap:///$2?preferredLanguage?sub?(|(mail=$=$0$_)(mailAlternateAddress=$=$0$_)(mailEquivalentAddress=$=$0$_))[
role.mapping:LDAP_USERS_LANGUAGE.rule =
  |BDN|*|*|* $C|LANG|$]ldap:///$1,o=internet?preferredLanguage?sub?(|(objectClass=inetDomain)(objectClass=inetDomainAlias))[
role.mapping:LDAP_USERS_LANGUAGE.rule = |LANG|* $CIMTA_TABLE:locale/$|LANGUAGE_LOCALES;$0|/,IMTA_LIB:locale/$|LANGUAGE_LOCALES;$0|/$$I$Y$E
msconfig> show mapping:LANGUAGE_LOCALES
role.mapping:LANGUAGE_LOCALES.rule = en C$Y
role.mapping:LANGUAGE_LOCALES.rule = de de$Y
role.mapping:LANGUAGE_LOCALES.rule = es es$Y
role.mapping:LANGUAGE_LOCALES.rule = fr fr$Y
role.mapping:LANGUAGE_LOCALES.rule = ja ja$Y
role.mapping:LANGUAGE_LOCALES.rule = zh-TW zh_TW$Y
role.mapping:LANGUAGE_LOCALES.rule = zh zh$Y
role.mapping:LANGUAGE_LOCALES.rule = ko ko$Y
role.mapping:LANGUAGE_LOCALES.rule = * $N
msconfig> show mapping:DISPOSITION_LANGUAGE
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|en*|*|* $IIMTA_TABLE:locale/C/,IMTA_LIB:locale/C/|UTF-8
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|de*|*|* $IIMTA_TABLE:locale/de/,IMTA_LIB:locale/de/|UTF-8
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|es*|*|* $IIMTA_TABLE:locale/es/,IMTA_LIB:locale/es/|UTF-8
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|fr*|*|* $IIMTA_TABLE:locale/fr/,IMTA_LIB:locale/fr/|UTF-8
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|ja*|*|* $IIMTA_TABLE:locale/ja/,IMTA_LIB:locale/ja/|UTF-8
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|zh-TW|*|* $IIMTA_TABLE:locale/zh_TW/,IMTA_LIB:locale/zh_TW/|UTF-8
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|zh*|*|* $IIMTA_TABLE:locale/zh/,IMTA_LIB:locale/zh/|UTF-8
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|ko*|*|* $IIMTA_TABLE:locale/ko/,IMTA_LIB:locale/ko/|UTF-8
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|$_*,$T**|*|* $R$0|$1|$2|$5|$6|$7
role.mapping:DISPOSITION_LANGUAGE.rule = *|*|*|*|*@*|* $C$|LDAP_USERS2_LANGUAGE;$4@$5|$E
msconfig> show mapping:LDAP_USERS2_LANGUAGE
role.mapping:LDAP_USERS2_LANGUAGE.rule = *@* $C|BDN|$0@$1|$}$1,_base_dn_{
role.mapping:LDAP_USERS2_LANGUAGE.rule =
  |BDN|*|* $C|LANG|$]ldap:///$1?preferredLanguage?sub?(|(mail=$=$0$_)(mailAlternateAddress=$=$0$_)(mailEquivalentAddress=$=$0$_))[
role.mapping:LDAP_USERS2_LANGUAGE.rule = |BDN|*@*|* $C|LANG|$}$1,preferredLanguage{
role.mapping:LDAP_USERS2_LANGUAGE.rule =
  |LANG|* $CIMTA_TABLE:locale/$|LANGUAGE_LOCALES;$0|/,IMTA_LIB:locale/$|LANGUAGE_LOCALES;$0|/$$I|UTF-8$Y$E
```

Note: Some output lines have been wrapped for clarity.

60.4 Notification message routing

When the MTA needs to generate a notification message, its default is to enqueue the notification message to the process channel. The new notification message will be enqueued to the process channel from whatever channel encountered the condition that required the notification message to be generated. For instance, a `tcp_local` channel when attempting to send a message out to the Internet (that is, `tcp_local` operating as an SMTP client) may need to generate a notification message if a message it is attempting to deliver encounters a permanent rejection error from a remote SMTP server. Or the `tcp_local` channel's SMTP server may need to generate a notification message if an incoming message that it is attempting to process is addressed to a local recipient who has a Sieve filter containing a syntax error; in this case while the original message gets delivered as "normal", the `tcp_local` channel also needs to generate a notification message to the local Sieve filter owner letting them know that their Sieve filter has a syntax error.

The process channel, having had a notification message enqueued to it, will then run to send the notification message onwards to an appropriate destination channel. (This is in fact the main purpose of the process channel, namely to handle notification messages: accept them being generated by other channels, and then properly enqueue them onwards to their destinations.)

Optionally, the MTA may be configured, on a per-channel basis, to enqueue notification messages to alternate `process_*` channels via the `notificationchannel` and `dispositionchannel` channel options. This may be useful when a site processes a large number of notification messages. Splitting up notification message traffic into different `process_*` channels, and then optionally using source-channel-specific rewrite rules (or the `CONVERSIONS` mapping table) to route the messages coming from different `process_*` channels out through different destination channels, may aid in managing large volumes of notification messages. (In particular, this may be of interest with special purpose channels that are subject to unusually high volumes of notification messages, or when dealing with rejections of spam messages that had forged From: addresses claiming to come from unresponsive rather than clearly nonexistent domains.)

For instance, suppose one adds new, special channel definitions that are variants of the usual `tcp_local` and `process` channels, so along the lines of:

```
tcp_local_dsn_out smtp mx single_sys subdirs 20 maxjobs 7 pool SMTP_POOL \
 loopcheck
tcp-dsn-out-daemon

process_dsn_out
process-dsn-out-daemon
```

then adds `notificationchannel process_dsn_out` to the regular `tcp_intranet` channel definition:

```
tcp_intranet ...usual-keywords... notificationchannel process_dsn_out
tcp_intranet-daemon
```

and configures special routing by using

```
CONVERSIONS

  IN-CHAN=process_dsn_out;OUT-CHAN=tcp_local;CONVERT    \
Yes,Channel=tcp_local_dsn_out
```

This will result in notifications generated by the `tcp_intranet` channel regarding messages originally from Internet senders (notifications back to Internet senders regarding the Internet senders' messages originally addressed to recipients on other internal hosts) to be routed out the special `tcp_local_dsn_out` channel, rather than out the usual `tcp_local` channel. This can then allow for special handling, or special tuning of the handling, of such messages.

Also, the new-in-6.3P1 $~ flag in the FROM_ACCESS mapping table provides, among other things, another way to do special routing of incoming notification messages (messages with empty envelope From). That is, this provides a way to associate a special source channel (and hence do special destination channel routing, or other special source-channel based handling) for notification messages generated external to this MTA. *E.g.*, with new, special channel definitions that are variants of the usual `tcp_local` and `tcp_lmtpcs` channels, so along the lines of:

```
tcp_local_dsn_in smtp mx single_sys remotehost inner switchchannel \
 subdirs 20 maxjobs 7 pool SMTP_POOL maytlsserver maysaslserver \
 saslswitchchannel tcp_auth missingrecipientpolicy 0 loopcheck
tcp-dsn-in-daemon

tcp_lmtpcs_dsn_out defragment lmtp multigate connectcanonical \
 fileinto @$4O:$U+$S@$D port 225 nomx single_sys subdirs 20 maxjobs 7 \
 pool SMTP_POOL dequeue_removeroute
lmtpcs-dsn-daemon
```

then use mappings along the lines of:

```
FROM_ACCESS

  TCP|*|SMTP*|MAIL|tcp_local||*  $Y$~tcp_local_dsn_in

CONVERSIONS

  IN-CHAN=tcp_local_dsn_in;OUT-CHAN=tcp_lmtpcs;CONVERT    \
Yes,Channel=tcp_lmtpcs_dsn_out
```

to cause notifications coming in from the Internet destined for LMTP recipients to get routed out the special `tcp_lmtpcs_dsn_out` delivery channel, rather than out the usual `tcp_lmtpcs` delivery channel.

60.5 Bounces of spam messages

Joe-job or *blow back* spam are terms for the following occurrence. When spam (unsolicited bulk e-mail) is sent with a forged From: address pointing to one of your users (or at least an address putatively in your domain), if that spam is then rejected (bounced) by some intended spam

recipient, the resulting notification messages (the bounces of the original spam messages) come back to *your* user, or at least your host! When one or more of your users' From: address gets forged on spam messages, this can then lead to a large volume, a "storm", of notification messages incoming to your users/hosts. One technique that can be helpful in such cases is to "isolate" incoming notification messages, as discussed in Notification message routing, and then perhaps do such things as "slow down" delivery of such notifications relative to other messages (for instance, reducing the `maxjobs` for the special delivery channel) and/or perform specially rigorous scanning of such incoming notifications and, when appropriate, discard them rather than deliver them.

Another issue that can occur with notifications and spam messages is when spam messages come in to your host with forged invalid (but not immediately obvious as such) From: addresses. If the spam messages are bounced, this can lead to a large burden of notification messages (regarding the spam) which your MTA is attempting to send (deliver) to what are in fact undeliverable recipient addresses (those invalid forged purported original sender addresses). When forged From: addresses on the original spam point to domains that will result in merely temporary errors upon delivery attempts (of the notifications concerning the bounces of the original spam), your MTA's outgoing message channels can get burdened with these large numbers of notifications that will never be deliverable (but meantime are cluttering up the outbound delivery channels). One approach to deal with this is to discard (rather than bounce) such spam; however, some sites for legal or other reasons can not use such a discard approach. In such cases, use of a `notificationchannel` and then a source-channel-specific rewrite rule (or CONVERSIONS mapping table entry) to route messages coming from the special `notificationchannel` in turn out a special outbound channel, can prevent such messages from unduly burdening your MTA and unduly interfering with other message processing. See Notification message routing for an example of such configuration.

60.6 Notification message logging

MTA message transaction log entries showing an empty envelope From address are the indication of a notification message, whether generated externally and merely passing through the MTA, or whether generated by the MTA itself.

For notification messages generated by the MTA itself, note that notification messages are generated through the process channel. Indeed, typically the generation of notification messages is the sole function of the process channel. So MTA message transaction log entries showing a message being enqueued to the process channel typically correspond exactly to the generation of a new notification message.

If the MTA option `log_message_id` is enabled, then when the MTA generates a notification message it will include both the original message-id and the message-id of the new, notification message in the message transaction log entry showing the notification message initial generation (that is, in the entry showing the notification message being enqueued to the process channel). Thus this allows correlating the original message with a corresponding notification message. Note that the presence of two message-id's in the message-id field is, also, a definite indication of MTA generation of a notification message.

Enabling the `log_process` MTA option is also helpful when investigating notification message generation, as it will show the same process enqueueing the newly generated notification message, and then recording whatever was the appropriate action on the original message, *e.g.*, an "`R`" record, a "`W`" record, an "`E`" record (as in the case of a notification due to a Sieve syntax error report, or message capture notification), *etc*. (See also the new-in-MS-8.0 "`P`" records.) A point to emphasize here is that the notification message generation, that is, the

enqueue to the process channel, occurs and hence is recorded before the completion of the operation on the original message, hence before the recording of what occurred to the original message.

60.7 Message size limits and notification messages

Administrative limits on message size can have interactions with notification messages.

First, note that it is very important to ensure that users can receive notification messages when messages they send can not be delivered. And note that bounce messages (non-delivery notifications) will sometimes include the contents of the originally sent message; so a non-delivery notification may be larger than the originally sent message. So when imposing administrative limits on message size, it is wise practice to make the limit on the size of message that may be received somewhat larger than the limit on the size of message that may be sent.

New behavior in MS 6.3-0.15 is that during address reversal of the envelope return address (envelope From address) of a message, the MTA fetches the block limit associated with that envelope return address and will set the NOTARY (RFCs 1891-1894) flag RET=HDRS (return only message header lines, not message content) on the message if no explicit return policy was already specified and the message size exceeds the block limit. This reduces cases where non-delivery reports regarding large messages are undeliverable themselves due to size.

The MTA options `bounce_block_limit` and `content_return_block_limit`, channel options such as `blocklimit`, and user LDAP attributes such as `mailMsgMaxBlocks` (or more precisely, whatever attribute is named by the `ldap_blocklimit` MTA option), can all affect what (whether and how much of an original message) gets included in notification messages.

60.8 Postmaster addresses

There are two sides to postmaster addresses: the postmaster addresses for which your site accepts mail, and the postmaster addresses your site emits as the From: address on notification messages your site generates.

Domain names for SMTP servers visible on the Internet are required to be able to accept mail addressed to `postmaster@`*`domain`*. This means that any host with an Internet-facing SMTP server, and any visible-on-the-Internet hosted domain names, are required to support a corresponding postmaster mailbox. And indeed, it is normal and strongly recommended to have a postmaster mailbox for each and every e-mail domain name (including any purely internal e-mail domain names) you support. The MTA itself will send warning messages and, (depending upon version) may default to sending copies of users' bounce messages to the postmaster.

It is critical that the postmaster address be a valid address for receiving mail! Hosting the postmaster mailbox directly on the Internet-facing SMTP server system may reduce the potential for problems arising in forwarding a message onwards. However, in a multi-tier deployment it is possible that you will not want to have to have someone log on regularly to the Internet-facing SMTP server system to check postmaster mail. If you do wish to direct postmaster mail to a different system, be sure to ensure that the connection between the e-mail Internet-facing system and that other system is a very reliable connection; and be prepared

that if something happens to break that connection, you will want to immediately change the postmaster address on the Internet-facing SMTP server system to some other functioning address or be prepared for the potential for serious e-mail problems. (Bouncing postmaster mail is not pretty.) See also the `aliaspostmaster` channel option which can sometimes simplify consolidation of postmaster addresses.

The special `postmaster` local-part is defined (see RFC 822) to be case-insensitive even if local-parts in general are allowed to be case-sensitive, and the MTA has special code to treat postmaster case-insensitively even if it has been configured (see the `alias_case` MTA option) to allow other local-parts to be case-sensitive.

Normal MTA configuration includes at least one postmaster address as an alias (whether in the alias file, or as an alias in Unified Configuration). In particular, in a modern Unified Configuration:

```
msconfig> show alias:root*
role.alias:root@&/IMTA_DEFAULTDOMAIN/.alias_entry = postmast
role.alias:root@&/IMTA_HOST/.alias_entry = postmast
msconfig> show alias:postmast*
role.alias:postmaster@&/IMTA_HOST/.alias_entry = postmast
```

which presumes that a valid user account (often the Messaging Server `admin` user) is provisioned with `postmast@/IMTA_DEFAULTDOMAIN/` as a `mailAlternateAddress` value.

As regards what postmaster address(es) your site emits on the notification messages your site generates, the MTA has a variety of configuration controls: the `return_address` and `return_personal` MTA options for MTA-wide defaults, the `returnaddress` and `returnpersonal` channel options for channel-specific settings, and the `mailDomainReportAddress` domain-level LDAP attribute (more precisely, the LDAP attribute named by the `ldap_domain_attr_report_address` MTA option) for a domain-specific setting, as well as potential language-specific override of the Postmaster personal name via the `RETURN_PERSONAL` option in language-specific `return_option.opt` files, or `FROM_ACCESS` mapping table overrides of the Postmaster address via `$(` or `$)` flags. The MTA defaults for `return_address` and `return_personal` mean that the MTA defaults to emitting as Postmaster address `postmaster@`*`local-host`* where *`local-host`* is the `official_host_name` on the L channel, and defaults to using as Postmaster personal name "`Internet Mail Delivery`".

Certain non-MTA options also affect the postmaster address emitted in cases of postmaster messages generated by other (non-MTA) components of Messaging Server; see also the `noticercpt` and `noticesender` Alarm options.

Chapter 61 Message tracking and recall

A general message tracking and recall facility has been implemented. The tracking aspect of this facility conforms to RFC 3885, RFC 3886, and RFC 3887. The recall aspect is implemented as a tracking extension. Additionally, some tracking extensions have been implemented to make it possible for a tracking client to track and recall messages submitted by a non-tracking client.

In order to enable message tracking and recall, a memcache server must be operating, and the `tracking_mode` MTA option must be set to `1` to enable use of memcache for message tracking purposes. Which messages get tracking information stored is controlled by various message tracking channel options.

61.1 Message tracking and recall setup and configuration

There are three parts to setting up message tracking and recall capabilities:

1. Setting up a shared memcached server (or other software that implements the memcache protocol in a compatible fashion) to store tracking/recall information.
2. Configuring all the MTAs in the deployment to enable tracking and recall.
3. Setting up Message Tracking and Query Protocol (MTQP) servers on every MTA and possibly additional hosts.

61.1.1 Memcache server setup

Setting up memcached or compatible server is beyond the scope of this document. That said, note that mecmached setup is very simple: Configuration consists of a small number of options on the command line. Indeed, it's often possible to simply say:

```
memcached -l <ip-address>
```

Where <ip-address> is the IP address where memcached accepts connections.

Once a server implementing the memcache protocol has been set up, every MTA in the deployment have to be configured to access it. This is done with the `memcache_host` MTA option; there is no tracking-specific host setting at the present time. The `memcache_port` MTA option must be explicitly set if the server is listening on a port other than 11211. It may be appropriate to set the `memcache_expire` MTA option to an appropriate value as well.

Tracking/recall is enabled within the MTA by setting the `tracking_mode` MTA option to 1. Logging tracking identifiers is good idea; this is controlled by the `log_tracking` MTA option.

Taken together, and assuming the memcache server is listening on the default port, the MTA option settings should look something like this:

```
msconfig> show memcache_host
role.mta.memcache_host memcache-server-ip
msconfig> show tracking_mode
role.mta.tracking_mode 1
msconfig> show log_tracking
role.mta.log_tracking 1
```

or in legacy configuration:

```
MEMCACHE_HOST=<memcache-server-ip>
TRACKING_MODE=1
LOG_TRACKING=1
```

61.1.2 MTA channel setup for message tracking and recall

The next step is to tell the tracking subsystem the semantics of the various channels in the deployment using the `trackinginternal`, `trackingrelayed`, and `trackingdelivered`. The general rules are:

1. Internal processing channels such as `process`, `reprocess`, `conversion`, and `defragment` require no special decoration.

2. Channels that perform final delivery must be marked with the `trackingdelivered` channel option. This includes not only `ims-ms` and `tcp_lmtpcs` channels, but also the `bitbucket` and `filter_discard` channels.

3. Any channel that relays messages to systems outside the deployment must be marked with the `trackingrelayed` channel option. Of course this includes the `tcp_local` channel, but would also include, say a special `tcp_aol` channel set up to handle mail to the aol.com domain.

4. Finally, any channel that relays message to other MTAs inside the deployment where tracking is enabled. This would typically be something like a `tcp_intranet` channel.

Note that for tracking and recall to work messages relayed to external systems MUST be handled by a different channel than messages relayed to other MTAs inside the deployment. (At a minimum, this tends to mean using a distinct `tcp_local` *vs.* `tcp_intranet` channel.) Meeting this requirement may require additional configuration changes.

The MTRK SMTP extension defined in RFC 3885 is used to transfer tracking/recall information from one MTA to another. Use of this extension MUST be enabled on SMTP connections between MTAs inside the deployment. It also must be enabled on SUBMIT channels used by tracking/recall-enabled clients.

Since MTRK is an SMTP extension, its use is negotiated by the SMTP client and server. So the simplest way to activate this extension is to put the `trackingclient` and `trackingserver` on the defaults channel. However, if you wish to avoid use of this extension with systems outside the deployment, a more targeted approach is needed: Place `trackingclient` on

every `tcp_*` channel that has `trackinginternal` set. Then place `trackingserver` on every channel that accepts messages from other hosts within the deployment. (Note that once again this may require configuration changes to separate internal and external traffic.)

61.1.3 MTQP server setup

An extended version of MTQP as specified in RFC 3887 is used to perform tracking and recall operations. If only tracking is desired a single MTQP server can be used for the entire deployment and can be run on any host. However, in order to recall messages an MTQP server must be running on every host with an MTA, and if "total recall" is enabled MTQP servers are required on all store hosts as well.

The MTQP server leverages existing MTA facilities which require a channel. Note that the MTQP channel doesn't sent or receive messages and has no rewrite rules or associated queue. The specification of such a channel is very simple. In legacy configuration:

```
mtqp smtp
mtqp-daemon
```

or in Unified Configuration:

```
msconfig> set channel:mtqp.officical_host_name mtqp-daemon
msconfig# set channel:mtqp.smtp
```

Although somewhat counterintuitive, the "`smtp`" channel option is required to indicate this is a channel with an associated server. Various optional channel options can also be specified, including:

- `maytlsserver` or `musttlsserver` are used to control whether SSL/TLS is allowed or required, respectively, before tracking/recall operations may be performed.
- `slave_debug` enables MTQP server debugging.
- `maysaslserver` may be specified to enable user authentication. User authentication is required in order to use the MTRACK and/or MRECALL commands.
- `disconnectbadauthlimit`, `disconnectbadcommandlimit`, and `disconnectcommandlimit` have their usual meanings.

Some MTQP-server-specific options are also available:

`TOTAL_RECALL` (boolean 0 or 1, default 0)	If set to 1, this option enables recall of messages from the store. Note that if this is used it will result in messages being deleted from recipient's folder irrespective of whether or not they have been read. Use of this option should only be undertaken with a full understanding of the possible consequences.
`AUTH_DEBUG` (debug token list, default "")	This option is used to specify authentication debugging tokens.
`COMMAND_TIMEOUT` (integer seconds, default 60)	This option specifies the time the server will wait for a command before disconnecting.

`STATUS_TIMEOUT` (integer seconds, default 60)	This option specifies the time the server will wait for a status write to the client before disconnecting.
`CUSTOM_BANNER_STRING` (string, default "")	This option specifies the name the server uses to announce itself.

Additionally, the server recognizes and will honor the TCP/IP channel-specific options `LOG_CONNECTION`, `TRACE_LEVEL`, `MAX_THREADS`, and `IGNORE_BAD_CERT`.

Finally, a Dispatcher service definition for the MTQP server is also required. In legacy configuration:

```
[SERVICE=MTQP]
PORT=1038
IMAGE=IMTA_BIN:mtqp
LOGFILE=IMTA_LOG:mtqp_server.log
STACKSIZE=2048000
```

or in Unified Configuration:

```
msconfig> set service:MTQP.image IMTA_BIN:mtqp
msconfig# set service:MTQP.tcp_ports 1038
msconfig# set service:MTQP.logfilename IMTA_LOG:mtqp_server.log
msconfig# set service:MTQP.stacksize 2048000
```

Chapter 62 TCP/IP channels

TCP/IP channels are used to link the MTA to TCP/IP based networks such as the Internet, as well as linking multiple hosts within a single site. The TCP/IP channels all use either the Simple Mail Transfer Protocol (SMTP), or the similar Local Mail Transport Protocol (LMTP). SMTP was defined originally in RFC 821 and updated in RFC 5321, and nowadays has many extensions such as those described in RFC 1426, RFC 1869, RFC 870, and RFC 1891. LMTP was defined in RFC 2033.[1] The descriptions of these protocols and extensions may be found at the Internet Engineering Task Force (IETF) web site, www.ietf.org.

The TCP/IP SMTP channel includes a multithreaded SMTP server which runs under the control of the MTA Dispatcher. Outgoing SMTP mail is processed by the multithreaded SMTP client channel program (`tcp_smtp_client`), run as needed under the control of the MTA Job Controller.

The TCP/IP LMTP channel similarly includes a multithreaded LMTP server which runs under the control of the MTA Dispatcher; indeed, on a back end LMTP Message Store host, usually the *only* components of the MTA that are used are the MTA Dispatcher and the MTA's LMTP server. The TCP/IP LMTP channel also includes a multithreaded LMTP client channel program (which is in fact the same code and program as the SMTP client channel program, merely configured a bit differently), run as needed (on full-blown MTA hosts front-ending an LMTP back end host) under the control of the MTA Job Controller.

At most sites, TCP/IP channels are the primary channels in use. See Typical TCP/IP channels and servers for an overview of the basic, minimally-configured, TCP/IP channels and servers included by default in a Unified Configuration. There are many, many configuration modifications that may be made to TCP/IP channels. Besides the normal Channel options and especially the SMTP and LMTP protocol channel options, see also the TCP/IP-channel-specific options. In legacy configuration, channel options were termed "channel keywords" and were set on channels in the `imta.cnf` file, whereas TCP/IP-channel-specific options were set in channel-specific files such as `tcp_local_option`. In Unified Configuration, these fundamentally different categories of options may be distinguished by the location at which they are set, with channel options appearing directly under the name of the channel for which they are set,

```
msconfig> show role.channel:tcp_local.pool
role.channel:tcp_local.pool = SMTP_POOL
```

whereas TCP/IP-channel-specific options are grouped under `options`,

```
msconfig> show role.channel:tcp_local.options.*
```

For normal hosts on the Internet, configuring to prevent being an open SMTP relay, that is, configuring to block open SMTP relaying, is an esssential step. Nowadays initial installation typically takes care of the basics of such configuration, but reviewing that configuration is recommended.

Certain special configurations of TCP/IP channels can be of particular use. Routing via gateway systems, describes how to establish a "gateway" channel to route mail through another system, as for instance to a mailhub or firewall system. Triggering message transfer with remote SMTP systems describes performing "polling" with TCP/IP channels, that is, requesting that a remote system attempt to deliver any stored messages to your system; for instance, this may be particularly useful over "intermittent" sorts of TCP/IP links, such as dial-up connections.

Note [1] When using LMTP to deliver messages to the Messaging Server Message Store, the MTA's LMTP server and LMTP client both make important use of several MTA proprietary LMTP extensions. These LMTP extensions are aimed to permit the LMTP server side of the LMTP transactions to be very simple, and not require "heavy weight" processing; the "heavier weight" processing of message addresses and message content is instead pre-performed on "front" MTAs. Thus the MTA's LMTP server is designed and intended to work *only* when "front-ended" by an MTA LMTP client host. The MTA's LMTP client, in contrast, may in principle be used with any LMTP back end.

62.1 Typical TCP/IP channels and servers

In Unified Configuration, several basic `tcp_*` channels are established by default in the configuration. (Any legacy configuration generated in any relatively modern MTA version will also normally have several basic `tcp_*` channels defined.) *E.g.*:

```
msconfig> show role.channel:tcp_*
role.channel:tcp_local.official_host_name = tcp-daemon
role.channel:tcp_local.daemon = mailgate.domain.com
role.channel:tcp_local.identnonenumeric (novalue)
role.channel:tcp_local.inner (novalue)
role.channel:tcp_local.loopcheck (novalue)
role.channel:tcp_local.maysaslserver (novalue)
role.channel:tcp_local.maytlsserver (novalue)
role.channel:tcp_local.nomx (novalue)
role.channel:tcp_local.pool = SMTP_POOL
role.channel:tcp_local.remotehost (novalue)
role.channel:tcp_local.saslswitchchannel = tcp_auth
role.channel:tcp_local.smtp (novalue)
role.channel:tcp_local.sourcetransitplugin = 1
role.channel:tcp_local.switchchannel (novalue)
role.channel:tcp_intranet.official_host_name = tcp_intranet-daemon
role.channel:tcp_intranet.allowswitchchannel (novalue)
role.channel:tcp_intranet.dequeueremoveroute (novalue)
role.channel:tcp_intranet.loopcheck (novalue)
role.channel:tcp_intranet.maysaslserver (novalue)
role.channel:tcp_intranet.maytlsserver (novalue)
role.channel:tcp_intranet.mx (novalue)
role.channel:tcp_intranet.pool = SMTP_POOL
role.channel:tcp_intranet.saslswitchchannel = tcp_auth
role.channel:tcp_intranet.single_sys (novalue)
role.channel:tcp_intranet.smtp (novalue)
role.channel:tcp_intranet.sourcetransitplugin = 1
role.channel:tcp_submit.official_host_name = tcp_submit-daemon
role.channel:tcp_submit.maytlsserver (novalue)
```

```
role.channel:tcp_submit.mustsaslserver (novalue)
role.channel:tcp_submit.saslswitchchannel = tcp_submit
role.channel:tcp_submit.smtp (novalue)
role.channel:tcp_submit.sourcetransitplugin = 1
role.channel:tcp_submit.submit (novalue)
role.channel:tcp_auth.official_host_name = tcp_auth-daemon
role.channel:tcp_auth.mustsaslserver (novalue)
role.channel:tcp_auth.smtp (novalue)
role.channel:tcp_auth.sourcetransitplugin = 1
role.channel:tcp_tas.official_host_name = tcp_tas-daemon
role.channel:tcp_tas.allowswitchchannel (novalue)
role.channel:tcp_tas.deliveryflags = 2
role.channel:tcp_tas.maytlsserver (novalue)
role.channel:tcp_tas.mustsaslserver (novalue)
role.channel:tcp_tas.smtp (novalue)
role.channel:tcp_tas.sourcetransitplugin = 1
msconfig>
```

with Dispatcher options (to complete the definitions of the SMTP and SMTP SUBMIT servers) of:

```
msconfig> show dispatcher.service:*MTP*
role.dispatcher.service:SMTP.image = IMTA_BIN:tcp_smtp_server
role.dispatcher.service:SMTP.logfilename = IMTA_LOG:tcp_smtp_server.log
role.dispatcher.service:SMTP.stacksize = 2048000
role.dispatcher.service:SMTP.tcp_ports = 25
role.dispatcher.service:SMTP_SUBMIT.image = IMTA_BIN:tcp_smtp_server
role.dispatcher.service:SMTP_SUBMIT.logfilename = IMTA_LOG:tcp_submit_server.log
role.dispatcher.service:SMTP_SUBMIT.parameter = CHANNEL=tcp_submit
role.dispatcher.service:SMTP_SUBMIT.stacksize = 2048000
role.dispatcher.service:SMTP_SUBMIT.tcp_ports = 587
```

This corresponds to what in legacy configuration would appear as channels in the `imta.cnf` file:

```
tcp_local daemon mailgate.domain.com identnonenumeric inner loopcheck \
 maysaslserver maytlsserver nomx pool SMTP_POOL remotehost \
 saslswitchchannel tcp_auth smtp sourcespamfilter1 switchchannel
tcp-daemon

tcp_intranet allowswitchchannel dequeueremoveroute loopcheck maysaslserver \
 maytlsserver ms pool SMTP_POOL saslswitchchannel tcp_auth single_sys smtp \
 sourcespamfilter1
tcp_intranet-daemon

tcp_submit maytlsserver mustsaslserver saslswitchchannel tcp_submit smtp \
 sourcespamfilter1
tcp_submit-daemon

tcp_auth mustsaslserver smtp sourcespamfilter1
tcp_auth-daemon
```

```
tcp_tas allowswitchchannel deliveryfalgs 2 maytlsserver mustsaslserver smtp \
 sourcespamfilter1
tcp_tas-daemon
```

And the corresponding legacy configuration Dispatcher part of the configuration -- the SMTP and SMTP SUBMIT servers -- would be:

```
!
! multithreaded SMTP server
!
[SERVICE=SMTP]
PORT=25
IMAGE=IMTA_BIN:tcp_smtp_server
LOGFILE=IMTA_LOG:tcp_smtp_server.log
STACKSIZE=2048000
! Uncomment the following line and set INTERFACE_ADDRESS to an appropriate
! host IP (dotted quad) if the dispatcher needs to listen on a specific
! interface (e.g. in a HA environment).
!INTERFACE_ADDRESS=
!
! rfc 2476 Submit server
!
[SERVICE=SMTP_SUBMIT]
PORT=587
! Uncomment the following line if you want to support SSL on the alternate port 465
!TLS_PORT=465
IMAGE=IMTA_BIN:tcp_smtp_server
LOGFILE=IMTA_LOG:tcp_submit_server.log
PARAMETER=CHANNEL=tcp_submit
STACKSIZE=2048000
! Uncomment the following line and set INTERFACE_ADDRESS to an appropriate
! host IP (dotted quad) if the dispatcher needs to listen on a specific
! interface (e.g. in a HA environment).
!INTERFACE_ADDRESS=
```

At sites using LMTP, so-called "front end" MTAs typically have, in addition to the TCP/IP channels shown above, one or more LMTP client channels, typically with `tcp_lmtpcs*` sorts of names, appearing in Unified Configuration as:

```
msconfig> show channel:tcp_lmtpcs*
role.channel:tcp_lmtpcs.backoff = PT5M PT10M PT30M PT1H PT2H PT4H
role.channel:tcp_lmtpcs.connectcanonical (novalue)
role.channel:tcp_lmtpcs.defragment (novalue)
role.channel:tcp_lmtpcs.dequeueremoveroute (novalue)
role.channel:tcp_lmtpcs.fileinto = @$4O:$U+$S@$D
role.channel:tcp_lmtpcs.lmtp (novalue)
role.channel:tcp_lmtpcs.multigate (novalue)
role.channel:tcp_lmtpcs.nomx (novalue)
role.channel:tcp_lmtpcs.official_host_name = lmtpcs-daemon
role.channel:tcp_lmtpcs.pool = SMTP_POOL
role.channel:tcp_lmtpcs.port = 225
role.channel:tcp_lmtpcs.single_sys (novalue)
```

Or in legacy configuration in the `imta.cnf` file appearing as:

```
!
! tcp_lmtpcs (LMTP client - store)
tcp_lmtpcs defragment lmtp multigate connectcanonical fileinto @$4O:$U+$S@$D \
  port 225 nomx single_sys pool SMTP_POOL dequeue_removeroute \
  backoff "PT5M" "PT10M" "PT30M" "PT1H" "PT2H" "PT4H"
lmtpcs-daemon
```

So-called "back end" LMTP systems run a simplified MTA configuration having only one (LMTP server) channel as discussed in LMTP back end TCP/IP channel.

62.2 SMTP SUBMIT servers

A TCP/IP channel marked with the `submit` channel option will function with respect to message submission as an SMTP SUBMIT server, as defined in RFC 6409 (Message Submission for Mail). Port 587 is reserved for SMTP SUBMIT use, so `submit` is normally set on the channel that, in the Dispatcher configuration, is associated with port 587; see the `dispatcher.tcp_ports` option (Unified Configuration). But SMTP SUBMIT service can also be set up on a different or other ports, if desired: any incoming channel marked with `submit` will operate as an SMTP SUBMIT server. RFC 5068 (Email Submission Operations: Access and Accountability Requirements), also known as BCP 134, encourages sites to support---and indeed transition to using---SMTP SUBMIT rather than regular SMTP for initial submission of user messages.

The configuration established when the MTA is installed normally includes an SMTP SUBMIT server in the form of a `tcp_submit` channel; this channel is marked with the `submit` channel option, and the Dispatcher configuration sets it to listen on port 587. In accord with RFC 5068's recommendations, the channel is also marked with `mustsaslserver` and `maytlsserver`, meaning that users *must* authenticate to submit messages to this channel and *may* use TLS. See Typical TCP/IP channels and servers for an example. (TLS use should be encouraged, but is not outright required in this typical configuration; sites that prefer to also require TLS use may instead set `musttlsserver`.)

Sites should encourage their local users to submit messages to the SMTP SUBMIT server on port 587, rather than to the regular SMTP server on port 25. But note that this does also imply that users *must* authenticate and *ought* to use TLS---some configuration of the users' clients may be needed to achieve this.

Extensions to SMTP SUBMIT permit additional functionality for users and user clients: see the `BURL_ACCESS` mapping table and SMTP SUBMIT FUTURERELEASE support.

62.2.1 BURL_ACCESS mapping table

As of Messaging Server 7.0, the MTA supports the BURL extension to SMTP SUBMIT, defined in RFC 4468 (Message Submission BURL Extension), and the Message Store IMAP server supports RFC 4467 (IMAP - URLAUTH Extension). BURL permits an email client to refer, in submitted messages, to content to be retrieved (using the IMAP URLAUTH extension) from an IMAP server. This allows email clients to submit messages including content without having to first download that content to the client and then upload (submit it) directly to the SMTP SUBMIT server itself: to include content by supplying a URL reference (including an authentication token allowing access) to the location of the content on an IMAP server. Availability of the BURL extension is controlled by the `BURL_ACCESS` mapping table, discussed below, and the MTA options `imap_username` and `imap_password`.

For the BURL extension to be made available, a BURL_ACCESS mapping table must be defined. Note that BURL is specifically an SMTP SUBMIT feature; in terms of MTA configuration, only channel(s) marked with the submit channel option are capable of offering BURL support.

Technical note: A client BURL command to an SMTP SUBMIT server for which BURL has not been enabled will be rejected with the error:

```
503 5.5.1 BURL has not been enabled.
```

BURL is only supported (may only be enabled) on SMTP SUBMIT channels; a client BURL command to an LMTP server will be rejected with the error:

```
503 5.5.0 BURL illegal on LMTP port.
```

while a client BURL command to an SMTP (non-SUBMIT) server will be rejected with the error:

```
503 5.5.1 BURL only allowed on submission port.
```

The BURL_ACCESS mapping table controls, via two different probe strings, first whether the BURL extension is advertised, and then second, whether a client's BURL command is accepted. The first probe is performed before responding to an EHLO command. It has the form:

port_access-probe-info|*channel*|*authentication-identity*|

Here port_access-probe-info consists of all the information usually included in a PORT_ACCESS mapping table probe. It will be blank if BURL is being used in a "disconnected" context such as batch SMTP. channel is the current source channel. authentication-identity is the user's canonical authenticated login identity, normally uid@canonical-domain (that is, the user's LDAP uid attribute value, an at sign, and the canonical domain name in which the user's entry resides as found during domain lookup). authentication-identity will be blank if no authentication has been performed. The "A" input flag will be set if SASL authentication has been performed, and the "T" input flag will be set if TLS is in use; thus the mapping templates may test using $:A and $:T, respectively. In order to offer BURL support, the mapping output for this first probe must set $Y; it may also optionally provide a space-separated list of supported URL types. imap is assumed if no explicit string is returned.

The second probe is performed when a BURL command is actually sent by the SUBMIT client and received by the SMTP SUBMIT server. In addition to the prior fields (described above), this second probe also includes as a final client-url field the URL specified in the client's BURL command:

port_access-probe-info|*channel*|*authentication-identity*|*client-url*

where client-url would normally be in URLAUTH syntax as defined in RFC 4467 (IMAP - URLAUTH Extension). See RFC 4467 for details on URLAUTH syntax, but for a rough idea to better understand the remainder of this discussion, consider that for BURL "submit user" access, the client-url will usually take a form along the lines of:

imap://*enc-user*@*hostport*/*optional-expire-clause*;URLAUTH=submit+*enc-user*:*mechanism*:*token*

(Other types of access in a URLAUTH and hence other forms of client-url, such as for "anonymous" access, are possible, but their use is more questionable---see the "Security

Considerations" section of RFC 4468 -- and therefore the remainder of this discussion will focus on enabling only "submit user" access.)

In this second (actual BURL command) `BURL_ACCESS` probe, as in the prior (advertise BURL) probe, the "`A`" input flag will be set if SASL authentication has been performed, and the "`T`" input flag will be set if TLS is in use; thus the mapping templates may test using `$:A` and `$:T`, respectively.

Additionally, for this second (actual received BURL command) probe, the vertical bar flag, `|`, will be set if the original URL sent by the client contained any vertical bars (which if present could possibly confuse some sorts of access checks), and thus the mapping entry template may test for vertical bars in the original client URL using the `$:|` test; note that the `mapping_paranoia` MTA option , if set, will cause any vertical bar within the client's original URL to be replaced in the probe by the specified alternate character (with the vertical bar input flag still being set). The mapping must set `$Y` for the URL to be accepted for processing. If `$D` is also set, then the string result of the mapping replaces the client's entire originally specified URL. New in 7.4-18.01, if `$M` is set, then the IMAP host name in the client's original URL will be replaced by the `mailHost` of the currently authenticated user; this tends to provide both better security (by enforcing that BURL connections will only be made to a site's own `mailHost` host(s)), and better performance (by more likely connecting to the "correct" host), than relying on the IMAP host name supplied by the user's client. See Table of BURL_ACCESS mapping flags for a summary of these available flags and tests.

Table 62.1 BURL_ACCESS mapping flags

Flag	Description
`$Yurl-types`	For the initial (EHLO) probe, enable advertising BURL support, optionally providing via the string argument `url-types` a space-separated list of the URL types to advertise.
`$Nstring`	For the later (BURL command) probes, reject access. If the optional `string` is supplied, use it as the (entire) SMTP rejection, including SMTP error code and extended code as well as text. If no such `string` is supplied, then the default SMTP error used for such rejections is `533 5.7.1 Access denied to specified URL.`®
`$I`	(New in 7.4-18.01) For the later (BURL command) probes, if specified in an entry with `$N` rejecting that BURL command, the `$I` means further to forcibly disconnect the session with disconnect reason text "BURL_ACCESS forced disconnect".®
`$Y`	For the later (BURL command) probes, a plain `$Y` flag allows the BURL command.
`$Dnew-url`	For the later (BURL command) probes, if `$Y` was also specified (allowing access), then use the specified `new-url` instead of the URL that the SMTP SUBMIT client provided.®
`$M`	(New in 7.4-18.01) For the later (BURL command) probes that succeed, in the actual BURL command override the IMAP host name in the client-provided URL and instead connect to the host of the `mailHost` attribute of the currently authenticated user. The BURL command probe itself will be considered to fail if the currently authenticated user has no `mailHost` attribute set.®

$T	(New in Messaging Server 7.0.5) For the later (BURL command) probes that succeed, force TLS use for opening the BURL URL (force TLS use in the connection to fetch the part specified in the client's BURL URL).®
$X	(New in Messaging Server 7.0.5) For the later (BURL command) probes that succeed, forcibly disable TLS use for opening the BURL URL (force non-use of TLS in the connection to fetch the part specified in the client's BURL URL).®
Flag comparisons	Description
$:|	Match only if the original client URL included the vertical bar character, |®
$;|	Match only if the original client URL included no vertical bar character, |®
$:A	Match only if SASL (SMTP AUTH) was used.
$;A	Match only if SASL (SMTP AUTH) was not used.
$:T	Match only if TLS was used.
$;T	Match only if TLS was not used.

®Available for the later (BURL command containing a URL) probes only; not available for the initial probe on whether or not to offer the BURL extension

At an absolute minimum, a site's BURL_ACCESS mapping table should be configured to verify that a proper type of URL has been specified: typically only imap: URLs should be allowed. Additionally, in the case of IMAP URLs used in SMTP SUBMIT message submission, a check ought to be made to insure that the URL "belongs" to the user: that is, that the access user in the URL matches the authenticated uid for the SUBMIT session. Indeed, typically sites will not even want to advertise BURL in the SMTP SUBMIT server response unless and until the client has authenticated---in terms of the BURL_ACCESS mapping table, this means to start with an entry that enables advertising BURL only if the authentication-identity field in the initial probe is non-empty. Additionally, it is almost always essential to restrict message fetching access via a BURL command's imap: URL to an appropriate set of IMAP servers. As of 7.4-18.01, use of the $M flag in the mapping template (right hand side) is a simple way to enforce that only users' own mailHost values are used as the IMAP server in the eventually executed BURL command. Prior to 7.4-18.01, the BURL_ACCESS mapping table should typically be setup up to explicitly look for (match) a list of known, internal IMAP servers (users' valid mailHost values) and only allow BURL commands using those IMAP server host names.

Thus as of 7.4-18.01, a minimal BURL_ACCESS mapping table might be something like (and initial configuration will generate):

```
BURL_ACCESS

! Initial entry to allow advertising BURL in EHLO response
   *|tcp_*|%*|                                  imap$Y
! Allow BURL commands, connecting to user's own mailHost
   *|*@*|imap://*;URLAUTH=submit+$1*:*        $:A$M$Y
```

Or if hosted domains are in use, then include an additional entry to match the hosted domain user use:

```
BURL_ACCESS
```

```
! Initial entry to allow advertising BURL in EHLO response
   *|tcp_*|%*|                                    imap$Y
! Allow BURL commands, connecting to (default domain) user's own mailHost
   *|*@*|imap://*;URLAUTH=submit+$1*:*            $:A$M$Y
! Allow BURL commands, connecting to (hosted domain) user's own mailHost
   *|*@*|imap://*;URLAUTH=submit+$1*%40$2*:*      $:A$M$Y
```

A better minimal BURL_ACCESS mapping table, implementing the recommended security provisions of RFC 4468 (that is, also requiring TLS encryption as well as SMTP AUTH authentication in order to allow BURL), would be (as of the 7.4-18.01 version):

```
BURL_ACCESS

! Initial entry to allow advertising BURL in EHLO response, if TLS was used
   *|tcp_*|%*|                                    $:T$Yimap
! Allow BURL commands, connecting to (default domain) user's own mailHost
   *|*@*|imap://*;URLAUTH=submit+$1*:*            $:A$:T$M$Y
! Allow BURL commands, connecting to (hosted domain) user's own mailHost
   *|*@*|imap://*;URLAUTH=submit+$1*%40$2*:*      $:A$:T$M$Y
```

In versions prior to 7.4-18.01, a minimal BURL_ACCESS mapping table would be more verbose. For instance, the following makes use of a subsidiary X-IMAP-HOSTS mapping table to list a site's valid IMAP server host names.

```
X-IMAP-HOSTS

  mail1.example.com          $Y
  mail2.example.com          $Y
  mail3.example.com          $Y

BURL_ACCESS

! Initial entry to allow advertising BURL in EHLO response
  *|tcp_*|%*|                                      imap$Y
! Allow BURL commands that request connecting to one of the "known" IMAP hosts
! listed in the X-IMAP-HOSTS mapping table
  *|*@*|imap://*@*/*;URLAUTH=submit+$1*:*          $C$:A$|X-IMAP-HOSTS;$4|$Y$E
! Ditto for users in hosted domains
  *|*@*|imap://*@*/*;URLAUTH=submit+$1*%40$2*:*    $C$:A$|X-IMAP-HOSTS;$4|$Y$E
```

Once the SMTP SUBMIT server has checked that BURL use should be allowed in a particular context, then in order to perform the IMAP URLAUTH operation specified in a BURL command, the SMTP SUBMIT server has to have the ability to log in to the IMAP server as the submit user. The imap_username and imap_password MTA options are used to accomplish this. imap_username specifies the submit user and defaults to the setting of the submituser IMAP option (in legacy configuration, the service.imap.submituser configutil option) if not specified. imap_password specifies the password which of course must match the value set for the submit user account. The imap_password option has no default value.

Technical note: Once logged in as the submit user, then the BURL check of the hashed authentication token in the URLAUTH is performed: only messages accessible to the user

issuing the BURL command will be fetched. That is, the submit user logs in, but it is not the submit user's message access that determines whether a message or message part can be fetched and incorporated but rather the access of the original user is validated from the URLAUTH.

When using BURL to fetch an entire, pre-composed message, a BURL command replaces the usual DATA command in an SMTP dialogue. Alternatively, when the SMTP extension CHUNKING is supported (see RFC 3030 and the `chunking*` channel options), then BURL and BDAT commands may be interlaced---meaning that a new message may be composed incorporating material (for instance, attachments) fetched via BURL commands. Unless explicitly disabled (see `nochunking*` channel options), the MTA's TCP/IP channels (and in particular its SMTP SUBMIT servers) by default support CHUNKING.

Note that new in 7.4-18.01, the MTA has a feature to force disconnection of the SMTP SUBMIT session if a user attempts "too many" bad (failed) BURL commands: see the `disconnectbadburllimit` channel option.

Note that as regards MTA message transaction logging, a message submitted using BURL will include a "U" modifier on its "E" enqueue record, or include "UC" if both BURL and CHUNKING were used; see MTA transaction log entry format.

62.2.2 SMTP SUBMIT FUTURERELEASE support

New in Messaging Server 7.0-0.04, the MTA supports the FUTURERELEASE extension to SMTP SUBMIT, defined in RFC 4865 (SMTP Submission Service Extension for Future Message Release). FUTURERELEASE permits a client to submit a message to the SMTP SUBMIT server for the server to hold onto in its (server) queue until releasing for delivery at a specified time in the future. This can be useful for clients that wish to compose messages "ahead of time", that will only become eligible for delivery at some later time, or which have issues with saving/retaining messages locally themselves, or with ensuring submission at the "right time". A typical use case might be for messages intended as announcements or event reminders.

FUTURERELEASE support is enabled by placing the `futurerelease` channel option on a `submit` source channel used for initial message submission. The `futurerelease` channel option takes a single integer argument: the maximum number of seconds a message can be held. Note that FUTURERELEASE is specifically an SMTP SUBMIT feature: in terms of MTA configuration, only channel(s) marked with the `submit` keyword are capable of offering FUTURERELEASE support. A client attempt to use a FUTURERELEASE parameter in a MAIL FROM command to an SMTP SUBMIT server for which FUTURERELEASE has not been enabled will be rejected with the error:

```
504 5.7.4 FUTURERELEASE extension not available.
```

or

```
503 5.7.1 FUTURERELEASE extension not available.
```

Care should be used when enabling future release since it allows messages to be in effect stored in the MTA's queues. FUTURERELEASE should only be used for channels handling initial message submission and authentication of the message submittor should be required.

Additionally, if you wish to make distinctions about just which senders may use FUTURERELEASE (or for how long different classes of senders may postpone message delivery), consider also using the `mailSMTPSubmitChannel` user attribute (or as of 8.0,

whatever LDAP attribute is named by the `ldap_auth_attr_submit_channel` MTA option) to sort different classes of senders into different source channels with appropriately different `futurerelease` settings.

Note that similar functionality was previously available: specification of a Deferred-delivery: header field in a submitted message coupled with use of the `deferred` channel keyword on the destination channel provided the ability to defer delivery of messages. However, FUTURERELEASE provides superior functionality:

1. The FUTURERELEASE facility is controlled by a setting on the source channel, allowing it to be provided to a subset of the user population. In contrast, placing `deferred` on a destination channel opened the door to *anyone* submitting a message destined for that channel to have that message be held for some period of time.

2. There's no way for a client which sets a Deferred-delivery: header field to know whether or not the header has actually caused the message to be deferred. The FUTURERELEASE SMTP SUBMIT extension, on the other hand, lets the client know how long a message can be held and an error will be returned to the client if the message cannot be held for the time the client requested.

3. With Deferred-delivery:, there was no (automatic) way to place a limit on the amount of time a message could be held. Instead what (normally) happened was that a message held longer than the channel's last `notices` value would simply be returned as undeliverable.

4. Deferred-delivery: settings on messages did not survive a Job Controller restart.

As part of the implementation work for FUTURERELEASE, the old Deferred-delivery: mechanism has been redesigned to address some (but not all) of these points. In particular, the `deferred` channel keyword has been replaced by two new channel options, `deferredsource` and `deferreddestination`. (The `deferred` option is now a synonym for `deferreddestination`.) Both of these options accept an optional integer argument specifying in seconds the maximum amount of time in the future a Deferred-delivery: header can specify and still be honored. The default if no argument is specified is 60*60*24*7, or 7 days. `deferredsource` enables Deferred-delivery: processing on the basis of the source channel while `deferreddestination` operates on destination channels. Finally, Deferred-delivery: settings on messages now survive Job Controller restarts. This addresses all of the points on the above list except (2): use of a Deferred-delivery: header field still provides no mechanism for informing the client whether or not their request will be honored.

Note that, as discussed above, FUTURERELEASE is an extension defined (and supported by the MTA) solely for use with SMTP SUBMIT. A client attempt to use FUTURERELEASE to the MTA's SMTP server will result in the error:

```
504 5.7.4 FUTURERELEASE is a SUBMIT extension; it cannot be used in SMTP.
```

or

```
503 5.7.1 FUTURERELEASE extension not available.
```

62.3 LMTP channels

LMTP over TCP/IP channels are a special case of TCP/IP channels. The MTA's LMTP channels come in two varieties, LMTP client and LMTP server. (Unlike the MTA's general SMTP over TCP/IP channels which are often configured for bidirectional use, the MTA's LMTP channels

are each dedicated to either client *or* server operation, the LMTP client channels operating on "front end" MTAs to transmit via LMTP over TCP/IP to back end Message Store systems, and the LMTP server operating on back end Message Store systems to deposit messages into the Message Store.)

The MTA's LMTP server operates as a sort of combination of the MTA's SMTP server, and the `ims-ms` channel (the delivery into the Message Store portion of the `ims-ms` channel). In particular, the IMAP error statuses that can be encountered by the `ims-ms` channel, discussed further in ims-ms channel error messages, also are relevant for the LMTP server (and indeed, since the LMTP server in turn passes such errors back in the form of SMTP error responses to the LMTP client, they are reported to the LMTP client also).

62.3.1 LMTP client TCP/IP channels

In the MTA's implementation of LMTP, an LMTP client channel is a specially configured TCP/IP channel. At its most basic, any outbound TCP/IP channel configured with the `lmtp` channel option is an LMTP client channel. However, additional channel options should also be set upon an LMTP client channel; see the example in Typical TCP/IP channels and servers.

In the Messaging Server implementation, the intended design is that, to the greatest extent possible, message processing (including address canonicalization, spam/virus filter package processing, user Sieve filter application, defragmentation of MIME message fragments, any content conversion implemented via the conversion channel, *etc.*), will be applied on the "front end" MTAs during (or prior to) enqueue to a `tcp_lmtpcs*` channel. (Then the LMTP server on the back end Message Store host need merely insert the already-entirely-pre-digested message into the Message Store.) In particular:

- In a typical LMTP configuration, various address transformations resulting from the interpretation of the `ldap_delivery_option` MTA option and coordinating LMTP-oriented rewrite rules are usually best handled by setting the `multigate` and `connectcanonical` channel options on `tcp_lmtpcs*` channels.
- Various TCP/IP or LMTP protocol relevant channel options, *e.g.*, `port` and `single_sys`, are commonly set.
- To ensure MIME defragmentation of any messages destined via LMTP to the Message Store, the `defragment` channel option should be set on the `tcp_lmtpcs` channels.
- And so that application of Sieve filters on the "front end" MTAs will properly convey any intended "`fileinto`" action effects back to the back end LMTP server, the `fileinto` channel option should be set on the `tcp_lmtpcs` channel(s).
- (The MTA's LMTP implementation also makes use of proprietary LMTP extensions to convey other important information from the LMTP client to the LMTP server, including quota data and IMAP flag Sieve effects; the MTA's LMTP server and LMTP client negotiate the extension use and send this information automatically.)

In the MTA implementation, the LMTP client channel code *is* the SMTP client channel code, merely configured specially: the many channel options and TCP/IP-channel-specific options affecting SMTP client operation may also be set and affect LMTP client operation. (Note that this in contrast to the MTA's LMTP server, which consists of distinct and separate code from the SMTP server, so configuration options for the SMTP server do not always have LMTP server counterparts.)

62.3.2 LMTP back end TCP/IP channel

On an LMTP back end Message Store host, the typical TCP/IP channels and servers are replaced instead by an LMTP server, defined in Unified Configuration as a `tcp_lmtpss` channel and corresponding `LMTPSS` service under the Dispatcher:

```
msconfig> show channel:tcp_*
role.channel:tcp_lmtpss.official_host_name = tcp_lmtpss-daemon
role.channel:tcp_lmtpss.flagtransfer (novalue)
role.channel:tcp_lmtpss.identnonenumeric (novalue)
role.channel:tcp_lmtpss.lmtp (novalue)
msconfig> show dispatcher.service:*MTP*
role.dispatcher.service:LMTPSS.image = IMTA_BIN:tcp_lmtp_server
role.dispatcher.service:LMTPSS.logfilename = IMTA_LOG:tcp_lmtpss_server.log
role.dispatcher.service:LMTPSS.parameter = CHANNEL=tcp_lmtpss
role.dispatcher.service:LMTPSS.stacksize = 2048000
role.dispatcher.service:LMTPSS.tcp_ports = 225
msconfig> show mapping:PORT_ACCESS
role.mapping:PORT_ACCESS.rule TCP|*|225|*|* $C$|INTERNAL_IP;$1|$Y$E
role.mapping:PORT_ACCESS.rule TCP|* $N500 Do not connect to this machine
msconfig> show mapping:INTERNAL_IP
role.mapping:INTERNAL_IP.rule internal-host-or-subnet $Y
role.mapping:INTERNAL_IP.rule another-internal-host-or-subnet $Y
...
role.mapping:INTERNAL_IP.rule ${::1} $Y
role.mapping.INTERNAL_IP.rule 127.0.0.l $Y
role.mapping:INTERNAL_IP.rule * $N
```

A recipe that creates this configuration would be:

```
description("Configure backend store accessible via LMTP");
keywords(["backend", "store", "LMTP"]);

# Back end's IP address
# Script will prompt for address if left black
#myIP = "10.133.152.193";
myIP = "";

# List of frontend machines that access this store via LMTP
# Script will prompt for addresses if left blank
#feIPs = ["10.133.152.192", "10.133.152.193"];
feIPs = [];

# Prompt for myIP and feIP if needed
if (length(myIP) <= 0) {
  myIP = read("Enter the IP address of this host: ");
}

if (length(feIPs) <= 0) {
  loop {
    ip = read("Enter the IP address of a frontend machine (<RET> if no more): ");
    exitif (ip == "");
    push(feIPs, ip);
  }
```

```
}

# Configure LMTP back end
if exists_channel("tcp_lmtpss") {
  warn("WARNING: tcp_lmtpss channel already exists, will not be added");
} else {
   print("INFO: Adding tcp_lmtpss channel\n");
   add_channel("tcp_lmtpss",
               ["flagtransfer", "",
                "identnonenumeric", "",
                "lmtp", "",
                "official_host_name", "tcp_lmtpss-daemon"]);
}

if exists_group("dispatcher.service:LMTPSS") {
  warn("WARNING: Dispatcher.service:LMTPSS group already exists, will not be created");
} else {
  print("INFO: Creating dispatcher.service:LMTPSS group\n");
  add_group("dispatcher.service:LMTPSS",
            ["image", "IMTA_BIN:tcp_lmtp_server",
             "logfilename", "IMTA_LOG:tcp_lmtpss_server.log",
             "parameter", "CHANNEL=tcp_lmtpss",
             "tcp_ports", "225",
             "stacksize", "2048000"]);
}

# Replace PORT_ACCESS mapping
print("INFO: Replace PORT_ACCESS mapping\n");
replace_mapping("PORT_ACCESS",
                ["TCP|*|225|*|*", "$C$|INTERNAL_IP;$1|$Y$E",
                 "TCP|*", "$N500 Do not connect to this machine"]);

# add PORT_ACCESS mapping entries
internal_ip = ["${::1}", "$Y",
               "127.0.0.1", "$Y",
               "*", "$N"];

# list of IP addresses
ipaddrs = [feIPs];
push(ipaddrs, myIP);

loop {
  exitif (ipaddrs == []);
  ip = pop(ipaddrs);
  push(internal_ip, "$Y");
  push(internal_ip, ip);
}

print("INFO: Replace INTERNAL_IP mapping\n");
replace_mapping("INTERNAL_IP", internal_ip);
```

In legacy configuration, this would be defined as a `tcp_lmtpss` channel in the `imta.cnf` file:

```
tcp_lmtpss flagtransfer identnonumeric lmtp
tcp_lmtpss-daemon
```

and a Dispatcher definition of the LMTPSS server in the `dispatcher.cnf` file:

```
!
! rfc 2033 LMTP server - store
!
[SERVICE=LMTPSS]
PORT=225
IMAGE=IMTA_BIN:tcp_lmtp_server
LOGFILE=IMTA_LOG:tcp_lmtpss_server.log
PARAMETER=CHANNEL=tcp_lmtpss
STACKSIZE=2048000
! Uncomment the following line and set INTERFACE_ADDRESS to an appropriate
! host IP (dotted quad) if the dispatcher needs to listen on a specific
! interface (e.g. in a HA environment).
!INTERFACE_ADDRESS=
```

and with `PORT_ACCESS` and `INTERNAL_IP` mapping tables in the `mappings` file:

```
PORT_ACCESS

 TCP|*|225|*|*   $C$|INTERNAL_IP;$1|$Y$E
 TCP|*           $N500 Do not connect to this machine

INTERNAL_IP

  host's-own-public-IP                    $Y
  another-public-IP-for-host              $Y
  ...
  internal-host-or-subnet                 $Y
  another-internal-host-or-subnet         $Y
  ...
  ${::1}                                  $Y
  127.0.0.1                               $Y
  *                                       $N
```

Note that this configuration is only appropriate for back ends where delivery is only performed by LMTP. In particular, the `PORT_ACCESS` and `INTERNAL_IP` mapping mapping tables shown here would not be appropriate for back ends that also accept mail via SMTP.

62.3.2.1 LMTP server options

The `loglevel` option may be set under the `tcp_lmtp_server` group to override for LMTP server purposes any MTA-wide setting (`mta.logfile.loglevel`) of the nslog log level (controlling any Message Store logging triggered from the LMTP server).

Note that all other options affecting LMTP server operation are instead either set as channel options (see especially the SMTP and LMTP protocol channel options), or as TCP/IP-channel-specific options. In particular, the `logging` channel option on the LMTP server channel, normally `tcp_lmtpss`, controls the MTA side of LMTP server logging.

62.4 TCP/IP-channel-specific options

TCP/IP channels support, in addition to the usual channel options, a number of TCP/IP-channel-specific options.[1] These TCP/IP-channel-specific options are set in legacy configuration in a channel-specific option file, or in Unified Configuration are set under the channel's `options` option. For instance:

```
msconfig> set channel:tcp_local.options.BANNER_PURGE_DELAY 200
```

Note that in Unified Configuration such channel-specific options (those set under the `options` option) are not (currently) schema checked: be careful when setting them as `msconfig` will not warn of invalid values or syntax as it would for regular channel options! (Nor will `msconfig` show whether or not such channel-specific options have any default value.)

In legacy configuration, where an option file is used, such an option file must be named *x*`_option` where *x* is the name of the channel, and stored in the MTA table directory. Since the name of the default channel for the SMTP server is usually `tcp_local`, the option file for the SMTP server is usually `IMTA_TABLE:tcp_local_option` on UNIX; similarly, the name of the default channel for the SMTP SUBMIT server is usually `tcp_submit`, so the option file for the SMTP SUBMIT server is usually `IMTA_TABLE:tcp_submit_option`.

For incoming messages, such TCP/IP-channel-specific options are actually options for the server (SMTP, SMTP SUBMIT, or LMTPSS) as a whole. In particular, the only TCP/IP-channel-specific options that matter for incoming SMTP submissions are those for the SMTP server's default channel, not any channel options for possible other channels that may putatively handle the incoming message due to a `*switchchannel` channel option based "switching". Thus for instance in a typical configuration, for all incoming SMTP messages to port 25, it is only the channel-specific options set under `channel:tcp_local.options` that matter (in legacy configuration, only the `tcp_local_option` file that matters); similarly, the channel-specific options set under `channel:tcp_submit.options` affect all SMTP SUBMIT submissions (in legacy configuration, the `tcp_submit_option` file affects all SMTP SUBMIT submissions); and the channel-specific options set under `channel:tcp_lmtpss.options` affect all messages accepted by the LMTP server (in legacy configuration, the `tcp_lmtpss_option` file affects all messages accepted by the LMTP server). Any other channel-specific options (in legacy configuration, any other `tcp_*_option` file(s)) would only be potentially relevant for outgoing SMTP or LMTP messages---only affect SMTP or LMTP client operation.

Note that while master channel programs (the outgoing channel direction or SMTP client) read their option file each time they run and usually do not keep running for an especially long time, a slave channel program (each SMTP, SMTP SUBMIT, or LMTP server process) reads its options (in legacy configuration, its option file) only when it is first started, hence will not see changes while it continues to run, and its running time may be on the scale of hours. Server processes do automatically shut down periodically, and the Dispatcher creates new server processes in replacement, as required; so changes affecting server processes can get seen eventually, even in the absence of an explicit restart of the relevant server processes---but the change is likely not to take effect "quickly" in the absence of an explicit restart.

Note also that as of Messaging Server 7.0, TCP/IP channel option files for SMTP channels and LMTP client channels (but *not* yet LMTP server channels) are incorporated as part of a compiled configuration, if one exists. So as of Messaging Server 7.0, if a compiled configuration exists, it is necessary to recompile to get changes seen:

```
# imsimta cnbuild
```

Then, no different than ever, when it is important or essential to get changes to take effect *quickly*, as opposed to waiting for existing server processes and channel delivery processes to naturally age, executing

```
# imsimta restart *
```

will restart (the otherwise often quite long-running) SMTP, SMTP SUBMIT, and LMTP server processes; and see the `imsimta qm` utility's `stop` and `start` commands, or alternatively its `stress` and `unstress` commands, which may be used to force quick replacement of the (usually relatively short-lived in any case) SMTP and LMTP client processes (master channel jobs).

[1] Most of the options described actually relate to the SMTP protocol itself, rather than to the TCP/IP transport. As such, other MTA channels that use the SMTP protocol over other transports may have similar options.

62.4.1 TCP/IP-channel-specific options: PERMANENT_ERROR_STRING_552 (string)

Important note: Prior to MS 8.0.1.3, the name of this option was 552_PERMANENT_ERROR_STRING. Unfortunately the leading digit "5" in the option makes this option unworkable in unified configuration due to XML token name restrictions, so the name of the option had to be changed to PERMANENT_ERROR_STRING_552. Both names work in 8.0.1.3 and later legacy configurations.

RFC 821 showed 552 as a temporary error at a RCPT TO: command (although in all other cases 500 numbers are permanent errors); some servers have implemented inconsistent use of the 552 error number. The MTA's SMTP client by default, if this option is not set, normally interprets 552 as a temporary error when seen as a response to an address command (MAIL FROM:, RCPT TO:, or VRFY:); but see below for a new-in-6.3 refinement of the MTA's behavior when a 5xy response is seen to the *first* RCPT TO: command in a transaction. If this SMTP client option is set, then when an 552 response is received to an address command (MAIL FROM:, RCPT TO:, or VRFY), then the string associated with the last line of that response (excluding the initial "552 ", but including any leading *x.y.z* extended error code) is compared against this string. If, and only if, the string matches will the 552 error be treated as permanent. Case is not significant in the comparison. For instance, if dealing with a remote server that will return "552 user no longer present" as an "intended" permanent error, then this option could be set to:

```
PERMANENT_ERROR_STRING_552=user no longer present
```

This option is not supported by the LMTP client; it is an SMTP client-only option.

New in 6.3, if the MTA's SMTP client sees any 5xy response including a 552 response to its *first* RCPT TO: command in a transaction and where after issuing its error the remote SMTP server then immediately disconnects the session, (which behavior is, by the way, a standards violation on the part of the remote SMTP server), then the MTA (regardless of the setting of this option) will unconditionally interpret this as a permanent error for that recipient, but will reenqueue any additional recipients of that message (copy) for another delivery attempt.

New in 7.0, the option value may use glob-style wildcards; this new feature is available to aid in cases where a remote server's error response includes the input address, hence where a static, fixed value does not provide adequate matching.

As of 8.0.1.3 multiple patterns can also be specified, separated by vertical bars ("|").

62.4.2 TCP/IP-channel-specific options: ALLOW_ETRNS_PER_SESSION (integer)

This SMTP server option sets a limit on the number of ETRN commands accepted per session. The default is 1. When the limit is exceeded, the SMTP server will issue an error response to any additional ETRN command of (prior to MS 7.0.5):

```
550 5.7.1 ETRN session limit reached.
```

or as of MS 7.0.5:

```
458 4.7.1 ETRN session limit reached
```

See also the `*etrn` channel options for a discussion of channel options affecting the MTA's response to ETRN commands.

62.4.3 TCP/IP-channel-specific options: ALLOW_RECIPIENTS_PER_TRANSACTION (integer)

This SMTP/LMTP server option set s a limit on the number of recipients allowed per message, and on the number of address verifications (VRFY: commands) permitted during a transaction. (Note that the count of actual recipients, RCPT TO:, is separate from the count of verifies, VRFY:; that is, VRFY:'s do not count against the RCPT TO: limit, nor do RCPT TO:'s count against the VRFY: limit; each is limited *independently* to the `ALLOW_RECIPIENTS_PER_TRANSACTION` value.) Any additional recipients will be rejected with a temporary error response to the RCPT TO: command:

```
451 4.5.3 Too many recipients specified
```

Any additional address verification attempts will be rejected with a temporary error

```
451 4.5.2 Verification blocked; too many operations performed
```

at the VRFY: line. The default is 128. (In iMS 5.2 and earlier, the default was no limit.) See also the `recipientlimit` and (in the case of SMTP) `disconnectrecipientlimit` channel options , and the `ldap_recipientlimit` and `ldap_domain_attr_recipientlimit` MTA options. Note that with any setting of `ALLOW_RECIPIENTS_PER_TRANSACTION` other than the maximum allowed integer (2147483647), the SMTP server will not allow multiple, comma-separated values on the RCPT TO: command line. (The LMTP server, in contrast, will always allow multiple, comma-separated values on the RCPT TO: command line --- though the MTA's LMTP client will not itself send such a RCPT TO command.)

Note also that, unlike a channel `recipientlimit` (which may be completely overridden on a per-user basis using the LDAP attribute named by the `ldap_recipientlimit` MTA option),

the TCP/IP-channel-specific option ALLOW_RECIPIENTS_PER_TRANSACTION imposes a hard upper-limit, which other settings may only modify by imposing even stricter limits but may not ignore (increase).

62.4.4 TCP/IP-channel-specific options: ALLOW_REJECTIONS_BEFORE_DEFERRAL (integer)

This SMTP server option sets a limit on the number of bad (failing) RCPT TO: or VRFY: addresses that will be allowed during a single session. (Note that unlike ALLOW_RECIPIENTS_PER_TRANSACTION and REJECT_RECIPIENTS_PER_TRANSACTION where the RCPT TO: and VRFY: counts are separate, this is a *combined* count; failing RCPT TO:'s and VRFY:'s are added together.) That is, after the specified number of To: addresses have been rejected at the RCPT TO: or at VRFY:, all subsequent recipients, good or bad, will be rejected at their RCPT TO: presentations with a temporary error

```
451 4.5.3 Too many rejections; try again later
```

or at VRFY: presentations with a temporary error

```
451 4.5.3 Verification blocked; too many rejections
```

The default is (essentially) no limit. See also the deferralrejectlimit channel option.

Compare this option with the REJECT_RECIPIENTS_PER_TRANSACTION TCP/IP-channel-specific option, which will cause *all* recipients to be rejected at the DATA command with a temporary error

```
451 4.5.3 Transaction blocked; too many recipients specified
```

62.4.5 TCP/IP-channel-specific options: ALLOW_SESSION_BLOCKS (integer)

The ALLOW_SESSION_BLOCKS TCP/IP-channel-specific option for the SMTP server imposes a block limit on the session as a whole. The session is disconnected if this limit is exceeded. If MTA transaction logging is enabled, the reason field in the close ("X") entry will show:

```
Maximum session data limit of xK octets has been exceeded
```

The default of 0 means no limit is imposed.

62.4.6 TCP/IP-channel-specific options: ALLOW_TRANSACTION_BLOCKS (integer)

The ALLOW_TRANSACTION_BLOCKS TCP/IP-channel-specific option for the SMTP server imposes a block limit on any transactions. The session is disconnected if this limit is exceeded. If MTA transaction logging is enabled, the reason field in the close ("X") entry will show:

```
Maximum transaction data limit of xK octets has been exceeded
```

The default of 0 means no limit is imposed.

62.4.7 TCP/IP-channel-specific options: ALLOW_TRANSACTIONS_PER_SESSION (integer)

This SMTP/LMTP server option sets a limit on the number of messages allowed per connection. The default is no limit. When the number of messages specified is exceeded, then normally the temporary error

```
451 4.5.3 No more transactions allowed
```

is returned at the MAIL FROM: line; but see the TRANSACTION_LIMIT_RCPT_TO TCP/IP-channel-specific option which will cause this temporary error to instead be issued at the RCPT TO: line. See also the transactionlimit and (in the case of SMTP) disconnecttransactionlimit channel options, which may be used to set such limits on a per-channel basis (hence providing finer-grained control than the ALLOW_TRANSACTIONS_PER_SESSION option which applies to all channels handled by the same default Dispatcher SMTP or LMTP service).

62.4.8 TCP/IP-channel-specific options: ATTEMPT_TRANSACTIONS_PER_SESSION (integer)

This SMTP/LMTP client option sets a limit on the number of messages the MTA will attempt to transfer during any one connection session.

62.4.9 TCP/IP-channel-specific options: AUTH_DEBUG (string)

(New in Messaging Server 7.4-18.01.) The AUTH_DEBUG SMTP server option allow enabling SASL (HULA) debugging. The string argument should consist of one or more, space-separated, of "perf", "connect", "authserv", "hula". In order for this option to take full effect, slave_debug debugging must be enabled. When AUTH_DEBUG is set, it overrides the debugkeys Base option setting for SMTP authentication logging purposes.

As an alternative to this channel-level enabling of SASL debug, note the PORT_ACCESS flag $A is an alternate way to enable SASL debug on a per-connection basis.

62.4.10 TCP/IP-channel-specific options: AUTH_PASSWORD (string), AUTH_USERNAME (string), EXTERNAL_IDENTITY (string)

New in Messaging Server 7.0 update 1. In legacy configuration, these SMTP/LMTP client options provide the credentials for SASL (SMTP AUTH) use by the SMTP/LMTP client; in Unified Configuration, these options are *not* used, having been replaced instead by the authpassword, authusername, and externalidentity channel options.

SASL authentication will be attempted if either the maysaslclient or mustsaslclient channel option is set, with success required for message transmission if mustsaslclient is set.

The PLAIN and EXTERNAL SASL mechanisms are currently supported. The AUTH_USERNAME and AUTH_PASSWORD TCP/IP-channel-specific options provide the credentials for the plain mechanism and the EXTERNAL_IDENTITY TCP/IP-channel-specific option provides the identity string for SASL EXTERNAL. (EXTERNAL_IDENTITY can be set to the empty string to enable SASL EXTERNAL without an identity string.)

See the Base certmap options for general configuration of certificate mapping, as needed for EXTERNAL authentication via client certificates.

62.4.11 TCP/IP-channel-specific options: BANNER_ADDITION (string)

This SMTP/LMTP server option adds the specified string to the SMTP/LMTP banner line. If the length of this addition string plus the MTA's regular banner line string (as constructed normally by the MTA---see in particular the CUSTOM_VERSION_STRING TCP/IP-channel-specific option) would be more than 80 characters, then the additional text will be put on a continuation line as part of a multi-line banner response, rather than being included on the initial 220 line. If the vertical bar character or "pipe" character, |, is included in the BANNER_ADDITION string, it is interpreted as a request for a line break; the MTA's regular banner line will be output as the first line of a multi-line banner response, and then each vertical bar separated portion of the string (including the very first, even if it is "short"), will be output on its own, separate line.

62.4.12 TCP/IP-channel-specific options: BANNER_HOST (string)

This option applies to both the SMTP/LMTP server and the SMTP/LMTP client. If specified, this value takes precedence over even a local_host_alias for the name used in the 220 banner (SMTP/LMTP server) and on the HELO/EHLO/LHLO line (SMTP/LMTP client).

62.4.13 TCP/IP-channel-specific options: BANNER_RECEIVE_TIME (integer)

This SMTP/LMTP client option specifies how long to wait to receive the SMTP/LMTP initial banner from the server. The default value is 2 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.14 TCP/IP-channel-specific options: BANNER_REVERSE_HOST (boolean)

This option applies to the SMTP/LMTP server. It defaults to 0 (false). If set to 1 (true), when a connection is accepted a reverse DNS lookup is performed on the local host's IP address.

if a result is returned it becomes the name used in the server's 220 banner. This value takes precedence over any BANNER_HOST value as well as any local_host_alias value.

62.4.15 TCP/IP-channel-specific options: BANNER_PURGE_DELAY (integer)

(New in MS 6.3.) A useful spam-fighting strategy is to delay sending the SMTP banner for a brief time (half a second, say), then clear the input buffer, and finally send the banner. The reason this works is that many spam clients are not standards-compliant and start blasting SMTP commands as soon as the connection is open. Spam clients that do this when this capability is enabled will lose the first few commands in the SMTP dialogue, rendering the remainder of the dialogue invalid.

The BANNER_PURGE_DELAY SMTP server option exists to implement this strategy. Set the BANNER_PURGE_DELAY option to the number of centiseconds to delay before purging the input buffer and sending the banner. The default value of 0 disables both the delay and purge. See also the PORT_ACCESS mapping table $D flag, which can also be used to set such a banner purge delay, in a more selective manner And note that the disconnectbadcommandlimit channel option may be of interest when using any such banner purge delay technique.

62.4.16 TCP/IP-channel-specific options: BUFFER_SIZE (integer)

(New in MS 6.3.) The BUFFER_SIZE option is available for the LMTP server only. It sets the buffer size for the LMTP server to do in-memory buffering of incoming messages, overriding the default 1,000,000 bytes. Thus this LMTP server option is analogous to the max_internal_blocks MTA option which controls similar buffering for components other than the LMTP server (and has no relationship to the MTA option with a similar name buffer_size but a completely different meaning).

Messaging exceeding the limit will be written to a temporary file and the temporary file will then be mapped into memory.

In unified configuration the option can be set as follows:

```
msconfig> set channel:tcp_lmtpss.options.buffer_size 1000000
```

62.4.17 TCP/IP-channel-specific options: CHECK_SOURCE (0 or 1)

The MTA's SMTP and LMTP server normally attempts to determine the name of the host from which a connection has been received, as specified by the ident* channel options. When the determined name does not match the name presented by the remote SMTP/LMTP client on the HELO/EHLO/LHLO line, the CHECK_SOURCE TCP/IP-channel-specific option controls whether the name found from a DNS lookup (or the IP domain literal, if DNS lookups have been disabled such as with the identnonenumeric channel option) is included in the constructed Received: header as a comment after the presented name. A value of 1 (the default) enables the inclusion of the determined name when different from the presented

name. A value of 0 disables the inclusion of any such comment and thus eliminates one of the more useful checks of message validity. For the SMTP server, setting CHECK_SOURCE to 0 also effectively blocks switchchannel channel switching from taking effect.

62.4.18 TCP/IP-channel-specific options: CLIENT_CERT_NICKNAME (string)

(New in Messaging Server 7.0.5) This SMTP client option specifies the certificate to use for SMTP client authentication via STARTTLS. The nickname follows the same format as other certificate nicknames in Messaging Server. It is split at the first ":" character, and the portion prior to the colon is the security token; the portion subsequent to the ":" character is the certificate nickname in that security token. If no ":" character is present, then the NSS built-in certificate databases are used. Note that CLIENT_CERT_NICKNAME should only be used with IGNORE_BAD_CERT=0 set, as otherwise the security it can provide is defeated.

62.4.19 TCP/IP-channel-specific options: CLIENT_STACK_SIZE (integer)

New in MS 8.0.1.3. This SMTP/LMTP client option takes an integer number indicating the stack size to allocate for SMTP client threads. The default value is 1024*1024 = 1048576. It is strongly recommended that this value only be increased.

62.4.20 TCP/IP-channel-specific options: COMMAND_RECEIVE_TIME (integer)

This SMTP/LMTP server option specifies how long to wait to receive general SMTP commands, (commands other than those with explicitly specified time out values set using other specifically named options). The default value is 10 minutes

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.21 TCP/IP-channel-specific options: COMMAND_TRANSMIT_TIME (integer)

This SMTP/LMTP client option specifies how long to spend transmitting general SMTP commands, (commands other than those with explicitly specified time out values set using other specifically named options). The default value is 10 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.22 TCP/IP-channel-specific options: CONTINUATION_CHARS (string)

DEPRECATED.

The CONTINUATION_CHARS TCP/IP-channel-specific option is supported by the SMTP server (but not the LMTP server), and by SMTP and LMTP clients. It takes a list of integer values specifying the ASCII positions of additional characters that act like the continuation character specified using the contchar channel option; that is, it specifies additional characters that will be accepted as line continuation characters.

This option was used to accomodate the peculiar form of batch SMTP that was employed by BITNET. Now that BITNET is no more, this option is obsolete and deprecated.

62.4.23 TCP/IP-channel-specific options: CUSTOM_VERSION_STRING (string)

Use of this option is **NOT RECOMMENDED!** This SMTP server option (not supported by the LMTP server) sets the IMTA version string to advertise on the SMTP server's 220 banner line. By default, the string "Oracle Communications Messaging Server <version-number> (<build-date>)" is used. This option is thus a complement to the (also not recommended) received_version MTA option.

62.4.24 TCP/IP-channel-specific options: DATA_RECEIVE_TIME (integer)

This SMTP/LMTP server option specifies how long to wait to receive each line of data during the DATA phase of an SMTP/LMTP dialogue. The default is 5 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.25 TCP/IP-channel-specific options: DATA_TRANSMIT_TIME (integer)

This SMTP/LMTP client option specifies how long to spend transmitting data during an SMTP/LMTP dialogue. The default is 10 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.26 TCP/IP-channel-specific options: DISABLE_ADDRESS (0 or 1)

The MTA's SMTP server implements a private command XADR. This command returns information about how an address is routed internally by the MTA as well as general channel information. Releasing such information may consistute a breach of security for some sites. Settting the SMTP server option DISABLE_ADDRESS to 1 disables the XADR command, so that the SMTP server returns the response

```
550 5.7.0 XADR command has been disabled.
```

to XADR attempts. The default is 0, which enables the XADR command. In 8.0, the default has changed to 1, disabling the XADR command.

SMTP server probes of the PORT_ACCESS mapping table can enable use of XADR (overriding a more general `DISABLE_ADDRESS=0` setting) for connections from particular source IPs (*e.g.*, the host itself, 127.0.0.1, and particular administrator systems) via the (new in 7.0) $V flag.

62.4.27 TCP/IP-channel-specific options: DISABLE_CIRCUIT (0 or 1)

The MTA's SMTP server implements a private command XCIR. This command returns MTA circuit check information. Releasing such information may consistute a breach of security for some sites. Setting the SMTP server option `DISABLE_CIRCUIT` to 1 disables the XCIR command, so that the SMTP server responds with the error

```
550 5.7.0 XCIR command has been disabled.
```

to any XCIR command attempts. Setting `DISABLE_CIRCUIT` to 0 enables the XCIR command. If `DISABLE_CIRCUIT` is not explicitly set, then use of the XCIR command is controlled by the `DISABLE_GENERAL` TCP/IP-channel-specific option setting. In 8.0, the default has changed to 1, disabling the XCIR command.

SMTP server probes of the PORT_ACCESS mapping table can enable use of XCIR (overriding a more general `DISABLE_ADDRESS=0` or `DISABLE_GENERAL=0` setting) for connections from particular source IPs (*e.g.*, the host itself, 127.0.0.1, and particular administrator systems) via the (new in Messaging Server 7.0) $V flag.

62.4.28 TCP/IP-channel-specific options: DISABLE_EXPAND (0 or 1)

The SMTP EXPN command is used to expand mailing lists. Exposing the contents of mailing lists to outside scrutiny may constitue a breach of security for some sites. The SMTP server option `DISABLE_EXPAND`, when set to 1, disables the EXPN command completely, causing the SMTP server to issue the response

```
550 5.7.2 EXPN command has been disabled
```

to any EXPN command. The default value is 0, which causes the EXPN command to work normally.

See also the `expnallow`, `expndefault`, and `expndisable` channel options that can be used to control this behavior on a per-channel, rather than per-SMTP-server, basis. And see the `expandable_default` MTA option which sets an MTA-wide default.

Note that mailing list expansion can also be blocked on a list-by-list basis with the Unified Configuration alias options `alias_expandable` and `alias_nonexpandable`, or the [EXPANDABLE] and [NONEXPANDABLE] alias file named parameters.

Note that an LDAP attribute named by the `ldap_expandable` MTA option (normally set to the attributes `mgmanMemberVisibility` and `expandable`) can also be used to disable expansion on a list-by-list basis (and can be used on user entries as well).

62.4.29 TCP/IP-channel-specific options: DISABLE_GENERAL (0 or 1)

The MTA's SMTP server implements a private command XGEN. This command returns status information about whether a compiled configuration and compiled character set are in use. Releasing such information may constitute a breach of security for some sites. Setting the SMTP server option `DISABLE_GENERAL` to 1 disables the XGEN command, so that the MTA responds with

```
550 5.7.0 XGEN command has been disabled.
```

to any XGEN command. The default is 0, which enables the XGEN command. In 8.0, the default has changed to 1, disabling the XGEN command.

SMTP server probes of the PORT_ACCESS mapping table can enable use of XGEN (overriding a more general `DISABLE_GENERAL=0` setting) for connections from particular source IPs (*e.g.*, the host itself, 127.0.0.1, and particular administrator systems) via the (new in Messaging Server 7.0) $V flag.

62.4.30 TCP/IP-channel-specific options: DISABLE_SEND (0 or 1)

This option applies to the MTA's SMTP server. The SMTP server is able to support the SEND FROM:, SAML FROM:, and SOML FROM: SMTP commands (see RFC 821) that allow for sending a broadcast message to a logged in user on the MTA system rather than or in addition to, an e-mail message. This support is disabled by default (`DISABLE_SEND=1`), so that the MTA will respond with

```
550 5.7.2 SEND/SAML/SOML commands have been disabled.
```

to any such commands. To enable support for these SMTP commands, set `DISABLE_SEND=0`.

62.4.31 TCP/IP-channel-specific options: DISABLE_STATUS (0 or 1)

The MTA's SMTP server implements a private command XSTA. This command returns status information about the number of messages processed and currently in the MTA channel queues, status information about current associations (TCP/IP connections), and status information about LDAP lookup caching. Releasing such information may constitute a breach of security for some sites. Settting the SMTP server option `DISABLE_STATUS` to 1 disables the XSTA command, so that the SMTP server responds with

```
550 5.7.0 XSTA command has been disabled.
```

The default is 0, which enables the XSTA command. In 8.0, the default has changed to 1, disabling the XSTA command.

SMTP server probes of the PORT_ACCESS mapping table can enable use of XSTA (overriding a more general `DISABLE_STATUS=0` setting) for connections from particular source IPs (*e.g.*,

the host itself, 127.0.0.1, and particular administrator systems) via the (new in Messaging Server 7.0) $V flag.

62.4.32 TCP/IP-channel-specific options: DOT_TRANSMIT_TIME (integer)

This SMTP/LMTP client option specifies how long to spend transmitting the dot (period) terminating the data in an SMTP/LMTP dialogue. The default is 10 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.33 TCP/IP-channel-specific options: FAST_SMTP_SESSION_TIME_LIMIT (integer)

This SMTP server option controls the time threshold for whether or not to create a *.data-failed file in cases where the SMTP connection has aborted (for instance, due to an SMTP client timing out) after the MTA SMTP server has received the final "." terminating the data, but before the MTA has acknowledged receipt with a "250 2.5.0 Ok" message. If the transaction (message transfer) has taken more than this amount of time, in seconds, then normally (see the REUSE_TIMED_OUT_TRANSFERS TCP/IP-channel-specific option) a *.data-failed file will be created in such cases where the MTA has not been able to successfully send back its acknowledgement of receipt of the message. If a transaction has taken less than the specified amount of time, in seconds, then a *.data-failed file will not be created. The default is 30.

62.4.34 TCP/IP-channel-specific options: HELLO_RECEIVE_TIME (integer)

(New in Messaging Server 7.0-3.01.) This SMTP server (but not LMTP server) option controls how long the SMTP server will wait for a client's initial HELO or EHLO command. (Prior to the addition of this option, that timeout was controlled by the COMMAND_RECEIVE_TIME TCP/IP-channel-specific option, which still controls the SMTP server's timeout for other commands.) The default is 1 minute.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.35 TCP/IP-channel-specific options: HIDE_VERIFY (0 or 1)

The SMTP VRFY command can be used to establish the legality of an address prior to actually using it. Unfortunately this command has been abused by automated query engines in some cases. The SMTP server option HIDE_VERIFY, when set to 1, tells the MTA not to return any useful information in the VRFY command result; in particular, when HIDE_VERIFY=1 is set the MTA will, for arguments that are at least syntactically legal, return for addresses that syntactically might be "local" only:

```
252 2.5.0 Possible local address <address>
```

or return the same response it returns regardless of HIDE_VERIFY setting for apparently remote addresses, namely:

```
252 2.5.0 Possible remote address not checked
```

The default value is 0, which causes VRFY to act normally. See also the channel options controlling this behavior, vrfyallow, vrfydefault, and vrfyhide.

62.4.36 TCP/IP-channel-specific options: IGNORE_BAD_CERT (bit-encoded integer)

This SMTP client and SMTP server option controls the MTA's reaction to bad (remote) certificates. Bit 0 (value 1) controls whether a bad client certificate is ignored even when musttls or musttlsserver is set. Bit 1 (value 2) controls whether a bad server certificate is ignored even when musttls or musttlsclient is set. (Note that bad certificates are always allowed in other cases -- *e.g.*, when maytls* is set.) The default is 3.

62.4.37 TCP/IP-channel-specific options: INITIAL_COMMAND (string)

The SMTP client option INITIAL_COMMAND may be used to specify an initial command to send, at the beginning of each SMTP session. By default, it is not set.

62.4.38 TCP/IP-channel-specific options: KILLED_IP_TIMEOUT (integer seconds)

The SMTP server option KILLED_IP_TIMEOUT may be used to specify an the timeout value, in seconds, for entries made in the internal killed IP hash table associated with the imsimta connkill -ip command. The default is twice the value of the COMMAND_RECEIVE_TIME TCP/IP channel-specific option.

Note that the timeout value affects storage of all IP entries, however, the setting is especially relevant when the -sticky switch is used.

62.4.39 TCP/IP-channel-specific options: KILLED_USER_TIMEOUT (integer seconds)

The SMTP server option KILLED_USER_TIMEOUT may be used to specify an the timeout value, in seconds, for entries made in the internal killed user hash table associated with the imsimta connkill -user command. The default is 600 seconds.

Note that the timeout value affects storage of all user entries, however, the setting is especially relevant when the -sticky switch is used.

62.4.40 TCP/IP-channel-specific options: LOG_BANNER (0 or 1)

The SMTP/LMTP client option LOG_BANNER controls whether the remote SMTP/LMTP server banner line is included in mail.log* file entries when the logging channel option is

enabled for the channel. A value of 1 (the default) enables logging of the remote SMTP server banner line; a value of 0 disables it. LOG_BANNER also affects whether a remote SMTP/LMTP banner line, if available, is included in bounce messages generated by the channel.

62.4.41 TCP/IP-channel-specific options: LOG_CONNECTION (integer)

The LOG_CONNECTION TCP/IP-channel-specific option controls whether or not connection information, *e.g.*, the domain name of the SMTP client sending the message, is saved in mail.log file entries and the writing of connection records when the logging channel option is enabled for the channel; it applies to both SMTP server and SMTP client, and to both LMTP server and LMTP client. This value is a decimal integer representing a bit-encoded integer, the interpretation of which is given in the table below.

Table 62.2 LOG_CONNECTION TCP/IP-channel-specific option bit mask values

Bit	Value	Usage
0	1	When set, connection information is included in E and D log records.
1	2	When set, connection open/close/fail records are logged by message enqueue and dequeue agents such as the SMTP and X.400 clients and servers.
2	4	When set, I records are logged recording ETRN events.

Bit 0 is the least significant bit.

This TCP/IP-channel-specific option defaults to the setting of the general MTA option log_connection (as set in the MTA option file (legacy configuration) or at the mta level in Unified Configuration). The TCP/IP-channel-specific option may be set explicitly to override on a per-channel basis the behavior requested by the general option. That is, a pair of settings such as:

```
msconfig> set mta.log_connection 7
msconfig> set channel:tcp_submit.options.LOG_CONNECTION 0
```

means that arbitrary tcp_* channels will log connection information, except for the tcp_submit channel which will *not* log such connection information.

62.4.42 TCP/IP-channel-specific options: LOG_TRANSPORTINFO (0 or 1)

The SMTP/LMTP client option LOG_TRANSPORTINFO controls whether or not transport information, such as the sending and receiving side IP numbers and port numbers:

```
TCP|MTA-IP|MTA-port|remote-IP|remote-port
```

are included in mail.log file dequeue entries when the logging channel option is enabled for the channel. A value of 1 enables transport information logging. A value of 0 disables it. If not explicitly set, the LOG_TRANSPORTINFO TCP/IP-channel-specific option defaults

to 1 (transport information logging enabled) if at least one of bits 0 or 3 (values 1 or 8) is set for the MTA option `log_connection` (`log_connection` as set in the MTA option file in legacy configuration, or at the `mta` level in Unified Configuration), and otherwise `LOG_TRANSPORTINFO` defaults to 0. The `LOG_TRANSPORTINFO` TCP/IP-channel-specific option may be set explicitly for a channel to control the logging of transport information regardless of whether connection logging is generally enabled.

`LOG_TRANSPORTINFO` also affects whether transport information, if available, is included in bounce messages generated by the channel.

62.4.43 TCP/IP-channel-specific options: MAIL_TRANSMIT_TIME (integer)

This SMTP/LMTP client option specifies how long to spend transmitting the SMTP command MAIL FROM:. The default is 10 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option. In particular, setting `TIMEOUT_MULTIPLIER` to 1 will change the units of this option to seconds.

62.4.44 TCP/IP-channel-specific options: MAILBOX_BUSY_FAST_RETRY (integer)

(New in MS 6.3.) This LMTP client option controls whether the LMTP client requests that the Job Controller schedule the message's next retry attempt with a special "short delay" (overriding the channel's usual `backoff` setting) in cases of temporary errors with a 4.2.1 extended response code. Since 4.2.1 is the extended response code used for the "Mailbox is busy" (IMAP_MAILBOX_LOCKED) error condition, which can occur when a mailbox is locked by another process due to another message delivery or to an IMAP message operation, in such cases attempting another delivery "quickly" is likely to be useful.

The default is 1, meaning to ask the Job Controller for a fairly quick retry. Setting the option to 0 disables the override of `backoff`. Positive values greater than 1 result in a retry, but not quite as quick of one. The default value of 1 corresponds to the (not configurable) formula that the `ims-ms` channel uses for such retries. (In 6.3 and 7.0.5.32 and later, the formula used is n + rand() % (120 * n) seconds. In release 7.0 through 7.0.5.31.0, the formula used is n + rand() % (4 * n) seconds.)

As of MS 8.0.2.2, this option is also supported by ims-ms channels.

62.4.45 TCP/IP-channel-specific options: MAX_A_RECORDS (integer)

This SMTP/LMTP client option specifies the maximum number of A records that the MTA should try using when attempting to deliver a message. The default is no limit.

62.4.46 TCP/IP-channel-specific options: MAX_B_ENTRIES (integer)

New in MS 6.2. This TCP/IP-channel-specific SMTP server option specifies the maximum number of "B" entries per SMTP connection session that the server will write to the MTA

message transaction log (`mail.log*`) file. Bad commands sent to the SMTP server are logged as "B" records in the MTA's message log file (`mail.log*`), if message logging has been enabled (the `logging` channel option). In such "B" entries, the recipient address field will contain the bad command that was rejected by the SMTP server as invalid, while the diagnostic field will contain the response the SMTP server gave. Once the value of `MAX_B_ENTRIES` has been reached, the SMTP server writes its final (for that session) "B" record, with the string

```
(limit reached; last B record for this session)
```

appended to the diagnostic field. The default value for `MAX_B_ENTRIES` is 10. Note that keeping this value set to a reasonable size keeps the MTA from wasting too much time writing "B" entries for unrecognized/illegal command attempts, so that deliberate fake command attempts will not distract the MTA from more important work; *i.e.*, it protects against a certain form of "denial of service" attack. See also the (new in MS 6.2) `disconnectbadcommandlimit` channel option.

62.4.47 TCP/IP-channel-specific options: MAX_CLIENT_THREADS (integer)

This SMTP/LMTP client option takes an integer number indicating the maximum number of simultaneous, outbound connections that the client channel program will allow. Note that multiple processes may be used for outbound connections, depending on how you have channel processing pools set up. This TCP/IP-channel-specific option controls the number of threads per process. The default value is 10.

62.4.48 TCP/IP-channel-specific options: MAX_H_ENTRIES (integer)

New in MS 8.1. This TCP/IP channel SMTP server option specifies the maximum number of "J" `mail.log*` entries to write during a single SMTP connection session. The default is 10.

Note that keeping this value set to a reasonable size keeps the MTA from wasting too much time writing "J" entries for VRFY and EXPN commands, so that deliberate abuse of these commands will not distract the MTA from more important work; *i.e.*, it protects against a certain form of "denial of service" attack.

When this limit is reached, the final "J" record for the session will contain (in addition to the "regular" text in a "J" record) the extra text "(limit reached; last H record for this session)".

62.4.49 TCP/IP-channel-specific options: MAX_HELO_DOMAIN_LENGTH (integer)

This SMTP/LMTP server option may be used to specify a maximum length of host name that a remote client may put on its HELO or EHLO line. If a longer name is seen on the HELO or EHLO line, then the SMTP or LMTP server will reject the command with an error (in the case of the SMTP server) of

```
501 5.5.0 Argument to HELO is too long.
```

or

```
501 5.5.0 Argument to EHLO is too long.
```

or (in the case of the LMTP server) of

```
501 5.5.0 Argument to LHLO is too long.
```

as appropriate. The default is no limit.

62.4.50 TCP/IP-channel-specific options: MAX_J_ENTRIES (integer)

This TCP/IP channel SMTP server option specifies the maximum number of "J" `mail.log*` entries to write during a single SMTP connection session. (Prior to MS 6.2 it also limited how many increments of the "Rejected" counter would occur during a single transaction.) The default is 10.

Note that keeping this value set to a reasonable size keeps the MTA from wasting too much time writing "J" entries for unsuccessful submission attempts, so that deliberate unsuccessful submission attempts will not distract the MTA from more important work; *i.e.*, it protects against a certain form of "denial of service" attack.

When this limit is reached, the final "J" record for the session will contain (in addition to the "regular" text in a "J" record) the extra text "(limit reached; last J record for this session)". (As of MS 6.2, the "Rejected" counter will continue to be incremented for each additional rejected attempt during the session.)

62.4.51 TCP/IP-channel-specific options: MAX_MX_RECORDS (integer <= 32)

This TCP/IP channel SMTP/LMTP client option specifies the maximum number of MX records that the MTA should try using when attempting to deliver a message. The maximum value is 32, which is also the default. (Note that the IP_ACCESS mapping table provides an alternate means to achieve such limits.)

62.4.52 TCP/IP-channel-specific options: MAX_SERVER_THREADS (integer; <= 47 on Solaris)

This TCP/IP channel SMTP/LMTP server option has little relevance today, and the little effect is does have is Solaris-specific. (Formerly, for the PMDF, pre-Dispatcher multithreaded SMTP server, it controlled the maximum number of simultaneous, inbound connections that the pre-Dispatcher multithreaded SMTP server program would allow. Note that since only one such server process was allowed, this option effectively controlled the total number of simultaneous, inbound SMTP connections that older versions of PMDF could handle.) Nowadays, this option's sole effect is that on Solaris only, it is taken into account in deciding the maximum number of file descriptors allowed for an SMTP server process. Since this value is multiplied by 5 and then 20 added, the effect of the default of 40 is that a maximum of 220 file descriptors are allowed.

The default value is 40. Note that setting a value of 48 or more on Solaris will cause the server process to exit with an error.

62.4.53 TCP/IP-channel-specific options: OPEN_CONNECTION_TIME (integer)

This option controls how long the SMTP/LMTP client waits for a TCP/IP connection to open. The default is 2 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option. In particular, setting `TIMEOUT_MULTIPLIER` to 1 will change the units of this option to seconds.

62.4.54 TCP/IP-channel-specific options: PACKET_SIZE_LIMIT (integer)

RESTRICTED. This option exists for potential debugging purposes; it should not normally be set by sites.

The `PACKET_SIZE_LIMIT` TCP/IP-channel-specific option is available both for SMTP and for LMTP. The default is 4096. Attempts to set this option to more than 4096 will result in a value of 4096 being used.

62.4.55 TCP/IP-channel-specific options: PROXY_PASSWORD (string)

The legacy configuration TCP/IP-channel-specific option `PROXY_PASSWORD` has been replaced in Unified Configuration by the `smtpproxypassword` MTA option.

In legacy configuration, in order for the MMP to perform SMTP proxying, this SMTP server option must be set to the same "secret" password as the MMP's `smtpproxypassword` value. If the `PROXY_PASSWORD` TCP/IP-channel-specific option is not set, client attempts to use the XPEHLO command will receive an error:

```
503 5.5.0 Proxy support is not enabled.
```

If the `PROXY_PASSWORD` TCP/IP-channel-specific option is set but its value does not match the MMP's value, client attempts to use the XPEHLO command will receive an error:

```
535 5.7.8 SMTP proxy authentication check failed.
```

62.4.55.1 XPEHLO proxy validation: `proxy_hash_algorithm` (hash algorithm name)

New in MS 8.1.0.3. The `proxy_hash_algorithm` MTA option controls what hash algorithm the MTA uses to authenticate the contents of an XPEHLO command. The value should be a hash algorithm supported by the MTA, one of MD2, MD4, MD5, SHA1, SHA256, SHA512, MD128, or MD160. MD5 is the default. Note that the setting of this option must be the same across a deployment for successful operation of the XPEHLO command.

62.4.56 TCP/IP-channel-specific options: RCPT_TRANSMIT_TIME (integer)

This SMTP/LMTP client option specifies how long to spend transmitting the SMTP command RCPT TO:. The default is 10 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option. In particular, setting `TIMEOUT_MULTIPLIER` to 1 will change the units of this option to seconds.

62.4.57 TCP/IP-channel-specific options: REJECT_RECIPIENTS_PER_TRANSACTION (integer)

This SMTP server option may be used to specify a limit on the number of recipients that will be accepted during a single transaction. For the SMTP server, it also limits the number of VRFY address verifications that may be performed. (Note that the count of actual recipients, RCPT TO:, is separate from the count of verifies, VRFY:; that is, VRFY:'s do not count against the RCPT TO: limit, nor do RCPT TO:'s count against the VRFY: limit; each is limited *independently* to the `REJECT_RECIPIENTS_PER_TRANSACTION` value.) If the RCPT TO: limit is exceeded, then at the DATA command the entire message to *all* recipients will be rejected with a temporary error:

```
451 4.5.3 Transaction blocked; too many recipients specified
```

(Compare with `ALLOW_RECIPIENTS_PER_TRANSACTION` which rejects merely the excess recipients with a

```
451 4.5.3 Too many recipients specified
```

error at the RCPT TO: command, allowing the message to be submitted to the initial recipients.) Attempts to VRFY more addresses than the limit will be rejected with a

```
451 4.5.3 Verification blocked; too many operations performed
```

error. The default is no limit. Note that if both `ALLOW_RECIPIENTS_PER_TRANSACTION` and `REJECT_RECIPIENTS_PER_TRANSACTION` are set, with `REJECT_RECIPIENTS_PER_TRANSACTION` being set to a larger value than `ALLOW_RECIPIENTS_PER_TRANSACTION`, then once `ALLOW_RECIPIENTS_PER_TRANSACTION` is exceeded any additional recipients receive a temporary error, and once `REJECT_RECIPIENTS_PER_TRANSACTION` is exceeded then the entire message is rejected with a temporary error.

See also the `recipientcutoff` and `disconnectrejectlimit` channel options, and the `ldap_recipientcutoff` and `ldap_domain_attr_recipientcutoff` MTA options.

62.4.58 TCP/IP-channel-specific options: REUSE_TIMED_OUT_TRANSFERS (0 or 1)

This SMTP server option controls creation and use of `*.data-failed` files; the default is 1, meaning that such files may be created and used. More specifically, this option controls

whether the MTA writes and uses `IMTA_QUEUE:tcp_*/spool/*.data-failed` files (MS 6.3 and earlier) or in JS Messaging Server 7.0, `$DATAROOT/queue/tcp_*/spool/*.data-failed` files. If enabled, the MTA writes such a file in cases where an SMTP client connection is dropped after the MTA has received the final "." terminating the message data, but before the MTA has successfully sent its "250 2.5.0 Ok." message acknowledging the receipt of the message back to the client, and checks for the existence of such a file when receiving an incoming message (so as to detect a "duplicate" attempted message submission). When such files are being created/used, the MTA will do a hash of each incoming message to compare the hash against any stored `*.data-failed` files to determine whether the current incoming message had in fact already been received in a previous transaction. When the MTA does see such a case, the MTA will issue a

```
250 2.5.0 Prior aborted transfer used
```

success back to the sending client (after the client finishes sending the message data). The MTA will only create such a `*.data-failed` file in the case of an incoming message where there was a significant delay in our sending of the "250 ok"; see the `FAST_SMTP_SESSION_TIME_LIMIT` TCP/IP-channel-specific option. The MTA assumes that cases of "short" disconnect times are where it's just a poorly behaved client, one that likes to disconnect immediately without waiting for the acknowledgement, that won't in fact be resending the message. Whereas the "long" timeout case, where the MTA will still make the `*.data-failed` file, is a case where it's reasonable that the client timed out on the connection, and the client likely will feel a need to try resending the message.

The `*.data-failed` files are normally retained in the incoming TCP/IP channel's `spool` subdirectory for the number of days specified by an IMTA_TCP_FLAG_RETENTION Tailor option, which defaults to 7 if not explicitly set. (The `return_units` MTA option has no effect here; this Tailor option is always interpreted in units of days.) Thus by default (no IMTA_TCP_FLAG_RETENTION Tailor option set) such `*.data-failed` files are retained for seven days. Note that disabling the MTA's SMTP server creation and use of `*.data-failed` files by setting `REUSE_TIMED_OUT_TRANSFERS=0` can provide a noticable performance (throughput) increase---perhaps 30% for the SMTP server; the downside is that disabling their use means that the MTA will no longer detect and avoid certain cases of duplicate submissions of messages, so users may receive "duplicate" copies of messages that might have been avoided.

62.4.59 TCP/IP-channel-specific options: SESSION_TIME (integer)

(New in Messaging Server 7.0-3.01.) This SMTP server (but not LMTP server) option controls the maximum amount of time, in minutes, that an SMTP session is allowed before the session will be disconnected. The default is 20 minutes. Note that, for performance reasons, this value is checked only once every 10 reads (in order to save on `time()` calls). Once the SMTP server notices that the specified session time limit has been exceeded, the session will be disconnected with an SMTP error:

```
450 4.7.0 Maximum session time of n minutes has been exceeded
```

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option. In particular, setting `TIMEOUT_MULTIPLIER` to 1 will change the units of this option to seconds.

62.4.60 TCP/IP-channel-specific options: SIZE_DELAY_THRESHHOLDS, SIZE_DELAY_AMOUNTS, RECIPIENT_DELAY_THRESHHOLDS, RECIPIENT_DELAY_AMOUNTS, TRANSACTION_DELAY_THRESHHOLDS, TRANSACTION_DELAY_AMOUNTS (comma-separated list of integers)

These are SMTP server options; (they are also supported by the LMTP servers, though unlikely to be useful in an LMTP context). The number of total message size, number of recipients, and number of transactions are tracked by the SMTP server on a per-session basis. And via these options, the SMTP server can impose punitive delays in responding when various threshhold levels are exceeded. That is, the SMTP server can in gradated fashion "slow down" its responses to clients that are submitting "large" numbers of "large" messages to "large" numbers of recipients.

These options come in pairs, each containing a list of up to ten, comma-separated integers. (The default is all zeros.) One list is the threshhold list, which specifies the point past which the additional delay specified by the corresponding number in the other list applies. The delay amounts are additive; that is, each delay value specifies an additional delay to impose, rather than representing an absolute delay. The current delay in effect is maximized with the result of summing the three contributors:

```
D_c=max(D_c,D_t+D_r+D_s)
```

Here D_c is the current delay, D_t is the delay due to transactions being exceeded, D_r is the delay due to recipients being exceeded, and D_s is the delay due to size being exceeded.

Note that the `SIZE_DELAY_THRESHHOLDS` are in bytes, *not* blocks. The `*_DELAY_AMOUNTS` values are interpreted as hundredths of seconds.

See also MeterMaid for an alternate way of implementing such intentional response delays.

62.4.61 TCP/IP-channel-specific options: SSL_CLIENT (0 or 1)

(New in 7.0.5) If set to 1, SSL/TLS negotiation will be performed immediately after any connection is established by the SMTP client (without any use of STARTTLS). It is thus the client analogue of the Dispatcher's `ssl_ports` option (`TLS_PORT` Dispatcher option in legacy configuration) for servers. The default for `SSL_CLIENT` is 0, meaning that such automatic (non STARTTLS) SSL/TLS negotiation will not be done by the client. (Client negotiation via STARTTLS is a separate issue and may still be performed, depending upon configuration; see the `*tlsclient` channel options.)

`SSL_CLIENT` is useful for establishing point to point links to other systems using `smtps:` on port 465. In particular, a typical use of the `SSL_CLIENT` option would be on a special tcp_* channel that has `port 465` set; e.g.:

```
msconfig> show channel:tcp_ssl_friend.port
instance.channel:tcp_ssl_friend.port = 465
msconfig> show channel:tcp_ssl_friend.options.SSL_CLIENT
instance.channel:tcp_ssl_friend.options.SSL_CLIENT = 1
```

62.4.62 TCP/IP-channel-specific options: STARTTLS_FAILURE_RECONNECT_DELAY (integer)

(New in 7.0.5.32.) When `maytlsclient` is in effect, this SMTP/LMTP client option specifies, in centiseconds, how long to wait after a TLS negotiation failure before reattempting connection without use of TLS. The default is 200.

62.4.63 TCP/IP-channel-specific options: STATUS_DATA_RECEIVE_TIME (integer)

This SMTP/LMTP client option specifies how long to wait to receive the SMTP response to our sent data; *i.e.*, how long to wait to receive a "250" (or other) response to the dot terminating sent data. The default value is 10 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option. In particular, setting `TIMEOUT_MULTIPLIER` to 1 will change the units of this option to seconds.

See also the `STATUS_DATA_RECV_PER_ADDR_TIME`, `STATUS_DATA_RECV_PER_BLOCK_TIME`, and `STATUS_DATA_RECV_PER_ADDR_PER_BLK_TIME` TCP/IP-channel-specific options.

62.4.64 TCP/IP-channel-specific options: STATUS_DATA_RECV_PER_ADDR_TIME (floating point value)

This SMTP/LMTP client option specifies an adjustment factor for how long to wait to receive the SMTP response to our sent data based on the number of addresses in the MAIL TO: command. This value is multiplied by the number of addresses and added to the base wait time (specified with the `STATUS_DATA_RECEIVE_TIME` TCP/IP-channel-specific option). The default is 0.083333 in units of minutes per address.

The base unit time is in units of minutes by default; as of MS 8.0.2.3 this may be adjusted with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option.

62.4.65 TCP/IP-channel-specific options: STATUS_DATA_RECV_PER_BLOCK_TIME (floating point value)

This SMTP/LMTP client option specifies an adjustment factor for how long to wait to receive the SMTP response to our sent data based on the number of blocks sent. This value is multiplied by the number of blocks and added to the base wait time (specified with the `STATUS_DATA_RECEIVE_TIME` TCP/IP-channel-specific option). The default is 0.001666

in units of minutes per block. (For purposes of this option, a block is always 512 bytes, *not* whatever block size might be defined by the `block_size` MTA option.)

The base unit time is in units of minutes by default; as of MS 8.0.2.3 this may be adjusted with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option.

62.4.66 TCP/IP-channel-specific options: STATUS_DATA_RECV_PER_ADDR_PER_BLK_TIME (floating point value)

This SMTP/LMTP client option specifies an adjustment factor for how long to wait to receive the SMTP response to our sent data based on the number of addresses (in the MAIL TO: command) per number of blocks sent. This value is multiplied by the number of addresses per block and added to the base wait time (specified with the `STATUS_DATA_RECEIVE_TIME` TCP/IP-channel-specific option). The default is 0.003333 (in units of minutes per block per address). (For purposes of this option, a block is always 512 bytes, *not* whatever block size might be defined by the `block_size` MTA option.)

The base unit time is in units of minutes by default; as of MS 8.0.2.3 this may be adjusted with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option.

62.4.67 TCP/IP-channel-specific options: STATUS_MAIL_RECEIVE_TIME (integer)

This SMTP/LMTP client option specifies how long to wait to receive the initial 220 banner line, how long to wait to receive a response to an HELO, EHLO, or RSET command, and how long to wait to receive the SMTP response to a sent MAIL FROM: command. The default is 10 minutes

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option. In particular, setting `TIMEOUT_MULTIPLIER` to 1 will change the units of this option to seconds.

62.4.68 TCP/IP-channel-specific options: STATUS_RCPT_RECEIVE_TIME (integer)

This SMTP/LMTP client option specifies how long to wait to receive the SMTP response to a sent RCPT TO: command. The default value is 10 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the `TIMEOUT_MULTIPLIER` TCP/IP-channel-specific option. In particular, setting `TIMEOUT_MULTIPLIER` to 1 will change the units of this option to seconds.

62.4.69 TCP/IP-channel-specific options: STATUS_RECEIVE_TIME (integer)

This SMTP/LMTP client option specifies how long to wait to receive the SMTP reply to general SMTP commands, (replies other than those with explicitly specified time out values set using other specifically named options). The default value is 10 minutes.

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.70 TCP/IP-channel-specific options: STATUS_TRANSMIT_TIME (integer)

This SMTP/LMTP server option specifies how long to spend transmitting the SMTP/LMTP reply to an SMTP/LMTP command. The default value is 10 minutes

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.71 TCP/IP-channel-specific options: TLS_NEGOTIATION_TIME (integer)

This SMTP/LMTP client option specifies how long the SMTP/LMTP client and server will wait for the opposite end during TLS negotiation. The default value is 1 minute.

The default units for this option are minutes. The units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.72 TCP/IP-channel-specific options: TIMEOUT_MULTIPLIER (integer)

This SMTP/LMTP client/server TCP/IP-channel-specific option specifies a multiplier value that is applied to various other TCP/IP-channel-specific timeout options. While any positive value is allowed, settings should be limited to 60 (the default), which causes the various associated timeout options to be interpreted in minutes, or 1, which causes the timeouts to be interpreted in seconds.

62.4.73 TCP/IP-channel-specific options: TRACE_LEVEL (0, 1, or 2)

This TCP/IP channel SMTP server and SMTP client option, and LMTP server and LMTP client option, controls whether TCP/IP level trace is included in debug log files. The default value is 0, meaning that no TCP/IP packet traces are included; a value of 1 tells the MTA to include TCP/IP packet traces in any debug log files; a value of 2 tells the MTA to include some additional information, such as DNS lookup information, in addition to the basic TCP/IP packet traces.

See also the $G flag of the PORT_ACCESS mapping table, which can be used to selectively enable TRACE_LEVEL=2 only for particular incoming SMTP/SMTP SUBMIT/LMTP connections.

62.4.74 TCP/IP-channel-specific options: TRANSACTION_LIMIT_RCPT_TO (0 or 1)

This SMTP/LMTP server option affects the MTA's behavior once ALLOW_TRANSACTIONS_PER_SESSION has been exceeded. The default is 0, meaning that once ALLOW_TRANSACTIONS_PER_SESSION has been exceeded, then the MTA will reject subsequent transactions (during that same session) at the MAIL FROM: command. If set to 1, the subsequent transactions will instead be rejected at the RCPT TO: command. In either case, the rejection will be done via an error:

```
451 4.5.3 No more transactions allowed
```

62.4.75 TCP/IP-channel-specific options: TRANSACTION_TIME (integer)

(New in Messaging Server 7.0-3.01.) This SMTP server (but not LMTP server) option controls the maximum amount of time that an SMTP transaction is allowed before the session will be disconnected. The default is 600 minutes. Note that, for performance reasons, this value is checked only once every 10 reads (in order to save on time() calls). Once the SMTP server notices that the specified transaction time limit has been exceeded, the session will be disconnected with an SMTP error:

```
450 4.7.0 Maximum transaction time of n minutes has been exceeded
```

The default units for this option are minutes. As of MS 8.0.2.3, the units of this option may be changed with the TIMEOUT_MULTIPLIER TCP/IP-channel-specific option. In particular, setting TIMEOUT_MULTIPLIER to 1 will change the units of this option to seconds.

62.4.76 TCP/IP-channel-specific options: WINDDOWN_TIMEOUT (integer)

This SMTP/LMTP client option sets the time, in seconds, to wait before killing active delivery threads. The default is 60*90 seconds (*i.e.*, 90 minutes).

62.5 DEQUEUE_ACCESS mapping table

New in 8.0.2.3 is the DEQUEUE_ACCESS mapping table, which is consulted at the beginning of message dequeue processing.

The default probe for the DEQUEUE_ACCESS mapping is of the form:

channel|*filename*|*queue-time*|*envelope-from*|*auth-parameter*|*auth-sender*|*priority*|*domain*

where *channel* is the channel from which the message is being dequeued, *filename* is the full file name of the message, *queue-time* is the approximate time in seconds that the message has been in the queue (or -1 if that value cannot be determined), *envelope-from* is the envelope From address for this message, *auth-parameter* is the unencoded value of any MAIL FROM AUTH= parameter associated with the message, *auth-sender* is the mail address associated with any authentication identity used to submit the message, *priority* is the MT-priority value for the message, and *domain* is the DNS name of the server to which the message is to be sent. Note that the mapping_paranoia MTA option, if set, will cause any vertical bar characters that would have been in the *envelope-from*, *auth-parameter*, *auth-sender*, or *domain* fields to be replaced by the specified character.

As of MS 8.0.2.3, the $R input flag will be set if the message is being accessed in read-only mode by a utility such as imsimta qm.

If bit 11, value 4096, of the include_conversiontag MTA option is set the probe changes to include the conversion tag for the message:

channel|*filename*|*queue-time*|*envelope-from*|*auth-parameter*|*auth-sender*|*priority*|*conversio*

If bit 1, value 2, of the include_retries MTA option is set the probe changes to include the count of previous retries for the message:

channel|*filename*|*retry-count*|*queue-time*|*envelope-from*|*auth-parameter*|*auth-sender*|*priori*

The DEQUEUE_ACCESS mapping should return a list of values delimited by vertical bars ("|").

(New in MS 8.1.0.6) The $> flag is used to indicate that a smartsend logging result has been returned. A value is consumed from the returned string and appended to the smartsend log value. Note that this value is only logged if the log_smartsend MTA option is set.

If $N is set by the mapping the current dequeue action is aborted without incrementing the retry count. If the $S flag is also set a new backoff time in seconds, expressed as an integer, is read from the mapping result string.

62.6 AUTH_ACCESS mapping table

New in 7.0.5 is the AUTH_ACCESS mapping table, which provides the means to exercise increased control over SMTP session characteristics. This access mapping is consulted during SMTP/LMTP client operations just prior to initiating client connections, and in particular, prior to DNS or host table lookup of destination domains. (In particular, and as compared to the later IP_ACCESS mapping, AUTH_ACCESS is consulted prior to MX record lookups.) The AUTH_ACCESS mapping allows control or override of various SMTP session level features.

The default probe for the AUTH_ACCESS mapping is of the form:

channel|*filename*|*queue-time*|*envelope-from*|*auth-parameter*|*username*|*domain*

where *channel* is the channel from which the message is being dequeued, *filename* is the full file name of the message, *queue-time* is the approximate time in seconds that the message has been in the queue (or -1 if that value cannot be determined), *envelope-from* is the envelope From address for this message, *auth-parameter* is the unencoded value of any MAIL FROM AUTH= parameter associated with the message, *username* is the authentication identity used to submit the message (plus an asterisk character suffix), and *domain* is the DNS name of the server to which the message would (if not overridden by this mapping) be sent. Note that the *username* is not necessarily the same as the user's canonical e-mail address (mail attribute value) or any other LDAP attribute value; rather, the *username* is a canonical identity constructed as *uid*@*canonical-domain*. Note also that the mapping_paranoia MTA option, if set, will cause any vertical bar characters that would have been in the *envelope-from*, *auth-parameter*, *username*, or *domain* fields to be replaced by the specified character.

New in MS 8.0.2.2, If bit 11, value 2048, of the include_conversiontag MTA option is set the probe changes to include the conversion tag for the message:

channel|*filename*|*queue-time*|*envelope-from*|*auth-parameter*|*username*|*conversiontag*|*domain*

New in MS 8.0.2.3, if bit 0, value 1, of the include_retries MTA option is set the probe changes to include the count of previous retries for the message:

channel|*filename*|*retry-count*|*queue-time*|*envelope-from*|*auth-parameter*|*username*|*domain*

The mapping template (right hand side) can contain a number of flags plus a series of vertical bar separated fields. Setting a flag causes the consumption of zero or more fields, processed in the order, and with the effects, shown in Table of AUTH_ACCESS mapping output flags.

Table 62.3 AUTH_ACCESS mapping output flags

Flag	Fields	Description
$U		Enable SMTP client debugging for this transaction. No fields are consumed.
$n	*error-text*	(New in MS 8.0.2.3.) Abort this connection attempt for this message. One field is used to specify the error text. No further processing of the mapping result is performed.
$N	*error-text*	Permanently fail the first recipient of the message and return a DSN. The delivery operation continues with the next recipient. The entire message fails if there is only one remaining recipient. One field is used to specify the error text. No further processing of the mapping result is performed.
$F	*env-from*	Override the message's envelope From address. One field is used to specify that address.
$A	*auth-param*	Override the MAIL FROM AUTH= parameter. One field is used to specify the override value.
$Q	*authorization*|*username*|*password*	Override the credentials used for PLAIN authentication. Three fields are consumed with use of this flag: the first specifies an authorization identity (normally left blank), the second specifies an authentication identity (the "username"), and the third specifies a password.
$/		Treat a PLAIN authentication attempt failure as an SMTP temporary failure. (Normally, when this flag is not set, such an authentication failure is instead treated as: ignored when maysaslclient is in effect, *vs.* causing an SMTP permanent failure (bounce) when mustsaslclient is in effect.)
$D	*host*	Override the DNS name of the server to which the message will be sent. One field is used to specify the new DNS name. (Note that use of this flag causes the TCP/IP-channel-specific option SSL_CLIENT to be ignored; instead use $S to enable smtps: use.)
$P	*port*	Override the value of the port channel option (default 25). One field is used to specify the new port number. (Note that use of this flag causes the

		TCP/IP-channel-specific option SSL_CLIENT to be ignored; instead use $S to enable smtps: use.)
$S		Enables the use of TLS (smtps:). No fields are consumed. Note that this flag enables smtps: use even when $D or $P has also been used.
$X		Disable MX lookups for connection establishment (overriding any channel *mx channel option setting). No fields are consumed.
$o		(New in MS 8.1.0.2) Treat nonauthoritative DNS lookup failures as temporary failures.
$O		(New in MS 8.1.0.2) Treat all DNS lookup failures as temporary failures.
$M		Enable MX lookups for connection establishment (overriding any channel *mx keyword setting); the effect is randommx MX record use. No fields are consumed.
$B	*lastresort-server*	Set a lastresort value, overriding the value specified by the lastresort channel option. One field is consumed as the lastresort server name.
$!	*min-version*|*max-version*	New in MS 8.1.0.1. Set tlsminversion and tlsmaxversion value, overriding the values specified by the corresponding channel options. Two field are consumed as the minimum and maximum values. Either field may be left blank to avoid affecting the corresponding value.
$T		Force musttlsclient on for this session. No fields are consumed.
$H		Disable TLS for this session. No fields are consumed.
$G		Force mustsaslclient on for this session. No fields are consumed.
$I		Disable SASL for this session. No fields are consumed.
$Z		(New in MS 8.1.0.1) Disable CHUNKING for this session. No fields are consumed.
$J	interface-address	(New in 8.0.2.2) Use the specified value as the source IP address. A single field containing the IP address to use is consumed. If a connection is currently open it will be closed unless the interface address has not changed.
$+.	host-name	(New in 8.0.2.3) Use the specified value as the host name in any EHLO/HELO/LHLO command that the client issues. A single field containing the banner host name is consumed.
$V	skip-count	(New in 8.0.2.3) Specify a new skip count to be encoded in the queue file name for the message. This flag is used by the smartsend plugin and is not

		intended for other purposes. One field containing an unsigned integer skip value is consumed.
$+R	attempt-count	(New in 8.0.2.3) Specify an override value for the ATTEMPT_TRANSACTION_PER_SESSION TCP/IP-specific channel option. A single field containing the override value is consumed.
$(	max-mx-count	(New in 8.0.2.3) Specify an override value for the MAX_MX_RECORDS TCP/IP-specific channel option. A single field containing the override value is consumed.
$+%	backoff-time	(New in 8.0.2.3) Specify an override value for the backoff time in the event this delivery attempt fails with a temporary error. A single field containing the time in seconds is consumed.
$*	header1,header2,...	(New in 8.1.0.1) Specifies a list of header fields to log in any transaction log entries that are generated. A single field is consumed.
$>	smartsend-log-string	(New in 8.1.0.6) Specified a string to append to the smartsend log value. A single field is consumed.
$,	deaccess-parameter-string	(New in 8.0.2.3) Specify the deaccess parameter string to pass to the AUTH_DEACCESSS mapping. Note that this consumes all remaining arguments in the mapping result stirng.
$Y		Perform no special overrides and send message normally. This explicit "no-op" result is useful for specifying mapping table match cases that cause SMTP client processing to proceed normally. No fields are consumed.
Input flag comparisons		Description
$:|		Match only if external material (*e.g.*, the envelope From address) in the probe contained a vertical bar
$;|		Match only if no vertical bars were present in any external material in the probe
$:S		(New in MS 8.0.2.3) Match only if a connection to the destination for this message is already open and is going to be reused.
$;S		(New in MS 8.0.2.3) Match only if no SMTP connection is open or if one is open it is going to be closed prior to processing this message.
$:T		(New in MS 8.0.2.3) Match only if STARTTLS is allowed or required for this connection
$;T		(New in MS 8.0.2.3) Match only if STARTTLS is not allowed for this connection.
$:U		(New in MS 8.0.2.3) Match only if smtps: is allowed or required for this connection
$;U		(New in MS 8.0.2.3) Match only if smtps: is not allowed for this connection.

As of MS 8.1.0.1, there are also a number of input flags:

Table 62.4 AUTH_ACCESS mapping input flags

Flag	Description
$S	Set if a connection is currently open that has the potential to be reused.
$D	Set if the destination host associated with the currently open connection matches the destination host for the current message. $D is only set if $S is also set.
$T	Set if current settings allow or require TLS.
$U	Set if current settings allow or require smtps.

The AUTH_ACCESS mapping table can be used for a variety of purposes, including various special-purpose, targetted, override effects on SMTP connections. However, the combination of effects it allows is especially intended to facilitate special-purpose identity/authentication scenarios, such as effective "on behalf of submission", also called "third party submission".

For instance, suppose that local user `adam.brown@local.domain.com` also has a remote identity and mailbox as `abrown@remote.domain.com`, and that this local user when submitting messages through your MTA would sometimes, for some messages, like those message to go out under the remote identity/address. In the example below, for specificity, assume further that the user client will authenticate when submitting such messages, submitting with the user's normal, local address as the envelope From, but with a MAIL FROM AUTH= parameter set to the remote address. Then an AUTH_ACCESS mapping to redirect such messages to a remote.domain.com server and submit the messages using the remote identity could be:

```
AUTH_ACCESS

 tcp_local|*|*|adam.brown@local.domain.com|abrown@remote.domain.com|$*adam.brown@local.domain.com|*  \
$Fabrown@remote.domain.com|$Q|abrown@remote.domain.com|remotepassword|$/$Dremote.domain.com|$P587
```

If such a setup is desired for multiple users, rather than just one or a few special users hard-coded (with their remote passwords!) into the AUTH_ACCESS mapping, then a more real-world example might also include storing such users' remote credentials (remote identity and remote password) in some data repository, for instance, perhaps in the regular user LDAP directory, or perhaps in a special LDAP directory accessed via extldap: URLs, or even in some other database, and then looking up the addresses and credential data when messages come through with a MAIL FROM AUTH= parameter differing from the envelope From. Note that in such setups, one of the most challenging aspects (not from the MTA configuration point of view, but rather from the design and maintenance of the data point of view) is likely to be establishing, and maintaining, a tight correspondence between each such local user identity and the remote identity (or identities) that local user is authorized to use.

In AUTH_ACCESS mapping example: third party submission, when SMTP AUTH was used to submit a message so that a username is present for the message, if also a MAIL FROM AUTH= parameter is present and differs from the username, then the username is looked up in LDAP and that user's LDAP entry is checked for whether a value of a special LDAP attribute, here assumed to be `mailRemoteIdentity`, matches the MAIL FROM AUTH= parameter value.

The user data is assumed, for purposes of AUTH_ACCESS mapping example: third party submission, to be organized in two LDAP directories: the usual user/group LDAP directory

(containing, in addition to all the usual attributes for users, a special site-added, potentially multi-valued, `mailRemoteIdentity` attribute, used to store any remote addresses that user is permitted to use), as well as a so-called "external" LDAP directory (containing remote domain names under which are stored the remote addresses with their credentials and an attribute for each remote address specifying which local address(es) are permitted to use that remote identity). See AUTH_ACCESS mapping example: Excerptoflocal user entry in user/group LDAP and AUTH_ACCESS mapping example: Excerpt of remote identity entries in alternate (external) LDAP for example excerpts of such a data setup. Administratively, the management and updating and access to the data in the "external" LDAP directory may well be somewhat separate and different than for the usual user/group LDAP directory. See the MTA options for configuration of external LDAP lookups, discussed in LDAP external directory lookup MTA options.

62.6.1 AUTH_ACCESS mapping example: Excerpt of local user entry in user/group LDAP

```
In the local.domain.com users portion of the DIT:

mail: adam.brown@local.domain.com
mailRemoteIdentity: abrown@remote1.domain.com
mailRemoteIdentity: adam.brown@remote2.domain.com
```

62.6.2 AUTH_ACCESS mapping example: Excerpt of remote identity entries in alternate (external) LDAP

```
Under the remote1.domain.com portion of the "external" LDAP DIT:

mail: abrown@remote1.domain.com
username: remote1-username
password: remote1-password
submittor: adam.brown@local.domain.com

Under the remote2.domain.com portion of the "external" LDAP DIT:

mail: adam.brown@remote2.domain.com
username: remote2-username
password: remote2-password
submittor: adam.brown@local.domain.com
```

Another important aspect to consider is such setups is error handling: what should happen to messages when (and note that it is almost certain to be a "when" not merely an "if" occurrence) the remote credentials are not accepted by the remote server, or the remote SMTP SUBMIT server is unavailable for an extended period of time. One possible approach, though surely not the only approach, is to have the MTA repeat attempting the remote submission a few times, but then "fall back" to emitting the message instead with the original From address (the locally verified, local user identity) as the sender. The probe to `AUTH_ACCESS` has access to the message `filename` and `queue-time`, which allows differential behavior based on the name (hence number of delivery attempts) or age (time in queue) of messages. And since `AUTH_ACCESS` operates by optionally overriding for a delivery attempt (but not in the underlying message file on disk!) delivery attempt aspects such as envelope From address, credentials, and remote server (and port) to which to connect, then message aspects such as

original envelope From, and recipient destination domain remain present in a message file that has failed delivery attempts, still available for "normal" use should one wish the MTA to "fall back" to attempting a normal delivery without regard to the purported remote identity. AUTH_ACCESS mapping example: third party submission incorporates such checks both on the number of delivery attempts, as well as the age (time in queue) of a message, in order to "fall back" to "normal" delivery (stop attempting the remote identity submission) after some elapsed time and number of attempts.

62.6.3 AUTH_ACCESS mapping example: third party submission

```
AUTH_ACCESS

! The following three entries detect the three cases, respectively:
!   (1) no MAIL FROM AUTH= parameter
!   (2) no username (message submitted without SMTP AUTH use)
!   (3) MAIL FROM AUTH= parameter matches username
! These are three cases where DUE TO INHERENT FEATURES of the original
! message submission, the message will be sent "normally" (no
! special action taken).
!
  tcp_local|*|*|*||*|*          $Y
  tcp_local|*|*|*|*||*          $Y
  tcp_local|*|*|*|*|$3*|*       $Y
!
! Now at the case where the MAIL FROM AUTH= parameter differs from the username.
!
! The following entry uses the subsidiary mapping table X-FILE-IS-OLD to
! check whether the message is "old" either in terms of retries (has had three
! or more delivery attempts) or in terms of time-in-queue (has been in the MTA
! queue for more than 3 hours).  If the message file is "old" in either sense,
! presumably due to trouble performing the remote identity submission,
! then "fall back" to sending the message "normally" (no further remote
! identity submission attempts).  That is, detect the case of a message where
! third party submission seemed appropriate and was attempted, but DUE TO
! OPERATIONAL TROUBLE with the third party submission, it is now desired to
! "fall back" to "normal" delivery.
!
  tcp_local|*|*|*|*|*|*   $C$|X-FILE-IS-OLD;$0$|$1|$Y
!
! If the X-FILE-IS-OLD mapping check "failed" (the message file is still fresh),
! then fall through (continue) with the same input probe.
! So look up the authenticated sender identity in the user LDAP directory and
! check a special mailRemoteIdentity attribute to see whether that sender
! should be allowed to try sending with that AUTH= parameter.
!
! Step (1): Find the base DN for the domain of the authenticated sender
! (username):
!
  tcp_local|*|*|*|*|$**@*|*     $C|BDN|$}$5,_base_dn_{|$3|$4@$5
!
! Step (2): If the base DN was found, then the probe is now
!   |BDN|<username-domain-baseDN>|<auth-param>|<username>
! The following entry checks for a user entry whose canonical address or some
! alias is the authenticated sender address, with a mailRemoteIdentity
! matching the AUTH= parameter.
!
  |BDN|*|*|*   \
$C|LYES|$1|$]ldap:///$0?mail?sub?(&(|(mail=$=$2$_)(mailAlternateAddress=$=$2$_)(mailRemoteIdentity=$=$1$_))[
!
! If the <username> user indeed has a mailRemoteIdentity value of the
! MAIL FROM AUTH= parameter, then the probe is now
```

```
!   |LYES|<auth-param>|<username>
! If not, then the probe is still
!   |BDN|<username-domain-baseDN>|<auth-param>|<username>
!
! For the "not" (still |BDN|...) case, send the message "normally"
!
   |BDN|*     $Y
!
! Step (3): For the |LYES|... case, now look up the <auth-param> in the external
! LDAP directory, assumed to have a structure of external user identities
! stored under their respective domains, with attributes in the external
! user entries including:
!  mail: <remote-user-address-as-in-AUTH-param>
!  username: <remote-username>
!  password: <remote-password>
!  submittor: <local-username>
!
! This entry is checking under the domain of the <auth-param> for an entry
! with mail=<auth-param> and submittor=<username> (<username> being the local
! username), and if there is such a match returning the username and password
! attribute values.
!
  |LYES|*@*|*  \
$C|RYES|$0@$1|$]extldap:///dc=$1?username?one?(&(mail=$=$0@$1$_)(submittor=$=$2$_))[|\
$]extldap:///dc=$1?password?one?(&(mail=$=$0@$1$_)(submittor=$=$2$_))[
!
! Step (4): If the above succeeded, the probe is now:
!   |RYES|<auth-param>|<remote-username>|<remote-password>
! so now connect to the submit port (587) of a server for the <auth-param>
! domain, using smtps:, overriding the original envelope From to instead use
! the <auth-param> value, and supplying the credentials (remote username
! and remote password) that were found with the extldap: lookups.
!
  |RYES|*@*|*|*     $F$Q$D$P$S|$0@$1||$2|$3|$1|587
!
! If the extldap: lookups didn't succeed, so the probe is still |LYES|... ,
! send the message "normally" (original From, etc.):
!
  |LYES|*        $Y

X-FILE-IS-OLD
! The X-FILE-IS-OLD mapping table expects a probe of the form:
!   <filename>|<seconds-in-queue>
! If the filename begins with other than ZZ..., ZY..., or ZX..., or if
! the <seconds-in-queue> is greater than 3 hours, then the
! mapping returns $Y; otherwise the mapping returns $N.
! When used in a callout from another mapping table, this means that an
! X-FILENAME-IS-OLD callout will only "succeed" if the file was "old".

  %%*|*  \
$`("$0"!="Z"$ ||$ !find("$1","ZYX")$ ||$ integer($3)>3*60*60)?"$$Y":"$$N"'
```

62.7 AUTH_DEACCESS mapping table

New in MS 8.0.2.3. The AUTH_DEACCESS mapping forms a pair with the AUTH_ACCESS mapping table. It is only called when the AUTH_ACCESS mapping has been called and has set a deaccess parameter string.

The call occurs immediately after the final connection associated with the AUTH_DEACCESS mapping has been closed. Note that this may occur right after the message associated with the AUTH_ACCESS call has been processed or it may occur many messages later as a result of connection reuse. And since AUTH_ACCESS is called for every message, there may have been

multiple intervening calls to the AUTH_ACCESS mapping, including a final one associated with setting up a new connection.

This mapping is intended to be used to release resources allocated by the AUTH_ACCESS mapping, typically through the use of a mapping callout. More specifically, AUTH_ACCESS can now be used to allocate some connection-related resource, which can then be used by one or more connections used to deliver the current message and possibly subsequent messages. The AUTH_DEACCESSS mapping is called when the last connection associated with this activity is finally closed.

The probe for the AUTH_DEACCESS mapping is of the form:

channel|*filename*|*deaccess-parameter-string*

Note that the *deaccess-parameter-string* may consist of multiple |-separated sections.

At present the result of the AUTH_DEACCESS is ignored.

62.8 MX_ACCESS mapping table

New in MS 8.1.0.1, the MX_ACCESS mapping table provides the means to control and/or override MX lookup operations.

The MX_ACCESS access mapping table is consulted during SMTP/LMTP client operations just prior to performing the MX lookup on the deatination domain. It thus provides a means of changing the server hosts for a given domain. c

The MX_ACCESS mapping table probe has the following default format:

source-channel|*to-address*|*domain*

Or if bit 16 (value 65536) of the include_conversiontag MTA option is set, then the format is:

source-channel|*conversion-tag*|*to-address*|*domain*

Here *source-channel* is the channel from which the message is being dequeued, *conversion-tag* is a comma-separated list of the conversion tags associated with the message, *to-address* first recipient address, and *domain* is the domain the message is being sent to.

The mapping can set the flags shown in Table of MX_ACCESS mapping flags.

Table 62.5 MX_ACCESS mapping flags

Flag	Description
$U	Enable channel debugging.
$F	Force a "host not found" error, as if the MX lookup failed because the domain does not exist.
$N	Force a temporary DNS error, as if the MX lookup failed due to a transient problem.
$T	Change the destination host to the mapping result string.

$Y	Force the MX result to be the list of hosts specified in the mapping result string. The order of this list will be randomized if mxrandom is in effect.

Note that at present all of the mapping actions are mutually exclusive, that is, it only makes sense to specify one of $F, $N, $T, or $Y.

62.9 IP_ACCESS mapping table

One form of SMTP and LMTP client connection control is provided by the IP_ACCESS mapping table. The IP_ACCESS mapping table was added for MS 6.3.

The IP_ACCESS access mapping table is consulted during SMTP/LMTP client operations just prior to attempting to open connections to a remote server. (In particular, and as compared to the AUTH_ACCESS mapping, the IP_ACCESS mapping is consulted after MX record lookup just before the A record is used.) It thus allows a "last moment" or "last ditch" check on the IP address to which the client would otherwise be about to connect---with the mapping table being able to cause the connection attempt to be aborted or redirected. This has the potential to be useful under certain special circumstances, such as security concerns where some potential destination IP address should *never* be connected to, or where it is wished to avoid connecting to known-to-be-bogus destination IP addresses (*e.g.*, 127.0.0.1 -- see also the loopcheck channel option), or where there is a desire to attempt to "fail over" to another destination IP address (similar to a lastresort channel option effect).

The IP_ACCESS mapping table probe has the following default format:

source-channel|*ip-current-count*|*ip-count*|*ip-current-address*|*hostname*

Or if bit 0 (value 1) of the (new in Messaging Server 7.0-0.04) use_ip_access MTA option is set, then the format is:

source-channel|*ip-current-count*|*ip-count*|*ip-current-address*|*hostname*|*retry-count*

Here *source-channel* is the channel from which the message is being dequeued, *ip-count* is the total number of IP addresses for the remote server, *ip-current-count* is the index of the current IP address being tried, *ip-current-address* is the current IP address, *hostname* is the symbolic name of the remote server, and *retry-count* is what number delivery attempt this is (based on how many prior delivery attempts, as determined by the message filename) or -1 if the data is not available (if the message filename does not follow the MTA's normal message filenaming conventions).

The mapping can set the flags shown in Table of IP_ACCESS mapping flags. In particular, setting a $N, $n, $F, or $f flag will cause the connection attempt to be aborted.

Table 62.6 IP_ACCESS mapping flags

Flag	Description
$N	Immediately reject the connection attempt, hence immediately bounce the message, generating a notification message with a "Illegal host/domain name found" reason and a "5.4.4 Illegal host/domain name found" error status in the notification message. Any supplied text will be logged as the reason for rejection but will not be included in the DSN.
$F	Synonym for $N: immediately reject the connection attempt and hence the message.

$I	Skip the current IP without attempting to connect.
$A	Replace the current IP address with the mapping result.

Possible applications of IP_ACCESS include:

- Detect when an apparently innocuous remote destination domain name resolves in the DNS to a known "bad" or "malicious" IP address, and abort (or redirect) connections to that remote destination.
- Detect and work around internal network or configuration problems, such as "surprise" internal host name assignments, to detect and avoid host name use that might otherwise result in messages looping or being misrouted.
- Forcibly re-route (or alternatively bounce) messages that have had multiple unsuccessful delivery attempts.
- Limit the number of MX records attempted on a per-hostname basis (as opposed to use of the TCP/IP-channel-specific option MAX_MX_RECORDS).
- Call out from IP_ACCESS to a MeterMaid table to achieve "throttling" of outbound connection attempts to some specially limited remote server.

As a concrete example, here is an example of throttling outbound connections performed by a special, dedicated-to-delivery-to-a-special-destination, channel. Note that this is not generally a useful or appropriate thing to do. Limits on a remote server are its business, and under its control. Any special configuration you attempt may become out-of-date, or counter-productive in any of several ways, with no notice to you. And usually the MTA's normal scheduling, retry strategies, and load management are effective and adaptable to wide ranges of circumstances, including even unusual remote server problems. Furthermore, attempting to "work around" limits that a remote server has intentionally imposed are likely to backfire if (or more likely when) the remote server notices you "pushing" its limit and instead decides to block all your system's submissions outright. However, should such special outbound throttling still be desired...

In this example, a "special", three limited remote destination domains are assumed to be slow1.domain.com, slow2.domain.com, and slow3.domain.com, assumed to be only able to accept two hundred messages per MX host every thirty minutes.

```
! Special rewrite rules to route slow1.domain.com, slow2.domain.com, and
! slow3.domain.com out the special new tcp_outlimit channel:
!
slow1.domain.com     $U%slow1.domain.com@tcp-outlimit-daemon

!
! Otherwise, fall through and perform the connection attempt as usual.
```

62.10 SASL_ACCESS mapping table

The new-in-MS-8.0.2 SASL_ACCESS mapping probe has the form:

operation|*transport-info*|*app-info*|*src-chan*|*bad-auth-count*|*username*|*admin-type*|*statusc*

Here *operation* is currently always "AUTHENTICATE". See discussion of the PORT_ACCESS mapping table, or the MAIL_ACCESS mapping table, for discussion of the *transport-info* and *app-info* portions of the probe string. *src-chan* is the currently selected source channel, *bad-auth-count* is a count of the number of previous failed authentication attempts on this connection, and *username* is the user name that the authentication operation bound to, if any. The *admin-type* is the administrator type from the account the authentication operation bound to, which will be one of:

- N/A

- NONE
- FULL
- READONlY
- DOMAIN
- UNKNOWN

Finally, *statuscode* is the status returned by the authentication operation attempt. The possible values are listed in the MTAauth errors table.

The SASL_ACCESS mapping template can set any of the following flags:

Table 62.7 SASL_ACCESS mapping table flags

Flag	Meaning
$U	Enable debugging
$<*string*	Send string to syslog
$>*string*	Send string to syslog if access is explicitly rejected
$N*string*	Reject access with authentication result specified by *string*
$F*string*	Synonym for $N
$X*string*	Override authentication result string with specified *string*
$D*n*	Delay sending response by *n* centiseconds
$A*n*	Update session protocol delay to be *n* centiseconds
$*	Disconnect session after sending response

62.11 TLS_ACCESS mapping table

(New in 8.0.1.) The TLS_ACCESS mapping table, if it exists, will be consulted by the SMTP server after a successful STARTTLS negotiation, and by the SMTP/LMTP client after a successful STARTTLS negotiation, to determine whether the MTA is happy with the STARTTLS negotiation. This allows the MTA to, for instance, decline to permit TLS use based upon a remote side's certificate issuer. If the mapping returns a N or F, then the TLS negotiation will be considered to have failed.

The probe has the form:

transport-info|*app-info*|*channel*|*cert-subject*|*cert-issuer*|*cert-user*

The *channel* field will be the source channel in the case of the SMTP server, or the operating channel in the case of the SMTP/LMTP client. The *cert-user* field will be empty in the case of the SMTP/LMTP client. See discussion of the PORT_ACCESS mapping table, or the MAIL_ACCESS mapping table, for discussion of the *transport-info* and *app-info* portions of the probe string, but note that the *app-info* will be limited in cases where TLS negotiation occurs before an EHLO/HELO command is issued.

Table 62.8 TLS_ACCESS mapping flags

Flag	Description

$<*string*	Send a *string* to syslog.
$>*string*	Send a *string* to syslog if a negotiation failure is forced ($F or ($N is also set).
$N	(New in 8.1.) Force TLS failure and close the connection, even though negotiation succeeded, with error string *string*. On outgoing connections $N differs from $F in that it allows fallback to an unencrypted connection.
$F*string*	Force TLS failure and close the connection, even though negotiation succeeded, with error string *string*.
$S*string*	(Incoming connections only.) Switch to channnel *string*.
$B	(New in 8.1.) (Incoming connections only.) Block any subsequent channel switch by the tlsswitchchannel channel option.

+ To use multiple flags with arguments, separate the arguments with the vertical bar character, |, placing the arguments in the order listed in this table.

62.12 SMTP_ACTIONS mapping table

New in MS 8.1, the SMTP_ACTIONS mapping table can be used to process SMTP failure responses and successful delivery of messages in the SMTP client and customize the MTA's handling in various ways.

If present, the SMTP_ACTIONS mapping is called whenever a failure is returned by the remote SMTP server. The mapping probe format is:

port_access-probe-info|*app-info*|*channel*|*domain*|*conversion-tags*|*what*|*reply*

New in MS 8.1.0.1, the *conversion-tags* are only included in the probe if bit 15, value 32768 of the include_conversiontag MTA is set.

Here *port_access-probe-info* consists of all the information usually included in a PORT_ACCESS mapping table probe (see PORT_ACCESS mapping table) and *app-info* is application-specific information, which here will usually be SMTP/*domain*/*mxhost* in the case of messages being relayed over SMTP and SMTP/*domain*/*mxhost*/TLS-*crypto-info*/*HELO-name* in the case of messages being relayed via SMTP over TLS. *channel* is the channel from which the message is being dequeued, *domain* is the destination domain, *mxhost* is the DNS name of the server to which the message is being relayed, *what* is the name of the SMTP command that produced the error (INITIAL, EHLO/HELO, STARTTLS, AUTH, MAIL, RCPT, DATASTART, DATAEND, RSET, QUIT), and *reply* is the SMTP reply string.

As previously noted, the SMTP_ACTIONS is only called when a command fails and unconditionally for the end of data (DATAEND) response.

Note also that the mapping_paranoia MTA option, if set, will cause any vertical bar characters that would have been in the *reply* field to be replaced by the specified character.

The following flags can be set by the mapping:

Table 62.9 SMTP_ACTIONS mapping flags

Flag	Fields	Description

$T		Treat the error as temporary even if a 5YZ code was returned.
$K		Treat the error as permanent even if a 4YZ code was returned.
$+#	*syslog-text*	Send the specified text to syslog. One return value is consumed.
$S	*comment-text*	Add the specified comment-text as a parenthetical comment to the logged diagnostic value. One return value is consumed.
$%	*backoff-value*	Replace the current backoff time with the specified value, expressed as an integer number of seconds. One return value is consumed.
$<		Minimize the supplied new backoff value with the current backoff value.
$>		Maximize the supplied new backoff value with the current backoff value.
$A	*header-text*	Add the specified header-text as a set of per-recipient DSN fields (see RFC 3464 section 2.3) to any DSN that is generated. One return value is consumed; is it processed as a tilde-separated list of header fields.

62.13 Routing via gateway systems

A local TCP/IP network may include one or more systems that are equipped to relay messages to machines not directly accessible on the local network. Such gateway systems accept addresses that are not palatable to the network itself.

One solution to this problem is to use appropriate MX records and a name resolver. However, this approach may be infeasible in some environments, so a different solution may be needed.

There is an alternate approach, in which routing to TCP/IP gateways is done by creating additional channels, one per gateway system or gateway "name" (a single gateway "name" may reference a set of gateway hosts via use of MX records), in the configuration. The name of each such channel must always begin with `tcp_`.

In Unified configuration, such a channel definition has the general form:

```
msconfig> show tcp_gateway.*
role.channel:tcp_gateway.official_host_name = gateway-system-name
role.channel:tcp_gateway.daemon = router
role.channel:tcp_gateway.smtp (novalue)
```

or equivalently

```
msconfig> show tcp_gateway.*
role.channel:tcp_gateway.official_host_name = arbitrary-placeholder-name
role.channel:tcp_gateway.daemon = gateway-system-name
role.channel:tcp_gateway.smtp (novalue)
```

In legacy configuration, the channel block for a gateway TCP/IP channel has the general form:

```
tcp_gateway smtp daemon router
gateway-system-name
```

or equivalently,

```
tcp_gateway smtp daemon gateway-system-name
arbitrary-placeholder-name
```

Rewrite rules must then be added to the configuration file to route the appropriate addresses to the gateway. See, for instance, Routing non-local mail to a mailhub.

The "daemon router" setting tells the SMTP client program not to open a connection directly to the first system named in the envelope address list, but to instead open a connection to the official host for this channel, *gateway-system-name*. Usually the default multiple setting is appropriate and desirable on gateway channels; but certain gateways may restrict the number of addresses that can appear in a single copy of a message, in which case it may be appropriate to add either the single or single_sys setting to those gateway channels. If the gateway can handle multiple simultaneous connections, then use of the threaddepth setting may be of interest to cause outgoing connections to be split amongst multiple threads.

Once a channel block for a gateway is created the channel should be ready to use.

Note that when addresses are being looked up in LDAP in a so-called "direct LDAP" configuration, then certain domain-level LDAP attributes including mailRoutingHosts and mailRoutingSmartHost (or more precisely, the LDAP attributes named by the MTA options ldap_domain_attr_routing_hosts and ldap_domain_attr_smarthost), may also potentially be used for similar route-to-gateway-host purposes. And so-called "detour host" functionality, typically used for purposes of routing through an SMTP host performing spam/virus filtering, also has a routing effect.

Typically, use of a daemon channel is especially appropriate for routing outbound (to the Internet) messages, when all such messages should go out through a gateway. In contrast, use of LDAP-based domain routing attributes is especially appropriate for controlling the routing to internally-destined messages, when such messages should go through an internal "smart host" that performs additional address handling. And use of "detour host" functionality is, as already mentioned above, intended for cases of detour routing through spam/virus filter boxes.

62.13.1 Routing non-local mail to a mailhub

Sometimes it is convenient to configure the MTA to route mail not for the local host, or a group of local machines, to a central machine and leave it up to that machine to deal with the mail, perhaps relaying it to the outside world or other local machines, or perhaps even gatewaying it into other mail systems. The following example configuration, Routing messages to a central system, illustrates doing just this.

In this example, the local host is host1.domain.com and two other local machines, host2.domain.com and host3.domain.com, are recognized. Mail for either of those two machines is sent via a tcp_local channel (SMTP over TCP/IP) to those hosts. All other mail not for host1, host2, or host3 is sent via another SMTP over TCP/IP channel, named

tcp_gateway, to the host mailhub.domain.com. A "match-all" rewrite rule is used to direct all mail not for host1, host2, or host3 to that channel. The daemon channel option is used with the tcp_gateway channel, telling the channel to routed messages queued to it through the host mailhub.domain.com. For additional discussion of such usage, see also Routing via gateway systems.

A legacy configuration example of routing to a central system would be:

```
!
! Rewrite rules for the local host/cluster
!
host1                              $U@host1.domain.com
host1.domain.com                   $U@host1.domain.com
!
! Rewrite rules for some internal systems
!
host2.domain.com                   $U%host2.domain.com@TCP-DAEMON
host3.domain.com                   $U%host3.domain.com@TCP-DAEMON
!
! Use a match all rewrite rule to route everything
! else to the mailhub.domain.com
!
.                                 $U%$H@mailhub.domain.com$A

l
host1.domain.com

tcp_local smtp single_sys mx
TCP-DAEMON

tcp_gateway smtp mx daemon router
mailhub.domain.com
```

62.14 Blocking SMTP relaying

One application of the ORIG_SEND_ACCESS mapping table, along with appropriate configuration of channels with switchchannel and saslswitchchannel channel options, is to prevent people from using your MTA to relay junk mail to hundreds or thousands of Internet mail boxes. By default, at a code level, the MTA does not prevent SMTP relaying activity. However, the normal installation and initial configuration does configure to prevent SMTP relaying from "external" sources.

Blocking unauthorized relaying while allowing it for legitimate local users requires configuring the MTA to know how to distinguish between the two classes of users. The distinction between "internal" *vs.* "external" users is achieved using a combination of the switchchannel and allowswitchchannel channel options in conjunction with a rewrite rule that compares connection source IP addresses against the INTERNAL_IP mapping table, plus user authentication during message submission in conjunction with the maysasl and saslswitchchannel channel options. The effect of such configuration is to "sort" incoming messages based on knowledge of the message's source (whether that knowledge is of the source of the IP connection, or of the sender of the messages) assigning the messages to different source channels. Once such assignment of source channel has been achieved, then the

desired relaying restrictions can be easily controlled in, *e.g.*, the ORIG_SEND_ACCESS mapping table.

When preventing unauthorized people from relaying SMTP mail through your system, keep in mind that you *do* want to allow local users to relay SMTP mail! For instance, POP and IMAP users typically rely upon using the MTA to send their mail. Note that local users may either be physically local, in which case their messages come in from an internal IP address, or may be physically remote but able to authenticate themselves as "local" users. It's those random people out on the Internet who you want to prevent from using you as a relay. With appropriate configuration to recognize the cases of "internal" source IP addresses or local user authenticated messages and handle them via special channels, rather than the default tcp_local channel, you can differentiate between these classes of users and block only the correct class. Specifically, (once "internal" users have been properly sorted for handling by one or another special incoming channel), you want to block mail from coming in your tcp_local channel and going back out that same channel. To that end, an ORIG_SEND_ACCESS mapping table may be conveniently used.

An ORIG_SEND_ACCESS mapping table may be used to block traffic based upon the source and destination channel. In this case, traffic from and back to the tcp_local channel is to be blocked. This is realized with the following ORIG_SEND_ACCESS mapping table:

```
ORIG_SEND_ACCESS

  tcp_local|*|tcp_local|*                $NRelaying$ not$ permitted
```

In the above, the entry states that messages cannot come in the tcp_local channel and go right back out it. That is, this entry disallows external mail from coming in your SMTP server and being relayed right back out to the Internet.

Note that an ORIG_SEND_ACCESS mapping table is used rather than a SEND_ACCESS mapping table, so that the blocking will not apply to addresses that originally match the l (lowercase "L") channel (but which may expand via an alias or mailing list definition back to an "external" address). With a SEND_ACCESS mapping table one would have to go to extra lengths to allow outsiders to send to mailing lists that expand back out to "external" users, or to send to users who forward their messages back out to "external" addresses.

A further refinement, to block attempts to relay "through" internal systems using source-routed addresses, is included in the following sample mapping table:

```
ORIG_SEND_ACCESS

  tcp_local|*|tcp_local|*              $NRelaying$ not$ permitted
!
! Block direct submission to MTA "intermediate" channels
!
  tcp_*|*|native|*       $N
  tcp_*|*|hold|*         $N
  tcp_*|*|pipe|*         $N
!
! Block direct submission to Message Store delivery channels;
! routing to such channel should only occur due to MTA address/alias
! processing
!
  tcp_*|*|ims-ms|*        $N
```

```
  tcp_*|tcp_lmtpcs*|*     $N
!
! Block "external" submissions of explicitly source-routed "internal" addresses
!
  tcp_local|*|tcp_intranet|@*:*.*   $N$D30|Explicit$ routing$ not$ allowed
  tcp_local|*|tcp_intranet|*$%*@*   $N$D30|Explicit$ routing$ not$ allowed
  tcp_local|*|tcp_intranet|*.*!*@*  $N$D30|Explicit$ routing$ not$ allowed
  tcp_local|*|tcp_intranet|"*@*"@*  $N$D30|Explicit$ routing$ not$ allowed
```

The final four entries will cause attempts by remote senders to submit explicitly source-routed messages to be immediately rejected. Note that depending upon the actual configuration of your other, internal hosts, it is often the case that even such explicitly source-routed attempts at relaying will not, in fact, end up truly getting relayed back out to the Internet, but will instead be rejected by the other, internal host. But by rejecting the attempts immediately, you can avoid getting (falsely) accused of being an open relay by carelessly constructed and operated relay testers, that only check if their relay attempt was initially blocked, rather than testing whether the probe message actually ever got relayed out and delivered.

62.14.1 SRS and Relay Blocking

Prior to the 8.0 release, decoding of SRS addresses happened invisibly before all other address processing (including probing of access mapping tables such as `ORIG_SEND_ACCESS`), with the result that when a remote site bounced a message from an SRS encoded sender address, the notification message returning to the encoded SRS address came to the MTA which decoded the address to (typically) discover a remote sender address and potentially reject the notification message as an attempt to "relay" (a notification message from a remote site to a remote original sender, in its attempt to pass through the MTA). As of 8.0, the still-SRS-encoded address is used in the `ORIG_SEND_ACCESS` probe, nullifying this problem. Meantime, in earlier versions, there is an approach to work around this problem.

Configuring with the `access_orcpt=2` and modifying the entries of the `ORIG_SEND_ACCESS` mapping table to expect an ORCPT field in each probe is one way to work around such an issue. In the following example, all the "usual" entries of `ORIG_SEND_ACCESS` have been modified to expect an additional field in the probe, the "orcpt" field, and an initial entry (prior to the basic `tcp_local` -> `tcp_local` block entry) has been added to allow passing through addresses that turn out to be "remote" when the MTA's own SRS encoding is removed:

```
ORIG_SEND_ACCESS

! Allow "relaying" of responses (such as notification messages) back to
! those original messages that came from remote senders to originally local
! recipients which the MTA relayed onwards, SRS-encoded, to remote recipients.
! That is, these are messages (notification messages) from remote sites to
! which local users had forwarded their e-mail, back to original senders to
! those (forwarding) local users:
! such messages that come in addressed using an SRS encoding with this MTA's
! own srs_domain, but which (once SRS encoding is removed) end up addressed
! back to a "remote" address.
!
  tcp_local|*|tcp_local|*|rfc822;SRS0=*<srs_domain>    $Y
!
! Normal relay blocking entry
!
```

```
  tcp_local|*|tcp_local|*|*              $NRelaying$ not$ permitted
!
! Block direct submission to MTA "intermediate" channels
!
  tcp_*|*|native|*|*       $N
  tcp_*|*|hold|*|*         $N
  tcp_*|*|pipe|*|*         $N
!
! Block direct submission to Message Store delivery channels;
! routing to such channel should only occur due to MTA address/alias
! processing
!
  tcp_*|*|ims-ms|*|*        $N
  tcp_*|tcp_lmtpcs*|*|*     $N
!
! Block "external" submissions of explicitly source-routed "internal" addresses
!
  tcp_local|*|tcp_intranet|@*:*.*|*   $N$D30|Explicit$ routing$ not$ allowed
  tcp_local|*|tcp_intranet|*$%*@*|*   $N$D30|Explicit$ routing$ not$ allowed
  tcp_local|*|tcp_intranet|*.*!*@*|*  $N$D30|Explicit$ routing$ not$ allowed
  tcp_local|*|tcp_intranet|"*@*"@*|*  $N$D30|Explicit$ routing$ not$ allowed
```

62.15 Triggering message transfer with remote SMTP systems

In cases where the network connection between two systems is only available at particular times---a "dial up" sort of connection for instance---there is an SMTP extension whereby one system can inform another that it is ready to receive mail. This is performed using the SMTP extension command ETRN, defined in RFC 1985: the side that desires to receive mail connects to the remote side's SMTP server and issues the command `ETRN` *`receivinghostname`*. If the remote side's SMTP server supports the ETRN command, it will then attempt delivery of any messages it has waiting to be sent to *`receivinghostname`*.

The MTA's SMTP server supports ETRN. In particular, the SMTP server interprets a received `ETRN` *`hostname`* command as a request to run the channel which *`hostname`* matches, a received `ETRN @`*`hostname`* as a request to deliver all messages in the *`hostname`* subnet, and a `ETRN #`*`channelname`* command as a request to run the channel *`channelname`*. By default, the SMTP server always responds to remote side's ETRN requests; if you wish to restrict this behavior, see `disableetrn` and related channel options, or the `ETRN_ACCESS` mapping table.

And outgoing SMTP-based channels, such as TCP/IP channels, can be configured to send an ETRN command at the beginning of an outgoing SMTP dialogue via the `sendetrn` channel option. For instance, suppose a system host1.acme.com has a dial-up connection to a remote system intermittent.some.where.com, where the intermittent.some.where.com system also supports ETRN. For a channel for connecting up to the remote side and sending ETRN, such a site might use a channel definition along the lines of:

```
tcp_dialup smtp mx daemon intermittent.some.where.com \
 periodic sendetrn host1.domain.com
TCP-DIALUP
```

As of iMS V5.0, there is an `ETRN_ACCESS` mapping table. Probes have the form:

transport-info|*app-info*|*channel-to-run*|*full-name*|*claimed-system*

(Here *claimed-system* is the ETRN parameter, and *full-name* is a processed version of that parameter.) If the mapping table returns a $N, $n, $F, or $f, then the ETRN command is rejected with a 459 4.5.0 error; by default

```
459 4.5.0 Cannot start delivery on channel - access denied
```

or if alternate text is included in the $N entry, then the alternate text is used.

If the ETRN_ACCESS mapping table returns a $S or $s, then the ETRN is attempted. If the mapping table also returns a $D*channel-name* or $d*channel-name*, then the MTA tries to lookup *channel-name* (in the channel/host table from the configuration file) and if that lookup is successful, runs that channel (rather than whatever channel the original ETRN command might have run).

62.16 Authentication errors and resultant SMTP errors

The authentication code performs various checks on the user account when attempting to authenticate, as for instance during SMTP AUTH processing. This may result in authentication errors being returned to the SMTP server, which will in turn issue an SMTP error back in response to the SMTP AUTH attempt. Errors of note include the following.

If the client's SMTP AUTH attempt uses either a bad username or a bad password, or the authentication mechanism is too weak for site policy, the SMTP server will issue the (same for each case) error response:

```
535 5.7.8 Bad username or password
```

though the SMTP server will optionally (log_message_id=1 and log_connection's bit 7/value 128 set) record the real cause of the authentication failure (respectively, "No such user" or "Bad password" or "Authentication mechanism is too weak") in the message-id field of the "U" connection transaction log entry.

If the LDAP attribute mailAllowedServiceAccess has been set to disallow SMTP access, the authentication attempt will be rejected with:

```
535 5.7.8 Authorization failure
```

If using this feature with the goal of disallowing certain users from sending messages, note that it is critically important to first configure so that users are *required* to use SMTP AUTH when submitting (see the mustsaslserver channel option); otherwise, in preventing certain users from sending when they properly authenticate, the unintentional (and undesirable) effect is likely to be to discourage those users from attempting authentication, instead effectively encouraging those users to send without authentication!

If the user's LDAP attribute mailUserStatus is set to inactive or disabled, then the SMTP error will be:

```
525 5.7.13 Account disabled
```

with, if MTA connection transaction logging is enabled and in particular if the optional SASL attempt logging is enabled, then in the resulting "U" connection transaction entry the message-id field will include additional detail: either "`Account disabled (inactive)`" or "`Account disabled (hold)`".

There are additional errors that may be returned, as for syntax problems in the client's SMTP AUTH command, or SASL mechanism problems, including:

```
501 5.7.0 Cannot decode BASE64
504 5.5.4 Unrecognized authentication type
501 5.5.0 Invalid input
523 5.7.10 Encryption needed to use mechanism
524 5.7.11 Password expired, has to be reset
```

Temporary LDAP errors will result in a temporary SMTP error:

```
454 4.7.0 Authentication server unavailable
```

62.17 Authentication errors

Table 62.10 HULA error status

Name	Text	Meaning
HULA_FAIL	Internal authentication error	
HULA_NOMEM	Not enough memory available	
HULA_BUFOVER	Internal buffer overflow	
HULA_NOMECH	Mechanism not available	
HULA_BADPROT	Invalid authentication protocol	
HULA_NOTDONE	Authentication not complete	
HULA_BADPARAM	Invalid parameter supplied	
HULA_TRYAGAIN	Transient failure -- try authentication again	
HULA_BADMAC	Message corrupted in transit	
HULA_BADSERV	Server failed authentication	
HULA_WRONGMECH	Mechanism doesn't support requested feature	
HULA_BADAUTH	Authentication failed	
HULA_NOAUTHZ	Not authorized to login asspecified user	
HULA_TOOWEAK	A stonger authentication mechanism is required	
HULA_ENCRYPT	Encryption required	
HULA_TRANS	A transition is needed to use the specified mechanism	
HULA_EXPIRED	Password expired	
HULA_DISABLED	Account disabled	Roughly speaking, a domain status of "`disabled`" or user status of "`disabled`". (More precisely, a domain status or user status that is not specially handled in another way: so for instance unrecognized status values also result in this error.)
HULA_NOUSER	User not found	
HULA_PWLOCK	Password locked	
HULA_NOCHANGE	No change was made	
HULA_NOTINIT	SASL library not initialized	

HULA_UNAVAIL	Service temporarily unavailable	Can't connect, or have trouble communicating with, the authentication server (*e.g.*, LDAP server).
HULA_NOVERIFY	Missing server authentication entry for user	
HULA_WEAKPASS	Password fails site security policy, try another	
HULA_NOUSERPASS	User supplied password not permitted	
HULA_INPROGRESS	Operation in progress	
HULA_SVRACCESS	Access control filter on server forbids connection	
HULA_DOMACCESS	Access control filter on domain forbids connection	
HULA_USERACCESS	Access control filter on user forbids connection	

Chapter 63 BSMTP channels

Batch SMTP (BSMTP) is a batch-mode implementation of the SMTP protocol which turns SMTP into a remote-submission protocol. For over a decade, batch SMTP was used quite heavily as a message transfer protocol on the international BITNET network. Cooperating MTA sites can use BSMTP as an effective means of moving mail in bulk between one another; for instance the exchange of company e-mail between two company offices by means of the Internet.

That is, it is possible to tunnel messages between two or more cooperating MTA systems using Batch SMTP (BSMTP). In addition, the MTA's general service conversion facilities can be used to provide services such as payload compression and digital signatures for authentication and integrity.

With BSMTP, messages are bundled together on one MTA system and then periodically transmitted through arbitrary MTAs and networks to a remote MTA system. Upon receipt at the remote system, the bundle is unpacked and the individual messages sent on to their recipients. Note that the bundled (encapsulated) handling of messages with BSMTP has the following inherent aspects which may be useful in some contexts:

1. The original message envelope information (sender, recipient, *etc*.) is not visible at the SMTP level on the intermediate MTAs; instead, the generic BSMTP addressing information is all that is visible at the outer message level.

2. The original message headers are transferred unaltered from the point of initial sending system's BSMTP bundling (encapsulation) until the destination system's BSMTP unbundling (message extraction) is performed.

Such aspects may be of interest in cases where it is desired to make *traffic analysis* (analysis of who is sending how much e-mail to whom) difficult, or when it is desired to protect original message headers from intermediate MTA processing, or desired to avoid exposing the intermediate MTA hops (*e.g.*, additional Received: header lines) to the final recipients. Furthermore, with the MTA's general service conversion facilities, arbitrary transformations can be performed on the bundles such as document conversion, compression, addition of digital signatures for authentication and integrity, *etc.*

63.1 Configuring the BSMTP channels

Each of the MTA systems which will be exchanging mail via BSMTP will need one incoming BSMTP channel and an outgoing BSMTP channel for each of the remote MTA systems. The channel definitions should be along the lines of:

```
bsin_gateway smtp
bsin.host0

bsout_remote1 smtp master user bsmtp daemon host1
BSOUT-REMOTE1
```

```
bsout_remote2 smtp master user bsmtp daemon host2
BSOUT-REMOTE2...

bsout_remoteN smtp master user bsmtp daemon hostN
BSOUT-REMOTEN
```

where host0 is the name of the local MTA host, as used by the other remote MTA systems, and host1, host2, ..., hostN are the host names of the remote MTA systems. The strings remote1, remote2, ... remoteN and REMOTE1, REMOTE2, ..., REMOTEN are arbitrary and need just be distinct from one another.

With the above definitions, the channel bsout_remote1 will bundle up its BSMTP parcels and send them on to the fixed address bsmtp@host1. Likewise for the remaining BSOUT channels.

The rewrite rules appear as:

```
domain1      $U%$H@BSOUT-REMOTE1$Nbsout_remote1
.domain1     $U%$H$D@BSOUT-REMOTE1$Nbsout_remote1
domain2      $U%$H@BSOUT-REMOTE2$Nbsout_remote2
.domain2     $U%$H$D@BSOUT-REMOTE2$Nbsout_remote2
...
domainN      $U%$H@BSOUT-REMOTEN$Nbsout_remoteN
.domainN     $U%$H$D@BSOUT-REMOTEN$Nbsout_remoteN
```

where domain1, domain2, ... domainN are the domain names of the remote MTA systems.

Finally, add to the FORWARD mapping table the entry

```
FORWARD

  bsmtp@host0     bsmtp@bsin.host0$Y$D
```

where, again, host0 is the host name for the local MTA system which will be used by the BSOUT channels on the remote MTA systems. That way, when they send BSMTP parcels to bsmtp@host0, it will be forwarded on to the local bsin_gateway channel.[1]

For example, assume that the domain.com domain will be exchanging BSMTP traffic with the domain.co.uk domain via the MTA hosts hub.domain.com and athena.domain.co.uk. Then hub.domain.com would have the configuration

```
domain.co.uk     $U%$H@BSOUT-REMOTE1$Nbsout_remote1
.domain.co.uk    $U%$H$D@BSOUT-REMOTE1$Nbsout_remote1

...

bsin_gateway smtp
bsin.hub.domain.com

bsout_remote1 smtp master user bsmtp daemon athena.domain.co.uk
BSOUT-REMOTE1
```

and the FORWARD mapping table entry

```
FORWARD

  bsmtp@hub.domain.com  bsmtp@bsin.hub.domain.com$Y$D
```

The system athena.domain.co.uk would have the configuration

```
domain.com    $U%$H@BSOUT-REMOTE1$Nbsout_remote1
.domain.com   $U%$H$D@BSOUT-REMOTE1$Nbsout_remote1

...

bsin_gateway smtp
bsin.athena.domain.co.uk

bsout_remote1 smtp master user bsmtp daemon hub.domain.com
BSOUT-REMOTE1
```

and the FORWARD mapping table entry

```
FORWARD

  bsmtp@athena.domain.co.uk  bsmtp@bsin.athena.domain.co.uk$Y$D
```

With the above configurations, when a user on hub.domain.com sends mail to user@domain.co.uk, the message is routed to the `bsout_remote1` channel. That channel will package the message up into a BSMTP parcel and send that parcel on to bsmtp@athena.domain.co.uk. Owing to the `$Nbsout_remote1` tag in the domain.co.uk rewrite rules, those rewrite rules will be ignored when the `bsout_remote1` channel enqueues the message. Instead, the normal rewrite rules for domain.co.uk will take effect and route the message containing the parcel out to the WAN (*e.g.*, the Internet).

Note that the outbound BSMTP channels can construct application/batch-smtp message parts containing multiple messages. As such, sites may wish to use the `after` channel option on their BSOUT channels. So doing may prove advantageous for sites who wish to bundle their mail up into large parcels and send those parcels only once every few minutes, hours, or days. Also, the ATTEMPT_TRANSACTIONS_PER_SESSION TCP/IP-channel-specific option might be used with the BSOUT channels to prevent cases where, under heavy load, a BSOUT channel just runs continuously bundling into a single parcel messages queuing up to be sent out. This option puts an upper limit on the number of messages placed in a single parcel and forces the channel to close a parcel, send it along, and start a new parcel when there are lots of messages to bundle up.

This completes the basic configuration so that BSMTP channels may run and deliver messages. Commonly, however, sites also desire to perform one or more forms of message transformation or processing on BSMTP messages; for further details, see BSMTP service conversions.

Note [1] Any of several mechanisms might be used to accomplish this forwarding. The most efficient is the use of an alias when `host0` is the official local host name for the MTA system. The least efficient is the `FORWARD` mapping table; which method is best for a given site depends upon site-specific issues. Use of the `FORWARD` mapping table is presented here because that method works in all cases.

63.2 BSMTP service conversions

The MTA's service conversion facility may be used with BSMTP channels to perform desired message transformations on incoming and outgoing messages.

Usually outgoing BSMTP channels, BSOUT channels, are configured to perform one sort of service conversion on the messages they emit, and incoming BSMTP channels, BSIN channels, are configured to perform the inverse service conversion on messages they receive. Thus when BSMTP channels are used, the configuration would also usually contain a `CHARSET-CONVERSION` mapping such as:

```
CHARSET-CONVERSION

  in-chan=bsout_*;out-chan=*;convert      yes
  in-chan=*;out-chan=bsin_*;convert       yes
```

whether in the MTA mappings file in legacy configuration, or in Unified Configuration alternatively appearing as:

```
msconfig> show mapping:CHARSET-CONVERSION
role.mapping:CHARSET-CONVERSION.rule = in-chan=bsout_*;out-chan=*;convert yes
role.mapping:CHARSET-CONVERSION.rule = in-chan=*;out-chan=bsin_*;convert yes
```

Note that the `CHARSET-CONVERSION` entries shown are such as to enable service conversions for messages sent from BSOUT channels (such as messages transitting through a BSOUT channel on their way out to an outgoing TCP/IP channel), as well as for messages sent to a BSIN channel (such as messages transitting through a BSIN channel on their way in from an incoming TCP/IP channel).

Once execution of service conversions has been enabled via a `CHARSET-CONVERSION` mapping such as that shown above, the specific service conversions to be performed must be configured: whether as conversions entries in Unified Configuration, or in the MTA `conversions` file in legacy configuration.

Chapter 64 ims-ms channels

ims-ms channels deliver messages to the Messaging Server Message Store. Normally, only one ims-ms channel is needed. But for special purposes, it is possible to define and use additional ims-ms_* channels.

64.1 ims-ms channel configuration

An appropriate initial ims-ms channel definition and rewrite rule(s) are normally set up by the initial Messaging Server MTA installation and configuration process. Such a channel definition usually looks something like:

```
msconfig> show channel:ims-ms
role.channel:ims-ms.official_host_name = ims-ms-daemon
role.channel:ims-ms.backoff = PT5M PT10M PT30M PT1H PT2H PT4H
role.channel:ims-ms.defragment (novalue)

role.channel:ims-ms.fileinto = $U+$S@$D
role.channel:ims-ms.maxjobs = 2
role.channel:ims-ms.notices = 1 7 14 21 28
role.channel:ims-ms.pool = IMS_POOL

role.channel:ims-ms.subdirs = 20
```

or in legacy configuration:

```
ims-ms defragment subdirs 20 notices 1 7 14 21 28 \
 backoff "pt5m" "pt10m" "pt30m" "pt1h" "pt2h" "pt4h" \
 maxjobs 2 pool IMS_POOL fileinto $U+$S@$D
ims-ms-daemon
```

Because the ims-ms channel is, on a typical system hosting a Message Store, such an important channel in the overall picture of message handling, here is a brief synopsis of these typical ims-ms channel option usages, discussed in turn.

- ims-ms channels should all normally be marked with the defragment channel option so that any incoming MIME fragmented messages will take a detour through the defragment channel to get an attempt at MIME message reassembly before being delivered to the Message Store.

- The ims-ms channel is typically a heavily used channel, at least on a system that hosts a Message Store with numerous active users. For a heavily used such channel, it is typically a good idea to configure with a generous number of subdirectories for performance reasons; thus the use of the subdirs option. On an especially busy Message Store system, where user quotas are enforced but a generous quota grace period is allowed, an even higher value for subdirs may be desirable. On a system that is only, or primarily, an SMTP relay host, that does not have a significantly used message store, use of subdirs may be unnecessary and the option might be removed.

- With the MTA option return_units at its (default) setting of 0 so that notices values are interpreted in units of days, the ims-ms channel is often set to retain messages for a rather long period, intended to cover the overquota grace period---that is, give users a chance to clean out old messages and receive their additional messages -- before eventually returning (bouncing) the messages as undeliverable. That is, a special setting rather more generous than the setting used for other channels (such as channels attempting to deliver out to the Internet) is often used.

- Fairly "rapid" initial additional delivery attempts are often configured for the ims-ms channel, via small initial backoff values. Since a user mailbox may get temporarily locked by the Message Store while another message is being delivered, or while a user is moving or copying a message to another folder via IMAP, it is possible to see short-term inabilities to deliver to a particular mailbox that will resolve relatively quickly. Thus it is worthwhile to re-attempt delivery at fairly rapid initial intervals. (This is unlike the case of a channel attempting to deliver to remote Internet hosts, where remote hosts may be unreachable for hours or days and hence where very rapid repeated delivery attempts may be useless and often even counter-productive, and where furthermore, Internet standards require waiting at least one half hour before reattempting message delivery to remote Internet hosts.)

- Due to the importance, in a typical deployment, of the ims-ms channel, a separate Job Controller pool intended for the sole use of the ims-ms channel is usually defined, and then the ims-ms channel is configured to run in that processing pool via the pool keyword. In particular, in this way the ims-ms channel runs in a separate Job Controller processing pool than TCP/IP channels (another heavily used type of channel), or than internal processing channels such as the process channel (used for processing notification messages, hence subject to periods of heavy use); the potential for competition for resources between these different types of channels is limited thereby. The maxjobs channel option is used to limit the number of simultaneously running ims-ms channel processes. Note that the ims-ms channel is multi-threaded; see the DELIVER_THREADS ims-ms-channel-specific option. So even a single ims-ms channel process can be attempting multiple deliveries at once. The Job Controller attempts to sort messages destined for a particular user into the same processing thread; this limits mailbox locking contention between different processing threads. (For another factor that can affect ims-ms channel performance, see the threaddepth channel option.)

- The fileinto channel option is used to specify support for Sieve fileinto actions. (That is, the fileinto channel option is used to specify what a Sieve fileinto action actually causes to occur---namely, changing the address to include the folder name as a subaddress. The ims-ms channel by default then interprets the subaddress as a request to deliver to the user's named folder, unless disabled via the ims-ms-channel-specific option FILEINTO.)

Rewrite rules for the ims-ms channel involve more complexity than the rewrite rules for many other types of channels, as they are fundamentally intertwined with direct LDAP lookup processing. This discussion will not attempt to cover the whole of direct LDAP

lookup processing; instead, this discussion will merely provide a brief overview (simplifying and omitting some details) of the basics of the rewriting involved in routing to the ims-ms channel.

Basic rewrite rules relevant for the ims-ms channel are normally set up by the initial Messaging Server MTA installation and configuration process. Those rewrite rules usually look something like:

```
! Basic direct LDAP rewrite rule to select local users
!
$* $A$E$F$U%$H$V$H@local-channel-official-host-name
!
! ...various other rewrite rules...
!
! ims-ms
.ims-ms-daemon $U%$H.ims-ms-daemon@ims-ms-daemon
```

where *local-channel-official-host-name* is the "l" channel's official host name, l.official_host_name in Unified Configuration, (or in legacy configuration, the first name on the second logical line of the c"l", lowercase ell, channel definition).

In Unified Configuration, this would appear as:

```
msconfig> show rewrite * $*
role.rewrite.rule = $* $A$E$F$U%$H$V$H@&/IMTA_HOST/
msconfig> show rewrite * .ims-ms-daemon
role.rewrite.rule = .ims-ms-daemon $U%$H.ims-ms-daemon@ims-ms-daemon
```

where note that the &/IMTA_HOST/ handles the insertion of the ldap_local_host value (which normally should match the channel:l.official_host_name value).

Also extremely relevant for the rewriting process for the ims-ms channel, and normal routing of messages to the ims-ms channel, are the MTA options alias_urlN, especially alias_url0, and delivery_options, especially its mailbox clause, normally set to:

```
*mailbox=$M%$\$2I$_+$2S@ims-ms-daemon
```

(And security-related settings are the use of the viaaliasrequired channel option on the local channel, and the ORIG_MAIL_ACCESS mapping table entry that blocks direct submission to *username*@ims-ms-daemon sorts of addresses; that is, these two configuration choices add in restrictions to mean that "local" addresses must have an alias in LDAP, and route to the ims-ms channel by way of an alias expansion.)

The normal process of routing messages to the ims-ms channel involves rewriting, alias expansion, and application of user LDAP attributes, as follows:

1. Initially, the domain in an envelope To address (recipient address) is used to do an LDAP search for the domain; this is done via the (direct LDAP domain lookup) rewrite rule:

```
$* $A$E$F$U%$H$V$H@local-channel-official-host-name
```

2. If the domain was found in LDAP, various domain level attributes are set and this rewrite rule (when the LDAP lookup succeeds) forcibly matches the address to the local (lowercase l) channel.

3. When an address matches the local (lowercase "l") channel, the MTA performs alias expansion on the address. In particular, this includes an LDAP lookup (the `alias_url0` lookup, and if other `alias_urlN` lookups are configured, then if necessary those lookups also) attempting to find an LDAP entry for this user address.

4. When a user entry is found in LDAP, the values of its `mailDeliveryOption` LDAP attribute (more specifically, the LDAP attribute named by the MTA option `ldap_delivery_option`) are inspected. A value of `mailbox` will cause the configured rule for the `mailbox` clause of the `delivery_options` MTA option to be applied; namely, the address will be converted to the form (if no subaddress/folder name is present):

   uid`%`*lowercased-domain-name*`@ims-ms-daemon`

   or if a subaddress/folder name is present:

   uid`%`*lowercased-domain-name*`+`*folder*`@ims-ms-daemon`

   Or if the domain name is actually the default domain name (as specified via either the `defaultdomain` option -- in legacy configuration, the configutil parameter `service.defaultdomain`, or the MTA option `ldap_default_domain`), then the domain name (and leading percent character) are omitted, hence:

   uid`@ims-ms-daemon`

   or

   uid`+`*folder*`@ims-ms-daemon`

5. This (transformed) address then goes through rewriting, and it forcibly matches the `ims-ms` channel, due to the matching official host name (`ims-ms-daemon`) for the channel: the message is routed to the `ims-ms` channel.

64.1.1 Additional ims-ms channels

It is possible to define additional `ims-ms_*` channels, if special needs would make additional such channels useful. Each such channel should have a name of the form `ims-ms_`*distinguishing-string*, and its own unique official channel host name. Note that due to the intimate connection between rewriting, alias expansion, and delivery options for `ims-ms` channels, getting additional `ims-ms_*` channels used by the MTA typically requires modification to other configuration choices also. For instance, one approach would be as follows.

In this example a new channel `ims-ms_shortterm` will have a shorter retention policy for holding onto messages that could not be delivered, while a new channel `ims-ms_vip` will have a faster delivery retry rate, and will run in its own Job Controller processing pool so as not to compete with the "regular" `ims-ms` channel and the `ims-ms_shortterm` channel.

First define additional `ims-ms_*` channels such as:

```
ims-ms_shortterm defragment subdirs 20 notices 1 7 14 \
 backoff "pt5m" "pt10m" "pt30m" "pt1h" "pt2h" "pt4h" \
 maxjobs 2 pool IMS_POOL fileinto $U+$S@$D
ims-ms-short-daemon

ims-ms_vip defragment subdirs 20 notices 1 7 14 21 28 \
 backoff "pt5m" "pt5m" "pt10m" "pt10m" "pt30m" "pt1h" "pt2h" \
 maxjobs 2 pool IMS_VIP_POOL fileinto $U+$S@$D
ims-ms-vip-daemon
```

Next tell the MTA about two new delivery option values, `mailboxshort` and `vipmailbox`, defining them in the MTA option `delivery_options`:

```
DELIVERY_OPTIONS=*mailbox=$M%$\$2I$_+$2S@ims-ms-daemon,\
 &members=*,\
 *mailboxshort=$M%$\$2I$_+$2S@ims-ms-short-daemon,\
 *vipmailbox=$M%$\$2I$_+$2S@ims-ms-vip-daemon,\
 *native=$M@native-daemon,\
 /hold=@hold-daemon:$A,\
 *unix=$M@native-daemon,\
 &file=+$F@native-daemon,\
 &@members_offline=*,\
 program=$M%$P@pipe-daemon,\
 #forward=**,\
 *^!autoreply=$M+$D@bitbucket
```

(In the above setting, note the use of a leading space before each continued line of the option value to avoid causing interpretation of characters such as # as a comment character. Note also that the site-specific definitions for `mailboxshort` and `vipmailbox` are added after the usual first two definitions for `mailbox` and `members` respectively, as these first two value clauses in the `delivery_options` definition have special meaning as far as being defaults.)

Finally, set appropriate users' LDAP entries with a value for the `mailDeliveryOption` attribute (or more precisely whatever attribute is named by the `ldap_delivery_option` MTA option) of `mailboxshort` or `vipmailbox` as desired.

64.2 ims-ms-channel-specific options

`ims-ms` channels support, in addition to the usual channel options, a number of `ims-ms`-channel-specific options. These `ims-ms`-channel-specific options are set in legacy configuration in a channel-specific option file, or in Unified Configuration are set under the channel's `options` option. For instance:

```
msconfig> set channel:ims-ms.options.DEBUG 4
```

Note that in Unified Configuration such channel-specific options (those set under the `options` option) are not (currently) schema checked: be careful when setting them as `msconfig` will not warn of invalid values or syntax as it would for regular channel options! (Nor will `msconfig` show whether or not such channel-specific options have any default value.)

In legacy configuration, where an option file is used, such an option file must be named *x*`_option` where *x* is the name of the channel, and stored in the MTA table directory. Hence the name of the `ims-ms` channel option file is `ims-ms_option`, *i.e.*`config-root/ims-ms_option`.

64.2.1 ims-ms-channel-specific options: DEBUG (integer)

The `DEBUG` ims-ms-channel-specific option can take values between 0, the default, up to 4; increasing values mean increasing amounts of debug output being written to the `imta` log file. The default of 0 means no debugging information. A value of 3 or more causes inclusion of information about the numbers of messages waiting and numbers of threads in use, and whether more threads must be started, and will also cause output when a thread exits, and if a shutdown request has been received. A value of 4 or more causes debug output regarding which message is currently being processed (specifically, the envelope From address for the current message), and debugging that such a message has been successfully delivered.

The debug output from setting `DEBUG` is normally directed to the `imta` file (not the `ims-ms_master.log-*` file), but will only be actually written to `imta` if the `loglevel` option for the MTA (in legacy configuration, the `logfile.imta.loglevel` configutil parameter) is set to the value `debug`. (And potentially, if the `syslogfacility` option is set -- `logfile.imta.syslogfacility` configutil parameter in legacy configuration -- then the output is instead directed to syslog.)

Setting the `master_debug` channel option on an `ims-ms` channel also forces a `DEBUG=4` level setting. `master_debug` itself will cause additional output, to a different log file, than the `DEBUG` ims-ms-channel-specific option; `master_debug` causes MTA processing debug output to be written to a *`channel-name`*`_master.log-*` file, normally an `ims-ms_master.log-*` file.

As of MS 6.2, see also the `activate` Message Trace option, which if set to `yes` will cause Message Store message tracing information to be written to the `msgtrace` file.

64.2.2 ims-ms-channel-specific options: DELIVER_THREADS (integer)

The `DELIVER_THREADS` ims-ms-channel-specific option controls the maximum number of delivery threads used by an individual `ims-ms` delivery process. The default is 15, unless the command line `-t` switch has been used to specify a different value. This option overrides such a command line `-t` switch.

64.2.3 ims-ms-channel-specific options: FILEINTO (0 or 1)

The `FILEINTO ims-ms`-channel-specific option controls whether subaddresses are interpreted as folder names for delivery purposes by the channel. The default is 1, meaning that such folder delivery is enabled. If this option is set to 0, then folder delivery is disabled.

This channel-specific option is not normally changed from the default value; but if it is, see also the general `fileinto` channel option, with whose setting this `ims-ms`-channel-specific option should be coordinated.

64.2.4 ims-ms-channel-specific options: LIFETIME_CAPACITY (integer)

The `LIFETIME_CAPACITY ims-ms`-channel-specific option specifies the maximum number of message files that a thread will handle before exitting. The default value is `-1`, meaning no limit. Note that this count of message files is based on the number of files handed to the channel, and that an individual message file, while from a single sender, may be destined for multiple recipients; in particular, the count is not based on the number of message recipients.

64.2.5 ims-ms-channel-specific options: LOG_DEQUEUE_RATE (0 or 1)

The `LOG_DEQUEUE_RATE ims-ms`-channel-specific option controls whether the channel logs the message dequeue rate. The default is 0, unless the command line `-d` switch has been used in which case the default is 1. The default of 0 means not to log message dequeue rate; a value of 0 means to log message dequeue rate; if the `DEBUG` level has been set to `2` or more, the message dequeue rate is periodically logged, rather than just a final summary being output.

64.3 ims-ms channel program switches

The Job Controller's default configuration has the Job Controller execute the `ims_master` channel program with no arguments:

```
msconfig> show job_controller.channel_class:ims-ms*.master_command
role.job_controller.channel_class:ims-ms*.master_command = IMTA_BIN:ims_master
```

But note that the `ims_master` channel program has two optional switches.

- `-d` specifies that minimal debugging is enabled (corresponds to setting the `DEBUG ims-ms`-channel-specific option to a value of 1; a higher `DEBUG` option value will override this command line effect).
- `-t`*`num-threads`* specifies that *`num-threads`* should be used; the `DELIVER_THREADS ims-ms`-channel-specific option, if specified, will override this value.

64.4 ims-ms channel debugging and error logging

Channel debugging output for the `ims-ms` channel goes to two (or three) places, the *`channel-name`*`_master.log-*` file, and the `imta` file, which is an NSLOG file, and as of MS 6.2, if message tracing is enabled (if the `messagetrace.activate` option in Unified Configuration or the `local.msgtrace.active` configutil parameter in legacy configuration is set to `yes`), then message tracing will also be written to the `msgtrace` file.

MTA processing debugging, including but not limited to the generation of nondelivery notifications, enabled for instance via the `master_debug` channel option, goes to a *`channel-name`*`_master.log-*` file. (Note that setting `master_debug` also forces the debug level controlled by `ims-ms.options.DEBUG` to at least 4, and as of MS 8.0.2, forces the `mta.logfile.loglevel` option setting to "debug".)

All ims-ms channel level processing goes to the imta file. In general, the level of detail recorded in the imta file is controlled by the mta.logfile.loglevel option in Unified Configuration or the configutil parameter logfile.imta.loglevel in legacy configuration; it can be set to any of the values critical, error, warning, notice, information, or debug.

In order for the debug output generated due to a non-zero DEBUG ims-ms-channel-specific option setting (ims-ms.options.DEBUG in Unified Configuration, or DEBUG option in the in the ims-ms channel option file in legacy configuration) to in fact get included in the imta log file, mta.logfile.loglevel (Unified Configuration) or logfile.imta.loglevel (legacy configuration) must hence be set to debug.

As of 8.0.1.2 the ims-ms.options.DEBUG option value defaults to 2. In earlier 8.0 versions the value is forced to 10 and the option setting is ignored. In 7.0.5 and earlier the default is 0, so either the channel-specific option or the master_debug channel option must be set in addition to mta.logfile.loglevel for debug output to appear.

A number of conditions can cause the ims-ms channel to fail to initialize. When this happens a critical error is sent to the imta file and the process exits with a nonzero status. Possible initialization failures include, but are not limited to:

PMDF_CHANNEL environment variable not defined	The PMDF_CHANNEL environment variable is used by the job controller to communicate the channel whose messages are to be processed. This error indicates that the variable is not set. This is usually an indication that the program has been run manually.
Failed to initialize the MTA	The MTA failed to initialized. This is usually the result of a configuration error of some sort
ims_master requires store.enable = 1	Self-explanatory.
ims_master requires store.dbtype = "bdb"	Self-explanatory.
inetu_uginit failed	The process was unable to initialize the LDAP client subsystem.
Failed to initialize the store API	The store failed to initialize. Additional errors may be logged providing more specific information

64.5 ims-ms channel error messages

MTA channels attempting to deliver to the Message Store, *i.e.*, ims-ms channels or tcp_lmtpcs* channels, can encounter several different sorts of issues: initialization errors (errors initializing the MTA, the Message Store, Message Store notify plugin code (if notifytarget named group options are set in Unified Configuration, or the local.store.notifyplugin configutil parameter is set in legacy configuration), domain map code, or LDAP pool code) many of which will cause the channel to abort, subsequent Message Store errors, subsequent trouble getting LDAP information about a domain or user, or IMAP error statuses when attempting to deliver particular messages. When encountering a problem doing an LDAP lookup for a domain or user while attempting to deliver a message, or an IMAP error status on a particular message, the MTA channel keeps running (and moves on to attempting to deliver any other messages awaiting delivery).

In particular, the IMAP error statuses reported by an `ims-ms` channel or LMTP server, when it attempts to access or manipulate the Message Store, are not specific to such channels, but rather are general IMAP error statuses (which may also be seen in other contexts, such as IMAP e-mail client attempts to access or manipulate the Message Store). Additional details on the underlying Message Store issue that gave rise to an IMAP error status may be available in the Message Store NSLOG logging for the component which encountered the issue; in the case of the `ims-ms` channel or LMTP server, see the `imta` NSLOG file discussed in ims-ms channel debugging and error logging.

Some IMAP error statuses are considered "permanent" errors: a message will be immediately bounced, if such an error is encountered. Other IMAP error statuses are considered "temporary" errors: a message will be retained in the MTA channel queue (`ims-ms` or LMTP client `tcp_lmtpcs*` channel) for further delivery attempts. See IMAP error statuses for a full listing of IMAP errors, or see IMAP error statuses relvant to the MTA for the subset of IMAP errors relevant to the MTA, and in particular relevant to the `ims-ms` and LMTP channels. (Note that in the case of LMTP, the IMAP error status is encountered by the LMTP server on a Message Store back end, which then reports the error to the LMTP client running on a "front end" MTA. So in the LMTP case, such errors may be reported in the LMTP server's message transaction log file, in an LMTP server log file, and also as a reported LMTP error in the LMTP client's log file or in the message transaction log file of the "front end" MTA running the LMTP client channel.)

Table 64.1 IMAP error statuses relevant to the MTA

Name	Type	Text+	Meaning
Delivery permanent errors			
IMAP_INVALID_USER	Permanent	Invalid user	The recipient address did not parse into syntactically valid uid, channel part, and optionally domain and/or folder portions
IMAP_QUOTA_EXCEEDED_PERSISTENT	Permanent	Over quota	The user has exceeded their configured quota for more than the configured grace period.
IMAP_MESSAGE_TOO_LARGE	Permanent	Message too large	Message is larger than the user's entire quota (`mailQuota`).
IMAP_MAILBOX_NONEXISTENT	Permanent	Mailbox does not exist	(Recall that these error messages are general IMAP error messages, that may occur in other contexts besides `ims-ms` channel or LMTP channel delivery.) When this error occurs in the context of an `ims-ms` or LMTP channel delivery, the meaning is as follows. Normally, the `ims-ms` channel and LMTP server `tcp_lmtpss*` channel will create a mailbox, if it does not exist. And when delivery to a specific folder is being attempted due to a Sieve `"fileinto"` action, and the folder does not exist, the channel will attempt to create the folder. (If the folder part of the address was not generated by the user's Sieve filter nor world writeable, then the channel will log a General facility, Information level notice to the `imta` file saying "`append_setup` *`path`* `failed, trying INBOX:`" followed by the IMAP_MAILBOX_NONEXISTENT error text. If the folder part was due to the user's Sieve filter but the folder could not be created, then the channel will log a General facility, Error level notice to the `imta` file saying "`mboxlist_createmailbox` *`path`* `failed, trying INBOX:`" with the specific IMAP error text.) But if the partition is bogus, then this error will be returned.
IMAP_MESSAGE_CONTAINSNULL	Permanent	Message contains NUL characters	(A message that has gone through the MTA will not normally cause such an error, as the MTA will normally legalize message content.)
IMAP_MESSAGE_CONTAINSNL	Permanent	Message contains bare newlines	(A message that has gone through the MTA will not normally cause such an error, as the MTA will normally canonicalize message content resulting in proper use of CRLF for line breaks, and encoded newlines in binary content; see the discussion of the `lmtp*` and `smtp*` channel options.)
IMAP_MESSAGE_BADHEADER	Permanent	Message contains invalid header	
IMAP_MESSAGE_NOBLANKLINE	Permanent	Message has no header/body separator	(A message that has gone through the MTA will not normally cause such an error, as the MTA will normally legalize messages one way or another; see the `*headertermination` channel options.)
IMAP_PERMISSION_DENIED	Permanent	Permission denied	
IMAP_CONFIG_ERROR	Permanent	Configuration error	Returned if either LDAP pool code, or the domain map code, cannot be initialized. (Note that normally such initialization is done when the `ims-ms` channel first starts up, and when the LMTP server first starts up, and errors initializing at that time will cause the channel or server to exit. So this is not expected to occur for the `ims-ms` channel and LMTP server `tcp_lmtpss*` channel at this later, message processing, stage.)

IMAP_PROXY_ONLY	Permanent	Server is not configured for local users	
IMAP_WRONG_MAILHOST	Permanent	Mailbox is on a different server	This suggest that either the user's LDAP entry is missing a `mailHost` attribute entirely, or their `mailHost` has been changed (their mailbox has been moved) while old messages were awaiting delivery in the `ims-ms` channel queue area, or that there is an error in the MTA configuration (causing it to attempt to deliver a message on the wrong `mailHost`), or operator error whereby messages have been manually moved (incorrectly) from one host to another.
IMAP_MAILBOX_BADNAME	Permanent	Invalid mailbox name	
	Delivery temporary errors		
IMAP_MAILBOX_LOCKED	Temporary	Mailbox is busy	The mailbox was locked. When this status is encountered, the MTA delivery channel (`ims-ms` or `tcp_lmtpcs*`) first retries 10 times at 100 millisecond intervals (before this error is ever even reported back from the channel). Prior to 8.0, lock attempts were nonblocking; a 1 second time is used in 8.0 or later. If the mailbox remains locked, then the channel gives up on this delivery attempt, generating a "`Q`" record with the "`Mailbox is busy`" reason if `logging` is enabled. And then there is special code in the `ims-ms` channel (and as of MS 7.0 in the LMTP client channel) to ask the Job Controller to retry delivery again very, very soon---with a randomly generated backoff of between one second and two minutes---overriding the normal `*backoff` values. Occasional occurrences of such a temporary error are normal, as for instance if a user is logged in and performing extensive, time-consuming operations on a mailbox; indeed, it is because an occasional such occurrence is "normal" that the delivery channels have special code to handle this (usually transient) error condition by retrying delivery very soon. However, persistent occurrences for the same user might suggest a problem with that user's mailbox. Or, if such errors suddenly start occurring at around the same time for all (or many) users, that could be a suggestion of some more widespread and general problem with the Message Store.
IMAP_MAILBOX_BADFORMAT	Temporary	Mailbox has an invalid format	The mailbox may be corrupted.
IMAP_MAILBOX_NOTSUPPORTED	Temporary	Operation is not supported on mailbox	The mailbox may be corrupted.
IMAP_IOERROR	Temporary	System I/O error. Administrator, check server log for details.	The Message Store may be corrupted, or otherwise inaccessible (*e.g.*, disk not mounted); or the Message Store `store.idx` file may have reached its 2 gigabyte size limit.
IMAP_PARTITION_UNKNOWN	Temporary	Unknown/invalid partition	The user's `mailMessageStore` LDAP attribute does not correspond to a *`partition-name`* defined via a `path` partition option in Unified Configuration (a `store.partition.`*`partition-name`*`.path` configutil parameter in legacy configuration), or the value of that option or configutil parameter does not point to a valid location, or contains invalid characters (only alphanumeric characters are allowed). (If a user does not have a `mailMessageStore` set at all, then the Message Store's default partition, `defaultpartition` Message Store option in Unified Configuration or `store.defaultpartition` configutil parameter in legacy configuration, is assumed, which defaults to `primary`. When the absence of an explicit `mailMessageStore` is causing use of the default partition, then whatever the default partition is, it must then have a valid path specified in the `path` option for that named partition in Unified Configuration (`partititon:`*`whatever`*`.path`) or the `store.partition.`*`whatever`*`.path` configutil parameter; in particular, when `store.defaultpartition` has its default value of `primary`, then the primary partition must have a valid path specified in `partition:primary.path` in Unified Configuration or `store.partition.primary.path` in legacy configuration.)
IMAP_PARTITION_FULL	Temporary	Store partition is full	See also the (new in MS 6.2) configutil parameters `local.store.checkdiskusage` and `local.store.diskusagethreshold` (initially instead named `local.store.diskthreshold` in MS 6.2), or in Unified Configuration the `checkdiskusage` and `diskusagethreshold` Message Store options, which control whether---and when---the store performs checks on its disk space usage. With such checks enabled, the store will "lock" a partition (at which point the IMAP_PARTITION_FULL error will be returned) slightly before the partition is actually filled up. This is a safety measure, to ensure that expunge operations (which need to rewrite the index files) have disk room in which to operate.
IMAP_QUOTA_EXCEEDED	Temporary	Over quota	The recipient has exceeded their configured quota, but for less than the configured grace period.
	Other statuses (not seen by `ims-ms` channels or LMTP channels)[++]		
IMAP_USERFLAG_EXHAUSTED		Too many keywords in mailbox	
IMAP_MAILBOX_EXISTS		Mailbox already exists	When attempting to create a folder, this is a success status
IMAP_MAILBOXLIST_NONEXISTENT		Mailbox list does not exist	
IMAP_INVALID_IDENTIFIER		Invalid identifier	May occur when attempting to set an ACL on a folder
IMAP_INVALID_MSGNO		Invalid message number	
IMAP_QUOTAROOT_NONEXISTENT		Quota root does not exist	

[+] The IMAP error text is localizable. The text shown in this table is merely the default text (which happens to be English).

[++] For completeness, additional IMAP statuses are listed, though they are not normally relevant (do not normally appear) as ims-ms channel or LMTP channel delivery error statuses.

The IMAP delivery temporary error statuses listed in IMAP error statuses relevant to the MTA may appear in the "history" field of messages that failed a delivery attempt; this is visible via, for instance, the history command of the imsimta qm utility, as well as being physically present in the history field in the deferred message files awaiting further delivery attempts in the MTA ims-ms channel disk queue area or tcp_lmtpcs* channel disk queue area. (Should a message eventually bounce due to "timing out", such history information may also be included in the bounce message, as controlled by the history_to_return MTA option.) Furthermore, the temporary error text will be included in the ims-ms channel's "Q" record in the MTA message transaction log file, should such logging be enabled via use of the logging channel option.

The IMAP delivery permanent error statuses shown in IMAP error statuses will appear in the ims-ms channel's or tcp_lmtpcs* channel's "R" or "K" record in the MTA message transaction log file, should such logging be enabled via use of the logging channel option.

As with other types of channel processes, the ims-ms channel processes do not have an infinite life time: after running for a (configurable) while, they shut down (and the Job Controller will start up new ims-ms channel processes, as needed). The Job Controller options max_life_time and max_life_askwork (max_life_age and max_life_conns, respectively, in legacy configuration) and the ims-ms channel's own 60 seconds limit on time to persist while idle, control the timing of the ims-ms channel process "recycling". In addition, an administrator restart of the Job Controller will cause the Job Controller to tell channel processes to shut down. So notices in the imta log file such as the following are part of normal operation:

At Notice level:

product ims_master *version* shutting down

product ims_master *version* starting up

And at Debug level: When the ims-ms channel process' threads have all been idle for 60 seconds or more (or are deadlocked):

idle shutdown

When a thread is exiting due to having no work to do:

T*thread-number* exiting

When the Job Controller is telling a process to shut down due to the process having gotten old:

EOF from job controller

And after an administrator restart of the Job Controller, the following sorts of messages can also be expected in the imta file. At Debug level:

`shutdown received`

When the Job Controller is telling a process to shut down due to an administrator `restart` command:

`exit from job controller` *`mta-status`*

A message (at Warning level) of

`Shutdown timeout, possible deadlock`

however, is an indication that one or more threads in a process attempting to shut down have not been able to finish their work. If this error repeats, it may indicate that a mailbox is corrupted or locked.

In an MTA message transaction log file "`Q`" or "`Z`" record, a reason of "`shutdown`" indicates that a delivery attempt for that recipient is being deferred due to a shutdown in progress---either an administrator's manual shutdown, or a shutdown due to a channel process "timing out".

Chapter 65 Other channels

The MTA has a number of subsidiary channels, (that is, channels used for internal or special processing purposes, rather than for delivery to local mailboxes or relaying to remote hosts), and a sample "generic" SMTP channel provided as an example of channel code, including:

- the Local channel,
- the `bitbucket` channel,
- the `defaults` and `nodefaults` pseudo-channels,
- the `conversion` channel,
- the `defragment` channel,
- the `filter_discard` channel,
- the "generic" SMTP channels,
- the `hold` channel,
- the `pipe` channel,
- the `process` and `reprocess` channels,

The `defaults` and `nodefaults` pseudo-channels, which are place-holders rather than actual channels, are discussed under Channel configuration. The `conversion` channel, which has relatively complex configuration, is discussed separately under Message conversions. The other channels listed are discussed in the chapter below.

65.1 Local channel

In modern usage, the local or "l" channel's main use is as a placeholder in identifying "local" addresses, in that (normally) only addresses that initially rewrite to the local channel will be checked for MTA aliasing. (See, however, the `aliaslocal` channel option.) The presence of the `viaaliasrequired` channel option on the "l" channel is critical both operationally and for security purposes, as it enforces that *only* those addresses that have a successful alias lookup (hence correspond to a provisioned address) are accepted as valid "local" addresses.

In principle, the local channel could also be used to deliver messages to UNIX mailboxes on the local host; however, that use is deprecated.

In principle, the local channel would also be considered to be the source of messages submitted on the iMS host itself via utilities such as `sendmail`, `mail`, `mailx`, `mailtools`, `imsimta send`, *etc.*; however, such submission is mostly moot nowadays.

Configuration settings on the "l" channel are somewhat privileged, since it is taken (in the absence of overriding configuration settings) as the default set of names for the MTA system itself. See the `notices` channel option. And compared to the "l" channel `official_host_name`, see the `id_domain` and `received_domain` MTA options and the BANNER_HOST TCP/IP-channel-specific option for some examples of configuration options to override this "l" channel value.

65.2 Bitbucket channel

As the name itself suggests, the bitbucket channel simply deletes any message enqueued to it. Indeed, messages that match the bitbucket channel are instantly deleted, without even being written to a bitbucket disk area. (In particular, note that no `IMTA_QUEUE:bitbucket/*` (or equivalently `$DATAROOT/queue/bitbucket/*`) message files are created---a message is simply discarded immediately once the MTA sees that it matches the bitbucket channel. However, if logging is enabled then the MTA does write MTA transaction log entries for the bitbucket channel as if it actually ran, for monitoring/statistics purposes. (Note that the bitbucket channel "`D`" supposed "dequeue" record is in fact written by the enqueueing process at the same time as it writes its "`E`" supposed "enqueue" record: note the identical time stamps and, if the MTA option `log_process=1` is set, the identical process id corresponding to the enqueuing process.)

Note that Sieve filter "`discard`" and "`jettison`" actions are, depending upon the setting of the `filter_discard` and `filter_jettison` MTA options, potential sources of purported "enqueues" to the bitbucket channel, as are matches of an attempted poster's envelope From address to the value of an `mgrpJettisonDomain` or `mgrpJettisonBroadcasters` LDAP attribute (more precisely to the value of whatever LDAP attributes are named by the `ldap_jettison_domain` or `ldap_jettison_url` MTA options), as well as `*_ACCESS` mapping table `$V`, `$v`, `$Z`, or `$z` flag effects.

65.2.1 Bitbucket channel configuration

Bitbucket channel configuration is quite simple and minimal, consisting of a bare bones channel definition and a few rewrite rules to recognize pseudodomain name(s) which will be used when directing messages to the bitbucket channel. (Even if users never explicitly type in a bitbucket domain name, note that the MTA itself uses some bitbucket pseudodomain names internally, as in certain `delivery_options` values.)

For instance, initial configuration normally creates:

```
msconfig> show channel:bitbucket
role.channel:bitbucket.official_host_name = bitbucket-daemon
msconfig> show rewrite.rule * bitbucket*
role.rewrite.rule = bitbucket $U%bitbucket.domain.com@bitbucket-daemon
role.rewrite.rule = bitbucket.&/IMTA_HOST/ $U%bitbucket.domain.com@bitbucket-daemon
```

65.3 Defragmentation channel

The MIME standard (RFC 2046) provides the message/partial content type for breaking up messages into smaller parts. This is useful when messages have to traverse networks with size limits. It can also be useful when sending over networks subject to connection drops, as a form of "check-pointing" of the sending of a message, since a connection drop during transmission of a fragment of a message will require resending only of that fragment, rather than of the entire message. Information is included in each part so that the message can be automatically reassembled once it arrives at its destination.

The `defragment` channel option (used on channels *other* than the defragmentation channel) and the defragmentation channel itself provide the means to reassemble messages in the MTA. When a channel is marked `defragment`, any message/partial messages queued to that channel will be placed in the defragmentation channel queue instead. The defragmentation channel maintains a database which is used to match the parts of each message up with each other. Once all the parts have arrived, the message is rebuilt and sent on its way.

The defragment database can optionally be stored on a filesystem accessible to multiple hosts (for instance, over NFS), and then shared by multiple hosts. Such sharing of the defragment database can be particularly useful for achieving appropriate and efficient message defragmentation in multi-tiered, multi-plexed deployments. See Multi-host defragmentation channel operation for further details.

All channels that perform local delivery or send messages on to hosts (*e.g.*, LMTP back end Message Store hosts) or networks that cannot deal with fragmented messages should be marked with the `defragment` channel option. In particular all `ims-ms` and `tcp_lmtpcs*` channels should be marked with the `defragment` channel option. The `defragment` channel option will have no effect unless a defragmentation channel is also defined.

A defragmentation channel is produced automatically by initial configuration.

65.3.1 Defragmentation channel configuration

A defragmentation channel is normally generated as part of an initial configuration.

In legacy configuration, the defragmentation channel definition consists of a channel entry, at its most minimal perhaps merely:

```
defragment
defragment-daemon
```

or as of 8.0:

```
defragment receivedstate "convert/defragment"
```

`defragment-daemon`

and rewrite rules of the form:

```
defragment                  $U@defragment.localhostname@defragment-daemon
defragment.localhostname    $U@defragment.localhostname@defragment-daemon
```

where `localhostname` should be replaced by the name of the local host.

In Unified Configuration, the equivalent would be:

```
msconfig> show channel:defragment.*
role.channel:defragment.official_host_name = defragment-daemon
msconfig> show rewrite.rule * defragment*
role.rewrite.rule = defragment $U%defragment.domain.com@defragment-daemon
role.rewrite.rule = defragment.&/IMTA_HOST/ $U%defragment.domain.com@defragment-daemon
```

(with `domain.com` being replaced by a site's own domain name).

Once such a defragment channel and rewrite rules are in the configuration, then an address of the form

user%host`@defragment.`*localhostname*

will be routed through the defragmentation channel. (Sending anything other than a message/partial message to the defragmentation channel causes the channel to simply requeue the message for normal delivery.)

65.3.2 Defragmentation-channel-specific option: MAX_PARTS (10 <= integer <= 100,000)

New in Messaging Server 7.4-18.01, the defragmentation channel supports, (in addition to the usual channel options), one defragmentation-channel-specific option, MAX_PARTS. MAX_PARTS specifies the maximum number of fragments a message can be broken into and still be reassembled. The maximum is 100,000; the minimum is 10; the default is 1000.

This defragmentation-channel-specific option would be set in legacy configuration in a channel-specific option file, `IMTA_TABLE:defragment_option`, or in Unified Configuration is set under the channel's `options` option. For instance:

```
msconfig> set channel:defragment.options.MAX_PARTS 500
```

Note that in Unified Configuration such channel-specific options are not (currently) schema checked: be careful when setting them as `msconfig` will not warn of invalid values or syntax as it would for regular channel options! (Nor will `msconfig` show whether or not such channel-specific options have any default value.)

In legacy configuration, where an option file is used, such an option file must be named `defragment_option`, and stored in the MTA table directory.

65.3.3 Defragmentation channel message retention time

Messages are retained in the defragment channel queue only for a limited time. When one half of the time before the first nondelivery notice is sent has elapsed[1] (and a backoff time has elapsed so that the channel is attempting to process relevant message fragments), the various parts of a message will be sent on without being reassembled. This choice of time value (normally) eliminates the possibility of a nondelivery notification being sent about a message in the defragment channel queue.

The notices channel option (and optionally its priority-sensitive variants, *notices) controls the amount of time that can elapse before nondelivery notifications are sent, while the backoff channel option (and optionally its priority-sensitive variants, *backoff) controls when message delivery attempts are made. So between the two of them, they control the amount of time messages are retained before being sent on in pieces, with notices normally being the primary control (controlling how long before the channel "gives us" on attempting to reassemble message fragments), modulated by when the backoff values in fact cause the channel to run and attempt message delivery (hence deliver message fragments that have lingered past half the final notices value and still do not make up a complete message "as is", without reassembly). Set the notices option value to twice the amount of time you wish to retain messages for possible defragmentation (and ensure that the backoff values in effect for the defragment channel are such that a delivery attempt will be made shortly after half the final notices value). For example, normally a notices value of 4 would cause retention of message fragments for two days:

```
defragment notices 4
defragment-daemon
```

Or if the more general backoff values do not align well with the defragment channel's notices time scale, then also set some sensible backoff values explicitly on the defragment channel. For instance, setting the final backoff value to p4h means that message (fragments) will get a reassembly-and-possible-delivery attempt every four hours. Hence the following sort of definition:

```
defragment backoff "p1h" "p2h" "p2h" "p4h" notices 4
```

will mean that message fragments will get sent on as is (still as fragments, rather than reassembled) after approximately forty-nine hours. (There will be message delivery attempts immediately, then at one hour, three hours, five hours, nine hours, then every four hours thereafter---so the first time past the two day point, the expiration of half of the notices final value, will be at forty-nine hours.)

When the defragment channel cannot reassemble a message, and decides to send onwards a message fragment, it will add a header line

```
Defragment-failed: official-local-host-name
```

showing the official_host_name from the L channel.

[1] Note that the "half" is calculated using integer integral division but not allowed to go below one, so for instance an initial notices value of 5 results in fragments being eligible for delivery after 2 days or hours depending upon return_units, but even an initial notices value of 1 still means fragments aren't eligible for delivery until after 1 day or hour.

65.3.4 Multi-host defragmentation channel operation

The defragment database can optionally be stored on a filesystem accessible to multiple hosts (for instance, over NFS[1]), and then shared by multiple hosts. This can be particularly useful when multiple "front end" hosts can potentially deliver to the same "back end" message stores, particularly when the "back end" message store can not do message defragmentation itself (as for LMTP message stores).

To set up such sharing, make a link from the `config-root/defragment_cache` on each individual system to whatever file you want to have be the shared defragment database on the shared (NFS) disk. Note that the NFS mounted file system should be set for "soft mount" with a relatively short time out, rather than for (the default for NFS) "hard mount". Regarding the NFS time out, the NFS mount option (see the `mount_nfs(1M)` man page) `timeo` will need to be set on the `/etc/dfs/dfstab` entry (or amtomount map) that causes the file system to be mounted. (With a "hard mount", if NFS went down then the defragment channel would hang, waiting for the access to the defragment cache to succeed. But with a "soft mount", the defragment channel will time out its attempt to access the defragment cache. So the channel will not hang; instead, in the unlikely event that all message fragments happen to end up on one host, that host's defragment channel should be able to reassemble the fragments and send the message onwards, properly reassembled; but more likely, the fragments will be spread among different hosts, none of which can reassemble or properly route to another host's defragment channel in the absence of successful access to the defragment cache, so instead the various fragments with eventually get sent onwards still as separate fragments.)

When setting up a defragment database that will be shared over NFS by multiple systems, note that the MTA user (typically `mailsrv` -- see the `user` option in `restricted.cnf`) on each system must be defined to have the same `uid` number on each system. If systems define the MTA user with different `uid` numbers, permission problems can be expected.

The defragment database entries include a field specifying the host upon which a message fragment resides. Once an initial part has been received and noted in the defragment database, any other parts of the message that are received on any other systems using the same defragment database will get routed to that "first" host that received the "first" part. (The defragment channel when it runs, first checks if any message fragment parts are already present, and if so on which host; then if a part or parts are already present on some other host, the defragment channel sends its just-received part onward to the other host, using explicit source routing to route to the other host, rather than retaining the part for reassembly attempts itself. See the Multi-host defragmentation channel operation example for an example.) Thus all remaining parts of a fragmented message end up getting redirected to the host whose defragment channel happened to attempt processing the very first (first to arrive, not necessarily part=1) part of the message; that host's defragment channel is then responsible for doing the message defragmentation (reassembly) once all fragments have been received. (One consequence is some load-balancing of the defragmentation of messages depending upon which host happens to receive the "first" part of each message.)

[1] Note that sharing the defragmentation database over NFS is an exception to the general rule that the MTA does not support sharing filesystems via NFS. The MTA's use of the defragment database has been specially designed with NFS' limited locking semantics in mind.

65.3.4.1 Multi-host defragmentation channel operation example

The defragmentation channel supports operating in a setup where multiple hosts share the same defragmentation database. In such setups, the routing of message fragments to and between defragment channels on a multi-host setup (when multiple hosts are sharing the same defragment database) is as follows:

1. "`message/partial; id=123; part=x`" arrives on host 1, and is routed to the defragment channel on host 1 due to the `defragment` keyword being present on what would otherwise be the destination/outbound channel.

2. The defragment channel on host 1 runs, checks the defragment database for whether any other parts of this message have yet arrived. None have, so the defragment channel (on host 1) enters this part into the defragment database marking the part as being on host 1.

3. "`message/partial; id=123; part=y`" arrives on host 2, and is routed to the defragment channel on host 2 due to the `defragment` keyword being present on what would otherwise be the destination/outbound channel.

4. The defragment channel on host 2 runs, checks the defragment database, sees that part x of this message is already present and stored on host 1. So the host 2 defragment channel redirects the message over to host 1 (source routes the address with `@host1`).

5. "`message/partial id=123; part=y`" arrives on host 1, is routed to the defragment channel, the host 1 defragment channel runs and enters it into the database, *etc*.

6. Eventually, the "final" fragment of the message gets to host 1 (possibly having first gone through another host such as host 2, which then routed the message to host 1). The defragment channel runs and now sees that it has all the fragments of the message, reassembles them all into the original message, and sends the message onwards to the intended recipient.

65.4 filter_discard channel

By default, messages discarded via a Sieve filter are immediately discarded (deleted) from the system. However, when users are first setting up Sieve filters (and perhaps making mistakes), or for debugging purposes, it can be useful to have the deletion operation delayed for a period. (Certain flags in *_ACCESS mapping tables cause Sieve filter like discarding of messages; such messages also are eligible for delayed deletion.)

To have Sieve filter discarded messages temporarily retained on the MTA system for later deletion, first add a `filter_discard` channel in your MTA configuration, *e.g.*:

```
filter_discard notices 7
FILTER-DISCARD
```

or in Unified Configuration:

```
msconfig> set role.channel:filter_discard.official_host_name FILTER_DISCARD
msconfig# set role.channel:filter_discard.notices 7
```

As of 8.0, use of the new-in-8.0 `receivedstate` channel option is recommended, so:

```
msconfig> set role.channel:filter_discard.receivedstate "quarantine/sieve-discarded"
```

or in legacy configuration:

```
filter_discard receivedstate "quarantine/sieve-discarded" notices 7
FILTER-DISCARD
```

with the notices channel option specifying the length of time (normally number of days) to retain the messages before deleting them. Then set the MTA option filter_discard=2:

```
msconfig# set role.filter_discard 2
```

By default, messages discarded due to a Sieve "jettison" action get the same handling as those discarded due to a "discard" action, as controlled by the filter_discard MTA option, either being deleted from disk immediately or retained in the filter_discard channel queue area. However, the filter_jettison MTA option may be used to differentiate the handling; for instance, if one wishes to retain messages discarded by a (presumably user level) "discard" action in the filter_discard channel, while immediately deleting messages discarded due to a (system level) "jettison" action, one could set filter_discard=2 and filter_jettison=1:

```
msconfig> set role.filter_discard 2
msconfig# set role.filter_jettison 1
```

Setting the MTA option filter_jettison=2 explicitly (or the implicit effect if the MTA option filter_discard=2 is set) will cause messages discarded due to a Sieve "jettison" action to be retained in the filter_discard channel.

Messages in the filter_discard channel queue area should be considered to be in an extension of users' personal wastebasket folders. As such, note that warning messages are never sent for messages in the filter_discard channel queue area, nor are such messages returned to their senders when a bounce or return is requested. Rather, the only action taken for such messages is to eventually silently delete them, either when the final notices value expires, or if a manual bounce is requested using a utility such as imsimta return or the imsimta qm utility's return command.

65.4.1 Retrieving messages from the filter_discard channel

One reason for configuring use of the filter_discard channel (rather than simply having "discarded" messages immediately deleted from disk) is that it permits the potential for the system administrator to "retrieve" messages while they are still in the filter_discard channel queue on disk. The general process for such "retrieval" is as follows:

1. Move the message files in question manually to the reprocess channel queue area (typically DATAROOT/queue/reprocess), changing the filename slightly (*e.g.*, from *.00 to *.02) when doing so, and making sure to preserve the proper ownership and protections on the message files.

2. Issue the command "imsimta cache -synch" so that the Job Controller will do an immediate scan to notice the moved message files. (If one is in no particular hurry for such messages to begin getting delivery attempts, this step can be omitted in favor of waiting for the Job Controller to get around to noticing such files on its own; the Job Controller normally scans automatically every four hours per its synch_time option.)

3. After the imsimta cache -synch has completed, one may issue the command "imsimta run reprocess " to run an extra reprocess channel job immediately, rather than

waiting for the Job Controller to get around to scheduling a reprocess job to process any messages (such as the recently moved messages) that it might have due for processing.

When the MTA applies a Sieve "discard" or "jettison" action, a bit in the message envelope gets set; if the MTA subsequently sees a message file that has that bit set, it will not again apply a Sieve "discard" or "jettison" action. The purpose of this is precisely so that the above sort of operation (moving a previously discarded message from the filter_discard channel to the reprocessing channel) can be used to get messages delivered, without the "discard" getting re-applied.

Note that the discarding of a message can be caused by a "discard" or "jettison" actions arising from any of a number of locations, including a number of potentially applicable Sieve filters (system, channel, user, group, domain, *etc.*), or by address-based *_ACCESS mapping table $v, $V, $z, or $Z flags. Wherever/whatever the source of the discarding action, the setting of the same ignore-future-discard-actions bit occurs, and if such a message is subsequently "retrieved" (reinjected into the MTA's regular channel queues typically being moved manually to the reprocess channel queue area), then *all* such discarding actions that might otherwise be applicable on this MTA will be henceforth ignored for the message in question (on this MTA -- such delivery flags are not normally transferred to other MTAs, though see the flagtransfer channel option).

One more note: messages enqueued to the filter_discard channel always get the username field for the message (the "owner" of the message for access purposes) set to the string "FILTER_DISCARD"; this value will, for instance, show up in the log_username field of the MTA message transaction log file.

65.5 Generic SMTP channels

The channel programs test_smtp_master and test_smtp_slave are provided as models upon which additional channels using the SMTP protocol can be built. They are intended as examples only and not as production channel programs.

Both programs require that the environment variable PMDF_CHANNEL (on UNIX) translate to the name of the channel they are servicing -- and expect that channel to be defined in the MTA configuration.

When test_smtp_master is executed, it asks the Job Controller for messages waiting to be processed by the channel PMDF_CHANNEL. SMTP commands are written to stdout and responses are expected on stdin.

Similarly, test_smtp_slave accepts SMTP commands on stdin and writes responses to stdout.

The the imsimta run utility and the regular configuration of the Job Controller never invoke test_smtp_master and will have to be modified in order to use test_smtp_master. The configuration to execute tcp_master can be used as a model to drive test_smtp_master.

test_smtp_master includes code to distinguish between use as a direct connection to the target system and use for routing through a gateway. This facility parallels the gateway support found in TCP/IP channels, namely support for the daemon option.

Though test_smtp_master and test_smtp_slave never open or receive, respectively, an actual TCP/IP connection, if the environment variables TRANSPORTINFO and

APPLICATIONINFO are set, then these programs will use that information to initialize the relevant fields that would be present in a real SMTP-over-TCP/IP message transport.

`test_smtp_master` and `test_smtp_slave` perform normal MTA channel initialization steps, including consulting the MTA configuration to determine if the named channel (the channel PMDF_CHANNEL translates to) has any `local_host_alias` set; they check for any TCP/IP-channel-specific options; and they "support" typical channel options relevant to SMTP-over-TCP/IP channels, such as `master_debug`, `slave_debug`, `smtp*`, and (as previously mentioned) the `daemon` channel option.

65.6 Hold channel

When messages are incoming to a user whose `mailUserStatus` attribute (more precisely, the attribute named by the `ldap_user_mail_status` MTA option) is set to a value of `hold`, or who is in a domain whose `mailDomainStatus` attribute (more precisely, the attribute named by the `ldap_domain_attr_mail_status` MTA option) is set to a value of `hold`, then the messages will be routed to the hold channel and will be marked as `.HELD`. (Both of these things---the routing to the hold channel, and the marking of the message as `.HELD`---are configured via the `delivery_options` MTA option's value for the `hold` clause.)

The hold channel is intended for temporarily detaining messages addressed to users (or to users in domains) for purposes such as migration of the users' (or an entire domain of users') mailboxes. The incoming messages can be sidelined in the hold channel queue area on disk, and then once the users' mailboxes are once again ready to receive e-mail, and the user and/or domain status has been set back to `active`, the messages can be delivered onwards.

Hold channel configuration discusses the basic configuration of the hold channel. Releasing messages from the hold channel discusses how to release messages from the hold channel.

65.6.1 Hold channel configuration

The initial configuration generated during an install generates a hold channel. The channel definition and basic rewrite rules would normally appear as

```
msconfig> show channel:hold
role.channel:hold.official_host_name = hold-daemon
msconfig> show rewrite * *hold*
role.rewrite.rule = hold-daemon $U%$H@hold-daemon
role.rewrite.rule = .hold-daemon $U%$H@hold-daemon
```

Or in legacy configuration:

```
hold
hold-daemon
```

and rewrite rules appearing as

```
hold-daemon $U%$H@hold-daemon
.hold-daemon $U%$H@hold-daemon
```

Note that as of MS 6.0, the hold "channel" is in fact merely a variant (same image, but run as a different channel) of the reprocess channel. In particular, the Job Controller configuration should include:

```
msconfig> show job_controller.channel_class:hold
role.job_controller.channel_class:hold.master_command = IMTA_BIN:reprocess
```

Or in legacy configuration, the Job Controller configuration file, normally `job_controller.cnf`, should contain a definition:

```
[CHANNEL=hold]
master_command=IMTA_BIN:reprocess
```

65.6.2 Releasing messages from the hold channel

To cause messages sidelined as `.HELD` in the hold channel queue area to become eligible for delivery (to be delivered onwards) once again, set the user's status (`mailUserStatus`) and domain status (`mailDomainStatus`) once again to `active`, and then use the `imsimta qm` utility's `release` command to release the held messages for processing. As of Messaging Server 7.0u4, the `imsimta qm` utility informs the Job Controller of such message release, which for normal messages usually results in an "immediate" (more-or-less, depending on current load on the MTA) delivery attempt. (But in some earlier versions, the released message would not get "seen" by the Job Controller until the next `cache -sync` occurred, whether via an explicit `imsimta cache -sync` command, or via the Job Controller's own automatic, periodic `cache -sync`.)

Note that attempting to release a message for a user who is still marked as "`hold`" will merely result in the message again getting sidelined as `.HELD` with a temporary error (recorded in the MTA message transaction log, and the message's own delivery history) using the `error_text_still_held` MTA option's text, so by default

```
452 4.2.1 cannot reenqueue while still held
```

65.6.3 Diagnosing .HELD files

The causes of `.HELD` files can be considered to fall into three major categories:

1. Messages `.HELD` due to a user status or domain status of "`hold`": These are messages that are, by intent of the MTA administrator, intentionally being side-lined, typically while some maintenance procedure is being performed, (*e.g.*, while moving user mailboxes).

2. Looping messages: messages that the MTA side-lined as `.HELD` because the MTA detected (via build-up of one or another sort of *Received: header lines) that the messages were looping.

3. Suspicious messages: messages that met some suspicion threshhold, and were therefore side-lined as `.HELD` for later, manual inspection and action by the MTA administrator. Messages can be side-lined as `.HELD` due to exceeding a configured maximum number of envelope recipients (see the `holdlimit` channel option), due to exceeding `max_mime_levels` or `max_mime_parts` if such an MTA option has been set to a negative integer, due to an MTA administrator `imsimta qclean`, `imsimta qm clean`

or `imsimta qm hold` command executed by the MTA administrator based on some suspicion of the message(s) in question, due to use of a "`hold`" action in a Sieve script or spam/virus filter package action, due to use of a Milter SMFIF_QUARANTINE action (or explicit "`hold;`" in a `QUARANTINE_ACTION` Milter plugin option), or due to a conversion command script exit status of `PMDF__FORCEHOLD`.

When diagnosing the reason why a particular message or messages are `.HELD`, consider the following:write file

1. All messages `.HELD` due to a user status or domain status of "`hold`"---and *only* messages `.HELD` for such a reason--- will normally be stored in the hold channel's queue area. That is, `.HELD` message files in the hold channel's queue area can be assumed to be `.HELD` due to user or domain status.

2. Messages `.HELD` due to the MTA having detected that they were looping can be expected to have a great many of one or another sort of *Received: header lines, when inspected. Furthermore, those Received: header lines typically illustrate the exact path of the message loop: look especially carefully at the hostnames and any recipient address information (*e.g.*, "`for` *`recipient`*" clauses or "`(ORCPT` *`recipient`*`)`" comments) appearing in such header lines. One cause of such message loops is user error: a user forwards their messages on system A to system B, and has system B set up to forward back to system A. (The solution is for the user to fix their forwarding definitions.) Another common cause of message loops is the MTA receiving a message that was addressed to the MTA host using a network name that the MTA does not recognize (has not been configured to recognize) as one of its own names. (The solution is to add the additional name to the list of names that your MTA recognizes as "its own"; more on this below). Or another possible cause is missing or erroneous host table entries or DNS records that cause routing back to the MTA of addresses in domains not intended to be handled by this MTA. (The solution in such a case should be to correct the name records at the TCP/IP level; when that can not be achieved, *some* host table or nameserver problems can be worked around by special routing configuration on the MTA, though solving any underlying name problems is preferable.) Note that the MTA's thresholds for determining that a message is likely "looping" are configurable; see Received header line MTA options. Also note that the MTA may optionally be configured---see the `held_sndopr` MTA option---to generate a syslog notice whenever a message is forced into `.HELD` state due to exceeding such a threshold. If syslog messages of

```
HELDMSG, Header count exceeded; message has been marked .HELD automatically
```

are present, then you know that this is occurring.

3. Messages `.HELD` due to some suspicious characteristic will of course exhibit that characteristic---though *a priori* that characteristic could be anything which the site has chosen to characterize as "suspicious". If you are an administrator of the MTA, you should attempt to stay reasonably aware of whatever such configuration choices and actions have been taken on your MTA. However, if you are not the only or original administrator of this MTA, then check the MTA configuration for any configured use of the `holdlimit` channel option, any use of the `$H` flag in the `FROM_ACCESS` mapping table or a recipient-address-based `*_ACCESS` mapping table, any negative value for the `max_mime_levels` or `max_mime_parts` MTA options, or any use of the "`hold`" action in any system Sieve file (the `systemfilter` MTA option/system level `imta.filter` file, or any channel level Sieve filters configured and named via use of `sourcefilter` or `destinationfilter` channel options) or spam/virus filter package action's Sieve scriptlet, or (when using a milter) use of the SMFIF_QUARANTINE milter action, or use of the conversion channel with a script that exits with the status PMDF__FORCEHOLD. Also ask any fellow MTA

administrators about any manual command line side-lining (via, for instance, a `imsimta qm clean` command) they might have recently performed. Note also that application of a Sieve filter "`hold`" action, whether from a system Sieve filter or from users' personal Sieve filters, may optionally be logged in MTA message transaction logging; see the `log_filter` MTA option. (As of MS 8.0 with its new, private Sieve "`transactionlog`" extension, MTA administrators may wish to make use of the "`transactionlog`" action in any Sieve filter that performs a "`hold`" action, to record details regarding the reason(s) that the "`hold`" was performed.)

65.7 Pipe channels

Pipe channels are used to effect delivery for specific addresses via a site-supplied program or script. While pipe channels are loosely based upon the | (pipe) functionality of sendmail, they have been carefully designed to not pose a security threat. First, the availability of a pipe channel is configurable: the MTA administrator may remove the pipe channel from the configuration if he or she prefers not to trust the technology. Second, the commands executed by the pipe channel are controlled by the MTA administrator, and no user supplied input can find its way into those commands: each command the administrator supplies is used verbatim with the exception of the optional substitution of a filename generated by the channel itself without reference to user supplied input. Finally, the decision to run a command is not based upon the presence of special characters appearing in a recipient address, but rather upon a recipient address exactly matching a specific address or host name in a table or database which the MTA administrator must provide. If an exact match between an incoming address and the site's table or database exists, then the command listed in the table for that match is executed.

Unlike the sendmail pipe functionality, the MTA's pipe channel does not pipe the message to be processed to the program or script. Instead, it writes the message to be processed to a temporary file and then forks a subprocess to run the site-supplied command for that message. The forked subprocess then opens the message file on stdin prior to executing the command.

The command can either read the message from stdin or it can make use of the name of the temporary file which can be substituted into the command by the channel. The temporary file should not be deleted or altered by the subprocess; the channel will delete it itself. If it is not possible to prevent the subprocess from disrupting the file, then the pipe channel should be marked with the `single` channel option.

If the subprocess exits with exit code of 0 (EX_OK) then the message is presumed to have been delivered successfully and is removed from the MTA's queues. If it exits with an exit code of 71, 74, 75, or 79 (EX_OSERR, EX_IOERR, EX_TEMPFAIL, or EX_DB) then a temporary error is presumed to have occurred and delivery of the message is deferred. If any other exit code is returned, then the message will be returned to its originator as undeliverable. These exit codes are defined in the system header file `sysexits.h`.

65.7.1 Setting up a pipe channel

There are two steps in setting up a pipe channel:

1. adding the channel definition to the configuration, (note that initial configuration normally generates a pipe channel itself), and

2. specifying the addresses to receive pipe channel processing and their corresponding processing, via LDAP attributes on users, or via the channel option file, pipe database, or profile database entries

65.7.1.1 Adding a pipe channel to the configuration

Initial configuration normally configures a pipe channel automatically. In Unified Configuration, that definition would appear as:

```
msconfig> show channel:pipe.*
role.channel:pipe.official_host_name = pipe-daemon
role.channel:pipe.defragment (novalue)
role.channel:pipe.single (novalue)
msconfig> show rewrite.rule * *pipe*
role.rewrite.rule = .pipe-daemon $U%$H.pipe-daemon@pipe-daemon
```

corresponding to the legacy configuration:

```
.pipe-daemon $U%$H.pipe-daemon@pipe-daemon
...rest-of-rewrite-rules...

...start-of-channel-definitions...

pipe single defragment
pipe-daemon
```

But for those wishing to add a pipe channel manually, the following discussion is provided. Note that usually a single `pipe` channel can suffice; but it is possible to configure multiple `pipe_*` channels, if desired.

A message to be processed by a pipe channel is usually routed to the channel via a combination of an alias and rewrite rules. For instance, the system domain.com might want all mail for the addresses info-list@domain.com and gripes@domain.com to be routed to a pipe channel. This could be accomplished with the alias file entries

```
info-list: info-list@pipe.domain.com
gripes: gripes@pipe.domain.com
```

where `pipe.domain.com` is in turn a host name associated with a pipe channel via rewrite rules. For instance,

```
pipe.domain.com          $u%pipe.domain.com@PIPE-DAEMON
```

So, to configure a pipe you need to determine the host names, `pipe1.domain`, `pipe2.domain`, ... which you wish to use. Once you have determined these, add them to the rewrite rules section of your MTA configuration file:

```
pipe1.domain           $u%pipe1.domain@PIPE-DAEMON
pipe2.domain           $u%pipe2.domain@PIPE-DAEMON
...                    ...
```

Then, to the end of your MTA configuration, add the definition of the pipe channel itself:

```
pipe
```

```
PIPE-DAEMON
```

Be sure to include a blank line *before and after* this channel definition.

The pipe channel runs by default as the Messaging Server user, as specified by the `user` option in `restricted.cnf`. So on UNIX, if you wish the pipe channel to run as some other user, you may use the `user` channel option to specify the desired username though that usage is deprecated as of MS 8.0; as of MS 8.0, the preferred usage is to use the `pipeuser` option in the `restricted.cnf` file. Note that the argument to `user` channel option is normally forced to lowercase, but original case will be preserved if the argument is quoted.

At this point, the pipe channel has been added to the configuration. However, it cannot be used until you create a channel option file, or define and set delivery methods for pipe channel addressees, as described next.

65.7.1.2 Pipe channel addressees and their handling

In order for a pipe channel to handle an address, each specific recipient address (or at least each domain) to be handled must be explicitly configured with the desired pipe channel handling. There are several ways to do this configuration.

Most typically users to receive pipe channel handling would get markings in their LDAP entries, and Pipe options would define the program(s) available to run to process these users. In this case addresses of the form "uid%programinfo@pipe-channel" are used. As of Messaging Server 8.0.1.3 recognition of "a%b" form address is enabled by bit 0 (value 1) of the ADDRESS_TYPES pipe channel-specific option. (Bit 0 is set by default.)

Older approaches using the MTA profile database or Pipe channel-specific option file also exist. In these cases addresses of the form "user+domain@pipe-channel" are used. As of MS 8.0.1.3 recognition of "a+b" form addresses is enabled by bit 1 (value 2) of the ADDRESS_TYPES pipe channel-specific option. (Bit 1 is set by default.)

Finally, as of MS 8.0.1.3, when bit 2 (value 4) of the ADDRESS_TYPES pipe channel-specific option is set (which is the default) addresses with a local part not containing a "%" or "+" are handled as if they had a local part of the form: "PIPE-USER%PIPE-CHANNEL_default", where "PIPE-USER" is the value of the `pipeuser` restricted.cnf option and "PIPE-CHANNEL" is the name of the pipe channel (normally "pipe").

65.7.1.2.1 User LDAP attributes for pipe channel processing

When the MTA finds a user entry in LDAP that has a `mailDeliveryOption` attribute (or whatever LDAP attribute is named by the `ldap_delivery_option` MTA option) value of `program`, the `delivery_option` MTA option's `program` clause defines this to mean (by default) to route the message to the pipe channel with the address composed of the user's `uid` value and the value of the user's `mailProgramDeliveryInfo` LDAP attribute (or whatever attribute is named by the `ldap_program_info` MTA option), *i.e.*, *uid@mailProgramDeliveryInfo*.

The definition of what that `mailProgramDeliveryInfo` value means is controlled by Pipe options.

65.7.1.2.1.1 Pipe options

A few options control operation of the Pipe channel when a user's `mailDeliveryOption` LDAP attribute (or more precisely, the attribute named by the `ldap_delivery_option`

MTA option) includes a value of `program`, with execution as defined via the MTA `delivery_options` option's `program` clause.

The `delivery_options` option's `program` clause (normally) defines such `program` delivery to mean routing to the pipe channel with an address of the form "uid%programinfo@pipe-channel", where "uid" is the user's uid (which will be the user the the program runs under) and "programinfo" is the value of the user's `mailProgramDeliveryInfo` attribute (or whatever attribute is named by the `ldap_program_info` MTA option).

The "programinfo" from the address is used as to construct a set of option names which then provide the command to execute, parameters, and permissions. For example, a "foo" program value would check the following options:

```
pipe:foo.command
pipe:foo.params
pipe:foo.perms
```

As of Messaging Server 8.0.1.3, pipe options are also used to handle pipe channel address that do not contain a "%" or "+" charracter. In this case, assuming that the usual pipe channel named "pipe" is used, the following options will be checked:

```
pipe:pipe_default.command
pipe:pipe_default.params
pipe:pipe_default.perms
```

65.7.1.2.1.1.1 `params` Option

The `params` Pipe option specifies program delivery arguments. The substitution sequence `%s` may be used in the value to cause substitution of the (current) username.

65.7.1.2.1.1.2 `perms` Option

The `perms` Pipe option specifies permissions for the pipe delivery program.

65.7.1.2.1.1.3 `command` Option

The `command` Pipe option specifies the location of the program to execute to perform delivery.

The path can be absolute or relative. The base for relative paths is `DATAROOT`/site-programs. msconfig checks to make sure the specified program exists; it will not allow the option to be set if it doesn't.

65.7.1.2.2 Profile database

The Profile database is located at `IMTA_DATAROOT:db/profiledb`.

Entries in the Profile database are created and managed using the `imsimta profile` utility.

65.7.1.2.3 Profile database entries for pipe channel addressees

Before looking in the pipe channel option file, a pipe channel first queries the MTA profile database checking whether there is a delivery method set for the addressee. Only if there is no such entry is the pipe option file consulted.

An MTA profile database delivery method entry for a pipe channel addressee is similar to that for a local (L) channel addressee, except that the pipe channel domain is used. For instance,

```
# imsimta profile
profile> set delivery MIME -user=jane.doe@pipe.domain.com
```

65.7.1.2.4 Pipe database

The pipe database was an alternate approach for storing larger numbers of address definitions than was convenient for the Pipe channel option file -- but this approach is now more-or-less obsolete.

65.7.1.2.5 Pipe channel option file

Unless you have a pipe database, or have established delivery methods for pipe channel addressees, each pipe channel must have an option file. If there are no delivery methods set in the MTA profile database, nor a pipe channel option file, nor a pipe database, then the channel will not operate.

The commands to execute for each envelope recipient address presented to the channel are specified in the MTA profile database, in the pipe database or in the pipe channel's option file. If an address does not appear in one of these locations, then an error notification is sent back to the message originator.

In legacy configuration, pipe channel option files are stored in the MTA configuration directory `CONFIGROOT/advanced` and have names of the form *x*`_option`, where *x* is the name of the pipe channel to which the option file applies. (In most instances, the file name will be `pipe_option`; *i.e.*, `CONFIGROOT/advanced/pipe_option` on UNIX.)

To process the address *`user@host`*, the pipe channel first probes the option file for an entry of the form

`user@host=command`

If no matching entry is found, the channel next probes the option file for an entry of the form

`host=command`

If still no matching entry is found, then the recipient address is deemed bad and an error notification is sent back to the message originator. See Pipe entry match order below for an additional discussion of the order in which probes of various forms are made to the various possible entry sources.

If, however, a probe does find a matching entry, then the specified command, *`command`*, is executed. Prior to being executed, any occurrences of the phrase `%s` or `%f` appearing in *`command`* are replaced with the name of the temporary file containing the message to be processed. It is important that the command to be executed neither delete nor otherwise alter the temporary message file as it may be needed for further pipe channel recipients of the same message. If disruption of the message file cannot be prevented, then mark the channel with the `single` channel option.

In Unified Configuration, the pipe channel option file is replaced by settings under `channel:pipe.options`, *e.g.*,

```
msconfig> set channel:pipe.options.user_host command
msconfig# set channel:pipe.options.host command
```

where all "@", "%", and "+" characters are replaced by underscores. Also note that any periods in the *host* will need to be backslash quoted. So for instance, if *host* is `mailhost.domain.com`, then the commands would appear as:

```
msconfig> set channel:pipe.options.user_mailhost\.domain\.com command
msconfig# set channel:pipe.options.mailhost\.domain\.com command
```

The command to be executed will be run by a subprocess of the process running the pipe channel. As such, it will be running with the privileges of the user named as the pipe channel processing account via (prior to MS 8.0) the `user` channel option on the pipe channel or (preferred approach as of MS 8.0) the `pipeuser` option in `restricted.cnf`, or if no pipe channel user was specified, then it will be running with the privileges of the MTA user account (see the `user` option in `restricted.cnf`). See Pipe channels for a description of the exit or completion codes with which the command should exit the subprocess.

Note: As with any MTA option file, it is important that the option file not be world writable. This is especially true of pipe channel option files.

In addition to the command entries in the pipe channel option file, there are additional general options available:[1]

[1] General UNIX L channel/native channel options may also be specified in a pipe option file, though their relevance for the pipe channel tends to be limited.

65.7.1.2.5.1 SHELL_TIMEOUT (integer; UNIX only)

The SHELL_TIMEOUT option may be used to control how long in seconds the channel will wait for a shell command to complete. Upon such time outs, the message will be returned back to the original sender with an error message along the lines of "Timeout waiting for ...'s shell command ... to complete". The default value is 600 (corresponding to 10 minutes).

65.7.1.2.5.2 SHELL_TMPDIR (directory-specification)

The SHELL_TMPDIR option may be used to control where the pipe channel creates its temporary files when delivering to a shell command. By default, such temporary files are created in the home directory of the MTA user (or the user specified by the `user` channel option). Via this option the MTA administrator may instead choose to have the temporary files created in some (single) other directory; *e.g.* (legacy configuration):

```
SHELL_TMPDIR=/tmp
```

or (Unified Configuration):

```
msconfig> set channel:pipe.options.SHELL_TMPDIR /tmp
```

65.7.1.2.5.3 ADDRESS_TYPES (0-7)

New in MS 8.0.1.3, the ADDRESS_TYPES pipe channel option controls what kinds of addresses this pipe channel allows. This is a bit encoded value, with the individual bits defined as follows:

Table 65.1 ADDRESS_TYPES pipe channel option bits

Bit	Value	Meaning
0	1	If set, process addresses of the form a%b.
1	2	If set, process addresses of the form a+b.
2	4	If set, process addresses using default programs.

The default value of this option is 7, meaning all types of processing are enabled.

One use of the ADDRESS_TYPES option is to allow the use of subaddresses with default programs. This can be accomplished by disabling processing of a+b address forms:

```
msconfig> set channel:pipe.options.ADDRESS_TYPES 5
```

65.7.1.2.5.4 UNIX_STYLE (0 or 1)

Setting UNIX_STYLE=1 causes the pipe channel to write out a UNIX style mbox file, including a colonless From line, if a pipe command such as

```
cat %s >> filename.txt
```

is used. UNIX_STYLE=1 is the default on UNIXplatforms. Setting UNIX_STYLE=0 tells the pipe channel not to write the colonless From line. *E.g.*, in Unified Configuration:

```
msconfig> set channel:pipe.options.UNIX_STYLE 0
```

65.7.2 Pipe entry match order

The logic for checking entries in the profile database (UNIX only), pipe database and pipe channel option file is as follows:

1. (UNIX only) Check the profile database for a `user@host` entry.
2. Check the pipe database for a `user@host` entry. (The "@" and any "+" or "%" characters are converted to a "_" when checking unified configuration pipe channel-specific options.)
3. Check the pipe option file for a `user@host` entry.
4. Check the pipe database for a `host` entry.
5. Check the pipe option file for a `host` entry.

If no profile database entry exists and if the pipe database does not exist, then only the pipe option file is checked, *i.e.*, steps (3) and (5) only. If no profile database entry exists and if the pipe database exists but cannot be opened, then the message is passed over --- the condition

is treated as a temporary error. And when checks (1)--(5) turn up no results, the message is bounced.

65.8 Process and Reprocess channels

The processing and reprocessing channels are essentially the intersection of all other channel programs --- they perform only those operations that are shared among all other channels. In other words, such a channel is simply a channel queue whose contents are processed and requeued to other channels. Messages receive no special processing whatsoever.

The difference between a reprocessing channel and a processing channel is that a reprocessing channel is normally "invisible" as a source or destination channel, as for instance in a `CONVERSIONS`, in a `CHARSET-CONVERSION`, or in a Recipient access mapping table such as `SEND_ACCESS`, or in a source channel or destination channel specific rewrite rule. A processing channel, on the other hand, is visible like other MTA channels.

It may appear that such a channel is effectively useless, but this turns out to be untrue. For example, the act of processing message bodies or generating message files for a message with a large number of recipients may be very time-consuming. Timeouts may occur if this is done during the operation of a channel slave program with an open network connection. So the MTA provides the `expandlimit` channel option, which forces requeuing of the message to the reprocessing channel. Address expansion is then done as the reprocessing channel runs, free of any network timing constraints. The reprocess channel is also normally used to achieve deferred ("off-line") processing of expansion of mailing lists (see the `defer_group_processing` MTA option), and implementation of Sieve "`redirect`" actions; and in cases of LDAP directory unresponsiveness, submissions from "local" users are normally deferred to the reprocess channel (see the `domain_failure` MTA option). As of MS 6.3, a spam/virus filter package becoming unresponsive also optionally may cause such deferral; see the `spamfilter`*`N`*`_optional` MTA options.

If a message destined to an address of the form *`user@domain`* is routed to the reprocessing channel, (*e.g.*, due to rewrite rules or the `expandlimit` channel option) then the reprocessing channel will simply re-enqueue the message to the channel associated with the domain *`domain`*; if a message destined to an address of the form *`user@reprocessing-domain`* is routed to the reprocessing channel, (*e.g.*, as may be the case for mailing lists using deferred expansion), then the reprocessing channel will re-enqueue the message to the local channel. In either case, the reprocessing channel performs any necessary expansion of the *`user`* part of the address.

When an MTA channel has to generate a notification (bounce) message, such a notification message is initially enqueued to the processing channel.

A processing channel and a reprocessing channel are produced automatically by the MTA configuration generator. Note: Furthermore, for its own uses, the MTA will act as if process and reprocess channels are defined even if they are not explicitly present in your configuration. But if you wish to make any site specific uses of such channels, explicitly addressing or rewriting to such channels, then you will need to have the channels explicitly present in your configuration.

Prior to the 8.0 release, the `reprocess` channel handled Sieve "`redirect`" messages; as of 8.0, Sieve "`redirect`" messages instead go through the `process` channel.

65.8.1 Reprocess channel operation as prior channel

The reprocess channel performs various checks and operations as if it "were" the prior channel (the channel that enqueued to the reprocess channel); this includes some of its logging, as discussed in Reprocess channel message transaction log entries. In particular, this operation-as-prior channel includes determination of whether channel debugging is enabled when the reprocess channel runs: the prior channel must have debugging enabled to obtain debugging for the reprocess channel. This operation as prior channel also includes the address-based *_ACCESS mapping table checks, where the probes are done "as if" the prior channel were probing; though note that as of 8.0, the $:R input flag check may be used to detect cases of the reprocess channel probing an address-based *_ACCESS mapping table.

Note that as of 7.0.5, transactionlimit settings from the prior channel are *not* applied when the reprocess channel is running.

65.8.1.1 Reprocess channel transaction log entries

Note that MTA message transaction (mail.log*) records involving the reprocess channel require a bit of special reading, as one of the whole goals of use of reprocess is to preserve the "original" source channel name (for purposes of access checks, *etc*.), and this then affects the message transaction log entries. For instance, in the case of a message enqueued (received) by the tcp_intranet channel and automatically deferred to the reprocess channel (perhaps because, say, the LDAP server is not currently responding, or because a Sieve "redirect" must be performed), relevant MTA message transaction log entries, with the MTA option log_process=1 set, might have the rough form:

```
date-time-1 SMTP-process-id tcp_intranet  reprocess  E ...
date-time-2 reprocess-id    tcp_intranet  tcp_local  E ...
date-time-3 reprocess-id    reprocess                D ...
```

That is, the reprocess channel's enqueue onwards is recorded (and access checked, if appropriate) as if it were an enqueue from the original enqueueing channel---but if you have log_process=1 set, then you can see by the process-id that it's actually the reprocess channel that did that second enqueue.

Prior to 8.0, the reprocess channel handled Sieve "redirect" messages; as of 8.0, Sieve "redirect" messages instead go through the process channel.

Chapter 66 SMS options

SMS (Short Message Service) configuration allows some global settings under `sms_gateway`, and below that is controlled via three named groups of options:

- General/global SMS gateway options,
- named groups of SMS gateway profile options, `sms_gateway.gateway_profile:profile-name.option-name`
- named groups of SMS `smpp_relay` options, `sms_gateway.smpp_relay:profile-name.option-name`, configuring aspects of the SMPP (Short Message Peer-to-Peer) relay operation, and
- named groups of SMS `smpp_server` options, `sms_gateway.smpp_server:profile-name.option-name`, configuring aspects of the SMPP (Short Message Peer-to-Peer) server operation.

66.1 SMS gateway options

The SMS options set directly under `sms_gateway` establish general values, and global defaults. In particular, the `enable` option enables the SMS gateway on `start-msg` startup.

66.1.1 `enable` Option Under sms_gateway

The `enable` SMS gateway option, `sms_gateway.enable` (Unified Configuration) or `local.smsgateway.enable` (legacy configuration), enables the SMS service on `start-msg` startup.

66.1.2 debug Option Under sms_gateway

The `sms_gateway.debug` option enables debug output for the SMS gateway. The default value is 6, which selects warning and error messages. The actual value of this option is a bit mask with the values shown below.

Table 66.1 SMS Gateway Debug Bit Mask Values

Bit	Value	Description
0-31	-1	Extremely verbose output
0	1	Informational messages
1	2	Warning messages
3	4	Error messages
3	8	Subroutine call tracing

4	16	Hash table diagnostics
5	32	I/O diagnostics, receive
6	64	I/O diagnostics, transmit
7	128	SMS to email conversion diagnostics (mobile originate and SMS notification)
8	256	PDU diagnostics, header data
9	512	PDU diagnostics, body data
10	1024	PDU diagnostics, type-length-value data
11	2048	Option processing; sends all option settings to the log file.

66.1.3 foreground Option

The `foreground` SMS gateway option, if set, means to run the SMS Gateway Server in the foreground with debugging enabled. See also the `sms_gateway.debug` option.

66.1.4 history_file_directory Option

The `history_file_directory` SMS gateway option specifies the absolute path to the directory to which to write the history files. The directory path will be created if it does not exist. The default value for this option is `IMTA_DATAROOT:sms_gateway_cache/`.

The directory used should be on a reasonably fast disk system and have more than sufficient free space for the anticipated storage; see SMS Gateway Server Storage Requirements to change this option to a more appropriate value.

66.1.5 history_file_mode Option

The `history_file_mode` SMS gateway option specifies permissions for files of historical data. The specified value is interpreted as an octal value.

66.1.6 history_file_flush_period Option

The `history_file_flush_period` SMS gateway option specifies how frequently cached history data is periodically flushed to disk; *i.e.*, the data is held solely in memory for no longer than `history_file_flush_period` milliseconds. By default, a value of 100 milliseconds (0.1 second) is used. Note that data written to disk is typically kept cached in memory as well. The data is written to disk so as to not lose it across server restarts.

66.1.7 history_file_flush_threshold Option

When the amount of cached history data exceeds the value of the `history_file_flush_threshold` SMS gateway option, the cached data is written to the history file. By default, a value of 16M is used.

66.1.8 history_file_rollover_period Option

The current history file is closed and a new one created every history_file_rollover_period seconds. By default, a value of 3600 seconds (60 minutes) is used.

66.1.9 max_conns Option Under sms_gateway

The max_conns SMS gateway option, sms_gateway.max_conns, specifies the maximum number of concurrent, inbound TCP connections to allow across all SMPP relay and server instantiations. A value of 0 (zero) indicates that there is no global limit on the number of connections. There may, however, be per relay or server limits imposed by a given relay or server instantiation; see the smpp_server.max_conns and smpp_relay.max_conns values.

66.1.10 record_lifetime Option

The record_lifetime SMS gateway option specifies the lifetime in seconds of a historical record. Records older than this lifetime will be purged from memory; history files older than this lifetime will be deleted from disk. By default, a value of 259,200 seconds (3 days) is used. Records stored in memory are purged in sweeps by a thread dedicated to managing the in-memory data. These sweeps occur every history_file_rollover_period seconds. Files on disk are purged when it becomes necessary to open a new history file.

66.1.11 thread_count_initial Option

The thread_count_initial SMS gateway option specifies the number of worker threads to initially create upon startup. By default, ten worker threads are initially created. The number of threads dynamically adjusts as the server runs.

66.1.12 thread_count_maximum Option

The thread_count_maximum SMS gateway option specifies the maximum number of concurrent worker threads to allow. By default, a maximum of fifty worker threads are allowed.

66.1.13 thread_stack_size Option

Each worker thread is outfitted with a stack whose maximum size is specified with the thread_stack_size SMS gateway option. By default, a stack size of 64K is used. Specify a value of zero to use the platform's default thread stack size which is usually documented under or within the platform's pthread_create documentaton. Any non-zero value specified with this option will be rounded up to the nearest multiple of 64K which is not less than the operating system's minimum thread stack size.

66.2 SMS gateway_profile options

66.2.1 text_to_subject Option

By default, the content of an SMS message, when gatewayed to e-mail, is split between the Subject: header line and body of the resultant e-mail message, as per the setting of the

parse_re_N options. When the value of the text_to_subject SMS gateway profile option, gateway_profile.text_to_subject, is set to 1, then the entire SMS text message is placed in the Subject: header line of the resulting e-mail message. No portion of the SMS text message is placed in the message's body.

66.2.2 mta_channel Option

The mta_channel SMS gateway profile option, gateway_profile.mta_channel, specifies the name of the MTA channel used to enqueue e-mail messages. If not specified, then sms is assumed. The specified channel must be defined in the MTA's configuration.

For discussion of MTA channel definitions, (in particular, for discussion of Unified Configuration options set under a channel group), see instead Channel_configuration.

66.2.3 email_body_charset Option

The email_body_charset SMS gateway profile option, gateway_profile.email_body_charset, specifies the character set to which to translate the SMS text prior to insertion into an e-mail message's body. If necessary, the translated text will be MIME encoded. The default value is US-ASCII. If the SMS message contains glyphs not available in the charset, they will be converted to mnemonic characters, which may or may not be meaningful to the recipient.

A list of the character sets known to the MTA may be found in the file charsets.txt.

This option is ignored when placement of the entire SMS message into the Subject: header line is enabled with the text_to_subject SMS gateway profile option.

66.2.4 email_header_charset Option

The character set to translate SMS text to prior to insertion into an RFC 822 Subject: header line. If necessary, the translated string will be MIME encoded. The default value is US-ASCII. If the SMS message contains glyphs not available in the charset, they will be converted to mnemonic characters, which may or may not be meaningful to the recipient.

66.2.5 from_domain Option

The from_domain SMS gateway_profile option, gateway_profile.from_domain, specifies the domain name to append to SMS source addresses when constructing envelope From addresses for e-mail messages. The name specified should be the correct name for routing e-mail back to SMS, (for example, the host name associated with the MTA SMS channel). If not specified, then the official host name of the channel specified with the mta_channel SMS gateway_profile option (CHANNEL in legacy configuration) will be used.

66.2.6 in_re Option

The in_re SMS gateway profile option specifies the prefix text to use in the Subject: line of a gatewayed response from SMS to E-mail. By default, the US-ASCII string "Re: " is used. The string should be specified using the same character set as that specified by the email_header_charset option.

66.2.7 Address extraction SMS options: parse_re_N (regular expression)

For mobile origination of e-mail, the gateway profile needs to extract a destination e-mail address from the text of the SMS message. This is done by means of one or more POSIX-compliant regular expressions (REs). The text of the SMS message will be evaluated by each regular expression until either a match producing a destination e-mail address is found or the list of regular expressions exhausted.

Note: Use of the parse_re_ and route_to options are mutually exclusive. Use of both in the same gateway profile is a configuration error.

Each regular expression must be POSIX compliant and encoded in the UTF-8 character set. The regular expressions must output as string 0 the destination address. They may optionally output text to use in a Subject: header line as string 1, and text to use in the message body as string 2. Any text not "consumed" by the regular expression will also be used in the message body, following any text output as string 2.

The regular expressions will be tried in the order parse_re_0, parse_re_1, ..., up to parse_re_9. If no regular expressions are specified and the option text_to_subject has the value 0, then the following default regular expression is used,

```
[ \t]*([^\( ]*)[ \t]*(?:\(([^\)]*)\))?[ \t]*(.*)
```

This default regular expression breaks into the following components:

```
[ \t]*
```

Ignore leading white space characters (SPACE and TAB).

```
([^\( ]*)
```

Destination e-mail address. This is the first reported string.

```
[ \t]*
```

Ignore white space characters.

```
(?:\(([^\)]*)\))?
```

Optional subject text enclosed in parentheses. This is the second reported string. The leading `?:` causes the outer parentheses to not report a string. They are being used merely for grouping their contents together into a single RE for the trailing ?. The trailing ? causes this RE component to match only zero or one time and is equivalent to the expression `{0,1}`.

```
[ \t]*
```

Ignore white space characters.

```
(.*)
```

Remaining text to message body. This is the third reported string.

For example, with the above regular expression, the sample SMS message:

```
dan@sesta.com(Testing)This is a test
```

yields the e-mail message:

```
To: dan@sesta.com
Subject: Testing

This is a test
```

As a second example, the SMS message:

```
sue@sesta.com This is another test
```

would yield:

```
To: sue@sesta.com

This is another test
```

Note that the SMS message, prior to evaluation with these regular expressions, will be translated to the UTF-16 encoding of Unicode. The translated text is then evaluated with the regular expressions which were previously converted from UTF-8 to UTF-16. The results of the evaluation are then translated to US-ASCII for the destination e-mail address, `email_header_charset` for the Subject: text, if any, and `email_body_charset` for the message body, if any.

When the option `text_to_subject` has the value 1, then the default value for `parse_re_0` is instead,

```
[ \t]*([^\( ]*)[ \t]*(.*)
```

With this default, the ability to split the SMS text between the resulting e-mail message's Subject: header line and body is no longer present. The entire SMS message is placed in the Subject: header line. This regular expression only describes how to distinguish the recipient's e-mail address from the remainder of the SMS message.

66.2.8 `profile` Option

The `profile`SMS gateway profile option specifies a SMS profile to assume. Presently this information is only used to map SMS priority flags to RFC 822 Priority: header lines. Consequently, this option has no effect when `use_sms_priority` has the value 0 (zero) which is the default setting for that option.

The permitted values for this option are "GSM", "TDMA", or "CDMA". The string "ANSI-136" is treated as a synonym for TDMA; the string "IS-95" as a synonym for "CDMA".

66.2.9 route_to Option

The route_to SMS gateway_profile option specifies an IP host name to which all SMS messages targeted to the profile will be rerouted, using an e-mail address of the form:

SMS-destination-address@route-to-value

where SMS-destination-address is the SMS message's destination address, and the route-to-value is the IP host name specified with this route_to option. The entire content of the SMS message is sent as the content of the resulting e-mail message.

Note: Use of parse_re_ and route_to options are mutually exclusive. Use of both in the same gateway profile is a configuration error.

66.2.10 select_re Option

The select_re SMS gateway_profile option specifies a US-ASCII POSIX-compliant regular expression to compare against each SMS message's SMS destination address. If an SMS message's destination address matches this RE, then the SMS message will be sent through the gateway to e-mail in accord with this gateway profile.

Note that since an SMS message's destination address is specified in the US-ASCII character set, this regular expression must also be expressed in US-ASCII.

66.2.11 smsc_default_charset Option

The smsc_default_charset SMS gateway_profile option specifies the name of the default character set used by the remote SMSC. The two common choices for this option are US-ASCII and UTF-16-BE (USC2). If not specified, US-ASCII is assumed.

66.2.12 use_sms_priority Option

By default, priority flags in SMS messages are ignored and not sent with the e-mail messages. To have the priority flags passed with the e-mail, specify use_sms_priority=1. When passed with the e-mail, the mapping from SMS to e-mail is as shown in Table of SMS Priority Flag Mappings to E-Mail.

Table 66.2 SMS Priority Flag Mappings to E-Mail

SMS Profile	SMS Priority Flag	Resulting E-Mail Priority: Header Line
GSM	0 (non-priority) 1, 2, 3 (priority)	No header line (implies "normal") Urgent
TDMA	0 (bulk) 1 (Normal) 2 (Urgent) 3 (Very Urgent)	Nonurgent No header line (implies Normal) Urgent Urgent
CDMA	0 (Normal) 1 (Interactive) 2 (Urgent) 3 (Emergency)	No header line (implies Normal) Urgent Urgent Urgent

Note that the e-mail Priority: header line values are Nonurgent, Normal, and Urgent.

66.2.13 use_sms_privacy Option

By default, SMS privacy indications are ignored and not sent with the e-mail messages. To have this information passed with the e-mail in a Sensitivity: header line, specify a value of 1 for the use_sms_privacy SMS gateway_profile option. When passed along in e-mail, the mapping from SMS to a Sensitivity: header line is as shown in Table of Privacy Flag Mappings from SMS to E-Mail,

Table 66.3 Privacy Flag Mappings from SMS to E-Mail

SMS Privacy Flag	Resulting E-Mail Sensitivity: Header Line
0 (Not restricted)	No header line
1 (Restricted)	Personal
2 (Confidential)	Private
3 (Secret)	Company-confidential

Note that the values of the e-mail Sensitivity: header line are Personal, Private, and Company-confidential.

66.3 SMS smpp_relay options

There are a number of options under smpp_relay.

66.3.1 backlog Option Under smpp_relay

The backlog SMS smpp_relay option (in legacy configuration, LISTEN_BACKLOG) specifies the size of the connection backlog for inbound SMPP client connections.

66.3.2 listen_addresses Option Under smpp_relay

The listen_addresses SMS smpp_relay option (in legacy configuration, LISTEN_INTERFACE_ADDRESS) specifies the network interface for inbound SMPP client connections. If this option is not set, then listen on INADDR_ANY (that is, all addresses).

66.3.3 listen_receive_timeout Option

The listen_receive_timeout option, available under smpp_relay and smpp_server, specifies the timeout (in seconds) to allow when waiting to read data from an SMPP client. The default value is 600 seconds (10 minutes).

66.3.4 listen_transmit_timeout Option

The listen_transmit_timeout option for the SMS smpp_relay and smpp_server specifies a timeout (in seconds) to allow when sending data to an SMPP client. The default value is 120 seconds (2 minutes).

66.3.5 make_source_addresses_unique Option

By default, the SMPP relay will append to each SMS source address a unique, ten digit string. The resulting SMS source address is then saved along with the other historical data. The result is a unique SMS address which may then be replied to by SMS users. The SMPP server will detect this address when used as an SMS destination address and will then send the SMS message to the correct e-mail originator.

To disable this generating of unique SMS source addresses (for one-way SMS), specify a value of 0 (zero) for the make_source_addresses_uniqueSMS smpp_relay option.

66.3.6 max_conns Option Under smpp_relay

The max_conns SMPP Relay option, smpp_relay.max_conns, specifies the maximum number of concurrent, inbound TCP connections to allow for this SMPP Relay instantiation. By default, a value of 7,000 connections is used. Note that this option will be ignored if it exceeds the global sms_gateway.max_conns setting.

66.3.7 server_host Option Under smpp_relay

The server_host SMPP Relay option specifies the SMPP server to which to relay SMPP client traffic. Either a hostname or IP address may be specified. Specification of this option is mandatory; there is no default value for this option.

66.3.8 server_port Option Under smpp_relay

The server_port SMS smpp_relay option specifies the TCP port for the remote SMPP server to which to relay. Specification of this option is mandatory; there is no default value for this option. There is no IANA assignment for this service; do not confuse with the IANA assignment for SNPP.

66.3.9 server_receive_timeout Option

The server_receive_timeout SMPP Relay option specifies the timeout (in seconds) to allow when waiting to read data from the SMPP server. The default value is 600 seconds (10 minutes).

66.3.10 server_transmit_timeout Option

The server_transmit_timeout SMPP Relay option specifies the timeout (in seconds) to allow when sending data to the SMPP server. The default value is 120 seconds (2 minutes).

66.3.11 tcp_ports Option Under smpp_relay

The tcp_ports SMS smpp_relay option specifies the TCP port for inbound SMPP client connections. Specification of this option is mandatory; there is no default value. Note also that there is no Internet Assigned Numbers Authority (IANA) assignment for this service.

66.4 SMS smpp_server options

There are a number of options under smpp_server.

66.4.1 backlog Option Under smpp_server

The backlog SMS smpp_server option (in legacy configuration, LISTEN_BACKLOG) specifies the size of the connection backlog for inbound SMPP server connections.

66.4.2 esme_address_npi Option

By default, when binding as a receiver in response to an OUTBIND request, the SMPP server will specify an ESME Numeric Plan Indicator (NPI) value of zero indicating an unknown NPI. Values for this option may be specified in one of three ways,

- A decimal value (for example, 10).
- A hexadecimal value prefixed by "0x" (for example, 0x0a).
- One of the case-insensitive text strings shown in Supported ESME NPI types

Table 66.4 Supported ESME NPI types

String	Hexadecimal Value
data	0x03
default	0x00
e.163	0x01
e.164	0x01
e.212	0x06
ermes	0x0a
f.69	0x04
internet	0x0e
ip	0x0e
isdn	0x01
land-mobile	0x06
national	0x08
private	0x09
telex	0x04
unknown	0x00
wap	0x12
x.121	0x03

This option is ignored unless the server_port is also specified. See the description of the various server_port options for further information.

66.4.3 esme_address_range Option

The ESME address range to present when binding as a receiver in response to an outbind request. By default, an empty string is used. For some SMSCs, an address range of "[:alnum:]*" may be appropriate. Any string specified must not exceed a length of 40 bytes.

66.4.4 esme_address_ton Option

By default, when binding as a receiver in response to an OUTBIND request, the SMPP server will specify an ESME Type of Number (TON) value of zero indicating an unknown TON. Values for this option may be specified in one of three ways,

- A decimal value (for example, 1).
- A hexadecimal value prefixed by "0x" (for example, 0x01).
- One of the case-insensitive text strings shown in Table of supported ESME TON types

Table 66.5 Supported ESME TON types

String	Hexadecimal Value
abbreviated	0x06
alphanumeric	0x05
default	0x00
international	0x01
national	0x02
network-specific	0x03
subscriber	0x04
unknown	0x00

This option is ignored unless the `smpp_server.server_port` option is also specified. See the description of the `server_port` option for further information.

66.4.5 esme_password Option

When binding as a receiver in response to an OUTBIND request, the SMPP server must specify an ESME password. By default, an empty string is used for the password. Use this option to specify a non-empty string. As with all ESME passwords, the maximum length of this string is 8 bytes.

66.4.6 esme_system_id Option

ESME system id to present when binding as a receiver in response to an OUTBIND request. By default, an empty string is used. Use this option to specify a string at most 15 bytes long.

66.4.7 esme_system_type Option

The `esme_system_type smpp_server` option specifies the ESME system type to present when binding as a receiver in response to an OUTBIND request. By default, an empty string is used. Use this option to specify a string at most 12 bytes long.

66.4.8 listen_addresses Option Under smpp_server

The `listen_addresses` SMS `smpp_server` option (in legacy configuration, LISTEN_INTERFACE_ADDRESS) specifies the network interface for inbound SMPP server connections. If this option is not set, then listen on `INADDR_ANY` (that is, all addresses).

66.4.9 listen_receive_timeout Option

The listen_receive_timeout option, available under smpp_relay and smpp_server, specifies the timeout (in seconds) to allow when waiting to read data from an SMPP client. The default value is 600 seconds (10 minutes).

66.4.10 listen_transmit_timeout Option

The listen_transmit_timeout option for the SMS smpp_relay and smpp_server specifies a timeout (in seconds) to allow when sending data to an SMPP client. The default value is 120 seconds (2 minutes).

66.4.11 max_conns Option Under smpp_server

The max_conns SMPP Server option, smpp_server.max_conns, specifies the maximum number of concurrent, inbound TCP connections to allow for this SMPP Server instantiation. By default, a value of 7,000 connections is used. Note that this option will be ignored if it exceeds the global sms_gateway.max_conns setting.

66.4.12 server_host Option Under smpp_server

The server_host SMPP Server option specifies the remote host to bind back to in response to an OUTBIND request. This option is ignored unless the server_port is also specified. See the description of the server_port option for further information.

66.4.13 server_port Option Under smpp_server

Some SMSCs incorrectly implement the OUTBIND operation by sending an OUTBIND PDU and then closing the TCP connection. As per the SMPP specification, the SMSC is expected to leave the connection open, allowing the receiver of the OUTBIND to then bind back as receiver over the same connection. Use the server_port SMPP Server option to interoperate with such SMSCs by specifying the TCP port to bind back to when an OUTBIND request is received. If the server_host SMPP Server option is not specified, then the source IP address associated with the current TCP connection is used.

See also the esme_address_npi, esme_address_range, esme_address_ton, esme_password, esme_system_id, and esme_system_type options.

66.4.14 system_id Option

An optional SMPP system_id string of zero to fifteen (0-15) US-ASCII characters may be specified. This string will then be returned as the SMPP server's system id in bind responses sent to SMPP clients. By default, an empty system id string is returned.

66.4.15 tcp_ports Option Under smpp_server

The tcp_ports SMS smpp_server option specifies the TCP port for inbound SMPP server connections. Specification of this option is mandatory; there is no default value. Note also that there is no Internet Assigned Numbers Authority (IANA) assignment for this service.

Chapter 67 Message capture

Message capture may be desired for purposes including: archiving, lawful interception, covert or administrative monitoring, or message replay (disaster recovery). The MTA has a number of facilities that can be used to "capture" messages, taking the message "outside" the normal message processing flow; this can be useful for tasks such as: monitoring (without a user's knowledge) the messages sent and received by the user such as for lawful interception purposes, or for making copies of messages passing through the MTA, possibly for archival purposes or to allow for possible future "message replay" as part of a disaster recovery strategy.

Note that the facilities discussed here are fundamentally different in spirit (as well as in details) from techniques such as automatically forwarding messages to an additional address---forwarding techniques that have the potential, as part of normal e-mail processing in cases of delivery problems for the "forwarded" message copy, to result in exposure of the fact of message "forwarding" or "copying" to end users, or which may, as part of normal e-mail processing in cases of group or alias expansion problems, prevent end users from being notified of certain sorts of recipient address problems even for the recipient(s) the end user did knowingly address. (That is, techniques such as adding LDAP attributes `mailDeliveryOption` with value `forward` and `mailForwardingAddress` to user LDAP entries, or use of a `FORWARD` mapping table, or use of `"redirect"` Sieve actions, or use of the `clonehosts` channel option to generate "clone" copies of messages to an additional destination, are not discussed here.) Rather, the techniques discussed here are those that have as a fundamental aspect the goal of separate handling of the "captured" message copies, techniques where the fact/process of copying is invisible to the end users. *Message capture is distinct from simple message forwarding.*

The main techniques that the MTA provides for interception/covert/archival "capture" of messages are:

- The `MESSAGE-SAVE-COPY` mapping table, used to copy message files from the MTA's disk queue area. This facility was originally designed for, and is especially well-suited for, making short-term copies of outbound messages for possible "message replay" (re-sending) in case of loss of messages on the destination host(s).

- The LDAP "capture" user attribute, used to capture copies of all messages sent or received by the user (by generating encapsulated copies of the messages and directing them to a specified capturer address), discussed in Capture triggered via LDAP attributes. This facility was originally designed for, and is especially well-suited for, monitoring of individual users' message traffic (*e.g.*, for legal purposes or administrative monitoring purposes). Or, by capturing such messages in Microsoft® Exchange "envelope journaling" format, the captured

message copies may be convenient for archiving purposes; see the (new in MS 7.0u4) `capture_format_default` MTA option, or (new in MS 8.0) use an LDAP tag `;format-journal-header` on the LDAP attributes named by the MTA options `ldap_capture` and (also new in MS 8.0) `ldap_domain_attr_capture`.

- (New in MS 8.0) The LDAP "capture" domain attribute (a domain-level analogue of the LDAP "capture" user attribute), used to capture copies of all messages sent or received by users in that domain, discussed in Capture triggered via LDAP attributes.

- (New in MS 6.2) The CAPTURE named parameter for aliases and mailing lists defined in the MTA alias file operates similarly to the LDAP "capture" user attribute. For the syntax of the CAPTURE named parameter for simple aliases and for groups or mailing lists, see Alias file format and Alias file named parameters. Nowadays MTA alias file definitions are less commonly used than LDAP provisioning of users and lists---but the CAPTURE named parameter is provided as an alternative that may be convenient for sites that do make more use of the MTA alias file. In Unified Configuration, the `alias_capture` alias option is the equivalent of the alias file named parameter CAPTURE.

- (New in MS 7.2-0.01) The JOURNAL named parameter for aliases and mailing lists defined in the MTA alias file operates similarly to the CAPTURE named parameter, but generates a Microsoft Exchange "envelope journaling" format message; this format may be especially useful for archiving purposes. In Unified Configuration, the `alias_journal` alias option is the equivalent.

- The MTA's address access mapping tables (see Address access mapping table flags) can be configured to trigger message capture via the `$M` flag; and new in MS 7.0.5, such captured messages can optionally be generated in Microsoft Exchange "envelope journaling" format, configured via the `$+L` flag. (Address access mapping table triggered capture is a less commonly used feature: although it allows for greater discrimination than a user LDAP "capture" attribute, since for instance a mapping entry might be configured to capture only messages from one specific sender to another specific recipient, it is less discriminating than use of a Sieve "`capture`" action. So unless configuration in an access mapping table is particularly convenient, more commonly some other technique such as Sieve "`capture`" would be employed.)

- The Sieve "`capture`" action, used to capture copies of messages meeting any Sieve-specifiable criteria, and directing encapsulated copies of the messages to a specified capturer address, discussed in Capturing messages via Sieve scripts. Because of Sieve flexibility, this is especially well-suited for capturing only specific categories of messages: messages meeting some rather specific (and Sieve specifiable) criteria. (New in MS 6.3, messages captured via a Sieve filter may optionally be sent without MIME encapsulation, but with an override of the original envelope From address. This new option for capture may be of special interest for archiving purposes, when the simpler, unencapsulated message form may be more convenient. Or yet another option, new in MS 7.0 update 2, is that such capture messages may be generated in Microsoft Exchange's "envelope journaling" format: a multipart MIME message where the first part contains semi-structured envelope information and the second part contains the actual original message. "envelope journaling" format may be more convenient for archiving purposes.)

- (New in MS 6.3) Integration with the AXS:One archive facility, used to generate message copies that will be archived by AXS:One, discussed in AXS:One archive integration. This is primarily suitable for compliance archiving.

Note that with any of the techniques discussed below, issues of use of "captured" message copies, and potentially issues of correlation (and elimination of "duplicate" copies of the "same"

message capt ured at different stages of processing) may arise; it is the responsibility of sites to devise strategies appropriate for their goals.

Note also that any "capture" of users' messages may, indeed is likely to, have legal ramifications. Sites are cautioned to **obtain legal advice** before beginning any use of message capture techniques.

67.1 MESSAGE-SAVE-COPY mapping table

The `MESSAGE-SAVE-COPY` mapping table provides a way to tell the MTA to copy (rename) message files from its disk queue area when dequeuing messages. The resulting files are in the MTA's disk queue area (proprietary) format. When copied (renamed) to some area outside the MTA's normal disk queue area, these copies of the MTA's message files are no longer subject to normal processing by the MTA. But if subsequently renamed back into the MTA's disk queue area, the message files are perfectly suited to being "picked up" by the MTA, and re-sent just as the original message files were sent.

The original motivation for this facility was as a means to capture copies of messages outbound from the MTA to be retained (for some period) for purposes of potential future "message replay", that is, it was intended to be used to resend messages in case of disaster on the original receiving host(s). (The new-in-MS-8.0 `clonehosts` channel option provides a different facility, with different trade-offs, that can also be suitable for certain "message replay" purposes.) The `MESSAGE-SAVE-COPY` facility can potentially be used, however, for other purposes such as monitoring (capturing) of messages sent by particular users, or as a way to obtain message copies for long-term archiving purposes.

When using this facility for purposes of monitoring particular users' e-mail messages, keep in mind that while capturing of messages sent *from* a particular user is straightforward enough (the `MESSAGE-SAVE-COPY` mapping table probes include the envelope From address as part of the probe field), the capturing of messages sent *to* a particular user is less straightforward with this facility, as it normally distinguishes only between classes of destination addresses---that is, it distinguishes on a destination channel basis (as the `MESSAGE-SAVE-COPY` mapping table probes include the destination channel, but not the envelope To recipient(s)). Thus if it is desired to use this facility to capture specifically those messages to a particular user or users, it may be necessary to either capture additional messages (to other recipients) as well and then in some site-supplied subsequent processing discard the undesired messages, or else to perform some additional, more complex, configuration of the MTA to allow the `MESSAGE-SAVE-COPY` mapping table to distinguish which messages are to the recipient(s) in question.

When using this facility to obtain message copies that will then be further processed, *e.g.*, delivered into an archiving system, note that the copies created are in MTA message file format. All access to such message files should be done via the MTA SDK. (Essentially, a channel program should be written to process the messages.) Accessing the message files only through the MTA SDK insulates applications from potential future changes in the MTA's message file structure (particularly, changes and additions to the message envelope portion of the message file).

The choice of when the `MESSAGE-SAVE-COPY` mapping table should be applied -- for which destination channel(s), and in a multi-host e-mail environment, on which hosts---should be carefully considered in relation to the fundamental goals of the message capture. And typically some thought needs to be given to issues of message "split up" -- the cases where a multi-recipient message may bifurcate into separate "copies" due to different recipients needing different types of handling -- in relation to the message capture goals. If the goal is simply

to capture "all messages going out a particular channel" (the case for which this facility was designed), achieving that goal is simple. But otherwise, other questions arise. Is the goal to capture each such message copy? Will there be a desire to "correlate" or "consolidate" the cases where separate eventual message copies all correspond to a single, originally submitted message? In a multi-host environment, is it desired to capture merely those messages passing through a particular host? Or do messages potentially need to be captured on multiple hosts and if so, does there need to be some "correlation" or "consolidation" of the message copies captured on different hosts (some of which copies may consist of the "same" message, at a different point in its processing life-cycle)? As regards message "split-up", a most basic example would be the case of a multi-recipient message where the recipients are destined out different channels. But there are also many other sorts of message processing that imply separate handling via separate message files, such as local recipients with different conversion tags, or mailing list recipients *vs.* directly addressed recipients, *etc.* Even on a single system, the potential use of any "intermediate" channels such as the conversion or reprocess channels should be considered in relation to timing of the `MESSAGE-SAVE-COPY` operation. And when operating in a multi-host environment, the timing and message bifurcation issues tend to become more complex.

67.1.1 MESSAGE-SAVE-COPY mapping table format and examples

The format of a `MESSAGE-SAVE-COPY` mapping table entry is, by default:

`out-channel``|`*`return-address`*`|D|`*`orig-file-path`* `$Y`*`result-file-path`*

where *`out-channel`* is the destination channel out which the message is being dequeued, *`return-address`* is the envelope From address, and *`orig-file-path`* and *`result-file-path`* are full file path specifications. Note that the template (right hand side) of the mapping table entry must include one of the flags $Y, $y, $T, or $t in order for the rename to be attempted.

If the new-in-6.3 `message_save_copy_flags` MTA option has all of its bits set (corresponding to a value of 7), then the probe format instead becomes

`transport-info``|`*`app-info`*`|`*`source-channel`*`|`*`conv-tags`*`|`*`out-channel`*`|`*`return-address`*`|D|`*`orig-file-path`*

where the *`transport-info`* and *`app-info`* are as usually defined (*`transport-info`* in particular corresponding to the fields seen in a `PORT_ACCESS` probe) -- see for instance their discussion in the discussion of the `MAIL_ACCESS` mapping table or in the discussion of the `log_connection` MTA option; where *`source-channel`* is the original source channel; and where *`conv-tags`* consists of any current conversion tags.

As a rename operation is used to rename the original file to the result (copied) file, the result file specification must be on the same disk as the original file path, and the path must be writable by the MTA. However, normally an area under the `IMTA_QUEUE` area should not be used as the result location, as that is the MTA's area for message files that it expects to be eligible for MTA automatic processing. Thus normally an area on the same disk, and owned by the MTA, but outside the actual `IMTA_QUEUE` area itself, should be used as the place to which to copy (rename) the message files.

As of the 8.0 release, `MESSAGE-SAVE-COPY` provides a means of copying message files instead of, or in addition to, renaming them. If $G is specified, then a file name is read from the mapping result and the current message file is copied there. If both $G and $Y are specified, then the file is both copied and renamed; in this case the mapping result must be of the form:

`$Y$G`*`copy-file-name`*`|`*`rename-file-name`*

If $Q is specified in addition to $Y, then an attempt will be made to tell the Job Controller to process the message file in its new location. $Q is intended to be used when a message file is moved from one queue to another.

Also new in 8.0 is the $S flag. $S can be used in a `MESSAGE-SAVE-COPY` mapping to say that the message file has been renamed or otherwise processed by the mapping template and the file should simply be closed, not deleted or otherwise modified. $S is only effective if $Y is not specified.

As an example, to capture a copy of each message file being dequeued out to the Internet (out the `tcp_local` channel), a mapping table as follows might be used:

```
MESSAGE-SAVE-COPY

  tcp_local|*|D|/opt/SUNWmsgsr/data/queue/tcp_local/%%%/*  \
    $Y/opt/SUNWmsgsr/msg-save/tcp_local/$1$2$3/$4
```

Note how in the above example the assumption is that the `subdirs` channel option is in use on the `tcp_local` channel (so that message files are stored in subdirectories under the `tcp_local` channel's disk queue area), and how the subdirectory structure is preserved due to the same values being substituted back in via the template.

As another example, to capture a copy of message file being dequeued out to the Message Store via the `ims-ms` channel, a mapping table such as the following might be used:

```
MESSAGE-SAVE-COPY

  ims-ms|*|D|IMTA_QUEUE:ims-ms/%%%/*  \
       $Y/opt/SUNWmsgsr/msg-save/ims-ms/$1$2$3/$4
```

To capture all messages from a particular user is straightforward via the `MESSAGE-SAVE-COPY` mapping table, by specifying that user's address as the *`return-address`* in the probe. However, capturing all messages to a particular user but only to that particular user via this facility would require a more complex configuration of the rest of the MTA: prior to MS 6.3, such a task would typically require use of a special delivery channel -- see Additional ims-ms channels -- or in MS 6.3 or later, an alternative approach for capturing messages to some special user(s) would be to configure the user(s) in question with some special `mailConversionTag` value, set the `message_save_copy_flags` MTA option to 4 (or some value including 4 in the bit mask) so that probes to `MESSAGE-SAVE-COPY` include conversion tags, and then use conversion tag sensitive entries in the `MESSAGE-SAVE-COPY` mapping table.

67.1.2 Message replay of captured message copies

Message files captured via the `MESSAGE-SAVE-COPY` mapping table, if moved back into appropriate MTA channel queue area(s), are perfectly suited to being "replayed"---redelivered.

```
# imsimta qm stopchannel-name
# imsimta qm cache -change -global -inorder_rebuild
# mvsaved-message-files/opt/SUNWmsgsr/data/queue/channel-name
# imsimta cache -synchronize
# imsimta qm startchannel-name
# imsimta qm cache -change -global -noinorder_rebuild
```

67.2 Capture triggered via LDAP attributes

The LDAP capture attribute (the exact attribute name is site-chosen, and specified via the `ldap_capture` MTA option) provides a way to tell the MTA to "capture" a copy of each message sent *to* or *from* a user who has the attribute present. The capture copy will be sent to the value (the address) specified in the LDAP capture attribute. Normally, the LDAP capture attribute itself should be configured in the LDAP directory as an attribute that the user can neither set nor even see themselves; that is to preserve the covert nature of the LDAP capture attribute.

Multiple capture attributes may apply to a particular user, or particular message copy (due either to multiple attributes on one user, or to attributes on both sender and recipient(s)).

New in MS 8.0, the MTA also supports enabling capture at the domain level; see the `ldap_domain_attr_capture` MTA option.

See Format of captured message copies for a discussion of the format of captured message copies.

Note that (LDAP attribute triggered) capture of messages that a user *sends* is triggered during address reversal, and hence in order to capture the messages that the user sends, it is critical to be performing address reversal, and in particular properly configured address reversal. See Intended side effects of LDAP address reversal.

(In the interests of symmetry and completeness, it could be noted that (LDAP attribute triggered) capture of messages *to* a user is triggered during LDAP alias expansion for the user (`alias_urlN` lookups), so for capture of messages to a user it is critical that such LDAP alias lookups be configured as normal. However, LDAP alias lookups are such a fundamental part of normal MTA operation, that unless a site has intentionally modified their configuration in abnormal ways, it would be very unusual for this to be a concern. This is in contrast to address reversal which, though strongly recommended nowadays, may still be omitted from older configurations at some sites.)

67.3 Capturing messages via Sieve scripts

The MTA has a private Sieve extension action, "`capture`", that takes an argument specifying a destination address to which to send an encapsulated copy of the original message. "`capture`" is supported only in system Sieves: that is, channel Sieves or the MTA `systemfilter` (in legacy configuration, the `imta.filter` file). By default, this causes generation of a new message to the capturer in almost exactly the same DSN format (see Format of captured message copies) as results from use of the `ldap_capture` attribute (discussed in Capture triggered via LDAP attribute).

New in MS 6.3 are the optional, nonpositional parameters `:dsn` and `:message`. The default is `:dsn`, which corresponds to the only behavior previously available, that of captured copies being in encapsulated format as with `ldap_capture` attribute use. However, if the new-in-6.3

"`:message`" parameter is specified, then the "capture" message copy may instead be generated without MIME encapsulation (though the envelope From address of the new message copy will be set to that of the "owner" of the Sieve filter).

New in MS 7.0 update 2 is the optional parameter `:journal`, which is an alternative to `:message` or `:dsn`. This new `:journal` parameter causes the Sieve "`capture`" action to produce Microsoft Exchange's "envelope journaling" format. This format consists of a multipart MIME message where the first part contains envelope information in a semi-structured format and the second part is the actual message.

Because the "`capture`" action can, like any other Sieve action, be coded into use in a Sieve script doing complicated filtering of messages, it is especially well-suited to cases where it is desired to "capture" only particular sorts of messages (*e.g.*, those containing particular header lines, particular combinations of senders and recipients, particular sorts of message contents, *etc.*). For some examples, see Example Sieve external lists with properties.

However, Sieve filter based "capture", especially with the new-in-6.3 `:message` argument or the new-in-7.0u2 `:journal` argument, may also be a useful part of an archiving approach. See Format of captured message copies for a discussion of the possible formats for captured message copies.

67.4 Format of captured message copies

"Captured" message copies by default are in the form of Delivery Status Notifications (see RFC 1892). So for instance, if an original message has the form shown in Original message to be captured, as submitted at the point when the MTA applies capture (for instance capture performed by the SMTP server when the message is first submitted)---and where, for comparison, that original message by the time it is delivered to a user mailbox might have a form as shown in Original message as delivered:

Original message to be captured, as submitted

```
Date: Tue, 13 Oct 2009 17:27:03 -0700 (PDT)
Subject: test message
From: user1@domain.com
To: user2@domain.com
Message-id: <0IH400G04EU3G800@host.domain.com>

an original line of text
```

Original message as delivered

```
Return-path: <user1@domain.com>
Received: from [10.1.110.115] ([10.1.110.115])
 by host.domain.com (Sun Java(tm) System Messaging Server 7.3-11.01 64bit
 (built Sep  1 2009)) with ESMTP id <0KRH00A3QAO42T10@host.domain.com>
 for user2@domain.com; Tue, 13 Oct 2009 17:28:52 -0700 (PDT)
Date: Tue, 13 Oct 2009 17:27:03 -0700 (PDT)
Subject: test message
From: user1@domain.com
```

```
To: user2@domain.com
Message-id: <0IH400G04EU3G800@host.domain.com>
Original-recipient: rfc822;user2@domain.com

an original line of text
```

then a captured message copy (the copy generated and sent to the value of an LDAP attribute named by the `ldap_domain_attr_capture` MTA option or the `ldap_capture` MTA option) would have the form shown in Captured message copy (default DSN format). Similarly, a captured message copy generated and sent to the address named in an unadorned "`capture`" Sieve action would have almost exactly that same form, with only a minor text difference as discussed at **(11)**.

Captured message copy (default DSN format)

```

--Boundary_(ID_nChZX4aV2kgbzSzzoDGCvw)--
```

In the captured message copy, note the following items of interest:

1. As with any DSN, note that the envelope From address on this DSN is empty. (Note that the addition of a Return-path: header line only occurs at final message delivery time; if looking at the capture message copy earlier, such as while it is transitting the MTA, this header line would not be expected to be present.)

2. Captured message copies are encapsulated, with the new, encapsulating message having the form of a notification message: an empty envelope From and a From: header value set to the postmaster address. (By default, the host's postmaster address is used, though an override postmaster address may be used if domain-specific postmasters are configured --- see the `ldap_domain_attr_report_address` MTA option --- or if use of an override postmaster address has been set by the `FROM_ACCESS` mapping table.)

3. The Subject: value for captured message copies defaults to the string "`Message Capture Copy`", or may be set to an alternate string (then used for all DSNs in the relevant language choice) using the SUBJECT option in the `return_option.opt` file, or may be modified on a per-type-of-DSN basis using the `$T` flag in the appropriate `NOTIFICATION_LANGUAGE` mapping table entries.

4. The message capture copies are sent to the address specified as the value of the attribute named by the `ldap_capture` or (new in MS 8.0) the `ldap_domain_attr_capture` MTA option; as for instance in this example the attribute is assumed to have the value `subpoena1-on-user1@domain.com`. (Or in the case of Sieve "`capture`" actions, the message capture copies are sent to the address specified in the "`capture`" action.)

5. The `return_prefix.txt` file is used to construct the first part of DSN messages: specifically, the MIME header lines, plus (typically, and in particular in this example) the introductory text line and insertion of a sample of the original message headers. Normally,

the NOTIFICATION_LANGUAGE mapping table is configured to choose an appropriate, language-specific such set of MIME header lines and introductory text.

6. When the return_prefix.txt file uses the %H substitution, exactly which header lines from the original message that will cause to be included in this first part normally is controlled, for all DSNs of all types in all languages, by the return_header.opt file. (New in MS 7.0 update 2, use of language-specific variants of return_header.opt may be configured.) That is, the use of %H substitution in return_prefix.txt causes inclusion of headers, with return_header.opt controlling exactly which headers.

7. The appropriate, language-specific return_capture.txt file specifies the text added here at the bottom of the first part of the DSN in the case of message capture copies.

8. The host and channel that are generating the DSN (the captured message copy in this case) are reported.

9. As of MS 7.0, the arrival date of when the message "arrived" at the reporting MTA is reported on an "Arrival-date:" line. Note that as this represents the time when the MTA *began* processing this message, it will tend to be a time slightly prior to the time of the Received: header line that the MTA added on this "capture" message copy (though this time is of course after the time at which the original message was composed).

10. For each current recipient of the message, a set of fields is output, reporting on that recipient. Normally this set consists of an "Original-recipient:" field, a "Final-recipient:" field (note that the useintermediate and suppressfinal channel options alter what is actually reported here), an "Action:" field (which is of course "capture" for capture copies), and a "Status:" field (for capture copies due to ldap_domain_attr_capture or ldap_capture, this field will contain a string along the lines of "Copy requested by capture attribute"; or for capture copies due to Sieve "capture", "Copy requested by capture filter").

11. The one difference between a captured copy due to use of the ldap_domain_attr_capture or ldap_capture attribute *vs.* use of a Sieve unadorned "capture" action is whether the text reported on the Status: line says "Copy requested by capture attribute" (or one of the new in MS 8.0 variants corresponding to tagged LDAP attribute value "Copy requested by journal attribute", "Copy requested by capture header attribute", "Copy requested by journal header attribute") *vs.* "Copy requested by capture filter".

12. The envelope From of the original message is reported on the Return-path: header line of the included original message.

13. For the captured message copy, a Received: header line closely corresponding to the Received: header line that was constructed for the original message during the processing at the time that the original message was captured, is constructed and reported here.

14. The entire header (all header lines) of the original message is included, as it existed at the point of capture.

Note that as usual with DSNs, some customization of the text intended to be human-readable is possible. The text value on the Subject: header line may be modified (for all DSNs in the relevant language choice) via the SUBJECT option in the return_option.opt file, or may be modified on a per-type-of-DSN basis using the $T flag in the appropriate NOTIFICATION_LANGUAGE mapping table entries. The first part of the DSN (the TEXT/PLAIN part), may be localized or site modified via the return_prefix.txt file and the

`return_capture.txt` file corresponding to the relevant language choice, as well as the general `return_header.opt` file. See DSN language and customization for further details.

When using an `ldap_capture` or (new in MS 8.0) an `ldap_domain_attr_capture` named LDAP attribute, the regular, DSN form of captured message copy, as shown in Captured message copy (default DSN format) (or with the slight variations configurable via DSN configuration as discussed there) is (prior to MS 8.0) always generated. (New in MS 8.0, the LDAP attributes named by the `ldap_capture` and `ldap_domain_attr_capture` MTA options supported tagged values, where the tags select the format to be generated. So as of MS 8.0, LDAP attribute triggered capture can also cause generation of "journal" format, or of modified DSN or "journal" format containing only headers of the original message -- which may be useful for administrative monitoring that preserves message content privacy.) That DSN format is also (essentially) the format generated by default when using the Sieve "`capture`" action. But when using the Sieve "`capture`" action, two other alternate formats may be generated.

Requesting "`capture :message`" results in a format such as shown in Captured `:message` message copy, where the capture copy is not much changed from the original message copy, other than the original envelope From address being overriden for the capture copy to be that of the relevant system Sieve's "owner" (normally the postmaster address), and differences in Received: header line(s) corresponding to the new routing of the capture message copy. Although such a "`capture :message`" copy does not have as much information regarding the original message as would a plain "`capture`" copy or even a "`capture :journal`" copy (as discussed in Captured journal 2003 format message copy) --- specifically, this form of capture does not have fields in which to record the original message copy's envelope From and envelope To values --- for some purposes it may provide sufficient information and its "simple" structure may be convenient. However, because the fact that this is a capture message copy is not called out obviously in the capture message copy's header, the recipient of such capture copies will *need to be alert* to the reason why he or she has received the capture copy! Hence, typically the mailbox receiving such capture copies should be either: (a) a special mailbox dedicated to receiving such capture copies, or (b) the mailbox of a sophisticated e-mail user who knows to expect capture copies, and knows to look carefully at all messages received so as to detect which messages are being received due to capturing and handle such received messages appropriately. (For instance, if a dedicated mailbox is not available, consider directing capture copies to a distinguished subaddress of the mailbox, combined with a Sieve filter that detects the presence of the subaddress to cause special handling, such as delivery into a special folder.)

Captured `:message` message copy

In the captured `:message` format message copy, note the following items of interest:

1. The envelope From address for a "`capture :message`" copy is the postmaster address; more specifically, it is the owner of whichever system Sieve performed the "`capture :message`" action, and system Sieves are all owned by the postmaster.

2. This is the Received: header line constructed during the enqueue from the reprocess channel to the delivery channel. (Unlike the other capture formats, which are notification messages processed through the process channel, the processing of a "`capture :message`" copy is more similar to the effect of a Sieve "`redirect`" action and in particular, (prior to MS 8.0) is handled through the reprocess channel. As of MS 8.0, the process channel, rather than the reprocess channel, handles these messages too.)

3. This is the Received: header line constructed by the SMTP server enqueuing this capture message copy to the reprocess channel. Note that this Received: header line in the capture message copy is very similar to the Received: header that the SMTP server added to the original message; the difference is in the respective "for *recipient-address*" clauses, as the capture message copy shows the recipient address for this capture message copy (if there is only one capture message recipient).

4. From here on, the copy consists of the original message (all its original header lines); in particular, the header From: is still that of the original message. Note that when capturing a message that had been relayed, the captured message copy would also contain more Received: header lines than shown here, if the original message (as in a relayed message) itself contained Received: header lines; but this example corresponds to an original message whose initial submission was to this MTA, with the capture being triggered during the processing of that initial submission.

Alternatively, again with the original message shown in Original message to be captured, as submitted, a basic (2003 format) "`capture :journal`" (or an LDAP attribute triggered capture due to an LDAP attribute named by `ldap_capture` or `ldap_domain_attr_capture` having a value tagged by `;format-journal`) message copy would have the form shown in Captured journal 2003 format message copy:

Captured journal 2003 format message copy

--Boundary_(ID_xWvHuuTuAMSgGf6g0CDWjg)--
```

In the captured journal format message copy, note the following items of interest:

1. The journal format is a notification message: it has an empty envelope From, as reported here on the Return-path: header line for this journal capture copy.

2. This is the Received: header line constructed during the enqueue from the process channel to the delivery channel. Note that journal format message copies, being constructed as notification messages, are generated via the process channel.

3. This is the Received: header line constructed by the SMTP server during its enqueue of this capture message to the process channel.

4. The header From: on such a journal message copy is that of the MTA postmaster.

5. The Subject: header line says "Message Journal Copy" for such copies -- unless use of different Subject: text has been configured as discussed in DSN language and customization.

6. The header To: shows the capturing address, as directed in the "`capture :journal`" action or (new in MS 8.0) the value (sans the `;format-journal` tag) of an LDAP attribute named by the `ldap_capture` or `ldap_domain_attr_capture` or MTA option.

7. New in MS 7.0u4, a X-MS-Journal-Report: header line is generated, as some third-party archive software appears to require such a header line.

8. Note that the journal format consists, at the outermost MIME level, of a multipart/mixed part; this is in contrast to the default, DSN format for captured messages, which, making use of the standard notification message format, consists of a multipart/report part at the outermost MIME level.

9. This text part contains the journal format's minimal set of envelope information for the captured message (itself contained in the subsequent part).

10. The envelope From address for the original message is reported on a "Sender:" line.

11. The Message-id: of the original message is reiterated here.

12. The list of envelope To recipients are reported, one envelope To recipient per line. As of MS 7.0u3, any source routes on the envelope To recipient address or addresses are removed. As of MS 7.0.5, it is the so-called "intermediate address" rather than the "final address" that is reported; this is especially notable for local Message Store recipients. This example corresponds to an original message having only one recipient (or more precisely, an original message having only one recipient at time of capture).

13. This message part contains the original message, essentially as it existed at time of capture, but with the addition of a Return-path: header line, plus a constructed Received: header line contemporaneous with capture processing.

14. The original envelope From address is reported here in a constructed Return-path: header line.

15. A Received: header line is present effectively corresponding to the Received: header line constructed for the original message while capture processing was occurring, though this journal capture copy Received: header line contains no "for ..." clause.

16. From here on, the original message as it existed at time of capture, is duplicated.

Alternatively, again with the same original message, a journal 2007 format message as generated due to a "`capture :journal`" action when the (new in MS 7.0.5) MTA option `journal_format` has bit 0 (value 1) set and when the `addrtypescan` channel option has been set on all relevant channels, would have the form shown in Captured journal 2007 format message copy:

Captured journal 2007 format message copy

In the captured journal format message copy, note the following items of interest:

1. The journal format is a notification message: it has an empty envelope From, as reported here on the Return-path: header line for this journal capture copy.

2. This is the Received: header line constructed during the enqueue from the process channel to the delivery channel. Note that journal format message copies, being constructed as notification messages, are generated via the process channel.

3. This is the Received: header line constructed by the SMTP server during its enqueue of this capture message to the process channel.

4. The header From: on such a journal message copy is, by default, that of the MTA postmaster. New in MS 7.0.5, if bit 1 (value 2) of the MTA option `journal_format` is set, then the From: field value will be set to that of the original message.

5. The Subject: header line normally says "Message Journal Copy" for such copies -- unless use of different Subject: text has been configured as discussed in DSN language and customization, or (new in MS 7.0.5) unless bit 1 (value 2) of the MTA option `journal_format` is set (in which case the Subject: field value is set to that of the original message).

6. The header To: normally shows the capturing address, as directed in the "`capture :journal`" action. New in MS 7.0.5, if bit 1 (value 2) of the MTA option `journal_format` is set, then the To: field value will be set to that of the original message.

7. New in MS 7.0u4, a X-MS-Journal-Report: header line is generated, as some third-party archive software appears to require such a header line. New in MS 7.0.5, if bit 2 (value 4) of the MTA option `journal_format` is set, then an X-MS-Exchange-Organization-Journal-Report: header line is generated rather than an X-MS-Journal-Report: header line.

8. Note that the journal format consists, at the outermost MIME level, of a multipart/mixed part; this is in contrast to the default, DSN format for captured messages, which, making use of the standard notification message format, consists of a multipart/report part at the outermost MIME level.

9. This text part contains the journal format's minimal set of envelope information for the captured message (itself contained in the subsequent part).

10. The envelope From address for the original message is reported on a "Sender:" line. (Note that unlike 2003 format, the envelope From is not enclosed in angle brackets.)

11. The Message-id: of the original message is reiterated here.

12. The list of envelope To recipients are reported, one envelope To recipient per line. As of MS 7.0u3, any source routes on the envelope To recipient address or addresses are removed. As of MS 7.0.5, it is the so-called "intermediate address" rather than the "final address" that is reported; this is especially notable for local Message Store recipients. With bit 0 (value 1) of the MTA option `journal_format` set, as well as optionally also bit 3 (value 8), what exactly will be noted on each envelope To recipient line will depend upon whether the `addrtypescan` channel option has applied, and if so, on whether envelope To recipient address strings *exactly* match recipient header values. This example corresponds to an original message having only one recipient (or more precisely, an original message having only one recipient at time of capture), and where that envelope To recipient string is *exactly* the same as a value on the To: header line. When the `addrtypescan` channel option has been applied, then envelope recipient addresses may be denoted with "`To:`" (if exactly matching a header To: or Resent-To: value), or denoted with "`Cc:`" or "`Bcc:`" similarly, or denoted with simply "`Recipient:`" if no such exact string match exists; "`Recipient:`" is also what is used whenever `addrtypescan`) was not applied. Recipient addresses may be further elaborated with "`Forwarded:`" or "`Expanded:`" labelling, *e.g.*,

    `To:` *`active-address`*`, Forwarded:` *`original-address`*

    in those cases where the MTA can detect that forwarding or list expansion, respectively, has occurred.

13. This message part contains the original message, essentially as it existed at time of capture, but with the addition of a Return-path: header line, plus a constructed Received: header line contemporaneous with capture processing.

14. The original envelope From address is reported here in a constructed Return-path: header line.

15. A Received: header line is present effectively corresponding to the Received: header line constructed for the original message while capture processing was occurring, though this journal capture copy Received: header line contains no "for ..." clause.

16. From here on, the original message as it existed at time of capture, is duplicated.

67.5 Archiving messages

Message archiving can take different forms, and serve different purposes. For record keeping (especially legal compliance) purposes, it may be desired to retain copies of "all" messages that have passed through the Messaging Server, or to retain copies of more specifically selected messages; in this sense, the "archive" is a long term record or history of message traffic, where this historical record of messages is intended for administrative/legal use, rather than (normally) being accessed directly by end e-mail users. For operational efficiency purposes, it may be desired to "archive" messages in the sense of "off-loading" older/larger/less frequently accessed messages to "more economical" storage, that is nevertheless still accessible; in this sense, the "archive" is an implementation-achieved efficiency measure, preferrably remaining reasonably conveniently usable by end users.

From the design point of view, these two distinct purposes for archiving mean somewhat different requirements for message access. For compliance archiving, the primary focus is on thoroughness of the scope of message capture, while the requirements for accessing messages are fewer; in particular, whether the message archive is accessible to end users may be optional. While for operational archiving, not all messages may need to be archived---but those messages that are archived must still be reasonably conveniently retrieved by end users.

67.5.1 Choosing which messages to archive

The choice of which messages to archive is a critical one for sites, especially when the archiving is for compliance purposes. This has three components: (1) choosing whose or which types of messages to archive, (2) choosing in what form and at what stage(s) of processing and transitting the MTA the messages should be captured for archiving, and (3) choosing whether Message Store IMAP APPEND operations (moving a message to a folder) should cause archiving. Of these three questions, the first (whose or which types of messages to archive) is usually well specified. The third question (whether to archive due to Message Store operations) also tends to be straightforward to decide. However, the second question may require additional consideration. Between initial message submission and eventual final delivery into a mailbox, while transitting the MTA, messages undergo various transformations, some trivial and some potentially dramatic. Such transformations can include: addition of Received: header lines, addition of other header lines (such as missing-but-required header lines such as Date:, or addition of spam filtering header lines, or addition of mailing list header lines, *etc.*), transformations ("address reversal") of addresses in header lines, alias or list expansion changing the currently active set of envelope recipients, "split up" of a multi-recipient message into different copies for different subsets of recipients, addition of "disclaimer" text, changes in Content-transfer-encoding, document conversion processing, conversion to a different charset (`CHARSET-CONVERSION`), *etc.*

Three possible approaches for selection of which messages transitting the MTA are eligible for archiving include:

1. Flow-based: Those messages passing through certain channels (such as channels delivering to the Message Store, or channels sending out to the Internet) should be archived.

2. User-based: Those messages sent to or from certain users (perhaps all users; perhaps all users in certain domains; perhaps only some distinguished subset of users) should be archived.

3. Content-based: Those messages containing certain content should be archived.

Such approaches correspond, respectively, to techniques of:

1. For flow-based archiving, it would be typical to trigger archiving via channel `*spamfilter*` options (if using an archiving callout approach) or via channel Sieve

filters (using a "capture" action in a channel Sieve filter located via a sourcefilter or destinationfilter, as relevant). Choice of the "correct" channels on which to trigger archiving is critical.

2. For user-based archiving, it would be typical to trigger archiving via some user-level (or new in MS 8.0, domain-level) LDAP attribute; see Capture triggered via LDAP attribute. Use of a class-of-service may be helpful in setting such an attribute on all (or large subsets) of users. Note that when such an ldap_capture or (new in MS 8.0) ldap_domain_attr_capture named LDAP attribute is used, then capture will occur at whatever channel stage a user alias is expanded (capturing messages to the user), as well as whenever address reversal occurs (capturing messages from the user). Since address reversal in particular normally occurs during every message enqueue, deployments involving multiple channel "hops" or multiple relay hosts may find multiple "copies" of messages---one "copy" per channel "hop" -- getting captured for archiving. Thus an alternative to such global use of an LDAP attribute is to use instead a Sieve filter "capture" action, perhaps consulting a Sieve external list (which may consist of consulting a user-level LDAP attribute). This technique of using a channel-specific Sieve filter that consults a Sieve external list allows more precisely timed (limited to specific channels) archiving that is still based on (provisioned via) LDAP attribute settings; see for instance Example Sieve external lists with properties.

3. For content-based archiving, it is critical to detect and label which messages contain the sort of content that needs archiving. If users and user e-mail agents can be relied upon to label such context *ab initio*, when messages are first generated, that is one solution for labelling. Very simple, and easy to detect, content criteria may be codable into a Sieve script---for instance, detecting certain MIME Content-type: labelling. More complex content detection, especially in cases of concerns about uncooperative users attempting to evade archiving requirements, may require special, third-party scanning-and-detection software, a la spam/virus filter software. As usual, the preferred approach for integrating such third party packages is via the MTA's spamfilter plug-in facility; if the third party package does not support such callout use, then the second best choice is to deploy the package "on the side" of the MTA using the usual aliasdetourhost/alternate conversion channel approach. In any case, once the messages are labelled in whatever way chosen, then the actual trigger for archiving can use Sieve filter based "capture" triggered by presence of the relevant label.

67.5.2 Message identifier generation

When doing archiving, whether with the AXS:One archiving module or via some other mechanism, it is typically useful or even required to "identify" messages via some identifier. The MTA has the ability to generate an identifying "hash" for messages passing through it, based on configurable selection of message features. It is also (at least typically) necessary to uniquely identify the recipient(s) of the archived message copies---and in some cases, using the recipient's (canonical) e-mail address may not be the preferred choice. The MTA has an option to control the generation of message recipient identifiers. These options will be discussed below.

Messages undergo more-or-less constant change during their traverse from initial submission to eventual final delivery: Received: header lines are added at each "hop"; mailing lists get expanded changing the set of recipients for a message; for a multi-recipient message, the message may need to get "split up" into separate copies for separate types of recipients; individual addresses undergo routing and esthetic transformations; message contents may be modified as for example addition of header lines indicating spam/virus filtering or content encoding changes or character set conversions, or addition of "disclaimer" text, *etc.* So "identifying" a message is not a straightforward question: one has to ask which portions

of a message "matter" as far as the identification is concerned, *vs*. which sorts of "changes" should be ignored. By default, the MTA generates a hash over the following message fields (or a different set may be selected using the `message_hash_fields` MTA option):

- Message-id:
- From:
- To:
- Cc:
- Bcc:
- Resent-message-id:
- Resent-From:
- Resent-To:
- Resent-Cc:
- Resent-Bcc:
- Subject:
- Content-id:
- Content-type:
- Content-description:

(Note that the Content-type: and Content-description: header are those from the top or outermost MIME level of the message.)

Keep in mind that the choice of when (which channel(s)) to generate a message hash will affect which version(s) of a message are archived. A typical configuration, especially for "operational" mode, might be to set `generatemessagehash` on channels delivering to the Message Store, such as `ims-ms` and `tcp_lmtpcs*` channels, with `deletemessagehash` (the default) on all other channels (especially `tcp_local`). Such a configuration would result in separate message hashes for each message copy separate at the time of enqueue to the final delivery channel. Or in other cases, where it is desired to archive only an "earlier" copy of messages, possibly a copy from before certain later message bifurcations have occurred, then another potentially useful configuration (especially in "compliance" mode) might be to set `generatemessagehash` "earlier", such as on any (known to be used) "intermediate" channels and on channels delivering to other internal hosts such as `tcp_intranet`. Any final delivery channels such as `ims-ms` or `tcp_lmtpcs*` will still need either `keepmessagehash` set (if such messages are guaranteed to have already passed through a channel that did hash generation---as in the case of messages that have already passed through a "front end" MTA) or `generatemessagehash` if it is possible for a message to get to the channel without a previously generated hash. And a channel delivering externally (such as `tcp_local`) should again be set `deletemessagehash`.

The `unique_id_template` MTA option may be used to configure how unique recipient identifiers will be generated for purposes of archiving.

67.5.3 AXS:One archive integration

One approach for message archiving is to make use of an AXS:One archive. The MTA and the Message Store support integration with AXS:One for archiving.

67.5.3.1 Architecture of the AXS:One integration

The Messaging Server integration with AXS:One has the following components:

- The MTA and Message Store can compute a message hash to be used as a unique identifier of the message for AXS:One's purposes.

- Data transfer between Messaging Server (either or both of the MTA and the Message Store) and AXS:One is via configuration-specific file drop directories.

  In one such file drop directory, the MTA and Message Store can deposit message copy files: for each message, AXS:One wants an "archive package" consisting of the message main body, any attachment files, and a `.info` file that contains the meta data of the message, the message hash computed by Messaging Server (and stored in the `.info` file's MessageId field), and references to the other files in that set (archive package).

  Technical note: The Messaging Server writes the `.info` files initially as `.tmp` files, only renaming to `.info` once all the files referenced by that `.info` file are written and the `.info` file itself is complete. That is, until an archive package is complete, the eventual `.info` file will appear instead as a `.tmp` file. On the AXS:One side, it consumes (and deletes) a `.info` file and all the files it references as part of its processing.

  In another file drop directory, AXS:One deposits report files to inform Message Server after it has archived messages.

  Technical note: AXS:One writes a single line record per message to the report file. When writing, AXS:One writes to a tmp file; when the file is completed, it is renamed to *`timestamp`*`_mamsg.txt`. (Such files will subsequently be consumed by `imarchive`.)

- The MTA's general "spam filter" plug-in approach can be used to call an AXS:One specific plug-in module. During message enqueues, the MTA can call the AXS:One integration plug-in which generates message copy files (an "archive package") suitable for AXS:One consumption and deposits those message copy files in the integration file drop directory. All the MTA's usual configuration options regarding which messages to copy for archiving are thereby available. As this archiving is occurring while messages are transitting the MTA, it is usually a part of compliance archiving.

- The Message Store's `imexpire` utility has an `archive` action. Expiration rules configured with the `archive` action control which messages are moved to the archive. This is primarily used for operational archiving: for instance, moving older (or larger) messages off to the archive. If the message already has a message hash identifier for the message , then `imexpire` will use it, but otherwise will generate a message hash itself; in either case, `imexpire` will both include the message hash in the archive package it generates for AXS:One, and insert the message hash into the msghash database.

- The Message Store's `imarchive` utility processes the report files generated by AXS:One. `imarchive` should be scheduled to run periodically to perform this processing task.

  Technical note When `imarchive` runs, it renames the *`timestamp`*`_mamsg.txt` file generated by AXS:One to *`timestamp`*`_mamsg.`*`pid`* before processing the records in the file. If such processing is successful, `imarchive` removes the file; otherwise, the file is renamed to *`timestamp`*`_mamsg.err`.

67.5.3.2 MTA support for AXS:One archiving

(New MS 6.3) The MTA has support for use with the AXS:One archive facility. AXS:One operates by scanning a directory for files to archive, so the MTA writes copies of the messages to be archived, in a special AXS:One format (in particular including a hash "identifier" for each copy of a message delivered to the Message Store), to this specified special directory (for AXS:One to then "pick up"). (The AXS:One archive facility will generate a message identifier

itself for messages that it finds without one, and this is sufficient for copies of messages that were delivered to external Internet sites. The presence of an identifier generated by the MTA on copies of messages delivered to the Message Store is instead important for correlation of the archived message copies with the message copies actually in the Message Store.)

Note that the MTA's generic facilities to generate and add an "identifer" to messages may be useful with other forms of archiving as well; see Message identifier generation, as well as the `*messagehash` channel options, and Message archival and hashing MTA options, for further discussion of the generation and addition to messages of such an identifying "hash" value.

While archiving is most often configured for all users and messages, it is possible to configure archiving only for certain sets of users, using the sorts of "opt-in" approaches (per-user "opt-in" LDAP attribute or channel-level "opt-in") available with the MTA's general spam/virus filter package integration approach (of which the MTA's AXS:One integration is one instance). See the `ldap_optin`*`N`* MTA options, the `*spamfilter`*`N`*`optin` channel options, and the (new in MS 6.3) `ldap_source_optin`*`N`* MTA options.

When `ldap_source_optinN` based triggering of archiving on a per-sending-user basis is desired, note that this is triggered during address reversal, and hence it is critical to be performing address reversal, and in particular properly configured address reversal. See Intended side effects of LDAP address reversal.

67.5.3.3 MTA configuration for AXS:One archiving

From the point of view of MTA configuration, the archiving support is configured rather similarly to configuring use of a third-party, integrated, spam/virus filter package; in particular, use of the archiving support routines is configured via `spamfilter`*`N`*`_config_file` and `spamfilter`*`N`*`_library` MTA options. For some value of *N*, the `spamfilter`*`N`*`_library` MTA option must be set to point to the `libarch.so` module, while the `spamfilter`*`N`*`_config_file` option points to an archive module option file (in MTA option file format) controlling a few options for the archiving module. For instance:

```
spamfilter1_library=IMTA_LIB:libarch.so
spamfilter1_config_file=IMTA_TABLE:archive.dat
```

See Archive_spamfilterN_config_file for further discussion of what may (and must) appear in the archive module option file.

In addition, when it is desired (as it normally is) to be able to correlate the messages in the Message Store with their archived version in the AXS:One system, then the MTA itself should be configured to generate an identifying hash for each message being delivered into the Message Store. (The AXS:One archiving module will generate an identifying message hash for each message that does not already have one itself; this is sufficient for archived messages that do not have a corresponding copy in the Message Store---for instance, archived copies of messages sent to remote recipients.) The material to be hashed, and the algorithm for generating the hash, are controlled via MTA options `message_hash_fields` and `message_hash_algorithm`; channels are individually configurable, via certain `*messagehash` channel options, as to whether they generate, preserve, or delete, such hashes for messages passing through them. See Message identifier generation for further discussion of the generation of such identifying hashes.

Finally, when archiving messages there is the question of identifying the user for whom messages were originally destined---a user identifier. By default, each user's canonical e-mail

address is used. However, the `unique_id_template` MTA option, also discussed in Message identifier generation, may be set to specify use of some alternate form of identifier; when set, the AXS:One archiving facility will generate and use unique user identifiers according to this template, rather than e-mail addresses as by default.

67.5.3.3.1 Example message archiving configuration

Here is an example configuration for using AXS:One archiving.

- In the MTA option file:

```
SPAMFILTER1_LIBRARY=IMTA_LIB:libarch.so
SPAMFILTER1_CONFIG_FILE=IMTA_TABLE:archive.dat
MESSAGE_HASH_ALGORITHM=MD5
!
! Not bothering to hash over Content-type: and Content-description:
!
MESSAGE_HASH_FIELDS=Message-id,Resent-message-id,From,Resent-From,\
 To,Resent-to,Cc,Resent-Cc,Bcc,Resent-Bcc,Subject,Content-id
```

- In the `archive.dat` file:

```
STYLE=1
DIRECTORY=/opt/SUNWmsgsr/archive/
! For compliance mode (legal archiving requirements compliance):
IDSUFFIX=-0000MD500
```

- If the desire is to archive a copy of each message getting delivered to the Message Store on the `ims-ms` channel, plus a copy of each message going out to the Internet on the `tcp_local` channel, then those two channels in the MTA configuration file, `imta.cnf`, would be marked with `destinationspamfilter1`, with the `ims-ms` channel also being marked `generatemessagehash` (so that archived copies could be correlated with the copies in the Message Store, delivered by the `ims-ms` channel), *e.g.*,

```
ims-ms ...rest-of-keywords... generatemessagehash destinationspamfilter1
ims-ms-daemon

...other-channel-definitions...

tcp_local ...rest-of-keywords... destinationspamfilter1
tcp-daemon
```

Or in Unified Configuration, the MTA and channel options set as:

```
msconfig> set mta.spamfilter1_library IMTA_LIB:libarch.so
msconfig# set mta.spamfilter1_config_file IMTA_TABLE:archive.dat
msconfig# set mta.message_hash_algorithm MD5
msconfig# set mta.message_hash_fields "Message-id Resent-message-id...etc..."
msconfig# set channel:ims-ms.generatemessagehash
msconfig# set channel:ims-ms.destinationspamfilter1
msconfig# set channel:tcp_local.destinationspamfilter1
```

and the IMTA_TABLE:archive.dat (*i.e., CONFIGROOT*/archive.dat) file:

```
STYLE=1
DIRECTORY=/opt/SUNWmsgsr/archive/
! For compliance mode (legal archiving requirements compliance):
IDSUFFIX=-0000MD500
```

Chapter 68 Monitoring the MTA

For monitoring the MTA, usually the best place to start is with the MTA's optional logging of message traffic; from this basic information, sites may gather statistics such as how many messages are passing through the MTA, and answering other questions on message traffic.

The command line utility `imsimta qm` may be used to scan what messages are present in the MTA queue area.

The MTA also has facilities to collect and monitor channel counters based upon RFC 1566, the Mail Monitoring MIB. Note that counters are intended for providing real-time "snap-shots" of MTA behavior, rather than for gathering the sort of statistics instead available from the log files. For a description of the MTA counters, see the discussion of MTA counters.

The MTA provides utilities to display the counters directly; see the `imsimta counters` and `imsimta qm` utilities, described in MTA command line utilities.

68.1 MTA transaction logging

The MTA's optional logging of message traffic is enabled via the `logging` channel option. Enabling `logging` causes the MTA to write an entry to a `mail.log*` file each time a message passes through an MTA channel. Such log entries can be useful if you wish to get statistics on how many messages are passing through the MTA (or through particular channels), or when investigating other questions such as whether and when a message was sent or delivered.

If you are only interested in gathering statistics on the number of messages passing through a few particular MTA channels, then you may wish to enable the `logging` channel option on just those MTA channels of main interest. But more generally, many sites prefer to enable logging on all MTA channels; in particular, if you are trying to track down problems, the first step in diagnosing some problems is to notice that messages are not going to the channel you expected or intended, and having logging enabled for all channels can help you spot such issues.

In addition to the basic information always provided when `logging` is enabled, additional, optional informational fields may also be logged in the `mail.log` files, controlled via various `log_*` MTA options. Particularly likely to be of interest are the `log_message_id`, `log_envelope_id`, `log_filename`, `log_connection`, `log_process`, and `log_username` options.

- Enabling `log_message_id` allows correlation of which entries relate to which message.

- Enabling log_envelope_id allows easier correlation of which entries from mail.log files from different systems correspond to the same message at the SMTP level.
- Enabling log_filename makes it easier to immediately spot how many times delivery of a particular message file has been retried, and can be useful in understanding when the MTA does or does not split a message to multiple recipients into separate message file copies on disk.
- Enabling log_connection causes the MTA to log TCP/IP connections, as well as message traffic, to the mail.log files by default; alternatively, the separate_connection_log option may be used to specify that connection log entries instead be written to connection.log files.
- When using log_connection to cause generation of TCP/IP connection entries, additionally enabling log_process allows correlation of which connection entries correspond to which message entries.
- log_username is mostly of interest in the case of users who authenticate their message submission using the SMTP AUTH command; in such cases, log_username causes logging of the user identity (prefixed with an asterisk character if the identity was established by authentication). As of the 8.0 release, the log_username option can also be used to log the primary mail address associated with the authenticated identity and in the case of "U" connection log entries, the authentication mechanism used.

The mail.log and connection.log entries may optionally be duplicated to syslog via the log_messages_syslog and log_connections_syslog options.

68.1.1 Managing the MTA transaction log files

When the logging channel option is enabled, all MTA message transaction log entries are made to the file mail.log_current in the MTA log directory, of MS 7.0.5 *DATAROOT*/log/mail.log_current; (prior to MS 7.0, the MTA message transaction log file was located via the imta_primary_log MTA Tailor option). If connection logging is enabled via the log_connection MTA option, connection transaction log entries are also by default written to the mail.log_current file, but if the MTA option separate_connection_log=1 has been set, then the connection transaction log entries will instead be written to the connection.log_current file.

The message return_job, which the Scheduler is typically configured to run every night shortly after midnight, appends any existing mail.log_yesterday to the cumulative log file, mail.log, renames the current mail.log_current file to mail.log_yesterday, and then begins a new mail.log_current file. It also performs the analogous operations for any connection.log* files. (In older versions of the MTA, the names and location of these log files were controlled by the imta_primary_log, imta_secondary_log, and imta_tertiary_log MTA Tailor options; as of MS 7.0.5, these names are not configurable and the location is derived from the SERVERROOT value.) (Note that the return_split_period MTA option can modify the frequency of such transaction log file "roll over".)

Note that the MTA itself by default never does anything to the cumulative mail.log file; it is up to each site to manage that log file however they choose, whether by periodically saving it to backup, deleting it, truncating it, or the like.

When considering how to manage the log files, note that the MTA periodic return_job will execute a site-supplied *DATAROOT*/site-programs/bin/daily_cleanup shell

script, if one exists. Thus some sites may choose to supply their own `daily_cleanup` that, for instance, renames the old `mail.log` file once a week (or once a month), *etc.* (Note that the `return_cleanup_period` MTA option can modify the frequency at which such "cleanup" is performed.)

68.1.2 MTA transaction log entry format

The format of message transaction log entries and connection transaction log entries is subject to change. By default, message transaction log entries and connection transaction log entries all appear in the same message log files (`mail.log*` files); however, if the MTA option `separate_connection_log=1` is set, then the connection transaction log entries will instead appear in the connection transaction log files (`connection.log*` files).

Currently, by default, each message transaction log entry contains eight or nine fields, *e.g.*,

```
19-Jan-1998 19:16:57.64 tcp_intranet tcp_local    E 1 adam@domain.com rfc822;mark@innosoft.com mark@innosoft.
          (1)         (2)             (3)      (4)(5)    (6)         (7)                        (8)
```

These fields are:

1. The date and time when the entry was made.
2. The channel name for the source channel.
3. The channel name for the destination channel.
4. The type of entry; see Message logging entry action type codes.
5. The size of the message.[1] This is expressed in kilobytes by default, although this default can be changed by using the `block_size` MTA option. If message size is not an exact `block_size` multiple, then the size is rounded up to the next block for logging purposes. (Note that in "Q" records, the size is not necessarily the size of the message as a whole, but rather indicates the amount of message processed before the delivery attempt failed: in particular, the size field in a "Q" record may be 0 such as in cases where the MTA's SMTP client encounters a connection failure, or the size field may correspond to the full size of the message such as in cases where the MTA's SMTP client encounters message rejection after the final ".", or in cases such as a network disconnect part way through message transfer the size field will indicate roughly at what point in message transfer the disconnect occurred.)
6. The envelope From address. Note that for messages with an empty envelope From address, such as notification messages, this field will be blank.
7. The original form of the envelope To address. (Note that this is the ORCPT value, and hence follows ORCPT syntax; see RFC 3461. Also note that the semantics of ORCPT are neither "originally submitted address", nor "address originally given to this MTA", and hence ORCPT only sometimes corresponds to one or the other or both. For the "address originally given to this MTA", see instead the `log_intermediate` MTA option.)
8. The active (current) form of the envelope To address.
9. The delivery status (SMTP channels only).

Table 68.1 Message logging entry action type codes

Type	Modifiers	Description
		General
B	E, P, A, S, U, B, C	(New in MS 6.2) Unrecognized/invalid SMTP command. Logging limit set by `MAX_B_ENTRIES` TCP/IP channel-specific option.
D	E, L, A, S, U, B, C	Successful dequeue
E	E, P, A, S, U, B, C, W, T	Enqueue. An "E" or null modifier will be present to indicate whether the enqueue was with EHLO or HELO, respectively.
H	E, P, A, S, U, B, C	(New in MS 8.1) VRFY/EXPN command. Logging limit set by `MAX_H_ENTRIES` TCP/IP channel-specific option.
J	E, P, A, S, U, B, C, W, T, R	Rejection of attempted enqueue (rejection by slave channel program). Logging limit set by `MAX_J_ENTRIES` TCP/IP channel-specific option,
K	E, L, S, U, B, C	Recipient address rejected on attempted dequeue (rejection by master channel program) when the recipient has the NOTIFY=NEVER DSN flag set (so no bounce message will be generated regarding this rejection), or deletion of a timed-out NOTIFY=NEVER message by the `return_job`; compare with "R" records which are the same sort of rejection/time-out occurring, but where a new notification message is also generated regarding this failed message
P	F, X, J, Y, D	(New in MS 8.0) Request to generate a Delivery Status Notification. (Note that in some cases no actual DSN will end up being sent.) "P" records are only generated in cases where the error causing the DSN isn't recorded in any other log entry. The various cases where this happens are further detailed by the presence of a modifier character on the action. Currently the defined modifiers are: • F - address errors detected during alias or mailing list expansion operations (this includes bad RCPT TO addresses that are allowed because the `acceptalladdresses` channel option is in effect) • X - capture operations • J - journal operations • Y - Sieve syntax or evaluation errors • D - success delivery receipts
Q	E, L, S, U, B, C	Temporary failure to dequeue
R	E, L, S, U, B, C	Recipient address rejected on attempted dequeue (rejection by master channel program), or generation of a failure/bounce message; compare with "K" records, which are the same sort of rejection/time-out occurring, but where no notification message is generated and the original message is just deleted
V	E, L, P, A, S, C	(New in MS 6.2p2) An incoming SMTP transaction ended prematurely; frequently corresponds to an address verification operation by a remote

		SMTP client. The "C" modifier was not recorded on "V" records until circa MS 7.0u4
W		Warning message (generated by the `return_job`) regarding a not-yet-delivered message
Z	E, L, P, A, S, U, B, C	Some successful recipients, but this recipient was temporarily unsuccessful; the original message file of all recipients was dequeued, and in its place a new message file for this and other unsuccessful recipients will be immediately reenqueued
LMTP server		
J	S, C	Rejection by LMTP server of address or message. Logging limit set by `MAX_J_ENTRIES` TCP/IP channel-specific option, As of MS 7.0, J records are routinely generated for LMTP server rejections (whereas in previous versions only LMTP rejections at the envelope address stages would be recorded, while LMTP rejections after the DATA would not be recorded). Prior to MS 7.0u4, note that unlike SMTP and SMTP SUBMIT server "J" records, LMTP server "J" records did not include any modifier letters; new in MS 7.0u4, "S" (TLS used) and/or "C" (CHUNKING used) modifiers may be present.
S	S, C	(New in MS 7.0) LMTP deposit into the store; in prior versions indicated with the (somewhat misleading) D action code instead; the addition of "S" (TLS used) and/or "C" (CHUNKING used) modifiers is new in MS 7.0u4.
SMTP/LMTP modifiers		
	E	(New in MS 6.3) ESMTP (EHLO) used
	L	(New in MS 6.3) LMTP (LHLO) used
		Absence of both "E" and "L" implies that HELO was used
	P	(New in MS 7.0) POP-before-SMTP used (via the MMP)
	Q	(New in 7.0) Pipelining used
	A	Authentication (SMTP AUTH) successfully used
	S	TLS (STARTTLS) successfully used
	U	(New in MS 7.0) BURL used.
	B	(New in MS 8.0) BINARYMIME used; see the `binaryserver` channel option.
	C	(New in MS 6.3) CHUNKING used without BINARYMIME; see the `chunking*` channel options.
	8	(New in MS 8.0) UTF-8 message transfer (UTF8SMTP) successfully used
	W	(New in MS 8.1.0.1) Lines longer than 1000 characters were found and wrapped
	T	(New in MS 8.1.0.1) Lines longer than 1000 characters were found and truncated
	R	(New in MS 8.1.0.1) Lines longer than 1000 characters were found, causing the message to be rejected

In addition to the default message transaction fields (shown above), the MTA may optionally be configured to log additional information to the message transaction log file; see the `log_*` MTA options described in Transaction logging MTA options. With `log_connection`,

log_filename, log_envelope_id, log_message_id, log_node, log_notary, log_sensitivity, log_priority, log_process, and log_username all enabled, the format becomes as follows. (Note that the sample transaction log entry line has been wrapped for typographic reasons; the actual message transaction log entry would appear on one physical line.)

```
19-Jan-1998 13:13:27.10 hosta   2e2d.5.1 tcp_local   tcp_intranet E 1 service@innosoft.com
          (1)           (10)     (11)     (2)        (3)        (4) (5)   (6)

         (14)                     (15)

 mailsrv innosoft.com (innosoft.com [192.160.253.66]) 0 3
 (16)    (17)                                         (18) (19)  (9)
```

Here the additional fields, beyond those already discussed above, are:

- (10) (log_node) The name of the node on which the channel process is running.
- (11) (log_process) The process id (expressed in hexadecimal), followed by a period (dot) character, if it is a multithreaded channel entry a process id and another period (dot), and finally a count.
- (12) (log_notary) The NOTARY (delivery receipt request) flags for the message, expressed as an integer.
- (13) (log_filename) The file name in the MTA queue area.
- (14) (log_envelope_id) The envelope id.
- (log_tracking new in MS 8.0 and not shown in the above example) Tracking ID.
- (log_times new in MS 8.0 and not shown in the above example) Deferred delivery time and expiry time.
- (15) (log_message_id) The message id.
- (16) (log_username) The username of the executing process. Note that in the case of Dispatcher services such as the SMTP server, this will be the username of the user who most recently did a startup of the Dispatcher.
- (log_auth new in MS 7.0.5 and not shown in the above example) The SMTP MAIL FROM's AUTH parameter value.
- (17) (log_connection) The exact connection information shown varies according to whether a message is incoming (E record) or outgoing (*e.g.*, D record), whether or not the channel is an SMTP (or LMTP) channel, and for SMTP/LMTP channels for incoming messages, the specific bits set for the log_connection MTA option. For incoming messages, the connection information consists of the sending system or channel name, such as the name presented by the sending system on the HELO/EHLO line (for incoming SMTP messages), or the enqueuing channel's official host name (for other sorts of channels). In

the case of TCP/IP channels, the sending system's real name, that is, the symbolic name as reported by a DNS reverse lookup and/or the IP address, can also be reported within parentheses as controlled by the `ident*` channel options. This sample assumes use of one of these options, for instance use of the default `identnone` channel option, that selects display of both the name found from the DNS and IP address. This example also assumes that `log_connection=1` is set, but that higher bits of `log_connection` are not set. If bit 5 (value 32) of `log_connection` were set, then the incoming connection information for a message incoming over TCP/IP would also include the entire transport information string, `TCP|`*`MTA-IP`*`|`*`MTA-port`*`|`*`remote-IP`*`|`*`remote-port`*. If bit 6 (value 64) of `log_connection` were set, then the incoming connection information would also include the application information string, just `SMTP` for the case of incoming SMTP messages. For outgoing messages, *e.g.*, D records, the connection information (due to `log_connection`'s bit 0/value 1 being set) is present only for SMTP/LMTP channels, and in such cases consists of the remote host name and the remote name as found in the DNS, the transport information string (see above), and the remote SMTP banner line. And this information is included at the start of the SMTP diagnostic field.

- (18) (`log_sensitivity`) The sensitivity for the message.
- (`log_mtpriority` new in MS 8.0 and not shown in the above example) The SMTP MT-PRIORITY associated with the transaction.
- (19) (`log_priority`) This effective processing priority for the message; 3 corresponds to "normal" priority. Note that the effective processing priority may not be the same as the message's Priority: header value (if any); for instance, the `*blocklimit` channel options can cause lowering of effective message processing priority.
- (`log_intermediate` not shown in the above example) The intermediate form of the recipient address.
- (`log_intermediate` not shown in the above example) The original (RCPT TO) form of the recipient address.
- (`log_uid` new in MS 8.0 and not shown in the above example) LDAP `uid` attribute for local users.
- (`log_mailbox_uid` new in MS 7.0.5 and not shown in the above example) For messages delivered to the MS Message Store, the UID and UIDVALIDITY.
- (`log_futurerelease` new in MS 8.0 and not shown in the above example) SMTP FUTURERELEASE value.
- (`log_filter` not shown in the above example) The Sieve filter actions applying to the message, including effects from verdicts from spam/virus package "plug-ins".
- (`log_reason` new in MS 6.3 and not shown in the above example) The reason field (due to setting `log_reason=1`). It would appear in a message transaction log entry corresponding to a message rejection (for instance, an "R" or "K" entry), appearing just before the SMTP delivery status (SMTP diagnostic) field.
- (`log_diagnostics` not shown in the above example) The SMTP delivery status/SMTP diagnostic field (due to having the default of `log_diagnostics=1` set)
- (`log_queue_time` new in MS 6.3 and not shown in the above example) The "time in queue" field (due to setting `log_queue_time=1`).

- (log_conversion_tag new in MS 7.0.5 and not shown in the above example) Any conversion tags on the message.
- (log_imap_flags new in MS 7.0.5 and not shown in the above example) Any IMAP flags that have been set on the message by the MTA.
- (log_delivery_flags new in MS 7.0.5 and not shown in the above example) Delivery flags.
- (log_callout_delays new in MS 8.0 and not shown in the above example) Callout delay timer values.
- (log_transactionlog new in MS 8.0 and not shown in the above example) String(s) logged due to the Sieve "transactionlog" action.

The maximum line length for message transaction records is 4096 characters.

Currently, each connection transaction log entry contains at least six fields, with the presence of up to five additional optional fields controlled by the MTA options log_node, log_process, log_message_id, log_username, and log_queue_time, *e.g.*, (note that for display purposes here, the output lines have been wrapped at the transport information field at (7)),

```
04-Sep-2002 01:00:04.23 host.domain.com 1f625.d.0 tcp_local    +            O
                    TCP|129.153.12.42|25|123.4.5.67|65228 SMTP
04-Sep-2002 01:00:05.21 host.domain.com 1f625.d.3 tcp_local    +            C
                    TCP|129.153.12.42|25|123.4.5.67|65228 SMTP/TLS-192-DES-CBC3-SHA
04-Sep-2002 01:00:06.23 host.domain.com 1f627.3.0 tcp_local    -            O
                    TCP|129.153.12.42|4303|123.45.6.7|25 SMTP/domain.com/mail.domain.com
04-Sep-2002 01:00:06.49 host.domain.com 1f627.3.3 tcp_local    -            C
                    TCP|129.153.12.42|4303|123.45.6.7|25 SMTP/domain.com/mail.domain.com/TLS-192-DES-CBC3-SHA

        (1)             (2)              (3)      (4)      (5)          (6)
                       (7)                            (8)
```

- (1) The date and time when the entry was made.
- (2) [Optional---only present when log_node=1 is set.] (New in MS 6.3) The host name of the MTA system.
- (3) [Optional---only present when log_process=1 is set.] The process id (expressed in hexadecimal), followed by a period (dot) character and then a thread id, followed by a period (dot) character and a count.
- (4)The channel name for the source channel. In the case of "-" entries (outgoing messages), this is the name of the channel acting as SMTP client or LMTP client. Note, however, that in the case of "+" entries (incoming messages), the name shown is that of the default channel for the Dispatcher service listening on the port and interface address for the incoming connection, so is typically merely one of tcp_local (for the SMTP server on port 25) or tcp_submit (for the SMTP SUBMIT server on port 587) or tcp_lmtpss (for the LMTP server); in particular, channel "switching" due to *switchchannel channel option based effects (such as switching to a tcp_intranet channel due to switchchannel or switching to a tcp_auth channel due to saslswitchchannel) is not reflected in such entries. (In the case of "I" records, that is, ETRN records, this "source" channel field instead is used to display the name of the channel which the ETRN command would cause to run.)
- (5) A plus, +, or minus, -, indicating whether this is an inbound or outbound connection, respectively. That is, a + indicates a connection inbound to an SMTP, SMTP SUBMIT, or

LMTP server; a - indicates a connection outbound by a channel acting as an SMTP (or LMTP) client.

- (6) A code indicating the type of entry; see Connection logging entry action type codes.
- (7) The transport information. This takes the form:

  `TCP|`*`local-IP`*`|`*`local-port`*`|`*`remote-IP`*`|`*`remote-port`*

- (8) The application information. For inbound connections (to the SMTP server), the "O" (that is, open) records will just show "SMTP" in this field; the "C" (that is, close) records will just show "SMTP" unless TLS was used, in which case this field will show "SMTP/TLS-info". The *TLS-info* string consists of "TLS-*bitstrength-cipherinfo*". (Note that the *cipherinfo* field may not be present, and if present may be unreliable in the MTA, especially as of MS 6.0 and later, as the cipher information is not reliably reported back by the underlying NSS library in use.) For outbound connections, the field has some additional information, showing the initial host name (prior to DNS lookup) to which to connect, and the host name found from doing a DNS lookup, that is, the host name to which the connection was really made/attempted. In the case of outbound connections where TLS was used, the TLS information will also be shown in the C (that is, close) record. So for outbound connections, the field takes the form

  `SMTP/`*`initial-host/DNS-host`*

  or when TLS was used, the C records will take the form

  `SMTP/`*`initial-host/DNS-host/TLS-info`*

  For instance, *initial-host* might be a name used for e-mail addresses which merely has MX records, and then *DNS-host* will be the actual host name to which the connection was made (the name pointed to by an MX record).

- (9) [Optional---only present if log_message_id=1.] In "I" records, the host name presented on the ETRN command line. In "U" records, the MTA AUTH error, if there was one.
- (10) [Optional---only present if log_username=1.] In "U" records, the authenticated user.
- (11) (New in MS 6.2) "C" records may include additional information about the reason for the close, if the close was due to an error. For instance, "Error reading SMTP packet" (in cases where the connection was dropped, for instance due to a network problem or the remote system aborting the connection), or "Timeout after *x* minutes trying to read SMTP packet" (in cases where the MTA times out the connection due to remote system inactivity).
- (12) [Optional---only present if log_queue_time=1.] (New in MS 6.3) "O" records may include the "time to open the connection", "Y" records may include the "time attempting to open a connection for an attempt that failed", and "C" records may include the total time the connection was open as a final field. This appears as a ct attribute in XML format logs.

Table 68.2 Connection logging entry action type codes

Type	Modifiers	Description

Actions		
C	F	Connection closed
O		Connection opened
T		PORT_ACCESS mapping table rejection; logged if both bit 1 (value 2) of the log_connection MTA option is set (or overridden by the LOG_CONNECTION TCP/IP-channel-specific option), and the $T flag is used in a PORT_ACCESS rejection entry
U		(New in MS 6.2) Authentication attempt (SMTP AUTH use), whether successful or failed; logged if bit 5 (value 32) of the log_connection MTA option is set
X	F	Connection rejected, or closed, due to an SMTP level error response
Y		Connection try failed before being established
I		ETRN command received; logged if bit 2 (value 4) of the log_connection MTA option is set (or overridden by the LOG_CONNECTION TCP/IP-channel-specific option)
Modifiers		
	F	(New in MS 7.1) A *.data-failed file was created; may be reported on "C" or "X" records for SMTP and SMTP SUBMIT connections (but not for LMTP connections, since *.data-failed files are never generated by the LMTP server)

The maximum line length for connection transaction records is 4096 characters.

[1]The mechanism for computing size values in enqueue entries in the MTA transaction logs was revised for MS 7.0 update 2. Previously message sizes were computed based on counting octets in the input, which did not take various things, including charset-conversion, into account. It was done this way in order to facilitate certain calculations needed for performing message fragmentation. Now that message fragmentation has become a rarity, this approach is no longer appropriate, and the code has been changed to work directly with the output message.

68.1.3 Triggering effects from transaction logging with LOG_ACTION

(LOG_ACTION itself was added in Messaging Server 7.0-3.01. But use of LOG_ACTION with MeterMaid---other than simple "throttle" calls -- typically requires MeterMaid features new in Messaging Server 7.2-0.01. In particular, MeterMaid "remove" and "test" routines are new in Messaging Server 7.2-0.01.)

The LOG_ACTION mapping table provides a way for any transactions recorded by the MTA to also, as a side-effect, trigger other effects. A great deal of information, of different types, can be reported in the MTA's message transaction and connection transaction log files. Sites may be interested in noticing certain sorts of log entries as evidence of certain sorts of occurrences, or counting (or at least monitoring trends for) certain sorts of occurrences, or making access decisions based on certain sorts of occurrences. The LOG_ACTION mapping table provides a way to turn MTA message transaction and connection transaction log file entries into syslog notices, or into MeterMaid counter updates; or if a site wishes to provide their own routine for the mapping table to call, to take whatever, site-defined "action" the site chooses, based upon relevant transaction log entries. For instance, a site might want to notice (via a syslog

notice) failed SMTP AUTH attempts as a warning of possible account break-in attempt; or a site might want to count (via MeterMaid) the number of failed (bad) recipients for users' outgoing messages, and react to "high" numbers as a possible sign of a user sending spam with a poor-quality recipient list.

68.1.3.1 LOG_ACTION operation

The LOG_ACTION mapping table is probed each time a message transaction or connection transaction log entry is written. At present the LOG_ACTION mapping table's only direct effect on the normal transaction log entries is its ability to disable output (recording) of specified entries. But its more interesting uses tend to be for its "side effects", which can be considered rather similar to the "side effects" available for the address based *_ACCESS mapping tables and FROM_ACCESS mapping table: In particular, LOG_ACTION has the potential to generate syslog notices, or make call-outs such as to MeterMaid.

68.1.3.2 Probe format

The format of the LOG_ACTION probe for a message transaction log entry consists at a minimum of the following, plus additional, optional fields:

```
source-channel|destination-channel|action|size|envelope-from|orig-envelope-to|current-envelope-to
```

Here *action* is the usually logged action code; (*i.e.*, the ac attribute's value in XML format MTA transaction logging). Additional log entry fields may be included in the probe, depending upon the setting of the corresponding log_* MTA options; usually bit 1 (value 2) for a log_* MTA option controls whether the field controlled by that option is included in the LOG_ACTION probe. For log_connection, where bit 1 already has another meaning, bit 8 (value 256) enables inclusion of the claimed source system (as claimed in the client's the HELO/EHLO command for SMTP channels, or the enqueueing channel's official host name for other types of channels), and the bit that enables inclusion of *application-info* and *transport-info* in the LOG_ACTION probe is bit 9 (value 512); for log_intermediate, bits 2 and 3 (values 4 and 8, respectively) control the inclusion of fields in the probe. These optional fields consist of:

```
|notary-bits|filename|envelope-id|message-id|username|source-system|sensitivity
|mt-priority|priority|intermediate-dest|initial-dest|ldap-uid|imap-uid:uidvalidity
|future-release|filter|reason|diagnostics|remote-mta|isc-status
|application-info|transport-info|time-in-queue|conversion-tags|imap-flags
|delivery-flags
```

The *source-system*, and *application-info* and *transport-info* fields result from two bits of log_connection. The *intermediate-dest* and *initial-dest* fields result from two bits of log_intermediate. The rest of the fields result from, respectively, log_notary, log_filename, log_envelope_id, log_message_id, log_username, log_sensitivity, log_mtpriority, log_priority, log_uid, log_mailbox_uid, log_futurerelease, log_filter, log_reason, log_diagnostics, log_remote_mta, log_isc_status, log_queue_time, log_conversion_tag, log_imap_flags, and log_delivery_flags.

The format of the probe for a connection transaction log entry consists at a minimum of the following, plus additional, optional fields:

source-channel|*direction*|*action*

The *direction* is either + for inbound connections, or - for outbound connections. *action* is the usually logged connection action code, with the possible addition of an "F" suffix (on "C" or "X" action entries), added if the entry corresponds to a case where the MTA encountered an error with its attempt to create a *.data-failed file. The optional fields consist of any subset of:

|*SASL-error-or-ETRN-host-name*|*username*|*extra*|*adminser*|*diagnostics*|*transport-info*|*application-info*|*queue-time*

Optional fields are enabled by the relevant bit or bits of log_message_id (bit 1, value 2 enables logging of the SASL error in "U" SMTP AUTH records and the host name from client ETRN commands in "I" ETRN records), log_username (especially relevant for U SMTP AUTH records), log_conversion_tag (especially relevant for open/close SMTP records), log_diagnostics, log_connection (bit 9, value 512 enables both *transport-info* and *application-info*), and log_queue_time. Note that the same bit (or bits) enable probe inclusion both for message transaction probes and connection transaction probes.

Mapping input flags are described in the following table.

Table 68.3 LOG_ACTION mapping input flags

Flag	Description
$|	(New in MS 8.0.1.2) Set if one or more of the input strings contains a vertical bar character. (A vertical bar in an input string has the potential of being misinterpreted as a delimiter.)
$R	(New in MS 8.0.1.2) Set if the source channel is an "internal" channel and the MTA is operating in reprocessing mode.
$S	(New in MS 8.0.2.3) Set if the per-entry save flag is set and the entry is going to be written to the log file; clear otherwise.

If the probe string matches the pattern (*i.e.*, the left hand side of an entry in the mapping table), then the resulting output template (right hand side) is checked. The output templates in the LOG_ACTION mapping table can use the special flags defined in the table below, as well, of course, as any general mapping table substitutions or metacharacters such as calling out to a routine.

Table 68.4 LOG_ACTION mapping output flags

Flag	Description
$F	Disable writing this entry to the transaction log file
$N	Disable writing this entry to the transaction log file
$+|	Causes any syslog message produced by $< or $> to consume all remaining arguments as well as including the vertical bars themselves.
Output flags with arguments, in argument reading order[1]	
$T*probe-tag*	(New in MS 8.0) (Only takes effect for message transaction probes, not connection transaction probes.) Prefix subsequent *_ACCESS mapping table probes with the tag *probe-tag*. The last such tag may optionally be prepended to the AUTH_REWRITE mapping table probe.
$D*N*	(New in MS 8.0.1.2) Delay the session after logging operation is complete. The delay is controlled by the signed integer parameter value *N*. Positive values of N specify the number of centiseconds to delay; if multiple log records are being written as part of a transaction the value associated with the last matching probe is used. Negative values of N are cumulative; the absolute values of matching probes are added together to produce the number of centiseconds to delay.
$<*string*	Send *string* to syslog (UNIX) if probe matches; see also the sndopr_priority MTA option.
$>*string*	Send *string* to syslog (UNIX) if access is rejected; see also the sndopr_priority MTA option.

[1] To use multiple flags with arguments, separate the arguments with the vertical bar character, |, placing the arguments in the order listed in this table.

68.1.3.3 Examples of LOG_ACTION use

This section shows examples of some possible uses of the LOG_ACTION mapping table. The syntax and general operation of the LOG_ACTION mapping table is discussed above. The first example below is a very simple use to disable recording of certain entries. The additional LOG_ACTION examples below are more sophisticated, making use of MeterMaid callouts.

68.1.3.3.1 Disabling logging of connections from a periodic monitoring source

One use of LOG_ACTION is to disable logging of some particular type of entry, while still retaining logging in general: for instance, connection attempts from some special source, when such connections are performed merely for "monitoring" or "heartbeat" reasons, may not deserve to be recorded.

For instance, if the monitor source IP is *monitor-ip*, then set bit 9 (value 512) of the log_connection MTA option and then use a LOG_ACTION mapping table along the lines of that shown below to disable the logging of the connection "O"pen and connection "C"lose records generated by the monitoring probe connections.

```
LOG_ACTION

  *|*|O|*|monitor-ip|*      $N
```

```
*|*|C|*|monitor-ip|*     $N
```

68.1.3.3.2 Syslog notices after SMTP AUTH attempts with bad password

One use of LOG_ACTION might be to generate a syslog notice if more than some site-chosen number of bad password SMTP AUTH attempts are made against any user account. This can be achieved by calling out to MeterMaid from LOG_ACTION, and then generating the syslog notice when MeterMaid's threshold is reached.

First, in the MTA option file make sure that appropriate data will be included in the LOG_ACTION mapping table probes by setting log_* MTA options as below, and set sndopr_priority to values for syslog facility and severity that will coordinate with your syslog.conf configuration for syslog notice handling:

```
# msconfig
msconfig> show log_connection
role.mta.log_connection = 6
instance.channel:tcp_monitor.log_connection = 0
msconfig> set mta.log_connection 134
msconfig# write -remark="Set bit 7/value 128 of log_connection to get U connection records"
msconfig> set log_message_id 3
msconfig# set log_username 3
msconfig# set log_diagnostics 3
msconfig# write -remark="Enable more fields in LOG_ACTION probes"
msconfig> set sndopr_priority 20
msconfig> set sndopr_prefix ""
msconfig# write -remark="MTA syslog notices to get LOG_MAIL+LOG_WARNING syslog.conf handling"
msconfig> quit
#
```

In legacy configuration mode, this would correspond to setting MTA options in the option.dat file along the lines of:

```
! Sites likely want additional bits of LOG_CONNECTION set; this example
! requires that bit 7/value 128 be set.
!
LOG_CONNECTION=128
LOG_MESSAGE_ID=3
LOG_USERNAME=3
LOG_DIAGNOSTICS=3
!
! Set SNDOPR_PRIORITY to a syslog facility+severity value that will
! coordinate with your syslog.conf configuration, e.g.
! SNDOPR_PRIORITY=20 to choose LOG_MAIL+LOG_WARNING syslog.conf handling.
!
SNDOPR_PRIORITY=20
!
! Eliminate the syslog prefix
!
SNDOPR_PREFIX=
```

(The above settings represent likely site practice, rather than what is strictly required, as they show log_* option values set so that regular MTA connection transaction log entries will be generated as well as fields in LOG_ACTION probes; but in principle, the LOG_ACTION probes could be set without having to enable the connection transaction logging.)

To have a MeterMaid table named `bad_password_attempts`, configure MeterMaid with a new table via:

```
# msconfig
msconfig> ! First check if MeterMaid has had basic configuration:
msconfig> show metermaid.*
role.metermaid_client.server_host = host-name
role.metermaid.enable = 1
role.metermaid.secret (suppressed)
msconfig> ! Yes, MeterMaid basics already configured;
msconfig> ! so now add a new bad_password_attempts table
msconfig> set metermaid.local_table:bad_password_attempts.data_type string
msconfig# set metermaid.local_table:bad_password_attempts.max_entries 1000
msconfig# set metermaid.local_table:bad_password_attempts.table_options "nocase penalize"
msconfig# set metermaid.local_table:bad_password_attempts.table_type throttle
msconfig# set metermaid.local_table:bad_password_attempts.quota 5
msconfig# set metermaid.local_table:bad_password_attempts.quota_time 3600
msconfig# write -remark="Added bad_password_attempts MeterMaid table"
msconfig> quit
#
```

In legacy configuration mode, (assuming basic MeterMaid configuration had already been performed via additional `configutil` parameters not shown below), this would correspond to a MeterMaid table configured via `configutil` values, including these (though note that many of the values shown being set are actually defaults):

```
metermaid.table.bad_password_attempts.data_type: string
metermaid.table.bad_password_attempts.max_entries: 1000
metermaid.table.bad_password_attempts.options: nocase,penalize
metermaid.table.bad_password_attempts.type: throttle
metermaid.table.bad_password_attempts.quota: 5
metermaid.table.bad_password_attempts.quota_time: 3600
```

Then a `LOG_ACTION` mapping table to make use of that MeterMaid table could be as follows:

```
LOG_ACTION

! With log_connection=128 set, we get "U" action records.
! With log_message_id=3 set, the SASL-error is recorded in the message-id field
! With log_username=3, get a username field
! With log_diagnostics=3, get a diagnostics field
!
! So probe format is:
!
! source-chan|direction|action|SASL-error|username|diagnostics
!
  tcp_*|+|U|Bad$ password$_*|$_*|*   \
$[IMTA_LIB:check_metermaid.so,throttle,bad_password_attempts,$1]$<LOGACTION,$ \
Too$ many$ bad$ password$ attempts$ for$ user$ $1
```

There is a subtlety in the above, which is that `log_diagnostics` is shown being set *purely* to ensure that there is at least one more vertical bar and (possibly empty) field appearing after the *`username`* field. Furthermore, asterisk wildcard for matching the *`username`* field has the

"minimal matching" $_ modifier set on it.) This is not strictly necessary for this *exact* example, but makes this example easier to extend with additional fields should sites wish to do so.

There is also a prior $_* match in the reason field portion of the pattern, just after "Bad$ password"; that is necessary as of 8.0 when additional detail text was added to the reason field.

68.1.3.3.3 Syslog notices after SMTP AUTH attempts with bad username

Another example would be to generate a syslog notice if the same source IP makes multiple attempts to authenticate with a bad username (hence suggestive of a possible "dictionary attack" against your user name space). With MTA options settings of:

```
# msconfig
msconfig> show log_connection
role.mta.log_connection = 2
msconfig> set mta.log_connection 642
msconfig# write -remark="Set bit 1/value 2 plus bit 7/value 128 plus bit
 9/value 512 of mta.log_connection to get O and C plus U connection records,
 plus application and transport fields included in LOG_ACTION probes"
msconfig> set log_message_id 3
msconfig# set log_username 3
msconfig# set log_diagnostics 3
msconfig# write -remark="Enable extra fields in LOG_ACTION probes"
msconfig# set sndopr_priority 20
msconfig# write -remark="MTA syslog notices to get LOG_MAIL+LOG_WARNING syslog.conf handling"
msconfig> quit
#
```

Or in legacy configuration mode:

```
! Sites likely want additional bits of LOG_CONNECTION set; this example
! requires that bit 1/value 2 plus bit 7/value 128 plus bit 9/value 512 be set.
LOG_CONNECTION=642
LOG_MESSAGE_ID=3
LOG_USERNAME=3
LOG_DIAGNOSTICS=3
!
! Set SNDOPR_PRIORITY to a syslog facility+severity value that will
! coordinate with your syslog.conf configuration, e.g.
! SNDOPR_PRIORITY=20 to choose LOG_MAIL+LOG_WARNING syslog.conf handling.
!
SNDOPR_PRIORITY=20
```

To have a MeterMaid table named `bad_user_attempts`, configure MeterMaid with a new table via:

```
# msconfig
msconfig> ! First check if MeterMaid has had basic configuration:
msconfig> show metermaid.*
role.metermaid_client.server_host = host-name
role.metermaid.enable = 1
role.metermaid.secret (suppressed)
msconfig> ! Yes, MeterMaid basics already configured;
msconfig> ! so now add a new bad_user_attempts table
msconfig> set metermaid.local_table:bad_user_attempts.data_type ipv4
```

```
msconfig# set metermaid.local_table:bad_user_attempts.max_entries 1000
msconfig# set metermaid.local_table:bad_user_attempts.table_options "penalize"
msconfig# set metermaid.local_table:bad_user_attempts.table_type throttle
msconfig# set metermaid.local_table:bad_user_attempts.quota 5
msconfig# set metermaid.local_table:bad_user_attempts.quota_time 3600
msconfig# write -remark="Added bad_user_attempts MeterMaid table"
msconfig> quit
#
```

In legacy configuration mode, (assuming basic MeterMaid configuration had already been performed via additional `configutil` parameters not shown below), this would correspond to a MeterMaid table configured via `configutil` values including:

```
metermaid.table.bad_user_attempts.data_type: ipv4
metermaid.table.bad_user_attempts.max_entries: 1000
metermaid.table.bad_user_attempts.options: penalize
metermaid.table.bad_user_attempts.type: throttle
metermaid.table.bad_user_attempts.quota: 5
metermaid.table.bad_user_attempts.quota_time: 3600
```

then a `LOG_ACTION` mapping table could be:

```
LOG_ACTION

! With log_connection=642 set, we get "U" action records and transport-info
! fields.
! With log_message_id=3 set, the SASL-error is recorded in the message-id field
! With log_username=3, get a username field
! With log_diagnostics=3, get a diagnostics field
!
! So probe format is:
!
! source-chan|direction|action|SASL-error|username|diagnostics|transport-info
! where transport-info is:  TCP|host-IP|host-port|source-IP|source-port
!
  tcp_*|+|U|No$ such$ user|*|*|TCP|$_*|$_*|$_*|*   \
$[IMTA_LIB:check_metermaid.so,throttle,bad_user_attempts,$5]$<LOGACTION,$ \
Too$ many$ wrong$ username$ attempts$ from$ $5$ (username$ attempted:$ $1)
```

68.1.3.3.4 Syslog notices after failing SMTP AUTH attempts, resetting after success

Both of the above examples could be improved by using the (new in 7.2-0.01) `remove` routine of MeterMaid to achieve a "reset" effect after desired "good" occurrences. For instance, with settings as above (including `log_diagnostics=3` and `log_connection=642`):

```
LOG_ACTION

! With log_connection=642 set, we get "U" action records and transport-info
! fields.
! With log_message_id=3 set, the SASL-error is recorded in the message-id field
```

```
! With log_username=3, get a username field
! With log_diagnostics=3, get a diagnostics field
!
! So probe format is:
!
! source-chan|direction|action|SASL-error|username|diagnostics|transport-info
! where transport-info is:  TCP|host-IP|host-port|source-IP|source-port
!
  tcp_*|+|U|Bad$ password|$_*|*    \
$[IMTA_LIB:check_metermaid.so,throttle,bad_password_attempts,$1]$<LOGACTION,$ \
Too$ many$ bad$ password$ attempts$ for$ user$ $1
  tcp_*|+|U|No$ such$ user|*|*|TCP|$_*|$_*|$_*|*    \
$[IMTA_LIB:check_metermaid.so,throttle,bad_user_attempts,$5]$<LOGACTION,$ \
Too$ many$ wrong$ username$ attempts$ from$ $5$ (username$ attempted:$ $1)
!
! Once a successful AUTH occurs, remove the entry for that username in the
! bad_password_attempts table, and remove the entry for that source IP in
! the bad_user_attempts table.  We want to try to remove the source IP entry in
! the second table, even if (for some reason) the MeterMaid callout on the
! first fails, so we split the store calls into two separate entries, rather
! than attempting two routine calls from one right hand side.
!
  tcp_*|+|U|*|*|*authentication$ successful*|TCP|$_*|$_*|$_*|*  $CCLEAR|$2|$7
!
! If the authentication was successful, then the probe is now:
! CLEAR|username|source-ip
!
  CLEAR|*|*  \
$CCLEAR|$0|$1$[IMTA_LIB:check_metermaid.so,remove,bad_password_attempts,$0]
  CLEAR|*|*    $[IMTA_LIB:check_metermaid.so,remove,bad_user_attempts,$1]
```

In the above example, it is convenient to detect successful authentication via the diagnostics field (the SMTP response). However, as of Messaging Server 7.3-11.01, an equivalent approach would be to detect successful authentication via the reason field (and use `log_reason=3`): as of Messaging Server 7.3-11.01, the reason field in cases of successful authentication would either be "`authentication successful`" or "`authentication successful - switched to channel channel-name`". (In prior versions, the reason field confounded some cases.)

68.1.3.3.5 Syslog notices when time-in-queue becomes "high", ceasing after any quick delivery

(Note that this example uses the MeterMaid "remove" routine, new in Messaging Server 7.2-0.01.) Another example of generating syslog notices when some condition occurs, and then resetting the MeterMaid table entry (and hence stopping the syslog notices) when the condition ceases, would be for cases where messages, while getting delivered upon first delivery attempt, are not getting delivered sufficiently promptly for the site's taste. That is, considering only messages that actually do manage to get delivered upon first attempt rather than failing a delivery attempt and having to be retried later (hence inherently taking a relatively "long" time to be delivered), the site wishes to watch for cases where that initial, successful, delivery attempt nevertheless was rather "slow". Here we will record in MeterMaid the destination domain for each new `ZZ*` message whose delivery is "slow" (taking 300 seconds or more), and generate a syslog notice for such domains once 5 messages have been slow within an hour (3600 seconds), but reset (to 0) the MeterMaid table entry for that domain once a "quick delivery" (within 60 seconds) has occurred.

```
LOG_FILENAME=3
LOG_QUEUE_TIME=3
!
! Set SNDOPR_PRIORITY to a syslog facility+severity value that will
! coordinate with your syslog.conf configuration, e.g.
! SNDOPR_PRIORITY=20 to choose LOG_MAIL+LOG_WARNING syslog.conf handling.
!
SNDOPR_PRIORITY=20

metermaid.table.slow_delivery.data_type: string
metermaid.table.slow_delivery.max_entries: 2000
metermaid.table.slow_delivery.options: nocase
metermaid.table.slow_delivery.type: throttle
metermaid.table.slow_delivery.quota: 5
metermaid.table.slow_delivery.quota_time: 3600

LOG_ACTION

! source-chan|dest-chan|D|size|env-from|orig-env-to|env-to|filename|queue-time
!
  *|*|D*|*|*|*|*@*|ZZ*|*   $CDEQUEUEDOMAINTIME|$7|$9
!
! Now probing with just DEQUEUEDOMAINTIME|domain|queue-time
!
  DEQUEUEDOMAINTIME|*|*    $CFASTDOMAIN|$`integer($1)<=60'|$0|$1
!
! Now the probe will be FASTDOMAIN|1|domain|queue-time for queue-time<=60s
! or FASTDOMAIN|0|domain|queue-time for queue-time>60
!
  FASTDOMAIN|1|*|*         \
$[IMTA_LIB:check_metermaid.so,remove,slow_delivery,$0]
  FASTDOMAIN|0|*|*         $CSLOWDOMAIN|$`integer($1)>=300'|$0|$1
!
! Now the probe will be SLOWDOMAIN|1|domain|queue-time for queue-time>=300s
! or SLOWDOMAIN|0|domain|queue-time for 60s<queue-time<300s
!
  SLOWDOMAIN|1|*|*         \
$[IMTA_LIB:check_metermaid.so,throttle,slow_delivery,$0]$<LOGACTION,$ \
Domain$ $0$ deliveries$ slow
```

The above example uses the mapping table expression substitution syntax, `$`expression'`, to perform a test on the value of the `queue-time` (time in queue) field: such an expression will evaluate to 1 if true, 0 if false, so such an expression substitution inserts the string `1` if the numeric test was true or inserts the string `0` if the numeric test was false.

68.1.3.3.6 Blocking submissions of local senders who may be spammers

(Note that this example uses the MeterMaid "test" routine, new in Messaging Server 7.0 update 2.) A different type of use of `LOG_ACTION` is to update a MeterMaid table with information relating to message dequeue, which a message enqueue access mapping table can then consult. That is, `LOG_ACTION` with MeterMaid can provide a way for decisions on allowing message enqueue to reference historical data regarding message dequeue. For instance, a local user

whose outbound to the Internet messages suffer a high number of rejections of bad addresses by remote destinations may raise the suspicion that that user is attempting to send spam using a poor quality recipient list; a site may wish to deny that account further submissions that day.

For any such access restrictions on senders, it is always strongly advisable to *require* local users to authenticate (use SMTP AUTH) in order to submit messages, and then to perform the access checks using the *authenticated* submission address. Because the SMTP envelope From is easy to forge in the base SMTP protocol, attempts to enforce access restrictions based solely upon envelope From are regrettably likely to unintentionally *encourage* (or at least motivate) users to forge their envelope From as a way to bypass the access restrictions. Thus poorly considered access restrictions on senders can cause more harm than good, by motivating users to obscure their identity to evade the restrictions. So this example will assume that a security-conscious configuration, where users are required to use SMTP AUTH to submit, is already in place, so that authentication information is available both for logging via the LOG_USERNAME MTA option, and for performing an access check from the FROM_ACCESS mapping table.

So with MTA options settings that include (legacy configuration style):

```
! Bit 1/value 2 is not set in any of:
!  LOG_NOTARY, LOG_FILENAME, LOG_ENVELOPE_ID, or LOG_MESSAGE_ID
LOG_REASON=3
LOG_USERNAME=3
LOG_DIAGNOSTICS=3
```

or in Unified Configuration:

```
msconfig> show log_*
role.mta.log_diagnostics = 3
role.mta.log_reason = 3
role.mta.log_username = 3
...and likely additional log_* MTA options settings...
```

and `configutil` MeterMaid table settings that, in addition to basic configuration not shown here, include:

```
metermaid.table.sends_to_bogus_recipients.data_type: string
metermaid.table.sends_to_bogus_recipients.max_entries: 5000
metermaid.table.sends_to_bogus_recipients.options: nocase,penalize
metermaid.table.sends_to_bogus_recipients.type: throttle
metermaid.table.sends_to_bogus_recipients.quota: 15
metermaid.table.sends_to_bogus_recipients.quota_time: 86400
```

then a `LOG_ACTION` mapping table to track in MeterMaid bad recipient addresses discovered at dequeue time, and a corresponding `FROM_ACCESS` mapping table that checks that MeterMaid data to decide whether to allow new message submissions, could be:

```
LOG_ACTION

! source-chan|dest-chan|action|size|env-from|orig-env-to|env-to|
!  username|reason|diagnostics
!
```

```
  tcp_local||R*|*|*|*|*|$**|Remote$ SMTP$ server$ has$ rejected$ address|*  \
$[IMTA_LIB:check_metermaid.so,throttle,sends_to_bogus_recipients,$5]
  tcp_local||K*|*|*|*|*|$**|Remote$ SMTP$ server$ has$ rejected$ address|*  \
$[IMTA_LIB:check_metermaid.so,throttle,sends_to_bogus_recipients,$5]

FROM_ACCESS

  TCP|*|*|*|*|SMTP*|MAIL|tcp_auth|*|*   \
$[IMTA_LIB:check_metermaid.so,test,sends_to_bogus_recipients,$6,>=15]$NYou$ \
have$ sent$ to$ too$ many$ bad$ addresses$ today
```

Note that since in the logging (MTA transaction log entries and hence the `LOG_ACTION` field) the username field resulting from SMTP AUTH authentication is actually the `mail` attribute value with the asterisk character prefixed, whereas in `FROM_ACCESS` the "username" field is simply the pure `mail` attribute value, above in `LOG_ACTION` the entries make sure to explicitly match the asterisk character and then *not* include it in the sends_to_bogus_recipients table updates, so that the `FROM_ACCESS` probes can match on just the username.

68.1.3.3.7 Blocking dictionary attack on user name space (botnet attack)

Automated spam engines may mount a so-called "dictionary attack", attempting to run quickly through possible recipient addresses when submitting messages. So a source that frequently submits messages with many bad (invalid) addresses in the local domain may be regarded with suspicion. One possible use of MeterMaid with `LOG_ACTION` is to throttle submissions from senders who cause many "J" records (rejections of attempted submissions).

So with `deferralrejectlimit 4` set on the `tcp_local` channel, and with MTA options settings that include:

```
LOG_CONNECTION=515
LOG_DIAGNOSTICS=3
```

or in Unified Configuration

```
msconfig> show log_*
role.mta.log_connection = 515
role.mta.log_diagnostics = 3
...and likely additional log_* MTA options settings...
```

and `configutil` MeterMaid table settings that, in addition to basic configuration not shown here, includes configuration of a MeterMaid "J-by-IP" table and a "J-jail" table:

```
metermaid.table.J-by-IP.data_type: ipv4
metermaid.table.J-by-IP.max_entries: 10000
metermaid.table.J-by-IP.quota: 4
metermaid.table.J-by-IP.quota_time: 600
metermaid.table.J-jail.data_type: ipv4
metermaid.table.J-jail.max_entries: 10000
metermaid.table.J-jail.quota: 1
metermaid.table.J-jail.quota_time: 3600
```

or in Unified Configuration:

```
metermaid.table.J-by-IP.data_type: ipv4
metermaid.table.J-by-IP.max_entries: 10000
metermaid.table.J-by-IP.quota: 4
metermaid.table.J-by-IP.quota_time: 600
metermaid.table.J-jail.data_type: ipv4
metermaid.table.J-jail.max_entries: 10000
metermaid.table.J-jail.quota: 1
metermaid.table.J-jail.quota_time: 3600
```

then a LOG_ACTION mapping table to track in MeterMaid "J" records, and a corresponding PORT_ACCESS mapping table that checks that MeterMaid data to decide whether or not to allow connections, could be:

```
PORT_ACCESS

 *|*|*|*|*  $C$|INTERNAL_IP;$3|$Y$E
 TCP|*|*|*|* \
$:A$C$[IMTA_LIB:check_metermaid.so,test,J-jail,$2,>0]$N$2-blocked2$E
 *  $YEXTERNAL

DONT_JAIL

 $<10.0.0.0/24> $N
 * $Y

LOG_ACTION

! To count only the "J" records that exceeded the chosen toleration
! level of 3, we look for the deferralrejectlimit error text:
!
tcp_local|*|J*|*|rfc822;|*|451$ 4.5.3$ Too$ many$ rejections;$ \
try$ again$ later.*|TCP|*|*|*|*|SMTP \
$C$|DONT_JAIL;$6|\
$[IMTA_LIB:check_metermaid.so,throttle,j-by-ip,$6]\
$[IMTA_LIB:check_metermaid.so,throttle,j-jail,$6]$E
```

The asterisk at the end of the diagnostic text is so that even a "final" "J" record for an SMTP session -- as when the TCP/IP-channel-specific option MAX_J_ENTRIES is exceeded, resulting in some additional, extra text -- will be counted.

68.1.3.3.8 Delay after bad username and password specified in SUBMIT

Given the following MTA option settings:

```
LOG_CONNECTION=515
LOG_USERNAME=3
LOG_DIAGNOSTICS=3
```

And mapping:

```
LOG_ACTION

  tcp_*|+|U|*|535*      $D300
```

A three second delay would follow any failed authentication attempt.

68.2 MTA counters

The MTA has facilities to collect and monitor channel counters based upon the Mail Monitoring MIB, RFC 2789 (which updates RFC 1566). Note that counters are intended for providing real-time "snap-shots" of MTA behavior, rather than for gathering the sort of statistics instead available from the MTA transaction log files. For a description of the MTA channel counters, see MTA channel counters.

New in 8.0, the MTA also maintains eight signed, 64 bit counters intended for updating from within Sieve scripts, for site-customizable use; see the Sieve adjustcounter extension.

The MTA provides utilities to display the counters directly; see the `imsimta counters` and `imsimta qm` utilities.

68.2.1 MTA channel counters

The MTA has facilities to collect and monitor channel counters based upon the Mail Monitoring MIB, RFC 2789 (which updates RFC 1566). These counters tabulate on a per channel basis the twelve items described in Table of channel counters from MADMAN MIB.

The MTA also supports some additional channel, association, and arbitrary counters; see this more extensive list at Table of MTA counters.

Table 68.5 Channel counters from MADMAN MIB

Field name	Description
RECEIVED_MESSAGES	The number of messages enqueued to the channel
SUBMITTED_MESSAGES	The number of messages enqueued by the channel
STORED_MESSAGES	The total number of messages currently stored for the channel
DELIVERED_MESSAGES	The number of messages dequeued by the channel
RECEIVED_VOLUME	The volume of messages enqueued to the channel as measured in MTA blocks
SUBMITTED_VOLUME	The volume of messages enqueued by the channel as measured in MTA blocks
STORED_VOLUME	The volume of messages currently stored for the channel as measured in MTA blocks
DELIVERED_VOLUME	The volume of messages dequeued by the channel as measured in MTA blocks
RECEIVED_RECIPIENTS	The total number of recipients specified in all messages enqueued to the channel
SUBMITTED_RECIPIENTS	The total number of recipients specified in all messages enqueued by the channel
STORED_RECIPIENTS	The total number of recipients specified in all messages currently stored for the channel

DELIVERED_RECIPIENTS	The total number of recipients specified in all messages dequeued by the channel

An MTA block is, by default, 1024 bytes. However, this size may vary from system to system. The size of an MTA block is controlled with the `block_size` MTA option.

Table 68.6 MTA counters

Accessible via PMDF API	
Field name	Description
received_messages	The number of messages enqueued to the channel
stored_messages	The total number of messages currently stored for the channel
delivered_messages	The number of messages dequeued by the channel
submitted_messages	The number of messages enqueued by the channel
attempted_messages	The number of temporary errors encountered during attempted message dequeues by the channel
rejected_messages	The number of attempted messages enqueues rejected by the channel
failed_messages	The number of permanent errors (hard delivery failures) encountered during attempted messages dequeues by the channel
received_volume	The volume of messages enqueued to the channel as measured in MTA blocks
stored_volume	The volume of messages currently stored for the channel as measured in MTA blocks
delivered_volume	The volume of messages dequeued by the channel as measured in MTA blocks
submitted_volume	The volume of messages enqueued by the channel as measured in MTA blocks
attempted_volume	The volume of messages that encountered temporary errors during attempted message dequeues by the channel as measured in MTA blocks
rejected_volume	The volume of the messages for message enqueues rejected by the channel as measured in MTA blocks
failed_volume	The number of permanent errors (hard delivery failures) encountered during attempted messages dequeues by the channel as measured in MTA blocks
received_recipients	The total number of recipients specified in all messages enqueued to the channel
stored_recipients	The total number of recipients specified in all messages currently stored for the channel
delivered_recipients	The total number of recipients specified in all messages dequeued by the channel
submitted_recipients	The total number of recipients specified in all messages enqueued by the channel
attempted_recipients	The total number of recipients encountering temporary errors during attempted message dequeues by the channel

rejected_recipients	The total number of recipients rejected by the channel
failed_recipients	The total number of recipients encountering permanent errors (hard delivery failures) during attempted messages dequeues by the channel
delivered_first_messages	The total number of messages enqueued to the channel which were either successfully delivered, or returned as undeliverable, upon their first processing attempt
delivered_first_queue_count	Cumulative count of first message delivery attempts made by the channel. When this value is less then received_messages, it means that delivery has not yet been attempted for all received messages. This is not unusual: this value is expected to lag behind received_messages.
delivered_first_queue_time	Cumulative count of elapsed seconds between when a message is enqueued and when processing of its first delivery attempt completes. The result of dividing delivered_first_queue_time by delivered_first_queue_count gives the average amount of time in seconds spent by a message in the processing queues as it awaits its initial delivery attempt.
delivered_queue_count	Cumulative count of message delivery attempts made by the channel
delivered_queue_time	Cumulative count of elapsed seconds between when a message is enqueued and when it is finally removed from the channel queue. The result of dividing delivered_queue_time by delivered_queue_count gives the average amount of time in seconds spent by a message in the processing queues.

Sieve counter [5]	
Sieve counter [6]	
Sieve counter [7]	

Sieve counter [8]	
Additional message counters	
Field name	Description
DeliveredVolumeBins	
DeliveredFirstQueueCountBins	
DeliveredFirstQueueTimeBins	
DeliveredQueueCountBins	
DeliveredQueueTimeBins	
LastInbound	Most recent "E" or "J" record for this (source) channel
LastOutbound	Most recent "D", "Q", "Z", or "R" record for this (destination) channel; (Bug # 6774400 is that "K" records don't update this counter)
ConvSuccessed	For the conversion channel, identical to DeliveredMessages; 0 for all other channels
ConvFailed	For the conversion channel, identical to FailedMessages; 0 for all other channels
HeldCount	Obtained by periodically scanning the queue directories and counting `.HELD` files. Whether this scan is performed is controlled by the `directoryscan` SNMP option (in legacy configuration, the `local.snmp.directoryscanconfigutil` parameter) which defaults to 1---TRUE.
OldestAge	
OldestMsgid	

- 1. An MTA block is, by default, 1024 bytes. However, this size may vary from system to system. The size of an MTA block is controlled with the `block_size` MTA option.

- 2. rejected_volume does not generally capture the entire volume of the messages rejected by the channel. Depending upon when, during attempted message submission, the rejection occurs, little to none of the message content and size may have been transferred (or made known) to the channel.

It is important to note that these counters generally need to be looked at over time noting the minimum values seen. The minimums may actually be negative for some channels. Such a negative value merely means that there were messages queued for a channel at the time that its counters were zeroed (*e.g.*, the cluster-wide database of counters created). When those messages were dequeued, the associated counters for the channel were decremented therefore leading to a negative minimum. For such a counter, the correct "absolute" value is the current value less the minimum value that counter has ever held since being initialized.

68.2.2 Purpose and design of MTA counters

MTA channel counters are intended for indicating the *health and performance trends* of your e-mail system. MTA channel counters are *neither designed nor intended* to provide an accurate accounting of message traffic; for precise accounting, instead see MTA transaction logging. The lack of accuracy in the MTA's channel counters in an inherent aspect of their design; it is not a bug. Specifically, the MTA's channel counters adhere to what Marshall Rose calls the fundamental axiom of management, which is that management must itself not interfere

with proper system and network operation by consuming anything but the tiniest amount of resource.

Therefore the MTA's channel counters are implemented using the lightest weight mechanisms available, namely a shared memory section on each system. Channel counters do not *try harder*: if an attempt to map the section fails, no information is recorded; if one of the locks in the section cannot be obtained almost immediately, no information is recorded; when a system is shut down, the information contained in the in-memory section is lost forever. MTA counters implementation provides further discussion of the implementation of counters.

68.2.3 MTA counters implementation

For performance reasons, each MTA host keeps a cache of MTA channel counters in memory using a shared memory section (on UNIX). As processes on the host enqueue and dequeue messages, they update the counters in this in-memory cache. If the in-memory section does not exist when a channel runs, the section will be created automatically. (The `imsimta startup` command also creates the in-memory section, if it does not exist.)

The command `imsimta counters -show` or the `imsimta qm` command `counters show` may be used to show the values of the counters.

The command `imsimta counters -clear` or the `imsimta qm` command `counters clear` may be used to reset the counters to zero.

In addition to the above commands for directly displaying the MTA's counters, on some platforms an SNMP subagent may be available to serve the MTA counters out through SNMP to any standards-based SNMP monitoring station.

68.2.4 SNMP subagents

On some platforms, SNMP subagents are available to serve out the MTA channel counters using the Mail and Directory Management (MADMAN) SNMP MIB described in RFC 2788 and RFC 2789 (originally RFC 1565 and RFC 1566). (See MIB variables served for a more detailed list of the exact MIB variables served, with OIDs and syntaces.) Presently, SNMP subagents are available for use with Net-SNMP used on Solaris platforms running Solaris 10, as well as Linux platforms.

Several options affect operation of these subagents; see SNMP options.

68.2.4.1 MIB variables served

The SNMP subagents serve out selected variables from the MADMAN MIBs (see RFC 2788 and RFC 2789, updating RFC 1565 and 1566), specifically, those variables from the applicationTable, mtaTable, and mtaGroupTable tables as shown in Table of supported MIB variables.

Table 68.7 Supported MIB variables

applicationTable variables			
Variable name	OID	Syntax	Value
applName	mib-2.27.1.1.2	SnmpAdminString	*instance-nameservice-name* on *host-name*
applVersion	mib-2.27.1.1.4	SnmpAdminString	*major-version*. *minor-version***or***major-version*. *minor-version* Patch *patch-version*
applDirectoryName	mib-2.27.1.1.3	SnmpAdminString	NULL

applUpTime	mib-2.27.1.1.5	TimeStamp	If the Job Controller is running, then the time (in hundredths of seconds) since the Job Controller was started up (or restarted); otherwise, 0
applOperStatus	mib-2.27.1.1.6	Integer	1 (up) **or** 2 (down)
applLastChange	mib-2.27.1.1.7	TimeStamp	Time (in hundredths of seconds) since the Job Controller's pidfile was modified
applInboundAssociations	mib-2.27.1.1.8	Gauge32	Sum over all mtaGroups (channels) of the mtaGroupInboundAssociations
applOutboundAssociations	mib-2.27.1.1.9	Gauge32	Sum over all mtaGroups (channels) of the mtaGroupOutboundAssociations
applAccumulatedInboundAssociations	mib-2.27.1.1.10	Counter32	Sum over all mtaGroups (channels) of the mtaGroupAccumulatedInboundAssociations
applAccumulatedOutboundAssociations	mib-2.27.1.1.11	Counter32	Sum over all mtaGroups (channels) of the mtaGroupAccumulatedOutboundAssociations
applLastInboundActivity	mib-2.27.1.1.12	TimeStamp	Most recent of the mtaGroupLastInboundActivity values
applLastOutboundActivity	mib-2.27.1.1.13	TimeStamp	Most recent of the mtaGroupLastInboundActivity values
applRejectedInboundAssociations	mib-2.27.1.1.14	Counter32	Sum over all mtaGroups (channels) of the mtaGroupRejectedInboundAssociations
applFailedOutboundAssociations	mib-2.27.1.1.15	Counter32	Sum over all mtaGroups (channels) of the mtaGroupFailedOutboundAssociations
applDescription	mib-2.27.1.1.16	SnmpAdminString	*ims-nameapplVersion-value*
applURL	mib-2.27.1.1.17	URLString	NULL
mtaTable variables			
Variable name	OID	Syntax	Derived from MTA counter
mtaReceivedMessages	mib-2.28.1.1.1	Counter32	received_messages
mtaStoredMessages	mib-2.28.1.1.2	Gauge32	stored_messages

mtaGroupOutboundConnectFailureReason	mib-2.2.28.1.22	SnmpAdminString	NULL
mtaGroupScheduledRetry	mib-2.2.28.1.23	TimeInterval	0
mtaGroupMailProtocol	mib-2.2.28.1.24	OID	*smtp-oid*, *i.e.*, 9.1.3.6.1.2.1.27.4.25
mtaGroupSuccessfulConvertedMessages	mib-2.28.2.1.26	Counter32	delivered_messages for a `conversion*` channel; 0 for all other channels
mtaGroupFailedConvertedMessages	mib-2.28.2.1.27	Counter32	failed_messages for a `conversion*` channel; 0 for all other channels
mtaGroupDescription	mib-2.28.2.1.28	SnmpAdminString	*instance-name* MTA *channel-name* channel
mtaGroupURL	mib-2.28.2.1.29	URLString	NULL
mtaGroupCreationTime	mib-2.28.2.1.30	TimeInterval	0x7FFFFFFF
mtaGroupHierarchy	mib-2.28.2.1.31	Integer	0
mtaGroupOldestMessageId	mib-2.28.2.1.32	SnmpAdminString	oldest_msgid: Message-id of the oldest, non-.HELD message present in the channel queue; the Job Controller updates the oldest_msgid MTA counter
mtaGroupLoopsDetected	mib-2.28.2.1.33	Counter32	Corresponds to the MTA's private HeldCount counter (which is a cached count of `.HELD` files seen during a periodic scan of the channel queue directory)
mtaGroupLastOutboundAssociationAttempt	mib-2.2.28.1.34	TimeInterval	mtaGroupLastOutboundActivity value

Note: the OID for mib-2 is 1.3.6.1.2.1.

Each MTA channel is identified with with an MTA group. Thus, for each channel, there will be a row in the mtaGroupTable. For example, if there are *M* channels, the OID mib-2.28.2.1.25.*n* gives the name of the channel associated with the *n*th row in the table where *n* satisfies 1<=n<=M .

Only one application and MTA is recognized by the subagent and consequently there is only one row in the applicationTable and mtaTable tables. The only valid instance identifier for those two tables is thus ".1"; *i.e.,* for either table, the OID for an instance of a variable is formed by taking the OID of the variable and appending ".1" to it. For example, a `get` operation on mib-2.27.1.1.4.1 would return the version number of MTA.

Each row of the mtaGroupTable table corresponds to a set of MTA channel counters maintained by the MTA. A description of each mtaGroupTable variable is given in Table of mtaGroupTable variable descriptions. These counters may be directly manipulated `imsimta counters` utility or the `imsimta qm` utility's `counters` command. Refer to the discussion of MTA channel counters for further information on the MTA channel counters.

Table 68.8 mtaGroupTable variable descriptions

mtaGroupTable variable	MTA counter	Description
mtaGroupReceivedMessages	RECEIVED_MESSAGES	Count of messages enqueued to the channel.
mtaGroupStoredMessages	STORED_MESSAGES	Count of messages enqueued to the channel but not yet delivered.
mtaGroupTransmittedMessages	DELIVERED_MESSAGES	Count of messages delivered (dequeued) by the channel.
mtaGroupReceivedVolume	RECEIVED_VOLUME	Volume of messages enqueued to the channel as measured in Kbytes = 1024 bytes.
mtaGroupStoredVolume	STORED_VOLUME	Volume of messages enqueued to the channel but not yet delivered as measured in Kbytes.
mtaGroupTransmittedVolume	DELIVERED_VOLUME	Volume of messages which have been delivered (dequeued) by the channel as measured in Kbytes.
mtaGroupReceivedRecipients	RECEIVED_RECIPIENTS	Volume of messages enqueued to the channel as measured by the total number of envelope recipient addresses.
mtaGroupStoredRecipients	STORED_RECIPIENTS	Volume of messages enqueued to the channel but not yet delivered as measured by the total number of envelope recipient addresses.
mtaGroupTransmittedRecipients	DELIVERED_RECIPIENTS	Volume of messages which have been delivered (dequeued) by the channel as measured by the total number of envelope recipient addresses.
mtaGroupName		Name of the channel.

The values in the mtaTable correspond to the column sums of the mtaGroupTable; *e.g.,* mtaReceivedMessages is the sum over all rows of the mtaGroupTable column mtaGroupReceivedMessages.

Note: The underlying MTA channel counters may take on negative values. However, the corresponding MIB variables must be non-negative. To reconcile this difference, the subagent tracks the minimum value seen for each channel counter and then uses that minimum to adjust the MIB variable such that it has a minimum of zero. This is done by subtracting the minimum value from the counter when that minimum is less than zero. For this reason, the values of the counters displayed with the `imsimta counters` command may differ from those displayed from an SNMP client.

Note: The MIB volume variables measure in units of kilobytes, whereas MTA counters measure message volume in units of MTA blocks. While the default MTA block size (`block_size` MTA option) is 1024 bytes = 1 kilobyte and thus identical to the units for the MIB volume variables, if the MTA block size has been set to some other value, then the MTA counters for volumes will be in different units than the kilobytes of MIB volume variables. The subagent will adjust the MTA counters volume values, if needed, to obtain kilobyte values for the MIB volume variables.

Chapter 69 MTA performance tuning

There are a variety of things which may be done to improve the MTA's performance. However, before trying to tune the MTA you should first feel comfortable with the MTA: have a basic understanding of how it works, be familiar with your configuration, and be able to recognize when the MTA isn't working on your system. In addition, it is important that you spend some time identifying what the bottlenecks are on your system: CPU resources, disk speed, memory, network speed or latencies, etc. Without a clear idea of where the bottlenecks are, any tuning you do is likely to be ineffective.

69.1 MTA performance: CPU and resources

Not necessarily in order of importance, here are some points to consider:

- In versions past, it was important to use a compiled configuration, to reduce the startup time of MTA processing jobs. As of 7.0.5 and Unified Configuration, this is no longer important.

- If your system has the memory to spare, increasing the size of message that processing jobs can buffer internally can reduce use of temporary buffer files on disk when receiving or processing large messages. See the discussion of the `max_internal_blocks` MTA option. On an LMTP back end system, see instead the `BUFFER_SIZE` TCP/IP-channel-specific option.

- Ensure that you have sufficient swap space for the needs of your configuration.

- Consider Job Controller pools for specific channels which you wish to ensure always have processing slots. The usual initial configuration establishes a basic set of pools suitable for the typical use of the channels in the initial configuration, but if you have added special purpose channels to your configuration, or if your site's message traffic has special characteristics or you have special needs, then you may benefit from adding new pool definitions and/or assigning particular channels to different pools. For instance, if you have a dedicated, heavy-use TCP/IP channel for sending to some sister site, then you may wish to define a separate pool that will be dedicated for the use of that special channel. Then use the `pool` channel option to direct the special channel to run in that new pool.

- The Dispatcher controls the creation and use of multithreaded SMTP server processes. If, as is typical, incoming SMTP over TCP/IP messages are a major component of e-mail traffic at your site, monitor how many simultaneous incoming SMTP connections you tend to have, and the pacing at which such connections come in. Tuning of Dispatcher configuration options controlling the number of SMTP server processes, the number of connections each can handle, the threshold at which new server processes are created, etc., may be beneficial if your site's incoming SMTP over TCP/IP traffic is unusually high or low.

- In general, for outgoing SMTP over TCP/IP channels, adjustment of the number of messages handled per thread (`threaddepth` channel option), the maximum number of threads

per process (MAX_CLIENT_THREADS TCP/IP-channel-specific option), the maximum number of processes for the channel (`maxjobs` channel option, potentially also limited by the Job Controller's `job_limit` option value for the `pool` in which the channel runs), can potentially be beneficial, especially if your site's message traffic has out of the ordinary characteristics. For typical SMTP over TCP/IP channels, used to send to multiple different remote systems, the MTA's multithreaded TCP/IP channel's default behavior of sorting messages to different destinations into different threads and then handling all messages (up to the channel's `threaddepth` channel option's value) to a single host in a single thread is desirable for performance; indeed, in some cases increasing such a channel's `threaddepth` may be useful. However, for a `daemon` TCP/IP channel, one dedicated to sending to a specific system, if the receiving system supports multiple simultaneous connections it may be preferable to force the MTA to split the outgoing messages into separate threads at a lower threshold, by using a "small" `threaddepth` value, and then perhaps correspondingly adjusting to allow more threads and/or more processes using the `MAX_CLIENT_THREADS` TCP/IP-channel-specific option or the `maxjobs` channel option, respectively. And see also the discussion above regarding defining and using new pools for particular channels, to control the degree of resource sharing/resource competion among separate outgoing TCP/IP channels.

- Disabling the MTA's SMTP server creation and use of `*.data-failed` files by setting the TCP/IP-channel-specific option `REUSE_TIMED_OUT_TRANSFERS=0` can provide a noticable performance (throughput) increase---perhaps 30% for the SMTP server; the downside is that disabling their use means that the MTA will no longer detect and avoid certain cases of duplicate submissions of messages, so users may receive "duplicate" copies of messages that might have been avoided. (The main performance issue here is not usually the creation of the actual files, but rather the CPU used while deciding whether to make such a file; that is, the performance impact of such potential file use exists whether or not any `*.data-failed` file is in fact ever created.)

- Another channel heavily used at typical sites is the `ims-ms` channel for delivery to the Message Store. This, like the TCP/IP channels, is a multithreaded channel, and controls over its `threaddepth`, `DELIVER_THREADS`ims-ms-channel-specific option, `maxjobs`, and the `job_limit` for the `pool` in which it runs can potentially be relevant to performance, particularly if your site's needs are out of the ordinary.

- Use of LMTP back ends allows separation of MTA systems from back end Message Store systems, so that individual systems may be dedicated to one type of functionality or the other. Configuration of MTA LMTP client channels can benefit both from the sorts of considerations for `ims-ms` channels (regarding Message Store delivery) and from the sorts of considerations for TCP/IP channels (regarding the network connectivity). Consider using a separate Job Controller `pool` or `pools` for the LMTP client channel(s). When there are multiple back end LMTP systems, note that there are tradeoffs between using one channel to deliver to all back ends, *vs*. creating separate channels to deliver to each back end.

- In direct LDAP mode, the caching of LDAP lookups represents a tradeoff between efficiency ("large" caches), *vs*. memory usage (which should not be too great a burden on a reasonably sized system) and small latency in LDAP entry changes ("small" caches). See especially the `alias_entry_cache_size`, `alias_entry_cache_timeout`, `reverse_address_cache_size`, `reverse_address_cache_timeout`, and `ldap_domain_timeout` MTA options, and to a lesser degree the `domain_match_cache_size` and `domain_match_cache_timeout` MTA options, which all fall into the category of LDAP lookup caching. Sites using Sieve filters should also see `filter_cache_size` and `filter_cache_timeout`; sites making heavy use of custom LDAP callouts (from mapping tables or rewrite rules) should also see

`url_result_cache_size` and `url_result_cache_timeout`, also in that same category of LDAP lookup caching.

- When generating very large "mass mailings", see Performance submitting mass mail messages.

- Note that increased processing or filtering of messages, such as that resulting from processing the inner levels of messages (`inner`, `innertrim` channel options), "sniffing" of message bodies (`thurman` or `uma` channel options or `CHARSET-CONVERSION` keywords), use of character set conversion, use of the conversion channel, use of Sieve filters, use of callouts to third party virus or spam detection software such as Brightmail or Spamassassin, MIME message fragmentation or defragmentation (`maxblocks`, `defragment` channel options), use of TLS for encryption of SMTP messages (`*tls*` channel options), use of DNS reverse lookups for incoming SMTP messages (`ident*` channel options, `forwardcheck*` channel options, `mailfromdnsverify` channel option, or `dns_verify*` image callouts from an `*_ACCESS` mapping table), *etc.*, requires the MTA to do extra work hence of course has a performance impact. This is not to discourage use of such features---such features exist because they are useful, and desirable features for message processing---but do keep in mind the potential performance impact of increased message processing.

- In particular, especially for system-wide or channel Sieve filters, it may be worth paying some attention to ensure that such Sieves use reasonable test logic, and are not really excessively long (excessively many tests).

- Also, when using mapping tables, such as `*_ACCESS` mapping tables, it is worthwhile to set up the mapping tables in an efficient way, without excessive numbers of entries, and attempting to keep the pattern matching reasonably efficient. As a rough rule of thumb, consider that once a mapping table has reached about 50 entries (lines), it is worth considering whether the table could be restructured to make use of general database callouts to do some of the specific matching, rather than having all matching text explicitly present in the mapping table itself.

- When callouts to third party spam/virus filter packages such as Brightmail or Spamassassin are part of the configuration, it is important to size and tune those third party filter packages adequately: their important filtering functionality tends to be inherently "expensive".

69.2 MTA performance: Disks and files

One of the more common bottlenecks for the MTA itself is disk I/O -- especially if the MTA is using the same disks or disk controller as the Message Store, which does a *lot* of disk I/O! The MTA itself does a lot of disk I/O. Try to keep the disks with the MTA's message queues below 66% capacity so that the operating system can efficiently manage file create and delete cycles. Also, use disk striping or other aggregate disk spindle techniques that help both read and writes. Avoid disk shadowing if possible. Disk is cheap these days: spend money on multiple spindles and sufficient free space.

By using symbolic links under the MTA's queue and log directories, you can redirect where the MTA keeps its store-and-forward message queues and log files. The MTA's command, executable, and configuration directories can also be separated if absolutely necessary.

Note that MTA debugging, which can be enabled for various components, and at various levels, (see for instance, the `job_controller.debug` and `dispatcher.debug` options for the Dispatcher and Job Controller, respectively, and the `master_debug` and `slave_debug` channel options for channels) is in some cases potentially very verbose and voluminous.

MTA debugging is distinct from MTA transaction logging (which is, however, also written to the MTA log directory). Debugging is intended for short-term use to track down problems. Leaving debugging enabled unnecessarily for extended periods may make the MTA log directory "hotter" than desirable for the long term.

The location for MTA temporary files can also be moved. The `tmpdir` MTA option (formerly `imta_tmp` in the MTA Tailor file) controls the location of temporary unnamed files (such as those used to buffer incoming large SMTP messages or incoming large messages submitted by local users, and to buffer *all* incoming LMTP messages); it also controls the location of temporary named files (such as those used by the conversion channel). `mta.tmpdir` defaults to `/tmp/`; note than on Linux, it tends to be preferable to set it explicitly to `/dev/shm/`. Note that if explicitly defining `tmpdir` (and intending to support message submissions directly from command line utilities by users logged onto the MTA system itself) it is important to point it to a device on which any user may create files.

By default, the messages for a given channel are stored in a single, channel-specific directory under the MTA queue directory, *`DATAROOT`*`/queue/`. File system performance degrades rapidly for directories with more than a couple thousand files; this can present a problem for channels which see heavy message traffic --- especially when the network associated with that channel is down and messages begin to queue up. Use the `subdirs` channel option to indicate that a channel should uniformly spread its messages across several subdirectories. For Internet sites with heavy traffic loads, this should be done for their outgoing TCP/IP channel, usually `tcp_local`.

MTA options such as `osync` and `buffer_size` may affect file system I/O performance and hence impact MTA performance.

UNIX sites may consider whether for their use it is acceptable to set the MTA option `fsync=0`. Doing so improves performance, but at the cost that if a UNIX (or NT) system crashes at just the wrong moment, messages not yet synched to disk could be lost.

Sites running on Solaris, and especially on Solaris 10 (which has a high default `rlim_fd_max` value), if running a version of the MTA prior to MS 6.4, should take steps to check and ensure that a high system maximum file descriptor limit is not unduly burdening the Job Controller and the channel delivery jobs that it initiates; see System parameters on Solaris.

69.3 System parameters on Solaris

69.3.1 For the Dispatcher:

As of Solaris 11, the `siffp_fd_max` parameter in `/etc/system` is likely to need to be increased from its default of 50 (which may be much too small for the Dispatcher's needs in handing off file descriptors to its worker processes) to some much larger value -- perhaps 50,000.

The system's heap size (datasize) must be enough to accomodate the Dispatcher's thread stack usage. For each Dispatcher service compute `stacksize`*`max_conns`, and then add up the values computed for each service. The system's heap size needs to be at least twice this number.

To display the heap size (*i.e.*, default datasize as reported by `limit` or default data size as reported by `ulimit`), use the csh command

```
# limit
```

or the ksh command (see the data result)

```
# ulimit -a
```

or the utility

```
# sysdef
```

69.3.2 For the Job Controller:

As of MS 6.4, the Job Controller will set its file descriptor limit to the lesser of 1024 or `rlim_fd_max`. Previously, the `rlim_fd_max` value would be used---which on systems with a high such value (in particular, on Solaris 10 where the default is 65535), would mean that the Job Controller -- and jobs it forks---could potentially spend significant time closing a great many unused file descriptors.

If running a version of the MTA prior to MS 6.4, and if the system has a high `rlim_fd_max` configured, it will benefit performance to modify the script that starts the Job Controller to issue an `rlimit` command setting a smaller file descriptor hard limit (for instance, 1024) before starting the Job Controller.

Chapter 70 Restricting information emitted

Some sites will have special, heightened concerns regarding emitting information about their internal user names, host names, *etc.*. There are various ways that information may "leak out"; some ways of controlling such information leakage are discussed here.

70.1 SMTP probe commands

During an SMTP connection, a remote sending side (or a person manually telnetting to your SMTP port) can issue commands requesting information such as a check on the validity of addresses. This very useful information can, however, be subject to abuse, *e.g.*, by automated search engines checking for valid email addresses on your firewall system. Therefore some sites may have an interest in disabling these helpful features.

Setting the option DISABLE_EXPAND=1 for your Internet TCP/IP channel (typically `tcp_local`) disables the SMTP EXPN command. The SMTP EXPN command is normally used to expand (get the membership of) mailing lists. Note that the alias options `alias_expandable` and `alias_nonexpandable` (in legacy configuration, mailing list named parameters [EXPANDABLE] and [NONEXPANDABLE]) can be used on a per-mailing-list basis to control the SMTP EXPN response for that mailing list. Note also that use of mailing list access controls, *e.g.*, LDAP list attributes such as `mgrpAllowedBroadcaster` and `mgrpDisallowedBroadcaster` (or more precisely, those attributes named by the `ldap_auth_url` and `ldap_cant_url` MTA options), or alias options`alias_auth_list`, `alias_auth_mapping`, *etc.*, (corresponding in legacy configuration to named parameters such as [AUTH_LIST], [AUTH_MAPPING], *etc.*), also affect the SMTP EXPN response for the mailing list so marked: only if an SMTP client has passed the access controls (for instance by issuing a MAIL FROM: command identifying as a sender allowed to post to the list) will the MTA's SMTP server then return an informative response to the client's SMTP EXPN command. So DISABLE_EXPAND=1 is suitable if you wish to disable *all* EXPN responses. However, if you only have some "sensitive" lists you can instead effectively get per-list controls on EXPN use.

Setting HIDE_VERIFY=1 for your Internet TCP/IP channel causes the MTA to return a "generic" response to the SMTP VRFY command. The SMTP VRFY command is normally used to check whether an address is a legitimate address on the local system. (Note that as it is required that SMTP servers support the VRFY command, the MTA has to return some sort of response; with HIDE_VERIFY=1, this response is simply a "maybe" sort of response rather than an explicit yes or no.) See also `domainvrfy` and related channel options for a discussion of channel options that can also be used to affect SMTP VRFY responses.

Setting DISABLE_ADDRESS=1 for your Internet TCP/IP channel causes the MTA to disable responses to its SMTP server's private XADR command, which normally returns information about the channel an address matches.

Setting DISABLE_CIRCUIT=1 for your Internet TCP/IP channel causes the MTA to disable responses to the its SMTP server's private XCIR command, which normally returns information about the MTA message circuit checking facility.

Setting DISABLE_STATUS=1 for your Internet TCP/IP channel causes the MTA to disable responses to its SMTP server's private XSTA command, which normally returns information about the numbers of messages in MTA queues.

Setting DISABLE_GENERAL=1 for your Internet TCP/IP channel option file causes the MTA to disable responses to its SMTP server's private XGEN command, which normally returns status information about whether an MTA compiled configuration and character set are in use.

Sample `msconfig` commands to disable such probes on a typical `tcp_local` channel would be:

```
msconfig> set channel:tcp_local.options.DISABLE_EXPAND 1
msconfig# set channel:tcp_local.options.HIDE_VERIFY 1
msconfig# set channel:tcp_local.options.DISABLE_ADDRESS 1
msconfig# set channel:tcp_local.options.DISABLE_CIRCUIT 1
msconfig# set channel:tcp_local.options.DISABLE_STATUS 1
msconfig# set channel:tcp_local.options.DISABLE_GENERAL 1
```

For legacy configuration, a sample TCP/IP channel option file to disable probing via the SMTP server, for a site using a `tcp_local` channel, would be as shown below:

```
DISABLE_EXPAND=1
HIDE_VERIFY=1
DISABLE_ADDRESS=1
DISABLE_CIRCUIT=1
DISABLE_STATUS=1
DISABLE_GENERAL=1
```

See TCPIP-channel-specific options for more details on these options.

70.2 Internal host names in Received: and Message-Id: header lines

Received: headers are normally exceptionally useful headers for displaying the routing that a message really took. Their worth can be particularly apparent in cases of dealing with apparently forged email, or in cases where one is trying to track down what happened to a broken messages, or in cases where a message does not appear to be repliable and one is trying to figure out who might know how to respond to the message. Received: headers are also used by the Messaging Server MTA (and other mailers) to try to detect message loops.

Message-id: headers are normally useful for message tracking and correlation.

However, on the converse side, Received: headers on messages you send out give the message recipient information about the routing that a message really took through your internal systems and tend to include internal system names and possibly an envelope recipient address. And Message-id: headers tend to include internal system names. At some sites, this may be considered a security exposure.

If your site is concerned about this information being emitted, first see if you can configure your internal systems to control what information they put in these headers. For instance, the MTA options `received_domain` and `id_domain` can be used on a Messaging Server system to specify the domain name to use when constructing Received: headers and Message-

id: headers, respectively. Although these options are not usually particularly relevant on an edge MTA system -- an edge system is by definition a system whose name is intended to be visible to the outside world --- if you have the MTA on internal systems also, the options may be of interest on those internal MTA systems. In a similar spirit, the channel keyword `noreceivedfor` can be used on channels on an MTA system to instruct the MTA not to include the envelope recipient address in the Received: header it constructs, if limiting the exposure of internal "routing" addresses is a concern for your site. And for those rare cases where the inclusion of original envelope From information in Received: headers constructed is of concern, the channel keyword `noreceivedfrom` can be used on channels on an MTA system to instruct the MTA not to include envelope From information in Received: headers it constructs in those cases (involving changing the envelope From, such as certain sorts of mailing list expansions) where the MTA would normally include the envelope From: address. New in MS 7.0.5.37, the `forcedreceivedfrom` channel option

Note that for messages that web clients submit through the MSHTTPD server to the MTA, the MSHTTPD server will (as of iMS 5.2p2) use any original client source IP present in an X-Forwarded-for: or Client-ip: or (as of MS 6.3) Proxy-ip: HTTP header to construct a "(Forwarded-for: *source-ip*)" comment clause in the Received: header line it (MSHTTP) submits to the MTA.

If necessary, address reversal on an MTA system can be used to "canonicalize" message id's, to remove undesired information, (though note that this removal of information may mean that the resulting message id's are no longer particularly useful). Note that the `use_reverse_database` MTA option must have bit 6 (value 64) set in order for address reversal to apply to message id's; for instance, if the option was previously set to the default value of 5, it must be set to 69 to apply to message id's. For instance, a site domain.com that wishes to ensure that no *host*.domain.com domains appear in message id's might use a `REVERSE` mapping such as:

```
REVERSE

  *@*.domain.com       $C$:I$0@domain.com$Y$E
```

This `REVERSE` mapping only applies to message id's, due to the `$:I` flag.

As regards Received: headers, only if you cannot configure your internal systems to control such sorts of information should you consider resorting to stripping such headers off entirely. Received: headers should not be removed lightly, due to their many and important uses, but if the internal routing and system name information in them is sensitive for your site and if you cannot configure your internal sytems to control what information appears in these headers, then you may wish to strip off those headers on messages going out to the Internet via header trimming on your outgoing TCP/IP channel.

Note: Do **not** remove Received: headers or remove or simplify Message-id: headers on general principles or because your users do not like them! Removing such headers, among other things, (1) removes one of the best tracking mechanisms you have, (2) removes information that may be critical in tracking down and solving problems, (3) removes one of the few (and best) warnings of forged mail you may have, and (4) blocks the mail system's ability to detect and short-circuit message loops. Only remove such headers if you *know* your site *needs* them removed.

To implement header trimming, put the `headertrim` channel option --- you will probably want the `innertrim` channel option as well --- on your outgoing external TCP/IP channel or

channels, generally tcp_local and possibly other tcp_* channels (possibly every tcp_* channel except your internal channel, tcp_internal), and create a header trimming file for each such channel. The headertrim keyword causes header trimming to be applied to the outer message headers; the innertrim keyword causes the header trimming to be applied also to embedded message parts (message/rfc822 parts) within the message. A sample header trimming file for a site using a tcp_local channel is shown below:

```
Received: MAXIMUM=-1
MR-Received: MAXIMUM=-1
X400-Received: MAXIMUM=-1
```

See the headertrim channel option for more details on header trimming.

As of MS 6.3, the Sieve "deleteheader" and "replaceheader" actions provide another approach -- very powerful, so use with caution! -- to modifying header lines to limit emission of internal host names.

70.3 Extra concerns for address canonicalization

Proper address canonicalization (converting any "internal" address forms to canonicalized, appropriate-for-external-use, forms) is, nowadays, typically part of proper domain provisioning in LDAP, in particular proper use of LDAP domain attributes such as (in Schema 1) aliasedObjectName and inetCanonicalDomainName and aliasedObjectName (or more precisely, those LDAP domain attributes named by the ldap_domain_attr_canonical and ldap_domain_attr_alias MTA options) or (in Schema 2) sunPreferredDomain and associatedDomain (or more precisely, those LDAP domain attributes named by the ldap_attr_domain1_schema2 and ldap_attr_domain2_schema2 MTA options) and proper user provisioning in LDAP, in particular proper use of mail, mailAlternateAddress, and maiLEquivalentAddress LDAP attributes (or more precisely, those LDAP user attributes named by the ldap_primary_address, ldap_alias_addresses, and ldap_equivalence_addresses MTA options). However, there are a few additional configuration items that may be of interest.

1. Put the inner keyword on (at least) your channels outgoing to the external world so that address rewriting will be applied to address in embedded message parts (message/rfc822 parts).

2. If you do not wish notification messages generated by MTA systems the internal address, then you may wish to use the suppressfinal channel option.

Chapter 71 MTA command line utilities

The MTA contains a modest collection of management utility programs, which are used to perform various maintenance, testing, and management tasks.

These utilities are generally invoked via `imsimta` commands, *e.g.*,

```
# imsimta version
```

Generally, use of these utilities requires superuser privileges, or being logged in as the MTA user (see the `user` option in the `restricted.cnf` file).

71.1 cache -change utility

Change Job Controller option effective values for the currently running Job Controller process.

71.1.1 Syntax

```
imsimta cache -change
```

Table 71.1 imsimta cache -change Command Switches

Switch	Default
`-global`	
`-debug=`*n*	
`-max_messages=`*n*	
`-template=`*name*	
`-master_job=`*command*	
`-slave_job=`*command*	
`-channel=`*name*	
`-thread_depth=`*n*	
`-job_limit=`*n*	
`-parallel_rebuild=`*n*	`-parallel_rebuild=12`
`-inorder_rebuild`	`-noinorder_rebuild`

71.1.2 Parameters

None.

71.1.3 Description

(New in MS 6.2.) The `imsimta cache -change` utility is used to change various Job Controller option effective values "on the fly" (that is, without requiring a restart of the Job Controller in order to take effect) for the currently running Job Controller process.

Exactly one of `-channel`, `-template`, or `-global` must be specified. `-channel` is for changing the behavior or definition of a *particular* channel: changing its effective `maxjobs` (`-job_limit`) or `threaddepth` (`-thread_depth`), or its `master_command` (`-master_job`) or `slave_command` (`-slave_job`). `-template` is for adding a new type of channel, or for changing the definition of all channels of that type: (re)defining its `master_command` (`-master_job`) and/or `slave_command` (`-slave_job`). `-global` is for setting certain global Job Controller options: `debug`, `max_cache_messages` (`-max_messages`), or (6.2p2 and later?) `rebuild_parallel_channels` (`-parallel_rebuild`).

Note that restarting the Job Controller is very much to be avoided on a production MTA that has messages already in its queues. So for certain sorts of Job Controller configuration changes that one might want to make on a running MTA, especially configuration changes to trace down problems (debugging) or re-deploy resources at times of heavy load (change

channel maxjobs via -job_limit or channel threaddepth via -thread_depth, or define new channels which one has added to the configuration to deal with additional load), it is desirable to make such changes "on the fly". This utility exists to allow making those changes that are both desirable, and feasible without too much disruption to existing Job Controller data structures.

71.1.4 Switches

71.1.4.1 -channel=*name*

Change a configuration setting for an existing channel, or inform the Job Controller of the name of a new channel (of a valid, already defined type) that has been added to the configuration.

71.1.4.2 -debug=*n*

Set a debug level for Job Controller operation. -global must be specified in order to use -debug.

71.1.4.3 -global

Set certain global Job Controller options.

71.1.4.4 -inorder_rebuild, -noinorder_rebuild

-inorder_rebuild directs the Job Controller to rebuild the message list in order. The -global switch must be specified in order to use -inorder_rebuild. -noinorder_rebuild (the default) means to not rebuild the queues in order: to simply insert messages into the queue cache in whatever order they are encountered while scanning the queue area.

71.1.4.5 -job_limit=*n*

The -channel=name switch must be specified in order to use -job_limit; override the effective maxjobs/job_limit for the specified channel.

71.1.4.6 -max_messages=*n*

Override the effective max_cache_messages value, or any previously set -max_messages value. -global must be specified in order to use -max_messages.

71.1.4.7 -master_job=*command*

Specify the command to execute (channel program to run) for the master direction of a channel. This switch may be used either with the -channel switch, to set the value for a particular channel, or with the -template switch, to set the value for a class of channels.

71.1.4.8 -slave_job=*command*

Specify the command to execute (channel program to run) for the slave direction of a channel. This switch may be used either with the -channel switch, to set the value for a particular channel, or with the -template switch, to set the value for a class of channels.

71.1.4.9 -parallel_rebuild=*n*

Override the value of the rebuild_parallel_channels Job Controller option. -global must be specified in order to use -parallel_rebuild.

71.1.4.10 -template=*channel-pattern*

Define a new type of channel, or redefine an existing type of channel. If redefining an existing type, all channels derived from that template are affected. The argument to *-template* should be a channel pattern; *e.g.*, tcp_*.

71.1.4.11 -thread_depth=*n*

The -channel=*name* switch must be specified in order to use -thread_depth; override the effective threaddepth for the specified channel.

71.1.5 Examples

```
# imsimta cache -change -global -debug=7
```

The above (UNIX) command turns on Job Controller debugging, at level 7.:

```
# imsimta cache -change -channel=tcp_special
```

This command informs the Job Controller of a new tcp_special channel that has been added to the configuration (in Unified Configuration, added using msconfig via an edit channels command or via appropriate set channel:tcp_special.* commands; in legacy configuration, added to the imta.cnf file). That is, this imsimta cache -change command does not in and of itself *define* the channel -- definition of the channel must be performed as normal; however, this command informs the Job Controller of the new channel, so that the Job Controller will know to begin running the channel, as needed.

71.2 cache -sync utility

Update the Job Controller's in-memory cache of message files in the queues so as to reflect all messages currently present in the message queues.

71.2.1 Syntax

```
imsimta cache -synchronize
```

Table 71.2 imsimta cache -synchronize Command Switches

Switch	Default
`-debug=`*n*	`-nodebug`
`-recipient`	`-recipient`

71.2.2 Parameters

None.

71.2.3 Description

The `imsimta cache -synchronize` utility tells the MTA Job Controller to re-scan the queue disk area, *DATAROOT*`/queue/*` on UNIX, checking for any (non-`.HELD`) message files not already present in the Job Controller's in-memory queue cache of message files.

71.2.4 Switches

71.2.4.1 `-debug=`*n*, `-nodebug` (default)

The `-debug` switch may be cause debugging of the cache synchronization. The default is `-nodebug`. Specifying `-debug` is equivalent to `-debug=1`.

71.2.4.2 `-recipient` (default), `-norecipient`

`-recipient`, which is the default, causes the cache synchronization to actually open message files to obtain full message details; this is slower than the "basic" operation (which can be selected with `-norecipient`), but gets more detailed message information.

71.2.5 Examples

To synchronize the queue cache, for instance after renaming a message file, issue the UNIX command

```
# imsimta cache -synchronize
```

71.3 cache -view utility

View the current entries for a channel in the MTA queue cache database.

71.3.1 Syntax

```
imsimta cache -view [channel-name]
```

71.3.1.1 Restrictions

Must have superuser privileges or be logged in as the MTA user (see the `user` option in `restricted.cnf`) in order to use this utility.

71.3.2 Parameters

71.3.2.1 *channel-name*

Optional parameter specifying the name of the channel for which to show entries. If no channel name is specified, all entries in the queue cache database will be shown.

71.3.3 Description

The `imsimta cache -view` utility shows the current entries in the MTA queue cache database for a channel.

71.3.4 Examples

This example shows checking the queue cache database for entries for the `ims-ms` channel and finding one such entry:

```
# imsimta cache -view ims-ms
                channel : ims-ms
              file name : /opt/sun/comms/messaging64/data/queue/ims-ms/010/ZYi041V0jMRS0.00
            subdirectory : 10
            enqueue time : 21-Sep-2015:10:51:36.00
   last delivery attempt : 21-Sep-2015:10:52:15.00
     processing priority : 3
      destination system :  ims-ms
         recipient count : 1
            message size : 1 (kbyte)
                   owner :
         expiration date : 18-Jan-2038:19:14:07.00
                due date : No due date recorded
-----------------------------------------------------
```

71.4 cache -walk utility

Cause the Job Controller to write its current state (in particular, what message entries it has in its queue cache) to its log file.

71.4.1 Syntax

```
imsimta cache -walk
```

Table 71.3 imsimta cache -walk Command Switches

Switch	Default
`-debug=`*n*	`-nodebug`

71.4.2 Parameters

None.

71.4.3 Description

The `imsimta cache -walk` utility tells the Job Controller to write its current state (in particular, its current list of message entries in its queue cache) to its log file.

71.4.4 Switches

71.4.4.1 `-debug=`*n*, `-nodebug` (default)

The `-debug` switch may be used to cause the inclusion of additional debug output in state description that the Job Controller writes to its log file. The default is `-nodebug`.

71.4.5 Examples

This UNIX example shows telling the Job Controller to write its current state to its log file, with its debug level for this state dump set to 80:

```
# imsimta cache -walk -debug=80
```

71.5 calc utility

The calc utility provides an interface to the MTA's internal expression parser and evaluator. Additional function "sets" can be added by specifying appropriate switches, e.g., the -mm switch provides access to the Sieve function set.

71.5.1 Syntax

```
imsimta calc [expression]
```

Table 71.4 imsimta calc Command Switches

Switch	Default
-input=*filename*	*None*
-output=*filename*	*None*
-statement=*n*	-statement=1
-debug[=*n*]	-debug=4
-uav=*n*	-uav=1
-multiple	-multiple
-mm	*See text*
-message=*filename*	*None*
-symbols	-nosymbols
-from	-from=""
-required	-required
-to	*None*
-system	-nosystem
-mtpriority=*n*	-mtpriority=0
-source=*source-channel-name*	-source=l
-rsecret=*recall-secret*	

71.5.1.1 Restrictions

None.

71.5.1.2 Prompts

calc>*expression*

71.5.2 Parameters

71.5.2.1 *expression*

The expression to evaluate.

71.5.3 Description

The `calc` utility is a calculator, for performing integer and string operations. See Operators in Order of Precedence for a list of basic arithmetic and symbolic operators available, and Symbol table functions for a list of functions available.

Variables can be created, and values assigned to them, using the "=" assignment operator, *e.g.*,

```
calc> a = 3
```

Use Ctrl-D to exit.

In addition to its use for performing simple calculations, the `imsimta calc` utility may also be helpful for testing planned use of calculations in Sieve filters, or in expressions inside MTA mapping tables. Compared with the `imsimta test -expression` utility, the `calc` utility is simpler for testing the fundamentals of mathematical calculation or string manipulation, but does not test, for instance, Sieve filter-specific syntax.

71.5.4 Switches

71.5.4.1 `-debug=`*`n`*, `-nodebug` (default)

The `-debug` switch may be used to enable debug output. Specifying `-debug` is equivalent to specifying `-debug=4`.

71.5.4.2 `-from=`*`address`*, `-to=`*`address`*

(`-from` new in MS 6.2; `-to` new in MS 6.3.) The `-mm` and `-message` switches must be used in order to use `-from` or `-to`. With `-from`, specify the envelope From address (for instance, for purposes of Sieve filter evaluation). If not specified, the MTA's default postmaster return address is assumed. If `-message` is not specified, then `-from` has no effect. With `-to`, specify the envelope To address.

71.5.4.3 `-input=`*`filename`*, `-noinput` (default)

The `-input` switch may be used to specify a file from which to read the expressions to be evaluated.

71.5.4.4 `-message=`*`filename`*, `-nomessage` (default)

Initialize the MTA as if for message submission of the specified message. The `-mm` switch must be used in order to use `-message`. When `-message` is used, the `-from` switch and `-to` switch also become available.

71.5.4.5 `-mm`, `-nomm` (default)

If specified, loads the Sieve function set. This causes an MTA initialization call to be made. Use of any of the `-message`, `-required`, or `-system` switches requires that `-mm` also be specified. The `-mm` and `-sy` switches are mutually exclusive (they cannot be used with each other).

71.5.4.6 `-mtpriority=`*`n`*, `-nomtpriority`

(New in MS 8.0) `-mtpriority` takes a required integer argument specifying the initial MT-PRIORITY value. It may only be specified when `-mm` has also been specified.

71.5.4.7 `-multiple` (default), `-nomultiple`

The default, `-multiple`, allows evaluating multiple, comma-separated statements per physical line. Specifying `-nomultiple` disables this, so that only the first result (from the physical line) is returned.

71.5.4.8 `-output=`*`filename`*, `-nooutput` (default)

The `-output` switch may be used to specify a file to which to write the output of the calculator.

71.5.4.9 `-required` (default), `-norequired`

(New in MS 6.2.) The `-mm` switch must be used in order to use `-required`.

71.5.4.10 `-rsecret=`*`recall-secret`*

(New in MS 8.0) Specify the recall secret.

71.5.4.11 `-source=`*`source-channel-name`*

(New in MS 8.0) Specify the source channel; the default is `l` (the "L"ocal channel).

71.5.4.12 `-statement=`*`n`*

n is a bit-encoded integer. The default is `-statement=1`. But note that specifying `-mm` forces setting bit 9 (value 512), overriding whether or not `-statement` set that bit, to allow bracketed lists.

See the `test -expression` utility's description of Statement parsing flags for details on the meaning of the bits for this switch's value.

To test Sieve scripts using the `"loop"` construct or (new in MS 8.0) `"sub"` construct, note that `-statement=3` must be specified.

71.5.4.13 `-symbols`, `-nosymbols` (default)

The `-symbols` switch, if specified, enables references to environment variables. `-nosymbols` is the default.

71.5.4.14 `-system`, `-nosystem` (default)

(New in MS 7.0.5) The `-mm` switch must be used in order to use `-system`. If `-system` is specified with `-mm`, then the Sieve is treated as a system-level Sieve; if not, then it is treated as a user-level Sieve.

71.5.4.15 `-uav=`*`n`*

The `-uav` switch controls the interpretation of unassigned variables. The default is `-uav=1`.

Table 71.5 calc utility's -uav switch values

Value	Usage
0	Variables must be predefined; variable creation not allowed
1	Assignment defines variable; no default value
2	Define variable upon first reference; default value ""
3	Define variable upon first reference except in modify operations; default value 0
4	(New in MS 8.0/patch to MS 7.0u5) Same as value 1 (assignment defines variable; no default value), with the difference (appropriate for Sieve usage) don't create a symbol table at parse time

71.6 chbuild utility

Compile the MTA character set conversion tables, and `tlds.txt` file.

71.6.1 Syntax

```
imsimta chbuild
```

Table 71.6 imsimta chbuild Command Switches

Switch	Default
`-image_file=`*`file-spec`*	`-image_file=IMTA_CHARSET_DATA`
`-maximum`	`-nomaximum`
`-option_file=`*`file-spec`*	`-nooption_file`
`-remove`	*None*
`-sizes`	`-nosizes`
`-statistics`	`-nostatistics`

71.6.1.1 Restrictions

Must have superuser privileges, or be logged in as the MTA user (see the `user` option in `restricted.cnf`) in order to use this utility.

71.6.2 Parameters

None.

71.6.3 Description

The `imsimta chbuild` utility compiles the character set conversion tables and loads the resulting image file into shared memory. As of MS 7.0.5, `imsimta chbuild` is also the means for informing the MTA of an updated `tlds.txt` file---the new file used as of MS 7.0.5 to store the IANA list of Top Level Domains.

The MTA ships with very complete character set tables so prior to MS 7.0.5, it was not normally necessary to run this utility. However, as of MS 7.0.5, `imsimta chbuild` should be used whenever an updated `tlds.txt` file has been fetched from IANA. (Note that to get updates to `tlds.txt` to take effect, it is not necessary to also do `imsimta cnbuild` after the `imsimta chbuild`---but it *is* necessary that processes be new in order to see the newly compiled charset/TLD data. So if in a hurry for the changes to take effect, issue an `imsimta restart` command.)

Prior to MS 7.0.5, two MTA Tailor options were relevant for `imsimta chbuild`: `imta_charset_data` specified the default output image file, and `imta_charset_option_file` specified an option file adjusting charset internal table sizes. As of MS 7.0.5, these MTA Tailor options have been deleted, and hard-coded file paths are used instead, *config-root*`/advanced/charset_data` and *server-root*`/lib/option_charset.dat`, where *server-root* is the product install directory or the value of the `SERVERROOT` environment variable.

71.6.4 Switches

71.6.4.1 -image_file[=*file-spec*], -noimage_file

By default, imsimta chbuild creates as output the image file (formerly named by the imta_charset_data option of the MTA tailor file) *CONFIGROOT*/advanced/charset_data. With the -image_file switch, an alternate file name may be specified. When the -noimage_file switch is specified, imsimta chbuild does not produce an output image file; this switch is used in conjunction with the -option_file switch to produce as output an option file which specifies table sizes adequate to hold the tables required by the processed input files.

71.6.4.2 -maximum, -nomaximum (default)

When -maximum is specified, the file *SERVERROOT*/lib/maximum_charset.dat is read, in addition to the charset option file (prior to MS 7.0.5 located via the imta_charset_option_file MTA Tailor option) *CONFIGROOT*/advanced/option_charset.dat. This maximum_charset.dat file specifies near maximum table sizes but does not change any other charset option file (option_charset.dat) parameter settings. Only use the -maximum switch if the current table sizes are inadequate. The -noimage_file and -option_file switches should always be used in conjunction with this switch -- it makes no sense to actually output the enormous configuration that is produced by -maximum, but it does make sense to use -maximum to get past size restrictions in order to build an updated charset option file (option_charset.dat) containing proper size settings so that a properly sized character set image can be built with a subsequent imsimta chbuild invocation.

71.6.4.3 -option_file[=*file-spec*], -nooption_file (default)

imsimta chbuild can optionally produce a charset option file that contains correct table sizes to hold the character set conversion tables which were just compiled (plus a little room for growth). The -option_file switch causes this file to be output, whereas use of the -nooption_file switch means that no option file will be output. Note that imsimta chbuild always *reads* any pre-existing charset option file (first looking for *CONFIGROOT*/advanced/option_charset.dat, then *CONFIGROOT*/option_charset.dat, then finally *SERVERROOT*/lib/option_charset.dat -- or prior to MS 7.0.5, looking for the file named by the imta_charset_option_file MTA Tailor option) -- use of the -nooption_file switch does not affect reading the old charset option file -- however, specifying -option_file causes imsimta chbuild to also *output* an updated charset option file. By default, the output charset option file is updated to the same location where the utility found the input charset option file. The value on the -option_file switch may be used to specify an alternate file name.

While the MTA ships with an initial *SERVERROOT*/lib/option_charset.dat, it is recommended that any site-generated option_charset.dat file instead be written to *CONFIGROOT*/advanced (or at least to *CONFIGROOT*) so that MTA updates will not overwrite the site-generated option_charset.dat. Thus the first time a site wishes to generate their own, modified option_charset.dat, the administrator should start by copying the distributed, initial option_charset.dat from the *SERVERROOT*/lib directory to the *CONFIGROOT*/advanced directory.

The -maximum switch may be used in conjunction with -option_file to cause imsimta chbuild to read options from maximum_charset.dat in addition to the charset option

file (`option_charset.dat`). This `maximum_charset.dat` file specifies near maximum table sizes. Only use the `-maximum` switch if the current table sizes are quite inadequate, and only use it to create a new charset option file. The `-noimage_file` switch should always be specified when `-maximum` is specified since a maximum-size image would be truly enormous and extremely wasteful.

71.6.4.4 `-remove`

Remove any existant compiled character set conversion table; *i.e.*, remove the file (prior to MS 7.0.5 located via the `imta_charset_data` MTA Tailor option) *CONFIGROOT*`/advanced/charset_data`.

71.6.4.5 `-sizes`, `-nosizes` (default)

The `-sizes` switch instructs `imsimta chbuild` to output information on the sizes of the uncompiled character set tables.

71.6.4.6 `-statistics`, `-nostatistics` (default)

The `-statistics` switch instructs `imsimta chbuild` to output information on the compiled conversion tables. These numbers give a rough measurement of the efficiency of the compilation, and may indicate whether or not an additional rebuild with the `-option_file` switch is needed.

71.6.5 Examples

The standard command used on UNIX to compile character set conversion tables is:

```
# imsimta chbuild
```

Or if a drastically increased set of Top Level Domains (`tlds.txt` file) or drastically increased set of character sets calls for a big increase in the size of the compiled charset set tables, then:

```
# # If a site has never before generated their own option_charset.dat,
# #    first copy the distributed option_charset.dat to the site's config area
# cp SERVERROOT/lib/option_charset.dat CONFIGROOT/advanced/option_charset.dat
# # Now have the chbuild utility figure out what it needs to resize...
# imsimta chbuild -noimage -option_file -maximum
# # Finally, build new compiled charset tables...
# imsimta chbuild
```

71.7 clbuild utility

Compile an MTA command definition file and generate an image file (suitable for memory mapping by MTA processes).

71.7.1 Syntax

```
imsimta clbuild cld-file-spec
```

Table 71.7 imsimta clbuild Command Switches

Switch	Default
`-debug`	`-nodebug`
`-image_file=`*`file-spec`*	`-noimage_file`
`-maximum`	`-nomaximum`
`-option_file=`*`file-spec`*	`-nooption_file`
`-sizes`	`-nosizes`
`-statistics`	`-nostatistics`

71.7.1.1 Restrictions

Must have superuser privileges or be logged in as the MTA user (see the `user` option in `restricted.cnf`) in order to use this utility.

71.7.2 Parameters

71.7.2.1 *cld-file-spec*

The file specification of an MTA command definition file to read as input; *e.g.,* on UNIX `SERVERROOT/lib/pmdf.cld`.

71.7.3 Description

The `imsimta clbuild` utility compiles a command line definition file and generates a binary file (suitable for memory mapping by MTA processes).

The MTA ships with any pre-compiled command line definition files it needs so it is not normally necessary to run this utility.

71.7.4 Switches

71.7.4.1 -debug, -nodebug (default)

The `-debug` switch causes `imsimta clbuild` to output debug information regarding its operation.

71.7.4.2 -image_file=*file-spec*, -noimage_file (default)

By default, imsimta clbuild does not produce a compiled command definition image file. In order to produce a compiled command definition file, the file to produce must be specified using the -image_file switch.

71.7.4.3 -maximum, -nomaximum (default)

The file SERVERROOT/lib/maximum_command.dat is read when -maximum is specified. This file specifies near maximum table sizes but does not change any other command option file parameter settings. Only use this switch if the current table sizes are inadequate. The -noimage_file and -option_file switches should always be used in conjunction with this switch---it makes no sense to output the enormous command definition image that is produced by -maximum, but it does make sense to use -maximum to get past size restrictions in order to build a properly sized command option file so that a properly sized command definition image can be built with a subsequent imsimta clbuild invocation.

71.7.4.4 -option_file[=*file-spec*], -nooption_file (default)

imsimta clbuild can optionally produce a command option file that contains correct table sizes to hold the command definitions which were just compiled (plus a little room for growth). The -option_file switch causes this file to read as input and a new such option file created as output. If -option_file is specified with no value, then the file written will have the same name as the input command definition file, but with the file extension .cop; for instance, if the file SERVERROOT/lib/pmdf.cld was the input parameter, then the default name for the output command option file would be SERVERROOT/lib/pmdf.cop. If the -nooption_file switch is specified (the default), then no option file will be output. Note that use of the -maximum switch causes imsimta clbuild to read options from maximum_command.dat in addition to any command option file. This file specifies near maximum table sizes. Only use this switch if the current table sizes are inadequate, and only use it to create a new option file. The -noimage_file switch should always be specified when -maximum is specified since a maximum-size image would be truly enormous and extremely wasteful.

71.7.4.5 -remove

Remove an existant compiled command definition image.

71.7.4.6 -sizes, -nosizes (default)

The -sizes switch instructs imsimta clbuild to output information on the sizes of the uncompiled command definitions.

71.7.4.7 -statistics, -nostatistics (default)

The -statistics switch instructs imsimta clbuild to output information on the compiled command definition image. These numbers give a rough measurement of the efficiency of the compilation, and may indicate whether or not an additional rebuild with the -option_file switch is needed.

71.7.5 Examples

The standard command used to compile the basic MTA command definition file on UNIX is:

```
# imsimta clbuild -option -image=IMTA_TABLE:advanced/command_data IMTA_LIB:pmdf.cld
```

To remove the compiled version of the basic MTA command definitions, use

```
# imsimta clbuild -remove IMTA_TABLE:advanced/command_data
```

71.8 cnbuild utility

Legacy configuration: Compile the MTA configuration, alias, mapping, conversion, system wide filter, circuit check, and option files, and various `configutil` parameters, as well as (optionally) the reverse "database", general "database", and forward "database", and also (as of MS 7.0) the Job Controller configuration file, the Dispatcher configuration file, and TCP/IP channel option files; generate an image file (suitable for memory mapping by MTA processes).

Unified Configuration: Compile `confdesc.xml` as well as (optionally) the reverse "database", general "database", and forward "database"; generate an image file (suitable for memory mapping by MTA processes).

71.8.1 Syntax

```
imsimta cnbuild
```

Table 71.8 imsimta cnbuild Command Switches

Switch	Default
`-image_file=`*`file-spec`*	`-image_file=IMTA_TABLE:advanced/config_data`
`-maximum`	`-nomaximum`
`-option_file=`*`file-spec`*	`-option_file=IMTA_TABLE:option.dat`
`-remove`	`-noremove`
`-sizes`	`-nosizes`
`-statistics`	`-nostatistics`
`-check`	`-nocheck`
`-synonyms`	`-nosynonyms`
`-xml_config`	`-noxml_config`

71.8.1.1 Restrictions

Must have superuser privileges, or be logged in as the MTA user (see the `user` option in `restricted.cnf`) in order to use this utility.

71.8.2 Description

With a legacy configuration, the `cnbuild` utility compiles the textual configuration, option, mapping, conversion, system wide filter, circuit check, and alias files, and various `configutil` parameters (see Basic configuration settings relevant to alias LDAP lookups and Basic configuration settings relevant to domain LDAP lookups), and (depending upon the setting of the `use_text_databases` MTA option) also optionally the reverse "database", general "database", and forward "database", and (as of MS 7.0) also the Job Controller configuration file, Dispatcher configuration file, and TCP/IP channel option files (for SMTP channels or LMTP client channels), and generates an image file (suitable for memory mapping by MTA processes). With a Unified Configuration, most of these files have been consolidated: when using a Unified Configuration, the `cnbuild` utility compiles the `confdesc.xml` file, and (depending upon the setting of the `use_text_databases` MTA option) also optionally

the reverse "database", general "database", and forward "database", and generates an image file (suitable for memory mapping by MTA processes). The resulting image is the file formerly named by the `imta_config_data` option of the MTA tailor file; as of MS 7.0.5, such MTA tailor file options have been replaced by consistent locations, and the image file is simply `IMTA_TABLE:advanced/config_data`.

Whenever a component of the MTA (*e.g.*, a channel program) must read any possibly compiled configuration component, it first checks to see whether a compiled configuration image file exists, and if so, the running program uses that image. There are five exceptions to this rule. The first is `imsimta cnbuild` itself, which for obvious reasons always reads the text files and never tries to use an image form of the configuration data. The remaining four exceptions are `imsimta test -domain_map`, `imsimta test -rewrite`, `imsimta test -mapping`, and `imsimta test -x400` which can all be instructed with the `-image_file` switch to use a different compiled configuration file. This facility in `imsimta test -rewrite` is useful for testing changes prior to compiling them.

One reason for compiling configuration information is simple: performance. Precompiling the MTA configuration allows MTA processes to quickly load that precompiled configuration and then get immediately to work, rather than each new MTA process needing to read the MTA configuration and build the in-memory representation of the configuration itself, before starting its own work. Note that MTA design includes short-lived, transient processes (*e.g.*, most channel delivery job processes), as well as long-lived processes (*e.g.*, Dispatcher and Job Controller), so avoiding the overhead of each MTA process, short-lived or not, repeating the same configuration-processing work reduces overhead.

A second, and nowadays often more important, reason for compiling configuration information is for convenience in configuration management and updating: due to the fact that when a compiled configuration exists the MTA processes will normally refer to it preferentially, the MTA administrator can make changes to the underlying configuration files at leisure, and optionally perform some testing of such changes (*e.g.*, using a `-noimage_file` switch with test utilities) prior to compiling the updated configuration and having the changes become "live"; meantime, the MTA continues running with the older, compiled configuration.

Once you begin to use a compiled configuration, it will be necessary to recompile the configuration every time changes are made to the settings and files comprising the source of the compiled configuration. For a Unified Configuration, this is primarily `confdesc.xml` (normally modified using the `msconfig` utility); if the `use_text_databases` MTA option has been set, then also potentially the reverse "database" replacement text file, the general "database" replacement text file, and the forward "database" replacement text file. Specifically, these are the files

- *CONFIGROOT*`/confdesc.xml`,
- *CONFIGROOT*`/reverse.txt`,
- *CONFIGROOT*`/general.txt`, and
- *CONFIGROOT*`/forward.txt`.

For a legacy configuration, this includes various relevant `configutil` parameters (see Basic configuration settings relevant to alias LDAP lookups and Basic configuration settings relevant to domain LDAP lookups) and the following files: the MTA configuration file (or any files referenced by it, such as `internet.rules`), the MTA system alias file, the MTA mapping file, the MTA option file, the MTA conversion file, system wide filter file, or the circuit check configuration file; if the `use_text_databases` MTA option has been set, then also the reverse "database" replacement text file, the general "database" replacement text file, the forward "database" replacement text file; as of MS 7.0, also the

Job Controller configuration file, the Dispatcher configuration file, and TCP/IP channel option files (affecting SMTP channels and LMTP client channels). Specifically, these are the files which, prior to MS 7.0.5, were pointed at by the MTA Tailor file options `imta_config_file`, `imta_alias_file`, `imta_mapping_file`, `imta_option_file`, `imta_conversion_file`, `imta_system_filter_file`, `imta_reverse_data`, `imta_general_data`, `imta_forward_data`, respectively, or nowadays are simply:

- *CONFIGROOT*`/imta.cnf`,
- *CONFIGROOT*`/aliases`,
- *CONFIGROOT*`/mappings`,
- *CONFIGROOT*`/option.dat`,
- *CONFIGROOT*`/conversions`,
- *CONFIGROOT*`/imta.filter`,
- *CONFIGROOT*`/reverse.txt`,
- *CONFIGROOT*`/general.txt`, and
- *CONFIGROOT*`/forward.txt`,

as well as the file *CONFIGROOT*`/circuitcheck.cnf`.

Until such time as the configuration is recompiled, changes to any of these files will not be visible to the MTA. Furthermore, even after recompiling the configuration, note that changes to the MTA compiled configuration will not be seen by *running* MTA processes unless and until the MTA configuration is reloaded via the `imsimta reload` utility, or until the process expires and is replaced by a new process. In the case of transient, short-lived processes, (*e.g.*, most channel delivery jobs) their own natural quick expiration may lead to them being replaced by new processes soon enough that any lag in making use of the new MTA configuration is relatively unimportant; however, for significant changes impacting the Job Controller, or the Dispatcher or its server processes (SMTP server processes, SMTP SUBMIT server processes, LMTP server processes), after performing `imsimta cnbuild` also consider performing `imsimta reload`, when the change needs to take effect "immediately" and `imsimta reload` will suffice. (Note that `imsimta reload` only updates certain parts of the precompiled MTA configuration; in particular, it does not reload the channel definitions and rewrite rules portions of the MTA configuration as they are complex and intertwined and require a full re-read of the configuration. Some additional cases of configuration changes relevant to the Job Controller can instead be modified "live", without requiring a restart of the Job Controller, via the `imsimta cache -change` utility.) A full restart of the MTA (especially restarting the Job Controller) should be avoided on production systems unless truly necessary as a restart interrupts and disrupts message delivery; however, a `imsimta restart *` to restart the various servers underneath the Dispatcher causes only brief disruption in acceptance of incoming messages, so is acceptable when enqueue processing changes beyond those covered by `imsimta reload` need to take effect "immediately" upon incoming messages.

Note that updates to the `tlds.txt` file (introduced in MS 7.0.5) do *not* require use of `imsimta cnbuild` to take effect; instead, updates to `tlds.txt` are incorporated by use of the `chbuild` utility.

See Compiling the MTA configuration for further details on the use of compiled configurations.

If `imsimta cnbuild` spots a syntactic error in one of the files that it is attempting to use to build the compiled configuration, it will be reported, typically as an error of the form

`time-stamp``: Error in mm_init -- `*`detail`*

where the `detail` provides additional, specific detail about the particular error. For instance (with output wrapped here for display convenience; in reality it would appear all on one line):

```
09:28:26.15: Error in mm_init -- duplicate host in channel table -- host.domain
com -- line #45 in file IMTA_CONFIG_FILE
```

Note that `imsimta cnbuild` does not know specifics of the syntax and semantics of the Dispatcher configuration file or Job Controller configuration file, or channel option files, so generally errors in the option settings in those files---other than egregiously, obviously broken syntax problems---will not be reported by the utility and instead will get reported by the component in question when it attempts to begin running.

As of MS 6.3p1, errors compiling the configuration (in particular, mm_init errors) will cause `imsimta cnbuild` to exit with a non-zero status. Prior to that version, while such errors would certainly cause `imsimta cnbuild` to exit with error text and without making a new compiled configuration, the exit status was nevertheless zero in many cases.

There is also a secondary, "tuning" use of `imsimta cnbuild`. When the MTA is building an in-memory representation of its configuration (whether that is to generate a compiled configuration, or whether in the absence of any compiled configuration MTA processes are each reading the MTA configuration and building their own private representations of the MTA configuration), it starts by assuming certain table sizes, and if those table sizes are not adequate, iteratively increases those sizes until reaching "big enough" tables in memory to hold the current configuration. The starting points for such table sizes are controlled by internal size MTA options . Using `imsimta cnbuild` with its `-statistics` switch provides information on how "close" the current internal size MTA options are to the sizes needed for the current MTA configuration, and using `imsimta cnbuild` with the set of switches `-noimage_file -maximum -option_file` will generate a new MTA option file with internal size MTA options set appropriately for the current MTA configuration. This sort of tuning permits more efficient compilation of the MTA configuration---though it is not strictly necessary (since the MTA will interatively resize, if necessary, on-the-fly while reading its configuration).

Since the MTA will resize its internal table sizes as needed, errors about exceeding table sizes are normally seen only if the MTA's more-or-less "hard" limits on resizing are reached. (The limits are established by the `maximum.dat` file and/or "hard" limits in the code.) And since the MTA's "hard" limits are *very* generous, exceeding the limits is usually an indication of either a configuration error of a type that has confused the MTA about the intended meaning of certain configuration inputs (for instance, an extraneous blank line in the rewrite rules, causing the MTA to attempt to interpret all remaining material as channel definitions), or configuration choices involving poor use of MTA facilities that would be better handled in an alternate manner (such as attempting to hard code many thousands of mapping table entries, rather than using a few general entries that do general database callouts> for the specific fields). In particular, reaching the limits specified in the normal `maximum.dat` file is usually an indication of poor configuration choices; you should contact Oracle if you believe you wish to exceed those limits, as you may be better served by alternate configuration tactics.

Finally, a command such as

```
# imsimta cnbuild -noimage_file -option_file=file-spec
```

may be used to list current option values (as specified in the current MTA option file, plus default values) in the file specified as *`file-spec`*. To list (most) default option values,

irrespective of override values specified in the current MTA option file, the current MTA option file must be "moved aside" before the above command is issued. (For instance, temporarily rename the MTA option file, then issue the above command, then rename the MTA option file back to its normal location.)

71.8.3 Switches

71.8.3.1 -check, -nocheck (default)

-check means to check the structure of the confdesc.xml file.

71.8.3.2 -image_file[=*file-spec*], -noimage_file

By default, imsimta cnbuild creates as output the image file named *CONFIGROOT*/advanced/config_data; (prior to MS 7.0.5, the file located via the imta_config_data MTA Tailor option). With the -image_file switch, an alternate file name may be specified. When the -noimage_file switch is specified, imsimta cnbuild does not produce an output image file. This switch is used in conjunction with the -option_file switch to produce as output an option file which specifies table sizes adequate to hold the configuration required by the processed input files.

71.8.3.3 -maximum, -nomaximum (default)

When -maximum is specified, the file *SERVERROOT*/lib/maximum.dat is read in addition to the internal size MTA options (which in legacy configuration would be stored in the MTA option.dat file, located prior to MS 7.0.5 via the imta_option_file MTA Tailor file option). The maximum.dat file specifies near maximum table sizes but does not change any other MTA option settings. Only use the -maximum switch if the current table sizes are inadequate. The -noimage_file and -option_file switches should always be used in conjunction with this switch---it makes no sense to output the enormous configuration that is produced by -maximum, but it does make sense to use -maximum to get past size restrictions in order to set properly adjusted MTA option values (in legacy configuration, build an MTA option file with properly adjusted option values) so that a properly sized configuration can be built with a subsequent imsimta cnbuild invocation.

71.8.3.4 -option_file[=*file-spec*], -nooption_file (default)

imsimta cnbuild can optionally set various internal size MTA options (in legacy configuration, produce an option file that contains correct table sizes) to hold the configuration that was just compiled (plus a little room for growth). The -option_file switch causes this file to be output. By default, this file is named *CONFIGROOT*/option.dat (or prior to MS 7.0.5, was located via the imta_option_file MTA Tailor file option). The value on the -option_file switch may be used to specify an alternate file name. If the -nooption_file switch is given, then no option file will be output. imsimta cnbuild always reads any MTA options previously set, whether set as Unified Configuration MTA options or set in the MTA option file, *CONFIGROOT*/option.dat; use of the -nooption_file switch will not alter this behavior. However, use of the -maximum switch causes imsimta cnbuild to also read MTA options from the file *CONFIGROOT*/advanced/maximum.dat This maximum.dat file specifies near maximum table sizes. Only use the -maximum switch if the current table sizes are inadequate, and only use it to generate new MTA option settings (set either as new values for MTA options in Unified Configuration, or by building a new option.dat file in legacy configuration). The -noimage_file switch should always be specified when -maximum is specified since a maximum-size image would be truly enormous and extremely wasteful.

71.8.3.5 -remove, -noremove (default)

The -remove switch causes removal of any existant compiled configuration; *i.e.*, removes the file *CONFIGROOT*/advanced/config_data (located prior to MS 7.0.5 via the imta_config_data MTA Tailor file option).

71.8.3.6 -sizes, -nosizes (default)

The -sizes switch instructs imsimta cnbuild to output information on the sizes of uncompiled MTA tables.

71.8.3.7 -statistics, -nostatistics (default)

The -statistics switch instructs imsimta cnbuild to output information on how much of the various tables in the compiled configuration were actually used to store data. These numbers give a rough measurement of the efficiency of the compilation, and may indicate whether or not an additional rebuild with the -option_file switch is needed. Specifying -statistics effectively forces -noimage_file.

71.8.3.8 -synonyms, -nosynonyms (default)

-synonyms means to output a list of MTA option and channel option synonyms; that is, output a list of the MTA options and channel option marked as aliases in confdesc.xml:

```
spamfilter_config_file -> spamfilter1_config_file
brightmail1_config_file -> spamfilter1_config_file
brightmail_config_file -> spamfilter1_config_file
...additional aliased MTA options...
733 -> percents
822 -> sourceroute
brightmail -> sourcespamfilter1
channelfilter -> destinationfilter
...additional aliased channel keywords...
```

71.8.3.9 -xml_config, -noxml_config (default)

-xml_config directs cnbuild to compile a Unified Configuration; -noxml_config directs cnbuild to compile a legay configuration.

71.8.4 Examples

```
# imsimta cnbuild
# #     Depending upon what has changed, consider issuing:
# # imsimta reload
# # imsimta restart *
```

This is the standard command used on UNIX to regenerate a compiled configuration. After compiling the configuration, restart any programs which may need to reload the new configuration; *e.g.*, the SMTP server should be restarted. (Note that the * character may need shell-quoting so that it will be passed through the shell properly to the MTA utility.)

```
# imsimta cnbuild -noimage_file -option_file -maximum
# imsimta cnbuild
```

Use these two UNIX commands when you encounter the infamous "`No room in table`" MTA error message.

71.9 connkill utility

iref item="Utilities" subitem="connutil"/>

Terminate MTA connections coming from a specified IP address or authenticated using a specified account. The termination can be a one-time thing only affecting current connections matching the given criteria (the default), or it can be "sticky" and made to apply to future connections until a timeout value is reached. The termination request can also be applied to all dispatcher services (the default), or only to services whose names match a specified pattern.

Note: At present only SMTP services respond to the kill requests sent by this utility.

71.9.1 Syntax

```
imsimta connkill -ip=<ip-address>
imsimta connkill -user=<user>
```

Table 71.9 imsimta connkill Command Switches

Switch	Default
`-ip=`*`ip-address`*	n/a
`-service=`*`service-pattern`*	`-service=*`
`-sticky`	`-nosticky`
`-user=`*`uid@domain`*	n/a

71.9.1.1 Restrictions

Must have superuser privileges, or be logged in as the MTA user (see the `user` option in `restricted.cnf`) in order to use this utility.

71.9.2 Description

Compromised hosts and user accounts are a fact of life in modern email environments. Blocking connections from specific IP addresses and suspending user accounts, respectively, are the usual of dealing with these threats.

However, blocking future connections doesn't affect currently active connections, which can continue to send mail until transaction limits are reached, connections time out, and so on.

It is therefore desirable to have some means of terminating active connections based on IP address or authentication state. The `imsimta connkill` utility provides this capability.

The command has two basic forms:

- The `-ip` switch is used to specify an IP address. In this case connections originating from this IP address are terminated.
- The `-user` switch is used to specify a user name of the form *uid@domain*. In this case connections that have authenticated to the account with the specified *uid* and in the specified domain are terminated.

At least one of `-ip` and `-user` are required, but they cannot be specified simultaneously. Both switches require an argument.

In both cases termination will occur the next time a command is read from the client.

Normally only current connections are affected - a subsequent connection from the specified IP address or authentication using the specified user will be allowed. The optional `-sticky` switch can be used to change this behavior. If `-sticky` is specified, subsequent connections or authentications will result in an immediate disconnect until the timeout in seconds specified by the `KILLED_IP_TIMEOUT` and `KILLED_USER_TIMEOUT` TCP/IP channel-specific options, respectively. The former defaults to twice the value of the `COMMAND_RECEIVE_TIME` TCP/IP channel-specific option; the latter defaults to 600 seconds.

Kill requests are sent to all dispatcher services by default. The `-service` switch can be used to specify which services requests are sent to. The required argument is a pattern the service name must match in order to receive the request.

71.10 counters -clear utility

Clear the in-memory cache of channel counters.

71.10.1 Syntax

```
imsimta counters -clear
```

71.10.1.1 Restrictions

The process must have the same UID as either the `root` or the MTA user (`user` option in `restricted.cnf`) accounts.

71.10.2 Parameters

None.

71.10.3 Description

To zero the in-memory channel counters, issue an `imsimta counters -clear` command.

The `imsimta counters -clear` command will create a new memory section, if one does not already exist. The values in the in-memory section will be set to zero, and then the stored messages, recipients, and volumes fields will be set from the values currently in the MTA queue cache database.

Since some initial values will be set based on entries in the MTA queue cache database, you may wish to issue the UNIX command

```
# imsimta cache -synchronize
```

before clearing the counters, to ensure that the MTA queue cache database entries are current.

71.11 counters -show utility

Display the contents of the in-memory cache of channel counters.

71.11.1 Syntax

```
imsimta counters -show
```

Table 71.10 imsimta counters -show Command Switches

Switch	Default
`-associations`	`-associations`
`-channels[=`*`channel-name`*`]`	`-channels`
`-debug`	`-nodebug`
`-format=`*`n`*	`-format=0`
`-headers`	`-headers`
`-output=`*`file-spec`*	*None*

71.11.1.1 Restrictions

On UNIX, normally none, but if a new in-memory section must be created then privileges sufficient to create such a section are required.

71.11.2 Description

The contents of the in-memory cache of channel counters may be displayed with the `imsimta counters -show` command.

A new in-memory section will be created if one does not already exist. Note that if a new in-memory section must be created, the initial values for the number of messages stored, number of recipients, and message volumes will be set based on the entries in the MTA queue cache database.

See MTA counters, especially the discussion of the Purpose and design of MTA counters.

71.11.3 Switches

71.11.3.1 `-associations` (default), `-noassociations`

The `-associations` switch specifies whether to show the in-memory cache of association counters.

71.11.3.2 `-channels[=`*`channel-name`*`]` (default), `-nochannels`

The `-channels` switch specifies whether to show the in-memory cache of channel counters. By default, counters for all channels are shown; specifying an argument to the `-channels` specifies a specific channel for which to show counters.

71.11.3.3 -debug, -nodebug (default)

The -debug qualifer enables debugging.

71.11.3.4 -format=0 (default=0)

Controls the format of the command output. The following values are supported:

0 Human-readable tabuular text

10 CVS format

11 JSON format, zero values omitted

12 JSON format, no values omitted

71.11.3.5 -headers (default), -noheaders

Controls whether or not a header line describing each column in the table of counters is output.

71.11.3.6 -output=*file-spec*

Direct the output to the specified file. By default the output appears on your display.

71.11.4 Examples

This example shows displaying the counters for all channels and associations.

```
# imsimta counters -show
Channel                     Messages  Recipients      Blocks

71.12 crdb utility

`imsimta crdb` is a utility used to create and update MTA (on-disk) database files.

71.12.1 Syntax

```
imsimta crdb input-file-spec output-database-spec
```

Table 71.11 imsimta crdb Command Switches

Switch	Default
`-append`	`-noappend`
`-count`	`-count`
`-dump`	*See text*
`-duplicates`	`-noduplicates`
`-exception_file=`*`file-spec`*	`-noexception_file`
`-huge_records`	`-huge_records`
`-long_records`	`-nolong_records`
`-quoted`	`-noquoted`
`-remove`	`-noremove`
`-statistics`	`-statistics`
`-strip_colons`	`-nostrip_colons`

71.12.2 Parameters

71.12.2.1 *input-file-spec*

A text file containing the entries to be placed into the database. Each line of the text file must correspond to a single entry.

71.12.2.2 *output-database-spec*

The initial name string of the file to which to write the database; the database will consist of a file named *output-database-spec*`.db`.

71.12.3 Description

`imsimta crdb` is a utility to create and or update MTA (on disk) database files. `imsimta crdb` simply converts a plain text file into MTA database records and from them either creates a new database or adds the records to an existing database.

If run from the `root` account, `imsimta crdb` will set the ownership of the database it creates to the MTA user account; see the `user` option from the `restricted.cnf` file, or in older versions of the MTA, see the `imta_user` MTA Tailor option. If run from an unprivileged account, then the database will be owned by that unprivileged user.

In general, each line of the input file must consist of a left hand side and a right hand side. The two sides are separated by one or more spaces or tabs. The left hand side is limited to

32 characters in a short database (the default variety) and 80 characters in a long database. The right hand side is limited to 80 characters in a short database and 256 in a long database. Spaces and tabs may not appear in the left hand side (but see the description of the `-quoted` switch below).

The format of the input file is described in the sections describing each particular MTA database. For instance, the format of the input file for an alias database is described in Alias database format; the format of the input file for the domain database (rewrite rule database) is described in Domain database; the format of the input file for the forward database is described in Forward database; the format of the input file for the general database is described in General database; the format of the input file for the address reversal database is described in Reverse database.

71.12.4 Switches

71.12.4.1 `-append`, `-noappend` (default)

When the default, `-noappend`, switch is in effect, a new database is created, overwriting any old database of that name. Use the `-append` switch to instruct the MTA to instead add the new records to an existing database.

71.12.4.2 `-count` (default), `-nocount`

Controls whether or not a count is output after each group of 100 input lines are processed.

71.12.4.3 `-dump`

`imsimta crdb -dump` is a synonym for `imsimta dumpdb`. It is used to dump an existing database to a flat text file---or to stdout if no output file is specified. The parameters are interpreted as the input database specification, and optionally a flat text file to which to write the output. No other switches are valid when `-dump` is specified.

71.12.4.4 `-duplicates`, `-noduplicates` (default)

Controls whether or not duplicate records are allowed in the output files. Currently duplicate records are of use only in the domain database (rewrite rules database) and databases associated with the directory channel.

71.12.4.5 `-exception_file=`*`file-spec`*, `-noexception_file` (default)

`imsimta crdb` may encounter records that cannot be loaded into the database. This usually means that these records had keys (left hand sides) that were duplicates of other keys previously encountered in the input file. These exception records can optionally be written to a separate output file for later examination; the `-exceptions_file` switch controls the writing of this file. Note that the lines in this file are not plain text; they are formatted as database entries.

71.12.4.6 `-long_records`, `-nolong_records` (default), `-huge_records`, `-nohuge_records`

These switches control the size of the output records. By default left hand sides are limited to 32 characters and right hand sides are limited to 80 characters. If `-long_records` is

specified, the limits are changed to 80 and 256, respectively. If `-huge_records` is specified, the limits are changed to 252 and 1024, respectively. Currently, `-huge_records` databases are supported only for the alias database.

71.12.4.7 `-quoted`, `-noquoted` (default)

This switch controls the handling of quotes. Normally `imsimta crdb` pays no particular attention to double quotes. If `-quoted` is specified, `imsimta crdb` matches up double quotes in the process of determining the break between the left and right hand sides of each input line. Spaces and tabs are then allowed in the left hand side if they are within a matching pair of quotes. This is useful for certain kinds of databases, where spaces may form a part of database keys. Note: The quotes are not removed unless the `-remove` switch is also specified.

71.12.4.8 `-remove`, `-noremove` (default)

These switches control the removal of quotes. If `imsimta crdb` is instructed to pay attention to quotes, the quotes are normally retained. If `-remove` is specified, `imsimta crdb` removes the outermost set of quotes from the left hand side of each input line. Spaces and tabs are then allowed in the left hand side if they are within a matching pair of quotes. This is useful for certain kinds of databases, where spaces may form a part of database keys. Note: `-remove` is ignored if `-quoted` is not in effect.

71.12.4.9 `-statistics` (default), `-nostatistics`

Controls whether or not some simple statistics are output by `imsimta crdb`, including the number of entries (lines) converted, the number of exceptions (usually duplicate records) detected, and the number of entries that could not be converted because they were too long to fit in the output database. `-nostatistics` suppresses output of this information.

71.12.4.10 `-strip_colons`, `-nostrip_colons` (default)

The `-strip_colons` switch instructs `imsimta crdb` to strip a trailing colon from the right end of the left hand side of each line it reads from the input file. This is useful for turning alias file entries into an alias database.

71.12.5 Examples

```
# imsimta crdb -long_records IMTA_DATAROOT:db/aliases.txt IMTA_DATAROOT:db/tmpdb
# imsimta renamedb IMTA_DATAROOT:db/tmpdb IMTA_DATAROOT:db/aliasesdb
```

The above example shows UNIX commands that may be used to create an alias database with "long" record entries; note that the creation is performed in a two-step process using a temporary database to minimize any window of time, such as during database generation, when the database would be locked and inaccessible to the MTA.

71.13 find utility

Find specified version of an MTA log file.

71.13.1 Syntax

```
imsimta find file-pattern
```

Table 71.12 imsimta find Command Switches

Switch	Default
`-debug`	*None*
`-f=offset-from-first`	*None*
`-first=offset-from-first`	*None*
`-l=offset-from-last`	*None*
`-last=offset-from-last`	*None*

71.13.1.1 Restrictions

Must have read access to the requested file.

71.13.2 Parameters

71.13.2.1 *file-pattern*

A file name pattern for which MTA debug log file to find. If no directory is specified, the utility looks in the MTA log directory (`imta_log`). Note that the utility does not support relative directory specifications; when specifying a directory, use an absolute directory specification.

71.13.3 Description

The `imsimta find` utility may be used to find the precise file name of the specified "version" of an MTA debug log file. MTA debug log files have a *-uniqueid* appended to the file name to allow for the creation of multiple "versions" of the log file; on UNIX, the *-uniqueid* is appended to the very end of the file name (the end of the file extension). (See for instance the `master_debug` and `slave_debug` channel options, and the `dispatcher.debug`job_controller.debug options.) The `imsimta find` utility understands these unique ids and can find the particular file name corresponding to the requested "version" of the file.

The default, if no offset switch is specified, is to find the most recent "version" of the file.

71.13.4 Switches

71.13.4.1 `-debug`

The `-debug` switch enables debug output.

71.13.4.2 -f=*offset-from-first*, -first=*offset-from-first*

The -f or -first switch is used to specify finding the *n*th "version" of the file (starting counting from 0). For instance, to find the earliest (oldest) "version" of the file, specify -f=0

71.13.4.3 -l=*offset-from-last*, -last=*offset-from-last*

The -l or -last switch is used to specify finding the *n*th from the last "version" of the file (starting decrementing from 0 as the most recent version). For instance, to find the most recent (newest) "version" of the file, specify -l=0

71.13.5 Examples

```
# imsimta find tcp_local_slave.log
```

The above UNIX command will print out the file name of the tcp_local_slave.log-*uniqueid* file most recently created in the MTA log directory.

```
# imsimta find tcp_local_master.log -f=0
```

The above UNIX command will display the file name of the oldest tcp_local_master.log-*uniqueid* file in the MTA log directory.

71.14 process utility

List currently executing MTA processes and jobs.

71.14.1 Syntax

```
imsimta process
```

71.14.2 Parameters

None.

71.14.3 Description

Show current MTA processes. Normally on a regular MTA system, the Dispatcher and Job Controller should always be present; typically some SMTP and SMTP SUBMIT server processes are present; and additional processes may be present if messages are currently being processed, or if certain additional MTA components are in use. On an LMTP back end Message Store system, the Dispatcher should always be present, and typically one or more LMTP server processes are present.

71.14.4 Examples

The following command shows currently executing Messaging Server MTA processes on a regular MTA system:

```
# imsimta process
    USER   PID S  VSZ  RSS    STIME        TIME COMMAND
 mailsrv   235 S 44592 20324 18:25:00       00:01 /opt/sun/comms/messaging64/lib/tcp_smtp_server
 mailsrv   236 S 44756 20924 18:25:00       00:04 /opt/sun/comms/messaging64/lib/tcp_smtp_server
 mailsrv   262 S 44816 21024 18:27:30       00:01 /opt/sun/comms/messaging64/lib/tcp_smtp_server
 mailsrv   358 S 44836 21052 18:37:30       00:04 /opt/sun/comms/messaging64/lib/tcp_smtp_server
 mailsrv  8286 S 44296 19724 08:55:08       00:00 /opt/sun/comms/messaging64/lib/managesieve
 mailsrv  8287 S 44232 19648 08:55:08       00:00 /opt/sun/comms/messaging64/lib/managesieve
 mailsrv 18763 S 42068 9004   Aug_23      03:44 /opt/sun/comms/messaging64/lib/dispatcher
 mailsrv 18775 S 37492 12044   Aug_23       00:06 /opt/sun/comms/messaging64/lib/job_controller
```

71.15 purge utility

Purge MTA log files.

71.15.1 Syntax

```
imsimta purge [file-pattern]
```

Table 71.13 imsimta purge Command Switches

Switch	Operation	Default
`-day=value`	Days after which the file should be deleted.	None
`-debug`	Display the action(s) purge would take but do not perform them	None
`-hour=value`	Hours after which the file should be deleted.	None
`-num=value`	`-num=5`	

71.15.2 Parameters

71.15.2.1 *file-pattern*

A file name pattern for which MTA log files to purge. The default, if no file name pattern is specified, is to purge *all* the files in the MTA log directory. (The MTA log directory has symbolic name IMTA_LOG:, which is the directory *DATAROOT*`/log`. If no directory path is included in the file name pattern, the default is to purge files matching the file name pattern from the MTA log directory.

IMPORTANT NOTE: imsimta knows nothing about the specifics of the log files it operates on; it uses generic file name patterns which can effect ANY file in the log directory. As such, administrators MUST avoid creating their own files in the log directory - whether that be a rename of logs the product creates, any derivative material from the logs (parsing output, tar, zip, ... any), or anything completely unrelated - putting it in the log directory is unsupported and may produce unexpected results.

If you want to do your own parsing and archiving of the logs,then that is fine, but make sure you put the results into some other directory.

As of 8.0.1.2, imsimta purge unconditionally ignores the connection and transaction log files mail.log, mail.log_current, and mail.log_yesderday and connection log files connection.log, connection.log_current, and connection.log_yesterday. Files with names beginning with "." are also ignored.

71.15.3 Description

`imsimta purge` purges back older versions of MTA log files. (`imsimta purge` can tell which log files are older based on the *uniqueid* strings terminating MTA log file names.)

71.15.4 Switches

71.15.4.1 -day=*d*

Specifying -day=*d* results in purging all but the last *d* days worth of log files. Note that here "day" means a 24 hour period, rather than a calendar day (midnight to midnight); *i.e.*, all but the log files created in the last 24*d* hours will be purged.

71.15.4.2 -debug

Specifying -debug enables some debug output to stdout.

71.15.4.3 -hour=*h*

Specifying -hour=*h* results in purging all but the last *h* hours worth of log files.

71.15.4.4 -num=*n*

Specifying -num=*n* results in purging all but the last *n* log files. The default is -num=5.

71.15.5 Examples

```
# imsimta purge
```

This UNIX command will purge all but the last five versions of each sort of log file in the MTA log directory, SERVERROOT/log.

```
# imsimta purge -num=10 tcp_local_master.log
```

This UNIX command will purge all but the last ten versions of any tcp_local_master.log-* files from the MTA log directory, *SERVERROOT*/log/.

71.16 qclean utility

Hold or delete message files from the MTA queue disk area that contain specified substrings in their envelope From address, Subject: header, or message content.

71.16.1 Syntax

```
imsimta qclean [channel]
```

Table 71.14 imsimta qclean Command Switches

Switch	Default
`-content=`*`substring`*	*None*
`-database`	`-database`
`-delete`	`-hold`
`-directory_tree`	`-database`
`-domain_to=`*`substring`*	*None*
`-env_from=`*`substring`*	*None*
`-env_to=`*`substring`*	*None*
`-from=`*`substring`*	*None*
`-hold`	`-hold`
`-ignore_zz`	`-noignore_zz`
`-match=`*`keyword`*	`-match=AND`
`-min_length=`*`n`*	`-min_length=24`
`-subject=`*`substring`*	*None*
`-threads=`*`n`*	`-nothreads`
`-to=`*`substring`*	*None*
`-verbose`	`-noverbose`

71.16.1.1 Restrictions

Privileges sufficient to read and delete files in the MTA channel queue directory tree, as well as read the MTA queue cache database (obtain information from the Job Controller), are required.

71.16.2 Parameters

71.16.2.1 *channel*

Optional parameter which specifies a specific MTA channel area to be searched for matching messages. * or ? wildcard characters may be used in the channel specification.

71.16.3 Description

Hold or delete message files containing specific substrings in their envelope From address, Subject: line, or content. (Note that `.HELD` message files are not checked or affected by

this utility.) By default, message files are held (`-hold`). Specify `-delete` to instead delete matching message files. The `-content`, `-domain_to`, `-env_from` (synonym `-from`), `-env_to` (synonym `-to`), and `-subject` switches are used to specify the substrings for which to search. Often, the specific user recipient is not as relevant as the domain of the recipient(s), so the `-domain_to` switch is available for the purpose of specifying the recipient domain.

Any combination of `-content`, `-domain_to`, `-env_from` (synonym `-from`), `-env_to` (synonym `-to`), and `-subject` may be specified. However, only one of each may be used. The `-match` switch controls whether a message file must contain all (`-match=AND`, the default) or only one of (`-match=OR`) the specified substrings in order to be held or deleted. The default is `-match=AND`.

By default, each substring to be searched for must be at least 24 bytes long (`-min_length=24`). This is a safety measure: the longer the substring, the less likely the chance of false "hits". Use the `-min_length` switch to override this limit, making sure to specify `-min_length` *before* any switches specifying "short" strings. And note that only values for `-min_length` of 5 or more will be respected; attempting to set a `-min_length` of less than 5 will result in a value of 5 being used. Also by default, only message files identified by the queue cache database are searched (`-database`). Use the `-directory_tree` switch to instead search all message files actually present in the channel queue directory tree.

The optional channel parameter restricts the search to message files in the specified channel. The channel parameter may use * and ? wild cards.

The `-threads` switch may be used to accelerate searching on multiprocessor systems by dividing the work amongst multiple, simultaneously running threads. To run *n* simultaneous searching threads, specify `-threads=`*n*. The value *n* must be in the range 1-8. The default is `-nothreads`.

Note that this utility does not bother to update the Job Controller's queue cache regarding the `.HELD`ing or deleting of message files; the utility merely makes the change directly to the message file on disk. (The Job Controller, when it happens to attempt to access and process such a modified or deleted message file, will see that the message file no longer exists in its previous form and then update its own data structure and continue on to process other messages.)

71.16.4 Switches

71.16.4.1 `-content=`*`substring`*, `-domain_to=`*`substring`*, `-env_from=`*`substring`*, `-env_to=`*`substring`*, `-subject=`*`substring`*, `-to=`*`substring`*

The `-content`, `-domain_to`, `-env_from` (synonym `-from`), `-env_to` (synonym `-to`), and `-subject` switches are used to specify the substrings for which to search. Any combination of `-content`, `-domain_to`, `-env_from` (synonym `-from`), `-env_to` (synonym `-to`), and `-subject` may be specified; explicit use of at least one such switch is required. However, only one occurrence of each such switch may be used. When a combination of such switches is used, the `-match` switch controls whether the switches are interpreted as further restrictions (`-match=AND`), or as alternatives (`-match=OR`).

71.16.4.2 `-database` (default), `-directory_tree`

The `-database` switch, the default, specifies that only message files identified by the Job Controller's queue cache be searched. Use the `-directory_tree` switch to instead search all message files actually present in the channel queue directory tree.

71.16.4.3 `-delete`, `-hold` (default)

`-hold` is the default and means that matching message files will be sidelined as `.HELD` files. Specify `-delete` to instead delete matching message files.

71.16.4.4 `-match=`*keyword*

The default is `-match=AND`, meaning that any criteria specified by `-content`, `-env_from`, and `-subject` switches must all match in order for the current hold or delete operation to be applied. Specifying `-match=OR` means that a message will match as long as at least one such criterion matches.

71.16.4.5 `-min_length=`*n*

By default, each substring to be searched for must be at least 24 bytes long (`-min_length=24`). This is a safety measure: the longer the substring, the less likely the chance of false "hits". Use the `-min_length` switch to override this limit, making sure to specify `-min_length` *before* any switches specifying "short" strings.

Note that the `-min_length` value must be 5 or more; attempting to set a smaller value will result in the value 5 being used.

71.16.4.6 `-threads=`*n*, `-nothreads` (default)

The `-threads` switch may be used to accelerate searching on multiprocessor systems by dividing the work amongst multiple, simultaneously running threads. To run *n* simultaneous searching threads, specify `-threads=`*n*. The value *n* must be an integer in the range 1-8. The default is `-nothreads`.

71.16.4.7 `-verbose`, `-noverbose` (default)

The `-verbose` switch may be used to request that the utility print out information about what it is doing as it operates.

71.16.5 Examples

```
# imsimta qclean -min_length=12 -subject="make money fast" -env_from="spammers.com"
%QM-I-QCLISTING, building a list of message files to scan from the queue cache
%QM-I-SCANNING, scanning 72 message files
%QM-I-SCANNED, scanned 72 message files in 3.7500 seconds (19.20 messages/second )
%QM-I-HELD, held 5 message files
```

The above UNIX example shows holding all message files in the MTA queue area that have the string "make money fast" in the Subject: header and have the string "spammers.com" in the envelope From address.

71.17 qtop utility

Display the most frequently occurring envelope From, envelope To, Subject:, or message content fields found in message files in the channel queues.

71.17.1 Syntax

```
imsimta qtop [channel]
```

Table 71.15 imsimta qtop Command Switches

Switch	Default
-content=*offset-specifier*	*None*
-database	-database
-directory_tree	-database
-domain_to=*offset-specifier*	*None*
-env_from=*offset-specifier*	*None*
-env_to=*offset-specifier*	*None*
-from=*offset-specifier*	*None*
-ignore_zz	-noignore_zz
-min_count=*n*	-min_count=2
-output=*file-spec*	*See text*
-subject=*offset-specifier*	-subject=(START=1,LENGTH=2147483647)
-threads=*n*	-nothreads
-to=*offset-specifier*	*None*
-top=*n*	-top=20
-verbose	-noverbose

71.17.1.1 Restrictions

Privileges sufficient to read files in the MTA channel queue directory tree, as well as read the MTA queue cache database, are required.

71.17.2 Parameters

71.17.2.1 *channel*

Optional parameter which specifies a specific MTA channel area to be scanned for string frequencies. * or ? wildcard characters may be used in the channel specification.

71.17.3 Description

Display the most frequently occurring envelope From, envelope To, Subject: field, or message content fields found in message files in the channel queues. (Note that .HELD

message files are not checked or displayed by this utility.) By default, only Subject: fields are shown (`-subject`). Use `-env_from` to display frequent envelope From fields, `-env_to` or `-domain_to` to display frequent envelope To fields, or `-content` to display frequent message contents. Any combination of `-content`, `-env_from`, `-env_to`, and `-subject` may be specified. However, only one of each may be used.

The optional channel parameter restricts the scan to message files in the specified channel. The channel parameter may use * and ? wild cards.

By default, the top 20 most frequently occurring fields are shown (`-top=20`) provided that they occur 2 or more times (`-min_count=2`). Use the `-top` and `-min_count` switches to alter this behavior. Also by default, only message files identified by the queue cache database are scanned (`-database`). Use the `-directory_tree` switch to instead scan all message files actually present in the channel queue directory tree.

The `-threads` switch may be used to accelerate scanning on multiprocessor systems by dividing the work amongst multiple, simultaneously running threads. To run *n* simultaneous scanning threads, specify `-threads=n`. The value *n* must be in the range 1-8. The default is `-nothreads`.

The `-content`, `-env_from`, `-env_to`, and `-subject` switches accept the optional qualifiers `start=`*n* and `length=`*n*. These qualifiers indicate the starting offset and number of bytes in the field to consider. The defaults are `-content=(START=1,LENGTH=256)`, `-env_from=(START=1,LENGTH=2147483647)`, `-env_to=(START=1,LENGTH=2147483647)`, and `-subject=(START=1,LENGTH=2147483647)`. Use of these qualifiers is useful when, for example, trying to identify occurrences of a spam message which uses random text at the start of the Subject: line.

71.17.4 Switches

71.17.4.1 -content[=*offset-specifier*], -domain_to[=*offset-specifier*], -env_from[=*offset-specifier*], -env_to[=*offset-specifier*], -from[=*offset-specifier*], -subject[=*offset-specifier*], -to[=*offset-specifier*]

The `-content`, `-domain_to`, `-env_from` (synonym `-from`), `-env_to` (synonym `-to`), and `-subject` switches are used to specify which frequently occurring fields should be displayed. By default, only Subject: fields are shown (`-subject`). Use `-env_from` to display frequent envelope From fields, `-env_to` or `-domain_to` to display frequent envelope To fields, or `-content` to display frequent message contents. Any combination of `-content`, `-domain_to`, `-env_from` (synonym `-from`), `-env_to` (synonym `-to`), and `-subject` may be specified. However, only one of each may be used. The `-content`, `-domain_to`, `-env_from` (synonym `-from`), `-env_to` (synonym `-to`), and `-subject` switches accept the optional qualifiers `START=`*n* and `LENGTH=`*n*. These qualifiers indicate the starting offset and number of bytes in the field to consider. The defaults are `-content=(START=1,LENGTH=256)`, `-env_from=(START=1,LENGTH=2147483647)`, `-env_to=(START=1,LENGTH=2147483647)`, and `-subject=(START=1,LENGTH=2147483647)`. Use of these qualifiers is useful when, for example, trying to identify occurrences of a spam message which uses random text at the start of the Subject: line.

71.17.4.2 -database (default), -directory_tree

The -database switch, the default, specifies that only message files identified by the queue cache database be searched. Use the -directory_tree switch to instead search all message files actually present in the channel queue directory tree.

71.17.4.3 -ignore_zz, -noignore_zz (default)

-noignore_zz is the default and means to scan all messages queued in a channel. -ignore_zz means to scan only those files which are not ZZ files; that is, only those files which have already had at least one delivery attempt.

71.17.4.4 -min_count=*n*

By default, a string must occur at least 2 times, -min_count=2, in order to be displayed.

71.17.4.5 -output=*file-spec*

By default, output goes to stdout. The -output switch may be used to direct the utility's output to a file instead.

71.17.4.6 -threads=*n*, -nothreads (default)

The -threads switch may be used to accelerate searching on multiprocessor systems by dividing the work amongst multiple, simultaneously running threads. To run *n* simultaneous searching threads, specify -threads=*n*. The value *n* must be an integer in the range 1-8. The default is -nothreads.

71.17.4.7 -top=*n*

By default, the top 20 most frequently occurring fields are shown, (-top=20).

71.17.4.8 -verbose, -noverbose (default)

The -verbose switch may be used to request that the utility print out information about what it is doing as it operates.

71.17.5 Examples

```
# imsimta qtop -subject -env_from
%QM-I-QCLISTING, building a list of message files to scan from the queue cache
%QM-I-SCANNING, scanning 73 message files
%QM-I-SCANNED, scanned 73 message files in 0.5600 seconds (130.36 messages/secon
d)
Top 20 Envelope From: addresses which occur 2 or more times
 Count  Envelope From: address
======  ============================================================
    27
    10  owner-ex-list@acme.com
     2  owner-test-list@acme.com

Top 20 Subject: header lines which occur 2 or more times
```

```
 Count  Subject
======  ========================================================================
     6  Re: your ex-list posting
     2  Test posting to test-list
```

The above UNIX example shows displaying the most frequently occurring Subject: field and envelope From addresses amongst messages in the MTA queue area.

```
# imsimta qtop -subject=START=12 -min_count=15
%QM-I-QCLISTING, building a list of message files to scan from the queue cache
%QM-I-SCANNING, scanning 73 message files
%QM-I-SCANNED, scanned 73 message files in 0.5600 seconds (130.36 messages/secon
d)
Top 20 Subject: header lines which occur 15 or more times
 Count  Subject
======  ========================================================================
    25  ake money fast $$$
```

The above UNIX example shows displaying the most frequently occuring Subject: lines that occur 20 times or more, starting from 12 characters into the Subject: header value. This may be useful when trying to spot spam that inserts random characters at the beginning of the Subject: header value.

71.18 reload utility

Reload portions of the MTA configuration.

71.18.1 Syntax

```
imsimta reload
```

71.18.2 Parameters

None.

71.18.3 Description

For compiled configurations, this utility reloads any mapping tables (`mapping` group settings in Unified Configuration or the mapping file in legacy configuration), and the general, reverse, and forward "databases", if the applicable bits of `use_text_databases` have been set. It does not, however, reload the entire compiled configuration; in particular, changes to channel definitions and rewrite rules (*e.g.*, the `imta.cnf` file in legacy configuration) are not propagated by `imsimta reload`. Nor does it, in general, reload changes to MTA options.

The `imsimta reload` utility also reloads authentication, SSL/TLS, and as of Messaging Server 8.0.2, affinity group options. This is done even if the MTA's configuration is not compiled.

For making certain changes "live" to a running Job Controller, see also the `cache -change` utility.

71.18.4 Error messages

Problems encountered attempting to reload the configuration can result in a syslog notice (sent with syslog facility and mask controlled by the `sndopr_priority` MTA option):

```
BADCONFIGLOAD, Attempt to load new configuration failed.
```

or

```
BADCONFIG, Attempt to map new configuration failed.
```

71.19 restart utility

Restart MTA components.

71.19.1 Syntax

```
imsimta restart [component]
```

71.19.1.1 Restrictions

Must have superuser privileges or use the Solaris RBAC feature in order to use this utility.

71.19.2 Parameters

71.19.2.1 *component*

Optional parameter which specifies a specific MTA component, or Dispatcher service, to be restarted. The components which may be restarted with this utility are `job_controller`, `dispatcher`. Any Dispatcher service may be restarted with this utility by specifying the service name; with the services in a typical configuration, this means `smtp`, `smtp_submit`, and `lmtpss`, but any other site-specific services may be restarted similarly by specifying their name. Note that restarting the MTA Dispatcher, *i.e.*, the `dispatcher` component, effectively restarts all the service components it handles, which may include `smtp`, `smtp_submit`, and `lmtpss`. If no component name is given, then all active components will be restarted. If the asterisk character, `*`, is specified as the "component", then all active services under the Dispatcher (but not the Dispatcher itself) will be restarted; note that to avoid shell interpretation and get the asterisk character passed through as an argument to the utility itself, it will usually be necessary to quote the asterisk character, `"*"`.

71.19.3 Description

Detached MTA processes should be restarted whenever relevant portions of the MTA configuration are altered---these processes load information from the configuration once only and generally need to be restarted in order for configuration changes to become visible to them. (In legacy configuration, in addition to general MTA configuration files such as the `imta.cnf` file, note that components such as the Dispatcher have their own specific configuration files, *e.g.*, `dispatcher.cnf`, and should be restarted after changes to any of these files.) However, note that *some* configuration changes can be put into effect without a restart: see the `imsimta reload` and `imsimta cache -change` utilities.

An `imsimta restart` command is equivalent to performing a `imsimta shutdown` followed by an `imsimta startup` on the specified component.

If no component name is specified, then the `imsimta restart` utility stops any old Job Controller process and Dispatcher process that might be running, and restarts the Job Controller and Dispatcher. If a component parameter is specified, then only detached processes associated with that component will be restarted. If an asterisk character, `*`, is specified, then all active services running under the Dispatcher will be restarted (though the Dispatcher itself will not be restarted in this case); note that shell interpretation will usually

require that the asterisk character be quoted so that the shell will pass the asterisk through as an argument to the `imsimta restart` command.

The standard component names are:

Table 71.16 Component Names

Component	Description
`dispatcher`	MTA multithreaded Dispatcher handling services such as SMTP, SMTP SUBMIT, and LMTP servers.
`job_controller`	MTA Job Controller.
`lmtpss`	LMTP server for Message Store delivery
`smtp`	SMTP server processes.
`smtp_submit`	SMTP SUBMIT (port 587) server processes.

Note that restarts of the Job Controller should be avoided, especially during periods of large message backlogs, unless such a restart is necessary. Note that a restart of the Job Controller requires that the Job Controller rescan the queue directory structure to re-discover all message files, and completely rebuild its internal data structures that control message delivery scheduling and the order of message delivery attempts. Such rescanning and rebuilding of data structures is designed to be fast, and have a low impact on the processing of any newly submitted messages that may come in during the rebuilding. But it is not intended to necessarily restore the exact state of the Job Controller's original scheduling, and in practice a certain degree of "out-of-order" processing of the backlogged messages (messages already existing on disk), and "unfair" division between channels of effort on processing the backlogged messages, is expected to occur after a restart of the Job Controller.

Whenever the Job Controller is shutdown (and a restart includes a shutdown of the "old" Job Controller process), before it shuts down it sends a "no more messages" notice to all its child processes (channel processes), which such processes will see once they finish up whatever current message they are working on and ask the Job Controller whether there are any more messages. That is, the Job Controller itself shuts down, but leaves a "poison" message that the channel jobs will see as they each finish up their own work. So generally (but with a couple of exceptions, to be discussed just below) any old channel processes that the Job Controller had previously started finish up whatever message they had already been working on. Once a channel process has finished its already started work and then asks for another message to process, it will see that there are no more messages for it to process, and exit. However, exceptions are the `ims-ms` channel, and less commonly, outbound TCP/IP channels. `ims-ms` channels will interrupt processing even of currently being processed messages after a brief amount of time (an additional 55 seconds) to attempt to complete processing of a current message; the remaining recipients of a message for which processing had begun will be deferred for later processing; (when logging is enabled, "Z" records with a reason, as of MS 8.0, of "`shutting down`" will be generated for those recipients; note that prior to MS 8.0, the reason was was "`shutdown`"). TCP/IP channels will abort processing after their configurable `WINDDOWN_TIMEOUT` channel-specific option time period has expired. (The default value for `WINDDOWN_TIMEOUT` is relatively "large" due to the potential for undesirable remote SMTP server handling of aborted message transfers, and the potential expense of resending a "large" message.)

71.19.4 Examples

```
# imsimta restart dispatcher
```

The above UNIX command restarts the Dispatcher, and hence all services under the dispatcher.

```
# imsimta restart "*"
```

The above UNIX command restarts all the services *under* the Dispatcher (typically `SMTP`, `SMTP_SUBMIT`, and `LMTPSS`) *without* restarting the Dispatcher itself.

```
# imsimta restart
```

The above UNIX command restarts *all* the MTA jobs, including the Job Controller (and should be avoided unless a restart of the Job Controller is truly needed).

```
# imsimta restart
Stopping dispatcher server 29615 .. done
Stopping job_controller server 29637 . done
Starting dispatcher server . 29645
Starting job_controller server . 29655
```

The above shows the sort of output shown as of MS 6.3, including in particular the pids of the stopped and started processes.

```
# imsimta restart job_controller
job_controller server is not running
Starting job_controller server .. 29683
```

The above shows the sort of output shown as of MS 6.3, if a `restart` command is given for the Job Controller when it is not actually currently running.

71.19.5 Error messages

Trouble communicating with the Dispatcher, shutting it down, or restarting it, will be reported back to `stderr`:

```
dispatcher server is not running
```

```
Cannot stop dispatcher server (pid=pid) with SIGTERM
Retrying with SIGKILL
```

```
dispatcher server is running already
```

Trouble restarting the Job Controller will be reported back to `stderr`:

```
job_controller server is not running
```

```
job_controller server is running already
```

71.20 return utility

Return (bounce) a mail message to its originator.

71.20.1 Syntax

```
imsimta return message-file-spec
```

71.20.1.1 Restrictions

Must have superuser privileges or be logged in as the MTA user (see the `user` option in `restricted.cnf`) in order to use this utility.

71.20.2 Parameters

71.20.2.1 *message-file-spec*

File specification of the message file to return. The specification may include wildcards, but if so, the specification must be quoted.

71.20.3 Description

The `imsimta return` utility returns a message to the message's originator, (unless the original message had NOTIFY=NEVER set, in which case the message is simply deleted without generation of a DSN). The returned message is in three parts. The first part explains the reason why the message is being returned; the text of the reason is contained in the file `return_bounced.txt` file located in the MTA language-specific directory. The second part of the returned message is a machine-readable report. The third part contains either the original message itself, or the original message's header (depending upon any RET=FULL *vs.* RET=HDRS setting on the original message, and on whether the original message size triggered application of MTA size limits such as `content_return_block_limit`).

As regards MTA transaction logging, when it is enabled via the `logging` channel option, such postmaster manual bounces will result in either a "R" (bounce original message with a DSN) or "K" (delete original message without a DSN since the original message requested NOTIFY=NEVER) MTA transaction log entry.

71.20.4 Examples

```
# imsimta return 'IMTA_QUEUE:ims-ms/*'
```

The above UNIX command will cause all of the messages currently in the `ims-ms` channel queue to be returned to their respective originators (*i.e.*, "bounced").

71.21 run utility

Process messages in a specified channel.

71.21.1 Syntax

```
imsimta run channel [poll-flag [start-time [start-id
  [channel-specific-argument [name-filter [min-priority:max-priority]]]]]]
```

71.21.1.1 Restrictions

Must be the MTA user (see the `user` option in `restricted.cnf`), or have superuser privileges (in which case the MTA will automatically become the MTA user) in order to use this utility.

71.21.2 Parameters

71.21.2.1 *channel*

This parameter specifies the channel to be processed.

71.21.2.2 *poll-flag*

Valid values for *poll-flag* are `nopoll` or its synonym `master` (the default), `poll`, or `slave`. By default, if neither `poll` nor `slave` is specified, then only the master direction of the channel will be run. If `poll` is specified, then first the master and then the slave directions of the channel will be run. If `slave` is specified, then only the slave direction of the channel will be run.

71.21.2.3 *queuename*

This parameter is of historical interest only, and has no effect when the Job Controller is in use.

71.21.2.4 *start-time*

This parameter is of historical interest only, and has no effect when the Job Controller is in use.

71.21.2.5 *start-id*

This parameter is of historical interest only, and has no effect when the Job Controller is in use.

71.21.2.6 *channel-specific-argument*

This parameter has no effect.

71.21.2.7 *name-filter*

For TCP/IP channel master jobs and for `ims-ms` channel jobs, the *name-filter* may be used to specify a message file name filter and/or a (destination) host name filter, using the syntax

file-name-filter@host-name-filter

This parameter is not respected by other channels.

71.21.2.8 *min-priority:max-priority*

This parameter is of historical interest only, and has no effect when the Job Controller is in use.

71.21.3 Description

The `imsimta run` utility processes the messages in the channel specified by the *channel* parameter.

In order to run the channel "outside" normal Job Controller processing (and the Job Controller's normal limits on job creation---that being one of the reasons that `imsimta run` is sometimes used, to force execution of a channel that the Job Controller would not normally want to run at that moment), a sort of light-weight, pseudo-Job Controller runs in your process, and it then forks the actual channel job. So some Job Controller-like output (Job Controller error output, or debug output if you have Job Controller debugging enabled) may be output at your terminal, and your terminal will be "tied up" for the duration of the operation of the utility, though the actual channel execution will be forked to a child process (which if channel debugging is enabled, will write its own debug log file, as usual).

See also the `imsimta submit` utility (or synonymous `imsimta submit_master` utility), which, unlike `imsimta run`, submits a request to start a job to the Job Controller (and the Job Controller then forks the actual channel job, as appropriate), so these other commands will not tie up your terminal.

As alluded to above, one of the typical purposes of using `imsimta run` is to start up an "extra" channel processing job, exempt from both the Job Controller's usual rules for triggering creation of a new job, and its configured limits on creation of channel processing jobs. As of MS 6.3, the `imsimta submit` utility will also trigger a new job creation (be exempt from the usual rules for triggering creation of a channel job), though only within the Job Controller's configured limit on the maximum number of channel processing jobs allowed. That is, either `imsimta run` or `imsimta submit` may be used to attempt to trigger an "additional" channel job---but only `imsimta run` guarantees that the request will in fact result in another job (possibly an "extra" job beyond the Job Controller's configured limits on numbers of jobs). Triggering creation of another job might be desired, for instance, when attempting to process a "large" backlog of messages; and creation of an "extra" job (beyond the usual `maxjobs` and `job_limit` limits) via `imsimta run` might be desired when you know that you want "extra" jobs beyond the Job Controller's configured limits.

Note that since `imsimta run` is using special routines to simulate Job Controller channel job creation from within your own process, it is not typically useful for purposes of viewing/debugging actual Job Controller operation.

71.21.4 Examples

```
# imsimta run tcp_local poll
```

The above UNIX command may be used to process any messages in the `tcp_local` channel.

71.22 shutdown utility

Shut down MTA components.

71.22.1 Syntax

```
imsimta shutdown [component]
```

71.22.1.1 Restrictions

Must have superuser privileges or use the Solaris RBAC feature in order to use this utility.

71.22.2 Parameters

71.22.2.1 *component*

The optional *component* parameter specifies a specific MTA component to be shut down. The components that may be specified are `job_controller`, `dispatcher`, and any services defined in the Dispatcher configuration, which typically might include `smtp`, `smtp_submit`, and `lmtpss`.

71.22.3 Description

The `imsimta shutdown` utility shuts down the MTA Job Controller and the MTA Dispatcher.

Note that shutting down the MTA Dispatcher causes a graceful shutdown of all services (*e.g.*, `SMTP`, `SMTP_SUBMIT`, `LMTPSS`) being managed by the MTA Dispatcher. That is, existing such server processes "finish up" whatever connections they currently have open, but do not accept new connections. As of MS 6.2p8, such server processes "finish up" processing of whatever message submissions were already in progress, but reject any attempts (even in the same, already opened connections) to submit further messages, with an effect as if `ALLOW_TRANSACTIONS_PER_SESSION`/`transactionlimit` had been reached. That is, prior to MS 6.2p8 while new connections would not be accepted, old connections might continue to work, accepting further message submissions; however, as of MS 6.2p8 even already existing connections are "poisoned" so that they may not receive additional new message submissions. (See the `disconnecttransactionlimit` channel option if you wish to have the server processes force a disconnect of connections once they will no longer accept further messages.)

Whenever the Job Controller is shutdown, before it shuts down it sends a "no more messages" notice to all its child processes (channel processes), which such processes will read from their communication buffer once they finish up whatever current message they are working on and wish to ask the Job Controller whether there are any more messages. That is, the Job Controller itself shuts down, but leaves a "poison" message in a buffer that the channel jobs will see as they each finish up their own work. So generally (but with a couple of exceptions, to be discussed just below) any old channel processes that the Job Controller had previously started finish up whatever message they had already been working on. Once a channel process has finished its already started work and then asks for another message to process, it will see that there are no more messages for it to process, and exit. However, exceptions are the `ims-ms` channel, and less commonly, outbound TCP/IP channels. When the Job Controller

has been shutdown, then `ims-ms` channels will interrupt processing even of currently being processed messages after a brief amount of time (an additional 55 seconds) spent attempting to complete processing of the current message; but the remaining recipients of a message for which processing had begun will be deferred for later processing; (when logging is enabled, "Z" records with a reason of "`shutdown`" will be generated for those recipients). TCP/IP channels will abort processing after their configurable `WINDDOWN_TIMEOUT` TCP/IP-channel-specific option time period has expired. (Note that the default value for `WINDDOWN_TIMEOUT` is relatively "large" due to the potential for undesirable remote SMTP server handling of aborted message transfers, and the potential expense of resending a "large" message.)

In typical Messaging Server configurations, `msprobe` may be configured to check periodically on the Job Controller, the SMTP server, and SMTP SUBMIT, and LMTP server; see the `msprobe.probe:job_controller.*`, `msprobe.probe:smtp.*`, `msprobe.probe:submit.*`, `msprobe.probe:lmtp.*`, and `schedule.task:msprobe.*` options in Unified Configuration. In particular, if with such configuration `msprobe` determines that the Job Controller, or a service managed by the Dispatcher, is not responding to its probe, and if autorestart has been enabled (`autorestart.enable` in Unified Configuration), then `msprobe` will ask the Watcher to restart the non-responsive process (such as the Job Controller or Dispatcher). So performing a `shutdown` of an MTA management process, or specific service (*e.g.*, `SMTP`) causes a temporary shutdown, but that shutdown is likely to be only temporary (unless such Messaging Server monitoring-and-automatic-restarting has not been enabled). (To shut down a service more permanently, the configuration should be more fundamentally modified: for instance, remove the Dispatcher's definition of the service in question, or to disable the Dispatcher or Job Controller, respectively, in Unified Configuration, set `dispatcher.enable` or `job_controller.enable` to `0`.) Thus the use/purpose of the `shutdown` command in modern usage tends to be to perform a *temporary* shutdown, perhaps while a configuration change is being made, with `imsimta startup` often used shortly thereafter, to start the component back up once a desired configuration change has been implemented.

71.22.4 Examples

```
# imsimta shutdown
Stopping dispatcher server 29020 ......... done
Stopping job_controller server 29637 . done
```

The above UNIX command shuts down the MS MTA, showing the sort of output shown in MS 6.3. (Earlier versions would not have as much/the same sort of output.)

```
# imsimta shutdown
dispatcher server is not running
job_controller server is not running
```

The above shows an example of the sort of output shown as of MS 6.3, if a `shutdown` command is issued when the MTA Dispatcher and Job Controller had not in fact been running.

71.22.5 Error messages

Trouble communicating with the Dispatcher, shutting it down, will be reported back to `stderr`:

```
dispatcher server is not running
```

or

```
Cannot stop dispatcher server (pid=pid) with SIGTERM
Retrying with SIGKILL
```

Trouble shutting down the Job Controller will be reported back to `stderr`:

```
job_controller server is not running
```

71.23 startup utility

Start the MTA Job Controller and the MTA Dispatcher.

71.23.1 Syntax

```
imsimta startup [component]
```

71.23.1.1 Restrictions

Must have superuser privileges or use the Solaris RBAC feature in order to use this utility.

71.23.2 Parameters

71.23.2.1 *component*

Optional parameter which specifies a specific MTA component to be started: `job_controller` or `dispatcher`. If no component name is given, then all active components will be started.

71.23.3 Description

The `imsimta startup` utility starts up detached MTA processes. If no component parameter is specified, then the MTA Job Controller and MTA Dispatcher are started. Note that starting the Dispatcher starts all services the Dispatcher is configured to handle, which may include, for instance, SMTP, SMTP SUBMIT, or LMTP servers. If a component parameter is specified, then only detached process associated with that component will be started. The standard component names are:

Table 71.17 `imsimta startup` Component Names

Component	Description
`dispatcher`	Dispatcher managing SMTP/SMTP SUBMIT/LMTP services
`job_controller`	Job Controller managing MTA channel processing jobs

Note that the services handled by the MTA Dispatcher must be started by starting (or restarting) the Dispatcher itself; only services *not* being handled by the Dispatcher can be individually started via the `imsimta startup` utility. (The Dispatcher may be configured to handle various services, *e.g.*, the SMTP, SMTP SUBMIT, and LMTP servers; see Dispatcher options for details.) Thus if adding a new service under the Dispatcher, or to reenable execution of a previously shutdown service which runs under the Dispatcher, on a running system you must restart the Dispatcher itself.

Since in Messaging Server usage, the overall Messaging Server startup command, `start-msg`, is normally used to start up not only the MTA but also other components of Messaging Server, the MTA-specific `imsimta startup` command is seldom used nowadays.

71.23.4 Examples

```
# imsimta startup
Starting dispatcher server ... 29034
Starting job_controller server . 29045
```

The above shows the sort of output shown as of MS 6.3, which includes the pids of the started Dispatcher and Job Controller processes.

```
# imsimta startup
dispatcher server is running already
job_controller server is running already
```

The above shows the sort of output issued in MS 6.3 if a `startup` command is issued when the MTA's Dispatcher and Job Controller were already running.

71.23.5 Error messages

Attempting to start up the Dispatcher when it is already running, or the Job Controller when it is already running, will be reported as an error to `stderr`:

```
dispatcher server is running already
```

```
job_controller server is running already
```

71.24 submit_master utility

Process messages in a specified channel.

71.24.1 Syntax

```
imsimta submit_master channel [poll-flag [host-pattern]]
```

Table 71.18 imsimta submit_master Command Switches

Switch	Default
`-delayed`	`-nodelayed`

71.24.1.1 Restrictions

Must have superuser privileges or be logged in as the MTA user (see the `user` option in `restricted.cnf`) in order to use this utility.

71.24.2 Parameters

71.24.2.1 *channel*

This required parameter specifies the channel to be processed.

71.24.2.2 *poll-flag*

Valid values for *poll-flag* are `nopoll` or its synonym `master` (the default), `poll`, or `slave`. By default, if neither `poll` nor `slave` is specified, the Job Controller will be requested to perform only a master direction execution of the channel (and the channel will not run unless there are actually messages waiting to be processed in that channel, whose `backoff` has expired). If `poll` is specified, the Job Controller will be requested to perform both master and slave direction executions of the channel. If `slave` is specified, the Job Controller will be requested to perform only a slave direction execution of the channel.

71.24.2.3 *host-pattern*

Specify a hostname for which to deliver. (This is not relevant for all channels, but for outgoing TCP/IP channels marked with the `single_sys` channel option, where the Job Controller maintains separate delivery queues for each distinct destination host, this parameter specifies which messages to consider delivering.)

71.24.3 Description

The `imsimta submit_master` utility requests that the Job Controller begin (consider beginning) a delivery job for the specified channel.

Note that stopped channels (`imsimta qm` utility's `stop` command) will not be run. And if there are already more than twice the `maxjobs` requests to run the channel, then this additional request will be ignored. A request will also be ignored if the backlog of messages

in the channel queue area is smaller than the number of already executing jobs for that channel times the `threaddepth` for the channel (unless there is only one executing job, in which case another job will be started). Note that the channel's `backoff` values will be respected in determing which, if any, messages to process. Thus it is rare that the `imsimta submit_master` utility is of much interest: generally, the Job Controller's intrinsic scheduling will already have started the maximum-appropriate-for-the-moment number of processing jobs for the channel, and so an `imsimta submit_master` command will have no immediate effect (other than causing the Job Controller to run through its checks before deciding that this additional request should be ignored). Since a limited (by `maxjobs`) number of such requests will be kept pending, in the medium term this utility may be used to attempt to influence the Job Controller to more aggressively schedule delivery of one destination host over another (within the same channel), via the *`host-pattern`* parameter; as the originally existing jobs terminate, the pending requests can begin to be honored.

See also the synonymous `imsimta submit` utility, and the `imsimta run` utility, which runs at your terminal outside the Job Controller's normally scheduling limits and checks (for instance, disregarding `backoff` conditions), rather than running as a regular Job Controller child process.

71.24.4 Switches

71.24.4.1 `-delayed`, `-nodelayed` (default)

By default (`-nodelayed`), the submitted job only considers and attempts processing of newly-submitted (have not yet received a delivery attempt) messages. To request delivery attempts for "old" messages (those that have already received one or more delivery attempts), use `-delayed`.

71.24.5 Examples

```
# imsimta submit_master tcp_local poll
```

The above UNIX command may be used to process any messages in the `tcp_local` channel.

71.25 submit utility

`imsimta submit` is an abbreviation for `imsimta submit_master`.

71.26 test -domain_map utility

Test a domain (domain map) lookup.

71.26.1 Syntax

```
imsimta test -domain_map [expression]
```

Table 71.19 imsimta test -domain_map Command Switches

Switch	Default
`-debug`	`-nodebug`
`-image_file`	`-noimage_file`
`-input=`*`filename`*	*None*
`-option_file=`*`file-spec`*	`-option_file=IMTA_TABLE:option.dat`
`-xml_config=`*`file-spec`*	*None*

71.26.2 Description

`imsimta test -domain_map` is an interactive utility for testing how domains are provisioned in LDAP.

Especially common uses/commands to use are to list (properly) provisioned domains in LDAP using the `ENUMERATE` command, or verify proper (as regards MTA requirements) provisioning of domains in LDAP using the `VERIFY` command.

Targetted probing of specific domain definitions can also be performed. A base command sequence is to `LOCATE` and then `SHOW` a domain:

```
DOMAIN_MAP> LOCATE DOMAIN mrochek.com
Entry located
DOMAIN_MAP> SHOW
Domain name: mrochek.com
Canonical name: mrochek.com
Lower case canonical name: mrochek.com
Base DN: o=mrochek.com,o=usergroup
Domain DN: dc=mrochek,dc=com,o=internet
```

After locating a domain, you can probe the value of a specific basic attributes:

```
DOMAIN_MAP> LOCATE DOMAIN mrochek.com
Entry located
DOMAIN_MAP> QUERY inetDomainBaseDN
Attribute value(s):
  [0] "o=doof,o-mrochek.org,o=usergroup"
DOMAIN_MAP> QUERY inetCanonicalDomainName
Attribute value(s):
  [0] "mrochek.org"
```

If you wish to know about other than the couple of basic attributes, then you have to let the utility know about such attributes via the ATTRIBUTE command *before* doing the LOCATE. *E.g.,*

```
DOMAIN_MAP> LOCATE DOMAIN mrochek.com
Entry located
DOMAIN_MAP> QUERY creatorsname
Not on known attribute list
DOMAIN_MAP> ATTRIBUTE creatorsname
Attribute now known to map
DOMAIN_MAP> LOCATE DOMAIN mrochek.com
Entry located
DOMAIN_MAP> QUERY creatorsname
Attribute value(s):
  [0] "cn=directory manager"
```

71.26.3 Commands

imsimta test -domain_map commands shows the interactive commands available.

Table 71.20 imsimta test -domain_map commands

Command	Purpose
ATTRIBUTE *attr-name*	Tell the utility the name of an LDAP attribute which you wish to be able to do QUERY on; only necessary for non-basic attributes.
CANONICALIZE *dn*	Return the canonicalized DN.
ENUMERATE [*extra-filter-terms*]	List all provisioned domains; or if some *extra-filter-terms* have been specified, all domains matching the filter.
ENUMERATE -ALIASES [*extra-filter-terms*]	(New in MS 7.4) List all provisioned domains and domain aliases; or if some *extra-filter-terms* have been specified, all domains and domain aliases matching the filter.
EXIT	Exit the utility.
LOCATE DOMAIN *domain*	Locate the specified (by name) domain entry. (Release any previously LOCATEd domain.)
LOCATE BASEDN *dn*	Locate the specified (by base DN) domain entry. (Release any previously LOCATEd domain.)
QUERY *attribute*	Return the value(s) of the specified *attribute* of the previously LOCATEd domain.
QUERY -LOCATION=*n* *attribute*	Return the *n*th value of the specified *attribute* of the previously LOCATEd domain. (Recall that the LDAP specification makes no guarantees regarding the order in which attributes and values are returned, so the result of such a command may vary even while the data in LDAP remains the same.)
QUIT	Quit the utility.
RELEASE	Release the presently LOCATEd domain entry.
SHOW	Show the (previously LOCATEd) domain.
USER ADD *dn*	Add the specified user to the utility's in-memory hash table of users belonging to the previously LOCATEd domain.

`USER DELETE` *dn*	Delete the specified user from the utility's in-memory hash table of users belonging to the previously `LOCATE`d domain.
`USER DNADMIN` *dn*	Check whether or not the specified (by DN) user is an admin. (In particular, an admin user entry will have the object classes `groupOfUniqueNames` and `inetMailAdministrator`.)
`USER IDADMIN` *id*	Check whether or not the specified (by ID) user is an admin. (In particular, an admin user entry will have the object classes `groupOfUniqueNames` and `inetMailAdministrator`.)
`USER TEST` *dn*	Check whether the specified user is in the utility's in-memory hash table of users belonging to the previously `LOCATE`d domain.
`VERIFY`	Check the provisioning of domains in LDAP, potentially returning various errors if any error (as regards MTA requirements for domain provisioning) is found.

71.26.4 Error messages

Below are listed possible warnings and errors that may be reported. Note that "errors" are reported when a domain is defined in a way not suitable for MTA use as an addressing or routing domain; however, if a domain is defined in LDAP for use by some component(s) other than (not including) Messaging Server, then it is not *necessarily* an error to have a domain defined in a fashion inappropriate for MTA domain usage. That is, reports of "errors" regarding domain definitions must be interpreted in light of a site's intended usage of domains: errors reported regarding domains used by the MTA are definitely problems, but "errors" reported regarding other domains must be interpreted in light of such a domain's intended usage.

`Missing, empty, invalid or duplicate entry`

- **Facility:** General
- **Severity:** Error
- **Explanation:** Problem with a domain entry

`Identifier too long`

- **Facility:** General (*e.g.*, `imsimta test -domain_map LOCATE` *`domain-name`*)
- **Severity:** Error
- **Explanation:** Specified domain name was too long.

`Attribute not listed`

- **Facility:** General (*e.g.*, `imsimta test -domain_map QUERY` *`attribute-name`*)
- **Severity:** Error
- **Explanation:** Specified attribute not found in domain entry.

`LDAP error`

- **Facility:** General
- **Severity:** Error
- **Explanation:** Trouble communicating with LDAP.

`Bad schema level`

- **Facility:** General
- **Severity:** Error
- **Explanation:** Schema mode other than 1 or 2 specified.

`%DMAP-E-ALIASANDBASEDN, Domain alias entry '`*`domain-name`*`' also contains a base DN`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The supposed domain alias entry has an `inetDomainBaseDN` LDAP attribute (in the case of the MTA, more precisely, whatever LDAP attribute is named by the `ldap_domain_attr_basedn` MTA option), which is an attribute that ought only to be present on an actual domain entry, not on a domain alias entry.
- **User Action:** If this domain entry is truly intended as a domain alias entry, then remove the `inetDomainBaseDN` LDAP attribute from it (while also making sure that the real domain entry does have an `inetDomainBaseDN` attribute present). If, however, this domain entry ought instead to be its own, real domain entry, then remove the LDAP attributes (such as `aliasedObjectName`) that are setting it up as a domain alias entry.

`%DMAP-E-ALIASTOOLONG, Domain alias '`*`domain-name`*`' in entry with DN '`*`DN-string`*`' is too long`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The domain entry has a `associatedDomain` LDAP attribute (or for the MTA, more precisely whatever LDAP attribute is named by the `ldap_attr_domain2_schema2` MTA option) with a value longer than 1024 characters.
- **User Action:** Shorten the `associatedDomain` value.

`%DMAP-E-BASEDNTOOLONG, Base DN '`*`DN-string`*`' in base entry for domain '`*`domain-name`*`' is too long`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** Schema 2. This domain entry has no explicit `inetDomainBaseDN` (optional in Schema 2) and the DN of this domain entry, when converted to a string, is longer than 1024 characters.
- **User Action:** One possibility is to add an explicit `inetDomainBaseDN` attribute (or more precisely, for the MTA add whatever attribute is named by the `ldap_domain_attr_basedn` MTA option) specifying where users/groups in this domain are stored in the DIT; while this may work around this immediate issue, note that if the DNs in your DIT are long enough to trigger this error, then you may encounter other processing difficulties due to the "long" DNs. Alternatively, shorten the DNs for your domains; this may require some restructuring of your domain names or DIT, but lead to more satisfactory processing in general.

`%DMAP-E-BASEDNTOOLONG, Base DN pointer '`*`DN-string`*`' in entry for domain '`*`domain-name`*`' is too long`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The `inetDomainBaseDN` value (for the MTA, more precisely the value of whatever attribute is named by the `ldap_domain_attr_basedn` MTA option) is longer than 1024 characters.
- **User Action:** Shorten the `inetDomainBaseDN`, restructuring the data in the directory, if necessary.

`%DMAP-E-CANONICAL, Overlapping domains '`*`domain-name-1`*`' and '`*`domain-name-2`*`' defined by entries '`*`DN-1`*`' and '`*`DN-2`*`' have different canonical domains '`*`canon-name-1`*`' and '`*`canon-name-2`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The domain name usage is not consistent: domains with overlapping sets of users have conflicting "canonical" domain names.
- **User Action:** Check the structuring of the domains, especially the use of the `inetDomainBaseDN` and `inetCanonicalDomainName` LDAP domain attributes (or more precisely, the attributes named by the `ldap_domain_attr_basedn` and `ldap_domain_attr_canonical` MTA options).

`%DMAP-E-CANONICALINVALID, Canonical domain '`*`canon-name`*`' defined/referenced by domain entry with DN '`*`dn-string`*`' is syntactically invalid`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The `inetCanonicalDomainName` domain attribute (or more precisely, the LDAP domain attribute named by the `ldap_domain_attr_canonical` MTA option) has a value which is not syntactically valid as a domain name.
- **User Action:** Ensure that the canonical domain name is a syntactically valid, fully-qualified, Internet domain name. (Note that a not-fully-qualified domain name, a "short form" host name, will instead result in the error below: `%DMAP-E-CANONICALSHORTFORM`.)

`%DMAP-E-CANONICALSHORTFORM, Short form canonical domain '`*`domain-name`*`' defined/reference by domain entry with DN '`*`dn-string`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The `inetCanonicalDomainName` (or more precisely, the LDAP domain attribute named by the `ldap_domain_attr_canonical` MTA option) has its value set to a "short form" host name value rather than a fully qualified domain name.
- **User Action:** Change the value to be a fully qualified domain name. There are some places where it is acceptable to use a "short form" host name, but the canonical domain name should be a fully qualified domain name.

`%DMAP-E-CANONICALTOOLONG, Canonical name '`*`canon-name`*`' in entry for domain '`*`domain-name`*`' is too long`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The `inetCanonicalDomainName` domain attribute (or more precisely, the LDAP domain attribute named by the `ldap_domain_attr_canonical` MTA option) has a value longer than 1024 characters.
- **User Action:** Shorten the canonical domain name.

`%DMAP-E-CANTCONVDCDN, Cannot convert alias pointer DN '`*`aliasedObjectName-value`*`' for domain alias `*`domain-name`*` to domain name`

- **Facility:** `dmap_verify`
- **Severity:** Error

- **Explanation:** The DN specified by the `aliasedObjectName` LDAP attribute (in the case of the MTA, more precisely, whatever LDAP attribute is named by the `ldap_domain_attr_alias` MTA option), could not be processed to produce a domain name; presumably it was not of a *organization* sort of form.
- **User Action:** Check that the `aliasedObjectName` value is correctly specified.

`%DMAP-E-CANTCONVDCDN, Cannot convert DN '`*`dn-string`*`' in DC tree to domain name`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** A failure occurred attempting to convert the domain's DN into a domain name.
- **User Action:** Check the LDAP domain structure.

`%DMAP-E-CANTEXTALIAS, Empty alias pointer attribute in '`*`domain-name`*`' domain alias entry`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The supposed domain alias entry has no `aliasedObjectName` LDAP attribute (in the case of the MTA, more precisely, none of whatever LDAP attribute is named by the `ldap_domain_attr_alias` MTA option).
- **User Action:** Add an `aliasedObjectName` attribute pointing to a "real" domain entry.

`%DMAP-F-CANTGETDN, Cannot obtain DN of domain entry, directory error`

- **Facility:** `dmap_verify` routine (called by, *e.g.*, `imsimta test -domain_map verify`)
- **Severity:** Fatal
- **Explanation:** An unexpected error: something "wrong" has happened with the data in the LDAP directory, or with retrieval and basic handling of that data.
- **User action:** There may be something seriously wrong with the LDAP directory. Verify that the LDAP directory is operating and its data is uncorrupted.

`%DMAP-W-DISALLOWEDATTR, Domain '`*`domain-name`*`' has a disallowed attribute '`*`attr-name`*`' with value '`*`string`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Warning

- **Explanation:** The `iplanet-am-user-account-life` domain attribute is present (and has a value set).
- **User Action:** Remove the attribute.

`%DMAP-E-DNTOOLONG, Domain entry DN beginning with '`*`dn-string`*`' is too long`

- **Facility:** `dmap_verify` routine (called by, *e.g.,* `imsimta test -domain_map verify`)
- **Severity:** Error
- **Explanation:** The DN for this domain is longer than the maximum permitted DN length (1024 characters).
- **User action:** If this domain is one that it is desired that the MTA make use of (say in addressing or routing), then change its DN to something shorter; this may require some restructuring of data and entries in LDAP.

`%DMAP-E-DOMAINALIASINVALID, Domain alias '`*`string`*`' defined/referenced by domain entry with DN '`*`DN-string`*`' is syntactically invalid`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** A domain alias, whether found via `aliasedObjectName` pointer in Schema 1 mode, or set as a `associatedDomain` in Schema 2 mode, (see the `ldap_domain_attr_alias` or `ldap_attr_domain2_schema2` MTA options) is not a syntactically valid domain name.
- **User Action:** Correct the domain alias.

`%DMAP-E-DOMAININVALID, Domain name '`*`domain-name`*`' defined/referenced by domain entry with DN '`*`DN-string`*`' is syntactically invalid`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The domain name (whether constructed from the "`dc`" chunks in the `DN` in Schema 1 mode, or found in the `sunPreferredDomain` attribute in Schema 2 mode) is not syntactically valid.
- **User Action:** Correct the domain entry.

`%DMAP-E-DOMAINMULTDEF, Domain '`*`domain-name`*`' multiply defined by entries with DNs '`*`DN-string-1`*`' and '`*`DN-string-2`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** Two different domain entries in Schema 2 mode both claim the same domain name, that is, have the same value in either of their respective `sunPreferredDomain` or `associatedDomain` LDAP attributes (or for the MTA, more precisely whatever LDAP attributes are named by the `ldap_attr_domain1_schema2` and `ldap_attr_domain2_schema2` MTA options).
- **User Action:** Correct the domain entries so that each domain entry has its own, unique, domain name (its own, unique, `sunPreferredDomain` value) and so that different domain entries do not claim the same domain alias (same `associatedDomain` value). Note that it is perfectly normal and legitimate to have domain aliases, and overlapping domain name usage is also legitimate and supported -- but there are correct ways to provision such usage. A domain alias is configured in Schema 2 via use of the `associatedDomain` LDAP attribute on the real domain entry. Overlapping domain name usage is configured by use of distinct domain entries that specify and control overlap via `inetDomainBaseDN` and `inetCanonicalDomain` LDAP attributes.

`%DMAP-E-DOMAINTOOLONG, Domain '`*`domain-name`*`' in entry with DN '`*`DN-string`*`' is too long`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The domain entry's (Schema 2 mode) domain name, that is, the value in its `sunPreferredDomain` LDAP attribute (or for the MTA, more precisely whatever LDAP attribute is named by the `ldap_attr_domain1_schema2` MTA option), is longer than 1024 characters.
- **User Action:** Shorten the `sunPreferredDomain` value so that it is at most 1024 characters long.

`%DMAP-E-DOMAINUNDEF, Domain name '`*`domain-name`*`' referenced by domain entry with DN '`*`DN-string`*`' never defined`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The domain name usage is not consistent; an undefined domain name has been found.
- **User Action:** Check the list of domains that can be properly located in the directory (see for instance the `ENUMERATE` command of `imsimta test -domain_map`), and compare with the list of domains you desire to have defined: look for any "orphan" (undefined/not located) domain name.

`%DMAP-W-EMPAPPSTAT, Domain '`*`domain-name`*`' has an empty application`

`status`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The `mailDomainStatus` domain attribute (or more precisely, the LDAP domain attribute named by the `ldap_domain_attr_mail_status` MTA option) is present but with no value set.
- **User Action:** The MTA interprets a missing value as meaning "`inactive`", but a valid value should be set (especially as non-MTA components may have other behaviors upon failing to find a valid value).

`%DMAP-W-EMPDEFMAILHOST, Domain '`*`domain-name`*`' has an empty mailHost default`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The domain LDAP attribute named by the `ldap_domain_attr_default_mailhost` MTA option (not set by default) is present, but has no value set.
- **User Action:** Set a valid value, or remove the attribute.

`%DMAP-W-EMPDISALLOWED, Domain '`*`domain-name`*`' has an empty disallowed attribute`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The `iplanet-am-user-account-life` domain attribute is present, but with no value set.
- **User Action:** Remove the attribute.

`%DMAP-W-EMPDOMSTAT, Domain '`*`domain-name`*`' base node at `*`DN-string`*` has an empty domain status`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** Schema 2. The domain entry has no `inetDomainStatus` attribute, or such an attribute has no value set. (For MTA purposes, more precisely the attribute named by the `ldap_domain_attr_status` MTA option is not present or is present but with no value set.) Processing will continue after this warning; indeed the MTA treats such a missing attribute or empty value as equivalent to a setting of `active`.

- **User Action:** Consider setting `inetDomainStatus` to a value of `active` for clarity (and to avoid this warning).

`%DMAP-E-EMPTYBASEDN, Domain '`*`domain-name`*`' has an empty base DN`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The domain entry has an `inetDomainBaseDN` attribute (or for the MTA, more precisely whatever attribute is named by the `ldap_domain_attr_basedn` MTA option), but with no value set for that attribute.
- **User Action:** In Schema 1 mode, this attribute must be present and must have a value: set a value for the attribute. In Schema 2 mode, this presence of this attribute is optional, but if present it must have a value: either remove the attribute entirely (if the user entries are all located directly under the domain entry), or set a correct value for the attribute.

`%DMAP-E-EMPTYCANONICAL, Domain '`*`domain-name`*`' has an empty canonical name`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The `inetCanonicalDomainName` domain attribute (or more precisely, the LDAP domain attribute named by the `ldap_domain_attr_canonical` MTA option) is present but does not have a value.
- **User Action:** Either remove the attribute, or set a valid value for it.

`%DMAP-W-EMPUIDSEP, Domain '`*`domain-name`*`' has an empty UID separator attribute`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The `domainUidSeparator` domain attribute (or more precisely, the LDAP attribute named by the `ldap_domain_attr_uid_separator` MTA option) is present, but with no value set.
- **User Action:** Set a valid value, or remove the attribute. Note that while the MTA doesn't directly use the value, the authentication library code *does* make use of the attribute's value.

`%DMAP-F-INTDEFERROR, Internal defined flag error on domain '`*`domain-name`*`', aborting`

- **Facility:** `dmap_verify`

- **Severity:** Fatal
- **Explanation:** The code encountered a problem with its internal hashed storage of domain names, possibly a coding error.
- **User Action:** Report this error to Oracle.

`%DMAP-F-INTHASHERROR, Internal hash error, aborting`

- **Facility:** `dmap_verify`
- **Severity:** Fatal
- **Explanation:** The code encountered a problem with its internal hashed storage of domain names or domain base DNs, possibly a coding error.
- **User Action:** Report this error to Oracle.

`%DMAP-F-INTHASHERROR, Internal tree structure error, aborting`

- **Facility:** `dmap_verify`
- **Severity:** Fatal
- **Explanation:** The code encountered a problem with its domain tree structure, possibly a coding error.
- **User Action:** Report this error to Oracle.

`%DMAP-F-INTTREESTRUCTERROR, Internal tree structure error, aborting`

- **Facility:** `dmap_verify`
- **Severity:** Fatal
- **Explanation:** The code encountered a problem with its domain tree structure, possibly a coding error.
- **User Action:** Report this error to Oracle.

`%DMAP-W-INVALIDAPPSTAT, Application status '`*`string`*`' for domain '`*`domain-name`*`' is invalid`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The `mailDomainStatus` domain attribute (or more precisely, the LDAP domain attribute named by the `ldap_domain_attr_mail_status` MTA option) has an invalid value set: a value which is none of `active`, `inactive`, `overquota`, `removed`, `unused`, `nonlocal`, `disabled`, `hold`, or `deleted`.

- **User Action:** Set a valid value. Although the MTA will interpret invalid values as meaning "`inactive`", it is unwise to rely on that effect when other components with other behavior may also interpret (and interpret differently) the attribute's value.

`%DMAP-E-INVALIDBASEDN, Base DN pointer '`*`DN-string`*`' in entry for domain '`*`domain-name`*`' is not a valid DN`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The `inetDomainBaseDN` domain attribute's value, (for MTA purposes, the value of whatever attribute is named by the `ldap_domain_attr_basedn` MTA option), does not parse properly as a DN.
- **User Action:** Check for syntax errors in the value of `inetDomainBaseDN`.

`%DMAP-E-INVALIDDEFMAILHOST, Default mailHost '`*`host-string`*`' for domain '`*`domain-name`*`' is invalid`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The domain LDAP attribute named by the `ldap_domain_attr_default_mailhost` MTA option (not set by default) is set to a value which is not a syntactically valid domain name.
- **User Action:** Specify a syntactically valid (and, one hopes, semantically correct) domain name as the value.

`%DMAP-W-INVALIDDOMSTAT, Domain status '`*`status`*`' for domain '`*`domain-name`*`' base node at `*`DN-string`*` is invalid`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** Schema 2. The `inetDomainStatus` value (for MTA purposes, the value of whatever attribute is named by `ldap_domain_attr_status`) was not valid: it was something other than `active`, `inactive`, or `deleted`. Processing will continue after this warning.
- **User Action:** If this is a domain intended for mail use by the MTA, set a valid value for `inetDomainStatus`; however, if this domain is not going to be used for mail purposes, this warning may not be of concern. (Note that "switching" of the meaning of `inetDomainStatus` and `inetDomainMailStatus` is supported by the MTA, by "switching" the values of `ldap_domain_attr_status` and `ldap_domain_attr_mail_status`, with the attribute named by `ldap_domain_attr_mail_status`, normally `inetDomainMailStatus`, allowing

additional supported values. So other than a simply outright "wrong" value for `inetDomainStatus`, another possibility is that the meanings and hence values were "switched" in a prior configuration.)

`%DMAP-W-INVALIDUIDSEP, Domain '`*`domain-name`*`' has an empty UID separator attribute`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The `domainUidSeparator` domain attribute (or more precisely, the LDAP attribute named by the `ldap_domain_attr_uid_separator` MTA option) is set to a value containing invalid characters.
- **User Action:** Set a valid value. Note that while the MTA doesn't directly use the value, the authentication library code *does* make use of the attribute's value.

`%DMAP-W-MULTDOMAINNAMES, Domain entry with DN '`*`DN-string`*`' has multiple domain names, used value '`*`name-1`*`' ignored '`*`name-2`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The domain entry has multiple values of the `sunPreferredDomain` LDAP attribute (or for the MTA, more precisely whatever LDAP attribute is named by the `ldap_attr_domain1_schema2` MTA option). Processing will continue---but this is presumably a provisioning error.
- **User Action:** Remove the extraneous `sunPreferredDomain` values.

`%DMAP-W-MULTIAPPSTAT, Multivalued application status in entry for domain '`*`domain-name`*`', used value '`*`first-found`*`' ignored '`*`later-found`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The `mailDomainStatus` domain attribute (or more precisely, the LDAP domain attribute named by the `ldap_domain_attr_mail_status` MTA option) has multiple values set.
- **User Action:** Remove the extraneous values: this should be a single-valued attribute. Note that as LDAP leaves unspecified the order in which values are returned, having multiple values set will result in unpredictable/unreliable results.

`%DMAP-W-MULTIBASEDN, Multivalued base DN pointer in entry for domain '`*`domain-name`*`', used value '`*`DN-string-1`*`' ignored '`*`DN-string-2`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The domain entry has two (or more) `inetDomainBaseDN` values (or for the MTA, more precisely multiple values of whatever LDAP attribute is named by the `ldap_domain_attr_basedn` MTA option). Processing continues, but a warning is issued since this is presumably a provisioning error.
- **User Action:** Remove all but one `inetDomainBaseDN` value, as only one value will be used. Note that if user/group entries for the domain are currently scattered under multiple locations in the DIT, attempting to set multiple `inetDomainBaseDN` values to point to those multiple locations will not work---instead, one `inetDomainBaseDN` must be specified above *all* the user/group entries for the domain, restructing the DIT if necessary to achieve this.

`%DMAP-E-MULTICANONICAL, Multivalued canonical name in entry for domain '`*`domain-name`*`', used value '`*`first-found`*`' ignored '`*`later-found`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The `inetCanonicalDomainName` domain attribute (or more precisely, the LDAP domain attribute named by the `ldap_domain_attr_canonical` MTA option) has multiple values set.
- **User Action:** It is a provisioning error to have multiple canonical domain names set: remove the extraneous value(s). Note that the LDAP specification does not define which value will be returned "first", and indeed the order may vary from LDAP query to LDAP query. So although processing will continue after such an error, the resulting effect during operation may be unreliable, if varying canonical names are returned.

`%DMAP-E-MULTIDEFMAILHOST, Multivalued mailhost default in entry for domain '`*`domain-name`*`', used value '`*`value-0`*`' ignored '`*`value-1`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** The domain LDAP attribute named by the `ldap_domain_attr_default_mailhost` MTA option (not set by default) has multiple values set.
- **User Action:** Remove the extraneous values.

`%DMAP-W-MULTIDOMSTAT, Multivalued domain status in entry for domain '`*`domain-name`*`' base node at `*`DN-string`*`, used value '`*`status-0`*`' ignored '`*`status-1`*`'`

- **Facility:** `dmap_verify`

- **Severity:** Warning
- **Explanation:** Schema 2. Multiple `inetDomainStatus` values (for MTA purposes, multiple values for whatever attribute is named by `ldap_domain_attr_status`) were found. Processing will continue after this warning, with whatever value LDAP happened to return first being used.
- **User Action:** Remove all but one (correct) value for `inetDomainStatus`.

`%DMAP-W-MULTIUIDSEP, Multivalued UID separator in entry for domain '`*`domain-name`*`', used value '`*`value-0`*`' ignored '`*`value-1`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The `domainUidSeparator` domain attribute (or more precisely, the LDAP attribute named by the `ldap_domain_attr_uid_separator` MTA option) has multiple values.
- **User Action:** Remove the extraneous values. Recall that as LDAP makes no guarantees regarding the order in which values are returned, having multiple values can lead to unpredictable/unreliable results. Note that while the MTA doesn't directly use the value, the authentication library code *does* make use of the attribute's value.

`%DMAP-W-MULTIVALIAS, Multivalued alias pointer in entry for domain alias '`*`domain-name`*`', used value '`*`DN-string-0`*`', ignored '`*`DN-string-x`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The supposed domain alias entry has multiple values of the `aliasedObjectName` LDAP attribute (in the case of the MTA, more precisely, multiple values for whatever LDAP attribute is named by the `ldap_domain_attr_alias` MTA option). All values other than the "first" that happened to be reported on this LDAP query will be ignored---but recall that LDAP makes no guarantee as to the order in which attributes are returned, so such ordering and hence which value is used may vary between different queries! Since getting inconsistent effects, varying with the order in which the LDAP directory happened to return results, is unlikely to be desirable, this is a warning of what can be presumed to be a provisioning error, though processing will continue using the "first" value reported by LDAP.
- **User Action:** Remove all the redundant or extraneous `aliasedObjectName` values, so that only the one correct value remains in the domain alias entry, and so that consistent processing will occur.

`%DMAP-E-NOBASEDN, Domain '`*`domain-name`*`' has no base DN`

- **Facility:** `dmap_verify`

- **Severity:** Error
- **Explanation:** Schema 1. This domain entry has no explicit `inetDomainBaseDN`, (or for the MTA, more precisely whatever LDAP attribute is named by the `ldap_domain_attr_basedn` MTA option); such an attribute is required in Schema 1.
- **User Action:** Add an `inetDomainBaseDN` attribute specifying where users/groups in this domain are stored in the DIT.

`%DMAP-E-NOBASEDN, Domain '`*`domain-name`*`' has an empty base DN`

- **Facility:** `dmap_verify`
- **Severity:** Error
- **Explanation:** Schema 1 or Schema 2. This domain entry has an `inetDomainBaseDN` LDAP attribute, (or for the MTA, more precisely whatever LDAP attribute is named by the `ldap_domain_attr_basedn` MTA option) with no value set.
- **User Action:** Specify a value for the `inetDomainBaseDN` LDAP attribute specifying where users/groups in this domain are stored in the DIT; or in Schema 2 *only* another alternative is to remove the `inetDomainBaseDN` attribute entirely, to indicate that users and groups in this domain will be located directly under this domain entry in the DIT.

`%DMAP-W-NOBASEDNNODE, Base DN pointer '`*`DN-string`*`' in entry for domain '`*`domain-name`*`' doesn't point at anything`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The `inetDomainBaseDN` value (for the MTA, more precisely the value of whatever attribute is named by the `ldap_domain_attr_basedn` MTA option) corresponds to no actual node in the directory. Processing will continue after this warning.
- **User Action:** If the domain in question is intended for current use, then this is a warning of some form of provisioning error: either the `inetDomainBaseDN` value is incorrect, or the data supposed to be in the directory is missing or in the "wrong" location. However, if this is a "place-holder" domain entry intended for later use, but not yet fully provisioned (in particular not yet provisioned with any users), then this warning may not be of concern at this time. Decide whether the domain in question is intended for current use, and if so, ensure that its `inetDomainBaseDN` value points to the intended base DN under which its users are, or will be, located.

`%DMAP-E-NODOMAINNAME, Domain entry with DN '`*`DN-string`*`' does not have a domain name`

- **Facility:** `dmap_verify`
- **Severity:** Error

- **Explanation:** Schema 2. The domain entry does not have a `sunPreferredDomain` LDAP attribute (or for the MTA, more precisely whatever LDAP attribute is named by the `ldap_attr_domain1_schema2` MTA option).
- **User Action:** Add the domain name to the entry; that is, add a `sunPreferredDomain` LDAP attribute specifying the desired domain name.

`%DMAP-W-NODOMAINNAME, Domain entry with DN '`*`DN-string`*`' has a blank domain alias`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** Schema 2. The domain entry has a `associatedDomain` LDAP attribute (or for the MTA, more precisely whatever LDAP attribute is named by the `ldap_attr_domain2_schema2` MTA option) with no value. Processing continues, but a warning is issued since this is presumably a provisioning error.
- **User Action:** Either set a valid value in `associatedDomain`, or remove the attribute.

`%DMAP-W-NOENTRIES, No domain entries found, aborting`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** No domain entries were found.
- **User Action:** This is the expected output if pointing to an LDAP directory that does not contain Schema 1 or Schema 2 compatible domain entries. However, if the MTA has been configured to consult an LDAP directory that does (supposedly) contain valid domain entries, then something is wrong with basic configuration: *e.g.*, MTA configuration for what LDAP directory to consult is incorrect, or the MTA cannot see the domain entries (authentication problems, or ACLs preventing access), or the MTA has not been configured properly for where in the DIT to look to find domain entries.

`%DMAP-W-SHORTFORMDEFMAILHOST, Default mailHost '`*`host-string`*`' for domain '`*`domain-name`*`' is a shortform name`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The domain LDAP attribute named by the `ldap_domain_attr_default_mailhost` MTA option (not set by default) is set to a short form hostname value, rather than to a fully qualified domain name.
- **User Action:** Use of fully qualified domain names is strongly recommended: change value to be in fully qualified form.

`%DMAP-W-SHORTFORMDOMAIN, Short form domain name '`*`domain-name`*`' defined/referenced by domain entry with DN '`*`DN-string`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** The domain name (whether constructed from the "`dc`" chunks in the `DN` in Schema 1 mode, or found in the `sunPreferredDomain` attribute in Schema 2 mode) is a "short form" host name, rather than a fully qualified domain name.
- **User Action:** Use of fully qualified domain names is *strongly* recommended; strongly consider revisiting domain name usage and switching to use of fully qualified domain names.

`%DMAP-W-SHORTFORMDOMAINALIAS, Short form domain alias '`*`string`*`' is defined/referenced by domain entry with DN '`*`DN-string`*`'`

- **Facility:** `dmap_verify`
- **Severity:** Warning
- **Explanation:** A domain alias has been specified in "short form" host name form, rather than as aa fully qualified domain name.
- **User Action:** Use of fully qualified domain names is *strongly* recommended; strongly consider revisiting domain name usage and switching to use of fully qualified domain names.

71.27 test -eightbit utility

Test whether a file contains eight bit material.

71.27.1 Syntax

```
imsimta test -eightbit filename
```

Table 71.21 imsimta test -eightbit Command Switches

Switch	Default
-performance	-noperformance
-summary	-nosummary
-number	-number
-mode=n	-mode=0

71.27.2 Parameters

71.27.2.1 *filename*

The name of the file to inspect for eight bit material.

71.27.3 Description

Check whether or not a file contains eight bit material.

The output of this utility will say either:

```
File contains one or more 8-bit chars
```

or

```
File contains no 8-bit chars
```

In -noperformance -nosummary operation (the default), the output will also show which line(s) contained eight bit material, with line numbers (unless -nonumber has been specified).

71.27.4 Switches

71.27.4.1 -performance, -noperformance (default)

When -performance is specified, the utility reads the entire file into memory and then scans the in-memory copy of the file. -performance operation may be faster, but does not allow for outputting which line(s) contained eight bit material. -performance may not be specified if -summary is specified.

71.27.4.2 -summary, -nosummary (default)

Specifying -summary disables outputting which specific lines contained eight bit material. -nosummary (meaning that such lines are output) is the default. -summary may not be explicitly specified if -performance is specified; -performance always causes summary-like output.

71.27.4.3 -number (default), -nonumber

-number (the default) means that when outputting lines containing eight bit material (which is done in -nosummary -noperformance operation), to prefix those lines with line numbers. -nonumber turns off the line numbering.

71.27.4.4 -mode=*n*

The default is -mode=0.

71.27.5 Examples

```
# imsimta test -eightbit IMTA_LIB:locale/en/return_error.txt
File contains no 8-bit chars
# imsimta test -eightbit IMTA_LIB:locale/fr/return_error.txt
     1 Des erreurs de traitement se sont produites lors de la distribution?:
     4 Le traitement de la distribution s'est poursuivi malgr? ces erreurs.
File contains one or more 8-bit chars
```

The above two commands show example output for a file containing no eight bit characters, compared to a file that does contain eight bit characters. (Note that unless you have gone to special work on a UNIX system to properly display eight bit characters, any eight bit character is likely to appear as a question mark, as shown in this example.)

71.28 test -expression utility

Test an expression, *e.g.*, a Sieve filter or configuration recipe.

71.28.1 Syntax

```
imsimta test -expression
```

Table 71.22 imsimta test -expression Command Switches

Switch	Default
`-statement=`*n*	`-statement=1`
`-multiple`	`-multiple`
`-block`	`-noblock`
`-symbols`	`-nosymbols`
`-uav=`*n*	`-uav=1`
`-input=`*filename*	*None*
`-output=`*filename*	*None*
`-parseonly`	*None*
`-string=`*n*	`-string=65535`
`-iterations=`*n*	`-iterations=`*max_sieve_match_iterations*
`-list=`*n*	`-list=`*max_sieve_list_size*
`-debug[=`*n*`]`	`-debug=1`
`-mm`	*See text*
`-xc`	*See text*
`-message=`*filename*	*None*
`-required`	`-required`
`-from=`*address*	`-from="`*postmaster-address*`"`
`-to=`*recipient-address*	`-noto`
`-envid=`*id*	`-noenvid`
`-system`	`-nosystem`
`-mtpriority=`*n*	`-mtpriority=0`
`-sender=`*sender*	`-nosender`
`-username=`*username*	`-nousername`
`-utf8`	`-noutf8`
`-source=`*source-channel-name*	`-source=l`
`-rsecret=`*recall-secret*	`-norsecret`

71.28.1.1 Restrictions

Must be superuser or the MTA user (the `user` option in `restricted.cnf`, or prior to MS 7.0.5, the `imta_user` MTA Tailor option value), or be in the group specified by the

group option in restricted.cnf (prior to MS 7.0.5, be in the group specified by the imta_world_group MTA Tailor option value), in order to have any hold or capture actions applied by a Sieve filter be shown in the utility's output.

71.28.1.2 Prompts

Table 71.23 imsimta test -exression Prompts

Prompt	Value
Expression:	*expression*

71.28.2 Description

Test an expression, such as a Sieve filter or a configuration recipe. test -expression -mm tests message enqueue functions, such as Sieve filters (with the -message switch). test -expression -xc tests recipe syntax operating on a Unified Configuration. Testing consists of parsing the expression, which converts it to an internal compiled form, and then evaluating the compiled form. The -parseonly switch can be used to disable the evaluation step.

Basic arithmetic and string operators are supported in expressions; and when variables may be used, that is, if the -symbols switch has been used, then additional operations upon variables are supported. For a list of the supported operators (with one exception), see the recipe language's list of Operators in Order of Precedence. The one difference between the operator support for the recipe language, *vs*. for Sieve filters, is that since in Sieve syntax square brackets represent lists, indexing into a string in Sieve must be performed using parentheses rather than square brackets. So for instance a Sieve script:

```
require "fileinto";
str := "12folderXYZ";
substr := str(3,9);
fileinto substr;
```

is equivalent to '`fileinto "folder";`'. (See Variable indices under Recipe language for further discussion of indexing into strings and lists.)

Without the -mm switch, test -expression tests symbol table functions (in general, comprising various string functions). The symbol table functions available include those shown in Symbol table functions. (Note that this set of functions supported by imsimta test -expression and by Sieve filters does *not* include all of the Recipe language functions discussed under Recipe language; the recipe language includes support for additional functions useful in configuration recipes.)

Conditional expressions may be used, having the form:

test ? *then-result* : *else-result*

However, "if..." tests of the form

if *test* {*then-result*} else {*else-result*}

are only allowed in certain contexts; in particular, they are not allowed when only basic expressions are permitted, as in mapping table expression substitutions.

Table 71.24 Symbol table functions

Function	Description
abs(*i***)**	Return the absolute value of *i*.
allof(*i1*[,*i2*...]**)**	Returns a nonzero value if all of *i1*, *i2*, ... are nonzero; returns 0 otherwise.
any(*s1*,*s2***)**	Return 2 if any character in *s1* appears as the first character of *s2*; return 0 otherwise.
anyof(*i1*[,*i2*...]**)**	Returns a nonzero value if any of *i1*, *i2*, ... are nonzero, returns 0 if all are zero.
bal(*c1*,*c2*,*c3*,*s***)**	Scan *s* looking for an occurence of a character in *c1* that is balanced with respect to *c2* and *c3*. Returns the position of the first balanced *c3* character in *s* if one is found, length(s)+1 if no *c3* character is found but the string as a whole is balanced, or 0 if the string isn't balanced.
center(*s1*,*n*,*s2***)**	Return a string that has string *s1*'s last character at position *n*, padding on the left with the character or characters from string *s2*. *s2* may be omitted, in which case space characters are used to pad out the string.
check8(*s***)**	Return 1 if string *s* contains any eight bit data; return 0 otherwise.
check8(*s*,*n***)**	If *n* is 0, it is ignored and the function returns 0 or 1 according to whether the string *s* contains any eight bit data. If *n* is any positive integer, then return the string *s* with any eight bit characters replaced by the question mark character, "?".
chr(*i1*[,*i2*...]**)**	Returns a string containing successive characters with decimal values *i1*,*i2*, ...
datetime	Return the current date and time, in RFC 822/RFC 1123 date-time string format, *e.g.*, "Fri, 10 Oct 2008 15:40:02 -0700 (PDT)"
decode *[:e] s*	Decodes the string *s* from the specified encoding *:e*. The *:e* nonpositional parameter must be one of :base64, :base85, :hex, :idn, or :quotedprintable. The default is :hex.
defined(*s***)**	Returns 1 if *s* is defined as a variable; return 0 otherwise.
encode *[:e] s*	Encodes the string *s* into the specified encoding *:e*. The *:e* nonpositional parameter must be one of :base64, :base85, :hex, :idn, :param, :quotedprintable, or :url. The default is :hex.
find(*s1*,*s2*[,*i*,*j*]**)**	Returns the position of the first occurence of *s1* in *s2*[*i*:*j*]. The entire string is searched if i and j are omitted.
find(*s*,*l*[,*i*,*j*]**)**	Returns the position of the first list element from *l*[*i*:*j*] that matches *s*. The entire list is searched if i and j are omitted.
genid	Return a unique id string, such as that used for generating Message-id's or message queue file names.
integer(*e***)**	Converts *e* to an integer. If *e* is already an integer it is returned unchanged; if *e* is a string it is read as a sequence of ASCII digits. If *e* is a list it must contain one element and is treated in the same way a string would be.

lcase(*e***)**	Converts any upper case characters in *e* to lower case. If *e* is a number it is converted to a string.
left(*s1***,***i***[,***s2***])**	Returns leftmost *i* characters of *s1*. If *i* is greater than length(*s1*) the result is padded with *s2*. As much of *s2* as is necessary will be used; if *s2* is too short it will be used multiple times. *s2* defaults to a space if it is omitted.
left(*l1***,***i***[,***l2***])**	Returns leftmost *i* elements of *l1*. If *i* is greater than length(*l1*) the result is padded with *l2*. As much of *l2* as is necessary will be used; if *l2* is too short it will be used multiple times. *l2* defaults to one empty list element if it is omitted.
length(*s***)**	Returns the number of 8-bit characters in the string *s*.
length(*l***)**	Returns the number of elements in the list *l*.
list(*s***[,***n***])**	Returns a list *n* elements long with each element equal to the string *s*. If omitted *n* defaults to 1.
list(*l***[,***n***])**	Returns a list consisting of *n* copies of list *l*. If omitted *n* defaults to 1.
map(*s1***,***s2***,***s3***)**	Returns a string obtained by mapping characters of *s1* that occur in *s2* into corresponding characters in *s3*. Characters that don't appear in *s2* are unchanged.
max(*i***,***j***[,...])**	Returns the largest element in a set of integers.
match(*r***,***s***)**	Returns 1 (true) if the regular expression *r* matches a substring of string *s*, 0 (false) otherwise. Note that the pattern *r* may be prefixed with "^" (match beginning of line) and suffixed with "$" (match end of line) to require a full string match. The regular expression vocabulary is compatible with that of the TCL/TK scripting language.
max(*s1***,***s2***[,...])**	Returns the largest element in a set of strings.
min(*i***,***j***[,...])**	Returns the smallest element in a set of integers.
min(*s1***,***s2***[,...])**	Returns the smallest element in a set of strings.
repl(*s***,***j***)**	Returns a string consisting of *j* concatenations of *s*.
repl(*l***,***j***)**	Returns a list consisting of *j* concatenations of *l*.
reverse(*s***)**	Reverses all the characters in *s* and returns the result.
reverse(*l***)**	Reverses all the elements in *l* and returns the result.
right(*s1***,***i***[,***s2***])**	Returns rightmost *i* characters of *s1*. If *i* is greater than length(*s1*) the result is padded with *s2*. As much of *s2* as is necessary will be used; if *s2* is too short it will be used multiple times. *s2* defaults to a space if it is omitted.
right(*l1***,***i***[,***l2***])**	Returns rightmost *i* elements of *l1*. If *i* is greater than length(*l1*) the result is padded with *l2*. As much of *l2* as is necessary will be used; if *l2* is too short it will be used multiple times. *l2* defaults to one empty list element if it is omitted.
sign(*i***)**	Returns -1 if *i* < 0, 0 if *i* = 0, +1 if *i* > 0.
sort(*l1***[,***i***[,***l2***]])**	Sorts the elements of *l1* to be in ascending order if *i* <> 0 and descending order if *i* = 0. *i* defaults to 1 if it is omitted. If *l2* is present its elements are shifted in the same way as elements in *l1* are shifted.

split(*s*[,*c*[,*i*]]**)**	Produces a list of elements consisting of pieces of *s* delineated by characters in *c*. If omitted *c* defaults to a comma. If *i* is 0 or 1, zero length elements are preserved; if *i* is 2, they are not. If omitted *i* defaults to 1.
split(*l*[,*c*[,*i*]]**)**	Produces a list of elements consisting of pieces of elements of *l* delineated by characters in *c*. If omitted *c* defaults to a comma. If *i* is 0, boundaries between the original elements aren't preserved and zero length elements can be output; if *i* is 1, boundaries are preserved and zero length elements can be output; if *i* is 2, boundaries aren't preserved and zero length elements are omitted. If omitted *i* defaults to 1.
string(*e***)**	Converts *e* to a string. If *e* is already a string it is returned unchanged. If *e* is an integer it is converted to a string. If *e* is a list, the string that results from concatenating the elements of *e* is returned.
string(*l*,*s***)**	Converts the list *l* to a string, inserting the string *s* between each pair of elements of *l*. So for instance `string(["a","cd","e"],"01")` would return the string `"a01cd01e"`.
string(*i*[,*j*[,*k*]]**)**	(New in MS 6.3 are the optional second and third arguments.) Converts the integer *i* to a string, optionally padding with zeros (on the left) so that the length of the string is *j*, and optionally outputting the result in the radix specified by *k*. So for instance `string(15,8,2)` returns `00001111`.
trim(*s*[,*c*]**)**	Returns *s* with any trailing characters found in *c* removed. *c* defaults to space and tab if omitted.
trim(*l*[,*c*]**)**	Returns *l* with any trailing characters found in *c* removed from each element. *c* defaults to space and tab if omitted.
type(*e***)**	Returns `"integer"` if *e* evaluates to an integer, `"string"` if *e* evaluates to a string, and `"list"` if *e* evaluates to a list.
ucase(*e***)**	Converts any lower case characters in *e* to upper case. If *e* is a number it is converted to a string.
Directory function	Description
gettag(*x***)**	If *x* evalutes to a string, returns the tag character for that string. If *x* evaluates to a list, returns the default and per-element tags as a string. An error will be returned if *x* evalutes to anything other than a string or list.
settag(*x*,*y***)**	Sets the tag or tags of *x* to *y*. *x* may be either a string or a list. If *x* is a string, then *y* must be a one character string. If *x* is a list, then *y* must be a string of length `length(`*x*`)+1` and the first character of *y* must be a space.

The expression to test may be read from a file via the `-input` switch. If `-input` is not specified, then the utility enters an interactive loop, prompting for expressions to test with an "`Expression:`" prompt; the utility will exit when CTRL/D (UNIX) is entered.

By default, each line of expression is evaluated independently (separately). The `-block` switch may be used to tell the utility to evaluate the entire block of input expression(s) at once, as a whole; thus in particular, `-block` is useful when evaluating a multi-line Sieve filter.

New in MS 7.0u2, `imsimta test -expression -mm` will return a nonzero status in the event of either a parse or evaluation error.

71.28.3 Switches

71.28.3.1 `-block`, `-noblock` (default)

By default (`-noblock`), input is evaluated one line at time. With the `-block` switch, evaluation is postponed until the entire input file has been read (if the `-input` switch is used), or until CTRL/D is entered (if `-input` is not used and expressions are being entered interactively). Thus in particular `-block` allows use of multi-line Sieve constructs.

71.28.3.2 `-debug[=`*n*`]`, `-nodebug` (default)

The `test -expression` utility is capable of outputting additional, detailed information about the internal steps of its operation. The `-debug` switch enables this output. Specifying `-debug` is equivalent to specifying `-debug=1`; greater amounts of debug information can be requested by specifying `-debug=`*n* for values of *n* up to 10.

Note that a debug level of 2 or more enables output of strings specified via Sieve "`debug`" actions. Note that a debug level of 3 or more enables output (via "`mmc_output_line(`*x*`) header line:`" debug output lines) of the header lines of the message file being processed, while a debug level of 4 or more enables output not only of the header lines, but also of the message body lines handled in memory (via "`mmc_output_line(`*x*`) internal body line:`" debug output lines) of the message file being processed, and a debug level of 5 or more enables output of the message body lines handled via an external file for "large" message bodies (via "`mmc_output_line(`*x*`) external body line:`" debug output lines). `-debug=1` is the default.

New in MS 7.0u2, `-nodebug` turns off the dump of the expression.

71.28.3.3 `-envid=`*id*, `-noenvid` (default)

(New in MS 7.0u3.) `-envid` is only available when `-mm` and `-message` are specified. `-envid` sets the envelope ENVID value for use with the Sieve envelope-dsn extension for envelope ENVID tests. `-noenvid` is the default.

71.28.3.4 `-from=`*return-address*, `-to=`*recipient-address*, `-noto` (default)

(`-from` new in MS 6.2; `-to` and `-noto` new in MS 6.3) `-from` and `-to` are only available when `-mm` and `-message` are specified. `-from` sets the return address for use in Sieve envelope From comparisons. If this switch is not used, the default postmaster address is assumed (see the `return_address` MTA option).

To specify an empty (null) envelope From, the command wants to see `-from=""`--- however shell quoting, *e.g.*, `-from=\"\"`, may be required in order to get such an argument through the shell.

`-to` sets the recipient address for use in Sieve envelope To comparisons. If this switch is not used, or if `-noto` is explicitly specified, then no recipient address is set.

71.28.3.5 -input=*filename*

The -input switch tells the utility to read its input from the specified file, rather than prompting for and reading input interactively. Note that when using -input to enter a Sieve filter file, one usually also wants to use -block (so that multi-line Sieve constructs can be handled).

71.28.3.6 -iterations=*n*

The -iterations switch may be used to specify the maximum number of iterations permitted in the internal code implementing :matches, overriding (for this command execution) any setting of the max_sieve_match_iterations MTA option. (Note that the default value of max_sieve_match_iterations is 1,000,000,000.)

71.28.3.7 -list=*n*

The -list switch may be used to specify the maximum size of list permitted, overriding (for this command execution) any setting of the max_sieve_list_size MTA option. (Note that the default value of max_sieve_list_size is 64.)

71.28.3.8 -message=*filename*

The -message switch may only be used when the -mm switch is present. It is used to specify an input message to process; this should be an RFC 822 message, not a message file from the MTA's queue area (which contains additional, envelope information beyond the basic RFC 822 message itself).

71.28.3.9 -mm, -xc

The -mm switch means to test using the MTA's normal enqueue code. The -xc switch (new in MS 7.5) means to test recipe language syntax, operating on a Unified Configuration. -mm and -xc may not be specified together.

71.28.3.10 -mtpriority=*n*, -nomtpriority (default)

(New in MS 8.0) -mtpriority takes a required integer argument specifying the initial MT-PRIORITY value. This can affect, for instance, the value of the Sieve environment item vnd.oracle.mtpriority. This may only be specified when -mm has also been specified. Furthermore, it is only relevant when -message has been specified (though it will not result in an error to specify -mtpriority without -message).

71.28.3.11 -multiple (default), -nomultiple

Specifying -nomultiple disables evaluating multiple, semicolon-separated, result-generating, statements per physical line. When -nomultiple is specified, only the first result found when evaluating the line will be returned. -multiple is the default.

71.28.3.12 -output=*filename*

The -output switch tells the utility to output to the specified file, rather than to the terminal screen.

71.28.3.13 -required (default), -norequired

(New in MS 6.2.) The `-required` or `-norequired` switch may only be used when `-mm` is specified. Specifying `-norequired` causes Sieve "`require`" clauses to not be required: any Sieve operation that would normally need an appropriate "`require`" clause in order to be permitted will be permitted even without such a "`require`" clause. In other words, `-norequired` gives an effect as if the Sieve script in question had initially done a

```
require list-of-all-possible-extensions;
```

71.28.3.14 `-rsecret=`*`recall-secret`*, `-norsecret` (default)

(New in MS 8.0) Specify the recall secret. This is only relevant when `-message` has been specified.

71.28.3.15 `-sender=`*`sender-address`*, `-nosender` (default)

(New in MS 8.0.) The `-sender` switch may be used to specify an "authenticated" sender address, as if SMTP AUTH had been used. For instance, the Sieve environment item `vnd.sun.authenticated-sender-address` will be set to the sender value, if specified. This is only relevant when `-message` has been specified.

71.28.3.16 `-source=`*`source-channel-name`*, `-nosource`

(New in MS 8.0) Specify the source channel; the default is `l` (the "L"ocal channel). This is only relevant when `-message` has been specified.

71.28.3.17 `-statement=`*`n`*

Set symbol table statement parsing flags. The argument is a bit-encoded integer, with default value 1. The meanings of the various bits are shown below.

Table 71.25 Statement parsing flags

Bit(s)	Value(s)	Usage
0	1	Allow statements
1	2	Allow loops, including the Sieve "`loop`" construct
2-4	4-28	Debug level (4, 8, 12, ... 28)
6	64	Allow mapped file
7	128	Allow directives
8	256	Enforce "`require`" must be used only at beginning of Sieve
9	512	Allow bracketed lists
10	1024	Return evaluation error details

Bit 0 is the least significant bit.

Note that use of the `-mm` switch sets bit 9 (allow bracketed lists). Use of the `-debug` switch sets bits 2 through 4 (debug level).

71.28.3.18 `-string=`*`n`*

The -string switch may be used to specify the maximum length of string permitted; the default is 65535.

71.28.3.19 -symbols, -nosymbols (default)

The -symbols switch allows the use of variables and symbolic values, and operations may be performed on variables. For instance, symbolic names such as IMTA_TABLE may be used to reference the imta_table directory specification, and assignments may be made to symbolic variable names, such as a := 1, and operators such as those shown in Operators in Order of Precedence of the recipe language may be used. -nosymbols is the default.

71.28.3.20 -system, -nosystem (default)

(New in MS 7.0.5) The -mm switch must be used in order to use -system. If -system is specified with -mm, then the Sieve is treated as a system-level Sieve; if not, then it is treated as a user-level Sieve.

71.28.3.21 -uav=*n*

The -uav switch controls the interpretation of unassigned variables. The default is -uav=1.

Table 71.26 Unassigned variable interpretation

Value	Usage
0	Variables must be predefined; variable creation not allowed
1	Assignment defines variable; no default value
2	Define variable upon first reference; default value ""
3	Define variable upon first reference except in modify operations; default value 0
4	(New in MS 8.0/patch to MS 7.0u5) Same as value 1 (assignment defines variable; no default value), with the difference (appropriate for Sieve usage) don't create a symbol table at parse time

71.28.3.22 -username=*username*, -nousername (default)

(New in MS 8.0) The -username switch may be used to specify a username, relevant when username-based checks are in use. For instance, the Sieve environment item vnd.sun.authenticated-sender-id will be set to the username value, if specified. This is only relevant when -message has been specified.

71.28.3.23 -utf8, -noutf8 (default)

(New in MS 8.0) The -utf8 switch specifies allowing use of internationalized email addresses, as with the SMTPUTF8 SMTP extension (from RFC 6531). -noutf8 is the default.

71.28.4 Examples

```
# ./imsimta test -expression -mm -block -message=msg.txt
```

```
Expression: require "fileinto";
Expression: if header :contains ["Subject"] ["foo"] { fileinto "foo"; }
Expression: if header :contains ["Subject"] ["test"] { discard; }
Expression: CTRL/D
Dump: header:2000111;0  3  1  :contains  1  "Subject"  1  "foo"  if
Dump: 5  ;  fileinto:2000110;0  1  1  "foo"  ;  header:2000111;0  3
Dump: 1  :contains  1  "Subject"  1  "test"  if  3  ;  discard:2000107;0
Dump: 0
Result: 1
Filter result: [ discard ]
```

The above command sequence tests the result of various Sieve filter command lines on a message file, `msg.txt`, that for the purposes of this example is assumed to have a Subject: header line that contains the word "test" but does not contain the word "foo".

```
# ./imsimta test -expression -mm -block -message=msg.txt -from=\"\"
Expression: require ["envelope","fileinto"];
Expression: if envelope :all :is "from" "" { fileinto "notifications"; }
Expression: CTRL/D
Dump: envelope:4000115;0  4  1  :all  1  :is  1  "from"  1  ""  if  5
Dump: ; fileinto:4000114;0  1  1  "notifications"
Result: "notifications" ' '
Filter result: [ fileinto "notifications" ]
```

The above command sequence tests the result of a Sieve filter script that files all notification messages (messages with empty envelope From) to a folder named "`notifications`", when that Sieve filter is presented with some message and when the envelope From is set to be empty via the `-from` switch.

```
# ./imsimta test -expression -mm -statement=3 -block -message=msg.txt"
Expression: loop { discard; exitif (true); }
Expression: CTRL/D
Dump: loop  5  discard;0  0  ;  1  exitif
Result: 1
Filter result: [ discard ]
```

The above example shows use of the new-in-MS-7.0.5 "`loop`" construct in a Sieve filter. Note that `-statement=3` must be specified on the command line in order to use a "`loop`" construct in this utility.

71.29 test -hash utility

Test generating a hash of a string or of file contents.

71.29.1 Syntax

```
imsimta test -hash hash-name [file-name]
```

Table 71.27 imsimta test -hash Command Switches

Switch	Default
`-string=`*`string`*	`-nostring`
`-repetitions=`*`n`*	*None*
`-key=`*`key`*	*None*

71.29.2 Parameters

71.29.2.1 *hash-name*

Required parameter specifying the hash function to use. Valid values are `MD2`, `MD4`, `MD5`, `SHA1`, `SHA256`, `SHA512`, `MD128`, or `MD160`.

71.29.2.2 *file-name*

Optional parameter specifying the name of a file whose contents to input to the hash function. The `-string` switch may not be used if a file is specified.

71.29.3 Description

The `imsimta test -hash` utility generates a hash of string or file input. This may be of interest when testing the MTA's ability to generate message hashes, a feature useful for message archiving purposes.

71.29.4 Switches

71.29.4.1 `-string=`*`string`*, `-nostring` (default)

`-string` may not be specified if a file-name parameter has been supplied.

71.29.4.2 `-key=`*`key`*

May only be used when a string is being hashed (`-string`), not when a file is specified.

71.29.4.3 `-repetitions=`*`n`*

May only be used when a string is being hashed (`-string`), not when a file is specified.

71.29.5 Examples

```
# ./imsimta test -hash -string="just a test" SHA1
Hash value: E6F36746CCBA42C288ACF906E636BB278EAEB7E8
```

In the above example, a hash of the string "`just a test`" is generated using the SHA-1 hash function.

71.30 test -header utility

Test message header processing.

71.30.1 Syntax

```
imsimta test -header
```

Table 71.28 imsimta test -header Command Switches

Switch	Default
`-length=`*`n`*	`-length=80`
`-increment=`*`n`*	`-increment=20`
`-alignment=`*`n`*	`-alignment=0`
`-options=`*`filename`*	*None*
`-push`	`-nopush`
`-apply`	`-noapply`
`-folds`	`-nofolds`
`-blank`	`-noblank`
`-digits`	`-nodigits`
`-trim`	`-trim`
`-keeporder`	`-nokeeporder`
`-input=`*`filename`*	*None*
`-output=`*`filename`*	*None*
`-postscript`	`-nopostscript`
`-dump`	`-nodump`

71.30.2 Parameters

None.

71.30.3 Description

The `imsimta test -header` utility parses header lines, optionally performing certain types of header trimming, and outputs the processed header lines (including, prior to MS 7.0u4, a PostScript version). The utility may either read header lines from a file (`-input=`*`filename`*) or from the command line (in that case prompting with `header>`). The output takes the general form:

```
--- Output with options ---

parsed> header-line-1
parsed> header-line-2
...
```

```
--- PS ---

PostScript-output

--- After decode/encode and no options ---

parsed> header-line-1
parsed> header-line-2
...
```

though as of MS 7.0u4, the PostScript output is optional and will not be included unless `-postscript` is explicitly specified. The "`Output with options`" section of the output is what results from performing any relevant header trimming specified via the `-options` switch. The "`After decode/encode and no options`" section of the output shows canonicalization effects on header field names and header field values, but does not include effects of `-options` header trimming unless `-apply` has been specified.

71.30.4 Switches

71.30.4.1 `-alignment=`*n*

Specify the alignment point for header lines, analogous to the `headerlabelalignment` channel option; the default is 0, which causes header lines not to be aligned.

71.30.4.2 `-apply`, `-noapply` (default)

`-apply` causes application of any relevant header trimming directives specified via the `-options=`*`filename`* switch, applying such trimming to the underlying header structure. Note that not all trim options make sense to apply to the underlying header structure, as some trim options relate to output, not to the underlying header storage. So for instance trim options such as RELABEL, and LINELENGTH, are not relevant (and will not occur) with `-apply`. `-apply` is only relevant when `-options` has been specified (`-apply` has no effect unless `-options` has been specified), so `-apply` cannot sensibly be combined with `-keeporder`; (as of MS 7.0u4, indeed the combination is an error).

71.30.4.3 `-blank`, `-noblank` (default)

The default is `-noblank`.

71.30.4.4 `-digits`, `-nodigits` (default)

The default is `-nodigits`.

71.30.4.5 `-dump`, `-nodump` (default)

(New in MS 7.0u4) When `-dump` is specified, the output includes, prior to the "After applying options" output:

```
--- Dump of header ---
dump of header structure
```

71.30.4.6 -folds, -nofolds (default)

The default -nofolds switch corresponds to the headerfoldremove channel option, while the -folds switch corresponds to the headerfoldpreserve channel option.

71.30.4.7 -increment=*n*

Specify the increment used when attempting to fold header lines, analogous to the headerlineincrement channel option; the default is 20.

71.30.4.8 -keeporder, -nokeeporder (default)

Specifying -keeporder causes -options to be ignored, and forces -noapply. (As of MS 7.0u4, attempting to specify either -options or -apply with -keeporder is an error.)

71.30.4.9 -linelength=*n*

Specify the length at which to wrap header lines, analogous to the headerlinelength channel option and the LINELENGTH header trimming option; the default is 80.

71.30.4.10 -options=*filename*, -nooptions (default)

The -options switch specifies a header trimming option file to open, read, and parse. Options relevant to output of header lines will be shown when -apply is not specified; if -apply is specified then only those options affecting the underlying header structure (header structure storage) will take effect. (In particular, with -apply set, only ADD, FILL, and PRECEDENCE will take effect. In contrast, with the default -noapply, then options such as RELABEL and LINELENGTH will also take effect.) -options can not be combined with -keeporder; (indeed, as of MS 7.0u4 specifying both is an error).

71.30.4.11 -postscript, -nopostscript (default)

(New in MS 7.0u4) -nopostscript (the default as of MS 7.0u4) disables the outputting of a PostScript version of the header lines. Specifying -postscript causes the PostScript version to be output; prior to MS 7.0u4, this was not controllable with the PostScript version always being output.

71.30.4.12 -push, -nopush (default)

Specifying -push causes the MTA to use a different way of reading header information. The results with -push *vs.* -nopush should always be identical; report to Oracle if differences are seen. -push is ignored if -input has been specified; (indeed, as of MS 7.0u4 attempting to specify both is an error). -nopush is the default.

71.30.4.13 -trim (default), -notrim

Control whether or not to trim trailing white space off header lines. The default is -trim, meaning to perform such white space trimming.

71.30.5 Examples

```
# ./imsimta test -header
header> CoNtEnT-TrAnsFeR-eNcOdInG: bAsE64
header>
--- After applying options ---

parsed> Content-transfer-encoding: bAsE64

--- PS ---

/Courier-Bold findfont 10 scalefont
/Courier findfont 10 scalefont
/SHOW_HEADERS where
{pop (Content-transfer-encoding: bAsE64) SHOW_HEADERS}
{35 720 moveto exch dup setfont (Content-transfer-encoding:) show exch dup
setfo
nt ( bAsE64) show} ifelse
pop pop

--- After decode/encode and no options ---

parsed> Content-transfer-encoding: BASE64
header> Ctrl-D
#
```

The above example from an older version (when the PostScript was included by default) shows the canonicalization of the Content-transfer-encoding: header line field name, and field value.

```
# ./imsimta test -header -options=IMTA_TABLE:return_header.opt -input=sample_headers.txt

--- Output with options ---

parsed> Message-id: <01NYWMSLISS600H4Y@domain.com>
parsed> Date: Mon, 14 Mar 2011 14:18:50 -0700 (PDT)
parsed> From: John Doe <jdoe@domain.com>
parsed> To: Jane Brown <jbrown@domain.com>
parsed> Subject: New report

--- After decode/encode and no options ---

parsed> Received: from localhost by host.domain.com
parsed>  (Oracle Communications Messaging Exchange Server 7u5-2.03 64bit)
parsed>  (built Feb  6 2011) with ESMTP id <0G8P00B01ZFNUV@domain.com>
parsed>  for jbrown@domain.com (ORCPT jbrown@domain.com); Mon,
parsed>  14 Mar 2011 15:47:47 -0800 (PDT)
parsed> Date: Mon, 14 Mar 2011 15:47:47 -0800 (PDT)
parsed> From: John Doe <jdoe@domain.com>
parsed> Subject: New report
parsed> To: Jane Brown <jbrown@domain.com>
parsed> Message-id: <01NYWMSLISS600H4Y@domain.com>
parsed> MIME-version: 1.0
parsed> Content-type: MULTIPART/MIXED
#
```

The above example shows applying the default header trimming file, `return_header.opt`, used when constructing DSNs; see Sample distributed `return_header.opt` file. Note that such trimming has removed the Received:, MIME-version:, and Content-type: header lines, and moved the Message-Id: header line above the other retained header lines.

71.31 test -mapping utility

Test an MTA mapping table.

71.31.1 Syntax

```
imsimta test -mapping [input-string]
```

Table 71.29 imsimta test -mapping Command Switches

Switch	Default
`-context`	`-context`
`-debug`	`-nodebug`
`-destination_channel=`*`channel`*	`-nodestination_channel`
`-flags=`*`list-of-characters`*	`-noflags`
`-image_file`	`-image_file`
`-mapping_file=`*`file-spec`*	`-mapping_file=IMTA_TABLE:mappings`
`-option_file=`*`file-spec`*	`-option_file=IMTA_TABLE:option.dat`
`-table=`*`table-name`*	*None*
`-reload`	`-noreload`
`-input=`*`file-spec`*	`-input=stdin`
`-originator=`*`address`*	`-nooriginator`
`-output=`*`file-spec`*	`-output=stdout`
`-sources`	`-sources`
`-source_channel=`*`channel`*	`-nosource_channel`

71.31.1.1 Prompts

Table 71.30 imsimta test -mapping Prompts

Prompt	Value
`Enter table name:`	*`table-name`*

71.31.2 Parameters

71.31.2.1 *`input-string`*

Optional input string to run through the mapping.

71.31.3 Description

`imsimta test -mapping` may be used to test the behavior of an MTA mapping table. The string resulting from mapping an input string will be output along with a list of any metacharacters specified in the output string.

If an input string is supplied on the command line, then only the result of mapping that input string will be output. If no input string is specified, then `imsimta test -mapping` will enter a loop, prompting for an input string, mapping that string, and prompting again for another input string. `imsimta test -mapping` will exit when a CTRL/D (UNIX) is entered.

Note that this utility is testing only the formal syntax and formal result of a mapping table; it is not testing what the mapping table *means* (the effect of the mapping table) for actual MTA operation. In particular, for testing the effect of the `FROM_ACCESS` mapping table or recipient address `*_ACCESS` mapping tables, see instead the `test -rewrite` utility.

Or in the other (less semantic, more syntactic) direction, note that the matching of wildcards in mapping table patterns (left hand sides of entries) may be tested in detail via the `test -match` utility, which may be of particular interest when using "complex" wildcards such as character "glob" matches, or IP address prefix matches.

71.31.4 Switches

71.31.4.1 `-context` (default), `-nocontext`

(New in MS 7.0) The `-context` switch is the default, and causes the mapping table to be probed as if operating in a normal, MTA usage, application (with normal MTA initialization having been performed). `-nocontext` causes the mapping table to be probed as if operating in a mode without normal MTA initialization, and hence may be useful for testing mapping table operation in non-MTA contexts.

71.31.4.2 `-debug`, `-nodebug` (default)

The mapping test process is capable of producing additional, detailed information about the sequence of steps in the mapping probe(s) and match(es). Such information is particularly likely to be of interest (useful) with iterative mapping tables, or mapping tables that involve callouts; that is, such debug information is most likely to be of interest when exploring implications of `$C`, `$L`, or `$R` metacharacter use, or effects of callouts such as to other mapping tables, to the general database, to LDAP, or to Oracle or site-supplied routines. The `-debug` switch enables this output; it is disabled by default.

71.31.4.3 `-destination_channel=`*`channel`*

(New in MS 8.1.0.1) The `-destination_channel` switch is used to specify a destination channel when the MTA is initialized for writing. The source channel is used if no desitnation channel is specified. See the documentation on the `-source_channel` switch below for additional information.

71.31.4.4 `-flags=`*`list-of-characters`*, `-noflags` (default)

The `-flags` switch is used to specify particular flags to set during the mapping testing; for instance, the E (envelope), B (header/body), R (backwards pointing), or I (message id) flags when testing a `REVERSE` mapping. Multiple flags may be specified by concatenating them, *e.g.*, `-flags=BR`.

71.31.4.5 `-image_file` (default), `-noimage_file`

When the `-image_file` switch is specified (the default), the MTA will load the compiled configuration file *CONFIGROOT*`/advanced/config_data` (located prior to MS 7.0 via

the imta_config_data MTA Tailor option). When -noimage_file is specified, then imsimta test -mapping will unconditionally ignore any compiled mapping information and instead read mapping information directly from the named MTA mapping groups (Unified Configuration) or the mappings file (legacy configuration).

71.31.4.6 -input=*filename*

(New in MS 8.0) By default, imsimta test -mapping takes input from stdin. The -input switch may be used to specify a different source for input.

71.31.4.7 -mapping_file=*filename*

This switch instructs imsimta test -mapping to use the specified mapping file rather than the default MTA mapping file, *CONFIGROOT*/mappings (located prior to MS 7.0 via the imta_mapping_file MTA Tailor option). This switch has no effect unless -noimage_file is specified or no compiled configuration exists; use of any compiled configuration will preclude reading any MTA mapping values (Unified Configuration) or physical mapping file (legacy configuration); this switch also has no effect when an XML configuration is in use.

71.31.4.8 -option_file=*filename*, -nooption_file

This switch instructs imsimta test -mapping to use the specified option file rather than the default MTA option file, *CONFIGROOT*/option.dat (prior to MS 7.0 located via the imta_option_file MTA Tailor option). This switch has no effect unless -noimage_file is specified or no compiled configuration exists; use of any compiled configuration will preclude reading any MTA options whether from mta.*option-name* (Unified Configuration) or from a physical option file (legacy configuration). Use of the switch -nooption_file will prevent the MTA option file from being read in when there is no compiled configuration. These switches have no effect when an XML configuration is in use.

71.31.4.9 -originator=*address*

(New in MS 8.1.0.1) The -originator switch is used to specify the envelope from (MAIL FROM) address when the MTA is initialized for writing. The value "mail@fom" is used if no originator address is specified. See the documentation on the -source_channel switch below for additional information.

71.31.4.10 -output=*output_file_spec*

(New in MS 8.0) By default, imsimta test -mapping writes output to stdout. The -output switch may be used to direct the output of imsimta test -mapping elsewhere.

71.31.4.11 -reload, -noreload (default)

The -reload switch may be used to tell the utility to reread MTA mapping group options (Unified Configuration) or the mappings file (legacy configuration) if the mapping table name specified is not found cached in memory.

71.31.4.12 -source_channel=*channel*

(New in MS 8.1.0.1) Mappings do not depend on the MTA being initialized for writing a message, but some mapping plugins do. In order to test such plugins, the -source_channel can be used to cause the enqueue logic to be initialized using the specified channel. Also see

the -originator and -destination_channel switches, which can be used to specify the envelope from (MAIL FROM) address and destination channel, respectively.

71.31.4.13 -sources (default), -nosources

(New in MS 8.0) The -nosources switch may be used to suppress the (new in MS 8.0) output of segment sources.

71.31.4.14 -table=*table-name*

This switch specifies the name of the mapping table to test. If this switch is not specified, then imsimta test -mapping will prompt for the name of a table to use.

71.31.5 Examples

```
# imsimta test -mapping -noimage_file -mapping_file=IMTA_TABLE:mac_mappings.sample
Enter table name: MAC-TO-MIME-CONTENT-TYPES
Input string: BINHEX|7344424e|4d535744|Test.doc
Output string: APPLICATION/MSWORD
Output flags: [0, 'Y' (89)]
Input string: ^D
#
```

In the above UNIX example, the sample MAC-TO-MIME-CONTENT-TYPES mapping is tested. The -mapping_file switch is used to select the mapping file mac_mappings.sample instead of the default mapping file.

```
# imsimta test -mapping -flags=A -table=X-FLAGS
Input string: testing
Output string: testing plus A flag
Output flags: [0, 'Y' (89)]
Input string: ^D
# imsimta test -mapping -flags=B -table=X-FLAGS
Input string: next
Output string: next without A flag
Output flags: [0, 'Y' (89)]
Input string: ^D
```

The above example assumes that the mappings file contains a mapping table:

```
X-FLAGS

   *              $C$:A$0$ plus$ A$ flag$Y$E
   *              $;A$0$ without$ A$ flag$Y
```

That X-FLAGS mapping table outputs the original input string plus suffix string " plus A flag" if the input flag "A" was present, or outputs the original input string plus suffix string " without A flag" if the input flag "A" was not set. In the above test -mapping utility output, it can be seen that input flags, if any, do *not* carry over to being present amongst the set of output flags: an input flag set via the -flags switch does not carry over to appear amongst the output flags in the "Output flags:" portion of the output. Input flags and

output flags are distinct and separately stored. Also note how the entry with the `$:A` test has that test "wrapped" with the "`$C`...`$E`"; this is to cause the mapping process to "continue on" if that entry (in particular the test for the presence of the input flag "`A`") failed, but "end" if the test succeeded. In this particular example, the "`$E`" could have been omitted since the only subsequent entry explicitly checked for the opposite ("`A`" flag not present) condition. However wrapping with "`$C`...`$E`" is better practice, and is commonly used in entries containing tests.

71.32 test -match utility

Test a mapping wildcard pattern.

71.32.1 Syntax

```
imsimta test -match
```

71.32.2 Parameters

None.

71.32.3 Description

`imsimta test -match` may be used to test a mapping pattern, particularly, to test wildcard and glob matching.

When invoked, `imsimta test -match` prompts for a pattern and then for a target string to compare against the pattern, and will output whether or not the target string matched and if it did match, which characters in the target string matched which wildcard or glob of the pattern. `imsimta test -match` will loop, prompting for input, until exitted with a CTRL/D (UNIX).

71.32.4 Examples

```
% imsimta test -match
Pattern: $[ax1]*@*.acme.com
  [  1S] cglob [1ax]
  [  2] "@"
  [  3S] glob, req 109, reps 2
  [  4] "."
  [  5] "a"
  [  6] "c"
  [  7] "m"
  [  8] "e"
  [  9] "."
  [ 10] "c"
  [ 11] "o"
  [ 12] "m"
Target: xx11a@sys1.acme.com
Match.
0 - xx11a
1 - sys1
Pattern: $[ax1]*@*.acme.com
  [  1S] cglob [1ax]
  [  2] "@"
  [  3S] glob, req 109, reps 2
  [  4] "."
  [  5] "a"
```

```
  [  6] "c"
  [  7] "m"
  [  8] "e"
  [  9] "."
  [ 10] "c"
  [ 11] "o"
  [ 12] "m"
Target: 12a@node.acme.com
No match.
Pattern: $[ax1]*@*.acme.com
  [  1S] cglob [1ax]
  [  2] "@"
  [  3S] glob, req 109, reps 2
  [  4] "."
  [  5] "a"
  [  6] "c"
  [  7] "m"
  [  8] "e"
  [  9] "."
  [ 10] "c"
  [ 11] "o"
  [ 12] "m"
Target: 1xa@node.acme.com
Match.
0 - 1xa
1 - node
Pattern: ^D
%
```

In the above UNIX example, the sample mapping pattern `$[ax1]*@*.acme.com` is tested for several sample target strings.

```
% imsimta test -match
Pattern: $(1.2.3.0/24)
  [  1S] ipv4 [1.2.3.0/255.255.255.0]
Target: 1.2.3.4
Match.
0 - 1.2.3.4
Pattern: $(1.2.3.0/24)
  [  1S] ipv4 [1.2.3.0/255.255.255.0]
Target: 1.2.8.0
No match.
Pattern: ^D
%
```

In the above UNIX example, the sample mapping pattern `$(1.2.3.0/24)` is tested for two sample target strings.

71.33 test -mime utility

Test a message's MIME structure.

71.33.1 Syntax

```
imsimta test -mime [input-file [output-file]]
```

Table 71.31 imsimta test -mime Command Switches

Switch	Default
-line	-noline
-convert	-noconvert
-header	-noheader
-thurman	-nothurman
-security	-nosecurity
-rotate[=*n*]	-rotate=0 or -norotate
-debug	-nodebug

-channel=*channel-name*	-channel=*scan_channel-value*
-scan=*sieve-expression*	*None*

71.33.1.1 Restrictions

None.

71.33.1.2 Prompts

Table 71.32 imsimta test -mime Prompts

Prompt	Value
`Input file:`	*`file-spec`*
`Output file:`	*`file-spec`*

71.33.2 Parameters

71.33.2.1 *`input-file`*

Parameter specifying the name of the input message file.

71.33.2.2 *`output-file`*

Optional parameter specifying a file to which to write the utility's output. If no output file is specified, the output is written to the terminal.

71.33.3 Description

`imsimta test -mime` may be used to test and analyze, or convert, a message's MIME structure. When used with `-convert` or `-archive`, the utility's output is respectively the result of converting, or constructing an archive version of, the message. When used with `-scan` and `-channel`, the utility runs the specified Sieve filter and/or channel configured spam/virus filtering. Otherwise, the output is an analyzed (and, depending on the switches specified, optionally somewhat annotated) copy of the original message.

71.33.4 Switches

71.33.4.1 `-archive=`*`archive-channel-name`*, `-noarchive` (default)

(New in MS 6.3.) `-archive` cannot be used with `-convert` or `-line`. The default is `-noarchive`. Specifying `-archive=`*`archive-channel-name`* causes the MTA to write an archive file per the configuration of the specified archive channel.

71.33.4.2 `-channel=`*`channel-name`*, `-nochannel` (default)

(New in 7.0.5) The `-channel` switch may be used when `-scan` is used; it must be used if it is desired to engage spam/virus filter package scanning. If `-channel` is specified without an argument, then the channel defaults to the setting of the `scan_channel` MTA option, or the local channel if `scan_channel` is not set. Note that spam/virus filter package scanning is only engaged if `-channel` is explicitly specified.

71.33.4.3 -convert, -noconvert (default)

-convert cannot be used with -archive or -line.

71.33.4.4 -describe, -nodescribe

-describe only matters when -line has been specified. Setting -new_charset overrides any setting of -describe or -nodescribe: depending upon whether the specified new charset is one known to the MTA the describe flag is either set, or cleared, respectively. In the absence of -new_charset, setting either -prefix or -suffix will force the describe flag to be set. When the describe flag is set, due either to one of the above-mentioned override effects, or otherwise via explicit -describe switch use, then a Content-transfer-encoding: header line and a Content-MD5: header line can be added to message parts.

71.33.4.5 -eightbit, -noeightbit

Specifying -eightbit sets the "eight always" handling; specifying -noeightbit sets the "seven only" handling. Note that the default behavior corresponds to neither keyword, corresponding instead to "eight negotiate" handling.

71.33.4.6 -encoding=*keyword*

The default is -encoding=NONE. Valid values for the encoding keyword are: NONE, QUOTED_PRINTABLE, BASE32, OBASE64, BASE64, CBASE64, DBASE64, HEXADECIMAL, UUENCODE, CUUENCODE, DUUENCODE, PATHWORKS, BINHEX, BTOA, BASE85, or CDATA.

71.33.4.7 -format=*keyword*

-format cannot be used unless -line is used. When -line is used, the default is -format=MIME. The valid keyword arguments for -format are: MIME, RFC1154, MAILWORKS, NEXT, HEADER_SET, and STREAM_DECODE.

71.33.4.8 -iencoding (default), -noiencoding

New in MS 6.3. The default is -iencoding, which means to interpret (decode) message content whose encoding is described by the non-standard Encoding: header line. Specifying -noiencoding means to ignore any such Encoding: header line; that is, not perform decoding. These switches are thus analogues of the channel options interpretencoding and ignoreencoding.

71.33.4.9 -iemessage (default), -noiemessage

New in MS 6.3. The default is -iemessage, which means to interpret (decode) encodings of MIME message parts; note that such encodings are illegal, but may sometimes be encountered in messages from incompliant software. Specifying -noiemessage means to ignore any such Content-transfer-encoding: illegally present on a message part. These switches are thus analogues of the channel options interpretmessageencoding and ignoremessageencoding.

71.33.4.10 -iemultipart (default), -noiemultipart

New in MS 6.3. The default is -iemultipart, which means to interpret (decode) encodings of MIME multiparts; note that such encodings are illegal, but may sometimes

be encountered in messages from incompliant software. Specifying `-noiemultipart` means to ignore any such Content-transfer-encoding: illegally present on a multipart. These switches are thus analogues of the channel options `interpretmultipartencoding` and `ignoremultipartencoding`.

71.33.4.11 `-line`, `-noline` (default)

`-line` cannot be used with `-convert` or `-archive`.

71.33.4.12 `-message_handling=`*keyword*

Valid arguments for `-message_handling` are: `KEEP`, `TOP`, `BOTTOM` or `END`, `DELETE`, or `MERGE`. The default is `-message_handling=KEEP`.

71.33.4.13 `-mode=`*keyword*

Valid arguments for `-mode` are: `CRATTRIBUTE`, `LFATTRIBUTE`, `CRLFATTRIBUTE`, `BLOCK`, `RECORD`, `TEXT[=n]`, `POSTSCRIPT`, `ENRICHED`, `FLOWED`, `HTML`, `DOUBLEAPPLE`, `SINGLEAPPLE`, `MACBINARY`, `BINHEX`, `VIRUSSCAN`. `-mode=text` means `-mode=text=80`.

71.33.4.14 `-number` (default), `-nonumber`

The `-number` switch is ignored when used with `-archive` or `-capture`. When used with `-line` (or with none of `-line`, `-archive`, or `-capture`), it tells the utility to output initial table heading lines prior to its output analyzing the message structure. Combined with `-line`, `-number` causes table heading lines of:

```
Line # ?
------ -
```

Or if none of `-line`, `-archive`, or `-capture` is specified, then `-number` causes table heading lines of:

```
Line # Level Count ?
------ ----- ----- -
```

Note that `-number` is the default; specifying `-nonumber` disables this table heading output.

71.33.4.15 `-rotate=`*n*, `-norotate` (default)

`-rotate` is equivalent to `-rotate=13`.

71.33.4.16 `-nmaximum=`*n*

(New in MS 6.0) Specify a maximum allowed length for the NAME parameter and for the FILENAME parameter on the Content-type: and Content-disposition: MIME header lines, respectively; longer parameters will be truncated. This switch is thus an analogue of the `nameparameterlengthlimit` channel option. The default is 128.

Note that other, general parameters on the Content-type: and Content-disposition: MIME header lines are controlled instead via the `-pmaximum` switch. (The reason why such lengths

are of interest, and why these switches exist, is due to the history in certain popular e-mail clients of security problems involving buffer overruns.)

71.33.4.17 -number (default), -nonumber

Specifying -nonumber turns off the display of line numbers in the output. -number is the default.

71.33.4.18 -pformat=*n*

The default is 0.

71.33.4.19 -pmaximum=*n*

(New in MS 6.0) Specify a maximum allowed length for general parameters on Content-type: and Content-disposition: MIME header lines; longer parameters will be truncated. This switch is thus an analogue of the parameterlengthlimit channel option. The default is 1024.

Note that the Content-type: NAME parameter and Content-disposition: FILENAME parameter maximum length are controlled separately via the -nmaximum switch. (The reason why such lengths of interest, and these switches exist, is due to the history in certain popular e-mail clients of security problems involving buffer overruns.)

71.33.4.20 -scan=*sieve-expression*, -noscan (default)

(New in MS 7.0.5) The -scan switch specifies a Sieve expression to apply to the input message. This emulates imexpire message scanning. If -channel is specified, then spam/virus filter package scanning can be engaged also. If -channel is not specified, then spam/virus filter package scanning is not engaged, and the channel value (when relevant) defaults to the value of the scan_channel MTA option.

71.33.4.21 -thurman, -nothurman (default)

Specifying -thurman causes the MTA to perform "sniffing" of non-MIME message bodies for UUENCODE or BINHEX "blobs" (akin to application of the thurman channel option), and to pull such "blobs" out into MIME attachments instead.

71.33.5 Examples

```
% imsimta test -mime not-zz.00

71.34.1.1 Restrictions

Must be superuser or the MTA user (the `user` option in `restricted.cnf`, or prior to MS 7.0.5, the `imta_user` MTA Tailor option value), or be in the group specified by the `group` option in `restricted.cnf` (prior to MS 7.0.5, be in the `imta_world_group` group), in order to display `-filter`, `-soptin`, or `-spares` output.

71.34.1.2 Prompts

Table 71.34 imsimta test -rewrite Prompts

Prompt	Value
`Address:`	*test-address*

71.34.2 Parameters

71.34.2.1 *test-address*

Optional parameter specifying one or more (comma-separated) addresses to rewrite.

71.34.3 Description

`imsimta test -rewrite` provides a straightforward test facility for examining the MTA's address rewriting and channel matching process without actually sending any message. Various switches can be used to control whether `imsimta test -rewrite` uses the configuration text files or the compiled configuration (if present), the amount of output produced, and so on.

The `imsimta test -rewrite` utility has several especially common and useful uses:

1. testing overall *syntactic* validity (though not *semantic* correctness) of the MTA configuration,
2. testing MTA configuration changes prior to making them "live" with `imsimta cnbuild`, and conversely checking that the compiled configuration in fact corresponds to the "most current" versions of the configuration files,
3. testing that the Messaging Server LDAP configuration information is accessible,
4. testing that the LDAP server is responding to domain and user/group lookups,
5. testing the rewriting, alias lookup and expansion, and resulting routing, of specific addresses,
6. testing the expansion (membership) of groups and mailing lists,
7. testing the canonicalization of specific (local) addresses resulting from address reversal (*i.e.*, testing how local addresses will appear in header lines),
8. testing the effects of address-based `*_ACCESS` mapping tables,
9. testing the effects of posting restrictions such as restrictions on mailing list postings,
10. determining which Sieve filters are applicable for a particular recipient address,
11. testing SRS/MUL encoding and decoding of addresses (if SRS MTA options have been configured).

If a test address is specified on the command line, `imsimta test -rewrite` applies MTA address rewriting to that address, reports the results, and exits. If no test address is specified, `imsimta test -rewrite` will enter a loop, prompting for an address, rewriting it, and prompting again for another address. `imsimta test -rewrite` will exit when CTRL/D (UNIX) is entered.

In interactive mode, note that the caret character, ^, may be used to enter a character or characters by ASCII value (in hexadecimal); each character must be entered as a two digit hexadecimal value, with a final caret character meaning to return to "normal" (as typed)

character entry. For instance, ^20^ is one way of entering a space character. To enter a literal caret character, caret-quote the caret, ^^.

When testing an alias corresponding to a mailing list which has an AUTH_ or CANT_ type of named parameter (legacy configuration) or an alias_auth_* or alias_cant_* alias option (Unified Configuration) controlling who may post to the list, or which has an mgrp[Dis]Allowed* LDAP attribute controlling who may post to the list, or when testing rewriting when SEND_ACCESS or related mapping tables are in effect, note that by default imsimta test -rewrite uses as the posting address the return address of the local postmaster as specified by the return_address MTA option. To specify a different posting address for the rewriting process, use the -from switch.

Note that as mentioned above, the imsimta test -rewrite utility also provides a basic "sanity check" of the syntactical correctness (though not the semantic correctness) of the configuration. In particular, if the utility returns any

```
Error in mm_init -- detail
```

error message, that is a warning of a serious configuration problem, preventing the MTA from operating.

If an active compiled configuration appears to be "out-of-date" compared to configuration files, then the imsimta test -rewrite utility will issue the following warning (but proceed to operate):

```
Warning - compiled configuration does not match configuration files
 -- detail
```

with further detail (such as what file(s) appear to have been modified subsequent to the compilation of the currently active compiled configuration) in the *detail* text.

The imsimta test -rewrite utility also provides a way of checking that the LDAP server is responsive. Using the -noimage switch, that is, using an imsimta test -rewrite -noimage command, is a way of checking that the Messaging Server configuration information in LDAP is accessible; if it is not, then the utility will return a warning of the general form:

```
[date-and-time] hostname [pid]: General Warning: could not get server configurat
ion in ldap, using cached configuration information
```

and then proceed to attempt to process the address using cached LDAP configuration information. Note that one of the more common cases where the above warning can be issued is where the LDAP server is in fact not responding, in which case the imsimta test -rewrite utility may further not be able to successfully lookup "local" domains and users. Then temporary errors of the form

```
4.0.0 Temporary lookup failure: address
```

(or whatever is configured via the domain_failure MTA option) when attempting to rewrite addresses suggest that the LDAP user/group directory is unavailable/unresponsive; further details on the underlying LDAP error may be obtained using the utility's -debug=level=3 switch.

71.34.4 Switches

71.34.4.1 -aby=*value*, -noaby (default)

(New in MS 8.0) The -aby switch may be used to specify an alternate address deliver by value. -noaby is the default.

71.34.4.2 -additions, -noadditions (default)

(New in MS 8.0) Specifying -additions causes any added prefix or suffix text to be displayed. (That is, -additions causes display of text added via alias options alias_prefix_text or alias_suffix_text, or via mailing list named parameters [PREFIX_TEXT] or [SUFFIX_TEXT], or via LDAP attributes such as mgrpMsgPrefixText or mgrpMsgSuffixText.) -noadditions is the default.

71.34.4.3 -alias_file=*filename*

If a compiled configuration is not being used, then imsimta test -rewrite normally consults the default alias file during the rewriting process. Prior to MS 7.0, that alias file was located via the imta_alias_file option of the MTA Tailor file, so usually IMTA_TABLE:aliases; as of MS 7.0, the alias file is located as *CONFIGROOT*/aliases. The -alias_file switch specifies an alternate file for imsimta test -rewrite to use. This switch has no effect unless -noimage_file is specified or no compiled configuration exists; use of a compiled configuration precludes direct reading of the alias file from any location; this switch also has no effect when an XML configuration is in use.

71.34.4.4 -alternate_recipient=*address*

(New in MS 8.0) Specify an alternate recipient address.

71.34.4.5 -applicationinfo=*string*

This switch is used to specify the application-info string to use during, for instance, FROM_ACCESS, ORIG_MAIL_ACCESS, and MAIL_ACCESS mapping table probes. For instance, for an incoming SMTP message where the sending client claimed (on its HELO/EHLO line) a hostname of domain.com, and where TLS was not used, the application-info string would be "SMTP/domain.com".

71.34.4.6 -by=*value*, -noby (default)

(New in MS 8.0) The -by switch may be used to specify a deliver by (SMTP DELIVERBY extension BY parameter) value. -noby is the default.

71.34.4.7 -channel*[=type]* (default), -nochannel

This switch controls whether the utility outputs detailed information, *e.g.*, channel flags, regarding the channel an address matches.

As of MS 8.0.2.1, this switch accepts an optional channel type, which controls which of the various channels selected by the rewriting process is displayed. Possible values are forward, backward, source, and destionation. The default is forward, which displays the channel selected by rewriting the input address in the "forward" direction. Note that source and

destination display channel information for the selected source and destination channels, which are not address-dependent.

71.34.4.8 -check_expansions, -nocheck_expansions (default)

This switch controls checking of alias address expansion. Normally the MTA considers the expansion of an alias to have been "successful" if *any* of the addresses to which the alias expands are legal. The `-check_expansions` switch causes a much stricter policy to be applied: `imsimta test -rewrite -check_expansions` checks each expanded address in detail and reports a list of any addresses, expanded or otherwise, that fail to rewrite properly. For addresses that match the L channel, the MTA also performs validity checks.

71.34.4.9 -configuration_file=*filename*

If no compiled configuration is being used, then `imsimta test rewrite` normally consults the default MTA configuration file during the rewriting process. Prior to MS 7.0, the MTA configuration file was located via the `imta_config_file` option of the MTA Tailor file, usually pointing to `IMTA_TABLE:imta.cnf`; as of MS 7.0, the MTA configuration file is located at *CONFIGROOT*`/imta.cnf`. The `-configuration_file` switch specifies an alternate file to use in place of the regular configuration file. This switch has no effect unless `-noimage_file` is specified or no compiled configuration exists; use of a compiled configuration will preclude direct reading of the MTA configuration file from any location; this switch also has no effect when an XML configuration is in use.

71.34.4.10 -conversion_file=*filename*, -noconversion_file

If no compiled configuration is being used, then `imsimta test rewrite` normally accesses the default conversion file as part of its initialization during the rewriting process; while the conversion file has no particular effect on address rewriting, it is considered part of the core configuration (and hence `imsimta test -rewrite` will warn of problems accessing the conversion file, or of out-of-date versions of the conversion file). Prior to MS 7.0, that default conversion file was located via the `imta_conversion_file` option of the Tailor file, so usually `IMTA_TABLE:conversions`; as of MS 7.0, in legacy configuration the conversion file is located as *CONFIGROOT*`/conversions`; in Unified Configuration, a separate file is not used and instead the `conversions` MTA option stores the conversions. The `-conversion_file` switch specifies an alternate file to use in place of the regular converison file. These switches have no effect unless `-noimage_file` is specified or no compiled configuration exists; use of a compiled configuration will preclude direct reading of the conversion file from any location. Use of the `-noconversion_file` switch will prevent the conversion file from being read in when there is no compiled configuration. These switches also have no effect when an XML configuration is in use.

71.34.4.11 -database=*database-list*

`imsimta test -rewrite` by default during its operation consults any of the usual MTA databases that it has been configured to use. (For MTA configuration controlling whether databases are normally used, see the Database MTA options, and in particular the `alias_magic`, `use_alias_database`, `use_domain_database`, `use_forward_database`, and `use_reverse_database` MTA options.) The `-database` switch is used to either disable references to various databases or to redirect the database paths to nonstandard locations. The allowed list items are `alias`, `noalias`, `personal_alias`, `nopersonal_alias`, `domain`, `nodomain`, `forward`, `noforward`, `general`, `nogeneral`, `reverse`, and `noreverse`. The list items beginning with "`no`" disable use of the

corresponding database. The remaining items require an associated value, which is taken to be the name of that database.

71.34.4.12 -debug, -nodebug (default)

The address rewriting process is capable of producing additional, detailed explanations of what actions are taken and why. The `-debug` switch enables this output; it is disabled by default. In cases of problems with address expansion, `-debug`, especially `-debug=level=3`, can also give more details as to the exact nature of the problem; for instance, the exact LDAP directory error returned in response to a domain lookup up, the exact LDAP directory error returned in response to a user lookup, rejection resulting from an recipient `*_ACCESS` mapping table, *etc.*. As of MS 7.0, note that the basic `-debug` output will report if address "duplicate elimination" occurs, via a debug output line of the form:

```
time-stamp:          - Duplicates previous recipient address, merge
```

This may be of particular interest when multiple, comma-separated addresses were provided initially.

71.34.4.13 -delivery_receipt, -nodelivery_receipt

The `-delivery_receipt` and `-nodelivery_receipt` switches, which explicitly set the corresponding receipt request flags, can be useful when testing the handling of receipt requests when rewriting forwarded addresses or mailing lists.

71.34.4.14 -destination_channel=*channel*

The `-destination_channel` switch controls for which destination or target channel `imsimta test -rewrite` rewrites addresses. Some address rewriting is destination channel specific; this switch allows control of the assumed destination channel.

71.34.4.15 -esmtpused, -noesmtpused (default)

(New in MS 6.3.) The `-esmtpused` switch may be used to set an internal flag indicating that ESMTP is in use. In particular, this may be useful when testing `*_ACCESS` mapping tables that make use of that flag (the `$:E` flag).

71.34.4.16 -expandlimit=*n*

(New in MS 6.3p1.) This switch may be used to initialize the MTA's internal alias expansion limit; this is intended for testing expansion limit interactions with mailing lists and other MTA facilities.

71.34.4.17 -extra_local_channel=*channel*

(New in MS 7.0u2) The `-extra_local_channel` switch may be used to specify the name of a channel to be treated as if it were the local channel.

71.34.4.18 -filter, -nofilter (default)

The `-filter` switch may be used to have `imsimta test -rewrite` output any Sieve filters (personal mailbox, so-called "Head of Household", channel, or system) applicable for the address in question. Note that a user's `mailAutoReply*` attributes are converted by the MTA into a Sieve "`vacation`" action which is incorporated at the beginning of the user's personal

Sieve filter. As of MS 6.1, the filter output will also be labelled as to which Sieve filter it came from, taking the form (under the addresses under the "`Submitted address list:`" portion of the output):

```
Filter: <type> name location [addr response-addr] [owner owner] (h) [i] {j}
```

or as of MS 6.2:

```
Filter: <type> name location [addr response-addr] [owner owner] (h) [i] )k( {j}
```

where *`type`* is either `system` or `user`, *`location`* is a URL to the location of the Sieve filter (or in the case of the system filter, as of the MS 6.2 patch time frame says merely `system:`), *`response-addr`* is the address to which a notification would be sent back (usually only relevant and non-null for the case of `vacation` actions, in which case it is the envelope From address), and *`owner`* is the address of the "owner" of this Sieve filter: normally the local postmaster address for system-level (the system and channel) filters, or the user himself for a personal Sieve filter, or the specified owner for a "Head of Household" Sieve filter. (The three or four, depending upon MTA version, integers in hexadecimal notation following are internal debug information, showing the location in memory of internal parts of the Sieve structure.) So for instance, one might see output such as the following (where additional line breaks have been inserted for display purposes):

```
Submitted address list:
  ims-ms
    uid%hosteddomain1.com@ims-ms-daemon (orig first.last@hosteddomain1.com,
     inter first.last@hosteddomain1.com, host ims-ms-daemon)
     *NOTIFY-FAILURES* *NOTIFY-DELAYS*

```

Note that the `-filter` output shows applicable Sieve filters, that is, which Sieve filters *would* get evaluated for this address. But it does not show the actual evaluation of those Sieve filters (as such evaluation can only be done in the context of actual message processing), thus it does not show what the effect(s) of those Sieve filters would be.

Must be superuser or the MTA user in order to display `-filter` output.

71.34.4.19 `-from=`*`address`*`, -nofrom`

The -from switch controls what envelope From address is used for access control probes and mailing list access probes. If this switch is omitted, then any such probes use the postmaster return address (as set via the return_address MTA option). Specifying -nofrom tells the MTA to use an empty envelope From address for access probes.

As of MS 7.0.5, note that returnenvelope (or mailfromdnsverify) or return_envelope settings that cause the MTA to attempt a "verification" of the From address can affect imsimta test -rewrite output: the output will include a warning if the From address appeared to be problematic, though the input address will still be rewritten as usual.

71.34.4.20 -header, -noheader (default)

The -header switch causes the utility to output any applicable header trimming option file associated with the channel of the destination address. This information will appear after the destination address itself, before any dumped filter information (from the -filter switch), hence before the "Submitted notifications list:" output. -noheader is the default. Note that -header merely outputs the header trimming option file; to investigate the potential effect(s) of a header trimming option file, see instead test -header.

71.34.4.21 -identifiers, -noidentifiers (default)

(New in MS 7.0.5) The -identifiers switch tells the utility to rewrite the parameter value as a message identifier, rather than as an address. (For instance, in the default mode of addresses, an a@b@c form will be turned into a %-route form, whereas in -identifiers mode a value of a@b@c would be quoted.)

71.34.4.22 -image_file (default), -noimage_file

When the -image_file switch is specified (the default), imsimta test -rewrite will load the compiled configuration. Prior to MS 7.0, this compiled configuration was located via the imta_config_data option in the MTA tailor file, usually pointing to IMTA_TABLE:advanced/config_data. As of MS 7.0, the compiled configuration is located as *CONFIGROOT*/advanced/config_data. When -noimage_file is specified, imsimta test -rewrite unconditionally ignores any previously compiled configuration and instead reads configuration information directly from the various text files.

71.34.4.23 -input=*input-file-spec*

By default, imsimta test -rewrite takes input from stdin. The -input switch may be used to specify a different source for input.

71.34.4.24 -jacket, -nojacket (default)

Specifying -jacket will result in passing any $I flag checks in the FROM_ACCESS mapping table or recipient address *_ACCESS mapping tables.

71.34.4.25 -lmtpused, -nolmtpused (default)

(New in MS 6.3.) The -lmtpused switch may be used to set an internal flag indicating that LMTP is in use. In particular, this may be useful when testing *_ACCESS mapping tables that make use of that flag (the $:L flag).

71.34.4.26 -local_alias=*value*, -nolocal_alias (default)

This switch controls the setting of an alias for the local host. The MTA supports multiple "identities" for the local host; the local host may have a different identity on each channel. This switch may be used to set the `local_host_alias` to the specified value; appearances of the local host in rewritten addresses will be replaced by this value.

71.34.4.27 `-multiple`, `-nomultiple`

(New in 8.0.1.2) Normally the specified address is presented to the enqueue machinery all at once. Specifying `-multiple` causes the argument to be treated as a comma-separated list of addresses; each address will be presented for enqueue processing separately, simulating the effect of multiple RCPT TOs.

The MTA's enqueue facilities handle the submission of multiple addresses at the same time as an extension. Specifying `-nomultiple` disables this capability; multiple addresses will be considered an error.

71.34.4.28 `-mapping_file[=`*`file-spec`*`]`, `-nomapping_file`

If no compiled configuration is being used, then this switch instructs `imsimta test -rewrite` to use the specified mapping file rather than the default mapping file. Prior to MS 7.0, the default mapping file was located via the `imta_mapping_file` option in the MTA tailor file, so usually `IMTA_TABLE:mappings`; as of MS 7.0, in legacy configuration the mappings file is located as *CONFIGROOT*`/mappings`; in Unified Configuration, a separate file is not used and instead mappings are stored under named `mapping` groups. These switches have no effect unless `-noimage_file` was specified or no compiled configuration exists; use of any compiled configuration will preclude direct reading of the mappings file. Use of the `-nomapping_file` switch will prevent the MTA mapping file from being read in when there is no compiled configuration. These switches also have no effect when an XML configuration is in use.

71.34.4.29 `-mtpriority=`*`n`*`, -nomtpriority` (default)

(New in MS 8.0) `-mtpriority` takes a required integer argument specifying the initial MT-PRIORITY value.

71.34.4.30 `-option_file[=`*`filename`*`]`, `-nooption_file`

If no compiled configuration is being used, then the `-option_file` switch instructs `imsimta test -rewrite` to use the specified option file rather than the default location MTA option file. Prior to MS 7.0, the MTA option file was located via the `imta_option_file` option in the MTA Tailor file, so usually `IMTA_TABLE:option.dat`; as of MS 7.0, in legacy configuration the MTA option file is located at *CONFIGROOT*`/option.dat`; in Unified Configuration, a separate file is not used and instead these are MTA options. These switches have no effect unless `-noimage_file` is specified or no compiled configuration exists; use of any compiled configuration will preclude direct reading of the MTA option file from any location. Use of the `-nooption_file` switch will prevent the MTA option file from being read in when there is no compiled configuration. These switches have no effect when an XML configuration is in use.

71.34.4.31 `-output=`*`output-file-spec`*

By default, `imsimta test -rewrite` writes output to `stdout`. The `-output` switch may be used to direct the output of `imsimta test -rewrite` elsewhere.

71.34.4.32 -password=

Used to specify the password for a password-protected list.

A prompt will appear that allows the password to be entered without echo.

71.34.4.33 -proxyused, -noproxyused (default)

(New in MS 6.3.) The -proxyused switch may be used to set an internal flag indicating that proxy authentication (POP-before-SMTP) is in use. In particular, this may be useful when testing *_ACCESS mapping tables that make use of that flag (the $:P flag).

71.34.4.34 -quotacheck (default), -noquotacheck

(New in MS 8.0.1.2.) The -quotacheck switch controls whether or not the alias expansion process treats an account's overquota status as an error. -quotacheck is the default; -noquotacheck may be used to disable the check. This may be useful in simulating the behavior of temporary failure reenqueue operations, which disable this check.

71.34.4.35 -read_receipt, -noread_receipt

The -read_receipt and -noread_receipt switches, which explicitly set the corresponding receipt request flags, can be useful when testing the handling of receipt requests when rewriting forwarded addresses or mailing lists.

71.34.4.36 -reprocessing (default), -noreprocessing

By default, the test -rewrite utility runs as if the -reprocessing switch is set, meaning that some operations that would normally be deferred for "off-line" execution by the reprocess channel will instead be performed directly by the test address processing. -noreprocessing may be used to tell the utility to run in a mode more similar to that of a "normal" channel, where various operations (*e.g.*, mailing list password lookups) will not be performed by the channel, and where instead the message will be forcibly routed to the reprocess channel which is expected to perform the necessary tasks later ("off-line").

71.34.4.37 -restricted=*setting*

This switch controls the setting of the restricted flag. By default, this flag has value 0. When set to 1, *i.e.*, -restricted=1, the restricted flag will be set on and addresses will be rewritten using the restricted mailbox encoding format recommended by RFC 1137. This flag is used to force rewriting of address mailbox names in accordance with the RFC 1137 specifications; see the restricted channel option for further details.

71.34.4.38 -rrvs=*ISO8601-value*, -norrvs

(New in MS 8.0) The -rrvs switch is used to specify an RRVS value (Require-Recipient-Valid-Since: value), in ISO 8601 format. -norrvs is the default.

71.34.4.39 -saslused, -nosaslused (default)

(New in MS 6.2p8.) The -saslused switch may be used to set an internal flag indicating that SASL authentication (SMTP AUTH) is in use. In particular, this may be useful when testing *_ACCESS mapping tables that make use of that flag (the $:A flag).

71.34.4.40 -sender=*address*, -nosender (default)

New in MS 6.2. The -sender switch may be used to set the "authenticated sender" field, for use in FROM_ACCESS mapping table probes.

71.34.4.41 -size=*n*, -nosize (default)

(New in MS 7.0.5) The -size switch sets an assumed "message size" (in bytes), as if the SMTP SIZE extension had been used. It requires an integer argument, which the MTA interprets as being in units of bytes. This can be useful for checking message size-based restrictions. -nosize is the default.

71.34.4.42 -soptin, -nosoptin (default)

(New in MS 7.0 update 2.) Control whether or not to show per-recipient spamfilter "opt-in".

Must be superuser or the MTA user in order to display -soptin output.

71.34.4.43 -source_channel=*channel*

The -source_channel switch controls which source channel to assume when rewriting addresses. Some address rewriting is source channel specific; imsimta test -rewrite by default assumes that the channel source for which it is rewriting is the local channel, l on UNIX.

71.34.4.44 -spares, -nospares (default)

(New in MS 7.0 update 2.) Control whether or not to show per-recipient "spare" LDAP attributes.

Must be superuser or the MTA user in order to display -spares output.

71.34.4.45 -statistics, -nostatistics (default)

The -statistics switch can be used to tell the MTA to output the direct LDAP lookup cache statistics for the rewriting performed; statistics for the domain cache, reverse cache, and alias cache will be displayed. -nostatistics is the default.

71.34.4.46 -srs=([domain=*domain*],[secrets=*secrets*], [maxage=*maxage*])

The -srs switch provides a way to override certain SRS-related MTA configuration options: The domain value overrides the srs_domain MTA option, the secrets value overrides the srs_secrets MTA option, and the maxage> value overrides the srs_maxage value.

Additionally, specification of -nosrs causes test -rewrite to act as it none of the srs_* options are set.

71.34.4.47 -system_filter=*filename*, -nosystem_filter

If no compiled configuration is being used, then imsimta test -rewrite normally consults the default system Sieve filter during the rewriting process: this is the systemfilter MTA option in Unified Configuration, or the system filter file in legacy configuration. Prior

to MS 7.0, the MTA system filter file was located via the imta_system_filter_file option of the MTA Tailor file, so usually IMTA_TABLE:imta.filter; as of MS 7.0, the MTA system filter file is located as *CONFIGROOT*/imta.filter. The -system_filter switch specifies an alternate file to use in place of the default system Sieve filter file. These switches have no effect unless -noimage_file is specified or no compiled configuration exists; use of a compiled configuration will preclude direct reading of the system filter file from any location. Use of the -nosystem_filter switch will prevent the MTA system filter file (legacy configuration) from being read in when there is no compiled configuration. These switches have no effect when an XML configuration is in use.

71.34.4.48 -tag=*tag-list*, -notag (default)

(New in MS 7.0.5) The -tag switch can be used to set the conversion tag (or comma-separated list of tags) that will be available at the time of REVERSE mapping table probes. This can be useful when bit 8 (value 256) of the include_conversiontag MTA option is set, so that REVERSE mapping table probes include conversion tags.

71.34.4.49 -tlsused, -notlsused (default)

(New in MS 6.2p8.) The -tlsused switch may be used to set an internal flag indicating that TLS is in use. In particular, this may be useful when testing *_ACCESS mapping tables that make use of that flag (the $:T flag).

71.34.4.50 -transportinfo=*string*

This switch is used to specify the transport-info string to use during, for instance, FROM_ACCESS, ORIG_MAIL_ACCESS, and MAIL_ACCESS mapping table probes. (Note that the PORT_ACCESS mapping table is *not* checked by the test -rewrite utility, as the PORT_ACCESS mapping table is consulted for decisions regarding TCP/IP connections, rather than for address handling; in particular the PORT_ACCESS mapping table is used by the Dispatcher, and then again by SMTP server processes, at a much earlier stage of processing than the address rewriting process.) Note that a typical transport-info string, of the form

TCP|*server-address*|*server-port*|*client-address*|*client-port*

contains vertical bar characters, |, which will require some quoting to pass through the shell; *e.g.*,

```
-transportinfo=TCP\|123.45.67.8\|12435\|10.0.0.1\|25
```

71.34.4.51 -xml_config[=*file-path*]

(New in MS 7.0.) imsimta test -rewrite normally reads its configuration from IMTA_TABLE:config.xml, if such a file exists. The -xml_config switch specifies use of a Unified Configuration (which is the MTA's default behavior if IMTA_TABLE:config.xml exists), and optionally specifies an alternate, XML format, configuration file to use in place of IMTA_TABLE:config.xml.

71.34.5 Examples

This UNIX example shows typical output generated by imsimta test -rewrite in MS 6.3. Perhaps the single most important piece of information generated by imsimta test

`-rewrite` is displayed on the last few lines of the output, **(6)**, showing the channel to which `imsimta test -rewrite` would submit a message with the specified test address and the form in which the test address would be rewritten for that channel. This output is invaluable when debugging configuration problems.

```
% imsimta test -rewrite dan@innosoft.com

   dan@innosoft.com
Submitted address list:                     (6)
   tcp_local
     dan@innosoft.com (orig dan@innosoft.com, host innosoft.com) *NOTIFY-FAILURES* *NOTIFY-DELAYS*

Submitted notifications list:               (7)
```

1. The channel to which, after rewriting as an envelope To address, the address is mapped.

2. The flags set for the channel indicated in (1). These flags are controlled by the channel options set on the channel (in legacy configuration, those channel options set on the first line of the channel control block for the specified channel). Any unknown options---options which may have been mistyped---will be interpreted as group ids and will appear on the line (4).

3. The channel's official host name as specified on the second line of the channel control block for the channel indicated in (1).

4. Any items appearing on the first line of the channel block which were not channel options are interpreted as group ids. Any group ids so specified for the channel are listed on this line.

5. The channel which the address would match if rewritten as an envelope From address.

6. The channel to which a message with the address dan@innosoft.com would be queued and the envelope To address which would be used. Here, the message would be submitted to the TCP/IP channel, `tcp_local`, using the address dan@innosoft.com. Other information appearing here might include an explicit Errors-to: address, which, if present, appears enclosed in square brackets; or notations such as `*RR*` or `*NRR*`, indicating whether or not the message is flagged for read receipts, or notations such as `*NOTIFY FAILURES*`, `*NOTIFY DELAYS*`, `*NOTIFY SUCCESSES*`, *etc.*, indicating the message's delivery receipt mechanism and flagging.

7. Notification addresses. If notifications need to be generated regarding this address, as for instance in the case of a group or list whose definition includes some (immediately obvious as such) bad addresses, then the addresses about which a notification needs to be generated will be listed here, along with the error corresponding to each such address. If an override envelope From is in effect for the original message, hence if the notification will go back to some address other than the original message's sender, then that address (the address to which the notification will be sent) will be shown enclosed in square brackets. Note that the recipient address for the notification will only be shown if it is something different than the original sender address (as specified via the `-from` switch, or defaulting to the postmaster address). New in MS 7.0u2, the word "`to`" will appear within such square brackets, to emphasize that the address shown is the address to which the notification will be sent.

The example below shows typical output generated by `imsimta test -rewrite` in MS 8.0.

```
% imsimta test -rewrite dan@innosoft.com
  address channel        = tcp_local                    (1)
  forward channel        = tcp_local                    (2)
  channel description    =
  channel caption        =
  channel user filter    =
  dest channel filter    =
  source channel filter  =
  phase filter  =
  channel flags #0       = BIDIRECTIONAL MULTIPLE IMMNONURGENT NOSERVICEALL  (3)
  channel flags #1       = SMTP_CRLF AFFINITYLIST IDENTNONENUMERIC DEFAULTDKIMIGNORE
  channel flags #2       = NOSENDPOST NOWARNPOST POSTHEADBODY HEADERINC NOEXPROUTE
  channel flags #3       = LOGGING NORESTRICTED RETAINSECURITYMULTIPARTS
  channel flags #4       = UTF8NEGOTIATE HEADERKEEPORDER NOHEADERREAD RULES
  channel flags #5       = TRUNCATESMTPLONGLINES
  defaulthost            = domain.com domain.com
  linelength             = 998
  addrsperfile           = 99
  channel env addr type  = SOURCEROUTE
  channel hdr addr type  = SOURCEROUTE

#
```

1. The channel to which, after performing any address reversal, the address matches an an envelope From address.

2. The channel which, rewriting as an envelope To address, the address matches.

3. The channel options set for the channel indicated in (2).

4. The channel's official host name as specified by the `official_host_name` option (Unified Configuration) or the second line of the channel block (legacy configuration) for the channel indicated in (2).

5. The channel which the address would match if rewritten as an envelope From address.

6. The channel to which a message with the address `dan@innosoft.com` would be queued and the envelope To address which would be used. Here, the message would be submitted to the TCP/IP channel `tcp_local` using the address `dan@innosoft.com`. Other information appearing here might include an explicit Errors-to: address, which, if present, appears enclosed in square brackets; or notations such as `*RR*` or `*NRR*`, indicating whether or not the message is flagged for read receipts, or notations such as `*NOTIFY FAILURES*`, `*NOTIFY DELAYS*`, `*NOTIFY SUCCESSES*`, *etc.*, indicating the message's delivery receipt mechanism and flagging.

7. Notification addresses. If notifications need to be generated regarding this address, as for instance in the case of a group or list whose definition includes some (immediately obvious

as such) bad addresses, then the addresses about which a notification needs to be generated will be listed here, along with the error corresponding to each such address. If an override envelope From is in effect for the original message, hence if the notification will go back to some address other than the original message's sender, then that address (the address to which the notification will be sent) will be shown enclosed in square brackets. Note that the recipient address for the notification will only be shown if it is something different than the original sender address (as specified via the `-from` switch, or defaulting to the postmaster address).

71.34.6 Error messages

Usually errors reported by `imsimta test -rewrite` are not actually errors regarding `imsimta test -rewrite` in particular, but rather are the utility warning of an underlying configuration problem. For instance, "`Error in mm_init:` ..." sorts of errors are typically configuration errors (whether errors of syntax, of access, of inconsistent/incompatible settings, *etc.*).

`Address list error -- unknown host or domain:`

The above error indicates that the domain name in the specified address did not rewrite to any MTA channel. Check that the domain name was correctly spelled. If the domain name was correct and was a locally hosted domain, then most likely it is not correctly provisioned as a domain in LDAP; see the *Schema Reference*. If the domain name was a correctly spelled external domain name, then most likely you need a new (or changed) rewrite rule in the MTA configuration to handle that domain name, or an updated `tlds.txt` file; see TLD comparison rewrites.

`Unknown group identifier ... found on channel ...`

Prior to MS 7.0, any word on a channel not recognized as a channel option was interpreted as a group identifier. So prior to MS 7.0, the above error was possible, meaning that you (the executor of the `imsimta test -rewrite` command) do not have the specified group identifier. Check that the word shown is truly intended to be present as a group identifier, rather than simply being a misspelled channel option.

71.35 test -time utility

Test date-time strings.

71.35.1 Syntax

```
imsimta test -time input-string
```

Table 71.35 imsimta test -time Command Switches

`-iso8601`	*None*
`-rfc822`	*None*
`-periodic`	`-noperiodic`
`-stamp`	*None*

71.35.2 Parameters

71.35.2.1 *string*

String to test for validity (and meaning) as a date-time.

71.35.3 Description

Test whether a string is a valid date-time string. See also the `imsimta test -zone` utility.

71.35.4 Switches

71.35.4.1 `-iso8601`, `-rfc822`, `-stamp`

The `-iso8601`, `-rfc822`, and `-stamp` qualifiers specify whether the input string is to be checked as a possible ISO 8601 time, an RFC 822 date-time, or as a "time stamp" string (such as from an MTA transaction log file entry), respectively. These qualifiers are mutually exclusive; one must be specified to obtain output. `-stamp` expects a 23 (or more) character long input, of the general form

DD-MMM-YYYY HH:MM:SS.cc

or alternatively

DD-MMM-YYYY:HH:MM:SS.cc

though as the *.cc* centiseconds are ignored, the output is determined only by the portion of the form:

DD-MMM-YYYY HH:MM:SS

or alternatively

DD-MMM-YYYY:*HH*:*MM*:*SS*

71.35.4.2 -periodic, -noperiodic

-periodic and -noperiodic (the default) switches are modifiers available with the -iso8601 qualifier, indicating whether ISO 8601 format is being tested, or ISO 8601 P format is being tested.

71.35.5 Examples

This example shows conversion of a time stamp (such as from an MTA transaction log entry) into other date-time formats.

```
# imsimta test -time -stamp "10-MAR-2013 12:13:14.55"
Result: 1362942794 Sun Mar 10 12:13:14 2013
After conversion to system time: "Sun, 10 Mar 2013 12:13:14 -0700 (PDT)"
After conversion back to time_t: 1362942794 Sun Mar 10 12:13:14 2013
```

This example shows checking the validity of an ISO 8601 format time.

```
# imsimta test -time -iso8601 "2014-06-01T020304.05"
Result: "Sun, 01 Jun 2014 02:03:04 -0700 (PDT)"
```

71.36 test -translation utility

Test charset translation.

71.36.1 Syntax

```
imsimta test -translation [input-string]
```

Table 71.36 imsimta test -translation Command Switches

Switch	Default
`-image_file=`*`filename`*	`-image_file=IMTA_TABLE:advanced/charset_data`
`-source=`*`charset-name`*	
`-destination=`*`charset-name`*	
`-input=`*`filename`*	
`-output=`*`filename`*	
`-strip_accent`	`-nostrip_accent`
`-call_reset`	`-nocall_reset`
`-generate`	`-nogenerate`
`-mnemonic_input`	`-nomnemonic_input`
`-utf8_input`	`-noutf8_input`

71.36.1.1 Prompts

Table 71.37 imsimta test -translate Prompts

Prompt	Value
`Destination character set:`	*`charset-name`*
`Source character set:`	*`charset-name`*
`Input string:`	*`string`*

71.36.2 Parameters

71.36.2.1 *input-string*

Input string to try translating to an alternate charset.

71.36.3 Description

The `imsimta test -translation` utility allows testing charset translation. Note that this is not *language* translation; rather, it is conversion of the representation of characters, from one charset representation, into another charset representation.

71.36.4 Switches

71.36.4.1 -image_file=*filename*

Specify the compiled charset data image file. By default, the image file used is IMTA_TABLE:advanced/charset_data (prior to MS 7.0, the file named by the imta_charset_data MTA Tailor option).

71.36.4.2 -source=*charset-name*

Specify a source charset: the charset used in the input string.

71.36.4.3 -destination=*charset-name*

Specify a destination charset: the charset to use in the output string.

71.36.4.4 -input=*filename*

Read input from the specified file.

71.36.4.5 -output=*filename*

Direct output to the specified file.

71.36.4.6 -strip_accent, -nostrip_accent (default)

When translating from one charset to another charset that does not have the actual character, but does have the character sans accent, specifying -strip_accent causes the accentless character to be output; effectively it "strips" accents. So for instance, -strip_accent may be useful when desiring to downgrade a charset such as ISO-8859-1 down to US-ASCII.

71.36.4.7 -call_reset, -nocall_reset (default)

Specifies whether or not the state of the charset converter is reset prior to each call.

71.36.4.8 -generate, -nogenerate (default)

Specifying -generate tells the utility to generate and output the entire charset table for converting from UTF-8 to the specified output charset. Specifying -generate implies -source=UTF-8. (Thus note that in particular, -generate and -source=*charset-name* cannot both be specified; and while some input file or string can be specified, it will be ignored.)

71.36.4.9 -mnemonic_input, -nomnemonic_input (default)

Specifies whether or not mnemonics can be used to enter non-US-ASCII characters.

71.36.4.10 -utf8_input, -noutf8_input (default)

Specifies whether or not escape sequences can be used to enter UTF-8 characters.

71.36.5 Examples

```
# imsimta test -trans -source=utf-8 -input=utf8.txt -dest=koi8-r -output=koi8r.txt
```

The above example shows a command line for translating the source file `utf8.txt` which is in the UTF-8 charset, into the destination file `koi8r.txt` which is in the KOI8-R charset.

```
# imsimta test -trans -source=koi8-r -dest=us-ascii -input=koi8r.txt -output=mnemonicized.txt
# cat mnemonicized.txt
U=V=E=L=I=C%I=T=%" P=R=O=D=A=Z%I=
```

"Converting" text to US-ASCII, when the original text contained characters not present in the US-ASCII charset, results in outputting the mnemonics (as defined in `charnames.txt`) for the "missing" characters. The above example shows outputting the character mnemonics corresponding to two (Russian language) words, originally represented in the KOI8-R charset; in this case, the output consists of mnemonics for a number of Cyrillic characters.

71.37 test -zone utility

Test a time zone string.

71.37.1 Syntax

```
imsimta test -zone string
```

71.37.2 Parameters

71.37.2.1 *string*

String to test for validity (and meaning) as a time zone name.

71.37.3 Description

Test whether a string is a recognized time zone name. See also the `imsimta test -time` utility.

71.37.4 Examples

This example shows a sample query on a recognized time zone name string. The offset shown is from GMT.

```
# imsimta test -zone PDT
Zone PDT decodes to -7 hours, 0 minutes.
```

This example shows testing a string that is not recognized by the MTA as a valid time zone name.

```
# imsimta test -zone bogus
Zone decode failed.
```

71.38 version utility

Print MTA version number.

71.38.1 Syntax

```
imsimta version
```

71.38.2 Parameters

None.

71.38.3 Description

`imsimta version` prints out the MTA version number, and displays the system's name, operating system release number and version, and hardware type.

As of Messaging Server 8.0 this utility also displays whether or not a compiled configuration is being used.

71.38.4 Example

```
# imsimta version
Oracle Communications Messaging Server 7.0.5.33.0 64bit (built Aug 22 2014)
libimta.so 7.0.5.33.0 64bit (built 00:04:52, Aug 22 2014)
Using /opt/sun/comms/messaging64/config/config.xml (compiled)
NSS Library Version: 3.16.3 Basic ECC
SunOS example 5.10 Generic_127128-11 i86pc i386 i86pc
```

The above example shows MTA version information for a Solaris x86 system running the 64 bit version of Oracle Messaging Server 7.0u6, running with a compiled unified configuration.

71.39 view utility

Display the contents of the specified "version" of an MTA log file.

71.39.1 Syntax

```
imsimta view file-pattern
```

Table 71.38 imsimta view Command Switches

Switch	Default
`-f=offset-from-first`	*None*
`-l=offset-from-last`	*None*

71.39.1.1 Restrictions

Must have read access to the requested file.

71.39.2 Parameters

71.39.2.1 *file-pattern*

A file name pattern for which MTA log file to display. A complete file path may be specified. Or if merely a file name (sans unique id) is specified, the utility will look in the MTA log directory, `imta_log`.

71.39.3 Description

The `imsimta view` utility may be used to display a specified "version" of an MTA log file. MTA log files have a *-uniqueid* appended to the file name to allow for the creation of multiple "versions" of the log file; on UNIX, the *-uniqueid* is appended to the very end of the file name (the end of the file extension). The `imsimta view` utility understands these unique ids and can display the contents of the particular file corresponding to the requested "version" of the file.

The default, if no offset switch is specified, is to display the most recent "version" of the file.

71.39.4 Switches

71.39.4.1 `-f=`*offset-from-first*

This switch is used to specify displaying the *n*th "version" of the file (starting counting from 0). For instance, to display the earliest (oldest) "version" of the file, specify `-f=0`

71.39.4.2 `-l=`*offset-from-last*

This switch is used to specify displaying the *n*th from the last "version" of the file (starting decrementing from 0 as the most recent version). For instance, to display the most recent (newest) "version" of the file, specify `-l=0`

71.39.5 Examples

```
# imsimta view -l=0 job_controller.log
fat_main: watch_connect failed: Connection refused
```

The above example shows displaying the most recent Job Controller log file, and finding logged therein that the Watcher though enabled (`watcher.enable` in Unified Configuration, or `local.watcher.enable` in legacy configuration) was apparently not running (which is what the error message shown in that log file indicates).

```
# imsimta view -f=0 tcp_intranet_master.log
13:00:16.79: Checking for TLS usage
13:00:16.79: Initializing TLS library
13:00:16.98: SMTP options read and set
13:00:16.98: Debug output enabled, system mail.domain.com, process 6597.1, SMTP client version V8.0 compiled Aug 11 2014 11:
13:00:16.98: Oracle Communications Messaging Server shared library version 8.0.0.0.0 linked 11:42:42, Aug  7 2014
13:00:16.98:      max concurrent threads 10, jobs/thread 10
13:00:16.98: ( 2)  tcp_intranet running
13:00:16.98: ( 2)  tcp_intranet -- delivering /opt/sun/comms/messaging64/data/queue/tcp_intranet/004/ZZi0Z6h0Ykfc0.00
13:00:30.29: waiting for 1 threads to exit, or 5400 seconds
13:00:32.31: ( 2)  tcp_intranet finished. did 1 messages
13:00:32.31: ( 2) No more hosts, ending connections
13:00:32.31: All message processing completed.
# imsimta view -f=1 tcp_intranet_master.log
13:00:16.98: Initializing message dequeue via quc_rinit, file "/opt/sun/comms/messaging64/data/queue/tcp_intranet/004/ZZi0Z6
13:00:16.98: Reading first To: address
13:00:16.98: log_queue_entry called.
13:00:16.98:   Originator address john.doe@domain.com
13:00:16.98:   Recipient address jane.doe@domain.com
13:00:16.98:   Original recipient address rfc822;jane.doe@domain.com
13:00:16.98: Forced routing to host1.domain.com
13:00:16.98: Setting up connection to "host1.domain.com", initial mailbox "jane.doe"
13:00:16.98: No connection currently open
13:00:16.98: Opening new connection for host1.domain.com
...etc...
```

The above example shows displaying two `tcp_intranet_master.log-*` files containing `master_debug` output, the (currently) oldest (which in this case is "controller" thread output), and the (currently) next-to-oldest (which in this case is output from a delivery thread, processing a particular message file).

Part VIII Additional components

Messaging Server includes a Personal Addressbook facility, SNMP support, and support for an Event Notification Service.

Chapter 72 PAB options

A number of options affect PAB (Personal Address Book) operation.

Note that for purposes of MTA queries of PABs, there are a number of PAB-related MTA options that can affect the MTA's PAB queries.

72.1 `enable` Option Under pab

The `enable` PAB option enables or disables the Personal Address Book (PAB) feature.

72.2 `defaulthostindex` Option

The `defaulthostindex` PAB option specifies the index of the default host.

72.3 `active` Option

The `active` PAB option should be set to 1 if PAB host is active, 0 otherwise.

72.4 `alwaysusedefaulthost` Option

The `alwaysusedefaulthost` PAB option enables one PAB server to be used (overriding hostname in PAB URIs).

72.5 `attributelist` Option

The `attributelist` PAB option allows adding new attributes to a personal address book entry. With this parameter, you can create an attribute that does not already exist.

72.6 `ldapbasedn` Option

The `ldapbasedn` PAB option specifies the base DN for PAB searches. If not set, it defaults to the value of the `ugldapbasednbase` option (`local.ugldapbasedn` in legacy configuration).

72.7 ldapbinddn Option

The ldapbinddn PAB option specifies the bind DN for PAB searches. If not set, it defaults to the value of the ugldapbinddnbase option (local.ugldapbinddn in legacy configuration).

72.8 ldaphost Option

The ldaphost PAB option specifies the hostname of the PAB Directory Server. If not set, it defaults to the value of the ugldaphostbase option (local.ugldaphost in legacy configuration).

72.9 ldappasswd Option

The ldappasswd PAB option specifies the password for the user specified by the ldapbinddn PAB option (respectively, local.service.pab.ldappasswd and local.service.pab.ldapbinddn in legacy configuration). If not set, ldappasswd defaults to the value of the ugldapbindcredbase option (local.ugldapbindcred in legacy configuration).

72.10 ldapport Option

The ldapport PAB option specifies the port number of the PAB Directory Server. If not set, it defaults to the value of the ugldapportbase option (local.ugldapport in legacy configuration).

72.11 ldapusessl Option

The ldapusessl PAB option specifies whether to use SSL to connect to the PAB Directory Server.

72.12 maxnumberofentries Option

The maxnumberofentries PAB option specifies the maximum number of entries a single PAB can store.

72.13 migrate415 Option

The migrate415 PAB option enables PAB migration when set to 1.

72.14 numberofhosts Option

The numberofhosts PAB option specifies the number of PAB servers (up to a maximum of 16).

Chapter 73 SNMP options

Several options affect operation of Messaging Server's SNMP subagent(s). Some options only affect Messaging Server's Net-SNMP based SNMP subagent, used on Solaris platforms running Solaris 10 and later, as well as Linux platforms, but do *not* apply to the legacy SNMP subagent supplied for Solaris platforms running Solaris 9 and earlier operating systems.

Note that while Messaging Server's SNMP support normally runs as a SNMP subagent, receiving SNMP requests via the platform's SNMP master agent, `snmpd`, Messaging Server's SNMP subagent can be run in a different mode, as an SNMP agent itself, independent of `snmpd`; see the `standalone`, `listenaddr`, and `port` SNMP options.

See also the logfile options set as `snmp.logfile.*`.

73.1 `enable` Option Under snmp

The `enable` SNMP option, `snmp.enable` (Unified Configuration) or `local.snmp.enable` (legacy configuration), enables the SNMP subagent on `start-msg` startup.

This option applies to both the Net-SNMP based SNMP subagent, and the legacy SNMP subagent for Solaris 9 and earlier.

73.2 `listenaddr` Option Under snmp

The `listenaddr` SNMP option specifies the IPv4 address to listen on when running as a SNMP master agent -- that is, when the `standalone` SNMP option has been set to `1`. The allowed values for `listenaddr` include an IPv4 address in dotted decimal form (e.g., `127.0.0.1`), or a short form or fully-qualified DNS host name which will be resolved to an IPv4 address by obtaining the DNS A record for the name. To explicitly specify the default value of binding to all available interfaces, the string "`INADDR_ANY`" may be used; (this is the default). To bind to the loopback device, `127.0.0.1`, the string "`localhost`" may be specified.

This option applies only to the Net-SNMP based SNMP subagent, but *not* to the legacy SNMP subagent for Solaris 9 and earlier.

73.3 `port` Option Under snmp

The `port` SNMP option specifies the UDP port to listen on when running as a SNMP master agent -- that is, when the `standalone` SNMP option has been set to `1`. The default is `161`.

This option applies only to the Net-SNMP based SNMP subagent, but *not* to the legacy SNMP subagent for Solaris 9 and earlier.

73.4 cachettl Option Under snmp

The cachettl SNMP option specifies the time to live (TTL) in seconds for cached monitoring data. That is, this option controls how long the subagent will report the same monitoring data before refreshing that data with new information obtained from Messaging Server. With the exception of message loop information, data is cached for no longer than 30 seconds by default. Loop information, as determined by scanning for .HELD files, is updated only once every 10 minutes. That because of the resource cost of scanning all the on-disk message queues; (see also the directoryscan SNMP option).

Note that the subagent does not continually update its monitoring data: it is only updated upon receipt of an SNMP request and the cached data has expired (that is, outlived its TTL). If the TTL is set to 30 seconds and SNMP requests are made only every five minutes, then each SNMP request will cause the subagent to obtain fresh data from Messaging Server. That is, data from Messaging Server will be obtained only once every five minutes. If, on the other hand, SNMP requests are made every 10 seconds, then the subagent will respond to some of those requests with cached data as old as 29 seconds; Messaging Server will be polled only once every 30 seconds.

This option applies to both the Net-SNMP based SNMP subagent, and the legacy SNMP subagent for Solaris 9 and earlier.

73.5 contextname Option

When the use of SNMP v3 context names has been enabled with the enablecontextname SNMP option, then the contextname SNMP option may be used to explicitly set the context name used by the subagent for its MIBs. The value supplied for this option is a string value and must be appropriate for use as a SNMP v3 context name. If not explicitly set, the default value for contextname is the value of the defaultdomain base option (the service.defaultdomain configutil parameter in legacy configuration). The contextname option is ignored when enablecontextname has the value 0.

This option applies only to the Net-SNMP based SNMP subagent, but *not* to the legacy SNMP subagent for Solaris 9 and earlier.

73.6 directoryscan Option

The directoryscan SNMP option selects whether or not the subagent performs scans of the MTA's on-disk channel message queues to count .HELD message files, and update its information on the oldest message files. That information corresponds to the mtaGroupLoopsDetected, mtaGroupOldestMessageStored and mtaGroupOldestMessageId MIB variables; see MIB variables served. When this option has the value 1 (or "true" in legacy configuration), then a cache of this information is maintained and updated as needed. Sites with thousands of queued messages, if not interested in these particular MIB variables, should consider setting this option's value to 0, as performing the message queue traversal involves some overhead.

This option applies to both the Net-SNMP based SNMP subagent, and the legacy SNMP subagent for Solaris 9 and earlier.

73.7 enablecontextname Option

The Net-SNMP based SNMP subagent has the ability to register its MIBs under an SNMP v3 context name. When this is done, the MIBs may only be requested by a SNMP v3 client which specifies the context name in its SNMP request. Use of context names allows multiple, independent subagents to register Network Services and MTA MIBs under the same OID tree (that is, under the same SNMP master agent).

The `enablecontextname` SNMP option controls whether to register this instance's MIBs under an SNMPv3 context name. When the option is set to a value of 1, the subagent will default to using the value of `defaultdomain` for its context name, unless a different context name has been specified using via the `contextname` SNMP option.

This option applies only to the Net-SNMP based SNMP subagent, but *not* to the legacy SNMP subagent for Solaris 9 and earlier.

73.8 registerindices Option

The `registerindices` SNMP option controls whether to register as visible MIB variables the applIndex, assocIndex, and mtaGroupIndex MIB indices. By default, these MIB variables are implicit and not explicitly shown as distinct MIB variables when walking the MIBs.

This option applies only to the Net-SNMP based SNMP subagent, but *not* to the legacy SNMP subagent for Solaris 9 and earlier.

73.9 servertimeout Option

The `servertimeout` SNMP option specifies the maximum number of seconds to wait for each step in probing a server (connect to, read from, write to, etc.).

The subagent determines the operational status of each monitored service by actually opening TCP connections to each service and undergoing a protocol exchange. This timeout value, measured in seconds, controls how long the subagent will wait for a response to each step in the protocol exchange. By default, a timeout value of five seconds is used.

This option applies to both the Net-SNMP based SNMP subagent, and the legacy SNMP subagent for Solaris 9 and earlier.

73.10 standalone Option

The `standalone` SNMP option may be set to run as a standalone SNMP agent when set to 1 (or "true" for the legacy configuration `local.snmp.standalone configutil` parameter).

Messaging Server's SNMP support normally runs as a SNMP subagent, receiving SNMP requests via the platform's SNMP master agent, `snmpd`. This operational mode is the default and is selected by giving the `standalone` option a value of 0 (or "false" for the legacy configuration parameter). However, the subagent may run in a "standalone" mode whereby it operates as a SNMP agent independent of `snmpd`. When run in standalone mode, the subagent--now a SNMP agent--listens directly for SNMP requests on the Ethernet interface and UDP port specified by, respectively, the `snmp.listenaddr` and `snmp.port` options (`configutil` parameters `local.snmp.listenaddr` and `local.snmp.port` in legacy

configuration). To run in this standalone mode, specify a value of 1 (or "true" in legacy configuration) for this option.

Running in standalone mode does not interfere with other SNMP master or subagents running on the system.

This option applies only to the Net-SNMP based SNMP subagent, but *not* to the legacy SNMP subagent for Solaris 9 and earlier.

Chapter 74 ENS options

Several options affecting operation of the ENS server may be set under the `ens` group; in particular, `ens.enable` must be set to enable running the ENS server. For additional, logging related options, see the logfile options set as `ens.logfile.*`.

For related functionality and options, see also the `base.listenaddr` option, the `enssub` value of the `debugkeys` option, the `msprobe.probe:ens.*`, and the `notifytarget` options.

74.1 `enable` Option Under ens

The `enable` ENS option enables the ENS server on `start-msg` startup. The default value is the value of `store.enable` (aka `local.store.enable` in legacy config).

74.2 `port` Option Under ens

The `port` ENS option specifies the TCP port the ENS server will listen on. The default is `7997`. Versions of ENS prior to 7 update 4 support inclusion of a server IP address in addition to a port number in the `local.ens.port` configutil option. That syntax is deprecated. In legacy configuration, the IP address portion is ignored as of 8.0.1. In Unified Configuration, the legacy syntax is disallowed. The `base.listenaddr` option (`service.listenaddr` in legacy configuration) is the recommend way to set the ENS server host IP for version 7 update 4 and later.

If `ens.port` is set, then the `notifytarget:`*`target-name`*`.ensport` option (`local.store.notifyplugin.*.ensport`in legacy configuration) must be configured to match. In legacy configuration, if the `local.ens.port configutil` parameter also specified a host IP address, then `local.store.notifyplugin.*.enshost` would also need to be set correspondingly. For Unified Configuration, the equivalent is that the `notifytarget:`*`target-name`*`.enshost` option value must match the `base.listenaddr` option value.

74.3 `enablesslport` Option Under ens

The `enablesslport` ENS option sets whether or not ENS over SSL service is started. Note that the `ens.sslport` option controls what port *is* the ENS+SSL port.

74.4 sslport Option Under ens

The sslport ENS option specifies the port number for the ENS over SSL port. Note that to enable the ENS+SSL service, the ens.enablesslport option must be set.

74.5 secret Option Under ens

The secret ENS option specifies the secret used to authenticate ENS clients with the server.

74.6 loglevel Option Under ens

The loglevel ENS option specifies the level of ENS client library logging to the process nslog file. Messages are also filtered per the loglevel of the process. Allowed values are as in the Unified Configuration logfile.loglevel option (logfile.*.loglevel in legacy configuration). But note that the value "debug" generates lots of data and is not recommended.

74.7 domainallowed Option Under ens

The domainallowed ENS option specifies access filters specifying which domains and/or IP addresses are allowed ENS access.

74.8 domainnotallowed Option Under ens

The domainnotallowed ENS option specifies access filters specifying which domains and/or IP addresses are not allowed ENS access.

74.9 sslnicknames Option Under ens

The sslnicknames ENS option specifies a list of SSL/TLS server certificate nicknames (only one per certificate type) for HTTP to offer clients if SSL/TLS enabled. Overrides for HTTP the base level sslnicknames option (corresponding to the legacy configuration encryption.rsa.nssslpersonalityssl configutil parameter).

74.10 mustauthenticate Option

The mustauthenticate option under ens, ens.mustauthenticate, specifies whether the ENS server requires authentication.

Chapter 75 eval_ldapd options

The Evaluation LDAP server (eval_ldapd) supports options controlling access via access filters.

75.1 `domainallowed` Option Under eval_ldapd

The `domainallowed` option under `eval_ldapd` allows setting access filters specifying which domains and/or IP addresses are allowed evaluation ldapd access.

75.2 `domainnotallowed` Option Under eval_ldapd

The `domainnotallowed` option under `eval_ldapd` allows setting access filters specifying which domains and/or IP addresses are *not* allowed evaluation ldapd access.

Appendix A Supported Standards

This information lists national, international, industry, and de-facto standards related to electronic messaging and for which support is claimed by Oracle Communications Messaging Server. Most of these are Internet standards, published by the RFC Editor and approved by the Internet Engineering Task Force (IETF). Standards for documents from other sources are noted.

Software compliant with older IETF RFCs is usually compatible with newer RFCs unless the protocol version changes. Where the table mentions a newer version in parentheses and that version is not listed in a separate row, we have not made a complete assessment of compatibility but are probably compatible with the new version unless otherwise stated. Newer versions of IETF specifications often drop features that were optional, rarely used or problematic. If we implemented features of note that are present only in the older specification, the older specification is listed on a separate row in addition to the parenthetical mention.

Features with status "Experimental" or "Work in Progress" may be changed incompatibly in a future version until the specification has settled. Features with status "De Facto" may not interoperate with all software as interpretations of the de facto standard may vary.

Table A.1 *Protocols*

Reference	Status	Feature and Information
RFC 3501	Proposed standard	*IMAP* (port 143) (Usage: Server Client) (Older specs: RFC2060) March 2003
RFC 2180	Informational	*IMAP4 Multi-Accessed Mailbox Practice* (port 143) (Usage: Server Client) July 1997
RFC 2061	Informational	*IMAP4 Compatibility with IMAP2bis* (port 143) (Usage: Server Client) (Older specs: RFC1730) December 1996
RFC 2062	Informational	*Internet Message Access Protocol - Obsolete Syntax* (port 143) (Usage: Server Client) December 1996
RFC 2683	Informational	*IMAP4 Implementation Recommendations* (port 143) (Usage: Server Client) September 1999
RFC 1730	Proposed standard	*IMAP4* (Usage: Server) (Newer specs: RFC2060 RFC2061) December 1994
RFC 3501 section 7.2.1	Proposed standard	*IMAP4rev1* Caveat: Cassandra store and ISS search are not complaint with the IMAP specification. (Usage: Server Client) (Older specs: RFC2060) March 2003

RFC 3501 section 6.2.1	Proposed standard	*IMAP STARTTLS* (Usage: Server Off-by-default) (Older specs: RFC2060) March 2003
RFC 8446		*TLS 1.3 as used by IMAP STARTTLS* (Usage: Server Off-by-default)
RFC 3501 section 6.2.3	Proposed standard	*IMAP LOGINDISABLED* (Usage: Server Off-by-default) (Older specs: RFC2060) March 2003
RFC 4422	Proposed standard	*AUTHENTICATE (SASL)* Caveat: SASLprep is not implemented. (Usage: Server Client) (Older specs: RFC2222) June 2006
RFC 3501 section 6.2.2	Proposed standard	*AUTHENTICATE (SASL)* Caveat: SASLprep is not implemented. (Usage: Server Client) (Older specs: RFC2060) March 2003
RFC 4616	Proposed standard	*IMAP AUTH=PLAIN* Caveat: SASLprep is not implemented. (Usage: Server Client) August 2006
RFC 4422 page 29	Proposed standard	*IMAP AUTH=EXTERNAL* (Usage: Server Off-by-default) (Older specs: RFC2222) June 2006
RFC 2245	Proposed standard	*IMAP AUTH=ANONYMOUS* (Usage: Server Off-by-default) (Newer specs: RFC4505) November 1997
RFC 2195	Proposed standard	*IMAP AUTH=CRAM-MD5* (Usage: Server Off-by-default) (Older specs: RFC2095) September 1997
RFC 2086	Proposed standard	*IMAP ACL* Caveat: Support for the 'p' right only works for user 'anyone' presently. (Usage: Server) (Newer specs: RFC4314) January 1997
RFC 2087	Proposed standard	*IMAP QUOTA* (Usage: Server) January 1997
RFC 2088	Proposed standard	*IMAP LITERAL+* (Usage: Server) January 1997
RFC 2342	Proposed standard	*IMAP NAMESPACE* (Usage: Server) May 1998

RFC 2359	Proposed standard	*IMAP UIDPLUS* (Usage: Server) (Newer specs: RFC4315) June 1998
RFC 3348	Informational	*IMAP CHILDREN* (Usage: Server) July 2002
RFC 3516	Proposed standard	*IMAP BINARY* (Usage: Server) April 2003
RFC 3691	Proposed standard	*IMAP UNSELECT* Added in release: 6.3 (Usage: Server) February 2004
RFC 2177	Proposed standard	*IMAP IDLE* Added in release: 6.3 (Usage: Server Off-by-default) (Enhancement Request: 12037435) June 1997
RFC 4959	Proposed standard	*IMAP SASL-IR* Added in release: 7.0 (Usage: Server) September 2007
RFC 4469	Proposed standard	*IMAP CATENATE* Added in release: 7.0 (Usage: Server) April 2006
RFC 5161	Proposed standard	*IMAP ENABLE* Added in release: 7.0 (Usage: Server) March 2008
RFC 4731	Proposed standard	*IMAP ESEARCH* Added in release: 7.0 (Usage: Server) November 2006
RFC 4551	Proposed standard	*IMAP CONDSTORE* Added in release: 7.0 (Usage: Server) (Newer specs: RFC7162) June 2006
RFC 5092	Proposed standard	*IMAP URL* Details: Used by IMAP referrals, URLFETCH and CATENATE Added in release: 8.0.1 (Usage: Server Client) (Older specs: RFC2192) (Enhancement Request: 21092120) November 2007
RFC 4467	Proposed standard	*IMAP URLAUTH* Added in release: 7.0 (Usage: Server Client) May 2006
RFC 5162	Proposed standard	*IMAP QRESYNC* Added in release: 7.0 (Usage: Server) (Newer specs: RFC7162) March 2008
RFC 5032	Proposed standard	*IMAP WITHIN* Added in release: 7.0 (Usage: Server) September 2007

RFC 2221	Proposed standard	*IMAP Login Referrals* Details: Used to detect user in transit via rehostuser utility. Added in release: 7.0 (Usage: Server Client) October 1997
RFC 5257	Experimental	*IMAP ANNOTATE* Added in release: 7.0 (Usage: Server) June 2008
RFC 5267	Proposed standard	*IMAP CONTEXT* Added in release: 7.0 (Usage: Server) July 2008
RFC 5256	Proposed standard	*IMAP THREAD* Caveat: We don't implement I18NLEVEL or i;unicode-casemap as required, and instead use a similar unicode collator Added in release: 7.0 (Usage: Server) June 2008
RFC 5256	Proposed standard	*IMAP SORT* Caveat: We don't implement I18NLEVEL or i;unicode-casemap as required, and instead use a similar unicode collator Added in release: 6.3 (Usage: Server Client) June 2008
RFC 5957	Proposed standard	*IMAP SORT=DISPLAY* Caveat: We don't implement I18NLEVEL or i;unicode-casemap as required, and instead use a similar unicode collator Added in release: 8.0 (Usage: Server) (Enhancement Request: 19597156) July 2010
RFC 5255	Proposed standard	*IMAP LANGUAGE* (Usage: Server Client) June 2008
RFC 5464	Proposed standard	*IMAP METADATA* Added in release: 7.0.5 (Usage: Server) February 2009
RFC 2971	Proposed standard	*IMAP ID* Added in release: 7 Update 4 (Usage: Server) (Enhancement Request: 12139651) October 2000
RFC 5530	Proposed standard	*IMAP Response Codes* Added in release: 7.0.5 (Usage: Server) May 2009
RFC 4314	Proposed standard	*IMAP ACL Extension* (Usage: Server) (Older specs: RFC2086) December 2005

RFC 5182	Proposed standard	*IMAP Referencing the Last SEARCH Result* Added in release: 7 Update 2 (Usage: Server) March 2008
RFC 5819	Proposed standard	*IMAP4 Extension for Returning STATUS Information in Extended LIST* Added in release: 8.0 (Usage: Server) (Enhancement Request: 16773851) March 2010
RFC 6154	Proposed standard	*IMAP LIST Extension for Special-Use Mailboxes* Added in release: 8.0 (Usage: Server) (Enhancement Request: 16773916) March 2011
RFC 7377	Proposed standard	*IMAP MULTISEARCH* Added in release: 8.0 (Usage: Server) (Older specs: RFC6237) (Enhancement Request: 17596568) October 2014
RFC 2221	Proposed standard	*IMAP LOGIN-REFERRALS* Added in release: 8.0.1 (Usage: Server Client) (Enhancement Request: 21092120) October 1997
RFC 6855	Proposed standard	*IMAP UTF8=ACCEPT* Caveat: The implementation is more permissive about using/allowing UTF-8 in the protocol than the specification. Added in release: 8.1 (Usage: Server) (Older specs: RFC5738) March 2013
RFC 5550	Proposed standard	*IMAP URL-PARTIAL* Added in release: 8.0.2.3 (Usage: Server) (Older specs: RFC4550) August 2009
RFC 8438		*IMAP STATUS=SIZE* Added in release: 8.0.2.3 (Usage: Server)
RFC 8437		*UNAUTHENTICATE* Added in release: future (Usage: Server)
RFC 8514		*SAVEDATE* Added in release: future (Usage: Server)
RFC 1939	Internet standard	*POP3* (port 110) (Usage: Server Client) (Older specs: RFC1725) May 1996

RFC 1957	Informational	*Some Observations on Implementations of the Post Office Protocol (POP3)* (port 110) (Usage: Server Client) June 1996
RFC 1939 section 7	Internet standard	*POP TOP* (Usage: Server) (Older specs: RFC1725) May 1996
RFC 1939 page 12	Internet standard	*POP UIDL* (Usage: Server Client) (Older specs: RFC1725) May 1996
RFC 1939 page 13	Internet standard	*POP USER / PASS* (Usage: Server Client) (Older specs: RFC1725) May 1996
RFC 1939 page 15	Internet standard	*APOP* (Usage: Server Off-by-default) (Older specs: RFC1725) May 1996
RFC 2449 section 6.3	Proposed standard	*POP SASL* (Usage: Server Client) November 1998
RFC 2449	Proposed standard	*POP CAPA* Caveat: We don't implement EXPIRE or LOGIN-DELAY. (Usage: Server) November 1998
RFC 2449 section 6.6	Proposed standard	*POP PIPELINING* (Usage: Server) November 1998
RFC 2449 section 6.4	Proposed standard	*POP RESP-CODES* (Usage: Server) November 1998
RFC 2449 section 6.9	Proposed standard	*POP IMPLEMENTATION* (Usage: Server) November 1998
RFC 2595 section 4	Proposed standard	*POP STLS* (Usage: Server Off-by-default) June 1999
RFC 8446		*TLS 1.3 as used by POP STLS* (Usage: Server Off-by-default)
RFC 3206	Proposed standard	*POP AUTH-RESP-CODES* (Usage: Server) February 2002
RFC 5321	Draft standard	*SMTP Specification* (port 25) (Usage: Server Client) (Older specs: RFC2821) October 2008
RFC 821	Internet standard	*SMTP Legacy Specification* (port 25) (Usage: Server Client) (Older specs: RFC0788) (Newer specs: RFC2821) August 1982
RFC 920	Unknown	*Domain requirements* (port 25) (Usage: Server Client) October 1984

RFC 974	Historic	*SMTP Mail Routing and DNS* (port 25) (Usage: Server Client) (Newer specs: RFC2821) January 1986
RFC 1123 section 5	Internet standard	*SMTP Host Requirements* (port 25) (Usage: Server Client) October 1989
RFC 2505	Best current practice	*Anti-Spam Recommendations for SMTP MTAs* (port 25) (Usage: Server Client) February 1999
RFC 3848	Draft standard	*ESMTP and LMTP Transmission Types Registration* (port 25) (Usage: Server Client) July 2004
RFC 1428	Informational	*Transition of Internet Mail from Just-Send-8 to 8bit-SMTP/MIME* (port 25) (Usage: Server Client) February 1993
RFC 6152	Internet standard	*SMTP 8BITMIME* (Usage: Server Client) (Older specs: RFC1652) March 2011
RFC 2920	Internet standard	*SMTP PIPELINING* (Usage: Server Client) (Older specs: RFC2197) September 2000
RFC 3030	Proposed standard	*SMTP CHUNKING* Caveat: Spec also contains BINARYMIME which has not been implemented. Added in release: 6.3 (Usage: Server Client) (Older specs: RFC1830) (Enhancement Request: 12143903) December 2000
RFC 3461	Draft standard	*SMTP DSN* (Usage: Server Client) (Older specs: RFC1891) January 2003
RFC 2034	Proposed standard	*SMTP ENHANCEDSTATUSCODES* (Usage: Server Client) October 1996
RFC 3463	Draft standard	*Enhanced Mail System Status Codes* (Usage: Server Client) (Older specs: RFC1893) January 2003
RFC 2821 section 4.1.1.7	Proposed standard	*SMTP EXPN* (Usage: Server) (Older specs: RFC0821 RFC0974 RFC1869) (Newer specs: RFC5321) April 2001
RFC 2821 section 4.1.1.8	Proposed standard	*SMTP HELP* (Usage: Server) (Older specs: RFC0821

		RFC0974 RFC1869) (Newer specs: RFC5321) April 2001
RFC 821 section 3.4	Internet standard	*SMTP SAML* (Usage: Server Off-by-default) (Older specs: RFC0788) (Newer specs: RFC2821) August 1982
RFC 821 section 3.4	Internet standard	*SMTP SEND* (Usage: Server Off-by-default) (Older specs: RFC0788) (Newer specs: RFC2821) August 1982
RFC 821 section 3.4	Internet standard	*SMTP SOML* (Usage: Server Off-by-default) (Older specs: RFC0788) (Newer specs: RFC2821) August 1982
RFC 821 section 3.8	Internet standard	*SMTP TURN* (Usage: Server Off-by-default) (Older specs: RFC0788) (Newer specs: RFC2821) August 1982
RFC 3207	Proposed standard	*SMTP STARTTLS* (Usage: Server Client Off-by-default) (Older specs: RFC2487) February 2002
RFC 8446		*TLS 1.3 as used by SMTP STARTTLS* (Usage: Server Client Off-by-default)
RFC 4954	Proposed standard	*SMTP AUTH* Caveat: SASLprep is not implemented. Versions 8.0 and prior may use different error codes than those in RFC 4954. Support for AUTH= mail parameter is server-only. (Usage: Server Client Off-by-default) (Older specs: RFC2554) July 2007
RFC 4422	Proposed standard	*SMTP AUTH* Caveat: SASLprep is not implemented. Versions 8.0 and prior may use different error codes than those in RFC 4954. Support for AUTH= mail parameter is server-only. (Usage: Server Client Off-by-default) (Older specs: RFC2222) June 2006
RFC 1985	Proposed standard	*SMTP ETRN* (Usage: Server) August 1996

RFC 1870	Internet standard	*SMTP SIZE* (Usage: Server) (Older specs: RFC1653) November 1995
RFC 1846	Experimental	*SMTP 521 Reply Code* (Usage: Client) September 1995
RFC 7505	Proposed standard	*Null MX No Service Resource Record* Details: Used to provide more timely reporting of SMTP errors Added in release: 8.0 (Usage: Client) June 2015
RFC 7372	Proposed standard	*Email Authentication Status Codes* Details: Used to provide more accurate reporting of SMTP DNS errors Added in release: 8.0 (Usage: Client) September 2014
RFC 3865	Proposed standard	*SMTP NO-SOLICITING* (Usage: Server Off-by-default) September 2004
SMTP AUTH=LOGIN	Widely Used or De Facto	*SMTP AUTH=LOGIN* Details: Undocumented pre-standard subset of AUTH PLAIN but with interoperability problems. (Usage: Server)
RFC 4408	Experimental	*Sender Permitted From* (Usage: Client) (Newer specs: RFC7208) April 2006
RFC 2852	Proposed standard	*SMTP Deliver By* Details: Control when message is returned as undeliverable Added in release: 8.0.1 (Usage: Server Client) June 2000
draft-melnikov-smtp-altrecip-on-error-01.txt	Work in Progress, subject to change	*SMTP ALTRECIP* Details: Delivery to alternate recipient on error Added in release: 8.0.1 (Usage: Client)
RFC 6710	Proposed standard	*SMTP Priority* Details: Envelope specification of message processing priority Added in release: 8.0 (Usage: Server Client) August 2012
RFC 6710	Proposed standard	*SMTP Priority Tunneling* Details: Tunneling of SMTP Message Transfer Priorities Added in release: 8.0.1 (Usage: Server Client) August 2012
RFC 6729	Proposed standard	*Received state* Details: Received: field indicator of the

		state attached to the message Added in release: 8.0 (Usage: Server) September 2012
RFC 7293	Proposed standard	*Require Recipient Valid Since* Details: Mailbox ownership change detection Added in release: 8.0 (Usage: Server Client) July 2014
RFC 6409	Internet standard	*Message Submission* Details: Superset of SMTP adding AUTH by default. (port 587) (Usage: Server Client) (Older specs: RFC4409) November 2011
RFC 4954	Proposed standard	*Submission AUTH* Caveat: SASLprep is not implemented. Versions 8.0 and prior may use different error codes than those in RFC 4954. Support for AUTH= mail parameter is server-only. (Usage: Server Client) (Older specs: RFC2554) July 2007
RFC 4422	Proposed standard	*Submission AUTH* Caveat: SASLprep is not implemented. Versions 8.0 and prior may use different error codes than those in RFC 4954. Support for AUTH= mail parameter is server-only. (Usage: Server Client) (Older specs: RFC2222) June 2006
RFC 4616	Proposed standard	*Submission AUTH PLAIN* Caveat: SASLprep is not implemented. (Usage: Server Client) August 2006
RFC 4422 page 29	Proposed standard	*Submission AUTH=EXTERNAL* (Usage: Server Client Off-by-default) (Older specs: RFC2222) June 2006
Submission AUTH=LOGIN	Widely Used or De Facto	*Submission AUTH=LOGIN* Details: Undocumented, subset of AUTH PLAIN functionality. (Usage: Server Client)
RFC 4468	Proposed standard	*Submission BURL* Added in release: 7.0 (Usage: Server) May 2006

RFC 4865	Proposed standard	*Submission Future Release* Added in release: 7.0 (Usage: Server) May 2007
RFC 3887	Proposed standard	*MTQP Specification* Details: Message Tracking Added in release: 8.0 (port 1038) (Usage: Server Client) September 2004
RFC 3886	Proposed standard	*Tracking response format* Details: Message Tracking Added in release: 8.0 (port 1038) (Usage: Server Client) September 2004
RFC 3885	Proposed standard	*SMTP MSGTRK extension* Details: Message Tracking Added in release: 8.0 (port 1038) (Usage: Server Client) September 2004
RFC 3888	Informational	*Tracking model and requirements* Details: Message Tracking Added in release: 8.0 (port 1038) (Usage: Server Client) September 2004
RFC 3458	Proposed standard	*Message Context for Internet Mail* Details: Gateway for pager/cell phone connectivity for SMS. (Usage: Server Client Off-by-default) January 2003
RFC 2251	Proposed standard	*LDAPv3* (port 389) (Usage: Client) (Newer specs: RFC4510 RFC4511 RFC4513 RFC4512) December 1997
RFC 8314		*IMAPS* Details: standard IMAP SSL port (port 993) (Usage: Server Client Off-by-default)
RFC 8314		*POP3S* Details: standard POP3 SSL port (port 995) (Usage: Server Client Off-by-default)
RFC 8314		*SUBMISSIONS* Details: standard mail submission SSL port (port 465) (Usage: Server Client Off-by-default)
RFC 1034	Internet standard	*Domain names - concepts and facilities* (port 53) (Usage: Client) (Older specs: RFC0973 RFC0882 RFC0883) November 1987
RFC 1035	Internet standard	*Domain names - implementation and specification* (port 53)

		(Usage: Client) (Older specs: RFC0973 RFC0882 RFC0883) November 1987
RFC 1035 section 3.4.1	Internet standard	*DNS A* (Usage: Client) (Older specs: RFC0973 RFC0882 RFC0883) November 1987
RFC 3596	Draft standard	*DNS AAAA* Details: Support can be configured on (Usage: Client) (Older specs: RFC3152 RFC1886) October 2003
RFC 1035 section 3.3.1	Internet standard	*DNS CNAME* (Usage: Client) (Older specs: RFC0973 RFC0882 RFC0883) November 1987
RFC 1035 section 3.3.9	Internet standard	*DNS MX* (Usage: Client) (Older specs: RFC0973 RFC0882 RFC0883) November 1987
RFC 934	Unknown	*DNS MX* (Usage: Client) January 1985
RFC 1035 section 3.3.12	Internet standard	*DNS PTR* (Usage: Client) (Older specs: RFC0973 RFC0882 RFC0883) November 1987
RFC 1035 section 3.3.14	Internet standard	*DNS TXT* Details: For RBL and SPF. (Usage: Client) (Older specs: RFC0973 RFC0882 RFC0883) November 1987
RFC 3507	Informational	*ICAP* Details: For Norton AV. (port 1344) (Usage: Client Off-by-default) April 2003
RFC 1928	Proposed standard	*SOCKS 5* (port 1080) (Usage: Client Off-by-default) March 1996
RFC 2788	Proposed standard	*SNMP Network Services MIB* Details: Provided via NetSNMP. (port 161) (Usage: Server Off-by-default) (Older specs: RFC2248) March 2000
RFC 2789	Proposed standard	*SNMP Mail MIB* Details: Provided via NetSNMP. (port 161) (Usage: Server Off-by-default) (Older specs: RFC2249 RFC1566) March 2000
RFC 2033	Informational	*LMTP* Caveat: The addressing model is non-standard in order to avoid the need for

		the LMTP server to perform address lookups in LDAP. Third-party use of this is not supported and will not work as expected. (port 225) (Usage: Server Client Off-by-default) October 1996

Table A.2 ***Data and File Formats, Schema***

Reference	Status	Feature and Information
RFC 822	Internet standard	*Legacy Internet Message Format* (Usage: Generate Accept Process) (Older specs: RFC0733) (Newer specs: RFC2822) August 1982
RFC 5322	Draft standard	*Internet Message Format* (Usage: Generate Accept Process) (Older specs: RFC2822) October 2008
RFC 6532	Proposed standard	*Internationalized Email Headers* (Usage: Generate Accept Process) (Older specs: RFC5335) February 2012
RFC 2045	Draft standard	*Multi-purpose Internet Mail Extensions (MIME)* (Usage: Generate Accept Process) (Older specs: RFC1521 RFC1522 RFC1590) November 1996
RFC 2046	Draft standard	*Multi-purpose Internet Mail Extensions (MIME)* (Usage: Generate Accept Process) (Older specs: RFC1521 RFC1522 RFC1590) November 1996
RFC 2049	Draft standard	*Multi-purpose Internet Mail Extensions (MIME)* (Usage: Generate Accept Process) (Older specs: RFC1521 RFC1522 RFC1590) November 1996
RFC 2047	Draft standard	*MIME International Headers* (Usage: Generate Accept Process Normalize) (Older specs: RFC1521 RFC1522 RFC1590) November 1996
RFC 2231	Proposed standard	*MIME International Parameters* (Usage: Accept Process)

		(Older specs: RFC2184) November 1997
RFC 2183	Proposed standard	*MIME Content-Disposition* (Usage: Generate Accept Process) (Older specs: RFC1806) August 1997
RFC 1864	Draft standard	*Content-MD5* (Usage: Process Validate) (Older specs: RFC1544) October 1995
RFC 3458	Proposed standard	*Message Context for Internet Mail* Details: For per-context quotas. Added in release: 6.3 (Usage: Generate Accept) January 2003
RFC 1740	Proposed standard	*Macintosh MIME Format* (Usage: MTA Translate Off-by-default) December 1994
RFC 1741	Informational	*Macintosh Binhex Encoding* (Usage: MTA Translate Off-by-default) December 1994
RFC 2045 section 6.7	Draft standard	*MIME base-64 and quoted-printable encodings* (Usage: Generate Accept Process MTA Translate Validate Normalize) (Older specs: RFC1521 RFC1522 RFC1590) November 1996
RFC 1847	Proposed standard	*MIME multipart/signed* (Usage: Process) October 1995
RFC 2480	Proposed standard	*Gateways and MIME Security Multiparts* (Usage: Process) January 1999
RFC 3280	Proposed standard	*X.509 Certificate Profile* Details: Generated by certutil. Accepted by SSL/TLS. (Usage: Accept Off-by-default) (Older specs: RFC2459) (Newer specs: RFC5280) April 2002
RFC 3462	Draft standard	*MIME multipart/report* (Usage: Generate Process) (Older specs: RFC1892) (Newer specs: RFC6522) January 2003
RFC 3464	Draft standard	*Delivery Status Notifications (DSN)* (Usage: Generate Process) (Older specs: RFC1894) January 2003
RFC 3798	Draft standard	*Message Disposition Notifications (MDN)* (Usage: Generate Process Off-

		by-default) (Older specs: RFC2298) May 2004
RFC 2442	Informational	*Batch SMTP* (Usage: Generate Accept Off-by-default) November 1998
RFC 5228	Proposed standard	*Sieve (Mail Filtering Language)* (Usage: Accept) (Older specs: RFC3028) January 2008
RFC 5173	Proposed standard	*Sieve body* Details: Includes some storage and complexity limits. Added in release: 7 Update 3 (Usage: Accept Off-by-default) April 2008
RFC 3894	Proposed standard	*Sieve :copy parameter* (Usage: Accept) October 2004
RFC 5260	Proposed standard	*Sieve date and index* Added in release: 7 Update 4 (Usage: Accept) (Enhancement Request: 12183152) July 2008
RFC 7352	Proposed standard	*Sieve duplicate* Added in release: 8.0 (Usage: Accept) September 2014
RFC 5293	Proposed standard	*Sieve Editheader* Added in release: 6.3 (Usage: Accept) August 2008
RFC 5228	Proposed standard	*Sieve Encoded-character extension* Added in release: 7.0 (Usage: Accept) (Older specs: RFC3028) January 2008
RFC 6069	Experimental	*Sieve envelope-dsn, redirect-dsn* Details: Messaging Server Support for envelope DSN access. Added in release: 7 Update 2 (Usage: Accept) December 2010
RFC 5183	Proposed standard	*Sieve Environment* Added in release: 7 Update 1 (Usage: Accept) May 2008
RFC 5429	Proposed standard	*Sieve ereject* Added in release: 7.0 (Usage: Accept) (Older specs: RFC3028) (Enhancement Request: 12228618) March 2009
draft-ietf-sieve-external-lists-10.txt	Work in Progress, subject to change	Messaging Server Support for Externally Stored Lists Sieve Extension Details: Likely subject to incompatible change in a future version. Caveat:

		Implementation includes additional features not in the current specification. Added in release: 7 Update 1 (Usage: Accept Off-by-default)
RFC 5463	Proposed standard	*Sieve ihave* Added in release: 7.0 (Usage: Accept) March 2009
RFC 5232	Proposed standard	*Sieve imap4flags* Added in release: 6.3p1 (Usage: Accept) (Enhancement Request: 12108510) January 2008
RFC 5703	Proposed standard	*Sieve MIME extension* Caveat: Only mime and foreverypart implemented, other extensions in spec not implemented (foreverypart added in pimento release) Added in release: 7 Update 2 (Usage: Accept) October 2009
draft-martin-sieve-notify-01.txt	Work in Progress, subject to change	*Sieve Notifications by email* Caveat: We only implement notify method email. Added in release: 6.2 (Usage: Accept Off-by-default) (Enhancement Request: 12070010)
RFC 5435	Proposed standard	*Sieve extension for notifications* Caveat: Only mailto: URLs are presently supported Added in release: 7.0.5 (Usage: Accept) January 2009
RFC 5436	Proposed standard	*Sieve notification mechanism: mailto* Added in release: 7.0.5 (Usage: Accept) January 2009
RFC 5231	Proposed standard	*Sieve Relational Tests* (Usage: Accept) (Older specs: RFC3431) January 2008
RFC 5233	Proposed standard	*Sieve subaddress* Added in release: 6.0 (Usage: Accept) (Older specs: RFC3598) January 2008
RFC 5235	Proposed standard	*Sieve Spamtest / Virustest* (Usage: Accept) (Older specs: RFC3685) January 2008
RFC 5230	Proposed standard	*Sieve vacation* (Usage: Accept) January 2008
RFC 6131	Proposed standard	*Sieve vacation seconds* Added in release: 7.0.5 (Usage: Accept) July 2011

RFC 5229	Proposed standard	*Sieve variables* Added in release: 6.3 (Usage: Accept) January 2008
RFC 952 section 1	Unknown	*Domain Name Syntax* (Usage: Accept Validate) (Older specs: RFC0810) October 1985
RFC 1123 section 2.1	Internet standard	*Domain Name Syntax* (Usage: Accept Validate) October 1989
RFC 2251	Proposed standard	*namingContexts of root DSE* Details: Used by comm_dssetup.pl with Directory Server 6 to determine naming contexts so customer can select one to use for user/group tree. Added in release: 6.3 (Usage: Accept) (Newer specs: RFC4510 RFC4511 RFC4513 RFC4512) December 1997
RFC 2849	Proposed standard	*LDAP Data Interchange Format (LDIF)* (Usage: Generate) June 2000
RFC 2254	Proposed standard	*LDAP Search Filter String Format* (Usage: Generate Accept Validate) (Older specs: RFC1960) (Newer specs: RFC4510 RFC4515) December 1997
RFC 2253	Proposed standard	*LDAP Distinguished Name String Format* (Usage: Generate MTA Translate Normalize) (Older specs: RFC1779) (Newer specs: RFC4510 RFC4514) December 1997
RFC 2255	Proposed standard	*LDAP URL Format* (Usage: Accept Validate) (Older specs: RFC1959) (Newer specs: RFC4510 RFC4516) December 1997
RFC 3280	Proposed standard	*PKIX* Details: Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile Caveat: As implemented by Mozilla NSS library, believed to be complete. Some new features in RFC 5280 not implemented. (Usage: Generate Accept Validate)

		(Older specs: RFC2459) (Newer specs: RFC5280) April 2002
ITU-T Rec. X.680, ITU-T Rec. X.690.	Other National/International	*ASN.1* Caveat: Only the LDAP, PKIX and SNMP subsets are implemented. (Usage: Generate Accept Validate)
RFC 1738 section 3.10	Proposed standard	*File URL Format* (Usage: Accept) (Newer specs: RFC4248 RFC4266) December 1994
RFC 3339	Proposed standard	*Internet Date / Time Timestamps* Details: Also ISO 8601. Used in a few places that don't require mail-specific timestamp format. (Usage: Generate) July 2002
Unix /var/mail mailbox file format	Widely Used or De Facto	*Unix /var/mail mailbox file format* Details: Traditional 'From ' Unix mailbox format (multiple messages per file). Used by MTA native channel and migration tool. (Usage: Generate MTA Translate)
RFC 8259		*application/json* Details: Used for Elastic search, ISS, etc. (Usage: Generate Accept)

Table A.3 ***Charsets***

Reference	Status	Feature and Information
ANSI X3.4-1986	Other National/International	*US-ASCII* Details: ANSI X3.4-1986 (Usage: Accept MTA Translate Validate IMAP Search)
RFC 3629	Internet standard	*UTF-8* Details: Unicode Transformation Format 8-bit. (Usage: Accept MTA Translate Validate Normalize IMAP Search) (Older specs: RFC2279) November 2003
ISO 8859 (1-10,14,15)	National/International	*ISO 8859 (1-10,14,15)* Details: ISO 8859 family of 8-bit charsets. Several languages with proper US-ASCII subset. (Usage: MTA Translate IMAP Search)
ISO 8859 11	National/International	*ISO 8859 11* Details: ISO 8859 8-bit Thai with ASCII subset.

		Added in release: 7 Update 3 (Usage: MTA Translate IMAP Search)
CNS 11643-1986, GB 2312-1980	Other National/International	*GB-2312* Details: Simplified Chinese, also CNS 11643-1986. (Usage: MTA Translate IMAP Search)
RFC 1842	Informational	*HZ-GB-2312* Details: Simplified Chinese. No MTA support. (Usage: IMAP Search) August 1995
Big5		*Big5* Details: Traditional Chinese (Usage: MTA Translate IMAP Search)
GB-18030	National/International	*GB-18030* Details: Extended Simplified Chinese with Unicode subset. (Usage: MTA Translate) (Enhancement Request: 12068067)
ISO/IEC 2022-1986	Other National/International	*ISO-2022* Details: ISO standard technique for code-switching; very complex so everything uses a subset. Caveat: We only implement a subset of full 2022 as needed by language-specific charsets and other MTA functions. (Usage: MTA Translate IMAP Search)
RFC 1468	Informational	*ISO-2022-JP* Details: Japanese, based on ISO 2022, JIS X 0201-1976, JIS X 0208-1990 (Usage: MTA Translate IMAP Search) June 1993
RFC 1554	Informational	*ISO-2022-JP-2* Details: Japanese, with additional language support, not widely used. (Usage: MTA Translate IMAP Search) December 1993
JIS X 0201-1976, JIS X 0208-1990 with EUC encoding	Other National/International	*EUC-JP* Details: Japanese. (Usage: MTA Translate IMAP Search)
RFC 1557	Informational	*ISO-2022-KR* Details: Korean KSC 5601-1987 with ISO 2022 encoding (Usage: MTA Translate IMAP Search) December 1993
RFC 1557	Informational	*EUC-KR* Details: Korean KSC 5601-1987 with EUC encoding

		(Usage: MTA Translate IMAP Search) December 1993
RFC 1345	Informational	*ks_c_5601-1987* Details: Alternate name for Korean KSC 5601-1987 with EUC encoding Added in release: 7.0.5.34.0 (Usage: MTA Translate IMAP Search) June 1992
RFC 1489	Informational	*KOI8-R* Details: Russian 8-bit with US-ASCII subset. (Usage: MTA Translate IMAP Search) July 1993
Thai Industrial Standard 620-2533	Other National/International	*TIS-620* Details: TIS-620. IMAP SEARCH support new in 7u4 (Usage: MTA Translate IMAP Search)
Windows-1250	Vendor Non-standard, subject to change	*Windows-1250* Details: Windows variant of ISO-8859-2 (Eastern/Central Latin) with extensions. IMAP SEARCH support new in 7u3 (Usage: MTA Translate IMAP Search)
Windows-1251	Vendor Non-standard, subject to change	*Windows-1251* Details: Windows variant of KOI8-R (Russian) with extensions. IMAP SEARCH support new in 7u3 (Usage: MTA Translate IMAP Search)
Windows-1252	Vendor Non-standard, subject to change	*Windows-1252* Details: Windows variant of ISO-8859-1 (Latin) with extensions. (Usage: MTA Translate IMAP Search)
Windows-1253	Vendor Non-standard, subject to change	*Windows-1253* Details: Windows incompatible variant of ISO-8859-7 (Greek) with extensions. IMAP SEARCH support new in 7u3 (Usage: MTA Translate IMAP Search)
Windows-1254	Vendor Non-standard, subject to change	*Windows-1254* Details: Windows variant of ISO-8859-9 (Turkish) with extensions. IMAP SEARCH support new in 7u3 (Usage: MTA Translate IMAP Search)
Windows-1255	Vendor Non-standard, subject to change	*Windows-1255* Details: Windows incompatible

		variant of ISO-8859-8 (Hebrew) with extensions. IMAP SEARCH support new in 7u3 (Usage: MTA Translate IMAP Search) (Enhancement Request: 12272449)
Windows-1256	Vendor Non-standard, subject to change	*Windows-1256* Details: Windows incompatible variant of ISO-8859-6 (Arabic) with extensions. (Usage: MTA Translate IMAP Search)
Windows-1257	Vendor Non-standard, subject to change	*Windows-1257* Details: Windows incompatible variant of ISO-8859-13 (Baltic) with extensions. IMAP SEARCH support new in 7u3 (Usage: MTA Translate IMAP Search)
Windows-1258	Vendor Non-standard, subject to change	*Windows-1258* Details: Windows Vietnamese 8-bit. IMAP SEARCH support new in 7u3 (Usage: MTA Translate IMAP Search)
RFC 2152	Informational	*UTF-7* Details: Use not recommended, doesn't interoperate well. (Usage: MTA Translate IMAP Search) (Older specs: RFC1642) May 1997
RFC 3501 section 5.1.3	Proposed standard	*IMAP Modified UTF-7* (Usage: Accept MTA Translate Validate) (Older specs: RFC2060) March 2003

Table A.4 ***Library files***

Reference	Status	Feature and Information
RFC 1345	Informational	*charnames.txt* Details: Defines the mnemonic character names (based on RFC 1345) used in charsets.txt (Usage: Accept) June 1992
RFC 1345	Informational	*charsets.txt* Details: Character set definitions based on RFC 1345 (Usage: Accept) June 1992
ISO 3166 country codes	Other National/International	*countries.txt* Details: List of ISO 3166 country codes (Usage: Accept)

IANA top-level domain list	Other National/International	*tlds.txt* Details: Copy of http://data.iana.org/TLD/tlds-alpha-by-domain.txt (Usage: Accept)
RFC 3066	Best current practice	*languages.txt* Details: List of language codes (Usage: Accept) (Older specs: RFC1766) (Newer specs: RFC4646 RFC4647) January 2001

Glossary

A

APOP

RFC 1939 (POP3) defines the APOP command. This is an alternate method for authenticating the user which, rather than sending the username and password in the clear over the network, encodes the password.

Authentication mechanism

An authentication mechanism is a particular method for a client to prove its identity to a server. APOP, PLAIN and CRAM-MD5 (mechanism names are as defined by RFC 2222 (SASL)), are examples of authentication mechanisms. Another, but non-standard, mechanism is the LOGIN mechanism. For discussions of particular mechanisms, see for instance RFC 2195 documenting CRAM-MD5, and RFC 1939 documenting APOP.

Authentication source

An authentication source is a file, database, interface to an LDAP directory, *etc.*, which is accessible to the server and wherein are stored authentication verifiers for users. The system password file, the user portion of the DIT in an LDAP directory, or a certificate database, are examples of authentication sources.

Authentication verifier

An authentication verifier (*e.g.*, password) is stored on the server and contains information used to verify a user's identity. The format of the authentication verifier may restrict which mechanisms can be used. The term authentication verifier is preferred in place of password, since while passwords are the most common instance of authentication verifiers, an authentication verifier could also be something like a certificate in an LDAP directory or the like; usually, however, one may think "password" wherever one sees "authentication verifier".

C

Certificate

In the security context, a certificate is a guarantee, signed by some trusted authority, that says that a piece of information is what it purports to be. For instance, certificates are often needed and encountered when using a public key pair.
See Also Public key pair.

Certificate Authority

A Certificate Authority is a recognized, generally well-trusted authority that is willing to sign other organization's certificates. A Certificate Authority has a well-published certificate (containing their public key) that other organizations can use to verify the Certificate Authority's signature on other certificates. Assuming that an organization trusts the Certificate Authority, this then gives them confidence in certificates that include a valid signature from the Certificate Authority. Verisign, Inc. (now owned by Symantec Corp.), and Thawte Consulting are two of the better known commercial Certificate Authorities. Large corporations will sometimes, for their own internal purposes, act as their own Certificate Authority.

Certificate request	A certificate request is a special form of a site's public key suitable for signing by a Certificate Authority. The signing of a certificate request generates a certificate. See Also Certificate Authority.
Channel	In the context of the Oracle MTA, a channel is an abstract combination of message transport and protocol, realized through a channel program. Each different transport and protocol combination has a corresponding different type of MTA channel. A channel represents a connection with another computer system or group of systems, over which messages may be transported. For instance, the MTA supports SMTP-over-TCP/IP channels, for sending and receiving messages from the Internet (as well as internal networks); typically, several distinct SMTP-over-TCP/IP channels are configured, for separate handling of SMTP-over-TCP/IP message traffic originating from, or destined to, different categories of remote and local systems. See Channels. See Also Channel program.
Channel block	The definition of an MTA channel appearing as a named set of options under a `channel` group (Unified Configuration) or in the MTA configuration file (legacy configuration) is called a channel block; see Channel configuration. See Also Channel.
Channel keyword	In Unified Configuration, channel options take the place of the legacy configuration channel keywords. A large number of channel options (channel keywords in legacy configuration) are available for use in MTA channel definitions (channel blocks) to control and modify the action of the channel to which a keyword is applied; see Channel options. See Also Channel.
Channel program	Loosely speaking, any program which enqueues or dequeues messages to or from the MTA's message queues. See the `master_command` and `slave_command` Job Controller options. See Also Channel.
CIDR (Classless Inter-Domain Routing)	CIDR is a method for allocating IP addresses and routing IP packets. In IPv4, it permits allocating address space on any address bit boundary, rather than necessarily in 8-bit groups.
CIDR notation	A notation of specifying IP addresses and their associated routing prefix. It appends a slash character to the address and the decimal number of leading bits of the routing prefix. See Also CIDR (Classless Inter-Domain Routing).
Cipher suite	A cipher suite is a set of cryptographic algorithms used for key exchange, encryption, and generation of hashes and signatures on content. In order for the SSL or TLS network protocol to be used, both sides of a communication must support a common cipher suite. Examples of cipher suites include RSA, Diffie-Hellman, Triple DES, and IDEA. See for instance the `ssladjustciphersuites` option. See Also SSL (Security Sockets Layer), TLS (Transport Layer Security).
Common name	In X.500 terminology, the common name or commonName or CN attribute is a multi-valued attribute that describes an entry; typically

it is something like a person's name, "First Middle Last", *etc*. The term is also used in other contexts, such as in a certificate, and in non-X.500 directories, especially LDAP directories.
See Also Certificate.

Conversion tag

Conversion tags are a private-to-the-MTA envelope field in message copies traversing the MTA. Conversion tags are stored per message copy (message file); so cases where different message recipients need to have different conversion tags set require that the MTA generate separate message files. Conversion tags may be initially set due to user or domain LDAP attributes (see `ldap_conversion_tag`, `ldap_source_conversion_tag`, `ldap_domain_attr_conversion_tag`, and `ldap_domain_attr_source_conversion_tag`) or set in Sieve scripts (see Sieve conversiontag extensions) or set in Unified Configuration in an alias option (see `alias_conversion_tag`) or correspondingly in legacy configuration in an alias file entry (see the `[CONVERSION_TAG]`named parameter), or set in an the `FROM_ACCESS` mapping table or recipient address `*_ACCESS` mapping tables (see the `$G` flag discussed in Address access mapping table flags). Conversion tag values may optionally be used in various mapping tables (see the `include_conversiontag` MTA option)), or may be tested in Sieve scripts (see Sieve conversiontag extensions). Conversion tags are normally consumed by the conversion channel; see the `TAG` conversion parameter discussed in Available conversion parameters, listed alphabetically.

CRAM-MD5

RFC 2195 (IMAP/POP AUTHorize Extension) defines the CRAM-MD5 mechanism (Challenge-Response Authentication Mechanism using the MD5 digest algorithm) for authenticating using an encoded password, rather than sending the user's password in the clear over the network.

D

Dequeue

The act of removing a mail message from the MTA's message queues. (Often but not always such removal is due to delivering the message; however dequeue encompasses other cases of removal, such as when a message expires (delivery attempts time out), or is intentionally deleted by the mail system administrator via a utility such as `imsimta qm delete`, or when an original message with multiple recipients has some recipients successfully delivered while other recipients suffer temporary failures, thereby resulting in a dequeue of the original, multi-recipient, message combined with a re-enqueue of a new message copy containing only the not-yet-delivered recipients.)

Directory Information Tree

Information in an LDAP directory is considered to be in the form of a directory information tree: information is stored in nodes, arranged in a hierarchical (tree) structure.

Distinguished name

In X.500 terminology, the distinguished name or distinguishedName or DN attribute uniquely identifies an object in the Directory Information Tree. The term is also used in other contexts, such as in a certificate, and in non-X.500 directories, especially LDAP directories.

	See Also Directory Information Tree.
DIT	An abbreviation for Directory Information Tree. See Also Directory Information Tree.
DNS (Domain Name System)	Distributed naming system for computers, services, *etc.*, on the Internet or on private networks, that in particular translates domain names into numerical IP addresses.
DNSBL	Another term for Realtime Black List (RBL). See Also RBL (Realtime Blackhole List, Realtime Block List, Realtime Blacklist).
Domain alias	A domain alias is another, synonymous, name used for a domain. The MTA supports various forms and mechanisms for domain aliases, some simple and some complex. See in particular the `ldap_domain_attr_alias` MTA option (Schema 1), the `ldap_attr_domain2_schema2` MTA option (Schema 2), and the `domain_uplevel` MTA option. See Also Virtual domain.

E

EAI (Email Address Internationalization)	EAI is a proposal from the EAI IETF working group to permit internationalized email, and in particular internationalized (non-ASCII) email addresses. See RFC 6530 (Overview and Framework for Internationalized Email) for an overview.
encoded-word	In the context of MIME messages and particularly in the headers of messages, see the MIME specifications, especially RFC 2047. See Also MIME.
Enqueue	The act of submitting for transmission a mail message to the MTA.
Envelope	Additional information may also be present in a message envelope, including notification flags, and various MTA-private fields. Sieve filters may access certain message envelope fields using the "`envelope`" test.) See Also Message envelope.

F

Final address	The "final" form of a recipient address is intended for machine-delivery, not necessarily user-visibility, and may include delivery-specific information, such as, in the case of messages being delivered to the Message Store, folder names or host names or MTA channel names. This "final" form is thus in contrast to the original form of the address, and the "intermediate" form also used by the MTA. See Also Intermediate address.
FQDN (Fully Qualified Domain Name)	A domain name specified fully, all the way out to a Top Level Domain, *e.g.*, host.domain.com, not merely a short form hostname. See Also TLD (Top Level Domain).

G

General database

In MTA usage, the term general database refers to a particular database, that can be used by the MTA for a variety of purposes; see for instance rewrite general database substitutions and mapping table general database substitutions. Depending upon the setting of the MTA option `use_text_databases`, the general "database" is either stored and accessed in the form of an on-disk, true database (the default), or else is stored as an in-memory, hashed structure built from an on-disk file. Alternatively, new in MS 8.0, it may be stored and accessed via memcache; see the `general_database_url` MTA option.

Grey-listing

Grey-listing refers to issuing a temporary rejection to attempted submissions of SMTP messages from "new" (not previously encountered) senders; that is, a temporary rejection is issued the first time the sender attempts to send the message, while accepting the message on any later submission attempt. This approach to reducing spam is based on the theory that automated spam blasters typically will not bother to attempt to resend messages, whereas messages from legitimate remote correspondents will get additional delivery attempts performed by remote MTAs. But not all sites are willing to accept imposing a delay on accepting messages from "new" remote senders.

Group

In the email context, shorthand for mail group.
See Also Mail group.

GUI (Graphical User Interface)

A Graphical User Interface or GUI is a visually oriented interface, such as typically seen on Mac or Windows systems.

I

ICAP (Internet Content Adaptation Protocol)

See RFC 3507 (Internet Content Adaptation Protocol (ICAP)), ICAP provides a lightweight protocol for executing a "remote procedure call" on HTTP messages. As such, it is suitable for purposes such as spam/virus scanningand HTML sanitization.

IETF

The IETF, Internet Engineering Task Force, is the Internet standards body.

Intermediate address

The MTA commonly deals with several forms of address, including the preserved "original" form of a recipient address (the ORCPT form---in principle, that form originally typed by the sending user, but in practice that true original form may not have been preserved and instead some "later", transformed version may be the earliest form preserved), the "recently" active form (referred to as the "intermediate" form) corresponding to the form of the address produced after list expansion but prior to any most recent forwarding applied by the MTA, and an altered "final" form of that recipient address (as for instance a final form after forwarding is applied, or after user mailbox name generation occurs as with the "mailbox" delivery option). For instance, the "intermediate" form of an address might be first.last@hosted.domain.com in contrast to a "final" form of uid%hosted.domain.com@ims-ms-daemon.

See Also Final address.

K

Keyword

Shorthand for Channel keyword.
See Also Channel keyword.

L

LDIF (LDAP Data Interchange Format)

LDIF is a standard plain text format for representing LDAP directory content; see RFC 2849 (LDIF).

local-part

The local-part is the non-domain portion of an email address: the portion sometimes thought of as the "username", plus optionally a subaddress; see RFC 5322.
See Also Subaddress.

M

MADMAN

MADMAN was the name of the Mail and Directory Management Working Group. The MADMAN group originated RFC 1566 (Mail Monitoring MIB).

Mail group

A set of addresses (or aliases to expand) which receive email addressed to some one address: a "mail forwarder". This is distinguished from true mailing lists, as mailing lists have additional semantics. A mail group is intended, and normally should only be used, for a small number of closely related addresses/recipients -- such as a group of mail system administrators, or a group of family members. See Proper use of lists rather than groups for further discussion.
See Also Mailing list.

Mailbox filter

Mailbox filters are rules for individual users, for MTA channels, or for the MTA as a whole, specifying screening and certain delivery handling features for incoming messages. Nowadays, Sieve filters are the common form of mailbox filters (and Sieve filters are also used in some non-MTA contexts, such as post-delivery processing by Sieve-enabled email clients, or use by the Message Store in filtering which messages to purge).
See Also Sieve.

Mailing list

A mailing list consists, at the most basic, of a mailing list address, a list owner address, and a set of member addresses to whom to post messages addressed to the list. Mailing lists optionally have many other configuration options -- see the MTA's support for mailing lists; mailing lists may restrict who can post to the list, restrict the content of what may be posted to the list, add header lines to postings, "tag" the Subject: header line, add disclaimer text, *etc.* But the fundamental and critical difference between a true mailing list and a mail group is the existence of a list owner address -- an address that replaces whatever envelope From was originally present on messages sent to the list address with that list owner address for the postings to the list membership. This has a number of semantic implications, especially as relates to potential

notification messages regarding delivery problems to list members. See Proper use of lists rather than groups for further discussion.
See Also Mail group.

Mapping table

Many components of the MTA make use of one or another mapping table: a table mapping input strings to output strings. All MTA mapping tables are stored in Unified Configuration as `mapping` XML elements, or in legacy configuration are stored in the MTA's mapping file.

Mass mailing

A mass mailing is any message sent to a (relatively) large number of recipients. The recipients might be all of the users hosted at a site, all of the users in some domain, all users in some organizational unit, all members (including external members) of a large mailing list, *etc.* The purpose of the message might be one of great urgency (such as an emergency communication), or it might be of general interest but low urgency (such as announcements). A number of considerations and configuration options relevant to mass mailings are discussed under Mass mailings.

Master channel program

Any program which enqueues messages to the MTA's message queues.
See Also Slave channel program.

Message archiving

Message archiving is a term used in several different senses, with different purposes. Two of the most common senses/forms are as follows. (1) Compliance archiving: By this is meant keeping a long term record of all message traffic (or of certain selected message traffic) to comply with legal or other requirements. For such compliance archiving, certainty that "relevant" messages have been captured is usually paramount; but the captured messages are intended for administrative/legal access, not normally for further direct end-user access. (2) Operational archiving: By this is meant "off-loading" storage of certain messages, especially for instance older messages, to more economical storage/access mechanisms. Part of operational archiving is an expectation that end-users will still be able to access "their" messages, when desired, reasonably conveniently. Some additional discussion of message archiving, along with techniques of interest, may be found under Message archival and hashing MTA options.

Message envelope

A message envelope specifies for MTA purposes (message routing purposes) who a message was sent from, and who its recipients are. The message envelope is not normally visible (directly) to end users, other than in special ways such as the Return-path: header line value (which records the final form of the envelope From: address), or as the list of message recipients in the user's message user agent message composition interface. (End users instead see the message header and message body.) In terms of the SMTP protocol, the message envelope includes the MAIL FROM: and RCPT TO: portions of the SMTP dialogue. The `imsimta qm` utility's `read` command may be used to show these fundamental envelope fields (as well as headers and optionally content) of a message in the MTA's queues. The MTA maintains additional envelope fields in its message files in the MTA queues, which it uses as appropriate and configured. (Note that some such fields have standardized meanings, such as notification flags; others are private to the MTA.) The format of all envelope fields as stored in message files in the MTA queue area is

	private to the MTA and hence envelope fields should not be accessed directly through inspection of message files, but rather be accessed through normal, supported MTA mechanisms, or if being accessed for custom purposes, should be accessed via the MTA SDK. Examples of normal, supported mechanisms involving envelope fields would include: Sieve filter access to certain message envelope fields using the "`envelope`" test; the conversion channel use of conversion tags; MTA transaction logging that may include envelope data; *etc.* See Also Envelope.
Message Store	The component of a messaging system that contains the user mailboxes, and facilities (*e.g.*, IMAP, POP, and HTTP servers) to access those messages; *e.g.*, the Oracle Message Store
MIB	MIB is an acronym for Management Information Base. In the email context, see RFC 1566 (Mail Monitoring MIB).
MIME	MIME stands for Multipurpose Internet Mail Extensions. It is the format used for standard representation of email messages across the Internet (and also used in HTTP for the World Wide Web). It was originally specified in RFC 1521 and RFC 1522, later updated by RFCs 2045--2049.
Moderated mailing list	A mailing list where only some senders are allowed to post directly to the list, while attempted postings from other senders are re-routed to a list moderator or moderators, who can then approve and post the message to the list, or disapprove the message and thereby prevent it from being posted.
MTA	Message transfer agent; *e.g.*, the Oracle Messaging Server MTA.
MUA	Mail user agent; see UA. See Also UA (User Agent).

N

NOTARY	See originally RFCs 1891-1894, now obsoleted by RFCs 3461-3464.

P

Polling	In the e-mail context, polling tends to mean an active step to query whether there are messages or data for the MTA to receive. This is as opposed to the MTA passively waiting to receive messages or data. For instance, the SMTP TURN and ESMTP ETRN commands are examples of polling at the SMTP protocol level.
Private key	A private key is the secret half of a public key pair. See Also Public key pair.
Public key	A public key is the published half of a public key pair. See Also Public key pair.
Public key encryption	So-called public key encryption refers to encryption and decryption using a pair of keys, referred to as a public key pair. One key is referred

to as the public key, and is generally published (visible to the outside world); the other key is referred to as the private key and is secret and known only to the owner of the public key pair. User A may encrypt data to send to user B using user B's public key, and then only user B will be able to decrypt the data by using user B's own private key.
See Also Public key pair, Public key, Private key.

Public key pair

Public key encryption uses pairs of keys, one kept secret and one published (made accessible) to the outside world. What the public key encrypts, the private key decrypts, and *vice-versa*. The keys together are called a public key pair.

Q

Queue cache database

The queue cache database, also referred to as the Job Controller queue cache, is an in-memory data structure maintained by the Job Controller (as one of its primary responsibilities) that lists the message files awaiting delivery in the MTA's channel queue areas. (In older versions of PMDF, the queue cache database was stored as an on-disk database.)

R

RBL (Realtime Blackhole List, Realtime Block List, Realtime Blacklist)

An RBL is a list, usually published through the DNS, of the IP addresses of problem message senders (spammers). The MTA can be configured to consult such lists via any of several mechanisms, most notably a `dns_verify` callout.

Rewrite rules

Also called domain rewriting rules: those rules specified in the MTA as `rewrite` XML elements in Unified Configuration, or configured in the upper half of the legacy configuration file, for transformating domain names in addresses.

RFC

Request For Comments; the Internet's method of publishing documents.

RFC 822 address

RFC 822 (Standard for the format of ARPA Internet text messages) defined the format for Internet e-mail addresses.
See Also EAI (Email Address Internationalization).

S

SASL (Simple Authentication and Security Layer)

See RFC 2222 (Simple Authentication and Security Layer).

Schema

Definitions, including structure and syntax, of the types of information that can be stored as entries in an LDAP Directory Server.

Schema tag

A tag (name) identifying the schema in use. The Oracle Messaging Server MTA has native support for several schemata (and can potentially support other, more or less compatible schemata), such as the Netscape Messaging Server 4.1 schema (schema tag `nms41`), the Sun Internet Mail Server 4.0 schema (schema tag `sims40`), and the iPlanet Messaging

	Server 5.0 schema (schema tag `ims50`); the MTA merely needs to be told which schema is in use. See in particular the `ldap_schematag` MTA option (and in legacy configuration, also see the `configutil` parameter `local.imta.schematag`). See Also Schema.
Security rule set	A security rule set is a set of rules determining which authentication mechanisms and sources are permitted or used by a server. For the MTA, the `PORT_ACCESS` mapping table is used to determine the security rule set to apply to an incoming connection, based on IP addresses and ports.
Sieve	In the context of e-mail, the term "Sieve" usually refers to the Sieve mail filtering language defined in RFC 5228, and extended in additional RFCs including RFC 3431 (Sieve Extension: Relational Tests), RFC 3598 (Sieve Email Filtering---Subaddress Extensions), RFC 3685 (Sieve Email Filtering: Spamtest and VirusTest Extensions), RFC 3894 (Sieve Extension: Copying Without Side Effects). Sieve scripts written in the Sieve filtering language can specify tests to perform on incoming messages, and then actions to take based on the tests, such as discarding certain messages, or filing certain messages into specific folders, etc. The Messaging Server MTA supports Sieve scripts, both at the system level (an MTA-wide Sieve script, and channel level scripts), and user Sieve scripts stored and evaluated at the MTA level (stored either in LDAP or in files on the MTA server). The Message Store supports use of Sieve tests for specifying which messages to purge.
Sign	In the context of a TLS certificate, to say that a certificate is signed means that a Certificate Authority has generated a hash of the contents of the certificate and used their own private key to encrypt that hash and then appended that encrypted hash to the original certificate. Then other sites that want to check on the validity of your certificate can use the Certificate Authority's well-published certificate (containing the Certificate Authority's public key) to verify the hash and thus verify that the contents of your supposed certificate match the contents that were seen and signed off on by the Certificate Authority. Assuming that the other site trusts the Certificate Authority, this then gives them confidence in your certificate. See Also Certificate, Certificate Authority, TLS (Transport Layer Security).
Slave channel program	Any program which dequeues messages from the MTA's message queues. See Also Master channel program.
SMTP (Simple Mail Transfer Protocol)	See RFC 821, or its update, RFC 5321.
Spam	Unsolicited bulk messages, especially e-mail messages, and usually undesired. The more formal term is Unsolicited Bulk E-mail (UBE). The term "spam" is believed to have originated from a Monty Python Flying Circus sketch.
SSL (Security Sockets Layer)	This protocol was developed by Netscape and has been superseded by TLS, which is backward compatible with SSL.

See Also TLS (Transport Layer Security).

Subaddress

A subaddress consists of extra detail information in the RFC 5322 "local-part" of an address (the portion to the left of the "@" sign"); the subaddress is typically encoded into the local-part by using a separator character such as the plus character, +, and is subject to site-specific interpretation. Use of subaddresses can be a convenient way, to *e.g.*:

- Request delivery directed to a named folder.
- Indicate that a message is being received due to membership of some mailing list.
- Request other special delivery handling, such as delivery to a voice mailbox.

See Also local-part.

Symmetric encryption

When encryption is done such that the same key encrypts and decrypts the data, it is said that the encryption is symmetric. This does require that the key that is used to encrypt the data must be given to the decryption side in a secure fashion.

T

Tar-pitting

Intentionally slowing down SMTP responses: every response dragged out slowly, as if in a tar pit.

TLD (Top Level Domain)

The permissible last part of domain names. For MTA purposes, see the `tlds.txt` file.

TLS (Transport Layer Security)

See RFC 2246 (The TLS Protocol).

Traffic analysis

Analysis of who is sending what to whom; in an e-mail context, who (what senders) are sending what e-mail messages (how big, etc.), to what recipients. In some contexts, such information may be considered useful (or sensitive) even in the absence of specific information about exact message contents: for instance, merely knowing whether communications have increased or decreased between two correspondents provide useful competitive information. Monitoring, especially message logging, may be useful in obtaining traffic information on an MTA system. Use of BSMTP channels may, in some cases, be of interest in blocking others from performing traffic analysis on your own messages.

U

UA (User Agent)

User agent; *e.g.*, the Messenger Express e-mail client, or the Convergence e-mail client.

UBE (Unsolicited Bulk E-mail)

Unsolicited bulk messages, especially e-mail messages, and usually undesired.
See Also Spam.

V

Vanity domain	An apparent domain for which addresses are supported, but which does not have a domain entry in the LDAP directory (nor is it a domain alias); instead it is supported more as a sort of analogue to an alias on a user entry (typically by placing an attribute `msgVanityDomain` on the user entry). The use of vanity domains is strongly discouraged; proper domain entries (or domain aliases and analogues such as domain "uplevel" support) is preferred.
VERP (Variable Envelope Return Path)	Variable Envelope Return Path (VERP) refers to emitting messages with each recipient's version of the message copy having a different variant of the envelope From (envelope return path). One use is for mailing list messages, so that a list maintainer can correlate bounces of messages to the list back to which list member had a delivery problem.
Virtual domain	When a system hosts multiple domain names, it is considered to be supporting virtual domains---pseudodomain names that do not correspond to a system dedicated to only that domain name. Such setups are routine for modern Messaging Server deployments, and are typically provisioned via domain entries in an LDAP directory. See Also Domain alias.

Colophon

This manual was automatically generated from Messaging Server source code. A series of custom stylesheets were used to produce DocBook 5 source, which was then processed using the DocBook XSL stylesheets to produce XSL:FO source. Finally, the XSL:FO source was processed using Apache FOP to produce a Portable Document Format file.

The titles in this document are typeset in Helvetica; the body text is in Palatino.
